Field-deployable diagnostics for trace vapor analysis have seen widespread adoption in the forensics and environmental monitoring communities due to numerous technological advancements over the past several years. Reduction of the cost and size of field-deployable analytical instruments is advantageous to field sampling and analyses, yet it is still not possible to match the sensitivity, repeatability, and detection limits of lab-based measurement approaches. Therefore, field-deployable sample collection for later analysis is appealing owing to the ability to utilize existing lab-based analytical instruments and techniques in tandem with relatively simple portable collection devices. One technique for vapor sample collection that uses adsorbent-coated capillary columns for sample preconcentration is Porous Layer Open Tubular-Cryoabsorption (PLOT-Cryo). This technique has been applied extensively in the lab to the analysis of fire debris, explosives detection, grave soil analysis, and vapor pressure measurements.¹⁻⁴ The PLOT-Cryo approach works by collecting vapors on an adsorbent layer within a chilled (~ 0°C) capillary column. This technique is fast, sensitive, and does not require large amounts of sample.

Building on the success of the lab-based approach, a portable device was developed and deployed in the field.^{5,6} The device has many advantages compared to alternative approaches, such as the ability to elute the sample in the field and, by utilizing many capillaries with different adsorbents, the ability to capture vapor samples without *a priori* knowledge of the analytes of interest. The device utilizes vortex tubes for temperature control of the capillary and a vacuum generator to sweep vapor samples through the capillary for collection. The performance was comparable to that of lab-based devices, but the use of vortex tubes and a vacuum generator required the use of an air compressor, which limited portability.

The device was redesigned to achieve true portability and is based on a much-improved laboratory dynamic headspace sampling apparatus—Dynamic Vapor Microextraction (DVME)—recently used to measure the vapor pressure of eicosane with orders of magnitude lower uncertainty compared with the PLOT-Cryo technique. The next generation portable headspace sampling device concept was designed in parallel with DVME. This new device abandoned the use of compressed air for cooling and vacuum generation in favor of a battery-powered design that utilizes a high-efficiency thermoelectric cooler for capillary vapor trap cooling and a positive displacement pump to generate flow. Additionally, an improved user interface that simplifies sample collection and tracking, and advanced data logging features for the capture of environmental parameters to further enhance the device's capabilities will be incorporated. A detailed explanation of the concept design, including heat transfer considerations and component selection, as well as future field studies are presented.

Field Deployable, Vapor Sampling, Microextraction

D3 The Use of Atmospheric Pressure Ionization (APPI) Coupled with Mass Spectrometry (MS) to Increase Sensitivity for the Identification of Disperse Dyes in Trace Evidence

Morgan Demmler, MS, North Carolina State University, Raleigh, NC; Nelson Vinueza, PhD, North Carolina State University, Raleigh, NC*

Learning Overview: After attending this presentation, attendees will learn about the differences between APPI and Electrospray Ionization (ESI) MS and how each ionization technique affects instrument sensitivity of disperse dyes, enhancing forensic analysis of trace fibers.

Impact Statement: This presentation will impact the forensics community by providing a novel way to thoroughly examine trace fibers of extremely small sizes by high-resolution mass spectrometry.

Textiles play a major role in connecting places, objects, and people to a crime scene. Oftentimes, small fibers can be found at a crime scene when a person's body or clothing comes into contact with a textile. This follows Locard's Principle, which states that when two objects come into contact with each other, there will be an exchange of microscopic material.¹ There are many different kinds of textiles that can be found at a crime scene. These include clothing, carpets, upholstery, and others. Trace evidence of textiles comes in the form of microscopic pieces of fiber. As with all trace evidence, a challenge arises due to the extremely small nature of this evidence. While microscopy and spectrophotometry do not require a large sample size, these techniques can only give very limited information on dye types.² Therefore, it is important to find more sensitive analytical techniques that can be successfully performed on microscopic samples.

Second to cotton, polyester is the most commonly produced textile. In addition, it accounts for 75% all synthetic fibers manufactured globally.³ Disperse dyes are commonly used to dye polyester textiles. In this study, three commercially available disperse dyes (Disperse Red 153, Disperse Yellow 211, Disperse Blue 56, and a combination of the three to make black) were used to dye samples of polyester fabric. Fibers from each sample were cut into 1mm pieces to represent trace evidence that could be found at a crime scene. Extraction of the dyes was done using an existing standard operating procedure and subsequently prepared for analysis.

APPI is a type of gas phase ionization technique used with MS. However, most studies done with dyes have focused on other, more common ionization techniques, such as ESI. Disperse dyes, because of their chemical nature, can be ionized using APPI, whereas some other dye types, like reactive dyes, cannot be seen using APPI. This study takes advantage of this feature to compare the sensitivity of APPI to ESI coupled with a quadrupole Time-Of-Flight Mass Spectrometer (qTOF-MS) under the same electronic conditions for the detection of disperse dyes extracted from fibers.

While commercial dyes are typically used in the textile industry, they come with certain drawbacks when it comes to analysis. These dyes are often patent protected, and the structures are not always correctly given. Two dyes may have the same Color Index (CI) value but different structures. In addition, commercial dyes are often not pure. This creates difficulties when trying to distinguish impurities from degradation products, which can be important when examining trace evidence. To address these problems, three similar disperse dyes (red, yellow, and blue) from North Carolina State University's historic Max Weaver Dye Library were chosen from the database using open-source Konstanz Information Miner (KNIME) software with a Tanimoto coefficient greater than 90%. This database contains 2,196 dyes that are unique to the Max Weaver Dye Library. Since the structures of these dyes are known, fragmentation spectra obtained using Tandem Mass Spectrometry (MS/MS) can be compared to those of the commercial dyes and help to predict possible dye structure similarities and degradation products.

Results show that the sample size required for detection using APPI is significantly less than that when using ESI for both commercial and Max Weaver disperse dyes extracted from trace fibers. This finding shows that APPI enhances the sensitivity of the dye characterization by MS.

D4 An Analysis of Polymer Composition and Dye of Textile Fibers by Direct Analysis in Real Time-Mass Spectrometry (DART®-MS) and Raman Microscopy

Miquellie Bonner*, Middle Tennessee State University, Murfreesboro, TN; Sing Chong, PhD, Middle Tennessee State University, Murfreesboro, TN; Mengliang Zhang, PhD, Middle Tennessee State University, Murfreesboro, TN

Learning Overview: After attending this presentation, attendees will better understand the capabilities of the DART®-MS and Raman microscopy for identifying the unique combination of polymer and dye constituting the fibers found at crime scenes. The pros and cons of both techniques, their complementary characteristics, and the possibility of combining these methods with other instrumental techniques will be presented.

Impact Statement: This research will impact the forensic science community by introducing quick and effective methods to textile fiber analysis that will aid in the advancement of the field. Besides enhancing the specificity of fiber identification based on the analysis of the unique combination of polymer and dye, both the DART®-MS and Raman methods have integrated the process of microextraction of analytes for successful dye identification in fibers weighing only 0.44-0.56mg.

The Thermal Desorption and Pyrolysis Combined With Direct Analysis in Real Time-Mass Spectrometry (TDP/DART®-MS) and the Surface-Enhanced Raman scattering (SERS) method were developed to analyze dyes on the textile fibers in this study. Past studies have illustrated that the TD-DART®-MS can be used for the successful identification of the polymeric backbone structures of different textile materials, such as cotton, nylon, polyester, cellulose triacetate, poly(propylene) and poly(acrylonitrile). The TDP/DART®-MS method also yielded other chemical information, such as the dyes.¹

Currently, there are thousands of textile dyes either derived from natural sources or synthetic pathways. Dyes are often classified into different categories according to their unique application method and chemical composition.² This classification, and the effectiveness of correctly identifying dyes of similar colors, hold high importance in connecting a suspect to trace evidence, such as carpet or clothing fibers.³

This study focused on nine blue dyes from five categories, including acid, basic, disperse, and blue/violet, commonly used in manufactured textiles. A TD-DART®-MS method was developed to analyze dyes and polymeric materials on an array of applicable fibers, which included silk, cotton, and nylon. The mass spectra were collected from the dye standards and dyes applied to fibers, with no extraction techniques. The multidimensional profile, including both the desorption time and mass spectra, was compared. The characteristic ions of dyes and polymeric materials were identified.

Dispersive Raman spectrometers with both 532nm and 785nm laser excitation were also used for the fiber analysis. Aqueous silver colloid was added to the fibers prior to microwave-assisted dye extraction to improve the signal-to-noise ratio of the Raman spectra of dyes while minimizing the contribution of background signal due to the polymer. The novel microwave-assisted dye extraction method was carried out in capillary tubing containing the dyed fiber and silver colloid derived from the Leopold and Lendl method. The subsequent analysis of dye adsorbed onto silver colloids showed a significant amplification of the Raman signal along with a distinct decrease of spectral interference due to fluorescence from the textile dyes or polymers.⁴ The unique Raman bands of the extracted dyes were distinguishable among the blue dyes studied.

The TDP/DART®-MS method requires a single fiber sample size and sample preparation time of approximately two minutes, but it offers a multidimensional profile within approximately seven minutes. Due to the method being both simple to perform and having high sample throughput potential, this method may significantly contribute to the identification of dyes on fibers at crime scenes.

The Raman data are based upon the project supported by the National Science Foundation under Grant No. 1920293. The MTSU Undergraduate Research Experience and Creative Activity (URECA) program is acknowledged for its support for this study.

Fiber, DART®-MS, Raman Microscopy

D5 A Comparison of Weathering Profiles of Ignitable Liquids (ILs) by Gas Chromatography/Mass Spectrometry (GC/MS) and Direct Analysis in Real-Time Mass Spectrometry (DART®-MS)

Shruthi Perna, MS, Middle Tennessee State University, Murfreesboro, TN; Ngee Sing Chong, PhD, Middle Tennessee State University, Murfreesboro, TN; Mengliang Zhang, PhD, Middle Tennessee State University, Murfreesboro, TN*

Learning Overview: Attendees will better understand the weathered chemical profiles of various ILs using GC/MS and DART®-MS.

Impact Statement: This presentation will impact the scientific community by showing the effect of weathering processes on the spectral profiles of the ILs and a comparative study of weathered samples on GC/MS and DART®-MS.

In many arson cases, fire is initiated by employing ILs.¹ Therefore, in the arson investigation process, the identification of ILs and IL residues at the scene plays a key role in identifying the cause of the fire and distinguishing the ILs used to initiate the fire. The most commonly used technique to analyze the fire debris is GC/MS; however, it has a major limitation of analyzing only the volatile components in ILs. The non-volatile or less-volatile components in ILs are likely to be contained in the fire debris and, hence, could yield corroborating evidence on the use of specific ILs in the investigation. DART®-MS is a sensitive tool with excellent analytical sensitivity to analyze non-volatile components in ILs.² In this study, the IL weathered chemical profiles are compared by GC/MS and DART®-MS methods.

In the present study, four ILs were selected: gasoline, diesel, kerosene, and Japan Drier. Aliquots of 1–10mL of each IL were weathered at three different temperatures, 30°C, 90°C, and 210°C, to different degrees of weathering at 30–99% mass reduction of IL prior to being analyzed. To analyze the IL samples on DART®-MS, an automated sample introduction apparatus with Linear Rail Enclosure that holds consumable Quickstrip™ sample cards were used. A 5µL sample volume was spotted on the Quickstrip™ card after diluting the sample in chloroform. For the GC/MS analysis, 20µL of the sample was added to 1mL of chloroform, followed by an injection of 1µL with a split ratio of 1:50.

The DART®-MS data were analyzed by averaging the mass spectra of ~60 scans after the spectral background subtraction. The mass spectral profiles of gasoline and Japan Drier are relatively consistent irrespective of weathering percentage. In the case of diesel and kerosene, as the weathering percentage increased, the mass spectral patterns shifted toward the higher mass range. The Total Ion Chromatogram (TIC) of GC/MS data of all ILs has shown a distinctive pattern corresponding to the extent of weathering. Collectively, for the highly weathered IL samples, the relative peak intensities increased for the less-volatile compounds. To evaluate the experimental factors in the sample preparation, such as weathering percentages and weathering temperatures, Analysis Of Variance-Principal Component Analysis (ANOVA-PCA) was used. The data indicated that the weathering percentage is the major factor responsible for the variance of the TIC data. The GC/MS data suggested that it is challenging to correlate the weathered IL to the non-weathered IL, because the weathering process significantly alters the relative quantities of the IL. The DART®-MS data of ILs provided less variable profiles and therefore may not be used to predict the weathering percentage of ILs. However, the capability of DART®-MS in detecting the less volatile IL constituents at high m/z values imparts its unique ability to discriminate among different types of ILs. Examples of these non-volatile additives include polyisobutylene succinimides and polyether amines in gasoline and carboxylate salts of zirconium, manganese, and cobalt in Japan Drier.

D6 Validation Testing of a Syntactic Authorship Identification Method Using Ground Truth Data From 20 Authors

Mariam Dar. PhD, The Institute for Linguistic Evidence, Georgetown, DE*

Learning Overview: In this presentation, attendees will learn about validation testing in forensic linguistic evidence, specifically author identification, in order to meet the reliability and error rate criteria for scientific evidence.

Impact Statement: This presentation will impact the forensic science community by providing results of validation testing using the Syntax-Based Authorship Identification (SynAID) method to determine the reliability and error rate of computational forensic linguistic author identification.

The first validation testing of forensic authorship identification methods came quite late to the field. Svartik coined the term “forensic linguistics” and used a syntactic and statistical analysis to determine authorship in a case.¹ However, afterward, no testing of the method to determine its reliability or error rate was performed. In fact, for close to three decades, academic linguists were providing reports and sometimes even testimony about authorship using methods that had never been tested to determine their reliability or accuracy.

Chaski began testing authorship identification techniques on “ground-truth” data (documents whose authorship was known), independent of any litigation, in order to determine error rate.^{2,3} For most of the tests, Chaski used four authors who were matched by age, dialect, educational level, and gender so any differences in style could not be attributed to demographics. Chaski’s results demonstrated that most ideas about authorship identification were highly unreliable, and even a combination of these techniques would get no better than 50% accuracy. Chaski published a validation test of a technique based on syntactic analysis, using text analysis software to analyze the syntactic patterns, syntactically classified punctuation and word lengths of texts to produce a numerical profile that is statistically analyzed using a leave-one-out, cross-validated discriminant function analysis (the SynAID method).⁴ In this validation testing, Chaski used ground-truth data from ten authors who were matched for age, dialect, and educational level with five men and five women.

Using the same dataset, Hirst and Feiguina performed validation testing of a different syntactic analysis method, the frequency of syntactic labels over two words in a row.⁵ Chaski reported additional validation tests.⁶ Nini and Grant performed validation testing using ground-truth data from three authors and, using non-syntactic features, could not differentiate those three authors.⁷ Juola reports a validation test of his software using blog posts, which are probably not ground truth data due to the nature of the internet and blog writing conventions.⁸

In the validation test in this presentation, ground-truth writing of 20 authors who have similar demographics are subjected to the SynAID method. The 20 authors are all male, White, middle-aged, college-educated, native English speakers with some executive or managerial experience. Their writing samples were all spontaneously written during the course of their daily lives. Test results with error rate and accuracy rate are reported for over 100 documents from these 20 authors. The 20 authors’ document numerical profiles were subjected to pair-wise statistical analysis using the protocol described in Chaski.⁴

Validation, Authorship Identification, Ground Truth Data

D7 Examining Conceptual Burstiness and Its Discursive Purpose in Violent Extremism Cases

Awni Etaywe*, University of New South Wales, Sydney, New South Wales, Australia

Learning Overview: This presentation showcases how to explore concepts with burstiness in discourse and how an empirical language analysis of “conceptual burstiness” can help security and intelligence investigators understand terrorist texts and interpret crucial information and semiotic cues on terrorism cases.

Impact Statement: This presentation provides cues applicable for risk contexts to suspect, characterize, and understand terrorism cases, particularly cues on intentions, agendas, ideological grounds for violence, and radical ideological perceptions. These linguistic contributions are a crucial part of what prosecution and intelligence analysts can use; failure to consider such contributions to evidence interpretation means that threat assessment and prosecution can easily go awry.

Linguistics can help security, intelligence, and law enforcement agents understand terrorism cases.¹ To date, limited forensic linguistic research has been undertaken on conceptual burstiness as a discursive marker in transnational terrorism cases despite recognition of the usefulness of this language feature in text authorship tasks, marking genres, topics and authors, and information retrieval.^{2,3} This presentation showcases how an empirical language analysis of conceptual burstiness can help investigators understand terrorist texts and interpret crucial information on terrorists’ agendas, ideologies, affiliations and stances, and on the discursive purpose of drawing on particular concepts. Repetition of particular concepts is taken as characteristic of the burstiness of these concepts and their subcategories. This presentation explores a set of “bursty concepts,” as textual elements of violent extremism, in a corpus of 20 terrorist public statements communicated openly (via the internet and media outlets) over 2001–2019 by four transnational terrorists: former al-Qaeda leader Osama bin Laden; former ISIS leader al-Baghdadi; Boko Haram leader Shekau; and the far-rightist Brenton Tarrant.

To elevate accuracy and reduce subjectivity, the most frequent lemmas were initially explored by AntConc software (version 3.5.8.0).⁴ To enable a broad overview of these lemmas, the number of times of word occurrence was set to a minimum of 10. For accuracy purposes, counts of synonyms such as *messenger* and *prophet*, *brother* and *brethren*, *Allah* and *God/lord* (in e.g., Shekau’s texts), or *iman* (Arabic word) and *faith* were added to each other, making one lexeme. The resulting lists of lemmas have produced a list totaling 8,659 repetitions of 264 lemmas, that is, 21.65% of the entire specialized corpus. The semantic categories of the groups of lexis were annotated manually. Based on a close examination of the lemmas in their concordance lines, the running concepts were identified. That is, words with close semantic proximity—whether encoding related concepts, indexing or evoking particular intertextual worlds (e.g., economics, religion, etc.), belonging to specific semantic fields or domains of experience (e.g., the military), or groupable under certain lexical sets identifiable in Roget’s Thesaurus—were grouped together under superordinate and subordinate groups of concepts, such as “violence” and “violent action,” respectively. The patterns of the most frequent lemmas were compared with full-fledged corpus linguistics studies of lexical categories of extremist discourse. Findings showed a network of bursty concepts of 5 superordinate categories—“people,” “religion,” “power,” “violence and military,” and “sayers” categories—and 17 subcategories. The concepts served as indicators of elements such as the underpinning religious and ethnic ideologies, the ideological motivations of violence threatened or incited for, the terrorists’ agendas of violent actions, their geographical spread, terrorists’ interests in political and economic control over out-groups, the participants involved, and their acts of stance taking.

Burstiness in the dataset was found as a function of the discursive purpose to which the heightened use of concepts is mobilized in these texts. That is, the terrorist texts tended to drive the burstiness of identified lemmas and their conceptual categories to serve the terrorists’ purposes, such as presenting the terrorists as powerful social actors in the argumentative discourse of violence, generating fear, prescribing specific forms of violence, legitimization of violence, and provoking hostility against religiously or politically different “others.”

Extremism, Forensic Linguistics, Transnational Terrorism

D8 Validation Testing for Authorship Identification Outside and Inside Casework

Carole E. Chaski, PhD*, Institute for Linguistic Evidence, Georgetown, DE

Learning Overview: After attending this presentation, attendees will better understand how validation testing occurs in the Syntax-Based Authorship Identification (SynAID) method for forensic author identification, both outside and inside casework.

Impact Statement: This presentation will impact the forensic science community by providing an example of how validation testing can occur within each case as well as outside casework, a technique that could be helpful to other methods of pattern-based evidence.

The first validation testing of forensic authorship identification methods began in 1997 with testing of authorship identification techniques on “ground-truth” data (documents whose authorship was known), independent of any litigation, in order to determine error rate.^{1,2} Most of these tests used four authors who were all native speakers of English, matched by age, dialect, educational level, and gender(i.e., a group controlled by demographics, which influence language use). Validation test results demonstrated that most ideas about authorship identification were highly unreliable, and even a combination of these techniques would get no better than 50% accuracy, a result that was replicated by other scholars.³ Again, conducted outside casework, a validation test of a technique based on syntactic analysis, using text analysis software to analyze the syntactic patterns, syntactically classified punctuation, and word lengths of texts to produce a numerical profile that is statistically analyzed using a leave-one-out, cross-validated discriminant function analysis (the SynAID method) was published.⁴ In this validation testing, ground-truth data from ten authors, who were matched for age, dialect, and educational level with five men and five women was used. The SynAID method was able to differentiate the documents of ten authors and assign the documents to the correct author with 95% cross-validated accuracy. Using the same dataset, Hirst and Feiguina validated a different syntactic analysis method, the frequency of syntactic labels over two words in a row.⁵ Furthermore, additional validation tests of the SynAID method was reported.⁶ Validation tests of the SynAID method outside casework continue and are crucial to meeting current reliability standards for forensic science.⁷⁻¹⁰

One difference between the SynAID method and other methods of forensic author identification is that the SynAID method provides a validation test of the method *inside each case*. The SynAID method first determines how well the known suspects can be differentiated from each other, creating a statistical model of authorship, then, using leave-one-out cross-validation tests, the statistical model of authorship to see how many times each known document will be assigned to the correct author. Thus, for each case in which SynAID is used, the SynAID method is tested on known documents (i.e., a case-internal validation test is conducted). If the method can differentiate and assign known documents with high accuracy (over 80%), then and only then are the questioned documents assigned statistically to one of the suspects. This study presents the results of over 20 such case-internal validation tests. Most importantly, the SynAID method demonstrates that other methods that rely on pattern-based evidence could implement the same technique of validating the method on known items in the case itself before handling questioned items.

Learning Overview: Attendees will learn about fairness in machine learning algorithms and their impact on automated forensic evidence pattern matching

Impact Statement: This presentation brings to the forefront a major issue with algorithmic pattern matching, addresses fairness concerns, and provides a unique way to get unbiased and reliable results

Machine learning algorithms fundamentally rely on the training sample being representative of the population under consideration. This becomes an issue when dealing with new samples that are considered not from the same population, or when the training sample is not a random sample of the underlying population. In such cases, the predictions from machine learning algorithms can lead to incorrect results. In usual settings, it is not possible to identify what the true underlying population is, and this becomes even more complicated when dealing with high-dimensional settings. Therefore, the training sample may or may not represent the true nature of the data that is to be modeled. This can lead to incorrect predictions and misclassified results. When dealing with critical areas like forensics, such incorrect predictions can have far-reaching effects and influence court proceedings catastrophically.

One such case arises when the class of new samples is from a multivariate location-shifted distribution when compared to the training sample distribution. When dealing with classification performance using probabilistic scores from machine learning, and under specified conditions, this problem can alternatively be viewed as the inability to get equal error rates at a pre-specified classification threshold when the test data set (or new unknown samples) and training samples are different in terms of the location parameter. With the goal of removing bias that stems directly from such covariate shifts, and ensuring equal error rates, a robust method of transforming the original problem of classification to a problem of classification via dependence modeling is provided for a class of scale-invariant machine learning algorithms. This is done in a way that the new predicted outcome is now considered “fair” with respect to sampling bias and algorithmic bias stemming from covariate shifts. Both sampling and algorithmic bias from covariate shifts can be treated differently depending on the algorithm under consideration. However, it is shown that when using random forests under the proposed conditions, sampling and algorithmic bias from covariate shifts are two sides of the same coin.

The performance of the proposed method was evaluated for forensics ballistics data. For the case of bullet matching algorithms, it can be specifically seen that the problem of covariate shifts, or multivariate location-shift, is analogous to training and test data sets representing different firearms. It is then shown that the proposed method outperforms previous state-of-the-art methods in automatic bullet matching in situations of shifted covariates.¹ Thus, robust predictions results are provided, agnostic to the firearm under consideration. The proposed method is also agnostic to the nature of forensic evidence data as long as the assumptions of method are satisfied and data quality standards are maintained to ensure that the sampling and algorithmic bias are only from covariate shifts.

D10 Validation Testing of the SynAID Method for Authorship Identification Using Ground Truth Data from Four Non-Native English Authors

Ángela Almela, PhD*, Universidad de Murcia, Murcia, Spain and Institute for Linguistic Evidence, Georgetown, DE; Pascual Cantos Gómez, PhD, Universidad de Murcia, Murcia, Spain

Learning Overview: Attendees will better understand validation testing in forensic linguistic evidence, specifically author identification, using the SynAID method on a dataset of non-native English speakers to meet the reliability and error rate criteria for scientific evidence.

Impact Statement: This presentation will have an impact on the forensic science community by providing validation testing results using the SynAID method to determine the reliability and error rate of computational forensic linguistic author identification when non-native English speakers write the documents.

The first validation testing of forensic authorship identification methods occurred quite late to the field. Svartvik coined the term “forensic linguistics” and used syntactic and statistical analysis to determine authorship in a case.¹ However, no testing of the method to determine its reliability or error rate was done after that. Indeed, for nearly three decades, academic linguists have been providing reports and, in some cases, testimony about authorship using methods that have never been tested to determine their reliability or accuracy. Chaski began testing authorship identification techniques on “ground-truth” data (documents whose authorship was known), independent of any litigation, in order to determine error rate.^{2,3} For most of the tests, Chaski used four authors who were all native speakers of English, matched by age, dialect, educational level, and gender, so that any differences in style could not be attributed to sociolects. Chaski’s results demonstrated that most ideas about authorship identification were highly unreliable, and even a combination of these techniques would get no better than 50% accuracy. Chaski published a validation test of a technique based on syntactic analysis, using text analysis software to analyze the syntactic patterns, syntactically classified punctuation, and word lengths of texts to produce a numerical profile that is statistically analyzed using a leave-one-out, cross-validated discriminant function analysis (the SynAID method).⁴ In this validation testing, Chaski used ground-truth data from ten authors, who were matched for age, dialect, and educational level with five men and five women. Using the same dataset, Hirst and Feiguina validated a different syntactic analysis method, the frequency of syntactic labels over two words in a row.⁵ Furthermore, Chaski reported additional validation tests.⁶

In the validation test presented, the ground-truth writing of four authors who were highly educated, sophisticated authors, and non-native speakers of English is analyzed. The known documents are subjected to the SynAID method, and validation test results with an error rate and accuracy rate are reported.

Forensic Computational Linguistics, Authorship Identification, Syntax

D11 A Comparison of Two Computational Approaches to Analyzing Last Words

Cristina Aggazzotti, PhD, Institute for Linguistic Evidence, Georgetown, DE

Learning Overview: After attending this presentation, attendees will have learned about two computational approaches for classifying the last words of inmates on death row.

Impact Statement: This presentation will impact the forensic science community by discussing and comparing two computational forensic text classification approaches on a relatively understudied text genre.

Most natural language processing research on final statements before death have focused on suicide notes with the aim of automatically identifying suicidal thoughts in order to help prevent a subsequent suicide. The last words of inmates on death row have primarily been treated as a comparative dataset for testing suicide note classifiers rather than as the focus of the classification research.

Recent work has shown that various versions of Long Short-Term Memory (LSTM) models are becoming more accurate for suicide note classification.¹⁻³ One follow-up study expanded on this work by additionally implementing a Transformer Recurrent Neural Network (TransformerRNN) to classify suicide notes, last words, and neutral online blog posts.⁴ The study found that although the TransformerRNN achieves new state-of-the-art in overall performance and in classifying suicide notes, LSTMs with attention perform better at classifying last words specifically.^{1,5}

ALIAS Suicide Note Assessment REsearch (SNARE), a computational tool that implements Linear Discriminant Function Analysis (LDFA) with leave-one-out cross-validation, achieves competitive accuracy on the similar task of distinguishing real suicide notes from various other related text genres, including simulated suicide notes, apology letters, love letters, and angry letters, among others.⁶ A previous pilot study applied SNARE to a dataset of last words to determine which text genres last words most closely resemble as a means of shedding light on the mental state of inmates immediately prior to death.⁷

Based on the recent success of LSTMs with attention for classifying last words, the present study implements an LSTM within SNARE to analyze the datasets of last words, suicide notes, and the various control document genres. The results of this preliminary test will be presented and compared to the LDFA results on the same task. Implications of this experimental comparison and directions for future research will also be discussed.

D12 The Lineup Technique for Forensic Author Identification

Carole E. Chaski, PhD, Institute for Linguistic Evidence, Georgetown, DE

Learning Overview: After attending this presentation, attendees will have learned how the lineup technique can be used properly in forensic author identification.

Impact Statement: This presentation will impact the forensic science community by providing principles of the lineup technique in forensic author identification when only one suspect related to the case investigation is available, a technique that can be extended to other kinds of document examination.

The “lineup technique” is used for eyewitness and earwitness identification of a suspect in relation to distractors. Currently known as the “sequential” lineup, the eyewitness is performing a pair-wise comparison between the photograph and the memory.¹⁻⁴ In an earwitness lineup, voice samples are presented sequentially.⁵ Underpinning all lineup techniques is the fundamental fairness of the procedure. A fair lineup is one in which the suspect and the distractors are similar enough that the suspect does not stand out from the distractors unfairly.

The lineup technique can be used for authorship identification under certain conditions. First, the lineup technique should only be used when there is only one suspect in the case. If there are several possible authors of a questioned document, all of the suspects should be tested in the “candidate pool.” There is no need for a lineup. Second, the distractors must be similar to the suspect. For authorship, the distractor authors must have the same demographics that affect language as the suspect author. The lineup authors must match the suspect author’s native language, sex, age range, education, race, work experience, and contemporaneous. It is patently unfair, although it has happened in case reports, to compare a 21st-century Black American prisoner to 20th-century French literary authors or to compare a 21st-century native-Swedish law professor to 19th-century native-English literary authors. Such unfairness should immediately disqualify experts who are obviously trying to rig their methods to identify the Black American prisoner or exculpate the Swedish law professor, just as any court would disqualify a lineup in which a male suspect is compared to only female distractors. Third, the lineup should follow the sequential, pair-wise testing to determine if the suspect author and each lineup author can be differentiated, and, if so, to whom the questioned document belongs.

This presentation presents an example of the lineup technique in which the SynAID method of forensic authorship identification was deployed. A sheriff was accused of harassing and cyberstalking a citizen by producing 11 anonymous documents. First, prosecutorial investigators had no other suspect than the sheriff. A lineup method was warranted. Second, the sheriff’s demographics were known so that 19 distractors who matched his demographics were used in the lineup. The 19 distractors were all contemporaneous, native-English, White, middle-aged, college-educated men with some executive experience. Third, 19 pairwise tests were run sequentially. Each line-up author was tested against the suspect to determine how well the SynAID method could differentiate the known writings of each author. If the statistical model of known authorship is over 80% accurate, then the model is used to assign each questioned document independently to one of the pair. The average accuracy of the 19 models of authorship was 95%. Given these strong models of authorship, the assignment of the questioned documents then occurred. Each of the 19 models of authorship overwhelmingly identified the sheriff rather than the distractor as the author of each questioned document. Finally, a binomial probability is used to determine the likelihood that a questioned document will be assigned x out of y tests.

Forensic Author Identification, Lineup Technique, Syntax

D13 A Comparison of Authorship Identification Methods Using Ground Truth Data from Four Non-Native English Authors

Pascual Cantos Gómez, PhD, Universidad de Murcia, Murcia, Spain; Angela Almela, PhD, Universidad de Murcia, Murcia, Spain and Institute for Linguistic Evidence, Georgetown, DE*

Learning Overview: After attending this presentation, attendees will better understand validation testing in forensic linguistic evidence, specifically authorship identification, using three different methods on the same dataset to meet the reliability and error rate criteria for scientific evidence.

Impact Statement: This presentation will impact the forensic science community by providing validation testing results to determine the reliability and error rate of using three different methods of author identification when the documents are written by non-native English speakers.

In the field of forensic sciences, the testing of methods to determine their reliability or accuracy prior to their application to cases has proved to be of utmost importance. However, in forensic linguistics, further proper validation testing of authorship identification methods is needed. The first syntactic and statistical analysis to determine authorship in a case was presented in 1968.¹ Still, no testing of Svartvik's method was performed to assess its reliability or error rate afterward. In fact, for close to three decades, academic linguists have been providing reports and sometimes even testimony about authorship using methods that have never been tested to determine their reliability or accuracy.

Chaski began testing authorship identification techniques on "ground-truth" data (documents whose authorship was known), independent of any litigation, to determine error rate.^{2,3} For most of the tests, Chaski used four authors who were all native speakers of English, matched by age, dialect, educational level, and gender, so that any differences in style could not be attributed to demographics. Chaski's results demonstrated that most ideas about authorship identification were highly unreliable, and even a combination of these techniques would get no better than 50% accuracy. Chaski published a validation test of a technique based on syntactic analysis (the SynAID method).⁴ In this validation testing, Chaski used ground-truth data from ten authors, who were matched for age, dialect, and educational level with five men and five women. Using the same dataset, Hirst and Feiguina performed validation testing of a different syntactic analysis method.⁵ Chaski reported additional validation tests in her law review on best practices.⁶ Nini and Grant performed validation testing using ground-truth data from three authors and, using non-syntactic features, could not differentiate those three authors.⁷ Stamatos presented a validation test of a character-based method, using texts that were all the same genre and topic.⁸ However, matching topic and genre does not reflect the reality of forensic casework. Juola reports a validation test of his software using blog posts.⁹ However, blog posts are probably not ground truth data due to the nature of the internet and blog writing conventions.

Generally, the three approaches to author identification are syntax-based, word-based, or character-based. These approaches can be tested using software called SynAID, LexiAIDE, and UniAIDE. In the validation test in this presentation, ground-truth writing of four authors who were highly educated, sophisticated authors, and non-native speakers of English, writing on different topics and in different but comparable genres, is analyzed. The known documents are subjected to the SynAID, LexiAIDE, and UniAIDE methods that measure syntax, words, and Unicode characters, respectively. The validation tests determine how often the method correctly identifies the author of each document in the dataset. Validation test results with an error rate and accuracy rate are reported for the syntactic, character, and lexical approaches to meet the reliability and error rate criteria for scientific evidence.

Forensic Computational Linguistics, Authorship Identification, Validation Testing

D14 A Quantitative Comparison of Last Words to Related Text Genres

Cristina Aggazzotti, PhD, Institute for Linguistic Evidence, Georgetown, DE

Learning Overview: After attending this presentation, attendees will better understand the last words of inmates on death row as a text genre and will learn about the characteristics they share with other related genres.

Impact Statement: This presentation will impact the forensic science community by quantitatively analyzing last words and identifying their similarities and differences with related text genres to which they have not yet been compared.

Previous research has either focused on last words as its own text genre or compared them to suicide notes and depressed notes.¹⁻⁵ This present study expands upon this research by examining last words in relation to not only suicide notes, but also several other text genres, such as apology letters and trauma narratives.

This project is an extension of a previous pilot study that uses ALIAS Suicide Note Assessment REsearch (SNARE), a computational tool that employs linear discriminant function analysis with leave-one-out cross-validation. SNARE compares a questioned document to a database composed of over 400 real suicide notes and 500 control documents ranging over several text types: apology letters, love letters, trauma narratives, angry letters, complaint letters, simulated and real threats to known targets, business letters related to insurance, and simulated and hoax suicide notes.⁶ The output of SNARE is a quantitative classification of the questioned document as either a real suicide note or a control document.

SNARE obtains an accuracy of 80% distinguishing real suicide notes from control documents and an even higher accuracy of 86% for suicide notes limited to 45 words or less.⁶ In comparison, mental health professionals obtain an accuracy of 63% to 71% identifying suicide notes as real or not.^{7,8}

The original pilot study tested a subset of the data—the first 100 final statements of death row inmates in Texas starting in 1982—which is publicly available on the Texas Department of Criminal Justice website.⁹ The results showed that last words were more often classified as a suicide note (85 out of 100) than as a control document (15 out of 100).

The present study extends the pilot study by incorporating all of the data (445 total final statements) and digging deeper into the results to examine the features that last words share with the comparison text genres. Viewing last words through the lens of each of these genres can help improve SNARE as a suicide note classifier and can provide further insight on the perspectives held by inmates immediately preceding death.

Computational Forensic Linguistics, Last Words, Suicide Note

D15 Critical Flow Behavior in Forensic Engineering Accidents

Chan-Seong Park, PhD, National Forensic Services, Wonju-si, Gangwon-do, Korea; Kwnag-Soo Choi, MSe, National Forensic Services, Wonju-si, Gangwon-do, Korea; Hong-Pil Jeon, MSe, National Forensic Services, Wonju-si, Gangwon-do, Korea; Researcher Seung-Ho Chae, MSe, National Forensic Services, Wonju-si, Gangwon-do, Korea*

Learning Overview: After attending this presentation, attendees will understand the mechanism underlying forensic engineering accidents caused by critical flow behavior.

Impact Statement: This presentation will impact the forensic science community by introducing the importance of critical flow behavior in forensic engineering accidents.

If a working fluid, such as compressible gas, is expanded across a flow device (e.g., a nozzle, an orifice, a valve, or the end of a pipe exit), its velocity and specific volume changes with upstream or downstream pressure. As the inlet pressure increases or the outlet pressure decreases, the gas velocity through the flow device reaches a sonic condition. When the gas velocity reaches sonic velocity, further increases in upstream pressure do not cause any further increases in gas velocity through the flow device. Once the sonic velocity is reached, further increase in the upstream pressure causes an increase of density, which in turn results in an increase of the mass flow rate. In the case of a fixed inlet condition, further decreases in the downstream pressure do not cause any further increase of either the velocity or the mass flow rate. These phenomena play key roles in pressure-relieving devices for vessels and an ignition mechanism in flammable gas system, such as an oxygen-enriched system.

This presentation introduces one case of an explosion accident that happened in a plant at a valve exit of an oxygen-enriched system. It is reported that fires in oxygen-enriched systems require a source of energy to trigger ignition. The most common ignition energy sources are mechanical impact, particle impact, friction, and pneumatic impact or compression heating.¹ When high purity oxygen under high pressure is released quickly through a valve into a low-pressure environment, the velocity can reach a sonic condition, resulting in near-adiabatic compression at an outlet flow obstacle. This phenomenon was verified through an experiment using nitrogen gas. The experiment was simulated by Computational Fluid Dynamics (CFD) with a change in the working fluid from nitrogen to pure oxygen.

Experiments with one spring-loaded pressure relief valve and one rupture-disk pressure relief valve with increasing inlet pressure at a fixed ambient exit pressure are also presented. The volumetric flow rate does not increase when the absolute pressure ratio reaches 1.89, which corresponds to the sonic velocity condition. The mass flow rate increases linearly regardless of the sonic velocity condition but remains almost constant above the absolute pressure ratio of 22.

This study introduces an analysis tool for the critical flow behavior of gas that can cause plant-related accidents and the flow characteristics of specific pressure relief valves in accordance with the pressure ratio that can explain the failure mechanism of a pressure vessel.

Forensic Engineering, Critical Flow, Pressure-Relief Device

D16 A Visualization of Overlapping Fingerprints by Hyperspectral Imaging in the Visible Region

Norimitsu Akiba, PhD*, National Research Institute of Police Science, Kashiwa, Chiba, Japan; Atsushi Nakamura, PhD, Waseda University, Shinjuku-ku, Tokyo, Japan; Takayuki Sota, PhD, Waseda University, Shinjuku-ku, Tokyo, Japan; Kazuhito Hibino, National Police Agency, Chiyoda-ky, Tokyo, Japan; Hidetoshi Kakuda, PhD, National Research Institute of Police Science, Kashiwa, Chiba, Japan; Kazunari Shibasaki MSc, National Research Institute of Police Science, Kashiwa, Chiba, Japan; Ken'ichi Tsuchiya, PhD, National Research Institute of Police Science, Kashiwa, Chiba, Japan; Kosuke Tanabe, MSc, National Research Institute of Police Science, Kashiwa, Chiba, Japan

Learning Overview: After attending this presentation, attendees will have a better understanding of a non-destructive detection method of fingerprints with a hyperspectral imager and a separation method of overlapping fingerprints.

Impact Statement: This presentation will impact the forensic community by providing a non-contact, non-destructive, and non-invasive method to detect fingerprints with a hyperspectral imager and a laser. It is shown that overlapping fingerprints can be effectively utilized by this method.

Fingerprints are one of the clues of personal identification and are important evidence in criminal investigations.¹ Fingerprint identification is done by comparing their minutiae. However, in past cases of the two or more overlapping fingerprints, even if the minutiae were found out, the overlapping part was not available for identification because it is not clear which fingerprint the minutiae of the overlapped part belonged to. Since the components of the fingerprint depend on the individual, the fluorescent spectra of each fingerprint are different and also change over time.² Therefore, if the fingerprint can be imaged using its different spectral information, it is possible to separate it into a single fingerprint.

Hyperspectral Imaging (HSI) is a method of obtaining a spectrum for each pixel in an image of the entire scene. It was reported that overlapping fingerprints were separated by subtracting and dividing the images acquired by HSI.³ Furthermore, Principal Component Regression (PCR) allowed this study to separate the overlapping fingerprints more clearly.⁴ In this study, Multivariate Curve Resolution-Alternating Least-Squares (MCR-ALS) was used to separate overlapping fingerprints in order to make better use of overlapping fingerprints.

Two overlapping fingerprints were prepared. The images of the fingerprints were acquired with a hyperspectral imager in a wavelength range of 414.7-983.6nm. The resolution of wavelength was 1.0nm, and the resolution of image was 600 x 960 pixel; 532nm continuous-wave laser was used as a light source.

Fluorescence spectra of the two fingerprints were observed from 560 to 760nm, and were different from each other. First, PCR was performed using 200 images from 560 to 760nm. As a result, two single fingerprint images were obtained in up to the sixth principal component. These images were clearer than those by subtraction and division methods. However, unclear parts in the fingerprints remained. One of the reasons is that loadings of PCR are permitted negative, although fluorescence spectrum is ordinarily only positive. On the other hand, since the calculation in the MCR-ALS is carried out under a non-negative constraint condition, it is possible to resolve into the spectrum similar to the actual spectrum. Since MCR-ALS requires initial conditions, it was calculated using the PCR components as initial conditions. As a result of spectral resolution by MCR-ALS and PCR, the areas that were unclear by the method of only PCR became clearer. It was demonstrated that the MCR-ALS and PCR method using HSI for the separation of overlapping fingerprints could be considered more effective.

D17 A Semi-Permeable Membrane Device for Canine Explosive-Detection: A Rate of Evaporation Study

Madison Reavis, BS, IUPUI, Indianapolis, IN; John Goodpaster, PhD, IUPUI, Indianapolis, IN*

Learning Overview: Attendees of this presentation will gain information and understanding about the quantity of odor that emits from a Semi-Permeable Membrane Device (SPMD) and its applicability to canine explosive-detection training.

Impact Statement: This presentation will impact the forensic science community by presenting information about the training of canines for explosive-detection using an SPMD for odor delivery and training aid storage.

When not in use, training aids used for canine explosive-detection training are typically stored in ammo cans held in large magazines, although there is no generally accepted storage method. Due to the lack of a perfect seal in the ammo can, explosive volatiles often contaminate materials that are stored nearby. To ensure canines are trained using uncontaminated training aids, an SPMD is being tested as a new way to store training aids to eliminate contamination and to train canines via odor delivery.

The SMPDs being tested consist of a glass jar, a membrane holder, and a gas-tight lid. The membrane holder, housed between the jar and gas-tight lid, contains an odor permeable membrane that is sealed by a gasket.

The goal of this research is to quantify the amount of explosive odor that escapes from the SPMD compared to unconfined explosives to determine if SPMDs can be used for canine training. The data obtained from this study will determine if evaporation rates of common solvents from the SPMD are predictable, reliable, and reproducible from day-to-day and from SPMD to SPMD.

Data for this research was obtained using a high-precision analytical balance. For each experiment, the SPMD was filled with 30mL of solvent and the membrane holder and gas-tight lid were then sealed. The gas-tight lid was removed before the SPMD was placed on the balance. The mass of the SPMD and its contents were recorded every 60 seconds for 60 minutes. This data was plotted to generate a graph of mass loss as a function of time. Data regression was performed to obtain values used to calculate evaporation rate relative to n-butyl acetate, which has a known and standardized rate of evaporation.

Preliminary data suggests that there is an exponential relationship between relative boiling point and evaporation rate. It has been determined that compounds with higher boiling points have lower evaporation rates than compounds that have lower boiling points, such as r-limonene (BP 178°C) and nitromethane (BP 101°C) with relative evaporation rates of 0.07 and 3.57, respectively. Work is currently being done to further explore this relationship and to determine an equation that dictates it. The materials studied thus far include nitromethane, nitroethane, 1-nitropropane, 2-ethyl-1-hexanol, r-limonene, Dyno Unimax, 2,4-dinitrotoluene, and tetryl. The effect of pore size in the odor permeable membrane on evaporation rate is also currently being investigated.

Forensic Explosive Analysis, Canine Training Aids, Semi-Permeable Membrane Device

D18 Noble Metal-Decorated Silica Monoliths for Forensic Analysis of Drugs and Pesticides Using Mass Spectrometry (MS)

Entesar Al-Hetlani, PhD*, Kuwait University, Khaldyia, Asimah, Kuwait; Mariam Ismail, MSc, Kuwait University, Khaldyia, Asimah, Kuwait; Mohamed Amin, MSc, Kuwait University, Khaldyia, Asimah, Kuwait

Learning Overview: The use of a minute amount of sample is of great interest to forensic scientists; most evidence recovered in the crime scene is of limited quality and quantity, which can affect its analysis. This work demonstrates the use of a minute amount of sample; drugs, pesticides, drugs in blood serum, and pesticides in beverages to detect species of forensic interest. The use of Surface Assisted Laser Desorption/Ionization-Mass Spectrometry (SALDI-MS) has recently proven to be a very powerful technique and highly suitable for forensic applications due to the relatively simple requirements and small sample consumption. It has been used for fingerprint, explosive, drug, and textile fiber analyses and produced satisfactory results with a good limit of detection. Drugs have always been one of the most commonly encountered evidence; recently, pesticides and rodenticide have emerged as a major concern for forensic scientists. As demonstrated by Blakey et al., such species have also been used as adulterants in street drugs.¹ Therefore, analysis of drugs and pesticides using SALDI-MS has a great potential for narcotics and toxicology applications.

Impact Statement: Recently, research into forensic drugs and pesticides analyses has gained wide attention. This is motivated by the rapidly developing street drug market and emergence of new drugs mixed with several adulterants. Several researchers have focused on drugs in biological fluids using conventional chromatographic techniques coupled with extraction for sample cleanup. Therefore, crime scene investigation of traces in a beverage or biological stain and the presence of drugs and poisons is of great significance. Therefore, this study explored the analysis of beverage and blood serum spiked with drugs and pesticides, respectively, using Surface-Assisted Laser Desorption/Ionization-Mass Spectrometry (SALDI-MS) using a small amount ($\approx 2\mu\text{L}$). The obtained mass spectra were investigated in terms of the effect of sample deposition and the presence of electrolytes and were carefully studied. Using Au-SiO₂ as a substrate offered the best results, with a Limit of Detection (LOD) of 10pg/mL to 1fg/mL for drugs and 10 g/mL to 10fg/mL for pesticides. Despite the presence of salts at high concentrations, the detection of drugs and pesticides was feasible. Future applications of the developed substrates can be extended to the analysis of Performance-Enhancing Drugs (PEDs) used by professional athletes.

Over the years, the development of MS methods has generated limitless possibilities for forensic toxicology and drugs analyses, where qualitative and quantitative analysis of drugs and poisons continue to be one of the most concerning issues to forensic investigators. Drugs are substances mainly used to cure diseases; however, they can be abused and be the source of violence, crimes, or even death. Furthermore, fatal poisoning by pesticides is not uncommon because there are cheap to obtain, widely available and accessible, and, therefore, can be used in suicide cases. In this work, four noble metal nanoparticles (NPs) Au, Ag, Pt, and Pd (M) were introduced on silica-based (SiO₂) monoliths 3D skeleton (M-SiO₂) via chemical reduction. Subsequently, they were used as SALDI-MS substrates for drugs and pesticides detection. The loading amount of the M-NPs on SiO₂ monolith, reducing agent concentration and reaction time, were optimized for all the substrates and monitored using an Ultraviolet/Visible (UV/Vis) spectrophotometer. Elemental and morphological analysis proved the successful loading of spherical noble metal NPs on SiO₂ monoliths without affecting the original morphology of the SiO₂ monoliths. The M-SiO₂ substrates were then employed for SALDI-MS; the results revealed that the sample deposition method influenced the SALDI performance and Au-SiO₂ substrate demonstrated the best results compared to other substrates in terms of the signal-to-noise (S/N) ratio. In addition, the tolerance toward electrolytes was investigated and Au-SiO₂ substrate exhibited high salt tolerance and detection was possible even at 500mM of NaCl. Finally, non-biological and biological samples, particularly carbonated malt drink and blood serum spiked with drugs and pesticides, respectively, were analyzed using Au-SiO₂ substrate. The prepared substrate offered sensitive detection of the analytes with a Limit Of Detection (LOD) of drug-spiked drinks of 1ng/mL for doxepin, 100ng/mL for desipramine, 1μg/mL for imipramine, amitriptyline, and trimipramine and pesticide-spiked serum of 100ng/mL for dimethametryn and thiodicarb, and 1ng/mL for metalaxyl and napropamide and a relative standard deviation (%RSD) of 7.21-22.22% and 2.68-26.29% for drugs and pesticides, respectively. There was no sample preparation for the carbonated drink and very simple preparation for the blood serum, yet the analytes were identified with low LOD and high shot-to-shot reproducibility. Au-SiO₂ monolith proved to be an efficient tool to detect small molecules in limited amounts of sample and thus their forensic applications could be further expanded.

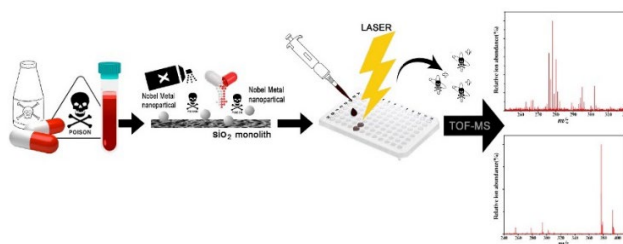

Figure 1. Schematic illustration of the experiments employed for the determination of drugs in blood serum and pesticides in spiked carbonated beverage. A 2μL amount of the sample was deposited on the optimized Au-SiO₂ monolith and analyzed using SALDI-MS to obtain the relative mass spectra for the drugs and pesticides.

D19 Automation in Forensic Science: The Future Ahead

Rattandeep Kaur, Msc, Panjab University, Chandigarh, India; Surya Kant Tripathi, PhD, Panjab University, Chandigarh, India*

Learning Overview: The goal of this presentation is to help attendees understand the challenges that are confronted in the application of Artificial Intelligence (AI) and Machine Learning (ML) to the field of forensic science.

Impact Statement: This study will impact the forensic science community by presenting the challenges faced by a forensic scientist while deploying AI and ML tools for the analysis of evidence and data. The probable solutions for the problems will be presented so that the benefits of AI and ML can be garnered by the forensic science community.

Technology has been an elixir for human beings and has grown and evolved just like humans due to which the role of humans has slowly diminished. AI and ML have proven their potential application in tasks like the Automated Fingerprinting Identification System, Forensic Ballistics Identification System, Probabilistic Genotyping Algorithms, etc. However, there is still wariness in accepting these automated systems openly for forensic applications as has been done in other fields. One of the reasons for this is that of all of the other areas, criminal justice and forensic science are the areas where the transition to automated systems is looked at with extreme caution.

The focus of this study is to present the problems caused by the introduction of automated systems in forensic case evaluations. The computational algorithms are found to be opaque, which makes them difficult to discern or control. This in turn leads to inefficient ML process and such uncertainties and errors in turn affect the output of the systems. The inefficiency in automated systems can be a result of the opaque nature of the algorithm. This opaqueness can be intentional, technical, or inherent. On one hand where market domination and competition are the reasons for intentional opacity, lack of skills and the presence of complex systems are the causes for technical and inherent opacity, respectively.¹ Probabilistic genotyping constitutes the use of statistical methods and computing in order to perform DNA profiling and has been one such area where the foundational validity of the methods used is sometimes challenged.

On the solution part, reviewing source code is one of the solutions posited, and efforts should be made to critically and scientifically evaluate the output of such automated systems.² As suggested in the National Academy of Sciences Report in 2009, research must be done with the intention of understanding the reliability and repeatability of the comparison methods used. Efforts should be made to design an algorithm that is comprehensible. Forensic scientists should make sure that the automated system they choose is capable of addressing the problem concerned and, last but not least, automated systems should be able to explain the decision-making process to the users.²

In summary, misrepresentation of facts by the automated systems can lead to jeopardizing human rights; hence, efforts should be made to align the evaluation of evidence on such protocols that are able to strengthen the trust in forensic science and eventually in the criminal justice system.

Artificial Intelligence, Algorithms, Forensic

D20 Physical Evidence Demonstrating Poor Maintenance in the Cause of an Axle Fracture and a Rollover Crash With Injuries

Kurt Weiss, MSME, Case Study Collision Science, LLC, Santa Barbara, CA; Mark Pozzi, MSSE, Sandia Safety Science, Edgewood, NM; David Bosch, PhD, Forensic Engineering, Inc., Phoenix, AZ*

Learning Overview: Forensic investigators will become informed as to how and why catastrophic axle failures occur, and the related circumstantial and physical evidence that can be analyzed to properly investigate such incidents.

Impact Statement: The forensic community will benefit from learning about these relatively uncommon but predictable failures that often result in catastrophic injury and death. The loss of control, traffic collisions, and rollover events typically occur at highway speeds with little or no warning. Forensic investigators involving criminalistics, engineering sciences, and jurisprudence should have particular interest in this topic.

At approximately 60mph, the driver of a small domestic SUV suddenly felt like something broke, and he could no longer control his vehicle. The vehicle unexpectedly steered left into the center median, where the right-side tires furrowed in the dirt, precipitating a passenger-side leading rollover. The right rear wheel assembly that had completely separated from the SUV was located during an inspection of the incident site. Although they had been replaced only three days before the crash, it was concluded the tires did not cause or contribute to the collision.

The SUV was inspected, and the entire rear axle assembly was removed to allow for high-resolution microscope and borescope imaging of the axle shaft. Approximately one cup of differential oil was drained in the process. The exposed end of the fractured axle shaft revealed the entire end bearing was missing, and the axle housing showed an unexpected wear pattern (Figure 1). Additionally, there were telltale signs of friction-generated heat on the axle housing adjacent to the failed end (Figure 2).

Located inboard relative to the flange assembly and wheel lug nuts, the solid axle features a bearing surface about which the end bearing rotates (Figure 3). Compared to the left axle shaft, the failed right component demonstrated a bearing surface with artifacts of excessive wear, abrasions, and marking related to metal-to-metal contact (Figure 4). It was concluded that insufficient lubrication contributed to the bearing failure. The failure likely occurred due to a lack of maintenance and inadequate inspection of the differential, pinion gear housing, and axle bearings prior to the incident.

Vehicle axle failures are uncommon, but are typically caused by lack of axle or bearing lubrication; failure to replace cotter pins in castle nuts leading to failure of hubs; overloading; roadway-induced impacts, collision-related damage; or in-service failures due to inadequate materials and design. The latter type of failure can cause an axle to fail catastrophically with little or no warning, often with no damage to the tire or wheel prior to axle fracture. The resulting loss of control often leads to collision or rollover.

Fuel economy and cost-reduction initiatives of the 1970s promoted downsized light trucks and SUVs, wherein passenger car axles are used to save weight and cost. Additional cost reductions eliminated pressed-on inner bearing races by converting the axle shaft surface into the inner bearing race. This process involved machining a bearing race into the axle and induction heating to harden the outer axle surface so it could withstand bearing wear. This had the negative effect of significantly reducing the diameter of ductile tough steel as the outer axle shaft surface was converted to brittle hardened steel. The net effect was axles that were not as durable or safe for their predictable use in trucks and SUVs on rough roads, towing, or hauling heavier loads. This led to increased incidents of operational failures of such axles in non-collision circumstances.

The dangers of heat-weakened axle shafts are exacerbated when they also require straightening, often as a direct result of the heat hardening of the inner bearing race area. The axle shaft is placed in an induction heater and straightened while red hot. This process is often repeated as necessary, sometimes as many as four times. This additional heating often further embrittled the outer surface of the axle, creating even greater likelihood of failure.

Axle Failure, Bearing Race, Rollover Crash

D21 The Mechanics of All-Terrain Vehicle (ATV) Rollovers

David Pienkowski, PhD, University of Kentucky, Lexington, KY*

Learning Overview: Attendees will gain a new appreciation for the risks of sideway and backward rollovers of youth and adult ATVs and the contributions to these risks attributable to varying terrain angles, throttle inputs, and number of ATV riders.

Impact Statement: Information provided in this presentation will aid the forensic engineer investigating the mechanics of ATV accidents because of the new data quantifying: (1) terrain angles at which backward rollovers become possible, especially when a second rider is positioned behind the ATV driver, and how this possibility can further increase due to maximum ATV throttle input; (2) relationships between ATV speeds and turn radii on level and terrain of varying incline angles; and (3) differences in sideway and backward rollover between youth- and adult-sized ATVs.

ATVs have enabled new mobility for those in rugged country terrain, but these vehicles are also associated with considerable injuries and deaths. ATV rollover is an unappreciated injury mechanism responsible for significant morbidity and mortality. Rollovers account for 63% of ATV crashes, making them the most prevalent type of ATV injury mechanism. Youths are more likely than adults to roll sideways on flat terrain, but adults are more likely to roll backward while riding uphill. ATV rollover injuries frequently occur because the hazards of ATV use are unrecognized or under-appreciated. The objective of this study was to quantify the mechanics attending side or backward rollovers for youth- and adult-sized ATVs for single and dual riders on varying terrain inclinations with varying engine throttle inputs.

Two new exemplar ATVs (one youth-sized, one adult-sized) were tested in a variety of side- and rear-directed inclinations in a controlled static laboratory environment using mathematical simulation. Centers of gravity of these ATVs were measured for one adult or one adult and one child rider (located at various seating positions on the ATV) for actual angular inclinations and simulated engine throttle positions. Rollover was considered to occur when the center of gravity extended beyond the footprint of the studied ATV tires.

The analyses showed that youth-sized ATVs are slightly less susceptible to sideway rollover than adult-sized ATVs. The presence of a rider behind the ATV driver, however, altered these findings. Thus, while youth-sized ATVs are slightly less susceptible to sideway rollover than adult-sized ATVs for a single rider, they are more susceptible to sideway rollover than adult-sized ATVs when a rider accompanies the driver.

The minimum turn radius that an ATV can safely negotiate increases sharply with increasing ATV speed. This is especially evident for speed changes from low initial take-off velocities. Specifically, an ATV can navigate a 3-4 four-foot turn radius only at low (10fps) speeds, while doubling the speed of the ATV to 20fps increases the safe minimum turn radius approximately 5–6-fold.

The likelihood of ATV tip-over with sharp radius turns is substantially increased by inclined terrain. A mild and commonly encountered 20° decline changes the minimum safe turn radius for an ATV moving at 30fps from approximately 35 feet to approximately 58 feet with a single occupant (the driver). A rider sitting behind the ATV driver doubles this safe minimum turn radius.

Backward rollovers become more likely as forward-approaching terrain inclination angles exceed 40° for youth- and adult-sized vehicles. This angle is substantially reduced in the adult-sized ATV when maximum throttle input is applied and to a lesser extent for the lower horsepower youth-sized ATV. The likelihood of backward ATV rollover also increases with the presence of a second rider behind the driver. Maximum throttle and a second rider elevate the likelihood of backward rollovers and reduce the critical angles of forward-approaching terrain angles to 15°–21°. Although youth-sized ATVs are almost equally susceptible to static backward rollover when only the driver is present, youth-sized ATVs are less tolerant of a rider behind the driver than adult-sized ATVs.

Risks inherent to actual ATV rollovers prohibited empirical testing and limited methods to static laboratory experimentation and theoretical torque values based on estimated engine responses. In conclusion, risk of sideway and backward rollover of ATVs can occur while turning at unexpectedly low speeds, especially when performed on inclined terrain, when full throttle is applied, or extra riders accompany the driver on the ATV. Compared to adult-sized ATVs, youth-sized ATVs do not provide substantial additional protection from sideway or backward rollovers.

ATV Accident, ATV Rollover, ATV Injury

D22 Runaway Mustang

Michael Rosenfield BS*, RSR Engineering, LLC, Mesa, AZ; Robert Anderson, MS, Biomechanics Analysis, Tempe, AZ

Learning Overview: Through a case study, attendees will be shown the steps taken to collect relevant physical and electronic evidence that was used to arrive at the conclusion of the existence of a sudden unintended acceleration that resulted in a significant automobile crash.

Impact Statement: This presentation will impact the forensic science community by presenting a case study that provides an example of an actual sudden unintended acceleration as well as outlining the investigation and analysis that was used to arrive at the conclusion that a sudden unintended acceleration had, in fact, occurred.

In this angled, head-on, rollover crash, a convertible driven by a teenager with three other teenage passengers ran a stop sign and struck a pickup. The convertible's driver claimed that a brake failure had prevented the vehicle from stopping. The passengers stated they heard the driver yelling, "I can't stop!"

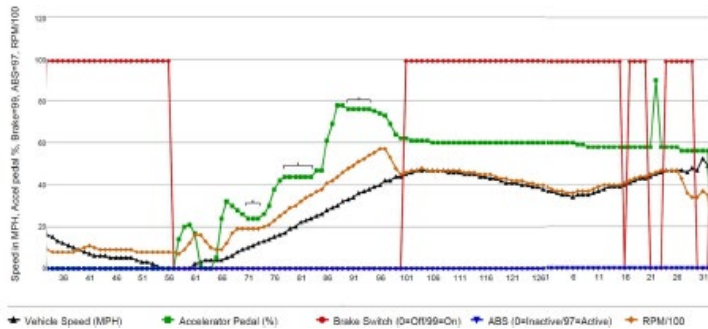

After failing to stop the vehicle at stop sign at a T-intersection, the driver reportedly switched strategies and attempted to make a right turn onto the main road but went into oncoming traffic. The assignment was to inspect the brake system to determine if there had been a brake failure and obtain pre-crash accelerator pedal and brake data from the Crash Data Retrieval (CDR) report to evaluate whether or not the driver had a pedal error.

Post-crash inspection of the convertible's brake system revealed that although the plastic master cylinder reservoir had become detached from the master cylinder during the collision, the hydraulic system was otherwise undamaged and in working order.

During the vehicle inspection, the Powertrain Control Module (PCM) was found to have significant damage, with a broken circuit board and missing components. Fortunately, the memory chip was still present so that the PCM data was obtained after a chip swap onto a surrogate PCM board.

The PCM data showed that the convertible accelerated at steady $\frac{1}{4}g$, while the accelerator was applied in a stepwise fashion for 1,000 feet before crashing into the pickup at about 50mph. This distance from the stop to the crash matches the vehicle's described path. The constant 60-percent accelerator pedal, with and without brake application, is inconsistent with a pedal error, but could indicate a stuck accelerator pedal.

The convertible was re-inspected, which showed that the accelerator pedal was entrapped in the top groove of the floor mat. In addition, the mat had longitudinal scrapes from the bottom the accelerator pedal and transverse impressions where the pedal appeared to have been held at discrete locations, including at the edges of the oval depressions.

This case study serves as an example of how a comprehensive look at the available evidence may be required to "get it right." The combination of the physical evidence, electronic evidence, and witness statements leave little doubt that there was an entrapped accelerator pedal that led to a runaway vehicle situation. Choosing to ignore or not pursue additional available evidence is a gamble that could lead to an incorrect conclusion. This case shows the importance of approaching an investigation with an open mind and looking for facts before jumping to conclusions.

Sudden Unintended Acceleration, Chip Swap, Floor Mat

D23 Recreation Vehicle (RV) Crashworthiness: Enhanced Injury Caused by Unsafe Vehicle Interior Structures Combined With Predictable Seat and Belt Failures

Mark Pozzi, MS, Sandia Safety Sciences, Edgewood, NM; Vijay Gupta, PhD, University of California-Los Angeles, Los Angeles, California; Jack Bish, PhD, SAFE Laboratories, Goleta, CA*

Learning Overview: This presentation shows a forensic field investigation that has been conducted to identify the cause and effect of these dangerous designs, as well as static and dynamic testing that discovered the failure mode of the seats and belts, as well as the predictable extreme hazards of unpadded interior structures. Safer alternative seat, head, and belt restraint designs were discovered that would have prevented hazardous occupant contact with the unpadded force-concentrating structures.

Impact Statement: This presentation will benefit the forensic community and humanity by showing that these severe hazards exist in RVs, why they exist, how they create enhanced injury, and how those injuries can be prevented using lightweight, economically and technologically feasible means. Vehicle crash investigators will learn how to identify recreational vehicle seat and belt failure, vehicle interior occupant contact witness marks, and associated forensic evidence that will allow more accurate assessment of occupant injuries in such circumstances.

Seat and belt failure in rear impact has been known to cause severe injury and death to both front and rear seat occupants. Unpadded rigid interior structures located within predictable occupant contact zones exacerbates these hazards. A case of predictable enhanced head injury was discovered in a recreational vehicle where a multi-position seat and lap-only belt failure was combined with rigid, unpadded, force-concentrating structures in the vehicle occupant compartment. Causation of these enhanced injuries was proven by a combination of accident reconstruction, human surrogate testing, and dynamic sled testing. Prevention of injury by lightweight, technologically and economically feasible means was also demonstrated.

It has been known for decades that head impact into narrow, force-concentrating structures can result in skull fracture, brain injury, spinal injury, and death at much lower load levels than if those same structures were adequately padded, contoured, or otherwise modified to reduce their lethality. To reduce or eliminate such injuries, Federal Motor Vehicle Safety Standard (FMVSS) 201, Occupant Protection from Interior Impact, has been part of the Code of Federal Regulations related to vehicle crashworthiness since 1967, with updates in the 1990s. It has required certain interior structures within the range of occupant contact zones to be effectively padded, flattened, rounded, and otherwise made less lethal when contacted by vehicle occupants, whether belted or unbelted. Therefore, dash panels and other vehicle interior trim is padded, and narrow, projecting controls and other structures have been eliminated in the forward areas of passenger vehicles for decades. These requirements are not applicable to the rear occupant seating areas of RVs, however, due to loopholes in the safety regulations.

Several contradictions to the well-known foregoing occupant protection principles have been discovered in late-model recreational vehicles, in which unpadded, force-concentrating structures have been placed into the predictable path of vehicle occupant's heads and upper torsos that are allowed to catapult rearward or sideways because of predictable seat and belt design deficiencies and failures. RV safety regulations permit lap-only belts and do not require head restraints for anything other than the front outboard seats. They also allow side-facing seating while the vehicle is in operation. These dangerous conditions have resulted in enhanced catastrophic injuries to vehicle occupants that would otherwise not have occurred if the seat had been in a forward-facing position, was crashworthy enough to remain reasonably upright, was equipped with an effective head restraint, and had an effective belt restraint system. Unless the seat remains upright, the belts and head restraints are not effective at protecting the occupant. The absence of energy-absorbing padding and the multitude of rigid, force-concentrating structures in the rear of the recreational vehicle interior exposes occupants to these extreme hazards even while wearing the ineffective lap-only belts while seated in low-back seats.

The reason that these dangerous conditions are occurring in late-model recreational vehicles is that there are no effective occupant protection standards for such vehicles, especially because there are no dynamic seat or belt performance standards for rear impact, and there are no requirements for equivalent padded structures in the rear of vehicle interiors like those found in the front-seating areas per FMVSS 201.

RV Crashworthiness, Seat and Belt Failure, Unsafe Vehicle Interior

D24 Heavy Truck Fuel Tank Protection in Frontal Impacts

Brian Herbst, BS*, SAFE, Goleta, CA; Steven E. Meyer, PE, SAFE, Goleta, CA; Jack Bish, PhD, SAFE Laboratories, Goleta, CA; Lauren Bell, BS, SAFE, Goleta, CA; Christopher Clarke, BS, SAFE, Goleta, CA; Chuck Rogers, SAFE, Goleta, CA

Learning Overview: This presentation explores three real-world crashes wherein a heavy truck experienced a frontal offset impact with a resulting fire and serious injury.

Impact Statement: This presentation will impact engineers, scientists, attorneys, police, and others involved in the analysis of vehicle accidents, specifically heavy truck crashes resulting in fire.

The dangers of exposed heavy truck front suspension and steering components and the risk of underrun in frontal collisions were recognized decades ago.¹ Since the 1970s, industry literature and government studies noted the dangers of heavy truck frontal crashes, suggested improving safety in these accidents, strengthening front suspension components and adding protective structures. The United States Department of Transportation (DOT) published Truck Occupant Protection in 1986, found post-crash fires were involved in 16% of heavy truck fatalities compared to 4% for cars.² The report identified several mechanisms of fuel tank rupture, including frontal impacts resulting in front axle contact with fuel tanks. In order to ensure vehicle occupants who survive a crash are not subjected to a post-crash fire, the fuel system should be designed for crash conditions an occupant is expected to survive.

The hazards of exposed side saddle fuel tanks have been known for decades, including hazards specific to heavy truck tanks mounted outside the frame rails.³⁻⁶ This fuel tank arrangement was abandoned decades ago in light vehicles due to its vulnerabilities. Heavy trucks still use the outboard tank location despite the known hazard.

In 1994, the United Nations Economic Commission for Europe (ECE) published a standard for heavy truck Front Underrun Protective Structures (FUPS), which became the basis for a similar Australian standard adopted in 2009. However, the United States still has no requirements regarding front underrun protection of heavy trucks. A FUPS prevents underride and engages the energy-absorbing structures of smaller impacting vehicles, provides protection of the truck's steering components, and helps prevent the truck's front axle from being displaced into the fuel tank, which can cause rupture and fire.

Three real-world crashes are presented wherein a heavy truck experienced a frontal impact, resulting in fire and serious injury. In each of these cases, sled testing was conducted on a production truck front structural assembly and compared to a similar FUPS equipped assembly. The effectiveness of FUPS in mitigating damage in these frontal crashes was assessed.

Case Study 1: The right side of a heavy truck side swiped the left rear of a parked tow truck, resulting in a flash fire. The production sled testing impacted the truck assembly at 27.4mph, induced significant damage, and broke away the front axle. The FUPS-equipped test was impacted at the same speed, but with significantly reduced penetration and depth of damage into the truck's structure. The FUPS increases the initial stiffness and energy-absorption characteristics of the front structure, allowing for earlier and faster separation of the accident vehicles and thereby reducing the probability of fuel tank interaction.

Case Study 2: A heavy truck impacted a bear in the roadway with its left front bumper, causing tire deflation and loss of control. The truck continued off the roadway, interacted with roadside terrain, and caught fire. The sled testing impacted an exemplar truck front assembly with a 255lb bear surrogate at 60mph and demonstrated significant interaction with and rotation of the steering wheel. This interaction would affect the driver's ability to maintain steering control. The sled testing showed that a FUPS virtually eliminates wheel interaction, preserving steering control.

Case Study 3: An SUV crossed the center line and impacted a heavy truck, causing major damage to the left front of both vehicles. The impact compromised the truck's fuel tank and caused a large explosion. Full-scale testing showed that a properly constructed FUPS was able to effectively deflect a mid-sized SUV at 55mph, while protecting the front axle and fuel tank.

D25 Unintended Recliner Connecting Rod Actuation in Rear Impacts: A Forensic Analysis

Steven E. Meyer, PE, SAFE, Goleta, CA; Brian R. Herbst, PhD, SAFE, Goleta, CA; Jeremy McMillin*, SAFE, Goleta, CA; Arin Nelson, SAFE, Goleta, CA; Davis Hock, SAFE, Goleta, CA; Jack Bish, PhD, SAFE Laboratories, Goleta, CA

Learning Overview: This presentation explores three real-world crashes wherein automotive seats have exhibited catastrophic failure due to recliner release via the recliner release rod, undermining the seat's ability to safely restrain the seated occupant and causing serious injury in rear-impact automotive collisions.

Impact Statement: This presentation will impact engineers, scientists, attorneys, police, and others involved in the analysis of vehicle restraint systems, specifically rear-end automotive crashes wherein front outboard seats are found excessively reclined post-crash.

In rear-impact automotive collisions, occupant safety, for both front- and rear-seated passengers, relies on free-standing seats to effectively restrain their seated occupants without intruding into the survival space of other occupants in the vehicle.¹⁻³ Restraining the occupant heavily depends on the seat's ability to keep the seatback sufficiently upright as to not allow the occupant to ramp up and out of the seatback before absorbing crash energy and providing effective occupant ride down. Occupant ramping can present harmful interactions with vehicle structures and/or other occupants, particularly children, seated in the vehicle.

Three real-world crashes will be presented wherein forensic analysis of post rear-impact crash evidence established recliner release during the rear-end collision event via actuation from the recliner release rod. This unintended recliner actuation caused/contributed to catastrophic seat back collapse, undermining the seat's ability to absorb crash energy and contain the occupant.

Case Study 1: A Hyundai® Accent® sedan was slowing for traffic when it was rear-ended by a Ford® Windstar® mini-van. The driver's seat of the Hyundai® collapsed rearward, and the driver ramped up and out of the seat, impacting rear structures of the vehicle, resulting in traumatic head injuries. Forensic analysis of the seat revealed the inboard side of the seat tore below the recliner, rotated the recliner release rod, and released the outboard recliner. No significant structural load deformation, evidencing load transfer, was found on the outboard seat structure.

Case Study 2: A Nissan® Titan® pick-up truck was stopped at a red light when it was rear ended by a Toyota® Sequoia® SUV. The driver's seat of the Nissan® collapsed rearward, allowing the driver to ramp up and out of the seat, impact rear structures of the vehicle, and resulted in cervical and thoracic spine fractures. Forensic analysis of both front seats revealed asymmetrical deformation below the inboard and outboard recliner, which resulted in rotation of the recliner release rod and recliner release on the lesser deformed side of the seat.

Case Study 3: A Honda® Fit® hatchback was slowing for stopped traffic when it was rear ended by a Chrysler® 300 sedan. The driver's seat of the Honda® failed to remain upright, allowing the driver to ramp up and out of his seat, and make forcible head contact with his son seated in the rear seat, resulting in skull fractures and traumatic brain injury to the child. Analysis of the seat structural deformation, when compared to the crash energy, indicated significantly less plastic deformation than expected based upon the structure's documented yield strength. Forensic analysis of the driver's seat revealed occupant interaction with the recliner release rod bent, creating a rotational moment at the connecting rod, and released both recliners.

Laboratory testing was utilized in each case to establish the recliner release via rotation of the recliner release rod.

Crashworthiness, Rear Impact, Seat Back

D26 Event Data Recorder (EDR) Data and Forensic Video Analysis Defends Municipality in Civil Rights Lawsuit After Officer Forcefully Subdues Fleeing Driving Under the Influence (DUI) Suspect

Kurt Weiss, MSME, Case Study Collision Science, LLC, Santa Barbara, CA; Parris, Ward, JD, Biodynamics Engineering, Inc., Pacific Palisades, CA*

Learning Overview: This presentation will show how careful review and analysis of case evidence led to overlooked information vital to a municipality's defense of a police use-of-force case.

Impact Statement: This presentation will demonstrate the traffic reconstruction that uses a multidisciplinary approach of combining roadway geometry, EDR pre-crash and crash data, along with the analysis of audio and video evidence that revealed facts that contradicted the plaintiff's sworn testimony.

Excessive speed and erratic vehicle movements alerted a law enforcement officer to what he suspected was an impaired driver. Without a turn indicator, the suspect suddenly exited the highway, and at the bottom of the off-ramp, unexpectedly accelerated in an attempt to flee. The officer gave chase, and both vehicles sped dangerously through a maze of residential streets. After descending a steep decline, the subject's pickup truck appeared to become airborne while crossing an intersecting road and proceeded the wrong way down a one-way street. The subject then failed to negotiate a sharp turn and his vehicle impacted a curb, striking several large sandstone boulders. The impact caused the frontal airbags to deploy, and knocked the large boulders into the roadway. The pickup was disabled and coasted to a stop, giving the chasing officer time to attempt apprehension.

The patrol car's onboard forward-facing video camera captured the incident. The subject exited his disabled pickup and appeared to have difficulty standing. The officer ordered the subject to "get down on the ground." The subject initially sat on the ground, but then stood up and attempted to flee by stumbling up a ramp to a business. The officer ran toward the subject and attempted to subdue him, and a struggle ensued. At one point, the officer pulled the subject up to a standing position, pivoted, and threw the subject down on the ramp. A second officer arrived on scene, and the subject was taken into custody and transported to a local hospital because he complained of back pain.

The subject suffered an L1 vertebral body compression fracture requiring spinal fusion at T11-L3 and lumbar laminectomy at T12-L2. The toxicological report revealed the presence of amphetamine and methamphetamine. The incident prompted a lawsuit alleging the officer's excessive force caused the spinal injury. At deposition, the subject testified that his back broke when he was slammed to the ground, describing pain like being hit with a sledgehammer.

Seventeen months after the incident, the subject's vehicle was located in a body shop, and arrangements were made to image the EDR. Pre-crash data provided crucial insight into the vehicle's speed prior to the curb strike. The incident scene was photographed, measured, and laser scanned. The collision reconstruction combined the vehicle's pre-crash speed data with the onboard video. The analysis showed the approximate vertical acceleration experienced by the subject when the vehicle slammed down after being airborne was the likely source of his spinal injury.

Audio and video evidence from two patrol cars also supported this defense. Both officers were wearing body-worn microphones that connected to their in-car recording systems. The first officer's microphone malfunctioned and that of the second officer recorded only loud music playing in his patrol car that obscured what could be heard on video. It was believed that conversations between the officers and subject were not recorded. However, when the second officer's audio channel was isolated, and the in-car videos were synchronized and enhanced, the mechanism of injury could be supported, and the subject's comments to officers could be heard. Immediately after the fall, the subject did not cry out in pain. Rather, he asked officers to let him go and said, "I hurt my back in that accident." The case was resolved in settlement before trial.

EDR, Compression Fracture, Audio/Video Evidence

D27 A Method for the Evaluation of Recreational Off-Highway Vehicle (ROV) Rollover Protective Structures (ROPS)

Brian Herbst, BS, SAFE, Goleta, CA; Christopher Clarke, BS, SAFE, Goleta, CA*

Learning Overview: After attending this presentation, attendees will better understand the history of the ROPS design standards used for ROVs and a ROPS testing methodology that is well suited to simulating real-world rollover conditions.

Impact Statement: This presentation will impact the forensic community by exploring an ROV rollover case study and presenting a testing methodology for evaluating ROV ROPS performance.

In recent decades, there has been significant development in the ROV sector and manufacturers now offer ROVs with unprecedented performance. Unfortunately, this new class of vehicles also presents unprecedented dangers.

Rollover has long been known as a significant cause of injuries and fatalities in off-highway vehicles. The **Society of Automotive Engineers** (SAE) published its first recommended practice for ROPS design in 1967, intended to protect earthmoving equipment operators traveling less than 10mph in limited operating conditions.¹ The SAE-recommended practice relied on force and energy absorption requirements in quasi-static loading tests, and, by 1980, it had been adopted as the **International Organization for Standardization** (ISO) 3471 standard.² The Occupational Safety and Health Administration (OSHA) adopted another SAE quasi-static test method for agricultural tractor ROPS structures in the 1970s.³

The Recreational Off-Highway Vehicle Association (ROHVA) adopted the ISO and the OSHA ROPS testing requirements in the 2011 edition of its American National Standards Institute (ANSI) -ROHVA standard.⁴ Unfortunately, these decades-old standards were intended for slow vehicles like bulldozers and have little relevance to the dynamic loading conditions that can occur in rollover accidents involving high-speed modern ROVs designed for sport driving on rough terrain. The ISO and OSHA tests generate minimal intrusion in the ROV ROPS, while real-world rollovers can result in the collapse of ANSI-ROHVA-compliant ROPS.

A rollover accident was evaluated in which a ROV traversed a sand dune at a speed of 25–30mph, became airborne, pitched nose down, and completed one roll end-for-end, coming to rest on its wheels. This type of rollover scenario would be unimaginable for a bulldozer but is not uncommon in high-performance ROVs due to their short wheelbase, long suspension travel, and sport driving capabilities. During the subject rollover, the ROPS interacted with the ground and crushed down into the occupant space. One of the vehicle occupants was paralyzed. Although the ROPS had been designed to comply with the ISO and OSHA ROPS standards, it failed catastrophically under the conditions of the real-world rollover. A number of other field accidents involving that same ROV exhibited a similar pattern of ROPS failures.

Drop testing is a standard impact test method utilized routinely to evaluate structural integrity and impact resistance in a number of different industries. Various entities have run inverted drop tests from as high as 3 to 12 feet in order to evaluate vehicle rollover performance. Inverted drop testing was conducted to evaluate the subject ROPS design as part of the subject accident investigation. An exemplar vehicle was inverted and suspended 30 inches above a load plate, then released to fall onto its ROPS under the influence of gravity. The test generated structural failures in the ROPS and intrusion into the occupant space consistent with what occurred during the subject rollover crash. Other improved ROPS structure designs were installed on the exemplar vehicle and subjected to the same 30-inch inverted drop conditions. An improved ROPS design fabricated out of higher strength steel and thicker tubing, resulting in a weight penalty of only 30lb, reduced the vertical intrusion on the impacted side of the ROPS by 81–94%. This testing and accident analysis suggests that the existing quasi-static test methods used to validate ROV rollcages is insufficient at addressing the forces and energies seen in many ROV accidents. The inverted drop test proved to be a useful method to assess ROV ROPS and reproduce real-world damage patterns. Simple fixes to the ROPS structure provided a dramatic increase in occupant survival space in the inverted drop tests conducted.

ROPS, ROV, Inverted Drop Testing

D28 A Comparison of Restraint Load Marks for Retained vs. Ejected Occupants in a Fatal Rollover Crash

David Porta, PhD, Bellarmine University, Louisville, KY and Corporeal Consulting, Louisville, KY*

Learning Overview: After attending this presentation, attendees will better understand the relationship of vehicle investigation to the determination of injuries in a rollover crash scenario.

Impact Statement: This presentation will impact the forensic community by providing important information that may assist injury reconstructionists with the determination of restraint use, its relation to driver versus passenger, and ejected versus retained occupants.

On a clear fall afternoon, police were called to a rural highway in a Midwestern state to investigate the report of a male subject lying on the roadway. On scene, officers found a juvenile boy lying on his left side, conscious but unresponsive, with an obvious head injury. Approximately 30 feet up the road was a 2001 domestic sports car upside down in a shallow ditch area. A 34-year-old female was found restrained and unconscious in the driver's seat. Police determined the vehicle left the right side of the roadway, for unknown reasons, struck a culvert, went airborne for 15ft and, upon landing, rolled onto its top. Furthermore, they determined the boy was ejected through the passenger window during the half roll. No airbags deployed, and it was noted that the passenger seat belt webbing was locked in an extended position. Although an Event Data Recorder (EDR) is reportedly present in this model vehicle, no download was available. The female driver died that day, and the boy survived with serious, permanent injuries.

Subsequently, a lawsuit was initiated on behalf of the surviving boy. Six months later, in the discovery phase, an injury reconstructionist was invited to examine the vehicle and determine if the restraint system functioned properly and what role it played in the occupant injuries. Vehicle-specific reports were studied to determine the history of the car as well as United States Department of Transportation (USDOT) National Highway Traffic Safety Administration (NHTSA) reports of Complaints, Investigations, and Recalls for this make/model vehicle. In order to become educated on the particular restraint system found in this car, websites with parts listings and diagrams were examined, and the seat belt mechanism from an exemplar vehicle in a local salvage lot was removed and studied. Inspection of the subject sports car revealed significant B-pillar and roof crush with intrusion into the driver's side of the cabin space; much less damage was noted on the passenger side. Examination of the restraint systems (webbings, D-rings, latch plates, etc.) for both occupants demonstrated interesting marks: one from occupant loading and one from the method used to secure the door during vehicle transport and storage. In rollovers, as well as side impacts, load marks are more common on the latch plate than the D-ring. Marks were found on the driver's latch plate only. Furthermore, the latch plate on the locked passenger belt would not reach the inboard buckle.

In conclusion, without proper preliminary research and a thorough vehicle inspection, investigators may have assumed (based on the fixed, extended passenger belt and load marks on the D-ring) that the juvenile passenger was three-point restrained and that a seat belt system failure must have allowed his ejection. However, the results in this case demonstrate that the boy was not properly restrained and his ejection was somewhat predictable. It is atypical to have a properly restrained driver die while an unrestrained, ejected passenger survives, albeit with serious permanent injuries. But this is explained by the significant level of cabin intrusion on the driver's side.

Seat Belt, Vehicle Inspection, Load Marks

D29 Criminal Engineering: The Ugly 50-Year History of Federal Motor Vehicle Safety Standard (FMVSS) 207 and Proposals for an Upgraded Safety Standard That Will Prevent Catastrophic Injury and Death

Mark Pozzi, MS, Sandia Safety Sciences, Edgewood, NM; Kenneth Saccalski, PhD, Environmental Research and Safety Technologists, Newport Beach, CA; Rachel Pozzi, MS, Sandia Safety Sciences, Edgewood, NM*

Learning Overview: This presentation explores the poor job that automakers and the federal government have done regarding their clear obligations to the public in automotive safety. The case histories and testing will provide a clear and accurate representation of the inadequacies and facts regarding grossly inadequate FMVSS standards, as well as how agency capture has enabled automotive defects to continue unabated for decades, despite ample proof of inexpensive alternative designs.

Impact Statement: This presentation will be of value to engineers, scientists, criminologists, attorneys, pathologists, police, and others involved in the forensic aspects of traffic accident investigation and reconstruction.

Widespread, life-threatening vehicle safety defects related to seats and seatbelts have been ignored for decades by automakers and the National Highway Traffic Safety Administration (NHTSA). Misinformation, deceit, and ethical lapses by automakers and safety regulators have aided and abetted this debacle that is one of the leading causes of preventable adult paralysis, fatalities, and catastrophic injuries to children in the United States. This research illustrates this is due, at least in part, to agency capture of Department of Transportation (DOT) officials.

Petitions to upgrade FMVSS 207 and to establish a rear-impact occupant protection standard have been “under review” at NHTSA since 1974. This includes multiple petitions since 1989. This ongoing dangerous vehicle safety hazard has continued to occur despite ample notice of thousands of preventable deaths and countless catastrophic injuries, and scientific research clearly proving far safer, economically feasible alternative designs. Even after the debacles of seat and belt failure shown on CBS *60 Minutes* in 1992, and on other broadcast documentaries since then, automakers continue to build vehicles with grossly inadequate seats that collapse rearward at school zone speeds, which also defeat seat belts, simply because the lax safety standard 207 and reduced requirements of FMVSS 209 allows them to do so. They also continue to ignore readily available inexpensive technology that would significantly reduce the threat of crash-induced seat and belt failures. As just one example, the Minicars Research Safety Vehicle (RSV) was developed in the 1970s to prove that fuel efficient, yet extremely safe, vehicles were readily producible by automakers. The RSV had seats that could withstand adult male loading in 50mph rear impacts by a 4,000-pound rigid moving barrier. NHTSA later intentionally destroyed the evidence of the remaining RSVs. NHTSA admitted in 1996 that FMVSS 207 is “flawed and inadequate” but has yet to change the standard 26 years later.

All these areas exemplify how agency capture of the DOT has occurred in violation of public trust. It will be seen that automakers and the government have and continue to fail to provide reasonable protection to the public in the event of automotive rear impacts and rollovers. Automakers continue to provide misleading and untrue information to the public and to NHTSA safety regulators, who in turn continue to turn a blind eye to ongoing serious safety defects that are killing and maiming children and adults every week. Hundreds of static and dynamic tests have been conducted to evaluate seats, belts, and alternative designs as well as decades of forensic cases involving catastrophic injury and deaths of adults and children have been investigated. Readily available, inexpensive technology has existed for decades to reduce or eliminate these hazards. Implementation of such recommendations to improve FMVSS 207 will be described in detail.

Seat Failure, FMVSS 207, Criminal Engineering

D30 Failure of Suture Materials Used for a Caesarean Section

Sarah V. Hainsworth, PhD, Aston University, Birmingham, United Kingdom*

Did Not Present.

D31 Fatal Compression of the Torso Due to the Sudden Trapping of a Saree in the Rotator of a Pulse Mill: An Unusual Incidence During the Performance of a Harmless Activity With a Careless Attitude

Nilesh Tumram, MD, Government Medical College Chandrapur, Chandrapur, Maharashtra, India*

Learning Overview: After attending this presentation, attendees will be familiar with the fatal compression of torso by long loose clothes like a saree getting trapped in a moving object like the rotators of a pulse mill, causing sudden fixation and loss of ventilatory capability.

Impact Statement: This presentation will impact the forensic science community by creating an understanding of the harm caused by compression of the torso by clothing trapped in a moving object. Autopsy findings such as patterned abrasion over the entire torso due to compressive force caused by the fabric of the saree and the internal structure damages can be of important forensic significance. Presented is a case study for highlighting this occurrence and its possible significance to correlate with such incidences.

In compression asphyxia, the respiration is prevented by external pressure on the body. Different cases of compression asphyxia in different circumstances have been reported, but compression asphyxia due to entrapment of a victim's saree in the rotator machine of a pulse mill is rarely reported.¹⁻³ Diagnosis is largely made by circumstantial evidence supported by traumatic injuries over the body explaining the death. In present case, a 38-year-old female victim who was assigned to cleaning activities in a pulse mill was trapped in an upright position due to sudden compression and fixation of her saree trapped in the rotator of a pulse mill; she was unable to rescue herself due to the force and power of the rotator, leading to compression of her torso and the subsequent fatality.

Autopsy findings showed patterned abrasion over the entire torso in conformity to the compression of the clothing worn by the victim, which included a thin apron, a saree, and a blouse. The internal visceral organs, such as the lungs, liver, and kidneys, showed hemorrhages. Ribs were fractured. Hemorrhages were also noted in the musculature of the torso and neck. There was tearing and transaction of coils of small intestine and also tearing and hemorrhages in the mesentery. The interesting findings were the spinal injuries at the cervical and thoracic level occurring due to the rotational movement of the rotator machine causing transmission of a spinning effect and strain over the spinal column, leading to its damage. The victim was unable to change position due to getting caught by her own clothing draped around her body and entrapped in the machine.

The history, circumstances, and findings observed in this particular case are very rare. Postmortem examination of victims of such incidences show relatively different external findings, which can be of significant forensic importance and can become crucial. In cases in which such accidental compression of the torso occurs, a detailed inspection of circumstances and bodily injuries may provide invaluable information.

Fatal Compression, Torso, Saree

D32 The Biomechanics of Strangulation: Should Limits Be Placed on Restraint Tactics?

Harold Franck, MSE, Advanced Engineering Associates, St. Petersburg, FL; Darren Franck, MSME, Advanced Engineering Associates, Charleston, WV*

Learning Overview: This presentation is intended to cast some clarity on the issue of this restraint system by quantifying the amount of force that may be produced in such a manner by the different methods that are employed.

Impact Statement: Biomechanical engineers and law enforcement regulators should benefit from this analysis of the dangers posed by these techniques.

Recent events in the news and the court systems have placed revealing evidence that choke-type holds and restraints have been widely used by law enforcement officials to subdue individuals who may have been involved or were suspected of criminal offenses. In most instances, law enforcement individuals have claimed that such measures are warranted and necessary to restrain combative subjects, even though the suspected perpetrators are handcuffed or restrained by multiple law enforcement individuals.

Historically, this technique of subjugation was used and taught in the martial arts and in law enforcement. In the martial arts, the technique is used to cause the subdued individual combatant to “give” by tapping out to notify the subduer and referee that the contest is over. At that point, the contest is over and the forces restraining the air and blood passages through the neck are released. Additionally, in martial arts contests, a referee controls the action and may end the contest at any point when a potential for serious injury arises. Unfortunately, that is not the case when law enforcement is involved in subduing a suspected perpetrator. In such cases, law enforcement is the sole judge on the amount of force and time that the restraint is applied. Fortunately, some police and law enforcement agencies have realized the dangers of this restraint system and no longer train and allow the restraint method.

This study conducted scientific tests utilizing an anthropometric test dummy to measure the forces that are applied by a variety of holds such as produced by the hands, the forearm, and the knee that can result in loss of blood flow to the brain and loss of air to the lungs. Manual strangulation is produced by using the hands, forearm, knee, or an object such as a baton that leads to the interference of blood flow to the brain and or a compression of the air passages to the lungs. When air is reduced to the lungs, the individual being strangled has the sensation of not being able to breathe and may struggle violently.

Asphyxia, Chokeholds, Force

D33 The Fatal Explosion of a Rubber Plug

Helmut Brosz, BASc, Forensic Science International Group, Markham, Ontario, Canada and Institute of Forensic Electrical and Mechanical Sciences, Markham, Ontario, Canada; Renee Knight BSc, Institute of Forensic Electrical and Mechanical Sciences, Markham, Ontario, Canada*

Learning Overview: This presentation will provide an understanding of how a widely used inflatable rubber plug device that is used to temporarily block/close off liquid-carrying pipes of various diameters can become a deadly projectile when it ruptures *in situ* and impacts a person. The physical, theoretical, practical, and possible criminal aspects of the issues will be presented.

Impact Statement: This presentation will impact the forensic science community by improving the ability of investigators and Authorities Having Jurisdiction (AHJ), including lawyers, medical examiners, and forensic engineers, to identify the investigative issues and key evidence required when investigating inflatable rubber plug fatalities and incidents.

On Friday, November 10, 2017, an employee of a plumbing company suffered a fatal injury while working to repair a corroded 24" spiral steel drain pipe. This pipe had collapsed and caused a roadway to cave in. Earlier that day, an inflatable pipe plug was installed in the drain pipe to block the flow of water from a pond to the excavation site. This enabled the employee to work on the repairing the drain pipe.

The plumbing company excavated the area around the cave-in to expose the 24" drain pipe. It was determined that the steel pipe was severely corroded; this caused water to flow from the pond to the excavation via the pipe while a pump was pumping the water out of the excavation site. The pipe was then blocked with the subject inflatable rubber plug in its protective rubber sleeve. The subject plug and another plug were inflated, with their protective sleeves, from the same regulated compressor and remained inflated for approximately two hours at a pressure not exceeding 35psi. While the employee was working in the excavation close to the pipe facing the pond, the inflated subject pipe plug suddenly exploded and was ejected by means of the compressed air within the plug.

The 35lb plug struck and killed the employee. The protective sleeve remained in the steel pipe, whereas the subject plug was found in the excavation area. Both were retrieved for forensic analysis.

Through ongoing forensic investigation, the following possibilities and issues were investigated: the inflatable plug potentially had (1) criminal tampering, (2) manufacturing defects, (3) been overinflated, (4) pre-existing damage, (5) inadequate warnings, (6) a lack of production tests and type tests, or (7) failed to follow the prescribed safety precautions. This forensic investigation and analysis of a rubber plug was established to find the most likely root cause(s).

Rubber, Plug, Fatality

D34 An Exotic Treatment for Chronic Paralysis by Kerosene Oil Ingestion: An Unusual Fatality by a Bizarre Form of Self Medication

Nilesh Tumram, MD, Government Medical College, Chandrapur, Chandrapur, Maharashtra, India*

Learning Overview: After attending this presentation, attendees will be able to identify the uniqueness of some exotic treatment for chronic illness like paralysis that are not only a weird form of self-medication, but also may prove fatal.

Impact Statement: This presentation will impact the forensic science community by informing attendees of exotic treatments that are peculiar forms of self-medication and may be of forensic significance if such cases were found in places without no witness to incident. Presented is a study for highlighting such an occurrence that has rarely been mentioned in available literature.

Usually most of the literature worldwide mentions kerosene poisoning due to accidental exposure or consumption. Sometimes it is consumed for attempted suicide. However, kerosene consumption for medicinal purposes is very infrequently reported and has not been seen in the available literature. A 10-year study was conducted to ascertain the practice of consumption of kerosene by individuals for medicinal purposes. It was found that almost in all cases, the person was suffering from one or other form of paralysis. Due to the chronic nature of the illness, the patient or their relatives became frustrated to the extent that they tried every possible measure to get cured of the illness. In the process, they not only try the traditional ayurveda or homeopathy treatment, but also some exotic treatments suggested by medical quacks.

Their treatment can be as odd as the consumption of cow's urine or cow-dung to some poisonous plants such as the milk of calotropins or the fruit or leaf juice of oleander plants, etc.¹ In continuation to similar practice, cases of fatalities by kerosene oil allegedly given or self-consumed for treatment of such chronic illness have been noticed. The dose of kerosene used was as small as a one teaspoonful (5ml) to as large as a 200ml bottle. In all these cases, the deceased were medicolegally autopsied. The lungs and respiratory tracts were the major organs to exhibit changes such as marked congestion and edema, while the heart and other organs showed multiple petechial hemorrhages.

This presentation will also discuss the importance of possessing the knowledge of such manners and causations of injuries leading to the death of victims and their relevance when dealing with these medicolegal cases.

Exotic Treatment, Kerosene Oil, Chronic Paralysis

D35 The Determination of Lumbar Disc Injury Potential from a Chair Collapse Incident

Michelle Hoffman, MS, Forensic Injury Analysis, LLC, Tempe, AZ; Robert Anderson, MS, Biomechanics Analysis, Tempe, AZ*

Learning Overview: After attending this presentation, attendees will better understand the importance of both the magnitude and direction of the loading on the lumbar spine with respect to disc injury potential resulting from a chair collapse incident.

Impact Statement: The presentation will add data collected from human volunteer testing for utilization of the forensic science community.

A 25-year-old, 5'7", 150-pound woman in a furniture store sat in a foldable lawn chair on display while holding her 1.5-year-old child. The chair's front dowel had been removed, so when she sat, the fabric pulled through the frame, allowing her to fall to the floor. Her fiancé took a photo after the incident before he helped her up (Figure 1). She first sought medical care six days later. The following question had to be answered: Would an L5-S1 disc herniation result from the loading experienced during the described chair collapse? This presentation describes how this question was addressed scientifically.

Figure 1 - Photo by fiancé.

The woman testified she held her child in front and sat "as you would in a normal chair," with the seat bottom's leading edge right above her calf. Afterward, she couldn't get herself out, "because of the angle it was at." She testified she first felt pain 1.5 hours later.

Research has shown that the only mechanism that produces lumbar disc injury from a single traumatic event is combined compression (z-axis or axial loading) and hyperflexion beyond the physiological range of motion.¹

Testing was conducted to measure the ground reaction forces and pelvic/lumbar accelerations experienced by a 49-year-old, 5' 7", 150-pound female surrogate, who sat in an exemplar chair with the front support dowel removed. She held a 20-pound rice sack to represent the child. Accelerations were measured in the x (fore-aft), y (left-right), and z (up-down or axial) directions. Four tests were also conducted on a 50-year-old, 5'7½", 200-pound male surrogate with no rice bag. Two flooring conditions were used: (1) rug on artificial turf on level concrete; and (2) rug on artificial turf on plastic decking on level concrete. For each condition, two tests were performed: one with a load cell between the concrete and the next layer of flooring, and one without a load cell. Pelvic/lumbar accelerations were measured in all tests. All tests were recorded with high-speed (500fps) video.

A photograph of the female surrogate after falling through the chair is shown next to the post-incident photo in Figure 2.

These photos, as well as a side view of the surrogate (Figure 3), made it clear that they did not land on their ischial tuberosities (sitting bones), but rather, their sacrum/low back areas made initial contact.

Figure 2- Post-incident photo (left) and surrogate photo (right) after chair collapse.

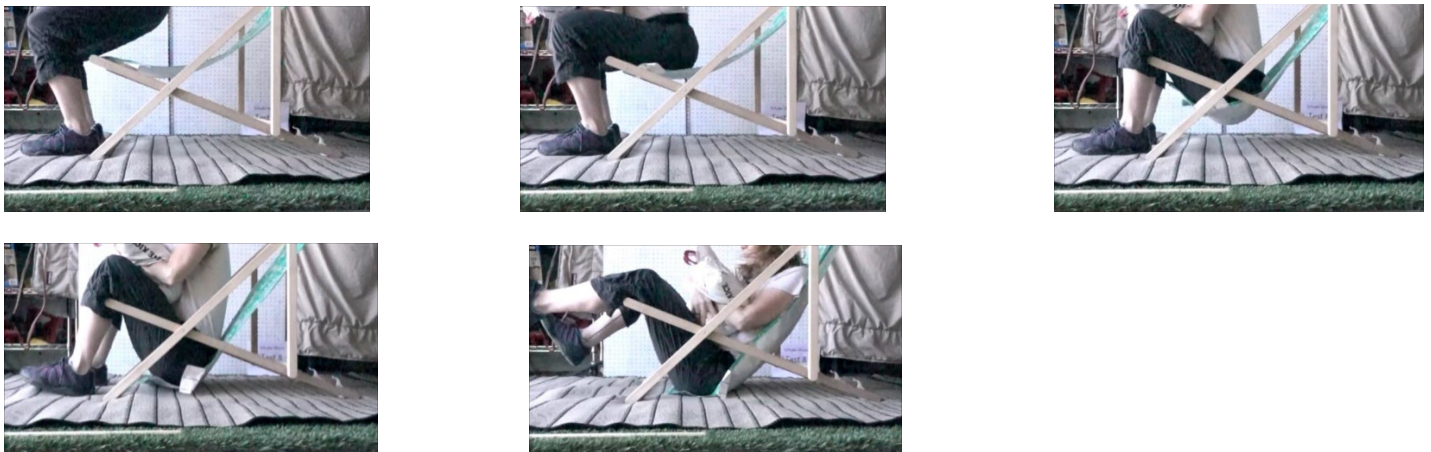

Figure 3 - Side view of surrogate showing ground contact with sacrum/low back.

6B	B	C,D,T,R	Y	-3.2	-3.3	-0.4	4.0	308	
7	B	C,T,R	N	-3.4	-2.6	-1.1	4.2	N/A	
8	B	C,D,T,R	N	-2.8	-1.5	-2.2	3.9	N/A	

A = 50-year-old, 5'7.5", 200-lb male
 B = 49-year-old, 5'7", 150-lb female
 C = Concrete
 D = Plastic decking
 T = Artificial Turf
 R = Rug
 FRF = Floor Reaction Force
 Res = Resultant Acceleration

Axial loading along the spine was minimal, and the largest accelerations were in the fore-aft direction for the pelvis/lumbar spine. Lumbar z-accelerations ranged from 0.4–2.2gs, while x-accelerations ranged from 2.7–13.7gs. High-speed video revealed that the shins were initially supported by the chair's front crossbar, and the pelvis rotated rearward and translated forward prior to, during, and after contact with the floor, which was consistent with the acceleration test results. Video stills from Test 8, which had the highest vertical acceleration, are shown in Figure 5.

Figure 4 - Chair Collapse Test Results.

5. Still images from high-speed video during Test 8.

In conclusion, analysis of the information available and testing of human surrogates with an exemplar lawn chair revealed that the magnitude and direction of the force applied to the pelvis/low back from the subject incident was not causal in an L5-S1 disc herniation.

D36 Technicalities of the Shotgun, Its Ammunition, and the Forensic Implications

John Nixon, MBA, ARC, Bippus, IN*

Learning Overview: This presentation is aimed at the non-specialist/semi-technical attendee and particularly jurists involved in criminal and civil litigation involving shotguns. Attendees will gain an appreciation of the basic science and technology behind shotguns and shotgun ammunition. The fundamental differences between shotguns and other classes of firearm will be explained in terms of, among other things, ease of use, accuracy, wounding potential, versatility, and terminal performance. Media-perpetrated myths regarding shotguns and their performance will be dispelled.

Impact Statement: City-dwelling jury members are likely to have very little knowledge of shotguns, other than the misinformation they have gleaned from TV shows and movies. The justice system will benefit from having courtroom practitioners who have a realistic basic understanding of shotguns and their ammunition and who are able to convey that knowledge to juries so they can dismiss the myths and make determinations based upon reliable knowledge and facts.

Rifles and pistols are single-projectile weapons that launch a single projectile that is spin-stabilized and retains significant velocity and energy over extended ranges. It is difficult to hit small moving targets with these single-projectile weapons, and they can inflict serious or fatal injuries at distances way beyond most intended targets.

Shotguns and their ammunition are radically different to other classes of firearm. Shotguns have been around for hundreds of years. They enable a shooter to more easily hit a moving target due to the multiple pellets they launch toward the target that form a cloud of small projectiles. The rapid deceleration and resulting short range of the pellets ensures that they have a relatively short danger zone, and this makes them suitable for use in semi-urban environments. Historically, shotguns have been extremely popular for vermin control and bird hunting.

In the early years, shotguns were single or double-barrel, but by the end of the 19th century, pump action and semiautomatic shotguns had been developed, and by WWI, they had been adopted by military units for use in urban and trench warfare.

Shotguns were widely adopted by police departments due to their devastating close-range effects and relative safety at medium ranges. Tens of millions of shotguns are currently in circulation in the United States, and while many are utilized for vermin control/crop protection, a large number are purchased for personal protection and security. Inevitably, some are used in crimes, and there are accidents.

Shotguns are considered to be very versatile weapons, because one gun can be used with many different types of ammunition. Small birdshot ammunition can be used to control vermin, while the same gun can be used with buckshot for security duty, and with a single projectile “slug” for deer hunting or protection from large predators.

The shotgun has garnered quite a reputation due to the dramatic misrepresentations of Hollywood and barroom talk. It is almost routine to see TV shows and movies where people shot with a shotgun fly backward through the air, cars explode upon impact, and holes the size of wagon wheels are blown through doors and walls.

From a forensic perspective, the questions most asked relate to safety (design and/or manufacture defects), range of fire determination, and shot size and weight used. The range of calibers (gauges) and the sheer diversity of ammunition available can be quite a challenge. This presentation utilizes technical data and presents examples from actual case studies to illustrate the principles involved.

Shotgun, Shotgun Ammunition, Shotgun Myths

D37 A Visualization of Organic Gunshot Residues with Hyperspectral Imaging (HSI) and Correlation Analysis

Kazunari Shibasaki, MSc*, National Research Institute of Police Science, Kashiwa, Chiba, Japan; Norimitsu Akiba, PhD, National Research Institute of Police Science, Kashiwa, Chiba, Japan; Hidetoshi Kakuda, PhD, National Research Institute of Police Science, Kashiwa, Chiba, Japan; Kosuke Tanabe, MSc, National Research Institute of Police Science, Kashiwa, Chiba, Japan

Learning Overview: After attending this presentation, attendees will understand how hyperspectral imaging can be used to visualize organic gunshot residues and that the method has the potential to be widely useful in forensic science.

Impact Statement: This presentation will impact the forensic community by providing a method that can visualize organic gunshot residues and indicate the possibility of firearm use even when no bullets are found at a crime scene.

“Gunshot residues” is a general term for particles produced by shooting and generally refers to metallic particles derived from bullets and priming powder. However, in a broad sense, it also includes organic materials such as unburned and partially burned powder. In this study, hyperspectral imaging and correlation analysis were tried to visualize partially burned powder as organic gunshot residues.

Hyperspectral imaging is widely utilized in the forensic science field because it allows non-contact measurement without destroying the sample. As applications, detection of latent fingerprints, separation of overlapped fingerprints, visualization of blunt trauma, and bloodstains have been reported.^{1,2} The data measured by hyperspectral imaging are layered images with high-resolution wavelength information, called a hypercube. By using the differences in fluorescence spectra resulting from excitation light irradiation, it is possible to visualize and discriminate samples.

A Automatic Colt® Pistol (45ACP) with a Lead Round Nose (LRN) was fired at a white cotton towel from a shooting distance of 5cm to produce a sample in which partially burned powder was dispersed around the projectile entrance. The measurement was performed by HSI using 415nm and 505nm Light-Emitting Diodes (LEDs) as excitation sources. The long-pass filter used was 450nm for 415nm excitation and 560nm for 505nm excitation. The scanning time of HSI is 190sec. The effective scanning area is 3cm x 3cm.

It was difficult to identify the dispersion of powder with the naked eye since the area around the projectile entrance was discolored black due to the adhesion of lead and other substances. In the case of 505nm excitation, the position of partially burned powder was well visualized because of the remarkable difference in fluorescence between the background and the powder. On the other hand, in the case of 415nm excitation, the prominent background fluorescence interfered with the identification of the powder. However, by normalizing the hypercube in the wavelength direction, good visualization of the powder was achieved.

The originality of this study is that the dimension reduction by principal component analysis was applied to the correlation matrix between fluorescence spectra of visualized particles. This method will enable clustering that takes into account the characteristics of particles and will provide more useful information to the crime scene.

D38 An Accessible Open-Source Implementation of the Congruent Matching Cells Algorithms for Cartridge Case Analysis

Joseph Zemmels, MSc*, Center for Statistics and Applications in Forensic Evidence, Ames, IA and Department of Statistics, Iowa State, Ames, IA; Susan VanderPlas, PhD, Center for Statistics and Applications in Forensic Evidence, Ames, IA and Department of Statistics, University of Nebraska-Lincoln, Lincoln, NE; Heike Hofmann, PhD, Center for Statistics and Applications in Forensic Evidence, Ames, IA and Department of Statistics, Iowa State, Ames, IA

Learning Overview: Attendees will learn about the open-source implementation of the Congruent Matching Cells (CMC) algorithm in the R package cmcR. The algorithm is implemented in a modular form; exposing relevant parameters. Attendees will learn about methods to evaluate different parameters. Additionally, attendees familiar with the R statistical programming language will learn how to use the CMC method by way of the cmcR package.

Impact Statement: Computational pattern-matching algorithms are becoming more important in many forensic science disciplines. It is important that such algorithms are auditable by the legal and forensic science communities. The open-source cmcR package is written to be transparent, auditable, and user-friendly. The process by which the CMC methods were implemented in the cmcR package can be used as a template for future open-source implementations of pattern-matching algorithms. Additionally, changes to the original CMC method are developed that result in an improved classification rate.

Scientific research is driven by the ability to use methods, procedures, and materials from previous studies and further this research by adding to it. As the need for computationally intensive methods to analyze large amount of data grows, the criteria needed to achieve reproducibility, specifically computational reproducibility, have become more sophisticated. In general, prosaic descriptions of algorithms are not detailed or precise enough to ensure complete reproducibility of a method. Results may be sensitive to conditions not commonly specified in written-word descriptions, such as implicit parameter settings or the programming language used. To achieve true computational reproducibility, it is necessary to provide all intermediate data and code used to produce published results.

In this presentation, a class of algorithms developed at the National Institute of Standards and Technology (NIST) to perform firearm evidence identification on cartridge case evidence known as the CMC method and its variants is considered.¹⁻³ To date, only textual descriptions of these algorithms have been published. The first open-source implementation of the CMC methods in the R package cmcR is introduced. The cmcR package is structured as a set of sequential, modularized functions intended to ease the process of parameter experimentation. The cmcR package and a novel variance ratio statistic are used to explore the CMC methodology and illustrate problems that arise when computationally ambiguous algorithm descriptions are provided. A training/test set validation procedure is introduced and used for an evaluation of parameter settings. Additionally, cmcR is used as a foundation to develop changes to the CMC methodology. The updated algorithm results in an improved classification rate compared to the original CMC methods.

D39 A Multifaceted Method for Evaluating the Driving Ability of Elderly Drivers: Toward Identifying Causes of Accidents Involving Elderly Drivers and Broadening the Recognition of Negligence Types

Syunsuke Tsuchiya, BE, Faculty of Engineering, University of Yamanashi, Kofu, Yamanashi, Japan; Yasumi Ito, PhD, Faculty of Engineering, University of Yamanashi, Kofu, Yamanashi, Japan; Kazuki Kamiunten, BE, Faculty of Engineering, University of Yamanashi, Kofu, Yamanashi, Japan; Qin Xu, MA, Faculty of Engineering, University of Yamanashi, Kofu, Yamanashi, Japan; Ryuichi Yamada, PhD, Faculty of Engineering, University of Yamanashi, Kofu, Yamanashi, Japan; Yoshiyuki Kagiya, PhD, Faculty of Engineering, University of Yamanashi, Kofu, Yamanashi, Japan; Yuji Tanaka, PhD, Faculty of Medicine, University of Yamanashi, Chuo, Yamanashi, Japan; Kei Sato, PhD, Faculty of Wellness, Shigakkan University, Obu, Aichi, Japan*

Learning Overview: After attending this presentation, attendees will be able to understand the relationship between the results of simple tests and personal attributes and the driving ability of elderly drivers, which will help improve negligence recognition in traffic accident reconstruction.

Impact Statement: This presentation will bring a new convergence of disciplines to the forensic science community by demonstrating the usefulness of multidimensional driving ability assessment of elderly drivers in traffic accident investigation and reconstruction.

In the current situation, the effects of various ability declines and diseases along with aging have not been sufficiently considered in determining the negligence of drivers in traffic accident reconstruction. In the first place, the technology for evaluating driving ability from various abilities and tendencies such as physical characteristics, which includes abilities such as brain functions, and social characteristics, which includes lifestyle habits, has not been established.

For example, in Japan, cognitive function tests have been conducted since 2007 for drivers aged 75 or older when they renew their licenses; however, the number of accidents involving elderly drivers has not decreased at all. In future, the introduction of a practical driving test at the time of license renewal for the elderly is expected to stop drivers with poor driving skills; however, even so, it is not sufficient to evaluate driving abilities, which involves a wide range of abilities such as brain processing capacity and social characteristics.

Therefore, since 2008, the Fujikawaguchiko Town Senior Driver Support Project has been continually investigating the relationship between physical functions, brain functions, and lifestyle habits of the elderly and their driving abilities and examining the changes over the years. As a result, it has been clarified that there is a relationship between the results of risk avoidance tests using a simplified Driving Simulator (DS) and the results of simple tests such as the Trail Making Test (TMT), which measures visual search processing ability, and the Tokyo Metropolitan Institute of Gerontology Index of Competence (TMIG-IC), which evaluates the life functions of the elderly, as well as personal attributes obtained from questionnaires about driving. Among them, a significant relationship between the DS score obtained from the simplified DS and the time required for TMT Part-B was obtained ($p < 0.005$), and all participants whose TMIG-IC score was less than 11 points showed a sharp decrease in DS score.

This study proposes indicators that can quantitatively evaluate the driving ability of elderly drivers from various perspectives by conducting longitudinal and cross-sectional analyses of the relationship between the results of simple tests such as TMT and TMIG-IC and the results of risk avoidance ability tests. In the near future, indices will be proposed that can be used to quantitatively evaluate the driving ability of elderly drivers from various perspectives by analyzing the relationship between the results of these indices and the results of risk-avoidance tests. In addition, by analyzing these indices and data on accidents involving people with a history of accidents, violations, or pre-existing conditions such as epilepsy, data will be provided that will be useful in determining the negligence of the perpetrators of traffic accidents. Furthermore, by using these results as a reference, it is considered that simple tests similar to TMT and TMIG-IC can be administered to the perpetrators of traffic accidents at the elderly person's training course at the time of license renewal and to the perpetrators after the accident to evaluate their respective abilities and to assess the human factors of the accident in detail.

Traffic Accident Reconstruction for Elderly Driver, Trail Making Test, Activity Capacity Index

D40 A Study of Injury Risk Assessment Methods for Pediatric Impacts with the Floor: An Estimation of Acceleration and Load the Human Body Is Subjected to Using Multi-Body Dynamics

Yuki Kunugi BE, University of Yamanashi, Takeda, Yamanashi, Japan; Ito Yasumi, PhD, University of Yamanashi, Takeda, Yamanashi, Japan; Sonoka Okura, BE, University of Yamanashi, Takeda, Yamanashi, Japan; Taiki Watanabe, University of Yamanashi, Takeda, Yamanashi, Japan; Ryuichi Yamada, PhD, University of Yamanashi, Takeda, Yamanashi, Japan; Yamanashi Kagiya, PhD, University of Yamanashi, Takeda, Yamanashi, Japan; Toshiyuki Harama, BE, Shizuoka Prefectural Police, Shizuoka, Japan; Police Kosuke Kurata MS, Shizuoka Prefectural Police, Shizuoka, Japan; Takao Ogura, Mie Prefectural Police, Tu, Mie, Japan; Tetsuya Nemoto, PhD, National Center for Geriatrics and Gerontology, Obu, Aichi, Japan*

Learning Overview: After attending this presentation, attendees will have learned about injury risk evaluation methods using multi-body dynamics analysis.

Impact Statement: This presentation will impact the forensic medicine and forensic engineering community by providing a method for injury risk evaluation using multi-body dynamics analysis.

In Japan, the number of cases of physical abuse of children has been increasing every year. Currently, physical abuse is judged based on the testimony of the victim and the diagnosis of the physician. Since this method of determining physical abuse is qualitative, there is a need for an objective and quantitative evaluation of the external force applied.

In previous studies, methods that estimate the external force from the degree of damage have been reported. However, it has not been possible to determine what kind of behavior caused the external force. Therefore, it is considered that a method that estimates the situation at the time of injury is required. By using previous research and multi-body dynamics analysis, it is considered possible to estimate the situation at the time of injury based on the degree of injury, and quantitatively determine the physical abuse of young children. This study proposes a method to estimate the risk of injury by simulating a child falling using multi-body dynamics analysis with MAThematical DYnamic MOdels (MADYMO) and calculating Head Injury Criteria (HIC) and other parameters.

In order to perform the analysis with MADYMO, it is necessary to determine the contact characteristics between the child dummy model and the floor (flooring, concrete, etc.). Therefore, this study adjusted the analysis parameters so that the acceleration waveform would be the same in the same analysis as in the experiment using the head impactor. In the experiment, the head impactor was dropped freely from a height of 90cm and collided with each floor. In the analysis, a sphere with the same radius and mass as the head impactor was dropped freely and collided with each floor under the same conditions as in the experiment. As a result, this study was able to determine the contact characteristics between the child dummy model and each floor.

In order to verify the accuracy of the MADYMO analysis, this study also performed the same analysis as in the experiment using a 3-year-old dummy doll (Hybrid III3YO) and compared the results. In the experiment, a Hybrid III3YO was dropped freely from a height of 90cm in a prone position and collided with the floor (flooring, concrete, etc.). In the analysis, MADYMO was used under the same conditions as in the experiment. As a result, this study was able to measure the same level of head acceleration in the experiment and analysis. Therefore, it was confirmed that the accuracy of the analysis was relatively good when the head first collided with the floor. The results of this study can be used to estimate the situation of child abuse from the degree of injury with higher accuracy.

Injury Risk, Estimating Children's Behavior Through Simulation, Child Abuse

D41 The Forensic Approach in the Analysis of Trauma: The Application of 3D Technology in the Reconstruction of Death

Isabella Aquila, MD, PhD, Institute of Legal Medicine, University Magna Graecia of Catanzaro, Catanzaro, Italy; Roberto Raffaele, MD, Institute of Legal Medicine, University Magna Graecia of Catanzaro, Catanzaro, Italy; Matteo Antonio Sacco, MD, Institute of Legal Medicine, University Magna Graecia of Catanzaro, Catanzaro, Italy; Pietrantonio Ricci, MD, PhD, Institute of Legal Medicine, University Magna Graecia of Catanzaro, Catanzaro, Italy*

Learning Overview: After attending this presentation, attendees will understand the role of 3D technology in cases of trauma.

Impact Statement: This presentation will impact the forensic science community by demonstrating the importance of 3D motion capture with circumstantial data in the evaluation of dynamics of traumatic death.

The effects of trauma are classified into general and local, direct and indirect, immediate and consecutive, primary and secondary, and anatomical and functional. The severity of the trauma depends on the mechanical force acting on the anatomical region and the type of anatomical region affected. There are many traumas in forensic pathology, from cutting or slashing, firearms, blunt instruments, explosions, crushing, precipitation, road accidents, and electrical or thermal causes. The autopsy always allows us to clarify the causes of death in these cases and to analyze in detail the characteristics of the injuries produced by trauma. However, it is increasingly difficult to analyze the ways in which the traumatic event occurred with respect to the surrounding environment and with respect to some variables that are part of the dynamic. In these cases, the role of the forensic pathologist becomes crucial to reconstruct the incident. Solving a crime always requires a systematic methodology. It proves indispensable especially when the dynamics of crime are complex; for example, when the weapons of the crime are multiple, there are no traces of the killer, the injuries on the victim are numerous, the testimonies of the suspects are doubtful or improbable. In these cases, investigators may have difficulty in reconstructing the event with certainty.

In recent years, forensic science has experienced a rapid development in the application of new computer technologies for crime scene reconstruction. In 3D technology, Motion Capture (MOCAP) enters the forensic field experimentally. It consists of a 3D virtual model based on motion capture. MOCAP is the recording of the movement of the human body (or other movements) that allows for virtual playback. This study reports a series of cases of traumatic deaths where it was necessary to clarify the circumstances and the dynamics of the events. In all cases, the reconstruction of the trauma was applied through 3D technology with the application of 3D MOCAP. This study proposes a new virtual method useful for reconstructing the dynamics of complex cases.¹⁻⁴ The proposed model is not routinely used in forensic medicine, and through the analysis of these cases, it demonstrates its applicative utility. In particular, the forensic purpose is to compare the lesions analyzed during the autopsy or the victim's visit with the possible dynamics compatible with the environments in which the event occurred, with the testimonies and the types of weapons used.

The experimental 3D model shown has several other advantages: the ability to perfectly keep a copy of the crime scene and its environment; the ability to easily compare various murder dynamics; being able to combine the reconstructed dynamics with the testimony; and being able to use video as judicial evidence in court. This study demonstrates that the 3D method must be able to be used in the forensic field; the crime scene is not a film and not a fiction; the reconstruction must always refer to the scientific evidence found on the scene or on the victim and cannot under any circumstances build from scratch a dynamic that cannot be demonstrated on the scene with scientific evidence. Therefore, the method represents a tool and a key to reading a piece of evidence found in forensic investigations. Doubt is the circumstance for which the forensic pathologist has reason to exist, but at the same time, it is the event that the forensic pathologist must cancel through the application of scientific rigor of the method, with the help of technology.

D42 Macro Photography in Forensic Pathology: A Useful Tool to Focus on Skin Lesions

Federico Manetti, MD, Department of Anatomical, Histological, Forensic and Orthopaedic Sciences, Sapienza University of Rome, Rome, Italy; Matteo Scopetti, MD, Department of Anatomical, Histological, Forensic and Orthopaedic Sciences, Sapienza University of Rome, Rome, Italy; Vittorio Gatto, MD, Department of Anatomical, Histological, Forensic and Orthopaedic Sciences, Sapienza University of Rome, Rome, Italy; Martina Padovano, MD, Department of Anatomical, Histological, Forensic and Orthopaedic Sciences, Sapienza University of Rome, Rome, Italy; Alessandro Santurro, MD, Department of Medicine, Surgery and Dentistry, University of Salerno, Salerno, Italy; Vittorio Fineschi, MD, Department of Anatomical, Histological, Forensic and Orthopaedic Sciences, Sapienza University of Rome, Rome, Italy*

Learning Overview: After attending this presentation, attendees will better understand the value of applying macro photography in the field of forensic pathology.

Impact Statement: This presentation will impact the forensic science community through the presentation of a series of macro images relating to skin lesions, with particular reference to the acquisition methodology and the benefits that can be obtained in terms of evidence in the course of forensic pathological investigations.

Macro photography is a branch of traditional photography, generally adopted in the representation of insects or small objects. From a technical point of view, a photograph is defined as a macro when the photographed object is represented in its original size or larger on the sensor of the camera body. It is possible thanks to the use of particular photographic lenses able to focus on objects very close to the observer and, compatibly with the limits of the used instrumentation, allows a considerable magnification capacity and the collection of a large amount of details.

This report presents a case series of autopsies in which macro photography was used in the determination of fine details of cutaneous lesions. The photographs were captured using a camera body with Advanced Photo System type-C (APS-C) format (23.5mm x 15.6mm) Complementary Metal Oxide Semiconductor (CMOS) sensor, a 105mm F/2.8 1:1 macro lens and a macro led ring flash. All images were captured using manual settings and focus; the acquisition settings used were significantly affected by many external factors, variable for each individual lesion such as, for example, the different depths of field required, the lighting conditions, as well as the possibility of using a tripod. The survey sample includes cases of external cadaveric inspection or judicial autopsy performed at the Department of Forensic Pathology of Sapienza University of Rome. In particular, the skin lesions studied, belonging to at least 20 cases of judicial interest, include cases of sharp and blunt injuries, gunshot wounds, and ligature marks.

The analysis of the obtained images made it possible to appreciate some distinctive elements of the skin lesions difficult to observe with the naked eye, able to direct the diagnostic judgment regarding the vitality of the lesion and the productive mechanisms, such as describing the asphyxiogenic medium features in cases of violent asphyxia, reconstructing the direction and characteristics of the blade in the case of sharp injuries, and identifying the typical characters of entrance and exit gunshot wounds, as well as accessory findings.

In conclusion, macro photography can be an important and practical tool in the study of skin lesions by virtue of the speed and ease of use, the low cost of the equipment, and the ease of interpretation of the observed findings. Certainly not being able to provide results comparable to the microscopic study of lesions, macro photography can be considered a preliminary study phase to it, already allowing, during the crime scene investigation or the first examination of a corpse, documentation of important semeiological findings and freezing elements for evidential purpose, with the ability to non-invasively and more easily locate small findings in the context of the entire lesion.

Macro Photography, Skin Lesions, Diagnostics

D43 The Challenges in Reproducible Capture and Analysis of Cannabinoids with an Impaction Filter Device

Kavita Jeerage, PhD*, National Institute of Standards and Technology, Boulder, CO; Tara Lovestead, PhD, National Institute of Standards and Technology, Boulder, CO; Veruska Malave, PhD, National Institute of Standards and Technology, Boulder, CO; Adam Friss, PhD, National Institute of Standards and Technology, Boulder, CO; Cheryle Beuning, PhD, National Institute of Standards and Technology, Boulder, CO; Cinnamon Bidwell, PhD, University of Colorado, Boulder, CO; Edward Garboczi, PhD, National Institute of Standards and Technology, Boulder, CO

Learning Overview: Attendees to this presentation will learn about devices for the collection of exhaled breath aerosols and challenges specific to the quantitative analysis of cannabinoids.

Impact Statement: This presentation will impact the forensic science community by discussing how human factors and device design impact the reproducible quantitation of cannabinoids in the exhaled breath of cannabis users, which is required for reliable, unbiased chemical determination of cannabis use.

Cannabis induces decreases in executive function and motor control that make drivers more likely to be involved in crashes than unimpaired drivers.¹ The premise behind a “cannabis breathalyzer” is that cannabis use can be quantified with field-deployable devices akin to those used for breath-alcohol analysis; however, ethanol (EtOH) and delta-9-tetrahydrocannabinol (Δ^9 THC) have dramatically different thermophysical properties that create challenges for breathalyzer development. EtOH is soluble in blood and, compared to other drugs, a large quantity can be consumed—a standard drink contains 14g. EtOH remains in the vapor phase (i.e., does not condense) during exhalation and quantitation and blood/breath ratios have been measured in thousands of individuals. By contrast, Δ^9 THC is expected to be carried by aerosol particles based on its low volatility (Δ^9 THC is 100 million times less volatile than EtOH).² Despite its low blood solubility and volatility, Δ^9 THC has been successfully recovered by concentrating analytes from a large volume of breath, with identification and quantitation by liquid chromatography and tandem mass spectrometry.³⁻⁷ Δ^9 THC spikes following cannabis use, then decreases, and has been recovered for time periods ranging from 1h to 3h following use.

Exhaled breath aerosols can be collected with surgical masks, electret filters, impaction filters, and condensate devices, which condense water vapor and volatile compounds in addition to capturing particles. The materials, dimensions, mode of action, and extraction methods influence which compounds are recovered and new designs are frequently reported, reflecting the early stage of aerosol collection. Future adoption of aerosol collection devices for evidentiary purposes requires an understanding of how human factors, ambient conditions, and device design impact cannabinoid recovery. For example, individuals differ in their production of aerosol particles, which increases with the ventilation ratio (V_R)—this is the tidal volume (V_T , which is the exhaled volume) divided by the vital capacity (V_C , which is the total volume that can be exhaled).⁸ Standardization is limited: breath has been collected for a specific time, number of breaths, or volume.³⁻⁷

This presentation will focus on the collection of exhaled breath aerosols with an impaction filter device consisting of a wide mouthpiece followed by three parallel collectors. The cylindrical collectors are 22mm long, have a 10mm internal diameter, and contain eight baffles perpendicular to the main direction of the flow that dictate the velocity profile. The device can be used alone or connected to a spirometer. Pre-consumption and post-consumption samples were collected from experienced cannabis users consuming a single legal market product in a naturalistic, observational design; compliance with protocol was verified with blood cannabinoid measurements.⁹ Each exhalation through the device followed a low lung volume breath hold to increase aerosol particle production.¹⁰ Analytical results will include a discussion of challenges related to Δ^9 THC extraction and quantitation. The presentation will also include laboratory studies of oral fluid contamination, measured via detection of alpha-amylase activity. Numerical simulation methods, specifically computational fluid particle dynamics, will be described to provide insight into the velocity profiles and particle capture efficiency of individual collectors. Inherent human variability can ultimately be mitigated by appropriate device design and standardized breath collection and analysis protocols.

D44 A Forensic Analysis of Cosmetic Smudges Using Mass Spectrometry: The Effect of Sampling, Surface, and Time

Entesar Al-Hetlani, PhD*, Kuwait University, Khaldyia, Asimah, Kuwait; Halemah AlSaeed, MSc, Kuwait University, Khaldyia, Asimah, Kuwait; Mohamed Amin, MSc, Kuwait University, Khaldyia, Asimah, Kuwait

Learning Overview: After attending this presentation, attendees will have learned about the results obtained on the recovery and analysis of cosmetic product smudges found on different surfaces common in every household and that can also be found in a crime scene. Cosmetic smudges have recently gained some attention and most of the focus is on the analysis of makeup products to discriminate between them using primarily spectroscopic techniques. Recently, the persistence of moisturizer products on human skin in relation to sexual assault investigations was covered using Gas Chromatography/Mass Spectrometry (GC/MS). This study broadened the research aspect by looking at different surfaces (glass, steel, and plastic) using five different cosmetic products that can be purchased without prescription and used by both genders without age restriction. In addition, to perform the analysis in an efficient way, Surface-Assisted Laser Desorption/Ionization (SALDI) -MS was employed without sample preparation and cleanup with a minute amount of sample. The results obtained are very promising and can be further used to include other products and to study their stability under different temperature and humidity conditions. Therefore, forensic analysis of cosmetic smudges can be performed directly without sample cleanup employing a small amount, which is highly beneficial for forensic applications.

Impact Statement: Recently, research into forensic smudge analysis has gained a lot of attention. This is motivated by the reality of crime scenes where there is no control over the quality and quantity of the physical evidence. Several researchers have focused on smudges of biological fluids and their importance in DNA analysis to convict or exonerate a suspect. Limited attention has been dedicated to the analysis of non-biological smudges recovered in a crime scene, in particular, analysis of cosmetic products that are highly relevant in crimes involving females. Therefore, for the first time, this study explored the analysis of cosmetic products using SALDI-MS using small amount of these products. The obtained mass spectra, the effect of surface on which they were deposited, and aging of the smudges were carefully studied. The smudge recovery approach in combination with SALDI-MS provides overall gains in discrimination power, analysis time, and reduces matrix effect. Moreover, the imposed lockdown during the COVID-19 global pandemic has increased the necessity for more advanced techniques that can coincide with the massive delays and sample backlog in forensic labs.

Cosmetic evidence recovered from crime scenes is emerging as a significant finding that can assist in linking or exonerating a suspect to certain crime or victim. Due to their texture and composition, cosmetics tend to strongly adhere to surfaces and persist for a long time. In this work, five cosmetic products containing different Active Pharmaceutical Ingredients (APIs) were investigated utilizing SALDI-MS. Bepanthen® cream, Reparil® gel, Eucerin® cream, Soskin® serum, and Clofen® cremagel containing dexpanthenol, diethylamine salicylate, urea, Salicylic Acid (SA), and Diclofenac Sodium (DCS) as APIs, respectively, were employed in this study. Initially, based on the signal intensity obtained for each API, the optimum extraction solvent was investigated using solvents of different polarity indices. Consequently, ethanol was recognized as the best solvent for salicylate, urea, and DCS, whereas propanol for SA, and lastly Dichloromethane (DCM) for dexpanthenol.

Often in a crime scene traces of cosmetics are encountered, therefore, Limits Of Detection (LOD) is of paramount importance. In this context, several dilutions were carried out and LOD of 300ng/mL for dexpanthenol, 30ng/mL for salicylate, 6ng/mL for urea, 1.20ng/mL for SA, and 600ng/mL for DCS were obtained. Furthermore, the Relative Standard Deviation (RSD) for each API was also calculated and the values ranged between 0.40 to 17.95%, which indicated good reproducibility. As a proof-of-concept, smudges of five cosmetics were freshly deposited on the SALDI-MS target plate in a small amount without extraction and the APIs were successfully detected. Subsequently, simulation of forensic samples by locating cosmetics smudges on three different surfaces of household items, namely plastic, glass, and stainless-steel (flask, Figure 1a), and recovered via two approaches. In the first approach, the smudges were swabbed with wet cotton (using the optimum solvent) and subjected to extraction; on the other hand, the second approach was based on swabbing the smudges with wet cotton (using the optimum solvent, Figure 1b) and placing it directly on the target plate (Figure 1c). Although in both approaches the APIs were detected, the second approach was superior and can be directly implemented in the crime scene due to its simplicity. Additionally, for more precise data interpretations, substrate control analysis was performed for the three surfaces and their contribution to the spectra was accounted for (Figures 1d and e). Finally, based on the results obtained for each surface, aging of the smudges of each product were studied over three weeks. Notably, four APIs—dexpanthenol, salicylate, urea, and SA—were detected with relatively high signal for up to three weeks, while DCS signal decreased after only one day; however, it remained detectable up to three weeks. Therefore, the results confirmed the stability of cosmetic products on surfaces for long-term periods and the superiority of SALDI-MS to detect the ingredients of such products with minimum sample handling and pretreatment.

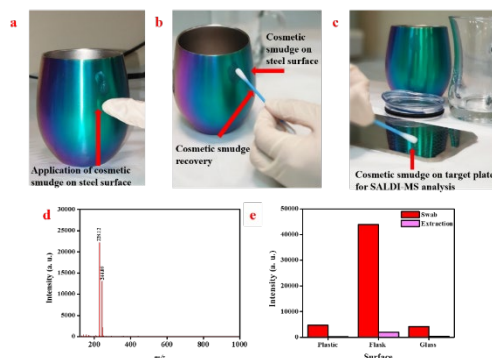

Figure 1. (a) Cream smudge placed on the flask (steel surface), (b) after 30 minutes of deposition, the smudge is collected via moistened cotton swab with the optimum solvent, (c) the swab was directly placed on the target plate and allowed to dry at room temperature prior to the analysis, (d) the obtained mass spectrum of Bepanthen® cream (as an example) showing sodiated and potassium adducts of dexpanthenol, (e) signal intensity obtained using the swab and extraction approaches on three different surfaces: plastic, steel (flask) and glass.

Forensic Smudge Analysis, Cosmetic Products, Mass Spectrometry

D45 Fluorescence Lifetime Imaging (FLIM) of Latent Fingerprints on Paper Emitting Strong Fluorescence at Excitation by 532 Nanometers (nm) Pulsed Laser

Hidetoshi Kakuda, PhD, National Research Institute of Police Science, Kashiwa, Chiba, Japan; Norimitsu Akiba, PhD, National Research Institute of Police Science, Kashiwa, Chiba, Japan; Kazuhito Hibino, National Police Agency, Chiyoda-ku, Tokyo, Japan; Kazunari Shibasaki, MSc, National Research Institute of Police Science, Kashiwa, Chiba, Japan; Ken'ichi Tsuchiya, PhD, National Research Institute of Police Science, Kashiwa, Chiba, Japan; Kosuke Tanabe, MSc, National Research Institute of Police Science, Kashiwa, Chiba, Japan*

Learning Overview: After attending this presentation, attendees will have a better understanding of visualizing latent fingerprints non-destructively by FLIM.

Impact Statement: This presentation will impact the forensic community by reporting a successful case of using FLIM for visualizing latent fingerprints on a background substrate that emits such strong fluorescence at laser irradiation that even the conventional time-resolved spectroscopy does not work.

Fingerprints are important evidence for human identification in criminal investigations. Visualization of latent fingerprints by photoexcitation using laser and then photographing fluorescence of fingerprints is a powerful method as a non-contact and non-destructive detection method.¹ Since background substrates of fingerprints often emit fluorescence, it becomes difficult to visualize latent fingerprints when background fluorescence is strong. Although differences in wavelength range and lifetime of fluorescence are utilized to reduce the effect of background fluorescence, it is hard to visualize latent fingerprints when none of these differences is available. Concretely, it is difficult to visualize latent fingerprints when the following three conditions are all satisfied: (1) background fluorescence is much stronger, (2) wavelength range of background fluorescence includes that of fingerprints, and (3) fluorescence lifetime of background is close to or longer than that of fingerprints.

FLIM is a method of constructing an image whose pixel value is a fluorescence lifetime of the sample at that pixel position. FLIM is widely used in the field of life and biomedical sciences and, in forensic sciences, application of FLIM to the detection of gunshot residues is reported.^{2,3} This study conducted FLIM on visualization of latent fingerprints for the case that the three conditions mentioned above are all satisfied.

An untreated fresh fingerprint was pressed on white, yellow, and pink paper. These samples were excited by a 532nm pulsed laser of 1mJ and pulse width of 3-5ns. Fluorescence images of samples were acquired with a fast-gated Intensified Charge-Coupled Device (ICCD) camera with a gate width of 2.8ns at the delay time of 6-20ns (1ns interval) to the laser pulse. The camera has a sensitivity to 200-850nm. The resolution of image is 1,024 x 1,024 pixels. A long-pass filter (>550nm) was placed between the sample and the camera. Fluorescence intensity and lifetime of each paper were as follows. Fluorescence intensity of white, yellow, and pink paper were about 2×10^2 , 8×10^2 , and 3×10^4 times larger than that of fingerprints, respectively. Fluorescence of pink paper was specifically strong. Fluorescence spectra of each paper covered the wavelength range of up to about 700nm and included that of fluorescence of fingerprints. Fluorescence lifetimes of each paper had a component of 5.9, 7.5, and 3.8ns, respectively, which were close to or longer than the fluorescence lifetime 3.7ns of fingerprints at 532nm excitation. In fluorescence images at any delay time, no fingerprint image was observed by the conventional time-resolved spectroscopy.

In spite of the largest fluorescence intensity of the pink paper by about four orders of magnitude larger than that of fingerprints, a latent fingerprint was visualized in the fluorescence lifetime image of the pink paper sample by FLIM. On the other hand, in white and yellow paper samples, fingerprints were not visualized in FLIM images. This seems to indicate that FLIM has the potential of enabling visualization of latent fingerprints on backgrounds emitting stronger fluorescence. It is shown that there is a case that FLIM visualizes latent fingerprints that cannot be visualized by the conventional time-resolved spectroscopy.

This work was supported by JSPS KAKENHI Grant Numbers JP19K20687 and JP17K01385.

D46 A Simulation Triad for Evaluating the Use of Engineering Simulation

Bart Kemper, BSME*, Kemper Engineering Services, Baton Rouge, LA

Learning Overview: After attending this presentation, attendees will understand key principles in using engineering simulations in support of forensic investigations, the legal pitfalls of simulation exclusion based on “simulations as a separate witness,” and how Verification & Validation (V&V) embodies best practices to connect the user’s skills to the simulation to enhance the likelihood given engineering simulations are admitted. This can be summed up as the proposed “Simulation Triad,” where one must establish two of the elements to seek a third. The three elements are theory, data, and simulation.

Impact Statement: This presentation will impact the forensic science community by mapping the legal principles that can result in the exclusion of simulations from testimony, enabling the practitioner to examine the work of others with a more critical eye as well as do the work to reduce the likelihood of a simulation being excluded.

The scientific method can be described as predicated on statistically analyzed experimentation for the falsification or validation of a null hypothesis. In forensic engineering, developing a controlled experiment may not be possible due to factors such as complexity, safety, or cost.¹ Perhaps a more fundamental difference is the scientific method is a way to investigate by testing a hypothesis, whereas engineering is about applying well-understood principles to achieve a predictable, repeatable outcome. Forensic engineering is often about applying these well-understood principles to model a theory regarding an event to predict a theoretical outcome or, conversely, to incorporate field data into these principles to test which physical models best match the data in order to develop a working theory of the event. The “theory” is defined as the sequence of events incorporating the applicable engineering principles, such as kinematics, heat transfer, Newtonian fluid flow, or strain energy failure theory.

Mathematical modeling can be done many ways, including simple calculations. As it becomes more complex and computers are incorporated, it can be termed a “simulation.” There are established numerical models such as Finite Element Analysis (FEA) and Computational Fluid Dynamics (CFD). The more complex the simulation is, the more potential there is for the workings of the simulation to be outside the individual’s personal control and understanding. This can result in the simulation being ruled to be a “separate witness,” which is not subject to cross-examination and is therefore excluded.²

While the concept of V&V is not new, it wasn’t until 2006 that a standard was developed for solid mechanics FEA, followed by CFD in 2009.^{3,4} Other standards have emerged. Properly used, V&V techniques can be used as a method to meet a *Daubert* challenge, or what is now a Federal Rule 702 challenge. Specifically, it can address three of the elements of a typical Rule 702 challenge of assessing: (1) whether the simulation-related testimony is based on sufficient facts or data; (2) whether the simulation-related testimony is the product of reliable principles and methods; and (3) whether the expert has reliably applied the simulation principles and methods to the facts of the case.

Understanding the methodology proposed in this presentation will guide the simulation practitioner to best practices and increase the likelihood to meet a Rule 702 challenge as well as give those reviewing the work of others a method to evaluate simulation use.

Simulation, Verification, Validation

D47 A Forensic Readiness Model for the Fused Filament Fabrication (FFF) -Based Additive Manufacturing (AM) Process

Muhammad Rais, MS, Virginia Commonwealth University, Richmond, VA; Irfan Ahmed, PhD, Virginia Commonwealth University, Richmond, VA*

Learning Overview: This presentation will familiarize attendees with the challenges in the existing forensic readiness capability in Additive Manufacturing (AM) processes and the problems in employing conventional IT forensic readiness models in an AM process. Attendees will also understand the advantage of using physical domain artifacts in the forensic readiness models of Cyber-Physical Systems (CPS).

Impact Statement: This presentation will impact the forensic community in three ways: (1) readily using the model and the case study to achieve forensic readiness for FFF-based AM process, (2) providing guidance to create models for forensic readiness for CPS employing physical domain artifacts, and (3) urging forensic researchers in formalizing regulatory compliance criteria or the best practices for security-sensitive and critical 3D printing setups.

Currently, industrial manufacturing is going through a transformation phase of adopting additive manufacturing technology, which is fundamentally different from conventional subtractive manufacturing and offers a separate set of vulnerabilities and attack opportunities. For instance, malicious variations in the internal structure, anisotropy, or thermodynamic profile can cause inconspicuous damages during 3D printing. Another unique phenomenon of the merger of Information Technology and Operational Technology is happening concurrently in the industry, exposing the relatively isolated and less vulnerable manufacturing industry to the world of cyberattacks. In case of failure of a critical 3D-printed component (such as a blade of a jet-engine's turbine), a forensic investigation is held to find answers to questions such as: did the blade fail due to an attack on the manufacturing process chain, how the attack was conducted, which printing parameters were modified, etc. An important phase of digital forensics, known as forensic readiness, comprises pre-incident information acquisition of important information to help find answers to forensic questions during the post-incident investigation. Unless captured during the operation, some critical information may not be retrievable later during the investigation phase. For this reason, regulators produce compliance criteria and best practices for users to timely collect the potentially useful information and properly preserve it. As additive manufacturing is a cyber-physical process, its forensic readiness requirements are different from conventional IT infrastructure. The AM process chain does not terminate in the cyber-domain, urging the need to recover information from the later part of the chain in the physical domain. The physical domain's knowledge (if captured) can provide detailed information about the attack. The precious artifacts extracted from the physical domain can play a pivotal role in answering many forensic questions.

No work in the existing literature discusses the forensic readiness of additive manufacturing processes. To fill this void, this study presents a forensic readiness model for FFF-based 3D printing process that not only highlights the conventional cyber-domain information of interest but also extends the digital forensics reach to the physical domain by employing authentic methods to acquire the object's state throughout the printing process. The model utilizes multi-domain algorithms on the acquired printing data to answer the forensic questions. The approach readily and authentically extracts the cyber- and physical-domain artifacts, such as the G-code file (printing instruction file) in use at the time of the attack, the printer's firmware, the geometrical layout of each printed layer, and so on. Through a case study on a common printer, the effectiveness of the model is evaluated under most of the attack scenarios available in the existing literature. For instance, if an attacker modifies the thermodynamic profile of the printer's nozzle to induce undesired thermal stresses or creates tiny cavities at critical locations in an object causing premature failure, the proposed approach successfully finds traces of the attacks.

Forensic Readiness, Additive Manufacturing, 3D Printers

D48 Microscopy—Criminalistics and Environmental Forensic Applications

James Millette, PhD, Millette Technical Consulting, Lilburn, GA*

Learning Overview: From this presentation, attendees will learn how microscopy may be useful in the analysis of particles in forensic engineering investigations to obtain results like those determined for a criminal trace evidence examination.

Impact Statement: This presentation will broaden the use of microscopical analysis of particulate in engineering fields by using the forensic methodologies that have been developed for use in criminal investigations of trace evidence.

The Locard Exchange Principle was proposed in the 1930s by Edmund Locard, the director of the crime laboratory in Lyon, France. Locard's Exchange Principle states that whenever two objects come into contact, a transfer of material will occur. By recognizing, documenting, and examining the nature and extent of this evidentiary exchange, Locard observed that criminals could be associated with particular locations, items, or evidence and victims. Microscopy played an important role in finding the evidence of particle exchange in the Shannon Melendi criminal case in Atlanta in 2005. Eleven years after the abduction of the Emory University student, microscopical analysis using scanning electron microscopy found an unusual assemblage of metal particles (cobalt, molybdenum, titanium, and tungsten) on masking tape and in a cloth bag containing the victim's ring that had been left in a phone booth after an anonymous call had been made concerning the abduction. The same assemblage of metal particles was found on the same type of type in the vehicle of the suspect, Colvin (Butch) Hinton III, as well as at the Delta Airlines technical support center where he worked. This trace evidence of particle exchange helped to lead to a successful conviction of Mr. Hinton, even without a body or crime scene.

Similar microscopy techniques were used to identify the source of a child's high blood level when analyses of the paint in her home showed no evidence lead-based paint. Particles containing lead matching those found in the dust of the family home were found in piles of ash outside an abandoned warehouse down the street from the family's house. The warehouse property eventually became an environmental superfund site and the owner was found guilty of neglect.

In another case, microscopical analyses found a mixture of two asbestos types in pieces of cloth that had been taken to the family home from worksites by the father of a woman who had contracted mesothelioma. Even though the cloths had been used for drapes and rags, and washed several times, amosite and chrysotile asbestos fibers were found among the cotton fibers. The two asbestos types together were consistent with the composition of a product called Kaylo that was shipped to worksites packed in a cheesecloth-type material.

Microanalysis, Particles, Dust

D49 Who Is a Good Boy? Finding Out What Makes a Performance Detection Dog

Student Clément Martin, MS, Uliège, Gembloux, Namur, Belgium; François Verheggen, Uliège, Gembloux, Namur, Belgium; Claire Diederich, Unamur, Namur, Belgium*

Learning Overview: This presentation will allow attendees to understand the practices of professional Detection Dog's (DD's) handlers to scientific knowledge. Also, a definition of what is a high-performance DD will be proposed. Finally, an easy-to-replicate method will be described to assess DDs' performances.

Impact Statement: This presentation will suggest axes of research to better decipher DDs' physiologies and behaviors. It will also define for the first time the concept of DDs' performances based on a common agreement among professional police DDs' handlers. Finally, an accurate test allowing the assessment of DDs' performance will be described.

Dogs are known to be efficient scent detection animals. Their powerful olfactory system and their training ability explain why they are widely used in so many police and military application fields. However, low performance observed in DDs may result from a lack of knowledge on their olfactory neurophysiology and related behaviors.^{1,2}

This work associated the results extracted from: (1) a deep review of the available literature, (2) an international survey sent to professional DD's handlers (n=50), and (3) an experimental assay performed on cadaver and drug DDs (n=20) to decipher what makes a performant DD and ultimately suggest a first definition of what is a high-performance DD.

The survey was sent to the police network for law enforcement dog professionals (Kynopol) and detailed answers were received from 50 cadaver DD teams. The questions were focused on the procedures of selection, training, and performance evaluation. Despite a lack of homogeneity in the selection methods used, selected DDs have usually the same physical and behavioral traits: the agility and the stamina of puppies were highlighted as the most important biological traits to pay attention to during the selection. Playfulness, curiosity, and sociability were also regularly pointed out in the answers received. Most surveyed handlers use reinforcement rather than punishment during their training sessions. Although a few teams practice negative reinforcement, the others use either toys, clickers, or encouragement as positive stimuli. Practitioners never use commercial training aids and prefer homemade biological aids that they declare being the most reliable. Both this survey and the literature review suggest that there is no existing definition of what a performant DD is, nor reliable test that could be used to evaluate post-training performance. Each team performs its own homemade method that is, in most cases, based on subjective measurements. Most of the surveyed DD teams define a performant DD as a dog which is confident, precise, with a high rate of success (low level of false negatives and positives, that is, high sensitivity and specificity of the detection) and which performs a strategic research.

Taking these results into account, this study set up a behavioral assay to assess DDs' performances in hope of validating this definition of a performant DD. Twenty dogs were assessed in a cinderblock half-circle arena (d=6m) in which a targeted odor was hidden among other distractive odors. A camera was placed on the ceiling (h=3m) and a video-tracking software was used to analyze the behavior, movement, and activity of the dog. This arena was validated based on co-inertia analysis between measured data in the arena and the dog evaluation by handlers. It allows the measurement of the dog's error rate and level of strategy.

Detection Dogs, Performance Assessment, Ethology

D50 An Evaluation of the Application of Data Fusion Technology to Sand Analysis

Sergey Mamedov, PhD, HORIBA Scientific, Piscataway, NJ*

Learning Overview: After attending this presentation, the attendees will have a better understanding of the application of Data Fusion technology to sand analysis, an essential part of forensic identification of these materials.

Impact Statement: This presentation will impact the forensic community by serving as critical aspects of sand analysis and an example of a practical application of the Data Fusion technology to materials identification.

This presentation aims to demonstrate the application of Data Fusion technology to classify sand from different sources. It will likewise show that Data Fusion technology can improve the results of such classification. This presentation will then compare and discuss the results of single source and data-fused analysis. X-Ray Fluorescence (XRF) is a valuable tool for the identification of substances and for confirming their identity with no sample preparation. XRF emission lines, specific to particular elements, enable elemental and chemical identification. XRF analysis has the potential to solve a wide variety of problems associated with forensic science. Statistical methods applied to a set of XRF spectra show the capability of detecting the slightest differences in the elemental composition of sand. Therefore, it plays a vital role in helping to determine the origin of sand. To illustrate the above, XRF spectra of sand will be highlighted in this presentation and the ability of XRF to identify sand from different geographic locations, including the United States, Europe, and the Middle East.

The XGT-900 XRF analytical microscope was used in this study. The XRF spectrum of the materials depends on the X-ray optical system, the detector's sensitivity, and accelerating voltage. In addition, the background from the substrate will contribute to the spectrum of the small pieces because excitation X-ray penetrates through the material and interacts with the substrate. Statistical data analysis such as Principal Component Analysis (PCA) or Partial Least Squares Discriminate Analysis (PLS-DA) takes these parameters into consideration.

This study collected and analyzed spectra of sand from different locations (the United States, Europe, and the Middle East) in the range of 1.00–40.96keV (<400 spectra). These spectra were used to build a data set for classification. The results show that PCA allows one to differentiate samples, which have very similar spectra features. To improve the accuracy of classification, the method of Data Fusion was applied to two sets of data. Examples of XRF spectra and trace element analysis of sand are presented, and the analysis results are compared and discussed. Data shows that the location of an unknown sample of sand may be predicted using PCA or/and Partial Least Squares Discriminant Analysis (PLSDA).

The combination of XRF and trace element analysis offers a powerful tool for the characterization and identification of sand. Pre-processing should be performed before concatenation of raw data. Classification of sand was improved using fused data. PCA model performed on fused data is more robust, and visual discrimination from class distributions is better than those results obtained by individual classification.

Sand Analysis, Data Fusion, XRF

E1 The Use of Smart Phone Applications in Crime Scene Analysis: Forensic Advantages and Limitations

Matteo Antonio Sacco, MD, Institute of Legal Medicine, University Magna Graecia of Catanzaro, Catanzaro, Italy; Pietrantonio Ricci, MD, PhD, Institute of Legal Medicine, University Magna Graecia of Catanzaro, Catanzaro, Italy; Isabella Aquila, MD, PhD, Institute of Legal Medicine, University Magna Graecia of Catanzaro, Catanzaro, Italy*

Learning Overview: After attending this presentation, attendees will understand the role of smart phone applications in crime scene investigation.

Impact Statement: This presentation will impact the forensic science community by demonstrating the advantages and limitations of apps to perform measurements with respect to reference points placed on the scene.

Crime scene analysis requires a systematic method. First, the investigators delimit the scene and make measurements with respect to reference points using tools such as extendable or flexible meters. This method needs access to the scene using appropriate precautions to avoid contamination of the scene. In recent years, the technology for smart phones and tablets is spreading in the forensic field thanks to the development of applications, often available for free or at low cost.^{1,2} To date, applications are available that take advantage of the smart phone's camera to measure the size of an object. The operator moves the camera, following the measurement direction until the endpoint. These applications allow also for the detection of the distance between two or more objects and place them in the surrounding space with respect to reference points.

This study used an application capable of taking measurements first in a test environment by measuring: (1) length, width, and depth of a single object; (2) distance between two or more objects; and (3) distance of two or more objects with respect to a reference point. The unit of measurement was the centimeter (cm) and the meter (m). Measurements were performed at a distance of 5 meters, then progressively nearer to the reference point. The same measurements were repeated varying the angle of the camera (90–45° to the right –0° center –45–90° to the left) and with different brightnesses. The measurements were photographed using the smart phone camera. The values obtained were compared with the real measurement or distance of the object using an extendable meter. Subsequently, the application was used in two forensic cases of judicial inspection in a closed environment. The investigators performed measurements of the distance of the corpse with respect to reference points. The data were analyzed and compared.

The use of smart phone apps has already been applied to measure elbow joint motions and to calculate the age of death and bloodstain age.^{3–5} This study has shown that the various apps allow 3D measurements of the dimensions of objects. The greatest advantage of this type of application is that they measure the distance between multiple objects, thus placing them in the surrounding space quickly. However, the comparison of the data with respect to the test environment has shown that the measurements may vary due to the distance and angle of the camera.

In this case, the app made it possible to estimate the distance of the body with respect to the reference points before the investigator entered the room, therefore without the risk of contaminating the scene or dispersing traces.

The advantages of smart phone apps are: (1) 3D measurements of single objects; (2) knowing the distance between multiple objects or with respect to a reference point; (3) documenting the scene without contaminating it; (4) speed in measurements; (5) possibility of simultaneously taking photos with measurements; (6) they are low cost or free; (7) intuitive interface and the possibility of repeating photos; and (8) a quick transfer of photos by sharing app or PC.

The limits are: (1) variability of measurement depending on distance; (2) they do not work in the dark; (3) problems with the measurement of long distances; and (4) minor applications in open space.

Forensic Science, Crime Scene Investigation, Smart Phone

E2 Autopsy Findings in Hydrogen Sulfide Toxicity

Robyn Parks, MD, Los Angeles County Department of Medical Examiner-Coroner, Los Angeles, CA; Christopher Rogers, MD, Los Angeles County Department of Medical Examiner-Coroner, Los Angeles, CA*

Learning Overview: After attending this presentation, attendees will understand the chemistry behind the production of hydrogen sulfide gas, along with the autopsy findings, including proper toxicologic examination, of hydrogen sulfide toxicity and be reminded of the importance of scene safety.

Impact Statement: The impact on the forensic science community includes highlighting the importance of scene safety during death investigation and reviewing a relatively uncommon method of suicide.

A 24 year-old healthy female was found unresponsive in her parked rental car outside the parking lot of a local recreation area by a deputy who was on routine patrol. As he approached the vehicle, he noticed a foul odor, became lightheaded, and observed a handwritten note in the window stating that the vehicle was toxic and to call the Hazardous Materials (HAZMAT) team. The HAZMAT team reported to the scene and observed chemicals mixed in a bucket in the passenger compartment. Upon entry into the vehicle, they identified multiple empty bottles of Lime Sulfur Dip® and The Works® toilet bowl cleaner within the car. A notebook within the vehicle contained a suicide note and a shopping list for the purchased chemicals.

Autopsy revealed gray-blue discoloration of the periorbital areas, mucosal surface of the lower lip, abdomen, and inner thighs. Internal examination revealed green-gray discoloration of the epiglottis, trachea, and mainstem bronchi with a moderate amount of frothy fluid noted in the upper and lower airways. Opening the cranial vault revealed the cerebrum and cerebellum to be diffusely gray in appearance. Coronal sectioning of the brain showed a striking accentuation of gray matter with a dark, olive green discoloration.

Toxicology performed on postmortem blood specimens revealed thiosulfate (18mcg/mL). Methemoglobin and sulfhemoglobin were requested but could not be performed due to specimen inadequacy. The cause of death was certified as hydrogen sulfide asphyxiation with the manner of death listed as suicide. Inhalation of hydrogen sulfide gas produced by mixing of chemicals was listed for the “how did injury occur” section.

Hydrogen sulfide (H₂S) gas is a colorless gas that smells like rotten eggs. While traditionally encountered in workplace exposure to “sewer gas” or commercial manufacturing, it can also be created by mixing toilet bowl cleaner (containing hydrogen chloride acid as an active ingredient) with a sulfide-containing chemical (often sulfur tree spray). Inhalation of the gas can cause rapid, almost immediate death by inhibiting cytochrome oxidase leading to respiratory paralysis and coma.¹

Autopsy findings are relatively non-specific, but may include evidence of irritation, including conjunctivitis, injected respiratory epithelium, and airway secretions. Additional findings may include green discoloration of the gray matter, cherry-red lividity, and dark brown blood. Toxicology should include thiosulfate levels, which is produced when exogenous sulfide is partially oxidized by hemoglobin and liver enzymes and can be measured with toxicological analysis.²

The oxidation of hemoglobin produces methemoglobin, which produces the dark brown appearance of blood noted upon phlebotomy. Sulfhemoglobin is not formed during the acute exposure to hydrogen sulfide and not only exists, in small amounts, in the body, but is also formed during the decomposition process.¹

This case highlights the importance of scene safety for law enforcement, medical professionals, and medical examiner/coroner personnel, along with revealing the autopsy and toxicologic findings.

Hydrogen Sulfide, Suicide, Exposure

E3 A Case of Skully: An Investigation of *X-Files* Proportion

Ashley Holmes, MS, Wake Forest School of Medicine, Winston-Salem, NC; Patrick Lantz, MD, Wake Forest School of Medicine, Winston-Salem, NC; Jerri McLemore, MD, Wake Forest School of Medicine, Winston-Salem, NC*

Learning Overview: After attending this presentation, attendees will appreciate how rapid and convenient access to forensic resources at a possible death/crime scene can potentially save time and money. Attendees will also be reminded that each case must be approached with an open mind.

Impact Statement: This presentation will impact the forensic science and law enforcement community by highlighting the inefficient use of time taken from forensic anthropologists/forensic pathologists in examining remains that turn out to be non-human. A brief discussion of the potential for telecommunication in this situation will be introduced.

A skull was found by construction workers during the draining of a pond. Law enforcement officers remembered that a person had been reported missing in the area years prior. Law enforcement transported the skull to Wake Forest Baptist Regional Autopsy Center, which was three hours away. The skull arrived at the autopsy center covered in adherent mud, obscuring details of the skull. As the mud was gently washed away, curious details of the skull became more apparent. Examination of the teeth and an X-ray of the skull were consistent with non-human, non-organic remains. The quality of the skull reproduction suggested a 3D printer composite or a very detailed mold where sutures appeared to be carefully created, possibly with a Dremel® bit.

Coroners/medical examiners and forensic anthropologists often receive requests for analysis of bones or possible body parts that appear to be human of which the majority of these discoveries turn out to be non-human. Investigation still takes up valuable time, especially if the suspected bones/parts have to be transported to a forensic anthropologist or coroner/medical examiner's office that may be a lengthy distance away. Use of telecommunication would be a readily available solution in these situations.

Death Investigation, Forensic Anthropology, Artifacts in Forensics

E4 Medicolegal Investigation in Two Cases of Suspected Anticoagulant Overdose

Camilla Bonci, MD, University of Turin, Turin, Italy; Lucia Tattoli, MD, PhD, AOU Città della Salute e della Scienza Torino, Turin, Italy; Francesca Capello, MD, University of Turin, Turin, Italy; Luana Bonaccorso, MD, University of Turin, Turin, Italy; Giuliana Mattioda, MD, University of Turin, Turin, Italy; Giancarlo Di Vella, MD, PhD, University of Turin, Turin, Italy*

Learning Overview: After attending this presentation, attendees will have a better understanding of the importance of a complete investigation to evaluate the role of medications in cases of anticoagulant users' deaths.

Impact Statement: This presentation will impact the forensic science community by underlying the need of combined clinical, laboratory, and toxicological approaches when evaluating a suspected case of anticoagulant overdose. The cases of two 80+-year-old patients under Vitamin K Antagonists (VKA) therapy with the suspicion of anticoagulant overdose will be presented.

Case 1: An 84-year-old woman taking warfarin for atrial fibrillation was admitted to the hospital for rectorrhagia. Laboratory tests revealed an International Normalized Ratio (INR) value >9 and high levels of creatinine and sodium, revealing a severe acute kidney injury. The patient died seven hours after admission. Autopsy revealed little hypostasis with evidence of rectorrhagia. Mucosal congestion involving the rectum and the distal colonic segment with bloody material in the lumen was found. Toxicological examination was not remarkable. The cause of death was due to a severe acute kidney failure.

Case 2: An 87-year-old man under acenocoumarol therapy for a prosthetic mitral valve was admitted to the emergency department with a history of diarrhea, drowsiness and altered consciousness with no evidence of recent head trauma. A Computed Tomography (CT) scan showed the presence of a subtle subarachnoid hemorrhage which, along with multiple bruises and a level of INR >20, which raised suspicion of an anticoagulant overdose. The patient died two hours after admission. Autopsy showed little hypostasis and extensive bruises. Severe bowel ischemia with melaena was found. Toxicological examination showed traces of acenocoumarol in the blood. The cause of death was due to multiorgan failure triggered by atherosclerosis-related mesenteric ischaemia.

VKA (acenocoumarol, warfarin) are widely prescribed for the prevention and treatment of thromboembolic complications of cardiovascular diseases.¹ Elderly and comorbid patients under anticoagulant therapy are at risk for anticoagulant overdose for altered kidney and liver function. According to an annual American report, 1,766 cases of exposure to prescription warfarin were observed and 84% of those accounted for unintentional overdose in 2014.² Bleeding is a frequent side effect of this treatment, and most of the risk factors in unintentional overdoses seem to be related to patients' lack of information and education.¹ In case of supra-therapeutic dosing, very high INR values are found. VKA overdoses are relatively rare. The majority of the cases are asymptomatic or with minor hemorrhagic symptoms mainly represented by gingival bleeding, and epistaxis. Major bleeding episodes include bleeding from the gastrointestinal tract, deep muscle hematoma, ecchymoses on the extremities, hematuria, intracerebral hematoma, and intra-alveolar bleeding.^{1,3-5}

Considering that chronic anticoagulant users should be monitored weekly by evaluating the INR, supra-therapeutic dosing may raise the suspicion of a medical liability or, even worse, intentional overdose. In cases of sudden death without a clear cause and with evidence of bleeding, performing toxicological tests and a complete autopsic examination as well as an accurate evaluation of medical records are recommended. All of the findings must be interpreted with considerable caution to avoid misinterpretation in such cases that may, in the worst case, lead to a miscarriage of justice.

Anticoagulant Therapy, Overdose, Medical Liability

E5 Sudden Cardiac Death in Myocardial Bridging

Angela Baldwin, MD, MPH*, Office of Chief Medical Examiner, New York City, NY; Sarah Thomas, MD, MS, Mayo Clinic, Rochester, MN; Barbara Sampson, MD, PhD, Office of Chief Medical Examiner, New York City, NY

Learning Overview: After attending this presentation, attendees will be aware that myocardial tunneling is a rare cause of sudden death and not always an incidental finding.

Impact Statement: Myocardial bridging as an etiologically specific cause of death is a diagnosis of exclusion in the face of grossly or microscopically demonstrable recent and/or remote cardiac ischemia in the anatomic territory of the particular bridged artery. The community will be able to understand the settings in which myocardial bridging should be considered as the cause of death.

Background: Myocardial bridging is a congenital coronary artery anomaly in which a coronary artery tunnels within the myocardium. While this anomaly can occur with any of the epicardial coronary arteries, myocardial bridges are usually found in the middle segment of the left anterior descending coronary artery.¹ Most patients with this condition are asymptomatic as it is generally considered benign.² At autopsy, it is oftentimes interpreted as incidental. One study revealed an overall prevalence of 19% (CI: 17-21%), with a prevalence of 42% (CI: 30-55%) in autopsy studies, 22% (CI: 18-25%) in CT studies, and 6% (CI: 5-8%) in coronary angiography.³ Myocardial bridges are of clinical and pathological significance when they involve the left anterior descending coronary artery and have a long (20-30mm) and deep (3-5 mm) intramyocardial course.⁴ When the condition is not benign, it can result in anginal symptoms, acute coronary syndrome, myocardial infarction, cardiac arrhythmias, and rarely, sudden death.^{1,2} In such instances, contraction of the peri-vascular myocardium in systole causes occlusion of the blood flow in the artery through compression of the artery lumen.^{4,5} Myocardial bridging as an etiologically specific cause of death is a diagnosis of exclusion in the face of grossly or microscopically demonstrable recent and/or remote cardiac ischemia in the anatomic territory of the particular bridged artery.

Case Report: Presented is the case of a 44-year-old Nigerian-American man with no past medical history who died due to myocardial bridging of the left anterior descending artery. The decedent was found by his wife dead at home in his bed. She had seen the decedent earlier in the morning and he had been in his normal state of health. He was last seen alive by his mother who visited in the early afternoon and left when he was asleep. When the wife was unable to wake him, she called emergency services and started resuscitative efforts. Emergency medical services arrived and attempted to resuscitate him but were unsuccessful. At autopsy, he had an unremarkable external examination apart from obesity (BMI 35.9kg/m²). On internal examination, he had slight hepatic steatosis and biventricular dilatation. Examination of the 260gm heart revealed myocardial bridging of the proximal-mid left anterior descending artery up to 0.5cm below the epicardial surface, for a span of 3.0cm. The coronary arteries had no atherosclerosis, including the bridged segment. The coronary ostia were normal in location and morphology. There was a focus of white fibrosis (0.2 x 0.2 x 0.2cm) within the subaortic septum. Similar slightly more yellow areas of pallor were noted at the superior aspects of the anterolateral left ventricular papillary muscle (2.0 x 0.7 x 0.7cm) and the posteromedial left ventricular papillary muscle. (1.0 x 0.4 x 0.4cm). The myocardium was otherwise homogeneous, dark red, firm, and free of hemorrhage or softening. The left and right ventricular walls were concentrically 1.1cm and 0.3cm in thickness, respectively, and the septum measured 1.3cm in thickness. The aortic valve had focal fenestrations. The endocardial surfaces and four cardiac valves were otherwise unremarkable and free of vegetations or thrombi. Microscopy revealed a focus of subepicardial acute interstitial hemorrhage within the anterior left ventricle, and focal interstitial, perivascular, and replacement fibrosis compatible with the foci seen grossly, which was highlighted by trichrome and reticulin stains. There was increased scattered interstitial fibrosis adjacent to intramyocardial left anterior descending artery and a few markedly hypertrophic myocytes associated with the areas of fibrosis. Toxicology was negative for drugs of common abuse. A cardiac-focused sudden death panel of 132 genes associated with various forms of cardiac channelopathy, non-cardiac channelopathy, and cardiomyopathy was negative.

Autopsy, Myocardial Tunneling, Myocardial Bridging

E6 Light Detection And Ranging (LiDAR) Sensor for 3D Reconstructions in the Autopsy Room

Alice Chiara Manetti, MD*, University of Pisa, Pisa, Tuscany, Italy; Andrea Scatena, MD, University of Pisa, Pisa, Tuscany, Italy; Giacomo Visi MD, University of Pisa, Pisa, Tuscany, Italy; Paola Santoro, MD, Sapienza University of Rome, Rome, Lazio, Italy; Fabio Del Duca, MD, Sapienza University of Rome, Rome, Lazio, Italy; Massimiliano Dell'Aquila, MD, Sapienza University of Rome, Rome, Lazio, Italy; Aniello Maiese, MD, PhD, University of Pisa, Pisa, Tuscany, Italy

Learning Overview: Through this presentation, attendees will learn that the LiDAR-sensor-integrated camera is a valid tool to introduce a sort of reproducibility into the autoptic practice.

Impact Statement: This presentation will highly impact the forensic science community because it shows the possible role of 3D modeling in the autoptic field. This work aims to promote the use of LiDAR-sensor-integrated cameras in the autopsy room.

Autopsy investigation is a complex and unrepeatable procedure. Therefore, it is essential to validate the autoptic findings for medicolegal purposes. Photography allows for the maintenance of archival data and to audit forensic practices. However, the quality and reliability of photographic records and autopsy reports are not always guaranteed.¹ Technical requirements and specific skills are indispensable to perform an adequate photographic report.^{2,3} Moreover, 2D images could lead to distortion and data misinterpretation. In recent years, 3D reconstruction has supplemented medicolegal activities, mainly in crime scene reconstruction.^{4,5} The introduction of photogrammetry has made 3D documentation easier than in the past. The required equipment consists basically of a camera and a computer.⁶ However, this method also has some limits (e.g., the intrinsic variability related to the type of camera and the operator's skills). A LiDAR sensor is a remote sensing device that uses an infrared-light-pulsed laser to calculate the distance between two points. Those data could be combined with photographic information and used to construct 3D models of objects and surfaces. The arrangement of a LiDAR scanner next to the camera of some smart phones and tablets has made precise 3D models extremely manageable, even in the autopsy room.

Herein, 3D models of entire corpses, single body areas, and single organs obtained during different forensic autopsies are presented. The app TRNIO was first used, then data were processed by MeshLab. 3D models were qualitatively evaluated to assess their reliability in reviewing the autoptic procedure. 3D models were realistic, accurate, and allowed precise measurements. Smart phones and tablets have been demonstrated to be a reliable tool in auditing and reviewing the autoptic procedure, thanks to 3D technology. Furthermore, displaying 3D models as evidence in court would probably improve the effectiveness and understandability of medicolegal dissertation, demonstrating the reliability and manageability of 3D models in forensic practice.

Autopsy Record, 3D Modeling, LiDAR Sensor

E7 Enhancing Postmortem Care for Transgender Decedents: An Analysis of Global Violence and Forensic Methodologies

Taylor Flaherty, MSc, University of Nevada-Las Vegas, Las Vegas, NV; Corrie Strayer, MA, North Carolina State University, Raleigh, NC; Adrienne Dizon, University of Nevada-Las Vegas, Las Vegas, NV; Jennifer Byrnes, PhD, University of Nevada-Las Vegas, Las Vegas, NV*

Learning Overview: Attendees will gain an understanding for the circumstances surrounding untimely deaths of transgender individuals globally and learn about the intersection of systemic violence, interpersonal violence, and postmortem analysis. Harm reduction strategies for forensic scientists will also be suggested.

Impact Statement: Transgender (trans) is an umbrella term utilized for individuals who identify as a gender other than the sex they were assigned at birth. Due to systemic and sociocultural biases against the trans community, these individuals face disproportionate rates of lethal violence. Since 1970, more than 4,200 deaths due to anti-transgender violence have been reported to the Transgender Day of Remembrance (TDOR) database across 75 countries. Unfortunately, these values likely under-represent the actual number of trans decedents within these parameters due to the lack of visibility offered to this community and the absence of standardized protocols for tracking this data. This under-reporting is further exacerbated by the lack of postmortem care received by trans decedents as forensic analysts typically assign a binary sex to a decedent based solely on external genitalia. Additionally, most medicolegal death records do not include a space to indicate gender identity, generating an added risk for inadequate postmortem care that may lead to individuals being misgendered, deadnamed, inaccurately identified, or unidentified. Many trans victims ultimately never receive justice simply because of their gender. These methodological flaws continue to feed the cycle of violence and marginalization experienced by the trans community.

Despite complications in tracking untimely deaths of trans individuals, TDOR has created a database using criminal reports, news articles, social media posts, petitions, and other documents to track trans decedents. This database offers extensive qualitative and quantitative information which provides insight into systemic and interpersonal violence, lethal risks, language usage, forensic methodologies, case status, cause of death, and circumstances around death for trans decedents. Thus, this presentation will utilize the TDOR database to inform the forensics community of the ongoing epidemic of trans violence and death, while also offering recommendations for harm reduction and enhanced postmortem care.

Circumstances and causes of death identified within this database are of forensic significance as they offer information crucial to decedent identification and completion of the death investigation. For example, of the thousands of cases recorded by TDOR, 84.3% of deaths have been categorized as violent, with most cases exhibiting blunt force, sharp force, gunshot wound, and/or thermal trauma. Violent deaths are followed by unknown causes of death (9.5%), suicides (4.1%), medical deaths (1.8%), and deaths in police custody (0.6%). Of those with known ages, the average age at death for trans individuals was 29.5 years, which is drastically lower than the global life expectancy of 72.6 years. The database also suggests that trans individuals within the Americas are the most at-risk geographically.

The disproportionate levels of interpersonal violence and lethal risk surrounding trans deaths indicates that forensic scientists must promote higher quality postmortem care for these individuals, as it is the responsibility of forensic analysts to reduce the harm done through death investigations. This presentation will offer a number of harm reduction strategies that should be adopted by all forensic scientists, such as including gender identity on medicolegal documentation, educating forensic analysts of gender, violence, and queer theory, standardizing data collection, modernizing language, and including trans individuals and advocacy groups in medicolegal training and death investigations.

Transgender Violence, Death Investigation, Human Rights

E8 Suicide Rates and Trends in Allegheny County, Pennsylvania, During 2010–2019

Odile Enslen, BS, Duquesne University Forensic Science and Law Program, Pittsburgh, PA; Lyndsie Ferrara, PhD, Duquesne University Forensic Science and Law Program, Pittsburgh, PA; Anita Zuberi, PhD, Duquesne University Department of Sociology, Pittsburgh, PA; Mandy Tinkey, MS, Allegheny County Medical Examiner's Office, Pittsburgh, PA*

Learning Overview: After attending this presentation, attendees will recognize the importance medical examiners play in educating and promoting public health issues to their community, while additionally learning the relevance the cause of death plays in suicide research.

Impact Statement: This presentation will impact the forensic community by displaying the wide scope of information collected by medical examiners and the unique analysis that could be done to highlight rates and trends.

In 2017, the suicide rate for the state of Pennsylvania was 13.8 deaths per 100,000 residents, while at the same time, Allegheny County's suicide rate was 15.8 deaths per 100,000 residents.¹ Suicide studies and research are not a newly studied area and numerous research studies have established trends within the scope of suicide, more commonly examined with gender, age, and race. Though a less-examined demographic in this area of study is income level by location.

In this study, suicide data from the Allegheny Medical Examiner's office during the period of 2010 through 2019 was examined along with poverty threshold data from the Census Bureau's American Community Surveys. This research examined whether impoverished communities have higher suicide rates than non-impoverished communities. A follow-up question that was asked was: do impoverished communities have different rates and trends when examining cause of death in suicides?

In defining key aspects of this research, poverty was defined using the Census Bureau's poverty threshold. This measure was used because the poverty thresholds calculated by the Census Bureau are meant for statistical analysis.² The poverty threshold is then compared to the income threshold, with these values being assigned by family size and composition. An example would be a family of four comprised of two children under 18, would have the poverty threshold of \$26,246 in 2020.² With 130 municipalities, Allegheny County was selected, given the variety of different communities.

The percent of households living under the designate poverty threshold varied drastically between municipalities. Even neighboring communities showed stark differences. For example, one municipality had an average of 40% of households living under the poverty threshold, while a neighboring municipality had only 13%. It was also calculated that the fluctuating suicide rate across the timeframe was 7.55% to 12.51%.

This research makes a unique contribution by pairing data collected by the medical examiner's office with place-based data from the Census Bureau. Results from this study aim to improve education and preventative measures in different communities with higher rates of suicide. Examining suicide rates in coordination with location and income levels provides a macroscopic examination of suicide beyond examining individual cases to provide another layer of contextual information that can aid future prevention efforts.

Suicide, Income Threshold, Cause of Death

E9 The Recent Rise of Eutylone Intoxications in Onondaga County, New York

Michel Tawil, MD, SUNY Upstate Medical University Hospital, Syracuse, NY; Katrina Thompson, MD, Onondaga County Medical Examiner's Office, Syracuse, NY; Lorenzo Gitto, MD, SUNY Upstate Medical University Hospital, Syracuse, NY*

Learning Overview: After attending this presentation, attendees will have a deeper knowledge of the characteristics of the popular emergent synthetic psychoactive stimulant commonly known as eutylone.

Impact Statement: This presentation will impact the forensic science community by presenting a review of cases and epidemiologic data focusing on the presence of eutylone in cases of death due to drug-related intoxication or toxicity.

Novel psychoactive substances have been rapidly emerging in recent years and are being identified by forensic laboratories worldwide. Eutylone is a novel psychoactive substance that is rapidly becoming one of the most popular synthetic stimulants. It is mostly found in powder form and mixed with other psychoactive substances, thus increasing the risk of severe or life-threatening complications.

A rise in the use of eutylone has been observed in Onondaga County in the recent period. In the present study, case files from the electronic database of the Onondaga County Medical Examiner's Office in Syracuse, NY, were reviewed from January 2020 to the present for drug toxin deaths in which eutylone was identified in postmortem samples. No limits regarding age, race, and sex were imposed. Only cases in which investigative and full toxicologic reports were available were included. Sixty-two subjects met the study criteria, 32 males and 30 females. Ages ranged from 20 to 69 with a mean of 38.8 years. Fifty-two subjects were listed as Caucasian, seven were African-American and three were other.

Recent experiments show that eutylone acts on the central nervous system in a similar way to cocaine, methamphetamine, and MDMA by binding monoamine transporters and inhibiting the reuptake of the neurotransmitters, dopamine, serotonin, and norepinephrine. The exact mechanism by which eutylone causes death is still unknown as many users mix eutylone with other substances and potentiators. Additionally, the current shortage of data concerning deaths related to eutylone prevents physiologic trends from being recognized, which may help in understanding its role in mortality.

This study will shed light on the rising trend of eutylone use and emphasizes the necessity of reporting deaths in which eutylone is present in toxicologic analysis in suspected overdose cases.

Eutylone, Intoxications, Drugs

E10 A Review of In-Custody Deaths at the West Tennessee Regional Forensic Center

William Stout, UTHSC College of Medicine, Memphis, TN and West Tennessee Regional Forensic Center, Memphis, TN; Danielle Harrell, DO, West Tennessee Regional Forensic Center, Memphis, TN*

Learning Overview: This study presents a 5.5 year review of the in-custody deaths at the West Tennessee Regional Forensic Center (WTRFC) with breakdown of deaths by manner and cause.

Impact Statement: This presentation will address the most common manners and causes of death in in-custody and police-involved deaths in the majority of West Tennessee over a 5.5 year time period.

The goal of this study is to categorize in-custody and police involved deaths by cause and manner.

The Death Investigation and Decedent Information (DIDI) database, used by the WTRFC for documentation, was reviewed for all deaths recorded as in-custody, to include local, state, or federal prison and police-involved deaths from January 2016 to June 2021. The cases were then categorized by manner of death (homicide, suicide, accident, could not be determined, and natural) and subsequently subcategorized by cause of death.

The most common manner of death was natural at 48.6%, with the most common causes attributed to cardiovascular disease at 47.8% and infection at 26.7%. The etiologies of cases due to infection were as follows: viral, 50.0%; bacterial, 45.8%; and fungal, 4.2%.

Accident was the second-most common manner of death at 20.0%, with 91.9% of these deaths due to drug toxicity. Methamphetamine (35.3%), fentanyl (23.5%), or the combination of the two (38.2%) accounted for 97.0% of the overdose-related accidental deaths. Cocaine comprised 2.9% of these deaths. The remaining manners of death were as follows: suicide, 14.6%; could not be determined, 3.8%; and homicide, 3.2%. The demographic breakdown of cases was as follows: male, 94.1%; female, 5.9%; White, 53.0%; Black, 45.4%; and other, 1.6%.

The majority of deaths attributed to suicide took place in a single-person cell (85.2%); 11.1% occurred with others, and 3.7% were unknown. The majority of suicidal deaths were due to hanging at 92.6%. The ligatures used in hanging-related deaths were as follows: bed sheet, 80.0%; shoelace, 12.0%; unknown/information not available, 8.0%. Toxicology analysis showed a positive finding in 55.6% of cases with the remaining either having negative toxicology (33.3%) or toxicology testing was not performed (11.1%). Illicit substances were detected in 37.0% of the cases with positive toxicology results.

A total of 29 police-involved deaths occurred in the past 5.5 years. The majority of cases were determined to be homicides (82.8%), with the remaining cases reported as could not be determined (6.9%), suicide (3.4%), and currently pending final report (6.9%) with 93.1% of causes due to gunshot wound-related injuries. The purpose for an encounter with law enforcement was reported as 31.0% being due to a response to a non-domestic crime; 27.6% due to the attempted service of a warrant; 20.7% due to a response to a domestic dispute; 13.8% due to a response to a mental health call, and 6.9% currently undetermined at the time of abstract submission.

In-custody deaths encountered at the WTRFC during this 5.5-year review were predominately due to natural etiologies. Similar to the overall leading cause of death in the United States, cardiovascular disease was the most common natural etiology. The significant number of deaths either directly due to illicit substances, or where illicit substances were concurrently detected on postmortem toxicology, especially in suicidal deaths, is of particular interest in an in-custody setting. Future goals include evaluation of mental health histories, drug histories, and temporal relationship between date of incarceration and death. The majority of police-involved deaths occurred during a non-domestic crime.

In-Custody, Police-Involved, Incarceration

E11 A Death in the Pool Is Not Just Drowning

Gianluca Musci, MD, Department of Interdisciplinary Medicine, Section of Legal Medicine, Policlinico di Bari Hospital, Bari, Italy; Carmelinda Angrisani, MD, Department of Interdisciplinary Medicine, Section of Legal Medicine, Policlinico di Bari Hospital, Bari, Italy; Adriano Acella, MD, Department of Interdisciplinary Medicine, Section of Legal Medicine, Policlinico di Bari Hospital, Bari, Italy; Giulia Gubinelli, MD, Department of Interdisciplinary Medicine, Section of Legal Medicine, Policlinico di Bari Hospital, Bari, Italy; Gianluca Gravili, Department of Interdisciplinary Medicine, Section of Legal Medicine, Policlinico di Bari Hospital, Bari, Italy; Antonio De Donno, Department of Interdisciplinary Medicine, Section of Legal Medicine, Policlinico di Bari Hospital, Bari, Italy*

Learning Overview: After attending this presentation, attendees will have a better understanding of the importance of complete postmortem examination in apparently simple cases to distinguish different types of sudden violent death.

Impact Statement: This presentation will impact the forensic science community by presenting the importance of complete postmortem examination in seemingly clear cases.

Diving into water, often by carelessly jumping head-first into water during recreational activities, can be very dangerous and cause severe spinal cord injuries. In these cases, mortality is generally due to head trauma with associated superior cervical trauma.¹

The importance of postmortem investigations lies in the necessity to discriminate between death by head/cervical trauma and drowning. The impact following the dive generally occurs between the cranial vertex and a rigid surface, and it results in a minimal injury at the site with a contusion (ecchymosis/abrasion) that may go unnoticed. This results in a transmission of forces at distance that causes damage to the cervical district.²

Presented is the case of a young subject found dead in a pool who has undergone a medicolegal investigation. In this case, the cervical injury was associated with inhalation of gastric material resulting in the development of asphyxia “ab ingestis.”

During the site inspection, it was reported that the young subject got sick while he was in the pool. The witnesses had seen his body in the water, but no one reported the event’s dynamics. When authorities arrived, the body had already been moved outside the water. Food material was found beside the corpse. It also emerged from those present that the subject suffered from a non-specific cardiac anomaly.

The *public prosecutor* ordered that a medical investigation should be carried out. The autopsy revealed the presence of a bruising-excoriated area near the cranial vertex and a minute brain area infiltrated with blood in the parietal cortex. The unexpected finding was the presence of hemorrhagic infiltration in the pre-vertebral region; when these tissues were removed, a fracturative lesion of the cervical vertebrae C5-C6 was observed.

The spinal cord below these fractures presented sub-meningeal, peri-medullary, and posterior tissues blood infiltration. The airways and the branches were filled with gastric food material. The only cardiac anomaly found was the presence of a minute hole in the oval trench, devoid of pathological significance.

Radiological investigation of the C3-C6 vertebral segment taken during the autopsy showed a minute localized “tear drop” fracture at the level of the antero-inferior margin of the C5 vertebra body; C6’s body was completely fractured and divided into multiple bone fragments. Toxicology analyses were negative.

Histopathological investigations revealed focal peri-vascular hemorrhagic infiltration at the level of the parietal lobe, hemorrhagic infiltration of the dura mater with marginal involvement of nervous tissue, and a spinal root in the cervical cord segment. Meat and vegetable fibers in the medium and large-caliber airways were also found, with associated hyperdistention of distal airspace and alveolar edema outbreaks.

Death was attributed to acute respiratory failure resulting from obstruction of the airways by food material (ab ingestis) due to the cranio-cervical trauma. In the reconstruction of the dynamic, it has been postulated that the subject had impacted with his head on a rigid surface, with consequent cranio-cervical trauma and fractures in C5-C6 with medullary involvement, which induced a loss of consciousness and consequent onset of vomiting.³ The loss of consciousness led to an alteration of the protective reflexes of the airways, failing that defense mechanism against liquids and/or solids entering into the airways.

In this singular case, the death is attributable to a combined mechanism consisting of cervical trauma, vertebral fractures, and spinal cord injuries associated with inhalation of food material resulting in respiratory failure from ab ingestis. Contrary to what was initially supposed, the hypothesis of death by drowning was excluded. Even in apparently clear cases, it is mandatory to perform an accurate medicolegal investigation in order to determine the certain cause of death.

Cranio-Cervical Trauma, Diving, Acute Ab Ingestis Asphyxia

E12 Hanging: Between Doubts and Certainties

Isabella Aquila, MD, PhD, Institute of Legal Medicine, University Magna Graecia of Catanzaro, Catanzaro, Italy; Pietrantonio Ricci, MD, PhD, Institute of Legal Medicine, University Magna Graecia of Catanzaro, Catanzaro, Italy*

Learning Overview: After attending this presentation, attendees will understand the role of forensic investigation and autopsy in cases of hanging.

Impact Statement: This presentation will impact the forensic science community by demonstrating the importance of circumstantial data and hanging marks in the evaluation of the dynamics of hanging.

Hanging is a form of death due to constriction of the neck when the force applied is derived from the gravitational drag of the victim's body weight. The most characteristic sign in death by hanging is the *hanging mark*. Characteristics of the hanging mark vary in relation to the type of suspensions and ligatures used.

This study describes a case series of hangings in which the hangings were doubtful or the means of suspension was not found around the neck of the corpse. The analysis of the suspension means used was conducted through the evaluation of the nature of ligatures: soft, smooth, hard, and rough. In addition, a detailed inspection was carried out with the analysis of the possible suspension means used by the victim and any reconstructions of the dynamics of the hanging with specific measurements. Finally, the compatibility of the analyzed means with the hanging mark was evaluated. In doubtful cases, the analysis of circumstantial data becomes fundamental and, in particular, the analysis of suicide notes, the analysis of the phones, and the social profiles of the victim through the application of the psychological autopsy method. Moreover, it is essential to analyze and compare all external lesions on the body and, in particular, the measurements of the possible means of suspension compatible with the lesions in the neck and the characteristics and course of the hanging mark.

The analysis of hanging marks allows us to assess the method of suspension used and to clarify the manner of death and the type of hanging. In particular, the forensic analysis of cases of hanging is not always easy, especially because, too often, despite being an asphyxiated death, an autopsy is not always requested and more and more often the scene is altered by rescuers or people who do not know how to move around the scene. Finally, when the dynamics with which the hanging took place are not clear, it is necessary to deepen the social and psychological context in which it took place in order to understand more than just the tip of the iceberg of a very widespread phenomenon.

Forensic Sciences, Hanging, Suicide

E13 Sudden Cardiac Death Related to COVID-19 in an Asymptomatic Teenager With a Negative Postmortem Swab

Mirella Sabatino, MD1, Department of Public Health, Experimental and Forensic Medicine of the University of Pavia, Pavia, Italy; Giulia Bini, MD*, Department of Public Health, Experimental and Forensic Medicine of the University of Pavia, Pavia, Italy; Giacomo Belli, MD, Department of Public Health, Experimental and Forensic Medicine of the University of Pavia, Pavia, Italy; Giorgia Lodetti, MD, Department of Public Health, Experimental and Forensic Medicine of the University of Pavia, Pavia, Italy; Dario Galatone, MD, Department of Public Health, Experimental and Forensic Medicine of the University of Pavia, Pavia, Italy; Elena Mercuri, MD, Department of Public Health, Experimental and Forensic Medicine of the University of Pavia, Pavia, Italy; Gulnaz T. Javan, PhD, Department of Physical Sciences and Forensic Science Programs, Alabama State University, Montgomery, AL; Silvia Damiana Visonà, PhD, Department of Public Health, Experimental and Forensic Medicine of the University of Pavia, Pavia, Italy; Luca Morini, PhD, Department of Public Health, Experimental and Forensic Medicine of the University of Pavia, Pavia, Italy; Pierangela Grignani, PhD, Department of Public Health, Experimental and Forensic Medicine of the University of Pavia, Pavia, Italy; Carlo Previderè, PhD, Department of Public Health, Experimental and Forensic Medicine of the University of Pavia, Pavia, Italy; Matteo Moretti, MD, Department of Public Health, Experimental and Forensic Medicine of the University of Pavia, Pavia, Italy

Learning Overview: After attending this presentation, attendees will: (1) be aware of a rare case of sudden cardiac death in an asymptomatic young boy affected by COVID-19; (2) discover the possibility of detecting a SARS-CoV-2 infection in the case of negative postmortem swab; (3) understand the importance of a careful anamnesis in sudden deaths of young people.

Impact Statement: This presentation will impact the forensic science community by reporting a rare case of sudden cardiac death in an asymptomatic young subject affected by COVID-19 in which histological and immunohistochemical study were essential to identify SARS-CoV-2.

Clinical features of SARS-CoV-2 infection are various; most affected people have mild or moderate symptoms and recover without hospitalization. The primary manifestation is acute pneumonia, but the SARS-CoV-2 infection can also involve the heart.^{1,2} Even though elderly people have the most severe prognosis, sometimes COVID-19 can affect young people with heavy consequences. This presentation reports a case of a young boy who died from a COVID-19 infection in Northern Italy.

The 14-year-old boy was found lifeless by his parents in his bedroom, laying on his bed. Hypostasis and rigor mortis were already evident. The first responder team could only confirm the death. Before this event, the young boy was in a good state of health; in fact, he practiced football at a competitive level, for which he was subjected to periodic cardiac controls with results being normal. The young boy was subjected to quarantine two months prior to his death because he had close contact with a relative who had tested positive for COVID-19. However, the young boy remained asymptomatic and was not subjected to any COVID-19 test.

A forensic autopsy was performed to clarify the cause of death. A postmortem antigenic nasal swab for COVID-19 was performed. Then, histological (hematoxylin eosin), immunohistochemical (using SARS-CoV-2 coronavirus nucleocapsid monoclonal antibody B46F), and toxicological investigations were performed. The autopsy was performed four days after death. The postmortem COVID-19 swab result was negative (it is important to note that there is no certain data in literature about the SARS-CoV-2 RNA detectability period in human bodies after death).^{3,4} Conjunctival and cardiac petechiae were detected. Macroscopic lung examination revealed a weight of, respectively, 520g (right lung) and 510g (left lung); both lungs showed severe blood congestion and edema. Poly-visceral blood congestion was found. Tissue samples and biological fluids were collected during autopsy. The toxicological analysis gave negative results. The histological examination revealed interstitial pneumonia. A mild lymphocytic infiltrate was also observed in the heart interstitium, especially surrounding the conduction system. Considering the pandemic situation and the interstitial pneumonia observed microscopically, despite the postmortem COVID-19 swab being negative, a specific immunohistochemical staining using primary antibodies against SARS-CoV-2 was performed on lung and heart samples. Only the lungs tested positive.

Overall, the findings illustrated above allowed the medical examiner to identify the cause of death in a fatal arrhythmia due to extensive heart inflammation, very likely related to an asymptomatic SARS-CoV-2 infection characterized by interstitial pneumonia. SARS-CoV-2 could be responsible for several clinical conditions also affecting the heart, but there are only a few reports of sudden cardiac death in a completely asymptomatic subject or with limited pathological heart involvement.⁵

E14 Older Adult Suicides in Clark County, Nevada (2017-2021): The Trends and Potential Impact of the COVID-19 Pandemic

Katherine Gaddis, MA, University of Nevada-Las Vegas, Las Vegas, NV; Jennifer Byrnes, PhD, University of Nevada-Las Vegas, Las Vegas, NV*

Learning Overview: After attending this presentation, attendees will have a better understanding of the potential impact(s) of the coronavirus (COVID-19) pandemic on older adult (>50 years) suicide trends.

Impact Statement: This presentation will impact the forensic science community by exploring whether observed trends and patterns of suicide among older adults has changed significantly since the beginning of the COVID-19 pandemic in March 2020.

The goal of this study was to assess the impact of the ongoing COVID-19 pandemic on older adults by exploring suicide trends in Clark County, NV, over the past five years. This investigation involved an analysis of differences in the rates at which suicides occurred, demographic trends, and causes of death before and after Nevada's initial emergency stay-at-home order was issued on March 12, 2020. It was hypothesized that stress and social isolation exacerbated by the pandemic may have contributed to an overall increase in older adult suicide deaths and that specific causes of death would differ among pre-pandemic and pandemic groups.

This preliminary sample included 997 adults aged 50 years and older whose manner of death was deemed a suicide by the Clark County Office of the Coroner and Medical Examiner (CCOCME) between the years 2017 and 2021. Ongoing research will include all older adult suicide deaths that occur until the end of this year. Older adult suicides occurring between January 2017 and February 2021 were analyzed as part of the pre-pandemic group in order to establish a more accurate baseline for the area. The data was then categorized into pre-pandemic (before March 12, 2021) and pandemic (after March 12, 2021) time periods and analyzed by demographic groups (i.e., sex, age, gender, race).

The data obtained from the CCOCME provided age, sex, and race demographics assigned by forensic staff as well as cause of death. This study focused upon trends among both older adults (>50 years) generally and older adults of geriatric age (65+ years) specifically. This was done in order to better understand the range of variation in suicide deaths among older adult age groups in regard to the pandemic. While not statistically different ($p=0.19$), 44.7% of the pre-pandemic group were of geriatric age at time of death compared to 49% of the pandemic group. There were no significant differences in race and/or sex between the two time periods. Regarding cause of death, there was an increase in the use of firearms (57.1% to 67.7%, $p=.002$) and a decrease in drug/alcohol-related suicides (19.2% to 10.8%, $p=0.001$) in the pandemic period as compared to the pre-pandemic period, both of which were statistically significant.

It was expected that rates of older adult suicides occurring in Clark County would increase following the beginning of the COVID-19 pandemic, regardless of sex and/or race. Therefore, it was surprising that no statistically significant differences were observed for any demographic group between the pre-pandemic and pandemic time periods. The observed changes in cause of death categories were expected, although the specific categories in which the change would be observed (i.e., firearm and drug/alcohol) were unknown. It is possible that the observed changes in cause of death may be attributed to changes in what means of suicide were easily accessible. That being said, the rise in firearm deaths was not entirely surprising. More than 45 percent of households in Clark County own a firearm and so, as Nevadans began spending more time indoors, many may have had better access to weapons usually kept in the home. At the same time, accessibility to illicit drugs and/or alcohol may have decreased as people were quarantining due to the pandemic.

Public Health, Suicide, COVID-19

E15 Excess Deaths in Shelby County, Tennessee, During the COVID-19 Pandemic

Morgan Lyttle, MS, UTHSC College of Medicine, Memphis, TN; Erica Curry, MD, UTHSC West Tennessee Regional Forensic Center, Memphis, TN; Benjamin Figura, UTHSC West Tennessee Regional Forensic Center, Memphis, TN*

Learning Overview: Attendees can expect to learn the general trends in death throughout the COVID-19 pandemic, particularly focusing on those deaths unrelated to COVID-19 infection. Sociologic barriers to wellness will be explored as well as factors contributing to increases in violent and accidental deaths.

Impact Statement: Novel findings are presented on the impact of an unprecedented global health crisis on deaths in Shelby County, TN. The implications of various health and socioeconomic disparities on mortality will be discussed in the context of the COVID-19 pandemic.

COVID-19 has been the attributing cause of over 600,000 deaths in the United States to date.¹ However, all causes of mortality have shown a distinct increase outside of COVID-19-related deaths. During the year following the onset of COVID-19, the United States saw an overall mortality increase of 15.9%.² In 2020, approximately 3,358,814 deaths occurred in the United States; COVID-19 was listed as an underlying or contributing cause in only 377,883 (11.25%) of those deaths.² A similar trend was seen in Shelby County, representing a microcosm of the impact of COVID-19 on the nation.

From March 24, 2020, to March 24, 2021, total deaths in Shelby County increased from 3,591 to 4,620, a percent change of 28.65%. However, deaths due to COVID-19 infection represented only 37 of the additional 1,029 deaths (0.8%). The largest total increase of deaths was in the “natural” category, an increase of 545. This largely included deaths attributable to chronic diseases and complications of long-term health conditions such as cardiovascular disease, hypertension, kidney disease, COPD, cancer, and diabetes. Many patients with long-term health conditions were reluctant to seek medical care, fearing exposure to COVID-19 in health care facilities.³ This could have exacerbated health complications that would otherwise have been treated, increasing the likelihood of fatality due to adverse events.

Deaths categorized as “accidents” in Shelby County increased from 851 to 1158, a 36.1% increase. Of these deaths, the largest contributors to accidental deaths were motor vehicle-related accidents and drug overdoses. Interestingly, despite the placement of stay-at-home orders, deaths due to motor vehicle accidents increased by 21.29%. This trend was seen throughout the nation, despite lower traffic counts, and could indicate an increase in risky driving behavior.⁴ Even more astounding was an increase in drug overdoses: a 63.85% increase in overdoses followed the onset of the pandemic. These were largely attributed to opioid drugs (79.54%) such as heroin and fentanyl. This could be due to changes in drug supply chains, encouraging the use of more potent drugs like fentanyl. Additionally, increased drug usage due to feelings of isolation and a decrease in the availability of bystanders to intervene during an overdose could have contributed to the increase in drug-related fatalities.

Historic increases in national homicide rates accompanied the COVID-19 pandemic, with a 30% increase in overall homicides.⁵ This trend was even more pronounced in Shelby County, with 40.88% more homicides compared to the previous year. Of particular note was a deeply troubling increase in gun violence. Gun-related homicides in Shelby County increased by 45.8%, compared to a national increase in gun assaults of 22%.⁵

At the onset of the pandemic, global uncertainty was compounded with isolation, causing many to anticipate an overwhelming increase in deaths of despair. Contrary to these expectations, national rates of suicide decreased from 2020-2021, even as local governments enforced social distancing measures.⁶ These trends were paralleled in Shelby County: despite an increase in total number of deaths by 28%, the percent of deaths due to suicide decreased in the year following the onset of the COVID-19 pandemic. Suicides contributed to 2.79% of deaths compared to the 3.56% the previous year, representing a 21.67% reduction in risk of suicide during the COVID-19 pandemic.

Overall, trends in death rates following the onset of COVID-19 indicate the important role of social and economic unrest in violent and drug-related deaths as well as the importance of mental health support and accessibility to health care resources in promoting favorable health outcomes.

Excess Deaths, Epidemiology, COVID-19

E16 COVID-19 Pandemic From the Forensic Standpoint: A Platform Against Future Biological Threats

Marina Korolija, PhD*, Forensic Science Centre Ivan Vučetić, Zagreb, City of Zagreb, Croatia; Rosa Karlič, PhD, University of Zagreb, Faculty of Science, Zagreb, City of Zagreb, Croatia; Ana Livun, PhD, University Hospital Dubrava, Zagreb, City of Zagreb, Croatia; Robert Belužić, PhD, Ruđer Bošković Institute, Zagreb, City of Zagreb, Croatia; Vjekoslav Tomaić, PhD, Ruđer Bošković Institute, Zagreb, City of Zagreb, Croatia; Dunja Glavaš, MSc, University of Zagreb, Faculty of Science, Zagreb, City of Zagreb, Croatia; Antonija Mamić, BS, University of Zagreb, Faculty of Science, Zagreb, City of Zagreb, Croatia; Andrea Ledić, MSc, Forensic Science Centre Ivan Vučetić, Zagreb, City of Zagreb, Croatia; Kristian Vlahoviček, PhD, University of Zagreb, Faculty of Science, Zagreb, City of Zagreb, Croatia

Learning Overview: After attending this presentation, attendees will understand that the scientific and experimental work found in the forensic field can be recognized and employed by the broader scientific community for solving particular problems. Attendees will learn how the contribution of the forensic institution on a multi-institutional SARS-CoV-2 project created the foundation for further development of forensic microbiology.

Impact Statement: The forensic science community will benefit from this growing-from-crisis experience because it well illustrates the need for flexibility, cooperation with other scientific fields, and accelerated adoption of technologically advanced procedures in forensics. This need is arising from increasingly complex challenges imposed on humanity by a rapidly changing global environment.

For almost a year and a half, the world has been struggling with challenges brought upon global society by the COVID-19 pandemic. The effort to adapt private and professional life conditions became an everyday routine for millions of individuals, businesses, and social entities alike. This study's governmental forensic DNA laboratory, in attempting to contribute to the COVID-19 response, has also experienced disruptions in forensic research activities, both in terms of human potential and infrastructure. Having recognized this lab's competences, academic partners included it in the nationally funded scientific project aimed at decoding the SARS-CoV-2 and COVID-19 host genetic sequencing.¹ Here is described the extent of the lab's contribution based on the internally validated protocol for Massively Parallel Sequencing (MPS) of the whole mitochondrial genomes.² Additionally, this study reports improvements of expertise on virus MPS by performing SARS-CoV-2 sequencing. Besides the evident social benefit from the collaboration of the national forensics laboratory with academia as a response to the immediate pandemic threat, this collaborative model opens up new aspects of future forensic research and development in the area of forensic microbiology.

MPS workflow of the Forensic Science Centre "Ivan Vučetić" Research DNA Laboratory is based on the Illumina® MiSeq® FGx® instrument for the whole mitochondrial DNA (mtDNA) sequencing from blood samples of COVID-19 patients (MiSeq® Reagent Kit v2 300cyc) and SARS-CoV-2 sequencing from patients' corresponding nasopharyngeal swabs (MiSeq® Reagent Kit v3 500cyc). Samples were collected and viral RNA was extracted (SaMag™ ViralNA Extraction Kit) and quantified (SARS-CoV-2 Real-Time) at the University Hospital Dubrava. Viral RNA was submitted to cDNA conversion (Quanti Tect® Reverse Transcription Kit) and library preparation (NEBNext® Ultra™ II DNA Library Prep Kit) at the Ruđer Bošković Institute, while the entire mtDNA workflow was conducted at the Forensic Science Centre "Ivan Vučetić" using Illumina® NexteraXT Library Prep Kit, as described previously.² Raw sequencing data were processed at the University of Zagreb, Faculty of Science. Sequences were mapped to reference genomes (either SARS-Cov-2 or human mtDNA) and variant calling was performed to determine viral mutations and mitochondrial haplogroups.

Ongoing project activities have so far resulted in optimization of the complex workflow, involving many researchers and institutions. Best results were obtained when nucleic acid samples were stored for less than 30 days after isolation and from individuals with the SARS-CoV-2 detection real-time Polymerase Chain Reaction (PCR) Ct values below 30. The molarity of viral sequencing libraries should exceed 5nM. Blood samples that were already used for the biochemical analyses are not compatible with mtDNA heteroplasmy analysis due to frequent cross-contamination, mandating the need for intact samples. For optimal sequencing cluster density, the molarity of SARS-CoV-2 libraries was increased from 12 to 20pM. For higher viral sequence coverage, PhiX control spike-in was decreased from 10% to 5%. Detected viral variants and their relative amounts followed patterns observed in neighboring countries and the rest of Europe (sequences available from GISAID and lineage assigned using PANGOLIN). Mitochondrial sequencing confirmed overall haplogroup distributions similar to that of the general population with, however, interestingly different haplogroup ratios between patient groups with mild and severe symptoms (fivefold higher proportion of macrohaplogroup K in patients with mild symptoms). Potential protective effect of any mitochondrial haplogroup should be further investigated in expanded patient pool.

Experience gained through this project is of huge benefit to the entire community, as multi-institutional effort in characterizing SARS-CoV-2 may be reflected in different forensic scenarios involving accidental or intentional biological agent release. We will therefore continue to strengthen and improve upon the established collaborative network and procedures beyond the current COVID-19 crisis, in order to minimize the harm from future biological incidents.

E17 Organizational, Adaptational, and Continuous Changes of the Forensic Sciences During the COVID-19 Pandemic: An Overview

Francesco Sessa, MS, PhD, Department of Clinical and Experimental Medicine, University of Foggia, Foggia, Italy; Massimiliano Esposito, MD, Department of Medical, Surgical and Advanced Technologies G.F. Ingrassia, University of Catania, Catania, Italy; Cristoforo Pomara, MD, PhD, Department of Medical, Surgical and Advanced Technologies G.F. Ingrassia, University of Catania, Catania, Italy; Monica Salerno, MD, PhD, Department of Medical, Surgical and Advanced Technologies G.F. Ingrassia, University of Catania, Catania, Italy*

Learning Overview: Following this presentation, attendees will understand how the restriction of the COVID-19 pandemic has affected forensic science.

Impact Statement: This presentation will impact the forensic community by providing up-to-date data about changes that the pandemic situation has imposed on forensic science approaches.

The COVID-19 pandemic had negatively impacted human life. To date, the predominant route of transmission of the SARS-CoV-2 is by air, through the droplets dissemination by virus-positive individuals. Nevertheless, there is evidence to support a risk of transmissibility of the infection that can also occur through contact with body fluids and tissues of COVID-19 subjects. Finally, the demonstrated persistence of the virus on different types of surfaces represents an additional source of risk. Given the characteristics associated with the transmissibility of the virus, forensic personnel have had to modify their actions in order to more effectively prevent the risk of SARS-CoV-2 infection.

Forensic science is defined as multidisciplinary, involving different expertise; the activities are very different, including crime scene investigation, external examination, autopsy, and genetic and toxicological examinations of tissues and/or biological fluids. At the same time, forensic operators may have direct contact with subjects in life, such as in the case of abuse victims (involving in some child cases), collecting biological samples from suspects, or visiting subjects in the case of medicolegal examinations. In similar cases, forensic operators are called on to implement methods to prevent the SARS-CoV-2 infection risk; particularly, a subject affected by SARS-CoV-2 infection could remain asymptomatic for 14 days or even more, before symptoms appear or, alternatively, remain asymptomatic.

This presentation aims to analyze how forensic personnel have modified their activities during the SARS-CoV-2 pandemic.

In forensic practices, all cases and relative specimens should be treated as potentially infectious. Several forensic organizations have demanded guidelines to perform forensic investigations and autopsies. The risks for operators become more evident in cases of DNA investigations, considering that the most used sample in order to obtain a DNA profile is the buccal swab. The sampling exposes the operator to a high risk of infection, so it is a procedure that should be performed with great care, using Personal Protective Equipment (PPE). Moreover, it has been suggested that all forensic laboratories should be classified as a Biosafety Level 2 (BSL-2) Laboratory, employing well-trained personnel, generating additional costs to guarantee biosafety practices and to modify the protocols used.

Finally, it is important to note that the forensic scenario is greatly changed: on the one hand, during the pandemic period the number of crimes has inevitably decreased (particularly for homicides and theft), on the other hand, it should be noted that medicolegal disputes have largely increased due to complaints about deaths that occurred in hospitals and in nursing homes related to COVID-19 disease.

Forensic Sciences, Multidisciplinary Approach, SARS-CoV-2

E18 Determining Postmortem Intervals of Fetal Pigs Buried in Fayetteville, Tennessee, in June 2021 Using Attenuated Total Reflectance Fourier Transform Infrared Instrumentation Blood Analysis

Catherine Walters, BS*, University of Alabama at Birmingham, Birmingham, AL; Elizabeth Gardner, PhD, University of Alabama at Birmingham, Birmingham, AL

Learning Overview: After attending this presentation, attendees will have a better understanding of the use of Fourier transform infrared instrumentation for analyzing extended decomposition.

Impact Statement: The presentation will impact the forensic science community by presenting an analysis of Attenuated Total Reflectance/Fourier Transform Infrared (ATR/FTIR) instrumentation on extended decomposition in fetal pigs.

There are many factors used in determining the Postmortem Interval (PMI) in questioned deaths. For example, one measure is based on core temperatures of a dead subject, but core temperature is affected by many factors, including environmental temperatures. In addition, the visual guide for PMI is subjective regarding the stages of decomposition involving rigor mortis, algor mortis, and livor mortis.¹ Recently, researchers have been investigating ATR/FTIR to track the changes in blood as an objective measure for determining the PMI. Zhang et al. documented the changes in rabbit plasma and pericardial fluid by ATR/FTIR for the first 48 hours postmortem for 105 male white rabbits.² They identified several trends. The largest changes were associated with proteins within 1,700-1,500cm⁻¹. The positively correlated loadings were in the antemortem group at 1,633cm⁻¹ and 1,515cm⁻¹. The negative loadings characteristic of increasing PMI included 1,650cm⁻¹ and 1,547cm⁻¹.²

This study focuses on the extended period of PMI of fetal pigs after approximately three days postmortem. Fetal pigs were chosen due to the similar composition of tissue to that of the human species.

Six frozen fetal pigs were thawed three days postmortem and then were buried in Fayetteville, TN. Samples of blood were taken at approximately 72 hours, 4 days, 5 days, and 6 days at peripheral and umbilical sites. The samples were analyzed using the Perkin Elmer Spectrum 100 FTIR with a zinc selenium ATR attachment with 16 scans. Both changes in peak intensity and shifts in peak wavelength were analyzed for 3,280cm⁻¹, 2,940cm⁻¹, and 1,400cm⁻¹. Several trends were identified for the extended periods of analysis between the six pigs. The intensity of the amides I's and amide II's peaks decreased in the span between 72 hours and 4 days in all specimens. However, for the remaining trends, at least one of the six pigs did not follow the pattern. Previous studies reported only the averages of the FTIR spectra, but this research showed variances in the data that indicated the average would not give a reliable representation in all cases samples.

PMI, ATR/FTIR, Decomposition

E19 Equine Scent Detection in Search and Rescue and Search and Recovery

Elsie-Kay Banks, MA, Maine Office of Chief Medical Examiner, Augusta, ME; Liam Funte, PhD, MD, Maine Office of Chief Medical Examiner, Augusta, ME; Anatasia Holobinko, PhD, State Medical Examiner's Office, Pearl, MS*

Learning Overview: After attending this presentation, attendees will understand the concept of equine scent detection, how it can benefit search and rescue (air scent) and search and recovery (human remains detection), and how it can be utilized by search and rescue organizations, medical examiner offices, and law enforcement agencies.

Impact Statement: This presentation will discuss the concept of equine scent detection, how it can be utilized in search and rescue and search and recovery missions, and how it can benefit both medical examiner offices and law enforcement agencies in finding and recovering human remains.

In 2021, Highlands Search and Rescue (HISAR) was created by members of various Maine Association of Search and Rescue (MASAR) personnel. The team consists of both Ground Searchers and Mounted Searchers. The President and one Vice President of HISAR are both in training to be certified in equine air scent, which involves searching for missing persons who are assumed to be alive. There is one member who is a Mounted Trainee. All members of HISAR and any MASAR team must be certified through MASAR as a Search Team Member and can obtain additional training that will benefit the SAR team.

HISAR has developed the first Mounted Air Scent Team Certification and is in the processes of making revisions.

SAR canines (K-9s) are the typical animal resource that is used and requested for locating missing persons because of their scenting abilities. K-9s are able to use air scent, cadaver scent (**Human Remains Detection** [HRD]), narcotics, ballistics, explosives, invasive species, COVID-19, etc. Horses also can use their olfactory skills to locate humans who are lost; they can also detect human remains and narcotics. There are very few organizations in the United States that train and deploy air scent and HRD horses, one which is led by Terry Nowacki, who has conducted clinics and trainings in Minnesota that HISAR Mounted team members have attended.

Although equine olfactory skills differ from K-9s, some researchers feel equine scent skills can be equal to, or greater than, that of K-9s. Even with domesticated horses, they must utilize their sense of smell daily; they must be able to find safe drinking water, safe food sources, mates, their offspring, and must always be aware of their surroundings as they are prey animals. Horses are unable to see objects directly in front of them and depend on the sense of smell. Horses have large flexible nostrils that can pull in large amounts of scent; when they sniff large amounts of scent, the odor is passed into nasal passages, allowing the receptor cells and the odor molecules time to interact and thus giving the horse time to evaluate the odor. Horses can scent on the ground or up to eight feet in the air. Horses are also able to cover a large search area, and having a rider atop the horse can give a different view than that of a ground searcher, K-9, or air searcher.

Equine Scent Detection, Human Remains Detection, Equine Search and Rescue

E20 Insect Activity During Decomposition in the Extreme Sonoran Desert Climate

Meghan Gast, BS*, Arizona State University, Phoenix, AZ; Kaitlyn Fulp, MA, Arizona State University, Phoenix, AZ; Jacob Harris, PhD, Arizona State University, Phoenix, AZ; Katelyn Bolhofner, PhD, Arizona State University, Phoenix, AZ

Learning Overview: The primary goal of this presentation is to describe insect activity patterns observed during decomposition in an extreme environment in the southwestern United States, specifically related to an investigation of methods used to estimate postmortem interval.

Impact Statement: This presentation will impact the forensic science community by reporting novel observations of insect activity made during a study of decomposition in a desert environment, contributing to the ongoing efforts of anthropologists, entomologists, and death investigators in documenting the postmortem period.

The Sonoran Desert, which covers a large portion of the southwestern United States and northern Mexico, is a unique environment with extreme fluctuations in temperature and humidity, even in a single season. During the summer months, the temperature averages 104°F (40°C) but can reach 118°F (48°C).¹ In a single day, the temperature can also drop as much as 59°F (15°C) overnight due to the lack of moisture and low vegetation.¹ During the summer, the Ultraviolet (UV) index averages in the 9-10 range of a scale from 0-11.² The UV index represents a measure of the intensity of the sun's UV radiation, where a higher number represents greater exposure. This extreme climate represents a stark deviation from the other geographic contexts where decomposition stages and rates have been studied extensively, and little is known about the resulting variation in macroscopic changes to the body or associated insect and predator activity.

Presented here are observations of insect activity made during a study of decomposition of porcine models in a period of extreme temperature fluctuations. During the summer of 2020, two porcine models were clothed and placed in observation cages in natural desert settings outside of Phoenix, AZ, as a single phase of an ongoing longitudinal study investigating the timeline and stages of decomposition in this climate. One model was placed in direct sunlight while the other was positioned in the shade of a cluster of Palo Verde trees. Photos were collected in 30-minute intervals, and temperature and humidity readings were collected every 10 minutes from June 28, 2020, to July 22, 2020.

Insect activity during decomposition is well documented in a number of geographic zones, but little research has been published investigating the effects of an extreme desert climate on insect activity during decomposition. Studies representing other climates have concluded that heat allows insect colonies to thrive, though extreme spikes in heat were determined to be the cause of insect deaths, which slowed the active decomposition.³ Insects have also been documented as showing signs of heat stress, resulting in a large number of deceased maggots on porcine carcasses left in the sun.⁴

This study's observations of insect activity differed from these reports. Despite differential sun exposure, the temperature ranges throughout the period observed were consistently similar for the two porcine models. However, the insect activity on each model exhibited observable differences. Within the first week of the study, maggots were active throughout the entire day on the model in the shade, while they were only active at sunrise and after sunset on the sun-exposed model. This study's observations suggest that temperature alone does not seem to drive maggot activity period in this environment, as both populations were exposed to similar heat. The apparent correlation between sun exposure and insect activity—not between heat and activity—will be explored in future studies through the collection of further measurements, especially the UV index in each location. This project represents the first phase in a long-term study that aims to bring clarity to these observations and to our understanding of the complicated patterning of decomposition in the Sonoran Desert.

Decomposition, Extreme Climates, Insect Activity

E21 Forensic Species Identification Using Phylogenetic Proteomics

Nicole Slattengren, BSc*, University of California-Davis, Davis, CA and California Department for Fish and Wildlife, Sacramento, CA; Ashley Spicer, MSFS, California Department for Fish and Wildlife, Sacramento, CA; Glendon Parker, PhD, University of California-Davis, Davis, CA

Learning Overview: After attending this presentation, attendees will have a better understanding of the forensic application of phylogenetic proteomics to wildlife crimes.

Impact Statement: The ability to categorically identify fur-bearing species, in the absence of detectable DNA, has the potential to fill a sizable gap in forensic monitoring and law enforcement of wildlife crimes.

The distribution of illegal fur products presents a major challenge for wildlife forensics and law enforcement. Processed fur is a major component of illegal trade. Illegal traffic in fur promotes and enhances other illegal commercial networks, including illicit drugs, human trafficking, and other environmental crime. Any policy from law enforcement and agencies tasked with combatting wildlife crime requires forensic tools to both positively identify a species; but also to exclude closely related, often legal, sister species. Unfortunately, modern industrial fur processing effectively removes DNA from the sample, depriving investigators of the major tool to identify listed and protected species. Even when DNA is available, this can be a challenge.¹ When DNA is absent, forensic investigators are forced to rely on morphological analysis that is time consuming, requires access to a limited number of highly trained individuals, and can have poor species resolution.

Phylogenetic information, however, can also be obtained from animal proteins, including proteins in animal hair and skin. With evolutionary biodistance amino acid sequence variants, single amino acid polymorphisms will become major alleles, then population-specific markers, and eventually species-specific markers. Over evolutionary time, and under the constraints of selective pressure and genetic drift, these accumulate and equivalent genes become less homologous. Genetic changes at the DNA level are also reflected by changes at the protein level, with species-specific changes accumulating in the amino acid sequence. As evolutionary distance increases, the proportion of common sequences and peptides between species is reduced. This can be used to identify unknown species. The mass spectrometry fragmentation spectra from the fur proteome will better match with protein sequences from the same or related species, giving great protein coverage.

To demonstrate this concept, this study processed hairs from a lion paw confiscated during law enforcement. Single hairs were processed using an optimized method for human hair and applied to a Q-Exactive™ mass spectrometer.² The resulting dataset was searched using the PEAKs peptide spectra matching algorithm and the closely related Leopard reference proteome. For single hairs, $1,020 \pm 110$ (av \pm SD) peptides were identified ($n=3$). The number of identified peptides was reduced with evolutionary distance. The more closely related leopard and tiger protein sequences, part of the *Panthera* genus, performed better than the less-related Cheetah proteome that was part of the *Acinonyx* genus. Hair-specific keratin proteins such as keratin 35, keratin 36, keratin 38, and keratin 75 all saw patterns of reducing alignment between spectra and protein sequences for leopard, tiger, then cheetah protein sequences. For example, the later protein, keratin 75, observed a protein coverage of 48%, 42%, and 39% when using the leopard, tiger, and cheetah proteomes respectively.

This demonstrates that protein coverage is a good surrogate for evolutionary distance, and that proteomics have the potential to identify species from single hairs from fur samples. With more information, this may be extended to differentiate different species and exclude sister species. The ability to categorically identify fur-bearing species in an automated manner and in the absence of detectable DNA should fill a sizable gap in forensic monitoring and law enforcement of wildlife crime.

Proteomics, Processed Fur, Environmental Crime

E22 Forensic and Investigative Scene Factors Associated With the Undetermined Manner of Death

Betsy Adelizzi, PhD, American Military University, Charles Town, WV*

Learning Overview: This research examined the forensic and investigative death scene field factors, in addition to the victim circumstances associated with the undetermined manner of death, through the lived experiences and insights of death investigators.

Impact Statement: The investigation, scene, victim, and investigator all serve as unique variables for understanding the patterns related to corroborating and excluding evidentiary information for the manner-of-death determination. Internal and external case resources can inhibit or help investigators reduce undetermined cases; medicolegal investigator training and certification standards were reported as inconsistent, and the lack of scene response was noted as hindering a comprehensive investigation; infant deaths, drug overdoses, and decomposed cases were susceptible to a greater risk of undetermined findings; both detailed and accurate death scene field factors and victim circumstances are necessary to reduce ambiguous manner-of-death findings; and gaps and problems still exist related to an undetermined manner of death.

Undetermined deaths in the United States are on the rise and correlated to misclassified suicides, accidental deaths, overlooked findings, and inaccurate outcomes within the criminal justice system. The undetermined category has not been separately assessed within the different types of medicolegal investigative agencies. This research examined the forensic and investigative death scene field factors, in addition to the victim circumstances associated with the undetermined manner of death, through the lived experiences and insights of death investigators. Two research questions were created to help understand the undetermined manner of death phenomenon: (1) What are the perceptions of study respondents regarding how examining the forensic investigative death scene field factors help reduce the undetermined manner of death findings?; and (2) What are the perceptions of study respondents regarding how examining the forensic investigative death scene victim circumstances help reduce the undetermined manner of death findings?

A qualitative case study was conducted by triangulating data with professional interviews, short answer surveys, and secondary data review. Coroner and medical examiner officials who certified death certificates and oversaw death investigations were interviewed. Death investigators submitted short answer survey feedback. Secondary data within the National Violent Death Reporting System (NVDRS) was also used. Thematic analysis identified patterns related to answer the research questions. Secondary data findings identified an increased rate of substance abuse and mental health problems, alcohol dependence, physical problems, and recent crisis as indicators for the undetermined manner. The investigation, scene, victim, and investigator all served as unique variables for understanding the patterns related to corroborating and excluding evidentiary information for the manner of death determination. Participant findings included the following: internal and external case resources can inhibit or help investigators reduce undetermined cases; medicolegal investigator training and certification standards were reported as inconsistent, and the lack of scene response was noted as hindering a comprehensive investigation; infant deaths, drug overdose, and decomposed cases were susceptible to a greater risk of undetermined findings; both detailed and accurate death scene field factors and victim circumstances are necessary to reduce ambiguous manner-of-death findings; and, gaps and problems still exist related to an undetermined manner of death. Further research into all sizes, designs, and jurisdictions for undetermined outcomes to better understand gaps, complexities, applications, and knowledge from those practices was recommended.

Medicolegal Death Investigation, Undetermined, Scene Investigation

E23 “Our Hearts Are Not at Rest”: A Critical Look at the Adequacy of Indigenous Death Investigations

Steff King, MA, Simon Fraser University, Burnaby, British Columbia, Canada; Ted Palys, PhD, Simon Fraser University, Burnaby, British Columbia, Canada; Annie Ross, PhD, Simon Fraser University, Burnaby, British Columbia, Canada; Gail Anderson, PhD, Simon Fraser University, Burnaby, British Columbia, Canada*

Learning Overview: Attendees can expect to learn how death investigation procedures conducted by law enforcement and medicolegal practitioners can be inadequate for Indigenous cases. This research will reveal common misconduct in Indigenous death investigations, express the need for decolonization in standard practices, and suggest alternative procedures that may best support the Indigenous community.

Impact Statement: The aim of this research is to teach death investigation practitioners how their practices may negatively impact Indigenous communities. The intention is to provide the forensic community with both the tools to start questioning colonial assumptions embedded in standard practices and suggestions for how to modify their approaches to better support future Indigenous cases.

Across Canada, thousands of Indigenous testimonies have reported deficiencies in how police and medicolegal professionals investigate their deaths. The problem, however, is that these individuals are summarily and systematically denied the resources to challenge investigators, and there are few cases that have done so successfully. This research establishes a comparative model to examine whether case investigation conduct aligns with standard investigative practice requirements. The qualitative sample includes three Indigenous case studies involving the suspicious deaths of young individuals in Prince Rupert, BC. The results present a central theme of inadequacy across all three cases, primarily in improper evidence collection, limited procedural follow-through, and withheld information. The outcomes of this study suggest a need for: (1) future research, (2) professional action to create and uphold effective accountability measures for investigators, and (3) a critical look into how colonial powers limit investigative effectiveness for Indigenous deaths.

Indigenous, Death Investigation, Best Practice

E24 Forensic Science Data Integration and Stakeholder Workflow for Medicolegal Death Investigation Systems

Matthew Gamette, MS, Idaho State Police Forensic Services, Meridian, ID; Jeri Roper-Miller, PhD, RTI International, Research Triangle Park, NC*

Learning Overview: After attending this presentation, attendees will have a better understanding of the data sharing and workflow processes among stakeholders of the medicolegal death investigation system.

Impact Statement: This presentation will impact the forensic science community by presenting the findings of a working group focusing on forensic sciences data exchange and stakeholder workflow processes for medicolegal death investigation systems. This presentation specifically describes data exchange needs and processes to seek improved data sharing methods, standardize data, and common language utilization for the medicolegal death investigation system.

The National Institute of Justice (NIJ), in partnership with its Forensic Technology Center of Excellence (FTCoE, 2016-MU-DX-K110) at RTI International and the Center for Disease Control and Prevention (CDC) convened a virtual Medicolegal Death Investigation Data Exchange Working Group (MDI-DATA-WG) over a 12-month period beginning in September 2020. The MDI-DATA-WG was formed to advance forensic science and ensure communication between Medical Examiners and Coroners (ME/C), death investigators, forensic scientists, and other stakeholders.

The objective of the MDI-DATA-WG was to identify data commonly collected by ME/C, data relied on by ME/C to make cause- and manner-of-death determinations, and data exchanged across the forensic science disciplines collection as it informs data integration processes. Particularly, the MDI-DATA-WG aimed to explain the ideal state of the MDI data exchange among data consumers and producers and the data types and systems they use.

The MDI-DATA-WG of more than 40 stakeholders (e.g., data producers like ME/C, data consumers like federal agencies) participated and further formed Subcommittees (SC) that focused on a specific purpose and goals. The MDI-DATA-WG met in five two-day meetings and intermittent SC monthly meetings. Approaches to collecting information included user case scenarios and feedback stakeholder types; presentations from invited guests with Q&A sessions; group experiential sharing; and forums with data programmers and technology developers. The work of the MDI-DATA-WG resulted in a final report published by NIJ's Forensic Technology Center of Excellence (FTCOE) and Centers for Disease Control and Prevention (CDC) to include guidance to move toward consistency, data standards, and best practice for improving the process. The efforts of this working group will result in various user case profiles, presentations, implementation forums, further research, and process mapping and evaluations of the various processes.

This presentation will focus on the work of one subcommittee directed on data types, data exchange systems (e.g., health information exchange systems), stakeholder data flow process relationships, and needs to improve upon the data exchange in an ME/C data system, as well as potential futuristic practices for collection. The MDI-DATA-WG produced guidance for what ME/C computerized information management systems should collect and archive. Other information collected includes various data sources available to pathologists from public safety, public health, and forensic science service providers, including information concerning initial response calls, police incident data, laboratory testing results, and information from first responders. The working group provided recommendations for drug terminology and ideas for how to network ME/C with other real-time data sources.

The demand to further understand and communicate data exchange needs and processes is critical for process improvements, to standardize data, and common language implementation for the MDI system. Stakeholder-informed data collection helps to address the opportunities and challenges for automated approaches and best practices to use and exchange data between medical examiners, coroners, forensic toxicologists, and other stakeholders. Additionally, next steps and observations for further research and resources to improve data sharing are presented and documented in a final report that is available on the FTCOE website (www.forensicCOE.org).

Medicolegal Death Investigation Systems, Data Exchange, Data Sharing

E25 Medicolegal Systems and Forensic Services Assessments: Methods to Better Understand the Needs and Challenges of Providing Structured Support and Building Sustainable Forensic Capacities

*A. Skylar Joseph, MS*1, International Committee of the Red Cross, Geneva, Switzerland; Maria Dolores Morcillo Mendez, MD, International Committee of the Red Cross, Geneva, Switzerland; Pierre Guyomarc'h, PhD, International Committee of the Red Cross, Geneva, Switzerland; Denise Abboud, PhD, International Committee of the Red Cross, Amman, Jordan; Eliane El Hajj, MBA, International Committee of the Red Cross, Beirut, Lebanon; Rawan Chaaban, MPH, International Committee of the Red Cross, Beirut, Lebanon; Myriam El Helou, BS, International Committee of the Red Cross, Beirut, Lebanon; Fondebrider, PhD, International Committee of the Red Cross, Geneva, Switzerland*

Learning Overview: After attending this presentation, attendees will have learned about the importance of medicolegal system assessments and a comprehensive tool developed for this purpose, which considers aspects beyond technical capacities. This presentation will focus on how medicolegal system assessments have allowed the International Committee of the Red Cross (ICRC) to develop and implement more structured strategies and activities to support affected populations, local authorities, and forensic practitioners as well as to build sustainable local capacities in the contexts the ICRC works in around the world.

Impact Statement: This presentation will impact the forensic science community by highlighting useful resources currently being utilized by the ICRC to assist in strengthening medicolegal systems and building sustainable forensic capacities around the world.

In the framework of its humanitarian mandate, the ICRC highlights the importance of the medicolegal system and forensic institutions to prevent and respond to humanitarian needs of people affected by armed conflict, emergencies, and other situations of violence. A reliable, well-functioning medicolegal system is essential both for a properly functioning justice system and contributing to prevention and protection in the social, legal, and humanitarian spheres. Forensic expertise and the proper use of forensic services by the judiciary help ensure adequate medicolegal investigations of suspicious deaths, including the necessary documentation and preservation of evidence required for investigation processes. This ensures that the dead and their families are treated with dignity and respect, to the best standards possible, and that bodies are identified and have a dignified final disposition. When searching for missing persons, the medicolegal system plays an important role in ensuring adequate integrated processes, proper involvement from families, and the provision of information. In the case of large-scale events, such as on-going/post-conflict situations, natural or man-made disasters, migration, and/or other emergency situations, the medicolegal system and forensic services must coordinate with other entities to ensure an efficient response.

Moreover, following events involving a rapid surge in the number of separated, missing, and/or deceased, few countries have the economic and structural capacities to properly respond. Even locations with well-developed medicolegal systems and advanced forensic facilities may become overwhelmed by the magnitude or complexity of these situations. This is especially so where the affected area lacks a pre-established or well-implemented emergency preparedness and response plan that entails the required actions toward the management of the dead and their families.

When the ICRC forensic unit is asked to assist local authorities and practitioners in their response to humanitarian needs, conducting a comprehensive forensic country assessment is key to understanding the current situation, identifying gaps in the current response, discovering the needs, limitations, and root causes, as well as assessing the capacities and working conditions of different actors. It also promotes better involvement of families in the search for missing persons and engagement with the relevant authorities. This process aids in determining context-specific priorities, developing strategies and programs, and identifying the needs of the affected populations, the communities, and the existing entities of the medicolegal system.

To achieve this, the medicolegal system assessment tool was developed to take into consideration the structural aspects of the judicial and investigative agencies, the technical capacities, while also analyzing the particular context, including existing political, economic, social, cultural/religious, and humanitarian settings. It enables ICRC forensic field staff to respond to changing environments and build upon the interventions of their predecessors through a clearer documentation process. This enables the development of an adequate Country Forensic Program that aligns with the specific context and needs, focused on three main humanitarian issues: (1) protection of and respect for the dead and their families in all circumstances; (2) preventing and resolving missing persons and ensuring support to their families; and (3) supporting the living victims of ill treatment, sexual violence, and other situations of violence.

Humanitarian and development organizations aim to support affected populations in various ways; it is often best to promote and implement programs that center community engagement, local partnerships, and that ultimately are aimed at building local capacities while being considerate of local religious/cultural practices and any political sensitivities. These types of considerations are essential in order to properly support the entities responsible for the protection and management of the dead and their families, through the clarification of the fate and whereabouts of missing persons from all circumstances.

Humanitarian Forensic Action, Medicolegal Systems, Protection of the Dead

E26 Addressing Emerging Humanitarian Challenges Through an Innovative Concept: The International Centre for Humanitarian Forensics (ICHF)

Melahat Elif Gunce Eskikoy, PhD, ICRC, New Delhi, India; Govindarajulu Rajesh Babu, PhD, NFSU, Gandhinagar, Gujarat, India; Darshana Ishwarbhai Sharma, PhD, ICRC, New Delhi, India; Abraham Johnson, PhD, NFSU, Gandhinagar, Gujarat, India*

Learning Overview: A meaningful novel concept integrating operations and academia in the field of Humanitarian Forensic Action (HFA) will be presented.

Impact Statement: Institutionalizing HFA within an existing university system can amplify available multidisciplinary expertise and existing technology and create regional and global synergies shaping the future of humanitarian forensic action.

In the past few decades, forensic science and forensic medicine methodologies and principles, employed in humanitarian settings, helped alleviate human suffering resulting from disasters, armed conflict, or other situations of violence. Along with attending to survivors and restoring critical infrastructure, caring for the dead is an essential pillar of humanitarian relief efforts.

Established in 1863, the International Committee of the Red Cross (ICRC) is an impartial, neutral, and independent non-political organization with a large scope of strictly humanitarian activities. Its mandate stems from the Geneva Conventions of 1949, their additional protocols of 1977, and the Statutes of the International Red Cross and Red Crescent Movement.

Since 2003, the ICRC offers forensic assistance exclusively for humanitarian purposes. The International Humanitarian Law (IHL) entails concrete obligations regarding the management of the dead and provides the legal framework for HFA, a concept which the ICRC helped to develop. ICRC's HFA provides technical advice and support to build a sustainable local forensic capacity and medicolegal infrastructure, promoting scientific best practices.

The National Forensic Sciences University (NFSU), established as the Gujarat Forensic Sciences University in 2009, is a unique and first-of-its-kind university offering academic programs, research, and consultancy in specialized areas of forensic sciences and has been elevated to the status of Central University and an Institution of National Importance in 2020. Starting with four courses in three institutes, the university currently has 12 schools and eight centers.

Exploring a feasible and meaningful way to connect operations and academia, NFSU and ICRC joined efforts and established the International Centre for Humanitarian Forensics (ICHF) in 2018 with the vision of being a one-stop Centre of Excellence in Humanitarian Forensics. This partnership between NFSU as a unique higher education institution specializing in forensic sciences and ICRC as a reference organization in HFA is a noteworthy opportunity to address a range of critical policy issues on emerging humanitarian challenges and to promote HFA globally. Acknowledging its domestic relevance, regional footprint, and worldwide potential, the Centre aims to set the standards in HFA focusing on advocacy and leadership, consultancy, research and innovation, and knowledge exchange. In a region prone to disasters, both natural and human induced, with limited and unevenly distributed resources for disaster response, the ICHF leads the way in developing regional and global contingency planning initiatives through transcontinental partnerships fostering important synergy. The Centre offers competitive academic programs producing a well-trained, competent workforce for the global marketplace and tailored institutional training for their professional development.

This novel concept of institutionalizing HFA within an existing university system intends to amplify available multidisciplinary expertise and existing technology and represents the future of humanitarian work to bridge the gap between theory, policy, and implementation while responding to mass fatalities and other relevant areas of HFA.

Humanitarian Forensic Action, Higher Education, Caring for the Dead

E27 Tapping an Overlooked Resource: Preparing and Utilizing Crime Scene Investigators to Recognize and Document Criminal Asphyxiation Cases

Kelsey McKay, JD*, McKay Training & Consulting, LLC, Austin, TX; Andrea Zaferes, BA*, Forensic Aquatic Consulting & Training, LLC, Shokan, NY; Rachel Johnson, MS*, Chesapeake Police Department, Chesapeake, VA

Learning Overview: After attending this presentation, attendees will understand the critical need of Crime Scene Investigators (CSI) to identify, document, and preserve potential evidence related to asphyxiation crimes.

Impact Statement: This presentation will impact the forensic science community by demonstrating the unique challenges presented by asphyxiation crimes and proposing novel solutions, tools, and protocols to utilize CSIs to identify and collect often-missed evidence.

Asphyxiation, whether criminal, accidental, or suicidal, is a process that can be fatal or non-fatal. Asphyxiation directly impedes respiration or blood flow to the brain through various methods, such as strangulation, drowning, and inert gas.¹⁻³ Criminal asphyxiation occurs in domestic violence, child/elder abuse, sex crimes, state and non-state torture, and human trafficking.⁴⁻⁷ The diagnosis of fatal asphyxia, criminal or benign, requires an informed and accurate scene investigation and a careful exclusion of underlying injury or disease processes.⁸

Despite the adoption of widespread legislation specifically targeting asphyxiation violence, evidence collection is sparse and convictions are rare.⁹ This is partly because criminal asphyxiation often presents with non-specific findings and minimal or no obvious external injury, can be a diagnosis of exclusion, and lends itself to crime scene staging.^{10,11} Therefore, these cases require the preservation and collection of often circumstantial evidence present at the initial scene. Capturing this evidence is especially critical when victims and witnesses may be unable to participate beyond the initial scene for fear of retaliation and safety. As such, CSIs are in a unique position to provide a variety of solutions.

It is the job of CSIs to document and process a scene (location, victim, suspect) in its totality as it appears upon arrival. In criminal asphyxiation cases, CSIs are the most apt to capture often-missed evidence, including fingernail scrapings and injuries present on suspects. CSIs may also be the only practitioners who can forensically document initial and follow-up injury presentation. For example, in non-sexual asphyxiation cases, victims are unlikely to receive forensic nurse examinations. CSIs' interactions with victims and suspects can also provide unique opportunities to identify and document signs and symptoms of asphyxia and indicators of abuse. For equivocal fatal cases, CSIs can provide the information necessary for investigators to detect staged scenes and for medical examiners to accurately determine cause and manner of death.

This novel use of CSIs can be achieved by developing protocols, using investigative forms, and implementing training. Protocols are needed to dispatch CSIs to possible criminal asphyxiation scenes and to provide guidance for evidence recognition, documentation, and processing. CSIs must also be properly equipped with knowledge and evidence-based forms in order to effectively work these often-challenging cases. A current obstacle, as will be demonstrated in this presentation, is insufficient CSI training on criminal asphyxiation in the United States as shown by a lack of its mention in CSI textbooks and training syllabi. Overcoming this requires a forensic community response. As a first step in this response, this presentation will introduce tools for CSIs, including investigative forms and protocols for possible asphyxiation scenes. This presentation illustrates the challenges of investigating criminal asphyxiation, offers solutions that CSIs can provide, and introduces CSI tools for investigating strangulation cases. With standardized agency protocols, tools, and specialized criminal asphyxiation training, CSIs can help identify, document, and preserve critical evidence in these cases.

E28 Forensics in the Wilderness: Lessons Learned

David Kintz, BS, Park County Coroner's Office, Fairplay, CO*

Learning Overview: This synopsis of complicated death scene investigations in the Rocky Mountains from 2010 to 2021 will educate attendees on the pitfalls they may face when conducting a death investigation in the wilderness or other complicated outside situations. There are very few published references on this topic and the best current learning tool we have is sharing real-life scene experience to educate forensic investigators.

Impact Statement: The impact of this presentation will be to educate investigators on the unique challenges encountered during wilderness investigations. Most death investigation training is based indoors and has many differences that investigators and other forensics scientists may be unfamiliar with.

This presentation will focus on the complex nature of handling death scene investigations in wilderness settings. These scenes can present difficult circumstances such as extended distance from road travel, weather and scavenger damage to evidence, and life hazards to investigators. When approaching these types of investigations, the investigator must have first, second, and third plans in place and be prepared to innovate at any given notice. Walking in blind to any of these scenes could lead to a compromised investigation or even the loss of life of a responder.

To illustrate the importance in approaching these scenes, this presentation will offer examples with different complications and different manners of death. One example is regarding skeletal remains found 4.5 miles from a trailhead while gaining 2,000ft in elevation. The weather windows were sporadic and presented risk of rain, high wind, and lightening. The investigator took a team of 11 people consisting of coroner staff, anthropologists, human remains detection canines, and Search and Rescue members. The find was reported in the evening. The weather forecast gave the next day as being the clearest and the following days having a higher risk for extreme weather. The team was organized in a rapid manner to be launched at 6:00 a.m. the next day. The hike took 4.5 hours. Upon arrival at the scene, it was found to be a large scattered skeletal scene. With the extent of the hike, time became critical to a successful investigation. The investigator had to break up the team into smaller teams to photograph, Global Positioning System (GPS), describe, and collect all evidence. At the same time, evidence needed to be assessed in the field to answer questions. This action is necessary because returning to the scene is not an easy task in difficult terrain.

A second example will be a found decomposing body that took a 12-hour hike to reach. In this case, the decedent was found to be in a cave situation from which the team was unable to extract. This is a difficult lesson to learn in the field and the purpose will be to drive home to attendees the point of having multiple plans and a team made up of numerous specialties to make the investigation successful.

Throughout the presentation there will be prompts for attendees to assess the situation and decide what they would do with their current knowledge. This will emphasize the point of this presentation to have numerous plans and specialties in place. Many times there will be only one attempt at a successful investigation, and it is imperative that lessons be learned before investigators confront these cases.

Wilderness, Death, investigation

E29 Homicide Victims and Location, Location, Location: Utilizing Body Dump Patterns and Forensic Archaeology in Outdoor Searches

Sharon Moses, PhD, Northern Arizona University, Flagstaff, AZ

Learning Objective: After attending this presentation, attendees will have a better understanding about relationship and environmental factors that influence homicide offenders' choices about where they dispose of their victims' bodies in outdoor settings. In addition, forensic archaeologists are usually sought after the body disposal site has already been located and the body recovery is complex. Attendees will see that including a forensic archaeologist in the search phase can be beneficial and that, historically, forensic archaeologists have played that role before. Traditional archaeological skill sets include an understanding of environmental factors in order to reconstruct human and animal behaviors at prehistoric and historic sites. Forensic archaeologists bring that skill set to contemporary crime scenes, which includes an understanding of scavenger behaviors and determining a point of origin, if possible, of the body disposal site.

Impact Statement: This presentation will impact the forensic community by demonstrating and promoting the value of utilizing forensic archaeologists not only in the body recovery itself, but in determining a search strategy for locating missing or suspected homicide victims. Enhanced search strategies can help law enforcement in locating human remains with more focus of resources. It can also aid in determining a point of origin (where the body was originally left) for surface body dumps depending upon the length of the postmortem interval, environment, taphonomic processes, and scavenging activity.

This presentation will demonstrate that the search as well as the body recovery effort should include forensic archaeologists and anthropologists. It will be informative in that forensic archaeologists have played an important role in search strategies in the past and it is hoped that this presentation will help to restore that interest. The taphonomic processes upon human remains have been the subject of many research efforts over the years, but this presentation will attempt to put those processes in the context of body dispersal by scavengers and forensic archaeologists' understanding of those animal behaviors for ways to narrow the search field and, if possible, calculate a point of origin after the scattered remains are found.

Scavengers, Body Dumps, Forensic Archaeology

E30 How the COVID-19 Pandemic and Related Restrictions Impacted Crime in Italy

Francesco Sessa, MS, PhD, Department of Clinical and Experimental Medicine, University of Foggia, Foggia, Italy; Massimiliano Esposito, MD, Department of Medical, Surgical and Advanced Technologies G.F. Ingrassia, University of Catania, Catania, Italy; Monica Salerno, MD, PhD, Department of Medical, Surgical and Advanced Technologies G.F. Ingrassia, University of Catania, Catania, Italy; Cristoforo Pomara, MD, PhD, Department of Medical, Surgical and Advanced Technologies G.F. Ingrassia, University of Catania, Catania, Italy*

Learning Overview: After attending this presentation, attendees will be able to comprehend how the COVID-19 pandemic and related restrictions have influenced crime activities in Italy.

Impact Statement: This presentation will impact the forensic community by providing up-to-date data on crime diffusion in order to present how the forensic investigation has been influenced by the pandemic situation. The data produced will be useful for both forensic practitioners and governments to implement targeted actions in the field of crime prevention.

The outbreak of the COVID-19 emergency worldwide and the subsequent measures taken by each government radically changed the nature of social interactions and economic activities. Many countries have applied a wide range of restrictions, adapting and readjusting their response according to the course of the pandemic. These changes have affected all aspects of life, including criminal activities and forensic investigation.

This research study aims to analyze the impact of the COVID-19 outbreak on the forensic investigation in Italy in the pandemic period. In particular, data were obtained by analyzing national data and those of the Institute of Forensic Medicine of the University of Catania in two periods: before COVID-19 (from February 2019 to January 2020) and during the COVID-19 outbreak (February 2020 to January 2021).

During the lockdowns, several important changes in lifestyles occurred, worsening socio-economic conditions. Analyzing the Italian data, the number of voluntary homicides was reduced (271 cases in 2020, compared to 315 in 2019); the same trend has been confirmed locally (one homicide in 2020 compared to seven in 2019). There was a slight increase in the number of female victims (from 111 in 2019 to 112 in 2020) and in the number of homicides in family relationships (from 94 to 98), maybe due to the weeks of forced cohabitation. It is important to note that in comparing the two analyzed periods, the number of suicides doubled in Italy; analyzing the same data locally, using the data of the Institute of Forensic Medicine of the University of Catania, the situation is dramatically increased: only one suicide is recorded in the pre-COVID period, compared to seven cases in the COVID period. This worrying situation could be related to the measures taken by governments to contain the pandemic, which in Italy included several lockdowns, generating social isolation and economic problems. Moreover, at the national level, the number of femicide-suicides increased among those who killed their wife or partner (from 10 to 21, with a suicide rate of up to 50%), as well as “couple femicides” (from three to five cases). These data are in agreement with other countries that have adopted similar choices in containing the pandemic. In fact, forced domestic cohabitation inevitably influenced the number of domestic violence incidents during the pandemic period. Finally, it is important to highlight that the number of medicolegal disputes has constantly increased due to COVID-19 deaths in both hospitals and nursing homes.

National data and the statistics of the Institute of Legal Medicine of the University of Catania demonstrate how some crimes are changing during this pandemic. According to the discussed data, the COVID-19 outbreak has undoubtedly led to a reduction in the number of voluntary crimes. On the other hand, the number of other types of crime (i.e., domestic violence and/or femicide) has increased considerably. In addition, the number of suicides is certainly alarming: COVID-19 can cause neurological disorders and the pandemic situation has increased mental health problems, such as depression and anxiety. In light of these new issues, governments should inevitably pay attention to them, setting up support programs for citizens. Similarly, the forensic investigator must be aware that in the typology of crimes, the relative investigations are inevitably modified.

Forensic Sciences, COVID-19, Crime Scene Investigation (CSI)

E31 COVID-19 Impacts on Medical Examiner/Coroner Offices and Their Response to the Pandemic

BeLinda Weimer, MA, RTI International, Research Triangle Park, NC; Peyton Attaway, BS, RTI International, Research Triangle Park, NC; Crystal Daye, MPA, RTI International, Research Triangle Park, NC; Camille Gourdet, JD, RTI International, Research Triangle Park, NC; Paul Speaker, PhD, West Virginia University, Morgantown, WV; Jeri Roper-Miller, PhD*, RTI International, Research Triangle Park, NC*

Learning Overview: After attending this presentation, attendees will understand how COVID-19 has impacted Medical Examiner and Coroner (ME/C) offices' outsourcing practices, staff, and caseloads, and the ways ME/Cs have adapted policies and procedures to address the impacts of COVID-19.

Impact Statement: This presentation will provide additional insight into the impact COVID-19 has had on ME/C outsourcing practices and the ways in which ME/Cs have adapted to address these impacts with their already stretched capacity and resources. This presentation will impact the forensics community by bringing awareness to a seldom-researched field and topic.

ME/Cs are a critical component of our nation's criminal justice system. The already existing challenges of high caseloads and dwindling funding, staffing, and resources are now compounded with the COVID-19 pandemic. Because of the COVID-19 pandemic, ME/Cs have had to implement changes in how they operate, especially related to how autopsies are conducted and how bodies are handled.¹ The increase in caseload among ME/Cs due to the COVID-19 pandemic is further exacerbated by the shortage of forensic pathologists and the inability to fill these positions.²

To examine the outsourcing practices and how the COVID-19 pandemic has impacted the operation and capacity of ME/Cs, the National Institute of Justice's Forensic Technology Center of Excellence (Award 2016-MU-DX-110) partnered with Project FORESIGHT to conduct a case study with ME/Cs across the country. Focus groups and qualitative interviews were conducted with nine ME/Cs of varying size, location, and type. Findings from the study related to the impact of COVID-19 on ME/C operations and outsourcing and the ways in which ME/Cs have adapted and adjusted procedures to accommodate the additional demands of COVID-19 will be presented.

This study supports local evidence that ME/Cs are doing more with less as their caseloads increase substantially in comparison to their operational capacity. Given the critical role of ME/Cs, research is needed to understand the COVID-19 impact, not just on ME/C operations, but also on the individual ME/C staff.

COVID-19, Outsourcing, Medical Examiners and Coroners

E32 An Examination of Medical Examiner/Coroner (ME/C) Outsourcing Practices

Peyton Attaway, BS, RTI International, Research Triangle Park, NC; BeLinda Weimer, MA, RTI International, Research Triangle Park, NC; Crystal Daye, MPA, RTI International, Research Triangle Park, NC; Camille Gourdet, JD, RTI International, Research Triangle Park, NC; Paul Speaker, PhD, West Virginia University, Morgantown, WV; Jeri Roper-Miller, PhD, RTI International, Research Triangle Park, NC*

Learning Overview: After attending this presentation, attendees will understand the current landscape of ME/C outsourcing practices and how these practices have been adapted to address the opioid epidemic, rise in drug overdoses, and COVID-19.

Impact Statement: This presentation will provide attendees with a review of current field practices for the outsourcing of specific ME/C testing functions and the context for which those practices are implemented. This presentation will impact the forensic community by bringing awareness to a seldom-researched field and topic.

The nation's ME/Cs are facing daunting caseloads and depleted funding, staffing, and resources, due to growing threats such as the opioid and other emerging drug crisis and the current COVID-19 pandemic. In addition to these considerations, there has been a shortage of forensic pathologists in the workforce since 2004 and the unprecedented levels of drug-related and other traumatic deaths (e.g., suicides and deaths resulting from motor vehicle incidents) have further exacerbated the impacts of this shortage on the ME/C field.¹ In order to extend their resources, many ME/Cs have turned to outsourcing certain tasks, especially toxicology.

To better understand the strain put on ME/Cs and their current outsourcing practices, the National Institute of Justice's Forensic Technology Center of Excellence (Award 2016-MU-BX-110) partnered with Project FORESIGHT to conduct a study with ME/Cs across the country. Focus groups and qualitative interviews were conducted with nine ME/Cs of varying size, location, and type. The findings related to the current state of ME/C operations and outsourcing and the ways in which ME/Cs have adapted and adjusted procedures to accommodate the additional demands of the opioid epidemic and the current COVID-19 pandemic will be presented.

This study supports anecdotal evidence that the ME/C field is accommodating increases in deaths requiring investigation and a national public health crisis, with little-to-no increase in operational capacity, staffing, health and wellbeing resources, infrastructure, and other assistance. Given the critical role of ME/Cs in the nation's public health and criminal justice fields, research is needed to understand the impact of increasing caseloads with no increase in resources, not just on ME/C operations, but also on the individual ME/C staff.

Medical Examiners, Coroners, Outsourcing

E33 “Cutting” for Profit in a Pandemic

Abby Chapman*, University of Alabama-Birmingham, Birmingham, AL; Cindy Moran, Arkansas State Crime Lab, Little Rock, AR; Daniel Dye, MD, University of Alabama-Birmingham, Birmingham, AL; Brandi McCleskey, MD, University of Alabama-Birmingham, Birmingham, AL

Learning Overview: After attending this presentation, attendees will understand the impact that the COVID-19 pandemic has had on the illicit drug supply and deaths associated with fentanyl-laced drugs.

Impact Statement: This presentation will impact the forensic science community by illustrating how the opioid epidemic has worsened with the COVID-19 pandemic.

Illicit drug use has had a longstanding history in the United States and has grown to epidemic proportions over the past two decades.¹ Illicit drugs tend to become more popular during times of war or economic downturns. For example, during the Civil War, opiates such as morphine were used as anesthetics and pain killers by doctors whose patients desperately needed amputations.^{2,3} Due to this endorsement, morphine began to be prescribed often as a treatment for other maladies and thus began a chain of morphine addictions.⁴ Alcohol, once prohibited by the United States government, became a popular source of comfort to those struggling economically during the Great Depression.⁵ During the 1980s, a decade that began with a recession, crack cocaine became popular due to its affordable prices in comparison to powder cocaine.⁶ This illustrates the drive that drug manufacturers have to increase profits without decreasing the addictive and/or active effects of the drugs. Fentanyl, a synthetic opioid, has been growing in popularity as a “cutting agent” in the North American heroin supply for years.⁷ Fentanyl “building blocks” can be obtained easily from the internet for a low cost in wholesale quantities, thus making this drug extremely profitable for manufacturers/dealers.⁸

During the COVID-19 pandemic (beginning in December 2019 with restrictions becoming more stringent in early 2020), fentanyl toxicity-related deaths have increased dramatically across the country.⁹ Data from the Jefferson County Coroner/Medical Examiner’s Office (JCCMEO) in Birmingham, AL, demonstrated a 25.6% rise in overall drug-related deaths from 2019 to 2020 and a 100% increase in fentanyl-related deaths during the same time period. The percentage of drug toxicity deaths with fentanyl detected has increased from 40.6% (2019) to 64.6% (2020) to 78.4% (1st quarter 2021) to 81.3% (2nd quarter 2021). The Arkansas State Crime Lab in Little Rock, AR, experienced an increase of 22.8% overall in drug-related deaths with an 88% increase in those with fentanyl detected. Fentanyl as a component of drugs detected in cases in Arkansas increased from 34.7% (2019) to 53.2% (2020).

These dramatic and disproportionate increases in fentanyl-related deaths are likely due to the ease in which one can acquire it from the internet and from trafficking channels between Mexico and the United States that are still being utilized despite COVID-19 restrictions and border closures. Throughout the pandemic, heroin prices have increased and the availability of fentanyl has decreased; however, purchasing heroin that has been cut with fentanyl will decrease the overall price as well as increase the potency of the drug.¹⁰ In addition to heroin, cocaine and methamphetamine preparations mixed with fentanyl have become the norm rather than the exception during the pandemic. The Centers for Disease Control and Prevention (CDC) report that fentanyl and other synthetic opioids “are the primary driver of the increases in [illicit drug] overdose deaths in the United States, increasing 38.4% during the 12-month period ending May 2020.”¹¹

With the latest information from JCCMEO, the continued increases observed in the 1st and 2nd quarter of 2021 project an even larger number of deaths related to drugs and fentanyl as the pandemic and the epidemic continue to rage on. The issue of fentanyl-related drug deaths has been exacerbated by the COVID-19 pandemic due to economic stressors and supply chain breaks, making mixed drugs the most cost-efficient route, albeit the most dangerous, for both the drug dealer and the drug purchaser. This deadly combination will continue to wreak havoc on the medicolegal death investigation system.

E34 The Assessment of Skin Lesions in Trafficking Victims: A Medicolegal Approach

Francesca Capello, MD, University of Turin, Turin, Italy; Camilla Bonci, MD, University of Turin, Turin, Italy; Niccolò Dino Melloni, MD, University of Turin, Turin, Italy; Alice Porceddu, MD, University of Turin, Turin, Italy; Davide Santovito, MD, AOU Città della Salute e della Scienza di Torino, Turin, Italy; Giancarlo Di Vella, MD, PhD, University of Turin, Turin, Italy*

Learning Overview: After attending this presentation, attendees will have a better understanding of the importance of a structured interview in a medicolegal examination to correctly discriminate the origin of skin lesions in trafficking victims.

Impact Statement: This presentation will impact the forensic science community by underlying the need of a multidisciplinary approach based on an accurate forensic examination along with empathic communication with the patient. The case of a young trafficking victim from west sub-Saharan Africa with peculiar skin lesions will be presented.

According to the United Nations Convention against Transnational Organized Crime, adopted by General Assembly resolution 55/25 of November 15, 2000, trafficking in human beings represents a serious violation of human rights. In recent years, in Italy, there has been a progressive increase in the number of asylum seekers and refugees with a history of exploitation (sexual slavery, forced labor, illegal activities, migrant smuggling). The identification of victims is a necessary prerequisite for assistance and protection measures provided by international laws.¹

It is important to recognize those who have experienced a trafficking event as early as possible in order to prevent forms of exploitation within the national territory. The Italian procedure for victims of trafficking primarily provides the execution of a structured interview for the purpose of ascertation and identification. During the medicolegal anamnestic investigation, thanks to the help of sociological and psychological experts and the use of a “non-judgmental listening” approach, it was possible to create an empathic relationship with the victim. The next step involves carrying out a forensic examination focused on distinctive anthropomorphic and anthropometric traits, as well as particular characteristics, such as scars or injuries. Victims of human trafficking may have skin lesions due to torture or other forms of mistreatment or abuse.² They may also present scars related to ethnical practices, such as ritual scarifications.

A self-proclaimed underage woman from west sub-Saharan Africa was forced to travel to Italy by migrant smugglers. She was then mistreated and forced to sell her body until she managed to escape from her persecutors. Since she had no identity documents, she was taken to an Italian hospital in order to assess her age. Therefore, she was visited by a pediatrician and a forensic expert for ascertaining and identifying purposes. The inspection of the left abdominal flank revealed the presence of three parallel oblique scars: the most proximal was 12 x 1.5cm, the central one was 12 x 1cm, and the distal one was 10 x 1.5cm. All the scars appeared diastased and superficial. During the structured interview, thanks to an empathic approach, it was possible to attribute the origin of the scars to traditional medical practices.

As a cultural practice among African tribes, scarification consists in creating wounds in order to cause indelible markings associated with a spiritual, political, or sexual significance.³ They are generally performed methodically and may show macroscopic differences from other forms of abuse and mistreatment. However, there is a wide range of morphological patterns of lesions perpetrated for different purposes.⁴ Scarification marks may even change through the years, becoming hypertrophic or keloidal and thus complicating the differential diagnosis.⁵

In a trafficking victim case, a multidisciplinary approach appears mandatory to correctly distinguish between cultural practices and signs of torture or maltreatment: the medicolegal assessment should be always supported by an empathic communication with the patient, in order to help the victim to reveal sensitive issues from his/her past. Understanding and interpreting such stories gives forensic experts the opportunity to better assess the origin of the lesions.

Human Trafficking, Multidisciplinary Age Estimation, Scarification

E35 The Role of MicroRNAs (miRNAs) as New Molecular Biomarkers for Dating the Age of Wound Production: A Systematic Review

Stefania De Simone, MD*, Department of Clinical and Experimental Medicine, University of Foggia, Foggia, Puglia, Italy; Elena Giacani, MD, Department of Clinical and Experimental Medicine, University of Foggia, Foggia, Puglia, Italy; Maria Antonella Bosco, MD, Department of Clinical and Experimental Medicine, University of Foggia, Foggia, Puglia, Italy; Francesco Sessa, MS, PhD, Department of Clinical and Experimental Medicine, University of Foggia, Foggia, Puglia, Italy; Giuseppe Bertozzi, MD, Department of Clinical and Experimental Medicine, University of Foggia, Foggia, Puglia, Italy; Luigi Cipolloni, MD, Department of Clinical and Experimental Medicine, University of Foggia, Foggia, Puglia, Italy; Raffaele La Russa, MD, Department of Clinical and Experimental Medicine, University of Foggia, Foggia, Puglia, Italy

Learning Overview: After attending this presentation, attendees will have a better comprehension of the multiple tools to date the age of wounds in forensic diagnostics.

Impact Statement: This presentation will impact the forensic science community by providing a systematic review on the use of immunohistochemical and biochemical techniques to estimate the age of wounds. Moreover, this presentation aims to suggest a new study hypothesis on the role of miRNAs as new molecular biomarkers for dating the age of wound production.

Determination of wound vitality in perimortem injuries and the interpretation of the chronological sequence of events is an important part of forensic work. Antemortem wounds show tissue reaction and consist essentially of acute inflammation. Then, the inflammatory process involves many biochemical molecules (such as miRNAs) and cells (such as neutrophil and mononuclear cell).¹

Many parameters have been studied to assess the vitality or timing of a skin lesion, including histological (presence of erythrocytes outside the vessels in tissue samples) and immunohistochemical (expression of various inflammatory molecules at different times, such as Selectin E, Selectin P, Cathepsin A and D, fibrin, IL-1 β , and others) factors.² Nevertheless, this challenge remains open for the forensic community: the identification of the exact moment when the lesion occurs could be very useful in several forensic cases. This literature review aims to analyze the state-of-the-art regarding the estimation of the wound's age, focusing on the use of miRNAs.

MiRNAs are small, non-coding RNA molecules (containing approximately 22 nucleotides) that target genes in a sequence-specific manner to modulate gene expression, mainly by degradation of mRNA or repression of expression.³ MiRNAs are stable and resistant to degradation. These characteristics make miRNAs potential biomarkers in the forensic practice of identifying antemortem and postmortem wounds, and also for dating lesions.⁴ MiRNA are extensively involved in the development of the skin, including epidermal cell proliferation, differentiation, aging, and hair follicle development⁷. MicroRNAs perform special functions in maintaining living cells after death. Therefore, miRNAs continue to be expressed after death, so they can provide important information.¹

Some databases, from 2000 to June 2019, were searched: MEDLINE®, Cochrane Central, Scopus®, ScienceDirect®, and Google® Scholar, using the following keywords: “miRNA,” “wound healing,” “wound age postmortem.” The main keywords were individually searched in association with each of the others.

Several miRNAs were investigated; miRNA-205 and miRNA-21 in particular were often studied. MiRNA-205 has a role in both normal development and cancer and is also highly expressed in healthy skin.¹⁻⁶

MiRNA-21 plays a crucial role in many biological functions and diseases, including development, cancer, cardiovascular diseases, and inflammation. Its production is induced by injured skin and promotes wound healing.⁵

In some studies, the expression of these miRNAs is higher 24 hours after death. Normally, after death, degradation of the cells and their components begins. Similarly, the expression of genes also decreases constantly. The miRNAs studied, on the other hand, are expressed continuously, even 48 hours after death, although at lower concentrations¹. However, the pattern of degradation of miRNAs after death has not been demonstrated. So this review would like to propose the study of postmortem decrementing of miRNAs so their concentration can be correlated to the estimation of wound production time.

In conclusion, the identification of new tools for wound age estimation represents an important challenge for the scientific community. There are few studies in molecular biology. In the past few years, several studies highlighted the role of miRNAs as a highly accurate diagnostic tool. It is important to accurately date the time of production of a wound because it is useful information in the forensic pathologic practice.

Estimating Wound Age, MiRNA, Postmortem Investigation

E36 The Dirty Truth: Does Bathing After Sexual Assault Prevent the Development of Combined DNA Index System (CODIS) -Eligible DNA Profiles?

Emily Black*, Brigham Young University, Provo, UT; Samuel Payne, Brigham Young University, Provo, UT; Julie Valentine, Brigham Young University, Provo, UT

Learning Overview: Attendees will have a better understanding of the importance of all victims getting tested after sexual assault, regardless of circumstantial factors that may have once prevented them from doing so.

Impact Statement: This presentation will impact the forensic science community by presenting the association between developing CODIS-eligible DNA profiles with bathing and time elapsed between assault and examination.

Victims of sexual assault are helped in the criminal justice system by the collection of physical evidence to help identify and convict assailants. DNA is collected from body swabs and reported through sexual assault kits that can then be used to attempt the creation of a CODIS profile. Due to financial or logistic limitations, not every kit is processed and not every swab is tested—sometimes this information is collected and stored for years or even thrown away.¹ For example, cases in which the victim bathed between the assault and the exam are sometimes not tested due to the belief that none of these cases will result in the development of a CODIS-eligible DNA profile.² Past studies have shown that it is untrue that bathing removes all traces of DNA.³

This study examined bathing in relation to time elapsed between assault and exam. It was seen that bathing was strongly associated with time elapsed, with a greater percentage of victims bathing with longer stretches of time between assault and examination. While there was a decrease in eligibility rates for victims who had bathed prior to their exam, some cases still developed profiles after swabs were taken after longer periods of time (up to eight days) and bathing.

The goal of this study is to encourage victims to get tested after sexual assault, regardless of factors that may have originally discouraged them to do so. In the future, these results could impact which cases are submitted for DNA testing, leading to a higher likelihood of victims receiving justice after suffering sexual assault.

CODIS-Eligible STR DNA Profile, Sexual Assault Medical Forensic Examination, Sexual Assault Kits

E37 Increased Sexual Assault Kit Submissions May Not Mean Increased Sexual Assault Prosecutions

Julie Valentine, PhD, Brigham Young University, Provo, UT; Leslie Miles, DNP, Brigham Young University, Provo, UT; Connor Alder, Brigham Young University, Provo, UT; Luke Johnson, Brigham Young University, Provo, UT*

Learning Overview: After this presentation, attendees will have increased knowledge about the current relationship between Sexual Assault Kit (SAK) submission rates and sexual assault prosecution rates.

Impact Statement: This presentation will impact the forensic science community by providing information comparing increases in SAK submission rates with stagnant sexual assault case processing.

With the discovery of thousands of untested SAKs throughout the United States, research on submission rates of SAKs was conducted in many areas of the United States.¹ The findings of hundreds of thousands of unsubmitted SAKs led to new legislation and policies to submit previously untested SAKs to crime laboratories for analysis. In addition, many jurisdictions also enacted legislation and policies to submit and test all SAKs to avoid future backlogged SAKs. Substantial funding and resources have supported this change to submit and test all SAKs.

The impact of submitting and testing all SAKs on sexual assault prosecution case outcomes should now be evaluated. The purpose of this presentation is to explore the question, “Do increased SAKs submission rates lead to increased sexual assault case prosecutions?”

This study implemented the National Institute of Justice Sexual Assault Nurse Examiner Toolkit on Criminal Case Outcomes in two counties in a United States Mountain-West state to evaluate criminal case outcomes in adult sexual assault cases in which victims had fully collected SAKs and chose to interview with law enforcement for case prosecution.² The Toolkit study findings on sexual assault case prosecution outcomes were then compared with SAK submission rates during the same time period (2010–2017).

Between 7% to 10% of sexual assault cases in which victims had fully collected SAKs and requested criminal justice system involvement to investigate and prosecute their cases were successfully prosecuted (plea bargain or trial with conviction). These prosecution percentages stayed fairly constant from 2010 to 2017. Yet, during this same time period, submission and testing rates of SAKs increased from 32% to 89% prior to state legislation mandating the submission and testing of all SAKs.

Resources and funding have been directed toward submission and testing of SAKs. Law enforcement agencies have significantly increased SAK submissions to the state crime laboratory, prior to state legislation mandating submission. Yet, case prosecution rates have remained very low. A shift to increasing resources to criminal justice systems is now recommended to decrease sexual violence and improve justice in adult sexual assault cases. Improving sexual assault case prosecution rates remains an elusive goal, even with increased testing of SAK evidence.³

E38 The Detection and Determination of the Levels of Physiologically Active Substances in Non-Alcoholic Beverages

Amarnath Mishra, PhD*, Amity Institute of Forensic Sciences, Amity University, Noida, UP, India; Akanksha Behl MSc, Amity Institute of Forensic Sciences, Amity University, Noida, UP, India

Learning Overview: The main purpose of this work was to detect the variation in the amount of the ingredients present in popular drinks and how it is a prevalent public health issue.

Impact Statement: In the present study, a variety of different parameters were considered, including caffeine, artificial sweeteners such as aspartame, acesulfame potassium, and saccharin, insecticides, and pesticides as well. This study was conducted with the objective of analyzing the quality, safety, and efficacy of the beverages available on the market. This study also shows how some products are mislabeled and misbranded when it comes to the allowed limit of such additives.

Non-alcoholic drinks such as energy drinks, ginger ale, and tonic water drinks have gained immense popularity over time. The most common ingredients present in these drinks are caffeine and artificial sweeteners. This experimental study was aimed at inspecting and determining the levels of ingredients present in these drinks.^{1,2} As these drinks claimed to be safe, they were also highly prone to adulteration and mislabeling.

Eight samples of these drinks were collected randomly, all belonging to different brands. They were subjected to chromatographic analysis; the High-Performance Liquid Chromatography (HPLC) method and the Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) method were utilized with Ultraviolet (UV) as a detector to determine the content levels of sugar, caffeine, and artificial sweetener, such as aspartame, acesulfame potassium, and saccharine.³ These samples were evaluated and the results were observed and noted consequently. The calibration standard (2.5mg/L, 5mg/L, 10mg/L, 25mg/L, 50mg/L, and 100mg/L) was prepared by diluting the above solution or already prepared stock solution with same diluent. Then 20µL of the calibration standard was injected in HPLC. However, out of eight samples, four samples failed the analysis as they contained the components over the limit of quantification according to the label information. The allowed detection limit of caffeine and aspartame in beverages is 25mg/kg. Levels of caffeine were found to be over the detection limit in samples 1,2,5, and 6 and the level of acesulfame K was found to be over the detection limit in sample 2.

Qualitative analysis was conducted to identify the presence of sugar in the beverages. Sugar was reported absent in only one out of the eight samples. Caffeine has been reported to cause toxicity and, forensically, there are special populations that must be perceived as being at a greater hazard risk.⁴ Energy drink ingestion could be a potential wellbeing hazard for the general populace, due to the high caffeine dosages. Aspartame metabolites have been reported to cause adverse side effects, including headache, memory-related problems, mood issues, and depression.^{5,6}

A variety of different parameters were considered, including caffeine, artificial sweeteners such as aspartame, acesulfame potassium, and saccharin, insecticides, and pesticides.^{7,8} This study was performed to analyze the quality, safety, and efficacy of market-available beverages and shows how some products are mislabeled and misbranded regarding the allowed limit of such additives.⁹ Previously, some drinks were under controversy as their ingredients were causing an opposing effect on the body, and have failed to conform to the standards. In the marketplace, most energy liquids available have been loaded with sugar, caffeine, and extra calories. The dangers related to their uncontrolled usage had to be highlighted.¹⁰⁻¹²

Food Forensics, Caffeine Toxicity, Energy Drinks

E39 Improving the Signal Detection Limit of a Portable Raman Spectrometer for Surface Enhanced Raman Spectroscopy (SERS) Detection of Gunshot Residue (GSR)

Megan Harper, BS, Towson University, Towson, MD; Dariush Aligholizadeh, BS, Towson University, Towson, MD; Lynn Krushinski, BS, Towson University, Towson, MD; Mary Devadas, PhD, Towson University, Towson, MD; Ellen Hondrogiannis, PhD, Towson University, Towson, MD*

Learning Overview: Presentation attendees can expect to learn: (1) the usefulness of SERS on a portable spectrometer for the screening of Ethyl Centralite (EC) and Sphenylamine (DPA) in smokeless powders recovered from GSR (or Improvised Explosive Devices [IEDs]); (2) how the analytical figures of merit for EC and DPA such as Signal Detection Limit (SDL), Limit Of Detection (LOD), accuracy, precision, and linearity are affected by the presence of Nanoparticles (NPs); (3) data analysis using Origin® software for normalizing, baseline correcting, and comparing spectra; (4) advantages and disadvantages of incorporating portable SERS with Scanning Electron Microscopy/Energy Dispersive X-ray Spectroscopy (SEM/EDX) for the confirmation of both the organic and inorganic components; (5) the type, size, and shape of NP that shows the most enhancement of the DPA and EC signals; and (6) recovery of DPA, EC, and NPs from the screening solution.

Impact Statement: This presentation on the effect of SERS on improving the detection limit of organic components of GSR will impact how the forensic science community approaches firearms, and possibly IED-related evidence at crime scenes. The goal is to inform experts about the usefulness of a portable Raman spectrometer as an alternative means for screening GSR in the field to eliminate unnecessary evidence collection followed by costly and time-consuming analysis with SEM/EDX in case that the screening test is negative. Firearm purchases have soared during 2020, implying that there may be an increase in upcoming gun-related homicides with data showing higher rates of gun-related homicides in states with higher levels of firearm ownership.^{1,2} Thus, there is a resulting need for more rapid analysis of evidence indicating a gun was fired.

Incorporating this SERS analysis will allow laboratories to focus more on evidence that is presumptively positive, resulting in faster turnaround times for presumptive positive samples and shorter times for prosecuting cases. Faster prosecution leads to faster apprehension of a criminal before they can carry out another crime. Since many laboratories have already stopped carrying out GSR testing, the proposed prescreening will help lighten the load on the laboratories carrying out the confirmatory analysis, and they will subsequently be able to absorb the casework from laboratories that no longer test for GSR.

The portability and simplicity of the Raman spectrometer ensures that rapid screening can be carried out, with minimal training, by law enforcement. Also, Raman analysis is cheaper and simpler than SEM/EDS. This study proposes that this test is more accurate than a color test since it will define an instrument signal and analyte LOD that can be presented in a court of law to make interpretation and presentation of the results less subjective.^{3,4} This study also aims to lay the groundwork for future research on the use of a portable microscope Raman for single particle analysis to measure both the organic and inorganic compounds and show its potential as a viable option for GSR confirmation. Finally, this presentation will provide experts with an idea of how sensitive these portable instruments are and the practicality of using them at crime scenes.

The current confirmatory technique for GSR, SEM-EDX is costly and time consuming.¹ In addition, it does not account for changing propellant formulations. While a variety of different techniques have been studied for the analysis of inorganic and organic components, many are still costly and/or time-consuming.²⁻⁶ Raman spectroscopy offers a viable alternative because it is inexpensive, user-friendly, requires minimal sample preparation, has short run times, and can be portable for use at crime scenes. In addition, it can couple with a microscope for single particle analysis and detect both the organic and inorganic components. Advances of Raman analysis of GSR have been summarized, and the usefulness of the portable Raman in analyzing forensic samples has been noted.⁷⁻¹² Major drawbacks of Raman spectroscopy, particularly portable Raman spectroscopy, are its low sensitivity and lack of chemical libraries. SERS overcomes low sensitivity by using metal NPs to enhance the analyte's signal via chemical or electromagnetic enhancement.^{13,14} This is particularly useful for the detection of forensically relevant trace evidence.¹⁵ The current study examined the effect that two different NPs, iron-cobalt and iron-cobalt with gold, have on the LOD of DPA and EC on a Progeny® X2 Rigaku portable Raman spectrometer. While López- López et al. illustrated the usefulness of measuring organic compounds in smokeless powders using a gold substrate and Raman microscopy, these authors carried out their work on thin films, whereas the current work is carried out in solution.¹⁶ Solution analysis allows for minimal preparation time and eliminates the issue of non-homogeneity that would exist in solid samples. In addition, the surface of NPs can more easily be modified with ligands that selectively interact with analytes, thereby increasing the local analyte concentration, which helps avoid pyrolysis and ignition of gunpowder that may occur on films by dissipating the laser energy. Peak height, Full Width at Half Maximum (FWHM), peak area, and peak position were calculated for solutions of DPA and EC in a 1:100 (v/v) ODCB:Hexanes solution ($n=7$). These same analytical figures of merit were then calculated for the same solutions to which iron-cobalt NPs ($n=3$) were added. Excel® and OriginPro® 2021 software were used to process the data. The calibration curves for peak area and peak intensity versus concentration (up to 300mM) gave R² values greater than 0.99. The SDL, Limit Of Quantitation (LOQ), and LOD were lowest for DPA at 1,604 wavenumbers (cm⁻¹) and EC at 1,003cm⁻¹. The addition of 1µL of iron-cobalt NPs to the DPA and EC solutions resulted in statistically significant changes in peak intensity, peak area, and FWHM for at least one of the DPA and EC peaks. The statistical significance was calculated using a p-test with a significance level of 0.05. This same data will also be reported for solutions containing DPA and EC in the presence of iron-cobalt with gold NPs. A library of the DPA and EC peaks obtained with this portable Raman spectrometer and their relevance for GSR analysis will be reported, in addition to the effect that the NPs have on each peak. Finally, the percent recovery of DPA, EC, and the NPs will be reported so the scientific community understands how the integrity of the probative sample is maintained as well as the potential of this low-cost analysis due to the reusability of the NPs.

Gunshot Residue, Nanoparticles, Raman

E40 A New Method for the Preservation of Forensic Fragrance/Odor Evidence for Future Analysis using Gas Chromatography/Mass Spectrometry (GC/MS)

Rylee Bosse*, Seattle University, Seattle, WA; Susannah Sherwood, Seattle University, Seattle, WA; Mariah Fernandez, BS, Seattle University, Seattle, WA; Aspen DeGoller, BS, Seattle University, Seattle, WA; Chesterene Cwiklik, BS, Cwiklik & Associates, Seattle, WA; Kristen Skogerboe, PhD, Seattle University, Seattle, WA

Learning Overview: Attendees will gain a greater understanding of the issues associated with the collection of fragrances/odors on forensic evidence as well as knowledge about a method to preserve this information for future analysis.

Impact Statement: This presentation will discuss the development of a low-cost method to aid in the collection and preservation of volatile trace evidence without disrupting existing DNA evidence.

When fabric/clothing is collected from a crime scene, it is stored in paper evidence bags. This storage method is not airtight, which allows moisture to dissipate and prevents molding. Mold on a sample can degrade DNA evidence, limiting its effectiveness and compromising evidence.¹ Even if an analyst was to detect a fragrance/odor on a piece of evidence, without an effective method to preserve that scent, storage in a paper bag would lead to the eventual dissipation of volatile components. Because DNA is so individualizing, maintaining its integrity will take priority over capturing volatile trace evidence. While DNA is often the most important piece of evidence collected at a crime scene, analysis of other chemical constituents of/on the sample could aid in the investigation.

The goal of this research is to demonstrate a non-destructive method that will allow investigators to collect and preserve fragrance/odor trace evidence without compromising the integrity of any DNA present on the sample. By placing an activated charcoal strip inside the paper evidence bag, investigators can preserve the evidence for future analysis. Activated charcoal strips are typically used in arson investigations for the collection and preservation of volatile components.² These strips have been validated and are conventionally used when headspace analysis is not available.

In this study, common fragrances that are readily available in drug or grocery stores were pipetted onto fabric samples of different types (cotton and polyester) with methyl nonanoate as an internal standard. Samples were then placed in both paper bags and in paint cans as a reference for airtight conditions, analogous to arson investigations. An activated charcoal strip was included with each sample for the collection of the fragrance trace evidence. Samples were stored at room temperature for 48 hours and for a month before the strips were removed and placed in airtight vials and stored in the freezer for future analysis, occurring up to nine months later.

Analysis was conducted using Solid-Phase Microextraction (SPME) GC/MS, both directly and with half a mL of ethyl ether as solvent.³ Results showed that at 48 hours post collection, the fragrances were readily detectable and distinguishable, both in bags and cans. Samples left in bags for one month showed some detectable peaks, but many had dissipated, and the fragrance chromatographic profile was no longer identifiable. Ongoing studies are being conducted to analyze samples after one week, rather than one month, to determine how long fragrances/odors persist under these conditions. Similar to the literature, differences were observed in the retention of odors based on fabric type.⁴ It was concluded that a model system for capturing and preserving fragrances/odors on forensic evidence has been developed and is undergoing further evaluation. Forensic evidence collection utilizing this low-cost additional step of adding an activated charcoal strip to preserve scent trace evidence is a promising practice for future investigations.

Fragrance/Odor, SPME-GC/MS, Forensic Evidence Preservation

E41 A Chemometrics Study for the Forensic Evidence Classification of Pet Foods Using Solid-Phase Microextraction-Gas Chromatography/Mass Spectrometry (SPME-GC/MS)

Susannah Sherwood, Seattle University, Seattle, WA; Rylee Bosse, Seattle University, Seattle, WA; Hazel Tran, BS, Seattle University, Seattle, WA; Anna Tran, BS, Seattle University, Seattle, WA; Aspen DeGolier, BS, Seattle University, Seattle, WA; Mariah Fernandez, BS, Seattle University, Seattle, WA; Luke Marney, PhD, Seattle University, Seattle, WA; Kristen Skogerboe, PhD, Seattle University, Seattle, WA*

Learning Overview: Attendees will be familiarized with current chemometrics techniques for the analysis of large chromatographic datasets, applied to the forensic classification of mock forensic evidence in the form of dry pet food.

Impact Statement: This study demonstrates that pet food evidence can be classified with SPME-GC/MS data, when combined with multivariate methods such as Principal Component Analysis (PCA) and evaluates the success of classification for both fresh and aged samples.

Pet food and other dry foodstuffs containing protein and grain ingredients have been a source of evidence in previous forensic cases, raising the question of whether such evidence can be classified to its correct brand and make.¹ SPME in combination with GC/MS allows for the detection of several volatile constituents in these non-perishable foodstuffs; however, differences between type and brand of pet food may be difficult to distinguish and quantify based on visual inspection of chromatograms alone.² Chemometrics methods, such as PCA, may provide a solution to this issue: large chromatographic datasets can be plotted in two or three dimensions for simple visualization, allowing for assignment of unknowns to a known class.³

This study demonstrates the potential of PCA for identification of the brand and type of several classes of commercially available pet food. Four types of dog food were used, two of them—denoted as “Puppy” and “Adult,” respectively—sourced from the same manufacturer and containing the same primary protein source (chicken) as their first ingredient. The other two types of dog food were both from different manufacturers and contained different primary protein sources (beef and buffalo, respectively). Ongoing studies are being conducted to add additional replicates, as well as additional classes that are sourced from different manufacturers and have different primary protein sources.

For each run, kibble was aliquoted to an SPME vial and analyzed with GC/MS. Samples were run fresh out of the bag, one week after the bag was opened, and two weeks after the bag was opened. Of over 30 peaks, 16 were selected and identified for further analysis. Of these, some constituents were present in some samples, and some were present in only some of the samples or classes. A 2D PCA plot shows clear clustering between class when samples are assigned to class independent of freshness, with slight overlap between the “Adult” and “Puppy” classes.

Twelve “unknowns” were compared to the training set using a k-Nearest Neighbors (k-NN) classification algorithm, using $k=7$ and determining the closest points to the unknown with a Euclidean distance measure of the first three principal components. Only one misclassification occurred: “Puppy” taken fresh out of the bag was incorrectly classified to “Adult.” Therefore, classification of an unknown to brand and specific make had a success rate of 91.67%, while classification to manufacturer had a success rate of 100%.

While this combination of statistical methods demonstrates success in classification of samples by manufacturer, other analytical methods may be needed to classify samples temporally as they change after being opened. Additional investigation of whether individual samples could be classified to assess their age was conducted; however, the success rate of determining week of origin for a specific type of dog food ranges from 33% to 67% with a similar k-NN algorithm ($k=3$). Despite this limitation, this model study establishes that this combination of analytical techniques and statistical processing has promise for forensic classification of dry foodstuffs containing meat and/or grain ingredients.

Pet Food/Foodstuffs, SPME-GC/MS, Principal Component Analysis

E42 Magnetic Resonance Imaging (MRI) of the Skin: Research Hypothesis, Objectives, Limitations, and Postmortem Examples

Giuseppe Bertozzi, MD, Department of Clinical and Experimental Medicine, University of Foggia, Foggia, Puglia, Italy; Michela Ferrara, MD, Department of Clinical and Experimental Medicine, University of Foggia, Foggia, Puglia, Italy; Giovanni Gurgoglione, MD, Department of Clinical and Experimental Medicine, University of Foggia, Foggia, Puglia, Italy; Maria Antonella Bosco, MD, Department of Clinical and Experimental Medicine, University of Foggia, Foggia, Puglia, Italy; Francesco Pio Cafarelli, MD, Department of Clinical and Experimental Medicine, University of Foggia, Foggia, Puglia, Italy; Giuseppe Guglielmi, MD, PhD, Department of Clinical and Experimental Medicine, University of Foggia, Foggia, Puglia, Italy; Luigi Cipolloni, MD, PhD, Department of Clinical and Experimental Medicine, University of Foggia, Foggia, Puglia, Italy; Raffaele La Russa, MD, PhD, Department of Clinical and Experimental Medicine, University of Foggia, Foggia, Puglia, Italy*

Learning Overview: The aim of this feasibility study was to investigate the potential role of *ex situ* MRI of the skin after formalin fixation in cases of traumatic death.

Impact Statement: This presentation will impact the forensic science community by demonstrating the ability to study an *ex situ* fixed-skin sample for forensic purposes with a MRI protocol.

Having been previously overlooked and considered with poor clinical interest, MRI is gaining more and more interest for forensic pathology. This deficiency has to first be linked to a lack of conspicuous data about the relationship between postmortem changes and MRI signal meaning, in addition to the lack of MRI machines in forensic units, so MRI scanners have to be shared with clinical imaging units; the lengthy time of acquisition for the examination from several minutes to an hour for MRI (versus seconds to a few minutes for Computed Tomography [CT], as forensic institutes are likely to have CT rather than MRI scanners); and last but not least, the cost.

This is even more true when it comes to skin, considering that even in the clinical setting it is reserved for a few centers of excellence. However, MRI of the skin could be an innovative diagnostic tool available for tissue characterization in forensics. Although it is difficult to draw up a systematic description of the architecture of the subcutaneous tissue and try to achieve high-quality images of this little structure, above all from postmortem samples, the study hypothesis arises as consequence of the great resolution of contrast of the MRI.

The simplest and most widespread method of evaluating skin lesions has always been the “naked eye” observation, which involves the bias of inter-observer variability (such as the squeezing appraisal of hypostasis after thumb pressure). However, this macroscopic method of evaluation does not always allow the characterization of the tissue/injuries, except with subsequent histological, histochemical, and immunohistochemical investigations. The aim of this study is to present the possible use, through literature review, of MRI in *in vivo* skin examination and analysis. Moreover, samples of *ex vivo* skin explanted and placed in formalin solution underwent a basic and rapid MRI protocol, performed with 1.5 T scanner. Two readers completed image analyses after randomization, blinded to cause of death, in order to recognize the simple tissue architecture of the skin. After having adequate imaging protocol of the normal skin, skin samples of wounds collected during autopsy of traumatic deaths (shotgun injuries, blunt lacerations, and penetrating injuries) were also investigated, in order to identify signal alterations useful for the identification of lesions.

Postmortem Magnetic Resonance Imaging, Skin Imaging, Skin Injuries

E43 The Development of a Rapid Drug Detection Method for Insects Using Paper Spray Ionization-Mass Spectrometry (PSI-MS)

Alexandria Plyler, BS, Duquesne University, Pittsburgh, PA*

Learning Overview: Attendees of this presentation can expect to learn about a toxicological method that, per research, contains a novel combination of methods and instrumentation. Forensic entomotoxicology is still a relatively underdeveloped field, making its study in an academic setting important should it ever be implemented in the field.

Impact Statement: PSI-MS as an analytical technique offers great advantages to not only forensic toxicology, but to forensic chemistry and trace evidence professions as well. Its ability to detect analytes with minimal sample preparation without sacrificing sensitivity or specificity can make it a valuable tool by which crime labs can combat the evidence backlog.

Insects have the ability to reflect the chemical environment in which they have developed. Thus, necrogenous insects can reflect the chemical environments of the cadavers on which they have fed. In cases where cadavers are skeletonized, burned, or otherwise too badly damaged for tissues to be collected, forensic scientists can potentially utilize insect larvae as an alternate toxicological matrix to detect drugs in cadavers.^{1,2} Traditional techniques for drug detection by Gas Chromatography/Mass Spectrometry (GC/MS) and/or Liquid Chromatography/Mass Spectrometry (LC/MS) often involve lengthy sample preparation, use expensive reagents, and are destructive to important evidence. This poses a problem for crime labs who do not possess the time, funding, or resources to perform such techniques.

Analysis of insects using PSI-MS, an analytical method requiring little-to-no sample preparation, could provide a rapid, cost-effective, and non-destructive alternative form of toxicological analysis. PSI-MS has the distinct advantage of being an ambient ionization technique, allowing for the running of insect samples with virtually no sample preparation at STP without sacrificing sensitivity and specificity. In addition, the use of disposable paper triangles during PSI-MS analysis greatly reduces sample carryover between runs.³

To validate a PSI-MS method for insects, several different extraction techniques for drug detection in the model insect *T. molitor* were explored. *T. molitor* larvae first fed on a substrate spiked with Phenethylamine (PEA), a surrogate for illicit monoamine drugs such as methamphetamine and MDMA. Various extraction techniques were then explored, including ethanol extraction, methanol extraction, and Quick, Easy, Cheap, Effective, Rugged, and Safe (QuEChERS) extraction. In addition, a novel “bug-spray” technique that bypassed insect sample preparation entirely was investigated. By employing each extraction method and analyzing the insect samples using PSI-MS with Collision Induced Dissociation (CID), the most time-efficient, cost-effective, and reliable detection method was developed. The successful implementation of PSI-MS in a forensic setting can pose a useful tool for combating the evidence backlog due to its rapid nature. The ability to study the chemical content of an insect’s environment could have significant potential not only in forensic science, but in conservation studies and the environmental sciences as well.

Mass Spectrometry, Entomotoxicology, Entomology

E44 An Examination of Lipstick Stains Via Fourier Transform Infrared (FTIR) Spectroscopy and Chemometric Methods

Vishal Sharma, PhD, Institute of Forensic Science & Criminology Panjab University, Chandigarh, UT, India*

Learning Overview: Attendees will learn about the analysis of trace evidence like lipstick stains and its analysis if found at the crime scene through the FTIR technique. The analysis of this chemical data is done through chemometric methods and hence the application of such evidence will be shown as the original study.

Impact Statement: For the past decade, there has been a surge in the research work related to the use of chemometric in the analysis of chemical data generated through spectroscopic or chromatographic techniques. Trace evidence has seen the application of chemometric methods combined with analytical techniques for characterization and discrimination of samples, which leads to the informative and representative examinations of samples. This presentation will discuss the examination of cosmetic stains (i.e., lipstick stains) recovered from the crime scene. It is suggested that these new techniques and mathematical/statistical methods are having a statistical significance and are hence highly suitable for forensic casework related to cosmetic forensics.

Among all the cosmetic products, lipsticks are the most commonly used cosmetic product by females worldwide. The composition of lipstick includes inorganic and organic constituents.^{1,2} In comparison to other cosmetic products, lipstick stains are the most easily transferred in various types of crimes like rape, sexual assault, murder, child abuse, child trafficking, burglary, and homicides. They may also be found on various other substances like cigarette butts, glasses, clothes, tissue paper, skin, etc. The prevalence of lipstick stains reveals physical contact between the victim and the criminal. Therefore, lipstick stains are considered to be a piece of crucial evidence present at the crime scene. In the present work, 25 lipstick samples are characterized and discriminated using Attenuated Total Reflectance (ATR) FTIR spectroscopy coupled with chemometric and statistical methods.³ This approach is non-destructive, fast, accurate, and provides reproducible results. The FTIR spectra demonstrated that lipstick stains comprised of various aliphatic and aromatic compounds (e.g., propyl ester of hexanoic acid, silicates, etc.) Further, the discrimination power was calculated using three approaches: visual examination, cluster analysis (Hierarchical Cluster Analysis [HCA] and k-means), and factor analysis methods. The multivariate method combined with t-statistics delivered a higher value of discriminating power (i.e., 100%), which is an improvement over the 99.00% discrimination power of the visual comparison method. The validation of the developed method is done on the basis of predicting unknown samples to their respective brands. The effect of heating (600°C and 700°C) on lipstick stains was also studied. This study establishes a method that provides proof of concept discrimination of lipstick samples. This research can be highly beneficial when it comes to the analysis of trace evidence like lipstick stains encountered at the crime scene. The likelihood of developing a database of lipstick samples using this approach for identifying unknown samples makes it a more important and effective method.

Lipstick, IR Spectroscopy, Chemometric

E45 Multiplex Reverse Transcription Polymerase Chain Reaction (RT-PCR) on a Centrifugal Microfluidic Platform for Field-Forward Messenger RNA (mRNA) Body Fluid Profiling

Renna Nouwairi, BS, University of Virginia, Charlottesville, VA; Tiffany Layne, PhD, University of Virginia, Charlottesville, VA; Rachel Fleming, PhD, Institute of Environmental Science and Research Ltd, Sandringham, Auckland, New Zealand; M. Shane Woolf, PhD, University of Virginia, Charlottesville, VA; James Landers, PhD, University of Virginia, Charlottesville, VA*

Learning Overview: After attending this presentation, attendees will have been introduced to a novel rotationally driven microfluidic device that integrates rapid amplification via multiplexed RT-PCR, electrophoresis, and fluorescence detection to detect and differentiate forensically relevant body fluids.

Impact Statement: This presentation will impact the forensic science community by demonstrating a cost-effective, rapid, portable platform for the detection of mRNA targets present in individual body fluids to identify and contextualize potentially probative evidence.

Forensic body fluid identification is a crucial aspect of criminal investigations that informs subsequent DNA analysis.¹ Unfortunately, this process is rarely straightforward as body fluids of interest are often present in small quantities or mixtures. Conventionally, presumptive assays, though rapid and simple, exhibit poor sensitivity and/or specificity; subsequent confirmatory tests involve time-consuming microscopic or immunological analysis that require operation of complex instrumentation by trained analysts.² Among recently emerging alternatives, transcriptomics, or the analysis of RNA, is especially appealing given its amenability for integration into the traditional forensic workflow without compromising the DNA available for analysis.³ However, conventional instrumentation for RNA-based body fluid identification involves massively parallel sequencing or amplification via RT-PCR—time- and labor-intensive techniques that remain largely tethered to centralized laboratories and require highly skilled operators.⁴ As such, the forensic community needs an accurate, portable, sample in-answer out platform that integrates multiple steps (e.g., sample extraction, amplification, electrophoretic separation, and detection) for rapid body fluid identification in the field.

Portable microfluidic systems offer numerous advantages over traditional laboratory techniques, including decreased analysis times, required user intervention, reagent and sample volume requirements, and, ultimately, cost. Microfluidic systems are often readily amenable to use by non-technical personnel, possess enclosed formats that minimize the risk of contamination, and may integrate multiple assays that conventionally require individual benchtop instruments. Here is described one such centrifugal microdevice capable of performing automated RT-PCR amplification and downstream electrophoretic separation on a platform for rapid body fluid identification. Specifically, centrifugal microfluidic devices control fluid flow via rotation, eliminating the need for cumbersome external hardware, such as pumps and syringes, and thus, promoting portability and ease of automation.⁵

The reported rotationally driven device represents significant progress toward development of a miniaturized Total Analysis System (uTAS) capable of performing automated, multiplexed RT-PCR and electrophoretic separation with minimal user intervention. The proposed system reduces the overall time-to-result relative to benchtop instrumentation by leveraging the accelerated PCR kinetics that occurs when working at the microscale.⁶ Specifically, total reaction scale was reduced and the surface area-to-volume ratio was drastically increased, enabling the 2-hour RT and 3.5-hour PCR steps to be reduced to ten minutes and one hour, respectively. Multiplexed amplification for differentiation of mixed composition samples was demonstrated using previously validated panels for the target body fluids, including saliva, venous blood, menstrual blood, vaginal fluid, and semen.⁷ Future work aims to incorporate automated co-extraction of DNA and RNA onto the microfluidic disc where RNA can be used for on-disc analysis and DNA is reserved for off-disc genetic testing. The work described presents significant progress toward a field-forward, sample in-answer out uTAS for a rapid, cost-effective body fluid identification instrument.

E46 Preliminary Perspectives of Environmental Conditions on Cocaine's Chemical Odorant Methyl Benzoate Via Dynamic Airflow Sampling

Ryan Thompson, BS, Texas Tech University, Lubbock, TX; Edgar O. Aviles-Rosa, PhD, Texas Tech University, Lubbock, TX; Nathaniel J. Hall, PhD, Texas Tech University, Lubbock, TX; Paola A. Prada-Tiedemann, PhD, Texas Tech University, Lubbock, TX*

Learning Overview: After attending this presentation, attendees will better understand the effects of controlled target odor delivery on the stability of cocaine's primary chemical odorant, methyl benzoate, when delivered into fluctuating environmental conditions.

Impact Statement: This presentation will impact the forensic science community by explaining the effects of controlled odorant airflow delivery into altering environmental conditions. The study focused on using cocaine's chemical odorant, methyl benzoate, under constant room conditions while the odor stimuli output was delivered into changing environmental conditions, depicting an evaluation of odor emission implications for canine detection.

Cocaine is one of the most used drugs in the United States, indicating the need for methods to detect cocaine quickly and accurately. One accepted method for narcotics detection is the use of canines, which are the most common bio-detectors for volatile odor signatures. These odor signatures are composed of Volatile Organic Compounds (VOCs) and are generally constituent compounds in the headspace above the narcotic sample. For example, methyl benzoate is widely accepted as the primary odorant VOC in the headspace of cocaine. Currently, there is a dearth of research as to the role of environmental conditions on canine performance; however, a tangential gap in literature lies in the effects of controlled target odor emission in these changing environments. Thus, the goal of this study is to first validate the olfactometer as an odorant delivery system, then to evaluate the stability of the target odorant as it is being delivered into fluctuating temperature/humidity conditions via a dynamic airflow sampling approach.

Pure methyl benzoate diluted to a 10^{-2} concentration in mineral oil was used as the cocaine odorant analog. The odor was extracted and analyzed with Solid Phase Microextraction (SPME) coupled to Gas Chromatography/Mass Spectrometry (GC/MS). The odor was delivered into an environmental chamber in a controlled amount at an odor/air dilution of 10^{-2} via an air dilution olfactometer, in which the odorant sample was kept at a constant condition of 36°C. The targeted conditions inside of the chamber were hot/humid, hot dry, cold humid, and cold dry. Extractions of the odor were performed by injecting the SPME fiber into the end of the olfactometer output line for 60 seconds while the target odorant was being delivered. The results showed that the air dilution olfactometer was able to deliver varying concentrations of methyl benzoate odor and the SPME-GC/MS methodology was able to detect these changes in concentration. Results depicted that the air dilution olfactometer successfully maintained similar methyl benzoate concentrations at the target odor port despite extreme changes in environmental conditions within the chamber. Despite extreme changes in environmental conditions within the chamber, there was no statistically significant impact on the concentration of methyl benzoate delivered to the target odor port.

SPME-GC/MS was determined to be a valid and reliable methodology for extracting methyl benzoate target odor stimuli. Furthermore, the olfactometer instrumentation proved to be a reliable odorant delivery system in which a consistent amount of methyl benzoate odorant was delivered to the output. However, this study did not find a statistically significant variation in the concentrations of methyl benzoate delivered to the olfactometer output line in different environmental conditions. This indicates that when the target odor source is kept at constant conditions, the concentration of odor emitted remains largely unaffected in the altered environment where it is emitted.

Cocaine, Odor, Environmental

E47 Exploring the Impact of Environmental Differences on Fiber Background Estimation in Forensic Investigation

Chimdia KeChi-okafor, MPhil, Northumbria University, Newcastle, Newcastle, United Kingdom*

WITHDRAWN

E48 Backlog Reduction by Implementing Shorter Gas Chromatography/Mass Spectrometry (GC/MS) Confirmation of Seized Drugs

Muhammad Chaudhary, MPhil, Punjab Forensic Science Agency, Lahore, Punjab, Pakistan; Imtiaz Hussain, MPhil, Punjab Forensic Science Agency, Lahore, Punjab, Pakistan; Tahir Jamshaid, MPhil, Punjab Forensic Science Agency, Lahore, Punjab, Pakistan; Muhammad Amjad Nadeem, MPhil, Punjab Forensic Science Agency, Lahore, Punjab, Pakistan; Muhammad Irfan Ashiq, PhD, Punjab Forensic Science Agency, Lahore, Punjab, Pakistan; Mohammad Tahir, PhD, Punjab Forensic Science Agency, Lahore, Punjab, Pakistan*

Learning Overview: This presentation will help attendees understand the use of a shorter and robust confirmation method for the most commonly encountered seized materials which, in turn, helps to control backlogs.

Impact Statement: The forensic science community will be able to identify the key steps of analysis that can be shortened effectively for the analysis of seized materials. Furthermore, attendees will be able to compare the work efficiency in pre- and post-implementation scenarios.

Forensic testing laboratories usually face the problem of increasing backlogs due to an increased influx of cases of seized drugs. Laboratories use various methods for controlling backlogs, such as efficient division of labor, increased work force, use of rapid analysis techniques, and increased work hours. Strategies for micro- and macro-administration are required to control increased workloads. Being an immediate neighbor to Afghanistan, increased trafficking and seizure of controlled substances is very common in Pakistan. In Pakistan, cannabis and cannabis products (cannabinoids) comprise nearly 92% of total seizures in a year. This study's laboratory identified that delayed analysis is one of the major causes of backlog build up. Cannabinoids are routinely reported based on the chemical spot test and validated GC/MS method having a total runtime of 12 minutes. Therefore, there was a need to develop and validate a new method with reduced runtime for rapid confirmation of cannabinoids.

Agilent® GC-7890A (DB-5MS-UI column 20m x180µm x0.18µm) coupled with MS-5975C was used in this study. A methanolic solution of cannabinoids (01 µL) was injected in GC-inlet (250°C) using split mode (50:1). Oven temperature was programmed initially at 200°C (1min) and then ramped to 50°C/minute, reaching a final temperature of 300°C (2min). Total runtime of the method was five minutes. MS was operated in scan mode ranging from 53-550amu. The method was validated for selectivity, limit of detection, reproducibility, and matrix effect as per United Nations Office on Drugs and Crime (UNODC) guidelines.

Major cannabinoids (THC, CBN and CBD) were selectively detected in 20 drug samples from different sources, including street samples and secondary standards with sufficient resolution and peak width. Limit of Detection (LOD) of the method was 80µg/ml. Even in the presence of adulterants, the method can be effectively used in routine forensic analysis of cannabinoids. No interference was observed with common adulterants and other controlled substances.

Based on this study, it was concluded that this method is sufficiently specific, selective, and reproducible with enough LOD that has reduced case analysis time up to 60% and improved case turnaround time.

Backlog, Cannabinoids, GC/MS

E49 Rapid Fentanyl Sensing Via Biochemical Assay

Giana Biddle*, Texas Tech University, Lubbock, TX; Jan Halamek, PhD, Texas Tech University, Lubbock, TX; Ashley Newland, Texas Tech University, Lubbock, TX

Learning Overview: After attending this presentation, attendees will understand the dangers of fentanyl and be introduced to a new method of fentanyl and opioid detection for use in both laboratory and field contexts.

Impact Statement: This presentation provides a novel, rapid method for the detection of the highly toxic opioid fentanyl.

Opioids are a class of compounds resembling opium in addictive properties or physiological effects. This class includes prescription pain relievers, heroin, and synthetic opioids such as fentanyl. In 2019, the United States alone saw nearly 50,000 deaths associated with opioid overdose.¹ Fentanyl and its analogs are of particular concern. While deaths involving heroin overdose have begun to decline, deaths involving fentanyl and other synthetic opioids have increased significantly.² The Drug Enforcement Administration (DEA) Field Divisions labeled fentanyl as “highly available” in 2018 and 2019, meaning drug seekers could easily obtain the substance at any time.²

Fentanyl is 50-100 times more potent than morphine and accounts for over half of opiate-related deaths.³ It is most commonly administered to treat pain after surgery, but illicit manufacturers across the United States and Mexico lead to the high availability of trafficked fentanyl and other opioids.^{2,3} Fentanyl and its analogs bind to opioid receptors in the blood and brain. Effects include euphoria, drowsiness, confusion, slowed or labored breathing, and loss of consciousness.³

With growing concerns around the use and sale of opioids, newer and safer methods of detection are required. At this time, law enforcement lacks an accurate and reliable method to detect the presence of these compounds in the field. Fentanyl is typically found as a white powder, resembling numerous other substances. To combat this growing issue, non-invasive, bioaffinity-based assays have been developed to detect the presence of opioids and other drugs. This simple system employs a biochemical reaction that elicits a color change visible to the naked eye. This assay is reprogrammable with different enzymes to detect different specific compounds.

The goal of this research is to identify and quantify fentanyl and its analogs on site. Fentanyl and other opioids inhibit butyrylcholinesterase activity. A decline in enzyme function is evaluated colorimetrically via Ultraviolet/Visible (UV-Vis) spectroscopy and a documented reporter reaction. This method is rapid, with results in 30 minutes, and sensitive to the analytes.

Preliminary trials have been performed in a laboratory setting; however, this method is deployable for use in the field. The enzymatic reaction can be bound to a portable strip, similar to the Enzyme-Linked Immuno-Sorbent Assay (ELISA) used in a pregnancy test. The colorimetric change can be compared to a set of known standards visually or quantitatively measured by a smart phone application. Similar strides have already been made by this research group with successful tests for the presence of ethanol and THC.^{4,5}

Drug Detection, Opioids, Field Deployable

E50 A Characterization of Metal-Peroxide Explosive Complexes Using Paper Spray Ionization-Tandem Mass Spectrometry (PSI-MS)

Kayla Massari*, Duquesne University, Pittsburgh, PA

Learning Overview: Attendees will learn about how the analysis of metal-peroxide complexes using PSI-MS allows the presence of these complexes to be detected and quantified in pre- and post-blast explosive residue.

Impact Statement: Organic peroxides have become a common agent in Improvised Explosive Devices (IEDs) because they are accessible for purchase and are susceptible to extremely exothermic reactions due to the instability of the peroxide bond.¹ IEDs have been used in acts of terrorism such as the Oklahoma City bombing and the Olympic Park bombing, and the detection of the explosive component is necessary in terms of eventually identifying the perpetrator who had the means and materials to make the IED.² Thus, a reliable and rapid detection method for organic peroxides commonly used in IEDs is of interest for the analysis of pre- and post-blast residue in forensic investigations.

The goal of this project is to develop PSI-MS with Collision-Induced Dissociation (CID) for detection, identification, and quantification of peroxide-based explosives. Benzoyl peroxide and dicumyl peroxide were used as model compounds. To complement experimental studies, Density Functional Theory (DFT) was used to determine probable ion structures. Benzoyl peroxide and dicumyl peroxide samples were spiked with lithium, sodium, and potassium alkali metal cations. The peroxides were also pipetted onto silver-impregnated filter paper. These samples were ionized utilizing the THERMO FISHER™LTQ-XL, and the fragmentation patterns of the peroxide-metal complexes were investigated using CID at the MS² stage. DFT calculations of ion structures were performed at the B3LYP/6-311+G(d) and B3LYP/MWB28/6-311+G(d) level of theory.

Initial experiments showed that both dicumyl and benzoyl peroxide form abundant complexes with Lithium Ion (Li⁺), Sodium (Na⁺), Potassium Ion (K⁺), and Silver Ion (Ag⁺) by PSI. In general, PSI produced 1:1 complexes between the peroxides and Li⁺, Na⁺, and K⁺. Studies completed with silver cations and both model peroxides showed that PSI will generate Ag⁺ complexes with one or two peroxide ligands. Because the silver-impregnated filter paper allowed for the Ag-peroxide complexes to form, it was determined that a swipe sampling method should be tested with the other metal-peroxide complexes. If this method is successful, it would allow a sample to be swiped from a surface using filter paper and analyzed using PSI with minimal sample preparation. Performance characteristics such as sensitivity and limit of detection are being determined and will also be reported.

Mass Spectrometry, IED, Peroxide-Based Explosives

E51 Determining the Method Threshold of Identification Via Gas Chromatography/Mass Spectrometry (GC/MS) of Weathered Gasoline Extracted From Laminate Flooring

Ellen Hondrogiannis, PhD Towson University, Towson, MD; Allyson Wesley, Towson University, Towson, MD*

Learning Overview: Attendees can expect to learn: (1) the mass/charge (m/z) of the ions that are most useful for the quantitative identification of gasoline target compounds identified in weathered gasoline extracted from laminate flooring; (2) the ratio of the base peak ion to qualifier ion 1 as well as the ratio of the base peak ion to qualifier ion 2 in gasoline target compounds in neat gasoline; (3) the percent of weathering above which the ion ratios fall outside the proposed threshold of acceptability; (4) the compounds present in laminate flooring that may interfere in the mass spectral identification of gasoline target compounds; (5) data analysis using Excel® on mass spectral data that the analyst already collects using American Society for Testing and Materials (ASTM) 1618; and (6) repeatability and reproducibility of this method.

Impact Statement: This presentation on determining the method threshold of identification of weathered gasoline samples extracted from burnt laminate flooring will impact the forensics community by providing the m/z of the ions that are most useful for the quantitative identification of gasoline target compounds identified in weathered gasoline extracted from laminate flooring. These m/z are chosen as the base peak (Q) and two quantifier ions (q_1 and q_2) whose ratios Q/q_1 and Q/q_2 fall within a defined limit relative to the same ion ratios identified in the same compounds in neat gasoline. The compounds from the matrix will also be presented as well as their impact on the identification of the gasoline target compounds using this method. The community will learn how to collect this data from data they are already collecting as part of their ignitable liquid analysis using ASTM 1618.

While the effect of weathering on overall pattern identification is well documented, there is no explicit way to determine if a sample is too weathered to be identified as an ignitable liquid. This is up to the discretion of the analyst. While several studies have offered data for probability matching, none outline the limit of detection procedures that should be used to validate the studies. The lack of investigation to determine a quantifiable identification limit when samples are heavily weathered has left a gap in experimental design.

Through studying the effects of weathering and matrix interference on the ion ratios of the target compounds, this work illustrates the use of ion ratios to definitively identify the compounds and thus to establish a threshold below which the analyst can state the compounds are not present in heavily weathered samples extracted from burnt laminate flooring. This method may be used to optimize GC/MS instrument analysis, allow for comparison of data between instruments, and eventually allow a minimum threshold of identification to be set and become part of Quality Assurance programs. Additionally, by incorporating ion ratios into the identification process, analysts will be able to go beyond pattern matching and instead use an identification process that relies on quantifiable data, limiting subjectivity.

Identifying ignitable liquids is a key step in analysis for an arson investigation. The identification of an ignitable liquid at an arson scene not only helps to determine the cause of the fire but also if the fire was started purposefully. The most common ignitable liquid found at arson scenes is gasoline due to its low cost and availability.¹

Currently, the forensic science community utilizes a pattern-matching technique outlined in ASTM E1618 to identify ignitable liquids from an arson scene.² This qualitative procedure is subjective and not straightforward, especially in cases where the sample is heavily weathered and/or there is considerable interference from the matrix. The goal of this work is to define a threshold using mass spectral data above which the analyst can definitively identify the presence of a gasoline target compound. The Organization of Scientific Area Committees defines threshold of identification as the minimum concentration of ignitable liquid identifiable from GC/MS data using accepted pattern identification criteria.³ This research examines the usefulness of base peak to qualifier ion ratios of six compounds for determining the threshold for identification of gasoline.

The ion ratios were established for each compound using neat gasoline. Ratios were then compared to those obtained for neat gasoline and 90% weathered gasoline spiked onto burnt laminate flooring and recovered from the laminate flooring using headspace extraction (ASTM 1412).⁴ The preliminary data show that the compounds extracted from laminate flooring do not interfere with the identification of the gasoline target compounds. In addition, all the ion ratios calculated for indane; 1,2,3,5 tetramethylbenzene (TMB); 5-methylindane; and 1-methylnaphthalene in unextracted neat gasoline fell within $\pm 20\%$ of the same ion ratios previously reported by Hondrogiannis et al.⁵ Ion ratios calculated for 1,2,4,5 TMB and 2-methylnaphthalene fell within 20% for their Q/q_1 ratios but their Q/q_2 ratios fell within 35% of the previous studies compounds. In this study, all but one ion ratio calculated for indane; 1,2,4,5 TMB; 1,2,3,5 TMB; 5-methylindane; 1-methylnaphthalene; and 2-methylnaphthalene in 90% weathered gasoline extracted from laminate flooring fell within 20% of the same ion ratios calculated for the same compounds in neat gasoline. The one ion that did not fall within 20% was Q/q_1 for 1,2,4,5 TMB, and it fell within 30% of the same ion ratios calculated for the same compounds in neat gasoline. This method thus provides a means of definitively identifying the gasoline target compounds. By incorporating ion ratios into the identification process, an analyst will be able to go beyond pattern matching, especially where peaks from gasoline-specific compounds are barely discernable, and instead use an identification process that relies on quantifiable data, limiting subjectivity.

Ion Ratios, Weathering, Gasoline

E52 Assessing the Rate of Loss of Fibers in Primary, Secondary, and Tertiary Transfers

Samantha Hadley, BS, George Mason University, Fairfax, VA; Steven Burmeister, MS, George Mason University, Fairfax, VA; Cary Oien, MS, Federal Bureau of Investigation, Quantico, VA*

Learning Overview: After attending this presentation, attendees will have a greater understanding of the impacts different environments have on the movement of fibers.

Impact Statement: This presentation will impact the forensic science community by adding to the validity of fibers as evidence, and aid crime scene investigators in making informed decisions about fiber collection and its value.

Trace evidence, while not individual, can be critical in forming investigative leads and adding value in other pieces of evidence. The goal of this research was to further understand how fibers move and transfer with different materials and under different conditions. An additional goal of this research was to assess the likelihood of fibers being found on different materials recovered. This was done by performing three different types of transfers (swipe, touch, and twist) with different substrates (cotton, wool, silk, nylon, carpet, and car seat) to assess how these transfers and substrates will interact with each other in primary, secondary, and tertiary transfers. This study also investigated the impact of force (in the form of weight) and how those different types of motion would be impacted by that force.

This study contains a total of 300 trials with each variable set being run ten times to ensure that potential patterns would be able to emerge. This experiment was conducted inside a transfer chamber, constructed out of wood, and covered in plastic sheeting, to ensure that fibers that were transferred into the environment were able to be recovered. Twenty-five fibers were placed on the initial donor material, then the transfer was conducted to the recipient material. After the transfer, the donor, recipient, and environment were searched, and fibers were counted and recorded. The environmental fibers were removed while the recipient fibers were as undisturbed as possible during counting. The recipient was then the donor for the second transfer and the process was repeated for secondary and tertiary transfers. Each material was tested under the three different transfer motions. The weight portion of the study was only done on the cotton and was also tested under the three transfer motions.

Fiber, Transfer, Trace

E53 A Physical Assessment of Torture: An Analysis on Medicolegal Degrees of Consistency Expressed According to the Istanbul Protocol

Lorenzo Franceschetti, MD, University of Brescia, Brescia, Italy and University of Milan, Milan, Italy; Francesca Magli, MSc, MA, University of Milan, Milan, Italy; Chiara Nava, MD, University of Milan, Milan, Italy; Lidia Maggioni, MD, University of Milan, Milan, Italy; Andrea Verzeletti, PhD, University of Brescia, Brescia, Italy; Cristina Cattaneo, PhD, University of Milan, Milan, Italy*

Learning Overview: After attending this presentation, attendees will better understand the critical issues involving the medicolegal assessment of asylum-seeker victims of alleged torture.

Impact Statement: This presentation will impact the forensic science community by providing an understanding of the relevance of the Istanbul Protocol and professional experience in cases involving the assessment of alleged victims of torture.

The Istanbul Protocol is an instrument for the investigation and documentation of torture or other inhuman, degrading, and cruel treatment. The medicolegal section inside the Istanbul Protocol delineated the guidelines for the correct management of physical examination and methods of assigning degrees of consistency in cases of torture. In everyday practice, the assessment of the compatibility of physical evidence with alleged torture is very challenging for the clinical forensic practitioner. Most cases exhibit highly heterogeneous lesions in terms of morphology (margins, shape, size, color, texture, etc.) with no specific features. The examiner therefore may be led to rely subjectively on his or her own experience.

The purpose of this work was to understand whether the experience factor (intended as the number of cases evaluated and the years of experience in this field) influences the evaluation and the final judgement and how objective and statistically relevant a conclusion is according to the Istanbul Protocol.

To this end, a survey containing 11 cases of asylum seekers evaluated by the University Institute of Forensic Medicine of Milan was sent to 30 Italian clinical forensic practitioners. The participants were invited to assign a degree of consistency to each case according to the Istanbul Protocol guidelines.

The answers were statistically grouped, and the inter-rater reliability through Fleiss' Kappa coefficient was calculated by dividing and layering the participants according to the number of cases evaluated (less or more than 25, more than 50), the years of experience (less or more than a year, more than five years), and both variables. Then, the overall agreement among observers was calculated and, afterward, the agreement between observers and an assumed standard reference.

The results showed a trend of improvement in terms of uniformity and homogeneity among the evaluation expressed by raters as the number of cases examined and the years of experience increased. The best Fleiss' Kappa coefficient (0.72) was reached by physicians who had more than five years of experience and visited more than 50 asylum seekers. The same category obtained an agreement of 0.83 with the standard reference.

What emerged from the present research is that a mere application of the Istanbul Protocol is not enough to express an appropriate evaluation, although the protocol tends to yield similar results among expert observers. The evaluations acquire significant values when the practitioner gains experience both in terms of years and number of cases. As for other scientific fields, training (and consequent professional experience) represents the backbone for a proper medicolegal assessment in cases of alleged torture.

Therefore, the proper application of the Istanbul Protocol is only the tip of the iceberg, as the study showed that the judgments are uniform among users with similar experience, albeit with the limitations outlined above. In consideration of the extremely delicate scenarios in which the Istanbul Protocol is used, the time is ripe to consider that the introduction of appropriately trained health professionals "expert in migrations and torture" could lower the risks of misinterpretation and make the assessment as reproducible as possible.

Istanbul Protocol, Asylum Seekers, Clinical Forensic Medicine

E54 Record Depths: 2019 Deep Water Recovery of “Password 33” at 18,600 Feet

Katherine Grosso, MA, Armed Forces Medical Examiner System, Dover Air Force Base, DE*

Learning Overview: Attendees will learn about the deep ocean salvage of the United States Navy’s “Password 33,” a C-2A Greyhound lost in the Philippine Sea in November 2017. This presentation will provide insight into the planning and execution of the deepest military recovery of aircraft and human remains on record.

Impact Statement: The forensic science community understands better than anyone that every case presents unique challenges, and no two are the same. This presentation will share strategies and findings in deep sea human remains recovery and provide helpful insight for application in the varied underwater search and recovery efforts that one may encounter in medicolegal investigation.

On November 22, 2017, “Password 33,” a United States Navy C-2A Greyhound assigned to VRC-30 in Atsugi, Japan, crashed on carrier approach in the Philippine Sea, representing the first operational loss within the C-2 community in 44 years. Of the 11 active-duty crew and passengers on board, only 8 were rescued before the plane submerged. Search and rescue efforts continued for three days, covering nearly 1,000 square miles of ocean before concluding on November 25, 2017, without recovery. In January 2018, the plane was located at a depth of 18,600 feet by the United States Navy Supervisor of Salvage and Diving (SUPSALV), and the discovery subsequently spurred a multiyear, international, and multidisciplinary effort to recover both the aircraft and the souls on board, then the deepest attempt at aircraft salvage on record.

This presentation will discuss the role played by medicolegal investigators from the Armed Forces Medical Examiner System in the planning, and, ultimately, successful execution of the record-setting recovery in May 2019, to include strategies for human remains recovery in a subsea environment using Remotely Operated Underwater Vehicle (ROV) technology, the challenges of executing a large-scale recovery operation at sea, and postmortem findings unique to an abyssal depth aquatic environment.

Aviation Mishap, Human Remains Recovery, Deep Ocean Salvage

E55 A Dismembered Pedestrian and a Debris Field: A Case Report of a Fatal Hit and Run

Stacey Chepren, MFS, University of Florida, Gainesville, FL*

Learning Overview: The goal of this presentation is to show the value of paint chip analysis and investigation of video footage from personal surveillance cameras on private residences.

Impact Statement: This presentation will impact the forensic science community by demonstrating the importance of a thorough investigation despite the presence of what appear to be obvious facts.

The city of Las Vegas, NV, has a high occurrence of vehicle versus pedestrian accidents. This case took place in the early hours of the morning in the northwest area of the Las Vegas valley. A pedestrian was walking in a crosswalk when he was fatally struck by a Ford® F-150 truck with two occupants. The driver did not stop at the scene and continued to his residence a short distance away. An individual riding a bicycle that morning came upon the scene where he saw a large debris field with pieces of a vehicle, an athletic shoe, and broken headphones. Just a short distance further, he found a dismembered body.

Once the local police were alerted to the incident, they began canvassing the neighborhoods surrounding the scene to look for a damaged vehicle. When they located an F-150 with extensive damage to the front driver's side, they made contact with the owner who claimed to have been asleep all night in his residence. The driver stated his truck must have been stolen and brought back.

Through further investigation, admissions were made by the passenger of the vehicle that the two had been drinking at a bar not far from the residence and that they knew they had hit "something" on the way home. The driver and passenger were captured on video footage at the bar consuming various alcoholic drinks, which was also verified by a bar tab and the bartender on shift. Additionally, investigators noticed a surveillance camera on a neighbor's house directly across from the driver's residence. Upon review of the video footage recorded that morning, it was discovered that the two had returned to the residence just a few hours prior. Not only did they return to the residence in the black F-150, they attempted to clean biological material off of the truck, changed their clothes, came back outside, and drove off in another vehicle that was parked at the residence.

The passenger admitted they had taken the other vehicle back to the scene to collect pieces of the truck, then driven out to the open desert and threw the pieces out. At autopsy, small, black chips of paint were collected from the victim's neck. Paint chip analysis showed multiple layers of paint, evidence the truck had been painted since the factory paint job. A match was made with the custom, aftermarket paint on the black F-150 with the front-end damage.

Throughout the entire case, the driver refused to admit he was the one driving. It was the overwhelming circumstantial evidence collected that showed he was driving the vehicle at the time it struck the pedestrian.

Hit and Run, Pedestrian Death, Evidence

E56 How Hot Is Too Hot? The Interior Temperature in Unattended Vehicles and the Effect on Children Left Inside

Laura Lathrop, MS, Sequoias Community College District, Visalia, CA*

Learning Overview: After attending this presentation, attendees will have learned more about how the temperature can rise in vehicles and affect children when left in unattended parked vehicles.

Impact Statement: This presentation will impact the forensic science community by giving attendees more knowledge as to temperature increase in vehicles left unattended and not running with children in them. This will provide additional information adding to the already existing literature on this topic. This study is meant to assist investigators in determining how hot vehicles can be when the ambient temperature is at varying degrees. Also, this study will help investigators determine the temperature and time it takes for a child left in a vehicle to succumb to a heat illness.

Since 1998, 887 children have died due to being left unattended in vehicles that are not running. This brings into question: how hot does the vehicle get inside to cause these deaths? How does the ambient air temperature affect the temperature inside a vehicle?

This study attempts to answer some of those questions. This study used temperatures from the Central Valley in Visalia, CA, during the months of July and August. This study was limited to those months, which tend to be the hottest time during the year in this region of California. Differing days were tested with differing ambient temperatures on a vehicle locked for several hours. The interior temperature of the vehicle was taken at various intervals to see how the temperature inside the vehicle rose and at what temperature the interior peaks. Different times of the days were tested to obtain different ambient temperatures. This study was limited to one location: Visalia, CA. The summer months range from 90 to over 100 degrees. As previous research has shown, every region will be a little different on ambient temperatures. The make, model, and color of the vehicle will give different temperatures as will the direction the vehicle is facing and the position in which the vehicle is located. This study adds to the information about the dangers of non-running vehicles and children.

Vehicles, Children, Unattended

E57 Have Cocaine, Will Travel: A Case Report of Body Packing

Anita Hasert, BS, Charleston County Coroner's Office, North Charleston, SC*

Learning Overview: After attending this presentation, attendees will be able to apply their understanding of the various thorough medicolegal death investigation practices. Attendees will understand the importance of utilizing their scene investigation skills, the value of communicating with various organizations, interviewing techniques, and the importance of performing a forensic autopsy. Attendees will also be able to describe the elements of a multidisciplinary approach from the beginning to end of an investigation involving the death investigation of a drug mule.

Impact Statement: This presentation will impact the forensic science community by contributing to the literature concerning drug absorption by passive diffusion, the use of the consumption of an antidiarrheal agent, and crucial medicolegal death investigation procedures. The procedures are needed to ensure accurate scene investigation, collaboration among the various agencies, and the need to perform a thorough forensic autopsy. Without the forensic autopsy, the drugs would not have been found, field tested and collected by federal law enforcement. This presentation will also provide information concerning the body packing process, the careful collection of the substances found, and the testing involved.

Passive diffusion is when a drug or drugs that have been consumed spread across a cell membrane from a region of high concentration to one that is of low concentration. An example of high concentration is the gastrointestinal fluids, like the case being presented, and an example of a low concentration region is blood. The rate of drug absorption varies based on the drug that is being introduced, its physiochemical properties, and the route of administration.¹ The purpose of ingesting an antidiarrheal agent is to slow down the intestinal movement for the smuggling of the drug. The drug mule being discussed in this presentation consumed loperamide, which is also known to cause cramping, bloating, gas, and pressure.²

The decedent was a Jamaican citizen traveling from Jamaica to New York to reportedly visit his daughter for a few weeks. He was traveling alone. It was determined that he had made multiple trips prior to this incident, but it is unknown if this was his first time traveling as a drug mule. According to the flight attendants, prior to becoming unresponsive while in flight, the decedent had been complaining of feeling cold and had been going back and forth to the bathroom. Once the flight was diverted to Charleston, SC, he was pronounced deceased at the airport. On scene, there was nothing found to assist in the determination of what happened to him. There were no medications found, no medical paperwork, and his luggage was checked by multiple people yielding no clues as to what may have transpired. In interviewing the spouse, the decedent consumed alcohol on occasion, cut back on tobacco use, and would not have used drugs due to the profession he was in. It is important to note that it was later determined that another piece of luggage was found upon debarkation in New York that belonged to the decedent. Once that was checked, drugs were found inside. The decedent left behind a wife and two young children. Based on the social history of the decedent, autopsy findings, drug analysis, and toxicology, the cause of death was determined to be cocaine toxicity. The manner of death was classified as an accident.

E58 Necrobiome Succession in Muscle Tissue as a Potential Indicator of Postmortem Interval (PMI)

Anna Wacker, MS*, Northern Michigan University, Marquette, MI; Josh Sharp, PhD, Northern Michigan University, Marquette, MI; Jane Harris, PhD, Northern Michigan University, Marquette, MI

Learning Overview: After attending this presentation, attendees will be familiar with bacterial markers, identified through 16S ribosomal RNA (16S rRNA) metagenomic sequencing of bacterial species present in decomposing human muscle tissue, that contribute to a novel approach for PMI estimation and may aid in the identification of unidentified human remains.

Impact Statement: This presentation will impact the forensic science community by providing a new way to estimate PMI by tracking successive necrobiome changes in muscle tissue samples from the arm (deltoid) and the thigh (vastus lateralis) throughout the decomposition process. This presentation will also illuminate the importance of the innate microbiome/necrobiome, unique to certain individuals, that could potentially be used to ascertain aspects of a decedent's diet, lifestyle, and medical history.

Human decomposition is a complex and variable process influenced by innumerable factors such as the weather, innate microbiome, extrinsic microbiome, scavenging activity (including insects), and a myriad of other factors.¹ PMI is a measurement of time since death using one or a combination of methods incorporating, among others, the physical condition of the body, biological and chemical classifications of the substrate surrounding the body, and botanical and entomological analysis.² Because of the complexity of decomposition processes and the varying methods used to classify these processes, there is a high variability among individual investigators in their estimates of PMI. By tracking sequential changes in the necrobiome of muscle tissue from samples taken from the arm and leg using 16S rRNA sequencing, one can determine a pattern of succession throughout the decomposition process that could be used to form a reliable, reproducible timeline correlating to PMI in conjunction with Accumulated Degree Days (ADDs). While patterns in necrobiome succession are known to reflect PMI, regardless of environment, location, etc., this study also reveals a novel application for necrobiome data.

Results from this study show a general shift from innate microbiome/necrobiome bacterial organisms to more environmentally associated microbes, such as insect, scavenger, soil, and air microbes. Commonly seen innate human microbes found in early decomposition include Pseudomonadaceae and Lactobacillaceae, while commonly seen extrinsic (later-decomposition) microbes included Wohlfahrtiimonadaceae and Clostridiaceae. When combined with ADD information, the general shift from innate to extrinsic microbes suggests a timeline associated with PMI.

Results from this study also suggest that the presence of specific bacterial organisms may reveal clues about the decedent's diet, lifestyle, overall health, illnesses, and, by extension, possibly cause of death. This could be incredibly important for building the medical and social histories of victims, which may aid identification in medicolegal death investigations. Specific bacterial organisms that have known associations with particular dietary and health-related conditions were isolated in the muscle tissue of the donors used for this study. Bacteria known to be associated with the consumption of dairy, meat, and fish, or that have known associations with particularly healthy or particularly unhealthy gut conditions were found in the muscle tissue of different human donors.³⁻⁵ In each case, a review of the donors' self-reported medical histories supported the bacterial findings. Such information may be particularly useful in generating leads when attempting to build a biological profile for unidentified human remains.

Necrobiome, Postmortem Interval, Decomposition

E59 Human Taphonomy Facilities: Considerations for Establishment in the United Kingdom

Claire Power, MSc, Queen Mary University of London, London, England, United Kingdom; Fiona Jane Wilcox, MD, Queen Mary University of London, London, England, United Kingdom; Richard Walters, LLB, Queen Mary University of London, London, England, United Kingdom; Nikolas Petros Lemos, PhD, Queen Mary University of London, London, England, United Kingdom*

Learning Overview: After attending this presentation, attendees will better understand why the United Kingdom does not yet have a Human Taphonomy Facility (HTF), and how establishment and body donation is likely to proceed under the current legislation. Active comparison to countries with existing HTFs will also allow attendees to gain an appreciation for the unique challenges faced by the United Kingdom: identifying the ethical, socioeconomic, and environmental considerations needed for carrying out human taphonomic research.

Impact Statement: This presentation will impact the forensic science community by highlighting a gap in United Kingdom research and the global effect this has on human taphonomy research. Analysis of differing international criteria for human tissue donation will also highlight the impact on diversity and inclusion as well as what is locally considered ethical.

As HTFs continue to proliferate around the globe, the United Kingdom remains without access to human taphonomic research. This situation has been made more acute by the United Kingdom's recent departure from the European Union. The lack of domestic research within the United Kingdom has negative implications for the education and training of law enforcement and academia.

In this presentation, the United Kingdom laws relevant to the removal, retention, and disposal of human tissue will be explored along with a review of the history of human research to contextualize the current legislation. The 11 HTFs existing outside of the United Kingdom are discussed, highlighting how they were legally allowed to open and how their body donation protocols differ. Further comparison of consent forms emphasizes the diverging international practices, including time restrictions for returning remains, and the United Kingdom not allowing donations by proxy.

Existing body donation programs operating in the United Kingdom were surveyed and the results will be discussed, comparing consent forms and procedures of medical institutes in the four nations of the United Kingdom: England, Scotland, Wales, and Northern Ireland. Attention is paid to cultural and religious differences, including how the lack of recognition of forensic research as beneficial to public health is limiting research within the United Kingdom.

The geographical constrictions of the United Kingdom are covered, given the limited land available in the comparatively small country. Important issues that could impact the environment are examined, ranging from sustainability to specific public health concerns, such as variant Creutzfeldt-Jakob disease potentially spreading due to scavenging. Also discussed will be the impact on the United Kingdom's economy as well as issues related to the funding of such a facility.

The use of non-human analogs for taphonomy research is analyzed, given this is the only form currently sanctioned in the United Kingdom. Some feel that the United Kingdom could continue to utilize data produced elsewhere; however, extrapolating results from overseas research weakens conclusions due to the United Kingdom-specific climate and entomological presence. The ethical use of animals is also questioned, in the face of access to consenting human subjects.

Finally, the strengths and weaknesses of the United Kingdom are reviewed with a focus on how they could allow it to contribute in a meaningful way to research already conducted, including how it has the potential to lead in diversity of human taphonomy research participants, which remains limited elsewhere.

Human Taphonomy, Body Donation Programs, United Kingdom

E60 The Effect of Necrophagous Entomofauna on Textile Damage During the Summer in Western Australia

Sotirios Ziogos, MFS, Murdoch University, Perth, Western Australia, Australia*

Learning Overview: After attending this presentation, attendees will have a better understanding of the impact and the artifacts produced by the activity of necrophagous entomofauna on stab-cuts and tear damage on different types of fabric during the postmortem period.

Impact Statement: This presentation will impact the forensic science community by increasing awareness of the effect of carrion insects on clothing and by providing a new body of information that will enhance the investigative role of clothing associated with decomposed and skeletonized remains.

Fatal stabbing incidents are the leading cause of homicides in countries with restricted access to firearms, such as Australia.¹ During a stabbing assault, the distinctive characteristics of a sharp implement will deposit specific features.² When the decomposition process impedes the physical examination of a stab wound, damage analysis of the clothing may provide information about the weapon or the actions that caused the injury.³ Studies have suggested that insect activity associated with decomposition can produce artifacts on textiles, modify perimortem textile damage or produce changes to clothing that imitate indicators of sexual homicides.⁴⁻⁷ However, the extent of such studies is currently limited and have not been conducted in Australia before. The aim of this research was to identify and characterize the effect of carrion insects on textile damage after a decomposition period during summer in Australia.

The effect of insect activity was analyzed on standardized cuts and tears to three different fabrics (100% cotton, 65% polyester-35% cotton, 80% nylon-20% spandex). Ninety stillborn piglets (*Sus scrofa domesticus* L.) were wrapped in one type of fabric each. Each clothed piglet was either stabbed by a stabbing apparatus or had its fabric torn. All piglets were placed simultaneously in a decomposition facility alongside controls of each combination of fabric and damage type, including 9 piglets clothed and intact; 6 piglets unclothed and stabbed or intact; 11 piglets enclosed in boxes; 36 field swatches; and 9 laboratory swatches. Over five sampling periods and until complete skeletonization (7, 12, 18, 26, 47 days since placement), 3 piglets of each type were removed, and entomological samples were collected. The fabric of each piglet was removed, photographed, and stored to dry in laboratory conditions before being analyzed. All controls and fabric swatches were collected on the final sampling day.

Data collection was comprehensive of piglet and fabric samples via field assessment, daily photo and video documentation, static camera recording, and direct collection of insect specimens. Analyses performed covered taphonomic aspects (degree of piglet decomposition), entomological (insect species and instar), and textile damage analysis. The collected fabrics were analyzed on different levels of fabric structure using a stereoscope and digital microscope and through photo and video analysis. Fibers of each sample type were collected and examined using optical microscopy and Scanning Electron Microscopy (SEM).

The results of this research show that stab cuts can adopt morphological characteristics over time that may resemble features of tear damage, whereas tear characteristics also tend to fade gradually. Insect interaction with bloodstains resulted in a distortion of the yarns and of the fabric surface after fly feeding. Due to the weakening of the fabric's structure, insect damage and consequent degradation may occur at the same location. The assessment and comparison of fabrics revealed how parameters such as the type of fabric and elasticity can influence insect damage, with natural fabrics being the most vulnerable. Lastly, this research emphasizes how the presence and the type of fabrics and textile damage affect the interaction of carrion insects with the decomposing medium, and consequently, how the rate of decomposition in a natural environment and in confined spaces is affected.

Stab Cuts, Tear Damage, Insect Textile Damage

E61 Step-Wise Lead-Poisoning of a Sheep: A Case Report Combining Virtopsy and Autopsy in a Ballistic Veterinary Case

Dagmar Mierzwiak, IRM, Zurich, Switzerland; Matthias Dennler, Vetsuisse, Zurich, Switzerland; Monika Hilbe, Vetsuisse, Zurich, Switzerland; Michael Thali, MD, IRM, Zurich, Switzerland; Wolf Schweitzer MD, IRM, Zurich, Switzerland; Stephan Bolliger, MD, IRM, Zurich, Switzerland*

Learning Overview: This presentation demonstrates cooperation between human and veterinary forensics in a ballistic case; the attendee will learn how to reconstruct gunshot wounds by using not only autopsy but also Postmortem Computed Tomography (PMCT).

Impact Statement: This case highlights the successful implementation of postmortem radiology in veterinary pathology, as has been shown in forensic pathology in the past.

On a pasture, police found a sheep with multiple gunshot injuries to the head, inflicted by the sheep's owner, lying on the ground without apparent consciousness but breathing and thus still alive. The sheep subsequently was euthanized and the confiscated carcass was taken to the University of Zurich's Veterinary Pathology for further examination. In cooperation with the Institute for Forensic Medicine, University of Zurich, it was subjected to PMCT scanning and autopsy to document the gunshot injuries.

By Swiss law, animal owners are allowed to kill their own animals, but the method chosen must immediately cause loss of perception and awareness, and also cause death at once. Typical methods are pentobarbital poisoning or using a stun gun aimed at the brain stem. In this case, the sheep's owner claimed that he had tried to kill the animal, which apparently had been suffering from cardiac failure, with two gunshots to the head, in compliance with the law. The main question therefore centered around these central tenets of our legislature, whether the head injuries were able to cause immediate loss of consciousness and cause death—being that the animal was not dead when found by police. The sheep underwent PMCT and autopsy, both which were performed in a close cooperation between the Institute for Veterinary Pathology and the Institute for Forensic Medicine.

Four entrance gunshot wounds were located at the top of the head. Furthermore, aided by the radiological findings, a number of wound channels and retained bullet fragments were noted; from that, the number of shots was at least four but could have been up to seven, based on imaging. According to police investigation, the police could not determine how many shots had been fired. Macroscopically, nasal structures were significantly injured and the olfactory brain was grazed, but no immediately vital areas of the brain, such as the brain stem, appeared to be affected. Diffuse axonal injury may still have occurred and caused loss of consciousness.

A shot sequence could not be ascertained, so it cannot be excluded with certainty that the sheep wasn't unconscious after a first shot, but it appears unlikely. If anything, the considerable number of shots did not cause death immediately. The non-fatality of at least four gunshot head injuries was documented in a veterinary case based on radiological and autopsy findings. This case highlights the successful implementation of postmortem radiology in veterinary pathology, as has been shown in forensic pathology in the past.

Ballistics, PMCT, Veterinary

E62 Morphology and Behavior: What Can Dog Bite Wound Morphology Tell Us About the Behavior Involved in Fatal Dog Attacks?

James Crosby, MS, University of Florida, Gainesville, FL*

Learning Overview: This presentation will examine the relationship between physical morphology of dog bite wounds and the related species-specific contributing behaviors in fatal dog attacks on human victims.

Impact Statement: This presentation will expand understanding of dog bite-related fatalities and allow analysis leading to better assessment of human responsibility in civil and criminal venues. This presentation will examine the relationship between reported “accidental” cases and criminal homicide and will examine the use of specific dog bite-related evidence to the investigative process of homicides.

Too often in the past, Dog Bite-Related Fatality (DBRF) cases have been regarded as either horrible “accidents” or as “the dog did it—we are done here.” This study has been able to combine behavioral studies, law enforcement experience, and specific advanced veterinary forensic training to gain a new overview of human fatalities caused by dog bite-related incidents.^{1,2} Physical responses to scenes across three continents, direct examination of evidence, and hands-on behavior evaluation of nearly 60 involved dog(s) in over 30 cases has opened new horizons in assessing these incidents. Guidelines for the investigation of DBRF cases have been written and the procedures presented to Law Enforcement and Animal Control investigators internationally.³

In addition, hundreds of case reports were examined for commonalities and divergences. Based on wound morphology and behavior analysis, categories of attacks and a comparative rating of human responsibility for the actions of the involved dog(s) has been established. Application of this analysis has led to successful criminal and civil prosecution of owners and others. The general categories identified range from true accidents, through defensive and offensive interactions, to the use of dog bite incidents to conceal and confuse the investigation of criminal homicides. Triggering stimuli are examined, and characteristics of individual dogs are examined in the aftermath of the incidents. This work has involved the comparison of autopsy results, necropsy analysis of accused dogs, dental analysis and comparison, and at times the exclusion of accused dogs and the exoneration of wrongly accused individuals.

Dog Bite, Fatal Attack, Bitemarks

E63 Are We Barking Up the Wrong Tree When Selecting Detection Canine Candidates?

Keir Davies, MSc, Queen Mary University London, London, England, United Kingdom; Nikolas Lemos, PhD, Queen Mary University London, London, England, United Kingdom*

Learning Overview: After attending this presentation, attendees will better understand the characteristics that make different canine breeds more suitable as detection dogs than others; the genetic connection, if any, to better olfactory capabilities; and the surprising finding that some smaller breeds that are not commonly employed in this capacity may actually perform equally well as those that have been traditionally used for this purpose.

Impact Statement: This presentation will impact the forensic science community by raising awareness on the shortcomings of our current selection criteria of canine detection dogs that may not be the most suitable based on their olfactory capabilities or genetic makeup, but that most of these dogs are actually selected due to our familiarity with their breeds. Additionally, it will be pointed out that the working relationship between a detection dog and its handler seems to be the most important factor for the canine team's success.

K-9 dogs are a commodity often utilized worldwide by law enforcement, with certain breeds being chosen most frequently, even though little is understood about the differences in their olfactory ability. Is it possible that the familiarity of seeing certain breeds in that role makes us assume that some are superior to others in this capacity? Multiple studies have been carried out in an effort to determine any genetic difference in olfactory ability, but currently there has been no success. There have been some suggestions that the presence or absence of certain single nucleotide polymorphisms within olfactory gene receptors result in either an increase or a reduction in olfactory performance; however, the process of successful scent detection is likely too complex to rely on a single polymorphism.

This study reviews the work of several international teams to determine if dog breed affects success in detection work, and whether we are currently utilizing the most suitable breed of dogs for this purpose. Comparison of these studies suggests that there are inherent differences in scent detection capabilities between breeds; however, a deeper understanding of why this is must be developed through further research. Due to some contrasting results between studies, there appears to be no single distinguishing factor, and breed selection likely comes down to an amalgamation of features. These include ease of training, motivation for reward, and even physical attributes. Breeds that are typically not reward-inclined are difficult to train to perform detection-related tasks, and results across studies have continually suggested that breeds with a long-standing working relationship with humans may in fact remain the best candidates for the job. A recurring theme throughout most research studies is that canines with a long-standing history of working with humans may remain the best candidates because the relationship between a dog and its handler is paramount for success. Surprisingly, it has been proposed that certain toy dog breeds may perform best when given the opportunity, making a more thorough review of olfactory receptor gene polymorphisms between a large variety of canines necessary to determine any genetic differences in that specific ability. Due to the combination of attributes that make for a successful detection canine and after a thorough review of the literature, this study is of the opinion that the current K-9s are likely to continue enjoying their current job security.

K-9 Dogs, Olfaction, Detection

E64 An Analysis of the Degradation and Contamination of Canine Training Aids Stored in Semi-Permeable Membrane Devices (SPMDs) and Traditional Storage Conditions Via Fourier Transform Infrared Spectroscopy (FTIR) and Gas Chromatography/Mass Spectrometry (GC/MS)

Kymeri Davis, MS, IUPUI, Indianapolis, IN; Courtney Cruse, BS, IUPUI, Indianapolis, IN; John Goodpaster, PhD, IUPUI, Indianapolis, IN*

Learning Overview: After attending this presentation, attendees will be informed about the degradation and contamination of canine training aids stored in traditional storage conditions and SPMDs.

Impact Statement: The forensic science community will be informed on the use of SPMDs to store canine training aids as well as cross-contamination between canine training aids stored in SPMDs and traditional storage conditions.

The purity and stability of explosives in canine training aids is of great importance because explosive-detecting canines must be frequently trained with explosive materials. These explosive materials must be free of cross-contamination and have minimal degradation to ensure the canines can accurately identify possible threats. Traditional storage conditions for explosive training aids include plastic bags, Velcro® bags, and drawstring bags. These storage conditions may lead to cross-contamination between the various types of explosive compounds.

For this work, SPMDs were used in addition to traditional storage conditions to monitor the contamination and degradation of 14 explosives used as canine training aids. SPMDs allow for the odor of the compounds to be released while also helping to prevent any contaminants from entering the container. Explosives were stored individually inside of either a traditional storage bag or inside of an SPMD. A set of each storage type was stored at Indiana University – Purdue University Indianapolis to act as the control and a set was stored at an Indianapolis Metropolitan Police Department location and were actively utilized as canine training aids. A sample from each storage type at both locations was collected at 0, 3, 6, and 9 months and analyzed using FTIR spectroscopy and GC/MS with solid-phase microextraction. For most explosives analyzed via FTIR, no degradation or contamination was identified as most spectra were visually indistinguishable. Chemical changes were seen in the FTIR spectrum for urea nitrate as the sample became dehydrated over time. Chemical changes were also seen in the FTIR spectrum for the cast booster sample. These changes are likely due to the heterogeneity of the sample and not from degradation or contamination. GC/MS spectra show cross-contamination from ethylene glycol dinitrate and/or 2,3-dimethyl-2,3-dinitrobutane across almost all samples regardless of storage condition.

FTIR and GC/MS analyses show that canine training aid explosives show no signs of degradation when stored in either traditional storage conditions or in a SPMD; however, cross-contamination is still of concern.

FTIR, GC/MS, Canine Training Aids

E65 Forensic Nurse Roles: Exploring the Future Within a Modern Forensic Science World

Joyce Williams, DNP, RN, Stevenson University, Owings Mills, MD*

Learning Overview: After attending this presentation, attendees will have a better understanding of the diversity of forensic nursing roles and how they contribute to clinical and research work.

Impact Statement: This presentation will impact the forensic science community by presenting evidence of forensic nursing clinical skills, research abilities, and contributions to partnerships with governmental and non-governmental agencies.

Forensic nurses most frequently work in hospitals, community anti-violence programs, coroner's and medical examiners offices, correctional institutions, and psychiatric hospitals to meet and surpass the challenges of a modern forensic science world. They may also be called on following mass disasters or community crisis situations. Forensic nurses bring a nursing perspective to an investigation as they play an integral role in bridging the gap between law and medicine. A portion of the work in the clinical setting involves observing, recording, and preserving evidence, and photographing injuries for evidence of wrongdoing that may eventually be used in court. Striving to improve crime victims' health outcomes, their interactions are notably within the legal arena, systems of care, and community agencies as well as with individuals. They interface with law enforcement and legal teams to support victims, often providing fact-based testimony in court cases. As grueling as this work can be, it comes with many benefits, including fighting for victims of abuse.

A brief introduction of the various careers of forensic nurses will be examined and how this specialization impacts the clinical arena, research and development, outside agency collaboration, and risk management will be discussed. While it will be impossible to enumerate all the positions in which forensic nurses excel, several appointments will be discussed.

Professionally, forensic nurses specialize following academic education and licensure plus practice in a medical setting. Most settings require that a nurse practice for a specific length of time before specialization. Depending upon what area of specialty is chosen, the nurse will engage in the required training, clinical hours, and possibly an internship with mentorship.

Some advanced practice forensic nurses choose to conduct research. This opportunity is widely available as is evidenced in the work of Ann Wolbert Burgess, who focused on developing ways to assess and treat trauma in rape victims. The military has engaged forensic nurses to analyze wounding in combat in order to better prevent mortality. Forensic nurses, as injury analysts, research morbidity and mortality injuries in clinical settings to determine intentional from unintentional wounds. The use of Artificial Intelligence (AI) is one emerging specialty focusing on the impact of medical interventions that stray from evidence-based practice causing harm to the patient. AI translates accumulated data into contextually relevant knowledge and conclusions to impact appropriate actions.

Forensic nurses are valuable partners with governmental and non-governmental agencies. They operate as subject matter experts to create legislation to improve criminal legal and community-based responses to domestic violence, sexual assault, dating violence, and more. Under the radar positions are employment with the Federal Bureau of Investigation (FBI) where the Bureau trains forensic nurses to be special agents or work as detectives investigating major crimes utilizing their expertise in an occupation that benefits from their specialized knowledge. The Federal Emergency Management Agency (FEMA) utilizes forensic nurses in several positions as leaders and specialists who deploy to disaster situations. The Organization of Scientific Area Committees (OSAC) makes use of forensic nurses who collaborate as members of a subcommittee to develop national standards for use in areas of practice.

The diverse roles of forensic nurses are wide-spread and their contributions to the medicolegal community affect the lives of many globally. The innovators of forensic nursing science have influenced the future of a profession that is continually developing.

Forensic Nurse, Roles, Partnerships

E66 A Global Response in the Frontiers of Forensic Nursing Science

Virginia A. Lynch, MSN, Forensic Nurse Consultants, International, Divide, CO*

Learning Overview: Attendees will learn the background of native cultures in countries within the accepted beliefs of culture, tradition, religions, and superstitions with patients, health care practitioners, and law enforcement's acceptance or rejection of the forensic nurse examiner. Attendees will learn the unique obstacles and benefits of introducing the forensic nursing concept where professional respect is not recognized in existing nursing roles by physicians and other barriers to education in international countries.

Impact Statement: This presentation will impact the urgency of founding forensic nursing science as a global initiative in health care and human rights that can help reduce and prevent violence against women, children, and vulnerable populations. This presentation will improve attendees knowledge, competence, and performance of trans-cultural nursing in the United States and internationally.

In a post-modern world filled with criminal violence, the forensic nurse has created a previously unrecognized resource for victims of domestic and international terrorism that often starts within the sociocultural, political, and religious traditions of the past.¹ The United States has led the advancement of forensic nursing throughout its 50 states as it continues to expand worldwide throughout developed and developing nations. The discipline of forensic nursing is well established in North America and our physicians are grateful. Some of our most successful programs were influenced by the American Academy of Forensic Sciences (AAFS), the first professional organization to recognize and encourage Forensic Nursing as a scientific discipline and that has now elevated this emergent science to the status of a section of its own: the Forensic Nursing Science Section.^{2,3}

The global forensic community is paying attention in 57 countries. The AAFS is renowned worldwide; their influence and leadership speak for its prestigious reputation. In addition to the United States, several countries with emerging initiatives in forensic nursing include those with major issues of prevalent crime, interpersonal and sexual violence, and the need to ensure human rights for women and children where they have been limited by cultural norms. There are multiple driving forces for the development of forensic nursing within these areas in which nurse-run clinics are the only source of health care and nurses certify death.

The first education program for forensic nurses outside of North America was in South Africa. The Northern Cape Institute of Forensic Studies in Nursing has become the precedence for other countries. This original program was initiated by Dr. J.E. Els, Chief of Forensic Medical Services, in a place so small it was difficult to find on a map. As so often happens, this action brought attention to the AAFS, the United Nations, and to the South African Minister of Health, leading the way for it to become the first country to designate forensic nursing as a national priority program in all nine provinces.

Terrorism, Nurse-Run Clinics, Emerging Initiatives

E67 Responding to the Future Challenges of Emergency Preparedness in a Modern Forensic Science World

Joyce Williams, DNP, RN, Stevenson University, Owings Mills, MD*

Learning Overview: After attending this presentation, attendees will have a better understanding of the importance of public health measures in emergency preparedness, how forensic nurses impact all phases of disaster preparedness, and thoughts on how to prepare for the future.

Impact Statement: This presentation will demonstrate the failures encountered during the current pandemic and how forensic nurses are valuable assets in all phases of emergency preparedness.

In the past decade, 2.6 billion people globally have been upended by earthquakes, floods, wildfires, and other natural disasters. Now, the global coronavirus pandemic has killed more than four million people worldwide. These crises disproportionately affect people of color, those with low incomes, those experiencing housing insecurity, and those with limited access to health care and transportation, ultimately exacerbating health disparities. For too long, the United States has overinvested in treating illness and underinvested in promoting health and well-being and preventing disease. Even before COVID-19 illuminated disparities and exacerbated inequities in the United States, forensic nurses were advocating for better care and access for individuals, families, and communities.

COVID-19 has shifted the world to a worrisome state of epic proportion. Pandemics occur relatively frequently, surfacing every few decades on average (for example, influenza). The biggest factor affecting the spread is the current interconnectedness of the world. Diseases move rather quickly now. This current pandemic revealed the fragility and brittleness among our public health system and health care delivery, supply chains, and supply chain logistics. The broad impact across not only the United States, but also globally, impacted the economy. While the direct cost of the pandemic exceeds \$16 trillion, the long-term health costs for the treatment of just one affected person is estimated at \$26,000 or more. However, the structural costs to communities are multi-faceted, including education, diversity, income disparity, and more.¹

During the height of the COVID-19 pandemic in the United States, data-collection shortcomings overwhelmed state health departments, impeding health officials' abilities to identify and contain outbreaks and raised the curtain on long-neglected state and local health systems. A six-month *Politico* investigation found delays in reporting COVID test results, sometimes by weeks, arcane computer programs hindering data collection, and severely understaffed contact tracing programs. Despite these limitations, federal agencies relied on states for case and death counts. Effective contact tracing failed.²

Effective response to humanitarian events is a recognized action of disaster teams, including forensic nurses, in efforts to secure and support nations. The response to the pandemic by health care was forceful, yet public health measures were ineffective, limited by poor communication and information sharing across regional and international borders. While there was a high degree of mobilization and adaptability to respond to the current needs of equipment and other public health deliverables, the overall result was reactive, lacking overall preparedness.

What preparations are needed for the future? Innovation must embrace technologies for early detection of threats, interventions, and improvements in nanobiophysics technology for mass scale surveillance. Can we employ smarter quarantine systems and next-generation health care delivery? The last influenza pandemic was in 2009 and recurs every 20–35 years. The G20 Nations Summit urged governments to promote the creation of a global surveillance network to detect the harbingers of a potential new pandemic. However, other threats exist: global warming, the emergence of new diseases, and antibiotic resistance. It is time to create a broader vision, listen to and appraise the data, and collaborate on a whole-of-society approach.

The medical and forensic science professionals are a cadre of valuable individuals who have the expertise to prepare and respond to mass casualty events. Forensic nurses are the frontline as the Chief Nursing Officer Assistant Secretary for Preparedness and Response (ASPR), Senior Advisor to National Disaster Medical System, or on disaster teams providing rapid assessment of the injured, casualty surges, displaced populations, violence prevention, care of human remains, and the mental health of victims, families, or staff. The expertise of forensic nurses as contributors to all aspects of preparedness is important to better design and monitor surveillance and reduce risks to populations.

Forensic Nurses, Pandemic, Preparedness

E68 Forensic Nursing Science: A Contemporary Response to Humanitarian and Human Rights

Virginia A. Lynch, MSN, Forensic Nurse Consultants, International, Divide, CO*

Learning Overview: The forensic nurse represents a previously unrecognized resource for expanding forensic services and is poised to fill a crucial role in the examination of patients, including victims or suspects of child and elderly abuse, intimate partner and sexual violence, domestic homicide, liability issues, persecution, and torture, and violations of human rights. Forensic nurses collaborate with other health care, criminal justice, and forensic sciences professionals. A shortage of clinical forensic physicians and forensic pathologists has alerted a need for additional health care resources worldwide.

Impact Statement: The American Academy of Forensic Sciences (AAFS) forensic nurses, other forensic specialists, and attendees will better understand the forensic aspects of nursing and recognize the need for forensically skilled nurses in the investigation of trauma, questioned death, and accountability to the AAFS codes of ethics and legislation of nursing practice.

“The current world situation is such that a nurse may become involved in innumerable circumstances requiring action on her/his part to safeguard human rights.”¹ As the science of nursing merged with the forensic sciences and criminal justice systems, a distinctive discipline has evolved: forensic nursing science. This emergent science has evolved in response to the consequences of global human violence. Problematic social, cultural, and political situations corresponding to the escalation of reported violence reinforces the need to define the dynamics, processes, and guidelines for forensic nursing practice. Forensic nursing is an essential discipline that recognizes human violence through a contemporary domain of scientific knowledge, health care, and human rights.

Forensic nursing science is objective and unbiased. It applies equally to either side of civil and criminal laws or other legal matters. Forensic nurses work with forensic scientist to help determine the truth in a court of law through the proper documentation, recovery of clinical forensic evidence, and testify in court as required. Forensic nursing care helps to provide improved health and justice outcomes.²

The need for nursing actions to safeguard human rights is not restricted to times of political upheaval and war. It pertains to the abuse or maltreatment of patients or others, whether witnessed or suspected.³ Forensic nurses are expected to perform examinations on victims or suspects before they are subjected to forms of interrogation, which may include torture. To ensure that the nurse is prepared and knowledgeable to provide or prevent the predictable treatment involved that meets the standards of International Law (IL) requires competence through a formidable forensic and nursing education including the Istanbul Protocol.

Health and justice organizations supporting forensic nursing principles and philosophies on human rights include the AAFS, Humanitarian and Human Rights Resource Center (HHRRC), International Council of Nursing (ICN), International Committee of the Red Cross (ICRC), International Association of Forensic Nurses (IAFN), and Amnesty International (AI). Each group encourages all members to engage in humanitarian and human rights applications to advance global health and justice.

Unbiased, Truth, Torture

E69 Forensic Nurse Hospitalist: The Comprehensive Role of the Forensic Nurse in a Hospital Setting

Kelly Berishaj, DNP, Oakland University, Rochester, MI; Christina Boyland, MSN, Turning Point, Macomb, MI; Kristin Reinink, MSN, Spectrum Health, Grand Rapids, MI; Virginia Lynch, MSN, Forensic Nurse Consultants, International, Divide, CO*

Learning Overview: Attendees will learn about the unique and evolving role of the forensic nurse hospitalist and the impact of this role on patients, providers, and health care systems when trauma is involved. Attendees will learn about the need for such a role in terms of the number of patients seen in the hospital setting who experience trauma, maltreatment, and violence and require expert care from specially educated and trained forensic nurses following best practice recommendations and national guidelines. Finally, educational considerations for nurses interested in pursuing the Forensic Nurse Hospitalist (FNH) role and how the role may be implemented into acute care settings will be described.

Impact Statement: This presentation will impact attendees in that they will learn about a new and unique role that may be currently lacking in their health care agency. Implementing the FNH role has the ability to positively impact health and legal outcomes of patients who have experienced trauma. The FNH can also impact and improve health care provider performance when delivering care to patient-victims. Finally, the FNH can help impact health care systems by serving as a leader in the development of policy, procedure, education, and consultation when trauma, violence, or maltreatment is involved.

The need for forensic nurses in the hospital setting continues to grow daily, and now more than ever, is becoming a crucial factor in successful patient outcomes.¹ “Forensic Nurse Hospitalist” is proposed as a new term to describe the role of the nurse who is qualified by licensure and education as a specialist in forensic nursing and practices specifically in the hospital setting. The FNH can provide comprehensive, medicolegal care to patients receiving treatment for trauma-related injury and questionable death in the acute care setting.

This presentation highlights the need for and importance of the FNH and describes the multifaceted responsibilities of the role as a transformational leader in health care today. The FH Conceptual Model was developed to illustrate the three pillars of influence impacted by the FNH role: patients, health care providers, and health care systems. It is vital that health care systems employ FNHs to deliver expert patient care, offer specialized consultation and collaboration, and implement system-wide policy and educational initiatives to best meet the needs of patients who have experienced intentional or unintentional trauma.

Forensic Nursing, Role Development, Specialty Advancement

E70 Exploring the Conditions, Challenges, and Situations for Nurses Involved in Forced Organ Transplants in China

Nancy Cabelus, DNP, University of New Haven, New Haven, CT*

Learning Overview: This presentation will define forced organ harvesting; identify vulnerable groups targeted by traffickers; and discuss the importance of the forensic nurse's role in preventing forced organ harvesting.

Impact Statement: This presentation will create awareness of underground criminal activity involving vulnerable populations and an international health care network.

During the past two decades, awareness of the crime of forced organ harvesting in China has been documented by international experts in ethics, medicine, and law. Organ transplant surgeries have quadrupled in China as compared to countries around the world.¹ The major source of donor organs is from northwest China and the donor population is a Chinese group of Falun Gong practitioners known as Uyghurs. Falun Gong is a spiritual practice based on truthfulness, compassion, and tolerance. Uyghurs are a particularly passive people and are therefore soft targets for predators who sit in powerful political positions and dictate who is next to die.

In the Western world, organ transplantation in the best of circumstances may take months or even years to find a suitable donor-recipient match. However, in China, a donor may be located in just a few days. The donor source is often a Falun Gong practitioner, a prisoner of conscience, who may be executed in exchange for the lucrative sale of viable organs on the black market.

Warranting further investigation is the role of the (forensic) nurse in the process of organ procurement, surgical interventions, and post-operative care of patients. There are limited resources that discuss the participatory role of nurses. China Organ Harvest Research Center reported that 10,000-15,000 transplants per year occur in China.² What is unknown is exactly how this underground network of matching donors to international recipients happens and how nurses are recruited to participate in this process. Are nurses forced to participate in this process or otherwise face punishment or death? If so, this certainly could be considered a form of labor trafficking and would pique the interest of law enforcement and human rights groups alike.

Forensic nurses practice where health care and legal systems join with forensic science. Nursing care of organ transplant patients, whether donors or recipients, is within the scope of forensic nursing practice. "The American Nurses Association believes that respect for the inherent dignity, worth, unique attributes, and human rights of all individuals is a fundamental principle."³ The International Association of Forensic Nurses supports that "when faced with ethical choices, forensic nurses should use recognized ethical frameworks for decision making. The guiding principles of ethical decision making are autonomy, justice, beneficence, and nonmaleficence."⁴

The International Council of Nurses Position Statement on Nurses and Human Rights states that, "Nurses have an obligation to safeguard, respect, and actively promote people's health rights at all times and in all places."⁵ Nurses are accountable to obtain informed consent in an understandable language from patients prior to their "consenting to treatment or procedures, including participation in research."⁵ "Inherent in nursing is a respect for human rights, cultural rights, the right to life and choice, and dignity, and to be treated with respect."⁵ Therefore, nurses who participate in the practice of forced organ harvesting would deliberately violate this protective code of values, ethics, and human rights.

Xie, J.F. et al. assessed the attitude and impact factors toward organ transplantation and donation among nurses in China.⁶ Of 536 questionnaires received, most nurses reported negative attitudes toward organ transplantation and donation. Only 33.4% of the nurses stated they would donate their organs after death and only 38.2% were willing to register in the national organ donation system. Since nurses would be an important group in the organ donation screening and transplantation processes, their negative attitude can significantly influence donor registration. Investigating what Chinese nurses know about forced organ harvesting could reveal information critical to stopping organ traffickers internationally and saving innocent lives.

Forced Organ Harvesting, Forensic Nursing, Human Rights

E71 The Forensic Nurse Response to Elder Abuse: Meeting and Surpassing the Challenges

Amy Carney, PhD, California State University San Marcos, San Marcos, CA*

Learning Overview: After attending this presentation, attendees will have a better understanding of elder maltreatment and the forensic nursing response to detection, intervention, and resolution.

Impact Statement: This presentation will impact the forensic community by broadening the education of those working with victims of violence and enhance the ability to intervene in maltreatment and prosecute the abuser.

The actual study of elder abuse is relatively recent in the United States. Claude Pepper, as the head of the House Select Committee on Aging, conducted hearing in the 1970s on elder mistreatment, then called “granny bashing,” but research and resources were years in coming. Like child abuse and domestic violence, harm to an older relative was considered a family matter and stayed behind closed doors. Much of early theory was based on patterns of family violence that had been studied in child abuse and the battered wife syndrome. With the growing understanding of the nature and extent of elder mistreatment came the awareness of the lack of forensic and medical markers that could be useful in the identification of abuse. There was no research that could assist investigators in establishing lacerations, bruising, fractures, or decubiti as elements of abuse or neglect. The aging patient frequently has physiological characteristics or medical conditions, which can mask or mimic markers of neglect and abuse, making it even more difficult to detect or evaluate. Unless an actual crime could be proven, such as homicide, charges were rarely filed against a suspected abuser. Arrest and prosecution for financial abuse or neglect was unheard of. Testimony by older patients could be difficult to obtain.

Specialization by forensic nurses in the field of elder maltreatment has increased the detection and prosecution of elder abuse. Advanced assessment, understanding of federal, state, and local statutes, and interfacing with law enforcement are some of the challenges forensic nursing confronts when working with abused and neglected elders. This presentation describes the role of the forensic nurse in meeting the needs of the elderly abuse victim.

Forensic Nursing, Elder Abuse, Maltreatment

E72 Forensic Nursing Science as an Indispensable Core Service in Modern Patient Care: The First Implementation Outcomes in Switzerland

Valeria Kaegi, RN, University of Zurich, Zurich, Switzerland; Michael J. Thali, MD, University of Zurich, Zurich, Switzerland; Rosa Maria Martinez, MD, University of Zurich, Zurich, Switzerland*

Learning Overview: After attending this presentation, attendees will have gained insight into the developmental milestones of forensic nursing in Switzerland, taking into consideration the differences in the health care system, educational programs for forensic nurses, and practical implementation of forensic nursing.

Impact Statement: This presentation will have an impact on modern patient care, especially in cases of interpersonal violence without the filing of criminal charges.

Victims of interpersonal violence are often admitted to hospital emergency departments before they are identified by hospital staff as victims of crime due to a lack of forensic training for nurses and clinical physicians. Therefore, the general demand for forensic nursing is increasingly growing in many Swiss hospitals and institutions, especially in cases arising from interpersonal violence without reported criminal charges. For this reason, the educational offering for nurses in the field of forensic nursing continues to be promoted, advanced, and developed in Switzerland. A sustainable implementation of this nursing specialization requires, among other things, clearly defined roles and competence descriptions for forensic nurses as well as defined institutional structures and frameworks.^{1,2} The Swiss Association Forensic Nurses (SAFN) has established the overarching competencies of forensic nurses, which enable the involved interfaces to call upon the resources and skills of forensically educated nurses in a demand-oriented and efficient manner. Efficient forensic case management in a hospital allows for timely documentation that can be used in court and proper handling of potential evidence so that it can be used efficiently if criminal charges are later filed. The implementation of forensic nursing and the superordinate competencies as well as the possible areas of application of forensically qualified nurses in Switzerland is comprehensively illustrated.

Forensic Nursing, Patient Care, Competencies and Limits

E73 Improving Care for the Sexual Assault Patient

Kathleen Sekula, PhD, Duquesne University, Pittsburgh, PA*

Learning Overview: This presentation describes the importance of increasing the number of Sexual Assault Nurse Examiners (SANEs) in practice in rural and underserved areas throughout the United States; explains the process of supporting SANEs in practice to decrease turnover; and outlines a mentoring program.

Impact Statement: This is an area of great need. There are not enough SANEs in practice to cover all areas where SANEs are needed. In addition, there is a high turnover with SANEs. It is challenging work. Grants have afforded us the opportunity to train many more SANEs and to create programs that support retention.

In many areas of the United States, no expert SANEs are available to provide services for survivors of sexual assault. Because of a lack of SANEs, resulting in poor care, survivors often do not report their assaults, with adverse effects on physical and mental health. Duquesne University School of Nursing (DUSON) received funding from the Health Resources and Services Administration (HRSA) to provide the education, clinical experience, and telehealth mentoring for Registered Nurses (RNs), Advanced Practice Registered Nurses (APRNs), and Forensic Nurses (FN) who choose to become certified SANEs. DUSON offers a rigorous SANE online didactic course and has offered a well-established forensic nursing graduate program since 2005. However, students are challenged in securing the necessary follow-up clinical experience because they lack qualified community-based SANE experts who can serve as preceptors.

The goals of the grant were to: (1) establish a coalition of academic and clinical partners, actively educating, training, or employing SANE nurses to leverage their resources to increase the number of certified SANE nurses nationally, with a focus on nurses serving rural and underserved areas; (2) develop and implement a model for comprehensive SANE education and training (didactic, clinical, and telehealth mentorship) with a focus on nurses serving rural and underserved areas; (3) prepare nurses for the national certification exam, including both participants in the proposed program and other nurses seeking SANE certification; and (4) develop a sustainability plan to support future nurses preparing for SANE certification and entering practice.

Outcomes currently include the education of over 170 nurses from 23 states, with 72 newly certified. The team is committed to disseminating outcomes and is confident that this innovative program utilizing telehealth mentoring will provide a model for the future.

SANE—A Practice, Rural/Underserved, Mentoring

E74 The Development and Successful Implementation of a State-Wide Sexual Assault Nurse Examiner (SANE) Coordinator Role: A Rural Perspective

Matthew Gamette, MS, Idaho State Police Forensic Services, Meridian, ID; Deborah Wetherelt, RN, Idaho State Police Forensic Services, Meridian, ID*

Learning Overview: After attending this presentation, attendees will have an understanding of some of the difficulties encountered in improving access to standardized care of the victim who has been sexually assaulted in a rural state and how those difficulties can be successfully surmounted.

Impact Statement: This presentation will impact the forensic science community by promoting an understanding of: (1) the importance of creating a state-wide working group (Multidisciplinary Team [MDT]) around sexual assault; (2) having a State Coordinator to facilitate standardized SANE training; (3) the benefits of the unique collaboration between a Nurse Coordinator and the state lab; (4) forensic practitioners partnering with the Nurse Coordinator to improve evidence collection and patient care; and (5) the need for state-wide protocols.

In 2018, the Idaho Legislature created the unfunded role of the Idaho Sexual Assault Nurse Examiner/Sexual Assault Response Team (SANE/SART) Coordinator; after some discussion, it was decided the position would be housed under the direction of the State Crime Lab Director to facilitate close relationships between the forensic scientists and the forensic nurse in the role and grant funding was procured.

The initial goal of the program was to train 250 Registered Nurses (RNs) as SANEs. After a trying hiring process, an experienced forensic nurse was brought on board and immediately began working to establish the educational curriculum that would meet the requirements of the International Association of Forensic Nurses Educational Planning Table for the 40-hour Adult/Adolescent SANE Course.¹ The first Coordinator trained 51 nurses, but moved on after eight months; it was several months before a replacement was found.

The second (and current) Coordinator had no direct forensic experience, but had extensive leadership and project management experience; the initial focus was for the Coordinator to contract with forensic nurses that were certified as Sexual Assault Nurse Examiner-Adult/Adolescents (SANE-As) to teach the 40-hour SANE-A course, schedule multiple courses across the state, create networks of forensic partners across the state, and begin the arduous process of becoming SANE-certified in less than a year.

COVID, of course, hampered the travel and education plans and only 31 nurses were trained in 2020. The Coordinator identified SANE programs across the state and successfully networked them together through group emails, quarterly virtual meetings of the Idaho SANE Program Leaders, quarterly newsletters, and personal contact. As recognition of the program and Coordinator grew, standardized evidence collection improved as forensic nurses reached out to the Coordinator for direction; the Coordinator and forensic scientists collaborated in creating a method to identify discrepancies in evidence collection of the Sexual Assault Evidence Collection Kits (SAECKs) and provide direct feedback to the collector, further improving collection methods and techniques.

The 40-hour course approval expired in 2021 and was revamped; eight courses have been scheduled across Idaho for 2021, and the Coordinator is encouraging organizations to schedule into 2022 to ensure continued education for staff. A four-hour *Medical Forensic Examinations for the ED Staff* was created to ensure emergency room physicians and nurses could properly complete evidence collection when a SANE was not available.

As with all successful programs, there is no time to rest; expansion of the program through collaboration with law enforcement and other partners is being developed as Idaho continues to pursue excellence in forensic practice.

E75 The Standardization of Sexual Assault Examination Kits in the United States: An Exploration of the Role Sexual Assault Nurse Examiners (SANEs) and Telehealth Have on the Sexual Assault Examination Process

Amy Southall-Malone, MFS, Mississippi Forensics Laboratory, Pearl, MS*

WITHDRAWN

E76 The Sexual Assault Nurse Examiner (SANE): A Responsive Strategy to Global Sexual Violence

Jamie Ferrell, MBA, BSN, RN, Memorial Hermann Healthcare System, Houston, TX*

Learning Overview: After attending this presentation, attendees will have an understanding of the specialized SANEs evidence-based practice across the life span, the improved health impact on survivors of sexual violence, the quality of forensic science results, and responsiveness to the judicial process.

Impact Statement: This presentation will impact the forensic science community by providing a blueprint that can be implemented globally as a response to sexual victimization through the evidence-based practice of the specialized adult or pediatric SANE.

Sexual violence and its associated trauma are pervasive through each society. Adverse childhood experiences such as sexual assault have been linked to leading causes of adult morbidity and mortality. Reducing this trauma is critical to avoiding multiple negative health and socioeconomic outcomes in adulthood. The likelihood of restoration following sexual violence is increased for victims who have access to medical professionals skilled in trauma-informed care that has important implications for their future health and well-being.¹

Experience indicates that successful prosecutions of sexual crimes require the coordination and cooperation of both skilled health care practitioners and the criminal justice system. Strategies to improve evidence-based global standards of care for victims of all ages post-sexual assault necessitate specialized forensic nursing education to include pertinent knowledge of the law. The patients' history of sexual assault and a comprehensive assessment are the important predictors to assist with decisions of evidence recovery.

SANEs are Registered Nurse health care providers qualified in the examination and evaluation of physical trauma with an emphasis on maximizing evidence recovery while minimizing emotional trauma with trauma-informed compassionate care modalities. Education of the SANE specialist in adult and pediatric populations entails a 41-hour adult SANE course and a minimum 120 hours of clinical training, observation, and precepted exams prior to caring for these patients.² Pediatric SANE education is an additional 43-hour pediatric SANE course along with a minimum of 104 hours of clinical training, observation, and precepted exams.²

Best-specimen recovery has inordinate significance in the criminal investigation of sexual violence. The SANE understands that the application of science and technology continues to enhance the implication of biomedical, trace, and physical evidence to unprecedented levels within the judicial domain. Sources of potential evidence are continually expanding with the advanced sensitivity of DNA testing. SANEs are specifically educated in the understanding of the evolution of DNA with saliva transfer or touch DNA in strangulation.³

Access to SANEs facilitates improved evidence collection kit results for sexual assault patients.^{4,5}

The SANE serves as a clinical liaison to the criminal investigation and is available to testify in court when required. While clinical responsibilities center on competency for quality patient outcomes, the application of scientific technology involving electronic documentation and digital imaging advances clinical outcomes and operational efficiency.

Sexual Assault Nurse Examiner, Sexual Violence, Evidence-Based

E77 Sexual Assault Victim and Assault Characteristics and Development of Combined DNA Index System (CODIS) -Eligible Short Tandem Repeat (STR) DNA Profiles

Julie Valentine, PhD, Brigham Young University, Provo, UT; Sam Payne, PhD, Brigham Young University, Provo, UT; Leslie Miles, DNP, Brigham Young University, Provo, UT; Luke Johnson, Brigham Young University, Provo, UT; Connor Alder, Brigham Young University, Provo, UT*

Learning Overview: After attending this presentation, attendees will have increased knowledge about sexual assault victim and assault characteristics associated with the development of CODIS-eligible STR DNA profiles from sexual assault evidence kits.

Impact Statement: This presentation will impact the forensic science community by adding to the few studies exploring victim and assault variables and association with DNA analysis development of STR DNA CODIS-eligible profiles.

When individuals report sexual assault within ~120 hours of the assault, they have the option of having evidence collected during Sexual Assault Medical Forensic Examinations (SAMFEs).¹ During SAMFEs, forensic examiners collect information about the victim and the assault to guide the examination and evidence collection. The SAMFE examination form is generally given with the Sexual Assault Kit (SAK) to law enforcement professionals who are responsible for submitting SAKs to crime laboratories for analysis.

The purpose of this study was to explore victim and assault variables contained in the SAMFE forms and the subsequent development of STR Deoxyribonucleic Acid (DNA) profiles eligible for entry in the Federal Bureau of Investigation Combined DNA Index System (CODIS). This retrospective, exploratory study of ~5,000 SAKs found that the following variables were statistically significant in increased development of STR DNA CODIS-eligible profiles: age; gender; time between assault and exam; suspect actions of grabbing/holding, physically hitting and/or strangling victim; vaginal-penile penetration; suspect oral contact on victim genitals and other body parts; ejaculation; higher number of penetrative acts; and victim with anogenital injuries and non-anogenital injuries. Variables associated with decreased development of STR DNA CODIS-eligible profiles included the following: increasing length of time between assault and exam; bathing/showering after assault and prior to exam; multiple suspects; and suspected drug-facilitated sexual assault. Logistic regression models were calculated to explore predictive power of statistically significant variables.

Exploring variables associated with development of STR DNA CODIS-eligible profiles is beneficial in practice and policy decisions for Sexual Assault Nurse Examiners (SANEs), forensic examiners, and forensic scientists. With the increased submission and testing of SAKs, crime labs are exploring options to improve workflow of SAK DNA analysis.² Other studies have been conducted and found variables associated with development of STR DNA CODIS-eligible profiles include time between assault and exam, history of consensual sexual contact, and bathing/showering.³

Sexual Assault, Sexual Assault Medical Forensic Examinations, STR DNA Codis-Eligible Profiles

E78 An Estimation of Error Rates in Library Matching of Forensic Textile Evidence Classified by Attenuated Total Reflectance/Fourier Transform Infrared (ATR/FTIR) Spectroscopy

Lauren Bouju Davies*, Seattle University, Seattle, WA; Braeden Camarota, Seattle University, Seattle, WA; Kristen Skogerboe, PhD, Seattle University, Seattle, WA

Learning Overview: The goal of this presentation is to instruct attendees on the use of ATR/FTIR in the creation of a spectra database for use in the classification of unknown forensic textile samples. This presentation will evaluate how fabrics are classified using spectral library matching of unknown fabric samples to a fabric library.

Impact Statement: This presentation will impact the forensic science community by providing an estimate of the error rate on an ATR/FTIR instrument when used to match textiles to a created in-house fabric library. Spectra from the in-house library were compared to published spectra to ensure accuracy. In forensic science, estimating the accuracy of testing methods is a point of scrutiny, so this project assesses the error rate of ATR/FTIR when applied to classification of forensic textile evidence.¹

FTIR is a powerful tool for identifying fabric type but is limited by the availability of public domain databases of FTIR spectra.² Forensic laboratories and educational institutions must either make their own library or purchase one of the limited fabrics FTIR databases in existence.³ This study establishes a fabric library using FTIR and evaluates its effectiveness in classification of unknown textile types. Pieces of fabric were tested instead of individual fibers because the ATR allows for the sampling of textile evidence, including very fragile textile samples, without causing further damage.

This project created a digital and accompanying physical fabric library of 36 “pure” samples (100% one fiber type) and 30 mixed samples (at least two fiber types). Both natural and synthetic fibers were cataloged. At least two different samples from different sources for each pure fabric type were tested, including varying colors, weaves, and dye techniques to simulate the diversity of samples that would arise in routine forensic case work.

For this study, a PerkinElmer® Spectrum Two ATR/FTIR was used to collect four scans of each sample to generate one spectrum. A total of 66 different fabrics were scanned to create an in-house fabric library. The same samples were then re-run through the ATR/FTIR as unknowns and searched against the fabric library. The top three matches and accompanying search scores, determined using the software’s built-in Euclidean distance algorithm, were recorded. All samples were tested in replicate. Three separate libraries were designated for testing purposes: (1) pure, $n=36$, (2) mixed, $n=30$, and (3) combined, $n=66$. For estimation of error rate, pure samples were run against a pure library, mixed samples were run against a mixed-only database, mixed samples were run against a pure library, and all samples were run against the combined library.

Generally, pure samples were more accurately matched by the fabric library compared to the mixed samples. To date, all pure samples matched to the same fabric type, but did not always self-match. Some mixed fabrics did not match by fabric type or self-match, indicating that the usefulness of FTIR for identifying unknown mixed fiber samples may be limited. Mixed fibers may need additional methodologies, including multivariate analysis techniques, to accurately classify the fiber types.⁴ Challenges specific to mixed samples will be presented. An operator well-trained in FTIR usage and spectra analysis can increase the accuracy of textile identification.

These results provide a baseline of data that show the success of spectral database matching. The results also illuminate problems with spectral matching of fabric types. This shows a path forward to improve the accuracy of textile classification using ATR/FTIR.

Forensic Fabric/Textiles, Library Matching Error Rate, ATR/FTIR

E79 An Assessment of Heat Damage on Fourier Transform Infrared (FTIR) Spectral Characteristics of Various Fabric Samples for Applications to Forensic Clothing Examination

Braeden Camarota, Seattle University, Seattle, WA; Cheyenne Smith, Ohio Northern University, Ada, OH; Lauren Bouju Davies, Seattle University, Seattle, WA; Chesterene Cwiklik, BS, Cwiklik & Associates, Seattle, WA; Kristen Skogerboe, PhD, Seattle University, Seattle, WA*

Learning Overview: After attending this presentation, attendees will have been introduced to the use of Attenuated Total Reflection/Fourier-Transform Infrared (ATR/FTIR) spectroscopy to distinguish between burnt, unburnt, and partially burnt fabric samples. Research results of controlled fabric damage demonstrate differences in functional groups present within samples that are changed or removed due to pyrolysis. This is applicable in cases where forensic fiber evidence was subjected to fire or other types of heat, conditions common in arson or when attempts to conceal a crime are made.

Impact Statement: This presentation will impact the forensic science community by assessing the utility of FTIR for the evaluation of heat damage to fabrics, including damage produced at fire crime scenes, by friction, hot gases from firearms, and discarded evidence from human rights cases. This work represents an extensive controlled study that evaluates changes in FTIR spectra when fabric is exposed to heat, and examines whether these would impact conclusions drawn from other testing of the evidence.

In this study, fabrics comprising ten different fiber types (cotton, silk, wool, polyester, rayon, nylon, leather, linen, lyocell, and polypropylene) were subject to heat damage from an open flame and from convection heat, with each type burned independently and paired with each other.¹ Heat damage occurred in visually distinct stages (evaluated microscopically and reported separately), with each damage stage assessed by ATR/FTIR.

There are limited, albeit growing, scientific studies dealing with heat damage of fabrics in a forensic context.^{2,3} For example, light chars and burns can be difficult to distinguish from brown or tan stains produced from liquids or suspensions. Similarly, it can be challenging to determine the type of fiber present in a sample turned to ash. This study offers insight to the use of ATR/FTIR to answer such questions.

A salient aspect of this study is the evaluation of spectral characteristics when multiple layers of different fabrics were burned together. This occurrence would be commonly expected in routine case work where layered fabrics are burnt together; deposits or transfer of aerosol products produced by burning cellulosic fabrics may also occur. This work describes the spectral characteristics of two fabrics in contact with each other subjected to various stages of heat damage and identifies numerous changes depending on fabric types.⁴

Ongoing studies are being performed to create a comprehensive understanding of spectral changes specific to various stages of heat damage and fabric type; the results will be presented in a tabular format. This work includes the creation of a spectral library of fabric that includes entries pre- and post-heat damage.

Forensic Fabric Evaluation, Heat Damage, ATR/FTIR

E80 A Quantitative Analysis of Smokeless Powder Particles in Post-Blast Debris Via Gas Chromatography/Vacuum Ultraviolet Spectroscopy (GC/VUV)

Madison Reavis, BS, IUPUI, Indianapolis, IN; John Goodpaster PhD, IUPUI, Indianapolis, IN*

Learning Overview: Attendees of this presentation will gain information about post-blast debris analysis via GC/VUV and the importance of the subsequent quantification of components present in post-blast smokeless powder particles.

Impact Statement: This presentation will impact the forensic science community by presenting information about the VUV spectrometer and the ability to utilize unique internal standards for the quantification of explosive components in post-blast debris.

The goal of this research is to quantify nitroglycerin, 2,4-dinitrotoluene, diphenylamine, ethyl centralite, and dibutyl phthalate in post-blast smokeless powder particles using heptadecane as an internal standard. An internal standard solution of 100ppm heptadecane in acetone was made and used as the solvent for all experiments.

Post-blast debris was obtained via controlled explosions with assistance from the Indiana State Police Bomb Squad. Two galvanized steel and two Polyvinyl Chloride (PVC) Improvised Explosive Devices (IED) were assembled. For both materials, one device contained IMR 4064 (single-base smokeless powder) and the other contained Alliant Red Dot (double-base smokeless powder). Each device was placed in a steel box to help retain the post-blast debris for collection.

Intact particles were extracted from debris using forceps and an Olympus® SZ61 stereomicroscope equipped with a Fiber-Lite MI-150 High Intensity Illuminator. Solutions containing intact powder were prepared at 1,000ppm in internal standard solution. These solutions were then filtered using a Polytetrafluoroethylene (PTFE) filter. Calibrants were prepared and analyzed on the same day as the post-blast samples to ensure reproducible and reliable quantification.

Each sample was injected into an Agilent® 7890B GC equipped with an Agilent® 7693 autosampler and a multimode inlet. The sample was introduced using hydrogen carrier gas at 2.4mL/min. The multimode inlet was in splitless mode with a temperature program beginning at 50°C and ramped to 200°C at 900°C/min. The analytes were then separated by a 15m x 320µm x 0.25µm Restek Rtx®-5MS column. The oven temperature began at 50°C, was held for 30 seconds, and was then ramped at 20°C/min to 250°C. The same oven temperature program was used for all samples. After separation, analytes were introduced into a VUV Analytics® VGA-101 VUV spectrometer at a transfer line and flow cell temperature of 300°C. Samples were analyzed using a scan rate of 4.5Hz, a deuterium lamp at 1.2V, a make-up gas pressure of 0.00psi, and a spectral range of 120–430nm. To improve the signal-to-noise ratio, the resulting chromatograms were analyzed using data from 125–240nm.

2,4-dinitrotoluene and diphenylamine were successfully quantified in the single-base smokeless powder post-blast debris while nitroglycerin, diphenylamine, and ethyl centralite were successfully quantified in the double-base smokeless powder post-blast debris. Compounds were detected as low as 7µg of 2,4-dinitrotoluene per mg of intact powder, <3µg of diphenylamine per mg of intact powder, 113µg of nitroglycerin per mg of intact powder, and <3µg of ethyl centralite per mg of intact powder in all devices. The concentration of 2,4-dinitrotoluene in IMR 4064 post-blast debris originating from the steel IED is lower than debris originating from the PVC IED. This could possibly be due to the steel IED reaching higher temperatures, leading to the increased consumption of 2,4-dinitrotoluene.

Vacuum Ultraviolet Spectroscopy, Forensic Explosive Analysis, Gas Chromatography

E81 Addressing the Quantitative Aspect of Single Grain Forensic Palynology

Luz Kelley, MS*, University of Central Florida, Orlando, FL; Matthieu Baudelet, PhD, University of Central Florida, Orlando, FL

Learning Overview: After attending this presentation, attendees will have gained an understanding of a non-destructive genomic analysis application of single pollen grains by combining the techniques of quantitative Polymerase Chain Reaction (qPCR), flow cytometry, and microscopy.

Impact Statement: This presentation will impact the forensic science community by providing a simplified and quantitative pollen grain analysis by combining two affordable techniques and their protocols for forensic labs at the state or local levels.

The ability to identify a plant species through pollen samples has played a role in various technological, industrial, and scientific fields throughout the years.¹ For example, airborne pollen monitoring to manage seasonal respiratory diseases, food quality control of honey, plant-pollinator interactions, and forensic botany.¹⁻⁷ However, pollen studies are limited by methods that are labor-intensive, time-consuming, and prone to misidentification.⁸ As a result, there is a growing need for quick and effective pollen identification that allows for quantification.⁸ The two most used methods for pollen identification are microscopy and DNA metabarcoding.

Microscopy is the gold standard for quantitative and qualitative pollen analysis.⁸ Pollen assemblages, consisting of hundreds of grains, are typically stained, and morphology is determined under a microscope.^{7,9} However, regardless of the field, pollen identification relies on expert knowledge examining the samples and high manual effort leading to a considerable cost, time-consuming, and low sample throughput.^{1,4,8,10} Another disadvantage to this method is that identification can only occur at the family level or higher for many species and may fail to detect rarer species.^{1,11} This identification level is because pollen grains from the same family cannot be differentiated due to their shared morphological features.² In recent studies, flow cytometry has been presented as an alternative optical method for counting and identifying pollen grains.⁸ In addition, it allows for higher capture rates than traditional microscopy.⁸ This study compares the conventional microscopy method with flow cytometry for pollen identification based on scattering and fluorescence characteristics on a single grain level. The combined data obtained from single grains opens the door for other downstream applications, including plant species identification at the individual grain level in soil, air collection, and clothing swabs samples.

DNA metabarcoding identifies large quantities of pollen samples at the species level using standardized barcode marker gene regions.⁸ To date, five genetic markers have been used for DNA barcoding and metabarcoding: *matK*, *rbcL*, ITS2, *trnH-psbA*, and *trnL*.⁴ One standard method to determine one species from another is through sequence variation using Polymerase Chain Reaction (PCR).¹² However, PCR alone cannot quantitatively assess the amount of DNA present at the beginning of the process before amplification, and qPCR is used in this respect.¹² Quantitative methods are commonly based on calibrations curves, either using threshold cycles as a proxy or initial seed values from amplification models of the experimental curves, as a function of the logarithm of DNA concentration.¹³ This study compares these approaches. QPCR analysis of the chloroplast genetic markers *rbcL* and *matK*, the second nuclear ribosomal ITS2 region, was used for each plant species. The species evaluated were *Ambrosia artemisiifolia* (common ragweed), *Paspalum notatum* (bahiagrass), *Artemisia vulgaris* (common mugwort), *Quercus virginiana* (southern live oak), *Pinus echinata* (shortleaf pine), *Taxodium distichum* (bald cypress), *Phalaris arundinacea* (reed canary grass), and *Plantago lanceolata* (ribwort plantain).

E83 Spectrally Based Color Calibration of Microscopes for the Analysis of Birefringence

Olivia Field, BS, University of Central Florida, Orlando, FL; Matthieu Baudelet, PhD, University of Central Florida, Orlando, FL*

Learning Overview: After attending this presentation, attendees will understand the importance of color calibration and the advantage of using appropriate color spaces to quantify fiber birefringence determination.

Impact Statement: This presentation will impact the forensic science community by providing a quantitative methodology for calibrating the color spaces in microscopy and using it for a more accurate birefringence determination of fibers.

In forensics, textile fibers are one of the most common pieces of trace evidence found at a crime scene. This provides a way to connect an assailant to a crime scene. The quantitative analysis of fibers is important to the growth of improving trace analysis techniques. Fibers are anisotropic, allowing for the determination of birefringence using interference colors. Each fiber has a range of possible birefringence values dependent on thickness that cause true identification to be difficult. Color analysis is crucial in being able to discriminate between fibers found at a crime scene. These colors can be used to estimate the birefringence range of a fiber. Typically, color is analyzed using a color space. The most common color spaces include RGB, XYZ, $L^*a^*b^*$, and $L^*u^*v^*$. Unfortunately, color is very subjective and often difficult to quantify accurately, even using digital detectors. Finding true matches of colors has been limited by factors including illumination, optics transmission function, and, in many cases, the human eye. The colors produced by the birefringence of fibers under analysis using Polarized Light Microscopy (PLM) are known to provide a quick information on the fiber identification. Nonetheless, the exact determination of the accurate colors is still either subjective to the operator or the correct calibration of the software.

A variety of textile fibers (nylon, rayon, acetate) were analyzed for birefringence using a PLM. Calibration of the color response of the microscope camera was performed using a Ultraviolet/Visible (UV-Vis) broadband spectrometer used to determine the CIE XYZ 1931 reference values for the illuminant. All the color images obtained with the camera were then transformed from the RGB color space using MATLAB® into $L^*a^*b^*$ color space using the references of the illuminant of the microscope just measured above. An empirical Michel-Levy chart was also designed using a quartz wedge in order to calibrate retardation with empirical $L^*a^*b^*$ color values.

The discriminatory power and uncertainty of color perception of the microscope camera and of human vision were measured and will be discussed in this presentation.

Microscopy, Color, Calibration

E84 The Persistence of Diatoms as Trace Evidence in Clothing Fabrics: The Effect of Active Removal (Machine Washing) and Passive Removal (Time and Environment)

Ross Flynn, MSc, Murdoch University, Murdoch, Western Australia, Australia; Paola Magni, PhD, Murdoch University, Murdoch, Western Australia, Australia; Ashiwin Vadiveloo, PhD, Murdoch University, Murdoch, Western Australia, Australia; Navid Moheimani, PhD, Murdoch University, Murdoch, Western Australia, Australia; Kari Pitts, PhD*, Chemcentre, Perth, Western Australia, Australia

Learning Overview: After attending this presentation, attendees will understand newly explored factors that influence the persistence of diatoms as a form of physical trace evidence within different variations of clothing fabrics when subjected to environmental removal pressures and settings. This presentation will increase attendees' awareness of diatoms, their potential applications, and their limit as trace evidence and factors affecting its role as such.

Impact Statement: This presentation will impact the forensic science community by increasing awareness of the use of the diatoms in forensics, specifically as trace evidence, as well as exploring aspects of their persistence in common clothing fabrics in practical contexts.^{1,2}

Aquatic crime scenes present a challenging environment for crime scene investigators to operate in. Generally, many conventional forms of evidence that are relied upon in terrestrial environments, such as trace evidence like fibers or hairs, are unavailable in aquatic environments due to their ephemeral nature and aquatic life therein. However, aquatic environments are host to organisms that can have evidential use in the absence of more traditional evidence. Diatoms are microscopic algae with cell walls composed of silica, initially largely used to aid in drowning diagnoses. More recent literature has shifted the attention of diatoms in forensics from the area of forensic pathology to that of trace evidence.^{3,4} So far, the research mostly centers on diatom transfer from environments to clothing and their subsequent extraction from clothing fabrics for analysis.^{2,5} Little research has yet been published concerning the persistence of diatoms in clothing fabrics.

The aim of this study is to analyze the effects that various active (manual) and passive (natural) removal pressures have on the persistence of diatoms within various common clothing fabric of different constructions and compositions (pure cotton knit, denim weave, pure polyester knit). Fabrics were submerged in Diatom-Enriched Waters (DEW) prepared using 50:50 mixed cultures of native and common Australian diatom species (*Chaetoceros muelleri* and *Navicula* sp.).

In the active experiment, the fabrics were washed in washing machines (top loader and front loader) at varying temperatures (cold and warm >40°C) for one, two, and three consecutive washes, to assess the persistence of diatoms in the fabric samples when subject to an attempt to remove them via machine washing actively. Additionally, some unsubmerged fabric samples were introduced to the washes to assess whether cross-contamination could occur.

In the passive experiments, the fabrics were left in various environments (indoors and outdoors) and sampled at increasingly longer time intervals for three months to assess any passive reduction due to natural passive pressures without any active influence.

This presentation will discuss the outcome of this study and provide interpretations and implications of the results in the light of future case work.

Diatoms, Persistence, Forensic Trace Evidence

E85 An Assessment of Swab Efficiency for Body Fluid Identification and DNA Isolation and Analysis in Different Types of Fabric

Gabriela Roca, PhD, SERATEC, Goettingen, Lower Saxony, Germany; Sara C. Zapico, PhD, New Jersey Institute of Technology, Newark, NJ and Smithsonian Institution, Washington, DC*

Learning Overview: After attending this presentation, attendees will understand the importance of swab types not only for efficient DNA isolation and analysis, but also for body fluid identification.

Impact Statement: This presentation will impact the forensic science community by introducing, for the first time, the simultaneous assessment of body fluid identification, DNA isolation, and characterization, taking into consideration the type of swab and fabrics, which will lead to applying these techniques in crime scene investigations.

Recovering appropriate evidence from crime scenes to identify perpetrators or in certain cases, the victim, is one of the main goals of forensic investigation. As a result, identification of body fluids could be crucial toward this purpose. Current techniques of body fluid identification include, among others, the use of Alternative Light Sources (ALS), chemical assays, and/or immunochromatographic tests. The latter are based on the specific antigen-antibody reaction against a human protein, with higher expression in the body fluid in question. These tests are simple, quick, and suitable to use at crime scenes.

As with any other tests, the first step to apply these immunochromatographic tests is to retrieve the potential sample with a swab moisturized in a specific buffer. The swabs normally used at crime scenes are cotton swabs. However, there are other types of swabs available in the market that have been proven to be efficient for subsequent DNA isolation and analysis.

The aim of this study is to assess the efficiency of different types of swabs for body fluid identification applying immunochromatographic tests, as well as DNA isolation and characterization.

Fifty microliters of human saliva were deposited in three different types of textiles (denim, cotton, and polyester). Three replicates per each swab type and fabrics were evaluated. After 24 hours at room temperature, saliva samples were recovered applying three different types of swabs: cotton swabs, COPAN® 4N6FLOQSwabs™ Regular size tip, and COPAN® 4N6FLOQSwabs™ Subungal Shape. Swabs were incubated in agitation in 300ul of extraction buffer from Seratec® SALIVA CS test, during 10 minutes. After that, three drops of buffer were added to the Seratec® SALIVA CS immunochromatographic test, and the results were recorded.

Total DNA was isolated from the extraction buffer using silica-based columns, and later quantified applying fluorescent methodology. Promega® PowerPlex® Fusion 6C System was used to amplify and characterize 23 autosomal Short Tandem Repeats (STRs) and Amelogenin gene in 1ng of DNA. Mitochondrial DNA (mtDNA) characterization was carried out using BigDye™ Direct Cycle Sequencing kit for Hypervariable Regions I and II. Statistical analyses were carried out in SPSS® Statistics version 26.

Immunochromatographic test results showed differences among swab types. In denim and cotton, band intensities are higher with 4N6FLOQSwabs™ Regular size tip and 4N6FLOQSwabs™ Subungal Shape than with cotton swabs. In contrast, polyester showed the same intensities in the three types of swabs.

DNA concentration showed the same pattern, obtaining higher yields of DNA with 4N6FLOQSwabs™ Regular size tip and 4N6FLOQSwabs™ Subungal Shape in denim and cotton, and similar concentrations with the three types of swab in polyester. A two-way Analysis of Variance (ANOVA) demonstrated that both type of swabs and fabrics, individually and together, influenced DNA yield.

After DNA profiling, three parameters were assessed toward determining DNA quality: summary of peak height, Mean Local Balance, and Profile Index, according to a previous publication. After calculation of these parameters and application of two-way ANOVA, in this case, only the swab type had an impact on DNA quality.

Findings from this research provide evidence that the swab type could be crucial to efficiently identify body fluids as well as increasing the DNA yield and quality in forensic samples.

Swab, Body Fluid, Saliva

E86 An Elemental Analysis of Bullets Via Atomic Absorption Spectroscopy

Jan Halámek, PhD, Texas Tech University, Lubbock, TX; Ashley Newland, MS, Texas Tech University, Lubbock, TX; Giana Biddle, MS, Texas Tech University, Lubbock, TX; Morgan Eldridge, PhD, Texas Tech University, Lubbock, TX*

Learning Overview: This presentation will address current issues with firearm and tool mark analysis while providing a scientific solution that is understandable to those in various fields.

Impact Statement: This research is beneficial to the forensic science community due to the necessity of scientific-based evidence implemented in court along with the opportunity for increased efficiency in criminal investigations.

Firearm identification is a vital element in thousands of crime scene investigations per year. As violent crimes involving firearm use increase, the need for accurate and scientific conclusions with quickly obtainable results increases as well.

Current modes of analysis have caused controversy in the legal system due to the subjectivity and non-scientific basis of the firearm and tool marks examiner's conclusions on whether projectiles found are a match to the suspected weapon used. Examiners base their findings on microscopic evaluations of markings found on the projectile. These observations are then compared to test-fired rounds and leads the examiner to four possible conclusions, which are identification, inconclusive, elimination, or not suitable for comparison. It is argued that evidence based on observation only is not sufficient as many individuals view objects differently.

A method in which a bullet can be identified without the recovery of the projectile or firearm at a crime scene has not been developed nor has scientific-based analysis of ballistic evidence been implemented in criminal investigations prior.

The aim of this project is to solve these current issues by introducing a new method of ballistic analysis via Atomic Absorption Spectroscopy (AAS). This instrumentation allows for the detection of various elements present in bullets. More specifically, the ratios of metal concentrations, which has shown to be unique to manufactures and types of bullets from the results of this research so far. Forensic scientists can accomplish this method with or without discovery of casings or bullets on the scene. The metal deposits created by contact between a surface and the bullet can be extracted, so there is no need for the physical projectile to identify the firearm in cases where the weapon is missing. Another goal of this research is to develop a database of these ratios specific to each manufacturer to determine the bullet type and brand for reference when comparing AAS results.

Implementation of this technology can be beneficial to these cases involving firearm use in many aspects. This scientific approach adds probative value to the expert witness' testimony in court to corroborate their statements along with decreased inconclusive or unsuitable for comparison conclusions. AAS instrumentation only requires a very small sample volume, which provides a solution for fragmented samples that fall under the category of the unsuitable for comparison conclusion. Additionally, damaged surfaces can serve as a replacement for the absence of ballistic evidence rather than simply having a missing piece of evidence that is important to solve the investigation.

Crime Scene Investigation, Forensic Ballistics, Atomic Absorption Spectroscopy

E87 A Pre-Post Experimental Study on the Life of Blood Stains on Different Soil Samples

Did Not Present.

E88 Investigation Into the Aging Mechanism of Bloodstains Post-Deposition Using Steady-State Fluorescence Spectroscopy for Forensic Purposes

Alexis Weber, MSFS*, SupreMEtric, Albany, NY; Anna Wójtowicz, BS, Jagiellonian University, Kraków, Poland; Igor Lednev, PhD, University at Albany, SUNY, Albany, NY

Learning Overview: After attending this presentation, attendees will have a better understanding of the biological aging mechanism of peripheral and menstrual bloodstains.

Impact Statement: This presentation will impact the forensic science community by presenting information on the fundamental aspects of blood aging.

Blood is one of the most common body fluids discovered at crime scenes involving violent actions.¹ It is considered one of the most important types of forensic evidence since it allows for the identification of the individual, providing that there is a match with a known DNA profile.² However, there is additional information that could be learned from bloodstains. Determining the Time Since Deposition (TSD) could further assist investigators by establishing when the crime occurred or if a bloodstain present is related to the investigated event. Additionally, if crime scenes contain multiple sets of bloodstains, the TSD determined for individual bloodstains should allow for the selection of bloodstains relevant to the crime and, therefore, reduce the number of samples that should be collected, documented, and processed, thus creating a more efficient workflow within the forensics community.

To develop a forensically sound method for determining the TSD of a bloodstain, it is necessary to understand the underlying biochemical mechanisms occurring during aging. As biochemical processes occurring in blood are necessary for the continued survival of living organisms, they are important subjects of human biology and biomedicine and are well understood. However, during a violent criminal event where bleeding occurs, the blood will be deposited onto a surface. The biochemistry of bloodstain aging *ex vivo* is primarily of interest to forensic scientists as it has not yet been thoroughly researched specifically.

This preliminary study utilizes steady-state fluorescence spectroscopy to probe and compare the changes in fluorescence properties of peripheral and menstrual blood up to 24 hours post-deposition.³ It was shown that peripheral and menstrual blood exhibited similar kinetic changes over time, assigned to the presence of the fluorophores: tryptophan, Nicotinamide Adenine Dinucleotide (NADH), and flavins in both biological fluids. The unique biochemical mechanisms of blood aging *ex vivo* will be discussed.

E89 A Membrane-Modulated Centrifugal Microfluidic Platform for Field-Forward Immunodetection of Opioids

Leah Dignan, BSc, University of Virginia, Charlottesville, VA; Michael Woolf, PhD, University of Virginia, Charlottesville, VA; Jennifer Ross, MD, MPH, University of Virginia Health System, Charlottesville, VA; Carly Baehr, PhD, University of Minnesota Medical School, Minneapolis, MN; Christopher Holstege, MD, University of Virginia Health System, Charlottesville, VA; Marco Pravetoni, PhD, University of Minnesota Medical School, Minneapolis, MN; James Landers, PhD, University of Virginia, Charlottesville, VA*

Learning Overview: After attending this presentation, attendees will have been introduced to a novel microfluidic method for antibody-based detection of opioids that leverages an Enzyme-Linked Immunosorbent Assay (ELISA) with colorimetric readout.

Impact Statement: This presentation will impact the forensic science community by presenting a cost-effective, portable method for immunodetection of forensically relevant illicit and misused substances.

Opioids are a common class of illicit or misused substances and currently cause the majority of overdose-related fatal intoxications.^{1,2} Such widespread use has exposed the need for accurate, reliable Point-of-Need (PoN) presumptive drug tests to produce actionable information on-site to inform an appropriate, timely response. However, many colorimetric forensic field tests are subjective and non-specific; spectroscopic techniques are often prohibitively expensive.³ As a result, many jurisdictions forgo field testing altogether, instead shipping seized samples directly to centralized laboratories.⁴ Immunoassays, including ELISAs, serve to presumptively identify substances prior to confirmatory spectroscopic analysis, but these methods are traditionally time-consuming and labor-intensive, requiring substantial manual sample handling by trained analysts. Such delays in obtaining accurate results can have markedly negative impacts on public prevention efforts attempting to avoid adverse public outcomes; there is a need for fast, reliable detection methods.

The goal of this work is to adapt ELISA workflow to a portable, centrifugal microfluidic platform that automates and expedites the assay for reliable, accurate opioid detection by non-technical personnel. Broadly, microfluidic strategies provide several advantages over traditional laboratory methods, including minimized sample and reagent consumption, decreased cost-per-test, ease of automation, enclosed formats, and shortened analytical intervals. Among these, centrifugal microfluidics is especially appealing given that simple, rotationally controlled fluid flow eliminates the need for bulky external equipment (e.g., pumps, to ensure portability).⁵ This study leverages this method to streamline ELISA workflow and permit strict adherence to the stepwise protocol needed for successful immunodetection. Incorporation of colorimetric output, and an associated objective interpretation method, ultimately permitted simultaneous, parallel detection of opioids from eight samples in as little as one hour—a marked decrease in required analytical time relative to the traditional multi-day timeline.

Optimized microarchitecture included embedded membrane microvalves to enhance on-disc fluidic control; at low rotational frequencies, fluid was temporally retained in the immunodetection chamber for incubation and/or mixing, whereas high-speed disc rotation drove flow through the microvalve and out of the chamber. On-disc chromogenesis was comparable with parallel traditional, plate-based ELISA results. Morphine and a key metabolite were detected in the ng/μL range, in buffer and artificial urine, respectively. Assay specificity was demonstrated through differentiation of opioids from several other drug classes with no observed cross-reactivity with common adulterants found in seized street-level substances. Together, these results highlight the broad potential application of this technology, spanning from use by law enforcement officers for roadside drug testing to toxicological urinalysis.

Future work involves integration of on-board reagent storage and parallel, simultaneous screening for multiple substances. The work described represents significant progress toward a true “lab-on-a-chip” device for affordable, simple, *in situ* drug testing.

E90 Non-Contact Detection of Fentanyl by a Field-Portable Ion Mobility Spectrometer

Ashley Fulton, PhD, U.S. Naval Research Laboratory, Washington, DC; Stephanie Vaughan, PhD, U.S. Naval Research Laboratory, Washington, DC; Lauryn DeGreeff, PhD, Formerly U.S. Naval Research Laboratory, Washington, DC*

Learning Overview: After attending this presentation, attendees will understand how a non-contact detection method for fentanyl was developed.

Impact Statement: This presentation will impact the forensic community by providing a non-intrusive and safer way for the detection of fentanyl and fentanyl-related substances.

Fentanyl is a potent synthetic opioid that has vast medical benefits. This Schedule II drug is approved as an analgesic for chronic pain, used as a general anesthetic, and is often given to women during childbirth. These medical benefits have been outweighed by the increased illicit use of fentanyl. At the height of the COVID-19 pandemic, there was an acceleration in deaths caused by opioids, with over 81,000 documented overdoses with illicitly manufactured fentanyl as one of its leading forces.¹ Inhaling mere milligrams of fentanyl can result in an overdose, which is not only dangerous to the user, but also law enforcement. To prevent exposure, the National Institute for Occupational Safety and Health (NIOSH) recommends that the scene be handled by specifically trained personnel wearing proper protective equipment.² The ability to safely detect fentanyl is imperative for first responders and law enforcement.

Currently, there are several ways to detect fentanyl in the field. However, all require direct sampling of bulk material, which puts the technician at risk. To date, there have been very few non-contact methods developed for the detection of fentanyl. A method using fentanyl vapor would provide a non-invasive and non-destructive manner of detecting fentanyl. Unfortunately, fentanyl has a low vapor pressure, making it virtually undetectable directly in the vapor phase. Conversely, by determining the vapor signature of fentanyl, the target analytes can be identified and used for detection in the vapor phase. Solid Phase Microextraction with Gas Chromatography/Mass Spectrometry (SPME-GC/MS) was used to identify the target analytes from the vapor signature of pharmaceutical-grade fentanyl, fentalogs, and street-grade fentanyl. Comparative analysis of the vapor profiles indicated two target analytes: N-Phenylpropanamide (NPPA) and N-Phenethyl-4-Piperidone (NPP). These target analytes can be used to detect fentanyl in the vapor phase using a portable vapor detector.

Hand-held Ion Mobility Spectrometers (IMS) offer a sensitive, user-friendly, and quick method for narcotics and explosives detection. This presentation describes the method developed for detection of target analytes for fentanyl using a handheld IMS. First, the drift times were determined to be 5.896ms for NPPA and 6.484ms for NPP. The drift times were then used to program alarms in the handheld IMS system. Finally, the two alarms were tested by sampling the vapors of NPP, NPPA, pharm-grade fentanyl, and adulterated pharm-grade fentanyl samples. The system was able to accurately identify the target analytes when sampling NPP and NPPA. Both analytes were found in pharm-grade fentanyl, while only NPPA was found in the adulterated pharm-grade samples. Common adulterants and over-the-counter drugs were tested and none alarmed for NPP or NPPA. Limit of detection was tested using two methods and determined to be as low as 5ng. Further development of the system is being conducted to accurately identify street-grade samples.

Vapor Detection, Fentanyl, Ion Mobility Spectrometry

E91 Sweat Analysis Leading to Possible On-Site Detection for Drugs and Alcohol in the Body

Jan Halamek, PhD, Texas Tech University, Lubbock, TX; Morgan Eldridge, Texas Tech University, Lubbock, TX; Giana Biddle, Texas Tech University, Lubbock, TX; Ashley Newland, Texas Tech University, Lubbock, TX*

Learning Overview: After attending this presentation, attendees will have a deeper understanding of the practicality and applications of colorimetric, non-invasive, on-site drug detection systems.

Impact Statement: This presentation will impact the forensic science community by introducing a novel, non-invasive sensing system that has the ability to transform the model of drug and alcohol testing in the field for law enforcement personnel.

As society advances, the advancement of analytical detection methods for illegal substances and their metabolites must advance in a parallel fashion. As such, there is a need for accurate, rapid testing methods for drugs and alcohol for medical purposes as well as for law enforcement personnel in the field.

The current technology used for testing bodily fluids for drugs and alcohol requires invasive sampling of blood or urine, as well as a laboratory with trained staff for analysis of the samples. The need for laboratory testing creates a time-related bottleneck for the return of results to the requesting parties, as well as introducing more room for error as the submitted sample ages between collection and analysis. This process can potentially lead to delaying any legal proceedings that depend on the accurate analysis of the sample.

Particularly, the detection methods for Blood Alcohol Content (BAC) are outdated, as alcohol has been legal to consume for decades across the country and current on-site BAC testing methods can still only be used as preliminary evidence for suspected operation of machinery or Driving While Intoxicated (DWI) charges.¹ Additionally, the recent legalization of marijuana for medical and recreational use in many states has led to a push for on-site testing capabilities to determine if a person is under the influence of the psychoactive component of marijuana, Tetrahydrocannabinol (THC), at the time of questioning under what is likely a zero-tolerance use policy.²

The aim of this research is to develop a non-invasive sensing concept for targeting and quantifying certain substances of interest in sweat, as it is easily collected from most individuals in a non-invasive manner. Two concepts for non-invasive sensing in sweat have been developed: one for ethanol quantification relating to BAC, and one for THC metabolite detection.^{3,4} These methods utilize enzymatic and immunoassay components, are non-invasive in nature, and provide colorimetric feedback. This method of result reporting provides an opportunity for advancing these systems to on-site detection via handheld Ultraviolet (UV) -visible spectrophotometry devices and even smart phones with specialized software for colorimetric analysis via the built-in camera.

This technology could pave the way for a simple, on-site visual test for multiple kinds of drugs and alcohol for law enforcement and medical staff to operate in that moment of need, instead of submitting the individual involved to traveling to a facility, having blood samples drawn for laboratory testing, and losing valuable time as the body continues to metabolize these compounds.

Non-Invasive Sensing, Sweat Analysis, Drug Detection

E92 A Multidisciplinary Forensic Approach: The Investigation of a “Kuman Thong”

Alessandra Radogna, MD, Department of Public Health, Experimental and Forensic Medicine, Pavia, Italy; Chiara Siodambro, MD, Department of Public Health, Experimental and Forensic Medicine, Pavia, Italy; Laura Scotti, MD, Department of Public Health, Experimental and Forensic Medicine, Pavia, Italy; Anna Lisa Nanni, MD, University of Study of Pavia, Pavia, Italy; Maria Sole Prevedoni Gorone, MD, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy; Silvia Damiana Visonà, MD, PhD, Department of Public Health, Experimental and Forensic Medicine, Pavia, Italy; Matteo Moretti, MD, Department of Public Health, Experimental and Forensic Medicine, Pavia, Italy; Pierangela Grignani, PhD, Department of Public Health, Experimental and Forensic Medicine, Pavia, Italy; Carlo Previderè, PhD, Department of Public Health, Experimental and Forensic Medicine, Pavia, Italy*

Learning Overview: The goal of this presentation is to underline how, in unusual and complicated cases of forensic interest, a multidisciplinary approach is pivotal in order to reach a solution.

Impact Statement: This presentation will impact the forensic science community by reporting an unusual case concerning the identification of a human-like amulet and describing the multidisciplinary approach adopted to define its nature and the species of belonging.

In the world of esotericism, some artifacts may reproduce human parts or features. Most difficulties concern the determination of their nature and, if real, whether they have an animal or human origin. In the present report, investigations carried out to determine the nature of a human fetus-like “Kuman Thong” are described.

In Thai culture, a “Kuman Thong” is a traditional amulet believed to bound the spirit of an unborn child, which, if properly revered, can bring prosperity and luck. According to tradition, Kuman Thongs were created from a human fetus.¹ The ritual included roasting the fetus at a cemetery and sometimes even soaking it in oil extracted from the skin of a person who died under violent circumstances. Once dried, the corpse was covered in lacquer and gold foil, from which derives the name Kuman Thong, which means literally “golden child.” Nowadays, Kuman Thongs are plastic or wooden statues shaped like a little boy or fetus.

In 2018, the owner of an unauthorized occult store was charged with holding illicit material. The police found a human fetus-like object contained in a jar filled with transparent liquid, decorated with jewels. The Kuman Thong was entrusted to specialists to define its origin. A multidisciplinary approach was applied, including forensic pathology, radiology, anthropology, and molecular biology.

Medical-legal macroscopic examination showed the body was tightly fixed in a fetal position, dressed in a cloth diaper. The body surface, with a stone-like texture, was almost entirely covered with lacquer and gold leaf. The corpse was also adorned with yantras (small tattoos) and little talismans. Numerous details on the body suggested it was not a sculpture; skull shape and body conformation were like those of a human being. Some uncovered portions of the skin were covered by soft hair and different human-like anatomical structures were recognized. A possible cause of death of the skeletonized fetus could not be identified.

Radiological analysis was performed by a Computed Tomography (CT) scans, using an MD Sensation 64 scanner, then a 3D reconstruction of images were obtained using Multiplanar (MPR) and Visual Tracking (VTR) method.

Internal organs were collected using a drill and the resulting powder was extracted using a silica-based automated method. The results of the following amplification of multiple Short Tandem Repeat (STR) markers contained in a commercial kit validated for human identification showed that no genetic profiles could be achieved from the samples; this outcome was probably due to a massive degradation of the genetic substrate subjected to physical or chemical modifications.^{2,3} Further studies on the mitochondrial DNA extracted from tissue samples are currently ongoing using conventional Sanger and Next Generation Sequencing (NGS) sequencing techniques.

Radiological and anthropological examination were unable to identify the nature of the Kuman Thong. CT detected and recognized both a complete and articulated fetal skeleton and images compatible in structure and density with human organs; anthropological measurements also gave an evaluation of fetus biological age and gender: based on development of the dental buds and diaphyseal lengths, the age was estimated to be 26-27 gestational weeks; and the shape of the jaw was compatible with a female subject.⁴⁻⁷

E93 Automatic Class Characteristic Recognition in Shoe Tread Images

Jayden Stack, University of Nebraska-Lincoln, Lincoln, NE and Center for Statistics and Applications in Forensic Evidence, Ames, IA; Susan VanderPlas, PhD, University of Nebraska-Lincoln, Lincoln, NE and Center for Statistics and Applications in Forensic Evidence, Ames, IA*

Learning Overview: After attending this presentation, attendees will have a basic understanding of the usefulness of machine learning for image identification and how this can help bridge the gap between unfriendly numerical features and descriptors used by examiners in practice.

Impact Statement: This presentation will impact the forensic science community by introducing a method of automatic pattern recognition in shoe soles for forensic evidence purposes.

One of the fundamental problems in footwear forensics is that the distribution of class characteristics in the local population is not currently knowable. Surveillance devices for gathering this data are just half of the battle; it is also necessary to process the data gathered using these devices and identify relevant features.

Machine learning has pioneered many developments in artificial intelligence for forensic science over the past ten years, however, efficient and effective object detection methods are being implemented using region proposal networks to pinpoint an object's location in an image.¹ This has resulted in the formation of the Faster Region-based Convolutional Neural Network (R-CNN). This network is especially helpful in detecting features in images and, in the case of this research, images of the bottoms of shoes.

The goal behind this research is to be able to feed an image of a shoe sole to a fine-tuned network that will output a set of object proposals. For example, after inputting an image of the bottom of a shoe, the network will output the same image but with bounding boxes around pre-determined objects. The objects in practice are shapes (circles, rectangles, quadrilaterals, etc.) and logos (Nike®, Adidas®, Polo®, etc.). A completed basic R-CNN model will be able to extract and identify the presence of any logo or shape in a shoe sole and predict with an "X" percent score that the object in question is that object.

This presentation will describe progress made in automatic identification of relevant footwear features—brand, shoe size, and tread pattern elements, as well as complications which arise when combining machine learning algorithms with human-friendly features. Using transfer learning to connect pre-trained neural networks to newly gathered and labeled training data, this method bridges the gap between unfriendly numerical features and descriptors used by examiners in practice. The Faster R-CNN has the capabilities to extract and identify features of an image the same way a human brain can. It can separate the areas of an image into background and regions of interest and then, subsequently, label the content of that region of interest to confirm or challenge a similar labeling task of an examiner.

Leveraging both clean training data and "messy" data gathered from the local community using newly developed footwear surveillance devices, this study will present developments in footwear forensics that will enable examiners to testify as to the frequency of class characteristics in the local population in the very near future.

Pattern Recognition, Footwear, Machine Learning

E94 A Comparison of Dust Cover Impact Marks on 200 Consecutively Fired Cartridge Cases From a Saiga 7.62x39mm Rifle

Malory Molt, BS, Washington State Patrol Crime Lab, Seattle, WA; Rick Wyant, MS, Washington State Patrol Crime Lab, Seattle, WA; Brian Smelser, BS, Washington State Patrol Crime Lab, Seattle, WA; Sarah Fox, Washington State Patrol Crime Lab, Seattle, WA*

Learning Overview: After attending this presentation, attendees will have a better understanding of how impact marks from the dust cover of a firearm imparted on cartridge cases have the ability to change over repeated firings, which may directly impact microscopic examination and a firearm examiner's ability to make an identification.

Impact Statement: This presentation will impact the forensic science community by presenting how over the life of a firearm, tool marks have the potential to change, directly affecting microscopic examination and comparison.

During the first half of 2017, a series of shootings occurred in the Seattle, WA, area that yielded over 200 cartridge cases during five months. Many of the cartridge cases found at the various crime scenes were identified to a recovered Saiga 7.62x39mm caliber, AK-47 type rifle. Comparisons of the breech face area markings of this rifle type have been historically challenging for examiners due to manufacturing marks present on ammunition, ammunition primer hardness, and lack of markings on the firearm. Cycling marks related to the ejector and dust cover impact mark areas are routinely utilized to supplement identification.

Several studies have been reported on the marking longevity of many types of firearms and surfaces, including chamber marks and breech face marks on pistols and revolvers. These studies consistently demonstrate that while some slight changes may occur over many firings, marks on cartridge cases are not altered beyond identification. However, none of these reported studies considered dust cover impact marks. During this investigation, questions arose related to the persistence and reproducibility of these marks due to repeated firings.

This study examines the origin and production of dust cover impact marks on cartridge cases fired in a 7.62x39mm rifle; specifically, the changes that occur from extended or repeated use of the firearm. Two hundred brass- and steel-cased cartridges were fired using a new dust cover on an AK-type firearm. High-Speed Video (HSV) was utilized to confirm the specific location of impact on the dust cover and identify the differing categories of impact marks that resulted based on impact location. Changes to the morphology of the dust cover were observed and documented. It was determined that these changes occur over repeated firings, effecting and likely reducing microscopic comparison qualities. The degree of change to the dust cover is dependent on the type of ammunition used.

Dust Cover, AK-47, 7.62x39

E95 An Open-Source Implementation of the Congruent Matching Profile Segments (CMPS) Algorithm for Assessing the Similarity of Bullets

Wangqian Ju, MSc*, Iowa State University, Ames, IA; Heike Hofmann, PhD, Iowa State University, Ames, IA

Learning Overview: Attendees will be introduced to an open-source implementation of the CMPS algorithm; they will learn about a principled evaluation framework of algorithmic results, which allows a comparison and cross-validation of parameter choices. Attendees familiar with the statistical software R will learn how to use the CMPS algorithm with the R package CMPS.

Impact Statement: More and more areas of forensic science are incorporating results from algorithms in the evaluation of forensic evidence to make results objective and reproducible. Open-source algorithms are needed for a fair execution that is transparent and accessible to everybody.

The R package CMPS introduces an open-source implementation of the CMPS method developed at the National Institute of Standards and Technology (NIST) for objective comparison of striated tool marks.¹ The functionality of the package is showcased by examples of bullet signatures that come with the package. Graphing tools are implemented in the package as well for users to assess and understand the CMPS results. Initial tests were performed on bullet signatures generated from two sets of 3D scans in the Hamby study under the framework suggested by the R package bulletxtctr.²⁻⁴ New metrics based on CMPS scores are introduced and compared with existing metrics. A measure called Sum of Squares Ratio is included, and how it can be used for evaluating different scans, metrics, or parameters is showcased with the Hamby study data sets. An open-source implementation of the CMPS algorithm makes the algorithm more accessible, generates reproducible results, and facilitates further studies of the algorithm, such as methods comparison.

3D Topographical Measurement, Pattern Matching, Firearm Evidence

E96 Blind Testing in Firearms: Preliminary Results From a Blind Quality Control Program

Maddisen Neuman, MA, Houston Forensic Science Center, Houston, TX and Center for Statistics and Applications in Forensic Evidence, Ames, IA; Callan Hundl, BS, Houston Forensic Science Center, Houston, TX; Aimee Grimaldi, MS, Houston Forensic Science Center, Houston, TX; Donna Eudaley, BS, Houston Forensic Science Center, Houston, TX; Darrell Stein, BS, Houston Forensic Science Center, Houston, TX; Peter Stout, PhD, Houston Forensic Science Center, Houston, TX*

Learning Overview: This presentation will inform attendees on preliminary findings from a blind testing program in the Firearms section at the Houston Forensic Science Center. Additionally, this presentation will detail trends in the data and discuss the benefits, limitations, and future directions of the blind testing program.

Impact Statement: The intent of this presentation is to evaluate a blind testing program in firearms examination and demonstrate how such a program can be a useful tool for assessing examiner and workflow processes. Attendees will be encouraged to consider the feasibility of incorporating similar blind testing programs into their laboratories' workflows.

Open proficiency tests created by external vendors meet accreditation requirements and help demonstrate examiner competence; however, the tests are limited in the ability to test the entire quality management system from evidence submission to reporting of results. Blind proficiency testing has been considered a more precise testing an individual's accuracy.¹ In December 2015, the Houston Forensic Science Center implemented a blind Quality Control (blind QC) program in firearms examination. The intent of the blind QC program is to supplement open proficiency tests by creating mock cases that mimic routine casework, so examiners are unaware that they are being tested. Blind QC cases are created by Firearms section management but submitted by members of the Quality Division, which is organizationally separate from the analytical sections.

This study examined the results of blind QCs submitted to the Firearms section for analysis. Firearms section management evaluates the created evidence prior to submission to determine the expected results and reviews the results of the completed blind QCs to determine satisfactory completion. A satisfactory result may include: (1) a result that conforms to the known ground truth, or (2) a result that does not necessarily conform to the known ground truth but is technically sound (i.e., a known elimination/identification that is reported as inconclusive based on the applicable standards in the field).² A firearms examiner can choose to conclude inconclusive if the item does not contain the quality or quantity of information needed to include or exclude from another item. Fragments, bullet cores, and poor-quality items are expected to be reported as unsuitable or insufficient regardless of ground truth based on availability of microscopic characteristics.

Fifty-one blind QC cases were reported between December 2015 and June 2021 resulting in 570 sufficiency and comparison conclusions. In 40.3% ($n=225$) of the comparisons, the ground truth result was either elimination or identification, but the examiner made an inconclusive conclusion. Variables such as the examiners assigned to the case, the training program, the examiner experience level, and the intended complexity of the case did not significantly contribute to the inconclusive results. The main factor contributing to the inconclusive conclusions was the type of evidence compared (e.g., bullets vs. cartridge cases).

While a blind QC program can be challenging to implement, the program has demonstrated great value. The program demonstrates that the quality management system and procedures used by the Firearms section can obtain accurate and reliable results and provides examiners added confidence in court. Additionally, the blind QC program can be tailored to target specific research questions and provide opportunities for collaboration with other laboratories and researchers.

Blind Testing, Proficiency Testing, Firearms Examination

E97 Ordinal Regression for Error Rates in a Black-Box Face Recognition Study

Larry Tang, PhD, University of Central Florida, Orlando, FL; Ngoc-Ty Nguyen, PhD, University of Central Florida, Orlando, FL*

Learning Overview: After attending this presentation, attendees will better understand: (1) how error rates in black box studies can be analyzed through ordinal regression method, and (2) how the uncertainty of these error rates can be quantified.

Impact Statement: This presentation will impact the forensic science community by introducing a regression method to evaluate ordinal decision scores from large-scale black-box studies, especially when error rates of multiple examiner groups are compared. The uncertainty quantification provides inherent sampling variabilities of the black box studies.

This study applied regression methods to assess error rates of face recognition based on a recent black box study by Phillips et al.¹ Participants included forensic facial examiners, facial reviewers, super recognizers, fingerprint examiners, and students. They were asked to provide ordinal-scale decision scores for image pairs based on their belief on whether the pairs belong to the same source. Scores are on a 7-point scale with +3 for the highest confidence of same source to -3 for the highest confidence of different sources. Image pairs from male and female were used in the study. Selected image pairs from Phillips et al. are shown in Figure 1.¹ Since human perception may exhibit differences regarding recognition of female faces and male faces, respectively, this study expected differences between the respective error rates. In addition, it is likely that the characteristics of source subjects may affect the error rates of face recognition.

The regression model includes the ordinal decision score as the response variable. The covariates in this dataset include race, gender, age of source subjects, and examiner groups. To accommodate ordinal decision scores, and in order to incorporate covariates of source subjects from the Phillips et al. black box study, the ordinal regression were employed instead of the regular linear regression.¹ The resulting covariate-specific receiver operating characteristic curves provide false positive rates and false negative rates. More importantly, the analysis provides the association between these error rates and characteristics of source subjects.

This study also calculated the error rates of examiner groups using the ordinal regression method and developed methods for calculating variances of these error rates to quantify the uncertainty for comparing examiner groups. Large-scale simulation studies were conducted to study the uncertainty of the error rates from simulated datasets. These simulation studies show that the error rates tend to have smaller variances as the sample sizes of black box studies increase.

Facial Recognition, Error Rates, Uncertainty Quantification

E98 A Forensic Decryption of Ludlings

David Simpson, BS, Federal Bureau of Investigation, Quantico, VA*

Learning Overview: Attendees can learn that there are forensic applications done by the Federal Bureau of Investigation (FBI) Lab that can deal with covert communication, up to and including criminals using ludlings like Pig Latin and Gibberish.

Impact Statement: The forensic science community will learn that there is an avenue to deal with unusual cases that cannot be typically dealt with outside of specific expertise, namely the ability to forensically decrypt covert communication.

Throughout time, criminals and law enforcement have undergone a never-ending battle to outwit each other. The eternal back and forth has resulted in the development of new scientific approaches and technologies that are astounding in their capabilities. However, the “old school” techniques should not be cast aside for the shiny and new.

The FBI Crime Laboratory has documented that criminals often use “old school” methods of cryptic communication to convey information about their crimes via phone calls from jails or prisons. One such method commonly encountered is the use of ludlings. Ludlings are seemingly simple language games that may even be heard on elementary school playgrounds. They are not true languages in and of themselves, but rather alterations of existing languages that are simple, yet effective, methods of concealing communications.¹ Potentially the most well-known ludling is Pig Latin. Pig Latin is not its own language. It is, at its core, the transposition and addition of English language syllables and can be translated by anyone familiar with the rules of the alteration scheme. However, there are many different versions and variations of ludlings, many with colorful names such as Ubbi Dubbi, Gibberish, Eggy Peggy, Tutnese, Ong, Sa-La, and many more.² Becoming so familiar with each ludling variation to be practically “fluent” is not a practical method of countering such covert communication. Therefore, the Cryptanalysis and Racketeering Records Unit at the FBI Laboratory has developed forensic standard operating methodologies to identify and decipher ludlings of any variation. Using these procedures, the FBI Laboratory has decrypted over 200 ludlings for law enforcement and testified in court proceedings, providing valuable evidence that has resulted in the identification of unknown accomplices, admissions of additional, yet unknown, felonies, the location of murder weapons, admissions of guilt, and much more.

FBI, Pig Latin, Ludlings

E99 Examining New Trends Exclusive to Latino Youth Gang Violence

Cliff Akiyama, MPH, MA, Akiyama and Associates, LLC, Philadelphia, PA*

Learning Overview: The purpose of this presentation is to present timely data on Latino gangs and offer strategies on how to recognize and interpret various tattoos and graffiti associated with these gangs, which could assist the medical examiner/coroner and death investigator in the positive identification of the decedent out in the field and/or in the autopsy room. This presentation will also discuss recent Latino gang trends that could help law enforcement in their investigations of this ongoing deadly problem confronting all our communities.

Impact Statement: This presentation will impact the forensic science community by offering a detailed examination of novel Latino youth gang trends out on the street that have never been presented before to the forensic science community.

One cannot open the newspaper or watch the local news without hearing of another casualty of gang violence. Throughout the country in urban, suburban, and rural communities, gang violence has reached epidemic proportions according to the Department of Justice, Office of Juvenile Justice and Delinquency Prevention. Furthermore, gangs have been identified in every single state, meaning that gangs are no longer just a California problem. Nationwide, there are 26,500 gangs with a gang membership of over 850,000, while the ethnic composition of these gangs includes 47% Latino, 31% African American, 13% Caucasian, 7% Asian, and 2% Mixed. Youth gang violence in the Latino community has had a dramatic increase in the past two years since COVID-19. In Los Angeles County, CA, alone, there are currently 850 documented Latino gangs with a gang membership of over 120,000. Demographics show a gang member average age of 15 with a range of 8–22 years. Other counties in California and nationwide have seen increases in Latino gangs, especially in rural communities, such as York, PA. The Mara Salvatrucha (MS 13), an El Salvadorian gang originating in the Pico-Union area of Los Angeles, CA, since 1983, has seen the largest increase in membership nationwide with over 88% in some states. Over 800 gang members were interviewed out in the streets, jails, and juvenile halls in California and Pennsylvania. This study identified eight distinct manifestations and recent trends exclusive to Latino youth gangs and nine ethnic differences and similarities among Latino gangs (i.e., definite cultural differences between Latino gangs and various other ethnic gangs; drugs; weaponry; killing over turf/territory; extortion; defacing property/graffiti; women in gangs).

This study found that Latino gangs are motivated by a state of mind driven by “La Raza,” which translated means “for the race.” It is important to note that La Raza is more of a cultural ideology than a gang-related motto. Latino gangs are extremely territorial and unlike African American gangs where the individual is important, for Latino gangs, it is the gang as a whole that is important and not the individual. To illustrate this point, when Latino gang members go to prison, they are run and controlled by one of two prison gangs, depending on the geographic location of the prison: La Eme or Nuestra Familia. La Eme, otherwise known as the Mexican Mafia, is a prison gang originating in California and considered the leadership arm of all Latino gangs in Southern California. The letter “M” in Spanish is pronounced “eme” and is the 13th letter of the alphabet. Consequently, throughout Southern California, Latino gangs will often call themselves by the city or area that they represent, followed by the number “13” to indicate “La Eme” or “Southern” by giving respect to the Mexican Mafia. In Northern California, the Nuestra Familia, which is translated to mean “our family,” is the prison gang that controls every Latino gang north of Fresno, CA, and is often indicated by the number “14” representing the letter “N” for Nuestra and Northern. It is important to remember that Latino gangs are not just a California problem, although California is where these gangs originated. Rural, suburban, and urban communities across the nation are now seeing an increase in Latino gangs that mimic the California-based Latino gangs, such as the MS 13.

Latino Gangs, Youth Violence, Law Enforcement

E100 Exploring the Effectiveness of a Fingerprint Powder Batch Acceptance Protocol: Interdisciplinary Considerations

Helen Earwaker, PhD, University of Portsmouth, Portsmouth, Hampshire, United Kingdom; Jodie Coulston, PhD, University of Portsmouth, Portsmouth, Hampshire, United Kingdom; Paul Smith, PhD, University of Portsmouth, Portsmouth, Hampshire, United Kingdom*

E101 Magnetic Nanoparticles Combined With Mass Spectrometry for the Extraction and Detection of Drugs and Toxic Metal From Fingermarks: A Novel Approach for the Forensic Chemist

Mohamed O. Amin, MSc*, Kuwait University, Kuwait, Asimah, Kuwait; Entesar Al-Hetlani, PhD, Kuwait University, Kuwait, Asimah, Kuwait; Simona Francese, PhD, Sheffield Hallam University, Sheffield, South Yorkshire, United Kingdom

Learning Overview: The present work demonstrates the use of magnetic nanoparticles and Surface-Assisted Laser Desorption/Ionization-Mass Spectrometry (SALDI-MS) to extract and detect fingerprint components. This work will appeal to a broad audience, including analytical chemists in general and forensic scientists in particular. Attendees will learn the importance of combining magnetic material and MS to analyze various fingerprint and forensically relevant samples that may be recovered from the crime scene with minimum sample consumption and pretreatment. Furthermore, attendees will be exposed to a facile approach to fabricate magnetic material using by-product from burnt candles (soot) that can be employed in different applications. Moreover, forensic scientists will be interested in the recovery of the fingerprint components from different surfaces and understand the potential contribution of each surface using a simple magnetic field to maneuver the magnetic substrate. Finally, this study will shed more light on the (bio)chemical composition of fingerprints as a source of a vital forensic evidence.

Impact Statement: For decades, the analysis of fingerprints has been used as the primary biometric means of human identification because no two people share the same fingerprint. Modern chemical analysis technologies have added the potential to determine the molecular composition of fingerprints and identify chemicals that the suspect may have encountered. Improvements in analytical detection of the chemical composition of fingerprints is therefore of obvious importance. This presentation will offer a facile approach to synthesize magnetic carbon nanoparticles from candle soot for extraction and detection of endogenous and exogenous components of the fingerprint from different surfaces using SALDI-MS. Specifically, this work covers extraction of several exogenous compounds such as antihistamines, antidepressants, antibiotic drugs, and lead ions. Successful extraction and detection of these compounds may help to understand or solve cases related to death by gun, suicide or poison. This will stimulate researchers with various backgrounds and interests to contribute new ideas and implement novel approaches. In addition, forensic practitioners will learn about emerging technologies and commit to their testing, evaluation and further development. New developed technologies for fingerprint analysis could be helpful and potentially adapted in various other areas, including medical diagnostics and tissue analysis, in particular.

For decades, the analysis of Fingerprints (FP) has been used as the primary biometric means of human identification. In parallel, the chemical analysis of Latent Fingerprints (LFM), “touch chemistry,” offers additional support to forensic examinations; thus, the development in analytical detection of the FM is crucial. In this regard, this study proposes a facile approach to synthesize Magnetic Carbon Nanoparticles (MCNPs) from candle soot for extraction and detection of endogenous and exogenous components of the FM. In this context, endogenous components of FM, including Fatty Acids (FAs), squalene, and Triacylglycerols (TAGs), were successfully extracted and detected using SALDI-MS. The proposed method was used for personal identification based on profiling organic materials, including antihistamines (methapyrilene and triprolidine), antidepressants (metoprolol and labetalol), and antibiotic (metronidazole and sulfamethoxazole) drugs, in FMs. This was further emphasized using high-energy collision-induced dissociation, which provided characteristic and unique fragmentation patterns of each drug in the FM matrix. Furthermore, exogenous contamination of lead ion (Pb^{2+}) on the suspect can aid in investigating cases related to death by gun; thus, this study has also successfully applied this approach for extracting inorganic toxic materials such as lead ions in FM with Limit Of Detection (LOD) in the nanorange. On the other hand, securing the crime scene and sample collection are vital steps for the evidence to be admissible in a court; therefore, the study reports a preliminary assessment of the influence of environmental conditions on the stability of the exogenous contaminants in FM. The contaminated FMs were exposed to different temperatures over 24 hours, and the results suggested that drugs were unstable at high temperatures and underwent different degrees of degradation, whereas lead ions were more stable toward thermal stress. Additional experiments were undertaken to investigate the presence of exogenous materials in FM upon handling drug tablets, and the findings indicated the presence of the drugs and/or their fragment in the spectrum as illustrated in Figure 1. The LOD values of the drugs in the tablet forms were 50, 200ng mL⁻¹ and 750ng mL⁻¹ for triprolidine, metoprolol, and sulfamethoxazole, respectively. Quantitative analysis of contact residues on fingers for parent drugs was estimated and recovery rates of 91.17, 94.67, and 120.86% were obtained for triprolidine, metoprolol, and sulfamethoxazole, respectively. Finally, a proof-concept study was constructed to extract and detect components of FM, following contact with traces of metoprolol commercial tablets, from metal and glass surfaces. Ultimately, the proposed method offered satisfactory extraction and detection efficiencies of FM components on both surfaces. Despite current FM analysis involved, several techniques, including Gas Chromatography/Mass Spectrometry (GC/MS), Raman spectroscopy and Inductively Coupled Plasma/Mass Spectrometry (ICP/MS), combining magnetic material with SALDI-MS for extraction and detection of FM components reinforce the importance of the current method in forensic analysis. Thus, the present study provides exciting opportunities for the use of MCNPs as new SALDI-MS substrate for both extraction and detection of FM components, providing more information pertaining to the donor's lifestyle.

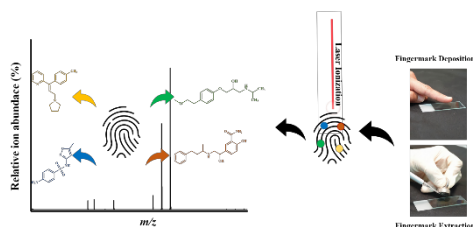

Figure 1: Schematic illustration of the experimental approach employed for the extraction and analysis of a fingerprint contaminated with drugs using SALDI-MS. Initially, the contaminated fingerprint was deposited on a surface and extracted using magnetic nanoparticles. Then, the nanoparticles were collected and deposited on the target plate for SALDI-MS analysis.

E103 Investigative Leads in Latent Prints: A Comparison of Laboratory Procedures

Amanda Wilson, MS, King County Regional AFIS, Seattle, WA; Sharon Kelley, JD, PhD, University of Virginia, Charlottesville, VA; Jeniffer Molina, BS, Houston Forensic Science Center, Houston, TX; Brett Gardner, PhD, University of Virginia, Charlottesville, VA; Maddisen Neuman, MA, University of Virginia, Charlottesville, VA*

Learning Overview: This presentation will educate attendees about how different latent print sections have defined “investigative leads.” This presentation will describe the procedures used by two different latent print sections to arrive at investigative leads and will discuss the relative strengths and limitations of each procedure.

Impact Statement: This presentation will encourage attendees to think in more critical and specific terms about a commonly used phrase. Attendees will also hear from examiners about relative strengths and weaknesses of different investigative lead procedures, allowing them to carefully consider the types of procedures that might be optimal to implement in their labs.

Introduction: Forensic science laboratories sometimes report information to law enforcement as “investigative leads.” Based on a review of available literature across several disciplines (e.g., latent prints, chemistry, biology, trace), the term investigative lead is generally used to refer to information that points to the possibility of an individual as the source of evidence relevant to a crime, but falls short of being a conclusive individualization or identification.¹⁻³

Interestingly, although an investigative lead appears to be a well-understood concept in general, the specific procedures and thresholds different laboratories use in defining investigative lead can vary tremendously. In theory, these procedural differences could affect the reliability of the information reported out and the overall utility of the information to a criminal investigation. This presentation will describe and contrast two laboratories’ operational definitions of investigative lead and the associated procedures and thresholds used before information is reported to law enforcement.

For the past five years, the Latent Print Section of the Houston Forensic Science Center (HFSC) has reported investigative leads in the form of “Preliminary Automated Fingerprint Identification System (AFIS) Associations” (PAA). PAAs occurred when an analyst determined that there was sufficient agreement to conclude that two prints may have originated from the same source. PAAs do not involve the full set of procedures in the traditional Analysis, Comparison, Evaluation-Verification (ACE-V) process and instead involve a truncated process so that information can be reported out to law enforcement more efficiently. Importantly, investigative lead reports involve clear language about the nature of the comparison (e.g., “An official identification HAS NOT been effected at this time ...”). Submitting agencies can request official confirmatory comparisons if they choose. In sum, these procedures aim to balance accuracy and expediency so that law enforcement receive useful information earlier in the investigation than they otherwise might without such procedures.

The King County Sheriff’s Office AFIS Identification Section defines investigative leads quite differently. Investigative leads are reserved for AFIS comparisons that result in inconclusive conclusions (i.e., AFIS inconclusives) that are then reviewed using the lab’s “Consensus Judgment” procedures. At King County, “Consensus Judgment” requires a minimum of five examiners (including the original examiner) to independently examine, compare, and chart the impressions. The group must determine whether the amount of consistency between the latent and AFIS candidate is “marginal” or “considerable;” comparisons with considerable consistency are reported as investigative leads. The unit supervisor then reviews all documentation to determine if the consensus decision complies with the standard operating procedures or if additional testing is warranted. Thus, these procedures utilize more extensive review (rather than more expedient review) to determine whether inconclusive information is sufficiently reliable to be of use in a criminal investigation.

Overall, these two sets of procedures highlight the strikingly different ways that latent print sections can define investigative leads: preliminary identifications versus extensively reviewed inconclusives. This presentation will explain these procedures in more detail, include case examples, and discuss their relative strengths and limitations, as perceived by examiners within each laboratory.

E104 Measuring Proficiency Among Latent Print Examiners: A Statistical Approach From Standardized Testing

Amanda Luby, PhD, Swarthmore College, Swarthmore, PA*

Learning Overview: After attending this presentation, attendees will have learned about a statistical approach to quantifying the proficiency of latent print examiners used prominently in standardized testing.

Impact Statement: This presentation will impact the forensic science community by offering a statistical method for evaluating the performance of latent print examiners in making source decisions. The statistical framework introduced is flexible and easily adaptable to many different decision-making scenarios.

In recent years, the reliability and validity of forensic analysis has received increased attention in many pattern evidence disciplines in forensic science. The current approach to characterizing uncertainty and variability in these disciplines has largely centered around conducting large-scale error rate and “black box” studies in order to calculate aggregated error rates.

The Federal Bureau of Investigation (FBI) “Black Box” Study is one such study that was designed to estimate casework error rates of latent print comparisons in the United States.¹ This study provided critical and necessary information about overall performance aggregated over many comparisons and set the bar for conducting “black box” studies in other pattern evidence disciplines. However, we cannot directly compare individual examiners’ error rates, since each participant was asked to evaluate a random subset of comparison tasks (items) and some items are more difficult than others due to, for example, partial prints or low image quality.

Item Response Theory (IRT), a class of statistical methods used prominently in educational testing, can be used to measure participant proficiency in error rate studies while simultaneously accounting for varying difficulty among items.² Using data from the aforementioned “Black Box” study, this presentation will explore the strengths of an IRT-based analysis over traditional “percent correct” scoring. Challenges in wide-scale implementation will also be discussed.

Using an IRT-based analysis, the largest variability in latent print examination decisions tends to occur in print quality assessments and inconclusive decisions, which is consistent with prior work.³ Some participants were likely to over- or under-report difficulty even after accounting for their proficiency, item difficulty, and other participants’ reported difficulty; and examiners who report items to be more difficult perform similarly to examiners who report items to be easier. These results underscore the importance of better understanding the cognitive factors involved in latent print examination decisions.

Latent Print Analysis, Statistics, Human Factors

E105 Modeling Latent Fingerprint Aging Processes by 2D Optical Methodologies

Josep De Alcaraz-Fossoul, PhD*, University of New Haven, West Haven, CT

Learning Overview: In this presentation, attendees will learn about modeling latent fingerprints' age estimation in 2D by using a digital camera and other common techniques. The model involves logistic regressions based on binning fingerprint data by age, which includes quantitative and qualitative measurements and assessments. The combined use of four morphometric-based age indicators is the foundation for time of deposition estimations.

Impact Statement: This presentation will impact the scientific community by demonstrating the feasibility of fingerprint age estimations that are based on measuring 2D topographical changes acquired by optical means alone in the visible light spectrum. This is a significant step forward to further strengthen the probative value of fingerprints and reduce potential bias in identifications.

For more than a century, fingerprinting methodologies have relied primarily on friction ridge skin patterns for the identification of crime suspects and victims.¹ While questions related to the source (the "who") have already been the topic of most research and publications, the issues associated to the activity-level (the "when") have only begun to be explored in depth more recently.² Despite decades of research and frequent court enquiries, the estimation of age by simple optical means is still perceived, in legal proceedings, as unreliable and subjective, frequently founded on the personal opinion of the forensic scientist, and often disqualified as reliable evidence.³⁻⁶

Surprisingly to this day, there are no mathematical models or computer algorithms to estimate the age of latent fingerprints (i.e., time elapsed from deposition to discovery). This type of evidence is invisible to the naked eye and requires enhancement treatments for visualization prior to analysis. Alterations of a fingerprint's topography as it ages have been described for years.^{3,7} It has been proven that some of these physical changes are time-sensitive, including modifications in ridge width and loss in color contrast once powdered in response to the surrounding environment (indoors).^{8,9} These are potential sources of data that can be used to determine the age of the impression; especially on non-porous surfaces.

In this research, four morphometric-based indicators of aging have been evaluated and combined to create the first mathematical model to estimate the time of deposition of powder-enhanced latent fingerprints. Experiments were designed to closely mimic field conditions, from deposition to visualization and analysis. It combined a pool of 34 different donors over a period of ten years, totaling 2,218 fingerprints photographed with a digital camera. Fingerprints were aged for up to 364 days while exposed to a variety of indoor conditions and enhanced with titanium dioxide or carbon black powders. Non-porous substrates (plastic, glass, or tile) and two sweat secretion types (sebaceous or eccrine-rich) were exposed to three natural light conditions—direct light, shade, or darkness. These images were then evaluated by ten examiners on the following visual indicators: (1) Quantitatively: loss of viable minutiae, differences in color contrast between ridges and furrows, presence of ridge discontinuities, and micro-variations in ridge width; and (2) Qualitatively: collection of ridge pattern Quality Scores (QS) on a scale from 1 to 4 and/or color-coded maps by the Universal Latent Workstation.⁸⁻¹⁴

In this project, the most influencing environmental factors involved in aging have been identified; for example, contrary to common belief, exposure to natural light does not necessarily accelerate degradation, while the type of substrate is the most significant factor of all those examined, followed by secretion type. In addition, biological sex, age, ethnicity, dietary regimens, and ridge type pattern show no distinctive impact on aging. Most importantly, the mathematical formulation allows for the categorization of age into: fresh, intermediate, and advanced degradation; while more research is needed for actual age estimations and error rates.

This proof-of-concept research concedes certain necessary limitations, including that glass substrates do not show significant ridge degradation under certain conditions; the use of specific powders for visualization; and the minimum quality threshold necessary for the analysis. Despite these constraints, the practical implications of these findings are enormous and an important step forward for forensic science. The results challenge the conventional assumption that external influences are too complicating a factor. In conclusion, this study has been able to successfully demonstrate and model with a high degree of accuracy the dynamics of the aging complexity of fingerprints under semi-controlled situations, introducing new kinetics of aging.

Aging, Morphometrics, Fingermark

E106 Similarities of Fingerprints Among Siblings

Angelina Lopez, MFS, Forensic Sciences Program, National University, La Jolla, CA; Ismail Sebetan, MD, PhD, Forensic Sciences Program, National University, La Jolla, CA; Paul Stein, PhD, Forensic Sciences Program, National University, La Jolla, CA*

Learning Overview: After attending this presentation, attendees will have a better understanding of how powerful fingerprint impressions are for personal identity. This is a comparative study aimed at determining if siblings have more similar fingerprint pattern characteristics than people not related.

Impact Statement: This presentation will impact the scientific community by looking at the following patterns and subtypes: arches (plain and tented), loops (left slant, right slant, whorls), plain, center pocket, double loop, and accidental. The objective of this study is not to refute any of the previous research on twins, rather it is to determine whether siblings have a higher rate of matching pattern types than non-siblings.

Over the past hundred years, research has shown that no two individuals have the same fingerprint. The ridge arrangement, placement, ridge size, and minutiae within the pattern are unique to the individual. These are evaluated as Level 1, Level 2, and Level 3 characteristics as determined by latent print examiners. Fingerprints offer an irrefutable means of personal identification. That is the underlying basis for establishing the identities of criminals. It is also used as a means of identification for missing persons, disaster victims, and unidentified human remains. Other uses are for personal identification for employment, to obtain applications for driver's licenses, and security entrance to government buildings. Other individual characteristics change, especially over time (with the exception being DNA); fingerprints can distinguish identical twins

There are 11 sets of biological siblings, including 1 pair of identical twins and 22 unrelated individuals that did not have a biological sibling in the study. The 11 sibling pairs have the same biological mother and father. The subject pools consisted of both genders (males, females) and are aged from 13 to 75 years.

A total of 44 fingerprints were evaluated by a latent print examiner for Level 1 ridge flow patterns (Loops [L], Whorls [W], and Arches [A]) and for their orientation. Fingerprints were obtained by rolling each of the ten fingers on an ink-pad and then pressing each inked finger on a ten-print file card.

A 5x "loupe" magnifying glass was used to examine each fingerprint pattern from the ten fingers of siblings and unrelated individuals. The data was entered into an EXCEL® spreadsheet. Analysis of Variance (ANOVA) and chi-square statistical tests were used to determine if there were significant differences (or not) in the totals of the fingerprint patterns. Significance in all statistical tests determined when p-values <.05. Spearman correlation test was done to see if any significant correlation existed between the observed patterns in the ten fingers: L vs. W, W vs. A, and A vs. L patterns in the sibling (and unrelated individual) data. A good correlation was considered when correlation coefficient $R_s \geq \pm 0.6$. Lastly, the number of shared characteristics whether L, W, or A between sibling pairs was compared to randomly paired, unrelated individual fingerprints. This data was analyzed by the Mann-Whitney test.

ANOVA indicated that totals of fingerprint pattern types were significantly different in hands of the siblings (ten fingers) and in the unrelated individuals ($L > W > A$; p-value <.0001). In fact, the number of Loops was over twice the number of W and A combined. Chi-square test results indicated that there was no significant difference (p-value >.05) between these numbers for the siblings and unrelated individual fingerprints. There was also a significant inverse correlation ($R_s = -0.6$) between L vs. W, W vs. A patterns (p<0.01), but no significant relationship between Loops and Arch patterns. It was thought that siblings would have more similar pattern types than unrelated individuals. However, there was no difference in the number of similar pattern types in the pair studies between siblings and unrelated individuals (p value=.07, mean 5.45 vs. 4.19).

Fingerprint patterns were significantly different in siblings (not unexpectedly). This was also found in unrelated fingerprint pattern types. There were more Loop patterns than Whorl and Arches combined. There was no difference in distribution of fingerprint pattern types between siblings and from unrelated individuals. This study indicated there was a significant inverse correlation between L and W and W and A patterns. There was no significant relationship between L and A patterns. The use of LiveScan technology will supplant other methods establishing identities of criminals.

Sibling Fingerprints, Criminal Investigations, Fingerprint Patterns

E107 An Examination of Pattern Types in Twins' Fingerprints and Bilateral Symmetry in an Unrelated Population

Kristine Duran, MFS, Carlsbad Police Department, Carlsbad, CA and Forensic Sciences Program, National University, La Jolla, CA; Ismail Sebetan, MD, PhD, Forensic Sciences Program, National University, La Jolla, CA; Paul Stein, PhD, Forensic Sciences Program, National University, La Jolla, CA*

Learning Overview: After attending this presentation, attendees will have a better understanding regarding if there are stronger genetic or environmental factors affecting fingerprint pattern development or another influence during fetal growth. The objective of this research is to indirectly assess the genotype versus environment influence on phenotype variation of fingerprint pattern types of monozygotic twins and dizygotic twins. This study examined the percentage of intra-pair variance of the monozygotic twins and dizygotic twins fingerprint pattern types homolaterally and bilaterally for their symmetry and compare their frequency statistics to a large population. In a separate study of 300 individuals regarding fingerprint pattern bilateral symmetry, 3,000 rolled fingerprints were examined and classified for each finger, 1-10, and opposing fingers were compared.

Impact Statement: This presentation will impact the forensic community by providing a more in-depth understanding of symmetry in fingerprint pattern types in twins both bilaterally and homolaterally and their pattern frequency statistics. Additionally, this study presents the frequency of bilateral symmetry of the right and left hands in an unrelated population.

Many researchers have investigated whether it is our genetics (genotype) that drive the development of pattern types or the environment, maternal effects in the mother's womb, that have a stronger influence on fetal pattern formation. Researchers consider it as a combination of our genotype and the environment that creates a phenotype using this formula: $VP=VG+VE$. A sum of 222 monozygotic twins and 56 dizygotic twins' fingerprints were collected for a classical twin study in dermatoglyphics to better understand the genetic and environmental influences in fingerprint pattern formation.

A total of 2,215 monozygotic twins' fingerprints and 560 dizygotic twins' fingerprints were examined and classified using the eight classifications: plain arch, tented arch, ulnar loop, radial loop, double loop whorl, plain whorl, central pocket loop whorl, and accidental whorl. Using the National Crime Information Center (NCIC) fingerprint classification codes, each finger's pattern was recorded, then compared homolaterally and bilaterally. In a separate study, a total of 3,000 rolled fingerprints were examined and classified using the same eight classifications. Using the NCIC codes, each finger's pattern was recorded, then compared bilaterally.

The homolateral concordant pattern types for the monozygotic twins' fingerprints (70.9%) exceeded the frequency of the dizygotic twins' fingerprints (58.1%). The frequency of bilateral symmetry in the monozygotic twins was 63.2%, less than the homolateral symmetry between the monozygotic twins 70.9%. The frequency of bilateral symmetry in the dizygotic twins was 49.6%, less than the homolateral symmetry between the dizygotic twins 58.1%. Seemingly, monozygotic and dizygotic twins' hands have more symmetry homolaterally to their twin than bilaterally on their own hands. The chi-square test found with both groups was a statistically significant, p value $<.0001$. The frequency statistics of the twins' eight fingerprint classifications was concordant to those reported by NIST from 22,264,713 males and females. In the study of bilateral symmetry of fingerprint patterns in 300 unrelated individuals, bilateral symmetry averaged 69.8% with the same classification occurring 1,047 out of 1,500 paired fingers from the right and left hands. The chi square found it statistically significant, p value $<.0001$.

Fingerprint pattern formation is influenced by a third factor, in addition to genetics and environment: developmental noise. Developmental noise or randomness produced at the cellular level on the volar surface of fetus's fingers during the critical stage of fingerprint development affects ridge flow and thus supports the unique formation of friction ridge skin at the class characteristic level of pattern type. The updated formula for total variance of this phenotype is $VP=VG+VE+VDN$.

Dermatoglyphics, Twins, Fingerprints

E108 An Analysis and Discrimination of Fingermarks Contaminated With Non-Steroidal Anti-Inflammatory Drugs (NSAIDs) Tablets Using Raman Spectroscopy and Chemometrics

Mohamed O. Amin, MSc*, Kuwait University, Asimah, Kuwait; Entesar Al-Hetlani, PhD, Kuwait University, Asimah, Kuwait; Igor K. Lednev, PhD, University at Albany, Albany, NY

Learning Overview: The present work demonstrates the use of Raman spectroscopy as a non-destructive technique along with multivariate statistical analysis to detect traces of NSAIDs in Fingermarks (FMs) and determine the type of drug present. The work will appeal to a broad audience including analytical chemists in general and forensic scientists in particular, and attendees will recognize the potential of Raman spectroscopy to analyze various fingerprint and forensically relevant samples that may be recovered from the crime scene, suspect, or victim. Furthermore, the application of chemometrics, including multivariate Partial Least Squares Discriminant Analysis (PLSDS) and a Genetic Algorithm (GA) to differentiate between several FM samples, will emphasize the significance of these methods to gain a profound understanding of the results and differentiate between different forensic evidence.

Impact Statement: For decades, the analysis of fingerprints has been used as the primary biometric means of human identification because no two people share the same fingerprint. Modern chemical analysis technologies have added the potential to determine the molecular composition of FMs and identify chemicals that the suspect may have encountered. Improvements in analytical detection of the chemical composition of FMs is therefore of obvious importance. This presentation offers a novel approach to differentiate between NSAIDs-contaminated FMs. Raman spectroscopy with advanced statistic enabled the detection of traces of NSAIDs in FM and determining the type of drug present in the FM, which can be of profound importance in forensic intelligence. This will stimulate researchers with various backgrounds and interests to contribute new ideas and implement novel approaches. In addition, forensic practitioners will learn about emerging technologies and commit to their testing, evaluation, and further development. New developed technologies for FM analysis could be helpful and potentially adapted in various other areas, including medical diagnostics and tissue analysis in particular.

Over the past years, chemical analysis of Latent Fingermarks (LFMs), “touch chemistry,” has offered additional support to forensic examination and advanced our understanding of the individual’s lifestyle. Modern chemical analysis technologies have greatly contributed to the chemical analysis of the FM and identify materials that a suspect may have come in contact with. On the other hand, more than 30 million people take Over-The-Counter (OTC) and prescription NSAIDs for pain relief, headaches, and arthritis every day, which increases the risk of their abuse; in addition, NSAIDs have been commonly linked to suicide cases. The present study demonstrates the potential of Raman spectroscopy as a rapid and non-destructive technique along with statistical analysis for discriminating if FMs made contact with several NSAID tablets without any sample pretreatment (Figure 1).

Multiple Raman spectra were obtained from each FM sample using automatic mapping to account for the inherent heterogeneity of the sample. Features corresponding to the drugs were clearly observed in the Raman spectra in addition to several peaks that can be attributed to the excipients present in the tablets. Furthermore, chemometrics were used to determine whether Raman spectroscopic analysis can be used to distinguish between FM samples. Initially, a Principal Component Analysis (PCA) model was applied to identify outliers, defined as spectra with high Hotelling’s T^2 and Q residuals values in all the data sets, and they were removed before any further statistical analysis. Multivariate PLSDS and GA were employed to differentiate between FM- and NSAID-contaminated FM groups with emphasis on the validation test to assure the applicability of the built models. A subject-wise Leave-One-Out Cross Validation (LOOCV) was utilized to examine the prediction performance of the models. The created PLSDA model using a training data set enabled the separation of sebaceous FM, aspirin-, diclofenac-, ibuprofen-, ketoprofen-, and naproxen-contaminated FMs, while LOOCV offered excellent results demonstrating the potential of the developed method for discriminating NSAID-contaminated FMs. Thus, the developed strategy is a promising approach to detect traces of NSAIDs and potentially other drugs in FM and determine the type of drug present, which can be of profound importance in forensic intelligence.

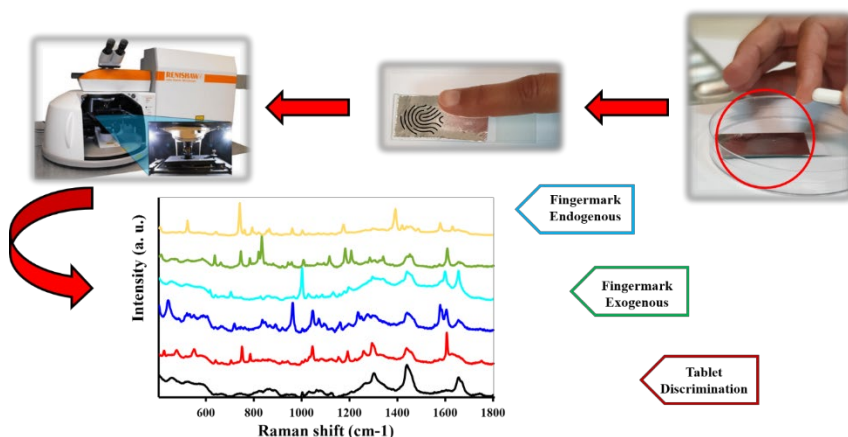

Figure 1: Schematic illustration of the experimental approach employed for the analysis FM following contact with NSAID tablets using Raman spectroscopy. Initially, the fingertip made contact with NSAID tablets, then the contaminated FMs were applied on the aluminum adhesive tape. The samples were subjected to Raman analysis and the averaged Raman spectra were obtained, which enabled the identification of FM endogenous and exogenous components in addition to the discrimination between commercial NSAID tablets with the aid of chemometrics.

E109 The Terminal Deposition of Latent Fingermarks Determined by Chemical and Physical Developers

Hannah Hubbard*, University of New Haven, New Haven, CT; Josep De Alcaraz-Fossoul, PhD, University of New Haven, New Haven, CT

Learning Overview: After attending this presentation, attendees will have a better understanding of the importance of detecting the terminal latent fingerprint in a depletion series and the feasibility (i.e., detection limit) of different developers.

Impact Statement: This presentation will impact the forensic science community by demonstrating the level of efficacy of different developers at visualizing fingerprints in sequential depositions and the sensitivity to the loss of ridge quality between depositions using statistical data.

It is a known notion, through decades of field observations and experiments, that a finger ridge skin impression (i.e., latent fingerprint) loses its visual quality, or is no longer detectable, after repeated contact with a surface. However, what is unknown is the number of touches required until the impression goes beyond recognition for identification purposes. Being able to determine the terminal latent fingerprint and the gradual or sudden loss of ridge quality over the series could lead to new approaches in the visualization of fingerprints and different analytical techniques. The goal of this study is to establish the “terminal” deposition among a limited number of donors; that is, the point at which fingerprints can no longer be successfully visualized after a series of successive depositions without adequate time to recharge sweat residue on skin.¹ The additional goal is to determine and quantify the decrease in ridge quality between every deposition.

For decades, researchers have been studying and optimizing new methods for latent fingerprint enhancements.² However, previous studies have minimally touched upon the evaluation of the visual quality of fingerprint depletions, but they did not cover the level of loss of quality across deposition series. In fact, a lot remains unknown about how much ridge quality is lost as well as the overall progression of a series.

Physical developers, such as black magnetic powder, are commonly used to bind to the latent fingerprint residue, resulting in an enhanced color contrast between ridges and furrows that can be viewed by the naked eye.^{3,4} Another way to visualize fingerprints would involve the application of a chemical developer such as cyanoacrylate (also referred to as super glue) to chemically react with the compounds contained within the latent fingerprint.⁵ The comparison of the two techniques may establish which one is the most sensitive at detecting different levels of fingerprint depletion and yield the most accurate results on ridge quality.

The experiment involved the deposition of sebaceous-rich latent fingerprints in sequential series from four donors. These impressions were deposited on glass and visualized 24 hours after. All samples were standardized with Photoshop® and the quality of the ridges was analyzed through Universal Latent Workstation (ULW). ULW is a computer program that automatically provides a value for the clarity of ridges, among other information. Statistical programs such as Microsoft® Excel® and Statistical Package for the Social Sciences (SPSS) tests were used to record data and conduct statistical analyses.

Through the visual observation of the loss of ridge quality in a depletion series, detection of any inconsistencies across depositions of the donors was analyzed. Preliminary data suggests a significant loss of quality after the 14th and 15th deposition, proving that fingerprints could be detectable for many touches without needing to “recharge.” Visual observations indicated that cyanoacrylate may be too efficient for the purpose of depletion analyses, whereas black magnetic powder appeared to be more suitable at detecting the loss of ridge quality.

E110 The Development of Fingerprints After Prolonged Submersion in Freshwater

Haley Bolt, MS, Marshall University, Huntington, WV; Katrina Willis, Banks County Sheriff's Office, Homer, GA; Bruce Willis, Piedmont University, Demorest, GA; Catherine Rushon, Marshall University, Huntington, WV*

Learning Overview: After attending this presentation, attendees will have a greater knowledge of the development of fingerprints that have been submerged in freshwater sources for prolonged periods of time and the appropriate methodology to use.

Impact Statement: This presentation will impact the forensic science community by presenting experimental methods of two fingerprint development techniques that can be used on evidentiary items from the field.

A crucial aspect of crime scene investigations is the discovery and development of sufficient fingerprint evidence that can link a potential suspect or victim to a crime. Water scenes are somewhat unmarked territory when it comes to latent prints and their success rates. Several studies have been conducted previously on development techniques that could assist investigators in developing crucial prints after they had been submerged in water for extended periods of time, either because of delayed discovery of a scene or lengthy scene investigations.¹⁻³

In 2017, one study was conducted by Somaya Madkour and her fellow associates on using cyanoacrylate fuming to develop prints on non-porous surfaces in fresh and seawater environments.² Their conclusions were that this development process was possible and worked efficiently with either water source; however the quality of the results decreased over time and the high salinity in saltwater damaged some of the prints.

The goal of this research study is to determine if cyanoacrylate fuming with a Rhodamine 6G Ardox M.B.D. dye stain (RAM) and Sudan Black are successful techniques for developing latent prints after being submerged in freshwater, and which method is more successful. The substrate types for the experiment will be non-porous and fall into one of three categories: aluminum, plastic, or glass. A trial study was conducted prior to an in-depth study to: (1) determine if either technique was even possible to use on these substrates, (2) eliminate any variables that would drastically affect the data, and (3) highlight which water type presented more information to expand upon.

In conclusion, the results indicated that cyanoacrylate fuming with RAM dye staining and Sudan Black were both highly responsive, with Sudan Black being more successful for sufficient print development. If any evidence was to be recovered from water scenes, regardless of the amount of time spent underwater, they should not be undervalued and should be tested for fingerprints using either of these methods.

E111 Environmental Influences on Latent Fingerprint Recovery

Madison Frese, BA, University of Central Oklahoma, Edmond, OK; Caitlin Porterfield, MS, University of Central Oklahoma, Edmond, OK*

Learning Overview: After attending this presentation, attendees will have a better understanding of how temperature and humidity affect latent print stability and development over time.

Impact Statement: This presentation will impact the forensic science community by showing how environmental factors, specifically temperature and humidity, affect fingerprint recovery in outdoor crime scenes.

The goal of this study was to see if there are any noticeable differences in recovered fingerprint quality over time when prints are kept in outdoor environments. Specifically, this study will focus on how temperature and humidity impact latent print processing and development.

Because of the variability of environmental conditions, it is difficult to control for all factors. In an effort to account for factors outside of temperature and humidity, this study was conducted in two phases. Phase one involved developing prints over time in different locations around the United States in outdoor environments. This allowed for the assessment of fingerprint stability and quality at varying temperatures and humidity over time but accounted for other environmental factors. Lab simulations were also conducted to replicate these locations and conditions in an effort to determine the actual impact of the temperature and heat variables without the presence of other factors. Preliminary results indicate that temperature and humidity do impact the ability to recover prints.

A difficult part of fingerprint analysis is figuring out how long a fingerprint has been at a scene. So far, there is no verifiable method for determining age.¹ If it is found that there is a pattern in recoverability and quality using temperature and humidity, this may allow for the creation of a method for determining relative age for outdoor crime scenes in different environmental conditions.

Fingerprint Analysis, Environmental Conditions, Recovery of Fingerprints

E112 Forensic Phenomics—An Applied Approach to Fingerprint Profiling for Intelligence Guided Investigations

Georgia Cottnam, Murdoch University, Murdoch, WA, Australia; Brendan Chapman, Murdoch University, Murdoch, WA, Australia; Berin Boughton, Murdoch University, Murdoch, WA, Australia; Torben Kimhofer, Murdoch University, Murdoch, WA, Australia*

Learning Overview: Upon the conclusion of this presentation, attendees will understand the current analytical techniques and future direction for the application of phenomics to forensic fingerprint evidence in the investigative landscape.

Impact Statement: This presentation will impact the forensic community by raising awareness of the field of forensic phenomics and its potential applications in criminal investigation and national security.

The identification of a perpetrator of crime remains the foremost significant aspect of forensic investigations; however, as forensic awareness increases within the community, the nature of evidence left behind at the crime scene has begun to change. As a result, the identification of new methods and techniques for the identification of an individual have become increasingly important.

To overcome current limitations imposed by fingerprint examination and comparison techniques for identification—such as the Automated Fingerprint Identification System (AFIS)—this study focused on the examination and exploitation of the chemical composition of fingerprint residue, including endogenous, semi-exogenous, and exogenous compounds present in the residue.¹

This study analyzed repeated fingerprint samples from 20 participants using a combination of mass spectrometric techniques, including mass spectrometry imaging using Matrix-Assisted Laser Desorption Ionization (MALDI) and Desorption Electrospray Ionization (DESI); and targeted liquid extractions of fingerprint residue swabs using Liquid Chromatography/Mass Spectrometry (LC/MS).

Identification of observed components was conducted using a combination of publicly available databases with statistical evaluation carried out to identify data trends and prominent unique features able to distinguish individuals, highlighting the applicability of the approach.

By increasing the tools available to those involved in criminal and national security investigations, it may be possible to identify points of investigative intelligence that can help identify suspects, help establish the order of events, or confirm/refute eyewitness statements concerning criminal activities. This research provides evidence for MS-based analytical techniques in forensic profiling and intelligence gathering during criminal and national security investigations and highlights key focus areas for the expansion of forensic phenomic research.

Phenomics, Fingerprint Profiling, Mass Spectrometry

E113 The Impact of Packaging and Transportation on the Preservation and Processing of Latent Friction Ridge Impressions

Sydney Baber, University of Central Oklahoma, Edmond, OK; Caitlin Porterfield, University of Central Oklahoma, Edmond, OK*

Learning Overview: After attending this presentation, attendees will understand the impact that packaging and transportation of items of evidence have on the ability to preserve and process latent friction ridge impressions deposited on those items.

Impact Statement: This presentation will impact the forensic science community by establishing the best method for preserving and processing latent friction ridge impressions. It will provide insight into whether it is better to process items at the scene or transport them to the lab. It will also indicate how packaging and length of transportation impact latent friction ridge impressions.

This study was conducted to determine if packaging and transportation of small items of evidence impacts the ability to preserve and process latent friction ridge impressions deposited on those items. Similar research has been completed with DNA evidence and researchers found that packaging and transportation did impact the quality of the DNA evidence when it was analyzed.¹ Since it has been established that packaging and transportation of items of DNA evidence can cause degradation, experts in the field are now working toward establishing best practices to reduce the level of degradation and improve the chances of recovering useable evidence.

This study focused on best methods for preserving and processing latent friction ridge impressions. Plastic bottles, aluminum cans, and ceramic white tiles were used as items of evidence. Fingerprints were deposited on the items and left for two hours to represent time between the crime being committed and the same crime being investigated. The evidence was then divided into two groups: one group processed without being transported and one group processed after being packaged in paper bags and driven in the car. These two groups represented evidence processed on scene and evidence processed after being packaged and taken to the lab. Time of transport ranged from 15 minutes to one hour. Temperature and humidity were also recorded. Latent impressions were then processed with black power and the prints lifted with tape. Latent impressions were analyzed for level 1 detail (cores, deltas, pattern type) and level 2 detail (ending ridges, bifurcations, dots, etc.). The value of the friction ridge detail was then compared between the items processed at scene and those items of evidence that were transported. Time of transportation was also taken into consideration. Comparisons are currently being conducted. Preliminary results suggest that packaging and length of transportation do impact the stability and subsequently the processing of latent impressions.

The goal of this study was to establish best practices and guidelines for preserving and processing latent friction ridge impressions in an effort to maintain the highest possible level of quality and quantity of detail and provide more value during the analysis phase.

Fingerprint Processing, Fingerprint Analysis, Crime Scene Investigation

E114 Raman Spectroscopy to Tackle the Analysis of Bloodstains in Crime Scene Conditions

Alexis Weber, MSFS, SupreMEtric, Albany, NY; Alexis Barber, BS, University at Albany, SUNY, Albany, NY; Igor Lednev, PhD, University at Albany, SUNY, Albany, NY*

Learning Overview: After attending this presentation, attendees will have a better understanding of the impact of environmental conditions on determining the time since deposition of bloodstains.

Impact Statement: This presentation will impact the forensic science community by presenting evidence of the broadened usability of Raman spectroscopy in forensic laboratories.

Blood traces are one of the most common biological samples found at crime scenes and can provide substantial information about individuals involved and the event that occurred. Blood evidence is frequently used for DNA analysis in order to create a genetic profile. However, currently the analysis of bloodstains is not being utilized to its full potential. Determining the time of crime is an important goal for crime scene investigations, which can be achieved by estimating the Time Since Deposition (TSD) of bloodstains.¹⁻³ Additionally, if crime scenes contain multiple sets of bloodstains, the calculated TSD should allow for the selection of bloodstains relevant to the crime and, therefore, reduce the number of samples that should be collected, documented, and processed.

Vibrational spectroscopy paired with chemometrics has been shown to provide reliable, rapid, and non-destructive methodologies to determine the TSD of bloodstains.⁴ However, research conducted with these techniques so far has analyzed the aging of bloodstains, specifically the degradation of hemoglobin, in ambient conditions. However, crime scenes are not always in such pristine environments and degradation rate of hemoglobin is commonly affected by the surrounding environment. Therefore, it is necessary to develop a model that is capable of estimating the TSD of bloodstains in different environments.

There are infinite varieties of potential environmental conditions. The goal is to determine how potentially “extreme” conditions affect the aging mechanism of bloodstains, high temperature in particular. For this purpose, fresh blood samples were collected so that no anticoagulants were present, which potentially can affect the *ex vivo* aging mechanism of blood. The bloodstains were then aged in a controlled heated environment and tested at numerous time points post-deposition. After the spectra were collected, they were loaded into statistical software for preprocessing and modeling. The reproducibility of heated blood analysis and a TSD determination model will be discussed.

Raman Spectroscopy, Time Since Deposition, Blood Analysis

E115 Optimizing Blood Removal Methodology for Visualizing Gunshot Residue (GSR) Patterns

Ashley Smith, BS, Pennsylvania State University, University Park, PA; Michael Kuslusi, MFS, Pennsylvania State University, University Park, PA*

Learning Overview: Through this presentation, attendees will gain a better understanding of photonic and chemographic visualization methods for GSR patterns, as well as the presence and removal of blood interferences.

Impact Statement: This presentation will provide more insight into photonic visualization of GSR patterns as a replacement for traditional chemographic processing. The impact of heavy bloodstaining on visualization and an evaluation of blood removal methods are also discussed.

GSR is the vapor and particulate matter that exits a firearm upon discharge, including smoke/soot, unburned and partially burned propellant, as well as components from the cartridge primer.¹ Visualization of GSR patterns is essential for shooting-incident reconstruction. Visualization of GSR patterns allows the muzzle-to-target distance to be estimated, based on the density and distribution of the residues on fabrics, skin, and other materials.¹

Chemographic techniques such as the Modified Griess Test (MGT) and the Sodium Rhodizonate Test (SRT) are well characterized and have long been the methods of choice in forensic laboratories. However, these methods have practical limitations as well. In addition to potentially exposing examiners to chemical hazards, these methods are also destructive to GSR patterns.² This study is part of a larger effort to develop photonic techniques, such as blue-orange fluorescence and infrared reflectance, for the non-destructive visualization of GSR patterns.^{2,3}

The presence of heavy bloodstaining over GSR patterns can both obscure imaging for photonic methods and impede the transfer of residues for chemographic methods.⁴⁻⁶ Reagents that can liberate bloodstains without damaging GSR patterns have been described previously.⁴⁻⁶ However, this study will address bloodstain removal specifically for photonic visualization. This is important for two reasons: incomplete removal of heme proteins is believed to liberate porphyrin compounds, which also fluoresce in the yellow-orange visible band.⁷ Fluorescence from residual porphyrins could mask the desired fluorescence of GSR patterns. And, unlike previous studies using chemographic processing, the resolution and non-destructive nature of photonic GSR imaging lends itself as a quantitative research tool for evaluating results. The ideal blood removal reagent would be suitable for both photonic and chemographic methods.

Three blood removal reagents were tested and evaluated for their performance at varying parameters, including reagent volume, soak time, and blood deposit concentration. A Design of Experiments (DOE) approach was implemented to analyze the interactions between parameters and the results of those combinations. In total, 24 combinations of parameters were tested, with 8 trials for each blood-removal reagent and each trial performed in quadruplicate.

The GSR patterns were visualized using blue-orange fluorescence (450nm excitation/630 barrier filter) and infrared reflectance (850nm) prior to blood deposition. Following blood-removal processing, the GSR patterns were visualized again and processed chemographically as well. Photonic images were evaluated for propellant particle brightness-contrast, particle loss, blood removal, and loss of smoke/soot deposits. Particle loss was measured using Image Access® Forensic Analyzer software. Propellant particle brightness-contrast, blood removal, and loss of smoke/soot were measured using Adobe® Photoshop®. Chemographic results were evaluated for blood removal efficiency as well.

Gunshot Residue, Blood Removal, Blue-Orange Fluorescence

E116 Utilizing the ECHO Model to Virtually Train Medical Examiners and Coroners on Drug Overdose Investigations and Mortality Data Improvement

Rachel Redding, MPH, ASTHO, Arlington, VA; Richa Ranade, MPH, ASTHO, Arlington, VA*

Learning Overview: The Association of State and Territorial Health Officials (ASTHO) received funding from the Centers for Disease Control and Prevention (CDC) to pilot a virtual training for Medical Examiners and Coroners (ME/Cs) to improve reporting of drug overdose deaths. Project ECHO:OD-FIT (Overdose Fatality Investigation Techniques) is the first large-scale training opportunity created specifically to engage ME/Cs in discussion about their response to the overdose crisis. Training and requirements for ME/Cs vary greatly across the United States, leading to inconsistency in how overdose deaths are reported. OD-FIT uses the ECHO model to fill ME/C training gaps and allow a virtual space for best practices and experience to be shared. Many ME/C offices in the United States lack funding, resources, and time to provide ample training for staff, and this shortage of opportunities has been exacerbated by the increase in drug overdoses during the COVID-19 pandemic.

This presentation will explain the ECHO model and lessons learned from the pilot year of ECHO: OD-FIT. Attendees will learn the format of each session, the continuous quality improvement process, evaluation results, and lessons learned. They will also understand the importance of accurate death reporting and how this affects the public health response to the overdose crisis and emerging disease trends. This ground-breaking and innovative training series on drug overdose is the first of its kind and offers opportunities for expansion or replication to other audiences.

The success of this ECHO series for a difficult-to-reach population can be replicated for other forensic science populations. As the COVID-19 pandemic has continued, many trainings have been canceled or translated to virtual learning. The ECHO model was specifically created for a virtual platform and provides access to training, colleagues affected by the pandemic, and those who work in rural and secluded areas.

Impact Statement: ME/Cs are vital to United States public health surveillance, certifying and reporting more than 20% of yearly total deaths in the United States.¹ As the overdose epidemic has continued in the United States, it is imperative for public health decision makers to understand current and emerging drug overdose trends and where they are occurring. Having accurate and complete death certifications assists public health decisions by providing local, state, and national mortality data. This data can then be used locally to distribute resources to prevent overdose deaths. The forensic science community must understand this delicate relationship and continue to improve data.

A study in Vermont found over half of completed death certificates had errors or major errors and 93% had incorrect International Statistical Classification of Diseases and Related Health Problems, 10th Revision (ICD-10) codes.² This negatively impacts the quality of local and national mortality data and highlights the importance of continuous training. Another study found that 20.3% of death certificates indicting an overdose death in 2016 did not include a specific drug and had more missing information when filled out by coroners instead of medical examiners.³ Project ECHO:OD-FIT is addressing that data gap by training ME/Cs to fill out death certifications completely and specifically. It is imperative for the forensic community to understand the importance of continuous training and improvement for practitioners to protect our nation's health. We must continue to engage providers with less resources virtually and effectively, even when in-person meetings resume.

This presentation will benefit any person or organization who wants to effectively train forensic practitioners virtually. Attendees may be considering new and innovative ways, like this ECHO model, to engage the forensic science community. This presentation will also highlight the important and often ignored significance of ME/Cs in public health surveillance.

Coroners, Training, Data

E117 Are Medical Students Prepared to Recognize Child Abuse and Neglect? The Evaluation of an Italian Sample

Francesco Lupariello, MD, University of Turin, Turin, Italy; Francesca Capello, MD, University of Turin, Turin, Italy; Camilla Bonci, MD, University of Turin, Turin, Italy; Giancarlo Di Vella, MD, PhD, University of Turin, Turin, Italy*

Learning Overview: After attending this presentation, attendees will have learned about Italian medical students' knowledge and training on child abuse and neglect.

Impact Statement: This presentation will impact the forensic science community by analyzing the degree of medical students' preparation on child abuse and by evaluating the medical school contributions on this topic.

Child abuse and neglect are widespread social and medical issues that often go unreported, despite being associated with significant morbidity and mortality.¹ They represent heterogeneous phenomena that widely vary in type, severity, and chronicity and, as a result, are challenging to identify: misdiagnosis may result in the development of psychiatric and other medical disorders.^{2,3} In the scientific literature, a limited number of studies have been conducted about health workers' abilities to recognize suspected child abuse, although some researchers also reported physicians' lack of knowledge on this topic.⁴ It is not clear if the reasons for this problem rely on insufficient preparation of students during medical school and/or a deficiency in continuing medical education during/after fellowships. For these reasons, a questionnaire was administered last year to medical students in order to evaluate the degree of knowledge on this theme. The study population included 179 Italian students, divided into two groups: Group A (79.8%)—students who attended pediatric traineeship and/or pediatric exam, and Group B (20.2%)—students who did not attend pediatric traineeship and/or pediatric exam. There were 12 questions focused on child sexual abuse, physical maltreatment, and neglect. Students' knowledge was considered as sufficient if the final score was $\geq 6/12$. Quantitative and statistical analysis were carried out by Excel® formulas.

Results pointed out an overall negative outcome for the most part of the 179 students (77.7% scored $< 6/12$). In this population, medical students' awareness of child anogenital anatomy/pathophysiology appeared particularly deficient; 55.9% incorrectly answered that rectal prolapse is a manifest sign of chronic anal penetration. Indeed, a marginal percentage (7.3%) of students was aware of the physiological aspect of adult and preadolescent hymens. Similar considerations were highlighted considering the knowledge of suspected trauma sentinel lesions (abusive or accidental).^{5,6} For all questions, results of chi-square tests yielded no statistical differences between the two groups: the deficiencies were not related to students' different levels of progression in medical school training and/or preparation. Therefore, this research clearly objectivated the need of a systematic implementation of basics in pediatrics, allowing specialists to acquire notions on child abuse and neglect.

The most significant limitation of this study relies on the difficulty of extending the abovementioned considerations to medical students from other geographical regions and/or countries. However, comparison of different medical school systems suggests common issues in students' education on child abuse and neglect.⁷ Thus, all these systems are at risk of generating students and future medical doctors who are unable to attend to the responsibility of protecting children from abuse and neglect.⁸ Study results and literature data suggested a widespread need to implement child abuse and neglect knowledge in medical schools. The present study highlighted the necessity for specific corrective interventions by governments and/or supranational organizations, as well as a proper pediatrics training.

Child Abuse, Neglect, Medical Students

E118 Characterizing the Use of Blind Verification and Blind Proficiency Testing at Forensic Laboratories

Anni Hong, BS*, Carnegie Mellon University, Pittsburgh, PA; Maddisen Neuman, MA, Houston Forensic Science Center, Houston, TX; Sharon Kelley, JD, PhD, University of Virginia, Charlottesville, VA; Brett Gardner, PhD, University of Virginia, Charlottesville, VA; Robin Mejia, MPH, PhD, Carnegie Mellon University, Pittsburgh, PA

Learning Overview: After attending this presentation, attendees will understand the frequency with which laboratories are implementing blind verification and proficiency tests

Impact Statement: As interest in incorporating blinded procedures has increased, in conversations with laboratory management and Quality Assurance (QA) staff, there have been inquiries about practices at other laboratories. This presentation will help assess the state of the practice in the community.

The 2014 Bureau of Justice survey of publicly funded forensic crime laboratories found that while 97% of the country's 409 public forensic labs reported using some type of proficiency testing, only 10% reported using blind tests.¹ Further, local or state laboratories were far less likely to be conducting blind tests than federal laboratories. In October 2018, the Center for Statistics and Applications in Forensic Evidence (CSAFE), with the Allegheny County Office of the Medical Examiner, hosted a meeting with representatives from seven forensic laboratory systems, ranging in size from a single laboratory with fewer than 50 employees to a seven-laboratory system with over 200 employees, to assess interest in implementing blind proficiency testing and found significant interest as well as numerous obstacles.² In recent years, an increasing interest in implementing blinding in analyst proficiency tests as well as components of case work, such as verification of findings, has been observed at laboratories of different sizes and in different jurisdictions. To help characterize the degree to which these methods are being implemented, websites of forensic laboratories that are accredited by the ANSI National Accreditation Board (ANAB) for latent print analysis are being reviewed to identify those that publish their Standard Operating Procedures (SOPs) publicly. Specifically, SOPs related to proficiency testing and latent print processing, comparison, and verification are being reviewed. To date, 23 SOPs have been collected. Being recorded are:

- if latent print analysis is performed;
- if blind proficiency tests are used;
- if so, the frequency with which analysts complete blind proficiency tests;
- if verification is performed for conclusions of a match or non-exclusion;
- if verification is performed on other cases, and, if so, with what frequency;
- if blind verification is performed for conclusions of a match or non-exclusion;
- if blind verification is performed on other cases, and, if so, with what frequency;
- whether and how verification is reported;
- the type of jurisdiction for the lab (local, regional, state, national, other).

After the data has been characterized, follow up with select laboratories will occur to request interviews to discuss the lab's policies, when they were implemented, and, if there have been changes in recent years, the reasons for the change. In initial background interviews conducted as part of designing the study, directors and QA staff at forensic laboratories expressed interest in understanding policies on verification and proficiency testing at other laboratories; therefore, strong interest in the findings from this study is expected.

Blinding, Verification, Proficiency test

E119 A Million Little Pieces: Pursuing Justice Through Methodology in Evidence

Michela Ferrara, MD, Department of Clinical and Experimental Medicine, University of Foggia, Foggia, Puglia, Italy; Giovanni Pollice, MD, Department of Clinical and Experimental Medicine, University of Foggia, Foggia, Puglia, Italy; Giovanni Gurgoglione, MD, Department of Clinical and Experimental Medicine, University of Foggia, Foggia, Puglia, Italy; Elena Giacani, MD, Department of Clinical and Experimental Medicine, University of Foggia, Foggia, Puglia, Italy; Stefania De Simone, MD, Department of Clinical and Experimental Medicine, University of Foggia, Foggia, Puglia, Italy; Francesco Sessa, MS, Department of Clinical and Experimental Medicine, University of Foggia, Foggia, Puglia, Italy; Giuseppe Bertozzi, MD, Department of Clinical and Experimental Medicine, University of Foggia, Foggia, Puglia, Italy*

Learning Overview: The goal of this presentation is to show how the multidisciplinary interactions led by a scientific forensic method play a substantial role not only to identify the cause of death but, above all, to serve justice.

Impact Statement: This presentation will have an effect on forensic pathologists by underlying the importance of a complete multidisciplinary approach in forensic practice. The cases proposed, in fact, demonstrate how the forensic pathologist can no longer be satisfied with the evidence deriving only from the macroscopic autopsy data, but with the integration of data deriving from a rigorous scientific method, if the truth is to be made explicit. (Pursuing Justice Through Method in Evidence.)

The heart of research in the field of forensic epistemology is research on the scientific method in the analysis and collection of case-specific evidence. This complex process cannot be separated from the exploration and experimentation of forensic sciences, especially in consideration of the goal of forensic activity, namely the search for truth. Therefore, it is no longer possible to be satisfied with only macroscopic data; in this regard, some cases are presented in which the execution of further investigations made it possible to completely change the supposed cause of death that emerged from the autopsy data.

The first case concerns the autopsy of a man involved in a road accident, found outside his vehicle. The autopsy macroscopic examination revealed the presence of an aortic transection at the isthmus level typical of the acceleration-deceleration dynamics, which affects the occupants of a vehicle involved in a high kinetic-energy collision. However, the study of the crime scene and the examination of the vehicle involved in the accident made it possible to collect evidence that led to the suspicion of being run over by a pedestrian. This last orientation of the investigations made it possible to determine that it was a murder committed by the son of the deceased for inheritance reasons.

The second case concerns a known criminal who fell into the water during a boat trip and was found floating near the boat. The circumstantial data was due to drowning, further supported by the absence of external damage detected by the forensic pathologist who intervened on the spot. The toxicological examination confirmed the presence of high concentrations of alcohol and cocaine in the blood. However, the Computed Tomography (CT) examination performed before the autopsy made it possible to identify the presence of the fracture of the tooth and axis according to a compression-extension mechanism, completely modifying the hypothesis on the cause of death.

The third case concerns an officer of an armed body who was found in the car compartment of his home, on the ground. The medical history was of the recent onset of acute low back pain for which he was being treated with intramuscular Non-Steroidal Anti-Inflammatory Drugs (NSAIDs). At the autopsy table, the hypothesis was of sudden cardiac death. However, the subsequent toxicological investigation made it possible to identify traces of cocaine in the blood and urine, causally relevant to the cause of death, taken by muscle-popping.

The fourth case concerns a Tunisian man found suspended by means of a rope wrapped around his neck. The external examination was confusing: on one hand, the body was covered by purple bruises probably caused by external blunt force trauma; on the other hand, some typical signs of a suicidal hanging (such as the double ligature mark around the neck, swollen face, and protruding tongue) were also presented. Subsequent investigations identified a group of people who allegedly beat the subject, who were then investigated for murder. However, the lawyer claimed that they had caused the injuries in a fight a few days earlier and that the man then would have hanged himself in shame. However, immunohistochemical staining showed a dermal strong positivity to CD15, tryptase, and IL-15 in the marginal zones above and below the hanging marks. Instead, the staining according to Perls' Prussian blue stain documented that the lesions produced dated back to less than 48–72 hours (the interval necessary for hemosiderin to form). They were then tried for murder.

Multidisciplinary Approach, Forensic Sciences, Pathology

E120 Taking a Sniff Ahead: Updates on the Development of National Standards for Canine Detection Applications

Paola Prada-Tiedemann, PhD, Texas Tech University, Lubbock, TX; Kenneth Furton, PhD, Florida International University, Miami, FL; Suzanne Perry, Old Dominion SAR, Sumner County, TN; Cynthia Otto, PhD, University of Pennsylvania, Philadelphia, PA*

Learning Overview: After attending this presentation, attendees will understand the progression and status of national standards development for detector dogs and sensors and the plans for the completion, dissemination, and implementation of these standards, and the expected impact on the forensic science community, including improved location of and interdiction of forensic evidence and greater courtroom acceptance of dog alert evidence.

Impact Statement: This presentation will impact the forensic science community by providing a better understanding of how the Organization of Scientific Area Committees (OSAC) and the Academy Standards Board (ASB) of the American Academy of Forensic Sciences (AAFS) is improving the consistency in the training, performance, and certification procedures of operational detector dog teams and their integration as a forensic detection tool.

This presentation includes the results of the latest work in drafting detection-specific standard documents and working with a Standard Development Organization (SDO) to publish dogs' and sensors' standards to be used by various agencies, including law enforcement, the military, and homeland security. There are a variety of factors that influence the measured performance of canine teams, including the source of training materials, the containment system used, how the training materials are presented to detection teams, and how the teams were trained and how they are maintained. This initiative was undertaken as a response to concerns coming from a variety of sectors regarding the need to improve the performance, reliability, and courtroom defensibility of detector dog teams and their optimized combination with electronic detection devices. This presentation will describe the development of canine training standards over the past 16 years, beginning with the establishment of the Scientific Working Group on Dogs and Orthogonal Detector Guidelines (SWGDOG) in 2004, which by 2014 had completed 24 guidelines totaling 436 pages, to the guidance materials currently being developed by the Dogs and Sensors subcommittee of OSAC, which began in 2014, through the standard development process with the ASB beginning in 2016 and options for encouraging and certifying implementation of published standards, including the formation of the International Commission on Detector Dogs (ICODD). These efforts have been federally funded over the years by the National Institute of Justice (NIJ), the Federal Bureau of Investigation (FBI), the Department of Homeland Security (DHS), the Technical Support Working Group (TSWG), and currently the National Institute of Standards and Technology (NIST).

Since its inception, the OSAC – Dogs and Sensors subcommittee has identified 28 OSAC standards and technical reports making their way through the process map for approval by the ASB Consensus Body and, ultimately, OSAC approval for placing on the federal registry. These 28 documents relate to other related forensic disciplines. One technical report and one standard have already been successfully published by the AAFS Standards Board: Dogs and Sensors Terms and Definitions and General Guidelines for Training, Certification, and Documentation of Canine Detection Disciplines. The following standards are awaiting the final publication process through the Dogs and Sensors ASB: Dogs and Sensors Standard for Training of Pre-scented Canines Aged Trail Search; Dogs and Sensors Standard for Training of Pre-scented Canines Location Check; Dogs and Sensors Standard for Training and Certification of Canine Detection of Humans: Patrol Canine Team; Dogs and Sensors Standard for Canine Selection, Kenneling, and Healthcare.

The success and efforts of the Dogs and Sensors subcommittee is dependent on the members and affiliates utilizing the input from the community to help inform and shape these important standards to be ultimately implemented across the wide range of detection threats and needs.

Detector Dogs, OSAC, Standards

E121 Standards Development Activities in Medicolegal Death Investigation

Kelly A. Keyes, BS, RTI International, Research Triangle Park, NC*

Learning Overview: After attending this presentation, attendees will have a better understanding of the status of discipline-specific standards pertinent to the field of medicolegal death investigation.

Impact Statement: The presentation will impact the forensic science community by creating greater awareness of standards development activities related to medicolegal death investigation. It will also increase awareness regarding training, tools, and resources that support implementation, compliance monitoring, and broader understanding.

The Organization of Scientific Area Committees (OSAC) for Forensic Science was created to strengthen the nation's use of forensic science by promoting the use of discipline-specific forensic science standards. To this end, the OSAC drafts standards that are forwarded to Standards Developing Organizations (SDOs) that further develop and publish them. The OSAC also reviews standards and recognizes them on the OSAC Registry, which serves as a central repository of high-quality, consensus-based, technically sound standards.

During this presentation, updates related to standards development in medicolegal death investigation will be discussed. These include:

Recent standards that have been added to the OSAC Registry (ANSI/ASB Best Practice Recommendation 094, Postmortem Impression Recovery: Guidance and Best Practices for Disaster Victim Identification, First Edition, 2021)

Other OSAC proposed standards (ANSI/ASB Best Practice Recommendation 006, Best Practice Recommendations for DNA Analysis for Human Identification in Mass Fatality Incidents, First Edition, 2019; ANSI/ASB Best Practice Recommendation 007, Postmortem Impression Submission Strategy for Comprehensive Searches of Essential Automated Fingerprint Identification System Databases, First Edition, 2018; ANSI/ASB Best Practice Recommendation 009, Best Practice Recommendations for the Examination of Human Remains by Forensic Pathologists in the Disaster Victim Identification Context, First Edition, 2019; ANSI/ASB Best Practice Recommendation 010, Forensic Anthropology in Disaster Victim Identification: Best Practice Recommendations for the Medicolegal Authority, First Edition, 2018; 2021-N-0007; Media Communications Following a Mass Fatality Incident: Best Practice Recommendations for the Medicolegal Authority; Victim Accounting: Best Practice Recommendations for Medicolegal Authorities in Mass Fatality Management)

Published standards from the Academy Standards Board (ASB) that have yet to go through the Registry approval process (BPR 008: Mass Fatality Scene Processing: Best Practice Recommendations for the Medicolegal Authority; BPR 094: Postmortem Fingerprint Recovery: Guidance and Best Practices for Disaster Victim Identification)

Documents currently in development at the OSAC or by the Academy Standards Board (ASB) (Workload limitations for Medicolegal Death Investigators; Best Practice Recommendation on MDI Scene Response; Best Practice Recommendations for Interactions with Next of Kin; Best Practice Recommendations for Interactions with Organ Procurement Organizations; Best Practice Recommendations for Fatality Management During a Pandemic; Standard for Disaster Victim Identification; Forensic Odontology in Disaster Victim Identification: Best Practice Recommendations for the Medicolegal Authority; Organizational and Foundation Standard for Medicolegal Death Investigation)

Priorities for new documents or work products (Commonly exchanged data in medicolegal death investigation; Family Engagement Following a Mass fatality Incident; Victim Information Center Best Practice Recommendations for Medicolegal Authority; Mass Fatality Management During a Pandemic; Best Practice Recommendations for Managing Disaster Victim Identification with Chemical, Biological, Radiological, Nuclear, and Explosive Trauma; Ethical Considerations in Disaster Victim Identification) and other highlights, including reference documents [newly published Principles to Promote Research in Medicolegal Death Investigation and Medicolegal Death Investigation Data Commonly Collected and Exchanged] and a glossary).

Opportunities for supplemental training related to discipline-specific standards will be presented, as well as additional resources and tools designed to facilitate gap analysis, compliance monitoring, and outreach efforts.

Medicolegal Death Investigation, Standards, OSAC

E122 Evidence Management and the Forensic Lab: Results From a Nationwide Survey of Evidence Handlers

Shannan Williams-Mitchem, MPP, National Institute of Standards and Technology, Gaithersburg, MD*

Learning Overview: This presentation will discuss results of the Evidence Management Survey with special emphasis on survey respondents who manage evidence at forensic laboratories. After attending this presentation, attendees will have learned about the current state of evidence management personnel, training, policies, and practice in forensic labs in comparison to other organizations involved in the management of physical evidence based on results from the Evidence Management Survey administered by the National Institute of Standards and Technology (NIST) and in close consultation with members of the Evidence Management Steering Committee (EMSC), a multidisciplinary group co-funded by NIST and the National Institute of Justice (NIJ).

This presentation will provide a summary of the findings in survey results with special emphasis on respondents from crime labs. An overview of EMSC activities, published reports, and upcoming activities will also be discussed.

Impact Statement: Maintaining the integrity of physical evidence is a fundamental aspect of the administration of justice. Every day, critical decisions are made to determine outcomes in legal proceedings based on evidence and how it is managed. Once identified as evidence, the item begins a long and often-complex journey until its final disposition (e.g., destruction, return to owner). Short- and long-term maintenance of the evidence involves a wide range of stakeholders, each with different organizational roles and responsibilities in the context of the larger system of justice. The forensic laboratory is just one of the critical organizations involved in the management of evidence.

In 2018, the EMSC was formed by NIST to develop best practices for the storage and preservation of physical evidence. One of the primary goals of the committee was to assess the state of the evidence management industry by performing a gap analysis of evidence management needs. The Evidence Management Survey was developed as one method to learn about evidence handlers, the organizations they work in, and the existing practices that enable them to retain, preserve, track, and dispose of evidence items.

Each inquiry in the 85-question instrument was carefully considered, vetted, and piloted in numerous discussions for over a year. Per federal regulations, the survey was approved for release by the Office of Management and Budget (OMB) and in accordance with NIST Institutional Review Board (IRB) requirements on January 12, 2021. The survey was widely distributed through multiple channels, including organizations represented by EMSC, NIST, NIJ, RTI International, and many others. The development of the electronic version of the survey and results analysis was supported by RTI International. The survey was closed on April 16, 2021.

There was a total of 1,443 responses to the Evidence Management Survey. Most respondents (51.42%) were from law enforcement agencies with the crime/forensic laboratory (26.96%) agency type being the second most common. Other agency types represented included medical examiner/coroner offices (7.42%), private industry (5.13%), court systems (4.92%), clinic/health care (3.74%), and correctional systems (0.42%).

This presentation will provide a summary of the findings in survey results with special emphasis on respondents from crime labs. An overview of EMSC activities, published reports, upcoming activities will also be discussed.

Evidence Management, Preservation, Storage

E123 A National Perspective of How Unidentified Human Remains Are Handled in the United States Using a 2018 Census of Medical Examiner and Coroner Office Data

Ashley Rodriguez, RTI International, Research Triangle Park, NC; Kelly Keyes, RTI International, Research Triangle Park, NC; Christopher Williams, RTI International, Research Triangle Park, NC; Donia Slack, RTI International, Research Triangle Park, NC; Stirling Cummings, RTI International, Research Triangle Park, NC; Jeri Roper-Miller, PhD, RTI International, Research Triangle Park, NC; Patricia Melton, RTI International, Research Triangle Park, NC*

Learning Overview: This presentation will discuss the findings of the 2018 Bureau of Justice Statistics' (BJS) Census of the Medical Examiner and Coroner Offices (CMECs), specifically focused on policies and procedures related to the handling of Unidentified Human Remains (UHRs) and the impact those policies and procedures have on the extent of UHR cases within the United States. At the end of this presentation, attendees will have a grasp of the most current, systematic information known about the extent of UHRs in the United States, and the resources, policies, and practices MECs use to investigate and track these cases.

Impact Statement: This presentation will impact the forensic community by highlighting the extent of UHR cases in the United States and demonstrating how policies and practices implemented by the MEC community have affected these cases.

In 2019, the United States BJS administered the CMEC, which included questions about how UHR cases were handled in 2018. In addition, agencies provided insights on policies regarding the retention of UHR evidence and reports as well as their use of national databases such as the National Missing and Unidentified Persons System (NamUs), National Crime Information Center (NCIC), and Combined DNA Index System (CODIS) in UHR investigations.¹⁻³ More than 1,600 agencies responded to the census request.

In 2019, RTI International conducted the 2018 CMEC on behalf of BJS (2017-MU-CX-K052). A questionnaire was designed, reviewed by a forensic expert panel, and piloted with select MEC offices. The census was fielded through mail-out, email correspondence and follow-up Computer-Assisted Telephone Interviewing (CATI). The MEC offices provided responses via mail, facsimile, CATI, and a web-based instrument. Questions focusing on the handling of unidentified human remains cases were analyzed and will be discussed. Where appropriate, selected comparisons were made with the 2004 CMEC data.

The results from this study provide insight into the policies and procedures enacted by MECs nationwide to handle UHR cases. Overall, the responding agencies had fewer UHR cases on file at the end of 2018 when compared to UHR cases reported during the 2004 CMEC administration. Key findings indicate most agencies do not have retention policies in place for evidence related to UHRs, and national database resources that have proven to aid in identifications have historically been underutilized by the MEC community.

The implications of the 2018 results will be discussed as they relate to the resolution of UHR cases, which point to needed resources, policy, and practice shifts. Lastly, limitations of the Census will be discussed and suggestions for future studies will be provided.

Unidentified Human Remains, Medical Examiner and Coroner Offices, Evidence Retention Policies

E124 Variation in Laboratory Policies and Procedures Related to Interpretation of DNA Mixtures

R. Austin Hicklin, PhD, Noblis, Reston, VA; Nicole Richetelli, PhD, Noblis, Reston, VA; Mitch Holland, MS, Noblis, Reston, VA; Robert Bever, PhD, Bode, Lorton, VA; Lauren Brinkac, MS, Noblis, Reston, VA; Jonathan Davoren, MS, Bode, Lorton, VA*

Learning Overview: After attending the presentation, attendees will have learned about the variability of policies and procedures between laboratories in analyzing DNA mixtures.

Impact Statement: This presentation will communicate the documented inter-laboratory variability in the policies and procedures to interpret DNA Mixtures.

The purpose of this presentation is to describe the first phase of the ongoing study, *Inter-laboratory Variation in Interpretation of DNA Mixtures* (NIJ Grant 2020-R2-CX-0049). The results of the Policies and Procedures (P&P) Questionnaire and variability in laboratories' standard operating procedures related to DNA mixtures will be presented. The study is being conducted to evaluate the current state of the practice of DNA mixture casework and is not restricted to specific products or statistical approaches.

Since 1995, the mixture interpretation process has been continually improved through numerous research and development efforts. Within the past five years the use of probabilistic genotyping has become common in laboratories as it significantly advances the mixture interpretation process. Almost all inter-laboratory studies reported to date were conducted prior to the widespread adoption of probabilistic genotyping software in crime laboratories. This study evaluates the current state of the practice in interpretation of DNA mixtures utilizing either binary or probabilistic genotyping protocols. The scope is limited to variability in interpretation and analysis of electropherograms; thereby eliminating variability due to laboratory processing of physical samples. The project expands on the results and lessons learned from DNA mixture inter-laboratory studies conducted to date, most notably the National Institute of Standards and Technology (NIST) MIX13 study, and address concerns regarding complex DNA mixtures raised by the President's Council of Advisors on Science and Technology (PCAST) Report on Forensic Science in Criminal Courts in 2016.¹

The study is composed of four phases conducted to assess the sources of variability in analyzing DNA mixtures:

- Policies and Procedures (P&P) Questionnaire—Online questionnaire to assess laboratory policies and procedures relevant to DNA mixture interpretation (notably systems, types of statistics reported, and parameter settings used).
- Casework Scenario Questionnaire—Online questionnaire presenting a number of casework-derived scenarios (without DNA data), asking participants to assess how they would conduct analysis for each scenario.
- Number of Contributors (NoC) Subtest—Assessment of suitability and number of contributors, given electropherogram data for 12 mixtures.
- Interpretation, Comparison, and Statistical Analysis (ICSA) Subtest—Interpretations and statistical analyses, given electropherogram data for eight mixtures, each provided with DNA profiles of potential contributors.

DNA Mixtures, Probabilistic Genotyping, Inter-Laboratory Variation

E125 Toward the Quantitative Evaluation of Pattern Evidence

Alicia Carriquiry, PhD, CSAFE-Iowa State University, Ames, IA*

Learning Overview: After attending this presentation, attendees will have a better understanding of the calculation of the likelihood ratio in pattern comparison disciplines, of the correct interpretation of findings in forensic evaluations, and of the barriers that must be overcome to apply these methods in practice.

Impact Statement: This presentation will discuss strategies to implement quantitative methods in case work and will mention some of the barriers that need to be eliminated. The impact resides on the potential to begin the transfer of knowledge from theory to practice.

In the past several years, forensic scientists offering testimony in court about pattern comparisons have faced challenges from lawyers invoking provisions in *Daubert*, the *Federal Rules of Evidence 702*, and similar provisions. While no judge has excluded pattern comparison testimony until now, the strength of the conclusions that examiners can report has been significantly curtailed in several recent cases involving firearm evidence.^{1,2}

Examiners in the pattern comparison disciplines have been reluctant to adopt quantitative methods to analyze and interpret evidence. This is understandable; applying quantitative methods to data that consist of images is challenging and most of the algorithms that have been developed are not yet “mature” enough or have not been tested sufficiently. Further, there has been spotty communication between the communities of forensic practitioners and of academic researchers, with the result that the exchange of knowledge has not been fluid, and adoption of quantitative methods has been slow.

This presentation addresses some of those challenges and offers suggestions for moving toward implementing quantitative methods in case work. This presentation first introduces the likelihood ratio approach using everyday language and intuitive ideas. Using various comparison disciplines as illustration, the discussion will then focus on *implementation* issues: What measurements can be obtained from pattern evidence? How can those measurements be used to calculate a likelihood ratio? How are the results interpreted correctly? To address those and other related questions, presenters will go over calculations using actual data obtained from bullet comparison studies and—time permitting—from footwear examination studies. In addition, the presentation will also discuss what is known thus far about the accuracy of the bullet comparison algorithm developed by Center for Statistics and Applications in Forensic Evidence (CSAFE) researchers as well as some of its limitations.³ Even though the algorithm appears to be accurate (albeit after insufficient testing), there are barriers that must be sorted before it can be applied in practice. These barriers, and how to overcome them, will be discussed.

The transition from subjective evidence evaluations and categorical conclusions to data-reliant, probabilistic conclusions is likely inevitable, but the new quantitative era will not be ushered in until communication and meaningful collaboration between practitioners and researchers become more fluid and fruitful. Recent black-box studies conducted in several disciplines have resulted in low estimated error rates, which may suggest to some that perhaps the current subjective approaches to evaluate pattern evidence will no longer be questioned. Rather, a worthy goal may be to combine the best of both approaches to optimize the performance of examiners. This presentation will propose strategies to pursue that goal.

Quantitative Methods, Pattern Comparison Disciplines, Implementation and Barriers

E126 Border Police Officers Versus Automatic Border Control Systems

Andrijana Filko, Croatian Forensic Science Centre i.Vucetic, Zagreb, Croatia*

Learning Overview: After attending this presentation, attendees will have a better understanding of the problematic of Automated Border Control Systems. Through the several possible scenario at the border crossing points that has been shown in this research, attendees will be learning how human factors impact on border control in general as well as how the use of Automated Border Control Systems may become a risk, reducing instead of increasing border security.

Impact Statement: This presentation will impact the forensic science community by raising awareness that Automated Border Control Systems alone are not sufficient to identify the impostors or look-alikes, especially regarding the facts that the most dangerous ID fraud involves impostors capable of fooling even the most advanced of today's facial recognition systems.

Look-alike fraud is one of the most common phenomena of fraud by abusing someone else's identity, whereby the holder of the document physically resembles the owner of the document. The main goal of this research was to indicate the advantages and disadvantages of Automated Border Control Systems in the light of misuse and/or forgery of (ID and) travel documents, as well as to point out new modalities of forgery (*modus operandi*). Nowadays, (ID and) travel document fraud is an important and growing problem connected with different forms of cross-border criminal behavior such as illegal immigration (including human trafficking), drug trafficking, money laundering, firearms smuggling, and terrorism. Border police officers almost daily encounter persons possessing two or more original travel documents of different issuing states and different names of the document holders. According to unofficial estimates, thousands of people with double or multiple identities cross the international borders daily by using authentic documents based on fraudulent identity.

The importance of this research is the awareness of an indisputable fact that the nature of (ID and) travel document fraud is evolving rapidly, involving new *modus operandi* and new forms of forgery to circumvent biometric checks. Based on a number of examples from this research as well from FRONTEX (the European Border and Coast Guard Agency) research, it is possible to conclude that the best way to prevent (ID and) travel document fraud is a technical and tactical approach (document check versus profiling) developed in tight cooperation with forensic document experts, who can provide any additional training on demand.

The main result of this research has shown that based on profiling and knowledge of *modus operandi*, it is possible to detect high-quality forged documents that are impossible to be detected by an automated verification device. Consequently, the main conclusion of this research is that it is necessary to continuously invest in the professional knowledge, skills, and competencies of border police officers, who will then, with the use of appropriate equipment and aids, successfully detect forged documents and impostors.

Document Fraud, Impostors, Automated Border Control Systems

E127 New Jersey's Drug Monitoring Initiative: Developing Forensic Intelligence to Identify Drug Trends, Support Law Enforcement Investigations, and Share Information With Laboratory and Public Health Partners

Adam Polhemus, BA, New Jersey State Police Drug Monitoring Initiative, West Trenton, NJ; Jason Piotrowski, BS, New Jersey State Police Drug Monitoring Initiative, West Trenton, NJ*

Learning Overview: After attending this presentation, attendees will be able to: (1) outline the need for building a Drug Monitoring Initiative (DMI) capability, based on forensic laboratory data and other key public safety and public health data sets, to identify drug trends and inform all relevant partners; (2) identify how the DMI utilizes forensic intelligence to support law enforcement investigations, interrupt the drug supply, and reduce community drug harms; and (3) recognize how monitoring and sharing forensic laboratory data allows forensic scientists and toxicologists awareness of new illegal substances and unique drug forms, contents, packaging, and emerging drug trends.

Impact Statement: New Jersey's DMI, the leading drug environment monitoring concept, enhances public safety and public health through an in-depth knowledge base that provides real-time awareness of drugs impacting New Jersey. Working intimately with statewide forensic laboratory data and integrating other key public safety and health data sets, the DMI compiles a robust collection of drug-related information. Leveraging current technologies, processes, and analytical capabilities allows for analysis and the DMI to develop forensic intelligence. This intelligence leads to: identification of emerging drugs and poly-drug adulteration; supporting law enforcement investigations and identifying connected drug cases; producing significant analytical products; informing nationwide forensic laboratory partners; and providing awareness to multiple community drug harm and multi-sector outreach initiatives.

DMI collects law enforcement narcotic seizures and overdose drug evidence information submitted to and analyzed by New Jersey laboratories. DMI analysts track spikes in overdoses, create a temporal analysis of where spikes are occurring while identifying the dangerous substances involved. In addition to the significant historical laboratory data DMI holds, New Jersey forensic laboratories will expedite analysis to confirm the substance's contents. DMI distributes intelligence products that identify these deadly brands and locations to transition narcotic operations to locate and dismantle the illicit activity and consumption of deadly substances.

Additional production of real-time drug-related alerts, warnings, and intelligence products are derived by continuously monitoring laboratory data and sharing forensic intelligence to multi-sector partners pertaining to the state's drug environment, thus enabling not only situational awareness of drugs analyzed, but pro-active deployment of investigative, prevention, and treatment resources to at-risk areas, populations, and individuals.

Recognized by the National Governor's Association, Office of National Drug Control Policy, and National High Intensity Drug Trafficking Area (HIDTA) as a nationwide best practice, the DMI initiative establishes an intelligence capacity allowing law enforcement and public health experts to better understand trends, implications, and threats from illicit drug activity having an impact within their jurisdictions. The DMI partnership represents good government, as disparate agencies are sharing information and collaborating to fight the illicit drug epidemic that New Jersey and other states in the region are facing. The combination of law enforcement data and forensic laboratories analysis with health care data has proven to be an effective tool to better understand the state's drug environment at micro and macro levels. The core data elements that provide a timely picture of the drug environment are those derived from drug seizures and drug overdoses. Access to these data sets in real-time enables understanding of the drug environment for emergent and strategic purposes. These data sets provide the DMI partners with the ability to be informed regarding overdose incidents, enabling them to better prepare for, respond to, and prevent overdose incidents in their jurisdictions. These data sets allow the DMI to provide the scientific community drug environment information related to new illegal substances; drug packaging, forms and trends; and presumptive and confirmatory analysis encountered in the field or laboratory. Long term, these data sets have enabled DMI partners to better understand the prevalence and patterns of substance abuse to develop effective substance abuse prevention strategies.

Intelligence, Investigations, Sharing

E128 How Educators in the American Academy of Forensic Sciences (AAFS) Have Met and Surpassed the Challenges of Providing Forensic Science Education During COVID-19 to Produce Improved Education and Training for the Modern Forensic Science World

Stewart Walker, PhD, Flinders University, Adelaide, South Australia, Australia*

Learning Overview: Attendees will consider examples of better practice in forensic science education and training arising from changes required during COVID-19 conditions and compare them with their own experiences.

Impact Statement: The forensic science (education and training) community will benefit from discussions of potential ways in which they can improve the delivery, assessment, and impact of forensic science methods during a pandemic. This will encourage discussion and dissemination of other examples of alterations that will benefit the community.

During the COVID-19 pandemic, universities, and other teaching and training establishments have had to quickly respond to the challenges of delivering and assessing forensic science education. This presentation will outline some of the processes that have been implemented and how these have led to improvements in forensic science education that meet and surpass the challenges of teaching forensic science in the modern world. It is anticipated that when things go back to “normal,” forensic science education will incorporate some of the modern approaches with the best of the traditional approaches to produce a product that is better than it was pre-COVID-19.

During forced lock-downs and isolation, forensic science, like other education areas, has had to quickly adapt to delivery by remote means rather than traditional face-to-face methods. This requires consideration of new ways of material delivery, hands-on practical experiences, and assessment.

Material Delivery: It is relatively easy to deliver old-fashioned 50-minute lectures with PowerPoint® slides via a number of different programs for uploading and disseminating content. However, to just record a talking-head with slides is underutilizing the potential for these programs and is not using the new technology to its best advantage. Splitting the material up into smaller “bites” was necessary to prevent files from being too large, but this had the advantage in that material could be more aligned with attention spans. Also, the ability to incorporate movies and illustrations helped to break up the material. Platforms that enabled communication between lecturer and students also could be used to change the presentation from being a monologue to being a dialogue—or even a polylogue. Setting tasks for students to find some information or cases and report back had the double advantage of expanding the material from what the lecturer taught to bring in other material and also got the students engaged, active (rather than passive,) and gave them some ownership of the material.

Hands-On Practical Experiences: Forensic science, in common with other disciplines, requires hands-on activities to reinforce concepts and effectively train future practitioners. Recording a technician doing the practical and then supplying data for processing may be the only option available but is not sufficient to “train” the students in a hands-on way. Due to restrictions in numbers and spacing, practical’s have been redesigned to still provide a learning experience without the need for four students to sit around one piece of apparatus for three hours. Concentrating on the preparation and analysis of evidence by individual students rather than working in pairs to fours has improved the learning experience for all students.

Assessment: The necessity to have assessment done remotely and delivered through computers, rather than in exam rooms, has required the re-assessment of how assessment is carried out and what is being assessed. Exam questions now need to be “search-engine-proof” to prevent the answers being searched and regurgitated from the Web. This has meant that assessment can require the student to think more and assess and structure answers to real problems, which may be a better and more realistic way of assessing the student’s ability to work on real problems in a realistic way in the workforce.

It is anticipated that when (or if) conditions return to “normal,” the advantages of some of these new approaches to delivery and assessment will be retained and mixed with the best of old practices to produce forensic science education that is actually better than it was before the pandemic. In this way the educators in the Academy will have met and surpassed the challenges of providing forensic science education in the modern forensic science world.

Education, COVID-19, Improved

E129 Integrating Cold Case Investigations in Forensic Science Education: Student Engagement in Research, Information Literacy, and Data Visualization

Krystal Hans, PhD, Purdue University, West Lafayette, IN; Rachael Rosselet, MPhil, Walden University, Minneapolis, MN*

Learning Overview: After attending this presentation, attendees will understand the importance of cold case investigations and the incorporation of forensic science educational strategies in these investigations.

Impact Statement: The information in this presentation will impact the forensic science community by presenting a forensic science educational tool and a developing database of cold case information that incorporates the work of students, forensic scientists, law enforcement, and citizen detectives.

In a collaboration between Uncovered and Purdue University, students in forensic science courses are completing projects on cold case investigations to participate in research, critical thinking assignments, and information evaluation.¹ The concepts of research, information literacy, and data visualization are highlighted in the student projects, and students learn about the ethical concepts of digital detective work, the value of collective impact, and the importance of inclusive victimology. Students are assigned a cold case, watch videos and hear lectures from Uncovered, and participate in group research to develop a comprehensive overview of the people, timeline, locations, sources, tips, and theories related to the case and the investigation. Students participate in group and class discussions, complete assignments, and reflection surveys throughout the semester. The culminating deliverable is the production of a detailed case spreadsheet, as well as an infographic to display all pertinent information about the cold case and investigation. Data on student learning, thematic analysis of information sources, and student experience will be collected from reflection surveys and interviews.

Uncovered, a Public Benefit Corporation, is a new and innovative software platform that combines data, analytics, and the “wisdom of the community” to help solve the cold cases of murdered or missing people. Uncovered is developing a comprehensive nationwide database of unsolved missing and murdered cases. All information is assembled into a Digital Case File that contains a visualized timeline of events overlaid onto a map of locations, a catalog of the people involved, and an extensive reference list. Finally, each case contains clear and direct calls to action on how the public can help the victim.

Using the Graph Theory and the open-source Neo4j platform, Uncovered is building an analytics and data model that focuses intently on Persons, Objects, Locations, and Events.² This will allow for unstructured discovery of its data, letting users make connections that were not visualized previously. Uncovered has also curated an engaged community of citizen solvers and digital volunteers to crowdsource the gaps in unsolved cases. Members are provided research tools and resources, training, and access to experts and others with a shared passion to solve a mystery.

The goal of this research is to develop a sustainable framework of student and community involvement that can be transferred to other universities with forensic science and criminal justice programs. This research and collaboration provide opportunities for new avenues in forensic science education, preparing students professionally with the incorporation of real-world experience and engagement with the greater law enforcement and forensic science community. Additionally, this also provides a real-world application for students to see the impact of their work directly.

E130 Examples and Lessons Learned From Virtual Reality Simulation Inclusion in Forensic Humanitarian Training

Ivett Kovari, PhD, ICRC, Geneva, Switzerland; Sherry Fox, PhD, ICRC, Geneva, Switzerland; Pierre Guyomarc'h, PhD, ICRC, Geneva, Switzerland; Melissa Kiehl, ICRC, Geneva, Switzerland; Christian Rouffaer, ICRC, Geneva, Switzerland; Xuan Wei, ICRC, Geneva, Switzerland; Kristy Winter, ICRC, Geneva, Switzerland*

Did Not Present.

E131 Mental Health and Resilience Education for Forensic Science Students

Karen Woodall, PhD, University of Toronto, Toronto, Ontario, Canada; Grace Gregory-Alcock, BSc, University of Toronto, Toronto, Ontario, Canada*

Learning Overview: After attending this presentation, attendees will understand the importance of introducing the topics of stress, resiliency, and Post-Traumatic Stress Disorder (PTSD) into the forensic science curriculum at the undergraduate level to help prepare the next generation of forensic science professionals.

Impact Statement: This presentation will provide the forensic science community with information on how to implement the topic of mental health issues into forensic science courses or training programs.

Recent research has shown the incidence of PTSD and mental health issues in the forensic community is significant and is likely to increase if it remains unaddressed.^{1,2} People working in forensics often deal with unique stressors; they are exposed to traumatic material from forensic cases and often work within an adversarial legal system. Current research is beginning to address this issue and, consequently, the importance and urgent need for resiliency training for individuals working in forensic science and related fields is becoming recognized. In addition to forensic science professionals, it would be beneficial for students contemplating a career in forensics to be aware of the various types of traumas, stresses, and the potential impacts that they may have during their career. Increasing the awareness of the various types of traumas that forensic professionals routinely encounter, and reducing the stigma associated with discussing mental health is an important step in preparing the future employees in forensic and law enforcement community.

The University of Toronto, Mississauga, offers an undergraduate degree program in Forensic Science with the opportunity to specialize in Anthropology, Biology, Chemistry, and Psychology with many graduates pursuing careers in law enforcement and forensic laboratories. A recent addition to the core curriculum was implemented to provide education about mental health, resiliency, and useful strategies to mitigate and reduce the impacts of stress. Students learned about vicarious trauma, PTSD, and how they relate to forensic professions, and the effects that exposure to trauma and stress can have on personal and professional performance. In addition to learning about mental health and resiliency, students had the opportunity to hear experiences directly from professionals who have first-hand experience working within the forensic community.

Educating the next generation of forensic scientists, beginning at the undergraduate level, will help meet the health and wellness needs of employees, avoid burnout, reduce decreased work performance, and help create a positive work environment.

Education, Resiliency, Curriculum

E132 Understanding Foundational Ethical Content Necessary for Educating Future Forensic Scientists

Sarah McKendrick, BA, Duquesne University, Pittsburgh, PA; Lyndsie Ferrara, PhD, Duquesne University, Pittsburgh, PA; Pamela Marshall, PhD, Duquesne University, Pittsburgh, PA; Sara Bitner, MS, Allegheny County Office of the Medical Examiner, Pittsburgh, PA; James Schreiber, PhD, Duquesne University, Pittsburgh, PA*

Learning Overview: After attending this presentation, attendees will understand the foundational ethical content described by active practitioners and educators as being necessary for educating future forensic scientists.

Impact Statement: This presentation will influence the forensic science community by highlighting the importance of ethics training and ethics education based on experiences from current practitioners and educators.

Generally, many people consider themselves to have a proficient understanding of ethics to work in their specific disciplines. Though this may be true sometimes, employers have reported a deficiency of ethics education in the workplace. Along with this deficiency, it has been noted that many people confuse ethics with morals. Given the requirement for ethics education by the Forensic Science Education Programs Accreditation Commission (FEPAC), the importance of ethics in forensic science can be observed. A lack of well-structured ethics courses steered toward forensic science calls for research to be conducted to investigate what should be included in such a course. The work completed focused on gathering information pertaining to ethical content that should be included in a foundational undergraduate ethics course directed toward forensic science majors. This work was completed in tandem with research being conducted to create course content for ethics education in forensic science.

This two-part study collected data from active forensic science practitioners and ethics educators. During Part One, interviews were conducted with a variety of ethics educators from a number of disciplines, including forensic science, theology, philosophy, business, and bioethics. Ethics educators who participated in an interview gave directions pertaining to which philosophers and philosophical ideas should be included in course content for ethics education in forensic science.

Results from interviews conducted with ethics educators indicated that philosophical ideas by Immanuel Kant, Aristotle, and David Hume should be included in course content aimed toward forensic science students. Additionally, it was determined that ethics is best taught through case studies and student engagement with course material.

Part Two included surveys and interviews completed by forensic scientists who were asked questions pertaining to experiences in the workplace and their understanding of ethics. Recruitment was conducted by an email sent to the American Academy of Forensic Sciences members of the Criminalistics section. Participants were invited to complete a survey through Qualtrics or an interview via Zoom. Questions asked pertained to the practitioner's experience related to ethics training, encountering unethical behavior in the workplace, and personal thoughts on the type of content necessary to educate future forensic practitioners. Those who participated in interviews were asked an additional question based on response from the survey.

Results from the survey indicate that 35% of participating practitioners have never encountered an ethical dilemma in the workplace. Moreover, it was observed that some practitioners do not believe that an improvement in ethics education would affect the ethical practices of future practitioners. Though many ethical dilemmas were mentioned through the survey, an overwhelming amount included attempted collusion by lawyers and prosecutors. Other dilemmas encountered included malpractice by laboratory management and co-workers. Over 85% of survey participants believe improved ethics education is important for future practitioners. Future direction of this research includes using the data to create ethics content for upcoming forensic scientists.

Ethics, Education, Behavior

E133 Bias—It's Not Just in Your Numbers: The Importance of Teaching Unconscious Bias in Forensic Education

Charla Skinner Perdue, MS, MFS, Florida State University, Panama City, FL*

Learning Overview: The goal of this presentation is to provide forensic science educators and practitioners who train with the ability to identify their own implicit biases and develop tools to educate others to recognize everyone has unconscious biases. This presentation will provide attendees with strategies to keep bias from impacting decision making. Attendees will be encouraged to acknowledge steps in the forensic process that can be problematic and be inspired to rethink practices that may be negatively affected by human performance.

Impact Statement: This presentation will impact the forensic science community by highlighting the role of the one analyzing or interpreting evidence and the benefits of developing well thought-out evidentiary procedures that mitigate the potential for implicit bias in the form of analysis subjectivity that impacts decision making in forensic science. The goal is for those in attendance to understand how the legitimacy of the criminal justice system requires unbiased judgement and their role in achieving it.

Neuroscientists have determined the brain uses bias to help humans quickly categorize information. Our brains will use old information we have learned, experiences we have had, past relationships, and all the other data we have on a subject and relate the past to new material received. It is a necessary function, and these created biases are not all bad. The problem is when these biases impact our decision making.

In forensic science, great strides have been made to mitigate bias from the scientific method. Despite the recent attention given to implicit bias and its unintentionality, most people still do not see themselves as biased. Many times, in forensic science, failure is caused by human performance, not process. The bias expressed in the subjectivity, discretion, and judgement of the expert in the form of interpretation partiality is where unconscious bias can impact decision making, and the area forensic science needs to continue to improve. The ability to accept bias in the procedure and not the decision maker is where good forensic education and training should begin.

Concentrating on the role of the one interpreting evidence and the benefits of developing well thought-out evidentiary procedures that mitigate the potential for implicit bias by the one performing the interpretation or analysis of the evidence will enhance outcomes and improve the role it performs in the criminal justice system. Focusing on the neuroscience and social-psychology research on implicit biases and how decision making in criminal justice-related work based on these biases can be dangerous, unproductive, and unjust should begin in the forensic science classroom and reinforced during training and professional development. The legitimacy of the criminal justice system requires unbiased judgement and is necessary to earn the trust of the communities served.

Unconscious Bias, Forensic Education, Professional Training and Development

E134 Facing the Field: An Innovative Virtual Reality Training for Recoveries in Weapon-Contaminated Environments

A. Skylar Joseph, MS, International Committee of the Red Cross, Geneva, Switzerland; Xuan Wei, MA, International Committee of the Red Cross, Geneva, Switzerland; Ryan Yates, BSc, International Committee of the Red Cross, Geneva, Switzerland; Daniel Perkins, MEng, Remeody Plan Spatial Limited, Truro, England, United Kingdom; Pierre Guyomarch, PhD, International Committee of the Red Cross, Geneva, Switzerland*

Learning Overview: After attending this presentation, attendees will have gained awareness of the benefits that Virtual Reality (VR) training scenarios can have in forensic contexts, with particular attention toward learning to work in weapon-contaminated environments.

Impact Statement: This presentation will impact the forensic science community by highlighting the need for more collaborative training approaches to tackle complex real-world situations and the benefits that Virtual Reality (VR) trainings can bring toward achieving this goal.

In recent decades, forensic expertise has become increasingly recognized as an important part of the humanitarian response to mass fatality events. When forensic expertise is needed in the aftermath of a conflict, forensic specialists and first responders will often be required to perform their work in environments that contain explosive hazards. In these situations, while maintaining dignified treatment for the dead is still a priority, the safety of the staff involved is paramount and humanitarian operations should only take place if staff are aware of the risks and know how to operate safely in a weapon-contaminated environment.

Forensic specialists, mine action staff, structural engineers, and/or emergency first responders may each need to be involved in the recovery of deceased individuals from weapon-contaminated environments. Proper training that promotes the collaboration between these different disciplines is thus necessary in order to ensure a safe, efficient, and respectful recovery. Standard training methods often require significant time and resources to organize, and it is often difficult or impossible to replicate the actual working environmental conditions one could experience. However, with the advent of VR, one can become completely immersed in realistic training scenarios.

VR simulations provide the participants with the unique experience of feeling like they are fully inhabiting and interacting with a real-world context through the creation of fully immersive 3D computer-generated environments. Due to their immersive effect, these scenarios help to not only build the cognitive and practical skills necessary for the role, but also aid in psychologically preparing the practitioner for the types of situations they may find themselves in when working in the field. Furthermore, these VR simulations aid in the standardization process for the administration of these types of trainings, acting as a beneficial supplement to courses and sensitization programs developed for varied backgrounds and levels of expertise.

The International Committee of the Red Cross (ICRC) Forensic Unit in collaboration with the Virtual Reality Unit and other units at the ICRC, including the Weapons Contaminated Unit, have been developing multiple VR training scenarios related to the proper management of the dead, including material focused on recoveries from weapon-contaminated environments. Through an overview of this scenario, its predicted benefits to the trainees, how it will promote a more collaborative working environment, and a discussion on the types of knowledge that are the most suitable to VR simulations, this presentation will seek to raise awareness of the potential benefits that VR training can have on the greater forensic community.

Management of the Dead, Humanitarian Forensic Action, Virtual Reality Training Simulations

F1 Post-Conviction DNA Testing: Annual Summary of a Law School and University Collaboration to Identify and Evaluate Post-Conviction Cases

Katherine A. Roberts, PhD, School of Criminal Justice and Criminalistics, California State University, Los Angeles, Los Angeles, CA and California Forensic Science Institute, Los Angeles, CA; Paula M. Mitchell, JD, Loyola Law School, Los Angeles, CA; Nikki Herst-Cook, JD, Loyola Law School, Los Angeles, CA; Paige McGrail, JD, Loyola Law School, Los Angeles, CA; Mehul Anjaria, MS, MBA DNA Consulting, LLC, Angeles, CA*

Learning Overview: After attending this presentation, attendees will understand the California Forensic Science Institute-Loyola Project for the Innocent (CFSI-LPI) case review model, emphasizing case prioritization, filing and arguing motions requesting DNA testing, and strategic approaches to case resolution.

Impact Statement: This presentation will impact the forensic science community by providing attendees with a law school-university collaboration model to tackle the logistical challenges related to post-conviction DNA testing.

The CFSI within the School of Criminal Justice and Criminalistics at California State University, Los Angeles, established a partnership with Loyola Law School's LPI in 2019 to review cases and locate and test evidence related to violent felony offenses where actual innocence might be demonstrated. The CFSI-LPI team was awarded Department of Justice (Bureau of Justice Assistance) funding under the 2020 Postconviction Testing of DNA Evidence solicitation to provide critical assistance to individuals convicted of a serious felony that meets specific criteria. Collectively, the CFSI-LPI team reviews violent felony cases to locate biological evidence for submission to a forensic laboratory for DNA testing to demonstrate their innocence or assist in their exoneration.

This presentation provides a one-year overview of the CFSI-LPI case review model, emphasizing identifying and evaluating cases that meet the criteria under CA Penal Code §1405 for post-conviction DNA testing. This summary will include the number of DNA cases reviewed and investigated; the crimes for which clients were convicted, including those that have a sexual assault component and/or resulted in the death of the victim(s); and the number of evidence searches conducted, specifying the cases where evidence was located vs. destroyed or missing. Further, this summary will disclose the number of items submitted for Short Tandem Repeat (STR), Y-chromosomal Short Tandem Repeat (Y-STR), mitochondrial DNA (mtDNA) analysis, and whether a viable profile was obtained in addition to the probative value of the DNA profile (supporting vs. refuting the post-conviction claim or inconclusive). Also specified will be the number of DNA profiles uploaded to the Combined DNA Index System (CODIS) vs. the number of CODIS hits. This presentation will conclude by describing obstacles to the project objectives during the 2020–2021 award period and demonstrate how the CFSI-LPI model provides forensic science graduate students an opportunity to participate in a service-learning social justice project.

Post-Conviction DNA Testing , Law School-University Collaboration , Service-Learning Social Justice Program

F2 *Qui Custodiet Ipsos Custodes?* (Who Guards the Guards?) Obligations and Rights of Parents and Children

Benedetta Pia De Luca, MD, Aldo Moro University, Bari, Italy; Mariela Marrone, Aldo Moro University, Bari, Italy; Nicola Laforgia, MD, Aldo Moro University, Bari, Italy; Alessandra Stellacci, MD, Aldo Moro University, Bari, Italy; Luigi Buongiorno, MD, Aldo Moro University, Bari, Italy; Francesco Vinci, MD, Aldo Moro University, Bari, Italy*

Learning Overview: To combat vaccination hesitation and encourage the acceptance of vaccination by minors, it is necessary to intervene by any means to disseminate and make available information through different communication tools on social networks and in schools.

Impact Statement: Adequate information is essential to ensure a reasoned choice. In fact, it is essential to provide the child with all the cognitive tools for joining the vaccination campaign, in the interest not only of their health, but of the health of those close to them and, more generally, of public health.

The World Health Organization has designated vaccination hesitation as one of the top ten threats to global health.

The vaccination campaigns against Sars-CoV-2 initially concerned the adult population, with different priorities concerning age. Following the authorization of the main agencies, including the European Medicines Agency (EMA), to combat the spread of the infection in younger people and to reduce the circulation of the virus, the Vaccination Plan also involved the population aged 12-18.¹

Unfortunately, the activity of anti-vaccine movements (no-vax), also supported by the circulation of “fake news” in social networks, has created problems relating to the vaccination of minors placed in family contexts in which one and both parents are “no vax.”²

Currently, a legally authorized representative (usually a parent or guardian) must give permission (also called consent) for vaccination for someone 1217 years of age, such as by completing a written consent form that the minor (the person under the age of 18) can bring to their vaccination appointment.

In the absence of a specific law, the National Bioethics Committee unanimously, on July 29, 2021, expressed its opinion that minors between the ages of 12 and 17 may, independently, decide whether or not to undergo vaccination, regardless of the wishes of the parents and/or guardian. This intervention of the Bioethics Committee, although it has no legal value, is authoritatively part of the debate on the administration of vaccines to minors.

In the evaluation of the child’s “best interest,” it should be considered that the refusal of vaccination by the parent or guardian, in addition to the inevitable increase in the circulation of the virus, risks creating a social distance, because the parent is led to keep the child in the house to avoid social contact, as a source of possible contagion.^{3,4}

The reduction of social contacts, particularly at very sensitive ages such as adolescence, has been correlated with the increase in the incidence of psychiatric diseases, a further reason to believe that the need to extend vaccination against SARS-Cov-2 must provide for public accountability.⁵

Lawmakers could enact laws that allow the child to decide on the vaccination plan, even without the consent of the parent or guardian, without the need to having to resort to the advice of the judge protect.

Adequate information is necessary to combat cases in which there is a willingness on the part of the parent or legal guardian to have the child vaccinated, but the child is opposed. The expression of the will of the child, following what is expressed by the National Bioethics Committee, cannot be accepted only in cases of consent to vaccination.

In conclusion, to combat vaccination hesitation and encourage the acceptance of vaccination by minors, it is necessary to intervene by any means to disseminate and make available information, through different communication tools, on social networks, and in schools.

For this reason, it is essential to provide the child with all the cognitive tools for joining the vaccination campaign, in the interest not only of his health, but of the health of those close to him and, more generally, of public health.

F3 Mandatory Vaccination for COVID-19? The Italian Case: Prevention Obligations and Ethical Profiles

Alberto Marchese, PhD, Department of Political Science and Law, University of Messina, Messina, Italy; Cristina Mondello, MD, PhD, Department BIOMORF, University of Messina, Messina, Italy; Luigi Cardia, MD, Clinical and Experimental Medicine Department, University of Messina, Messina, Italy; Elvira Ventura Spagnolo, MD, PhD, Department PROMISE, University of Palermo, Palermo, Italy; Aurora Vesto, PhD, University Dante Alighieri of Reggio Calabria, Reggio Calabria, Italy*

Learning Overview: After attending this presentation, attendees will understand the importance of improving knowledge about mandatory vaccinations, including for the COVID-19 pandemic.

Impact Statement: This presentation will impact the forensic scientific community by highlighting the importance of the topic of vaccinations. The focus on this topic has increased exponentially since the first vaccines for the COVID-19 epidemic were produced.

To be effective in eliminating communicable diseases, vaccines must be given to a sufficient number of people in the community.

Due to the success and mandatory nature of vaccinations, most people would probably not consider vaccination an optional method of medical treatment. Since the smallpox vaccine was introduced, vaccination has had its critics. In the two centuries since then, many different kinds of objections have been raised, with some questioning the scientific qualifications of mass immunization. Others have focused on the interests of personal freedom at stake and objected to the paternalistic nature of the government's imposition of what is considered a personal medical choice. Still others opposed the vaccination for personal or religious reasons.

Italy is the first nation to have imposed the obligation to vaccinate against COVID-19. The rule as it is currently limited in its operation to the deadline of December 31, 2021, and limited to a specific sector of work, health, determines important repercussions on the employment relationship for those who do not intend to accept the vaccination obligation.

With Art. 4 of the D.L. April 1, 2021, n. 44 (Urgent measures for the containment of the COVID-19 epidemic, in the matter of anti-SARS-CoV-2 vaccinations, justice and public competitions), in fact, the Government has introduced the "anti-COVID" vaccination obligation for health personnel, in order to protect public health and maintain adequate safety conditions in the provision of care and assistance services. The compulsory vaccination has also been foreseen through forms of indirect coercion, such as the reduction of the salary for those who do not want to be vaccinated and carrying out certain activities (e.g., teachers in public schools). In this context, the legislation on the so-called "green pass," even if justified for reasons of collective health, seems to be in contrast with the provisions of the Constitution of the Italian Republic, which provides for compulsory health care only in the cases provided for by law. The Privacy Guarantor intervened on this point and with provision of May 13, 2021, n. 198, Guidance document—Vaccination in the workplace: general indications for the processing of personal data (Privacy Code—EU Regulation 2016/679).

The aforementioned legislation must be systematically interpreted with the National Strategic Vaccine Plan for the prevention of SARS-CoV-2 infections approved by Decree March 12, 2021, in which Article 1 provides that: "pursuant to art. 1, paragraph 457 of the law of 30 December 2020, n. 178, the National Strategic Vaccine Plan for the prevention of SARS-CoV-2 infections was adopted, consisting of the document 'Elements of preparation of the vaccination strategy,' referred to in the decree of the Minister of Health January 2, 2021."

Paragraph 8 of Legislative Decree no. 44/2021 states that "the employer assigns the worker, where possible, to tasks, even lower, different [...], with the treatment corresponding to the tasks performed, and which, in any case, do not involve risks of spreading the infection. When the assignment to different duties is not possible, for the period of suspension [...], the salary, emolument, however called 'is not due.'" The legal precept, in addition to the issues of legitimacy and constitutionality, creates a macroscopic disparity of consequences among health sector operators.

Mandatory Vaccination, COVID-19 Pandemic, Mass Immunization

F4 Standards Development Activities in Forensic Science: Legal Impacts Moving Forward

Christopher Plourd, JD, Superior Court, El Centro, CA*

Learning Overview: After attending this presentation, attendees will have a better understanding of the status of discipline-specific standards within the forensic sciences.

Impact Statement: This presentation will impact the forensic science community by increasing awareness of standards development and their legal impact. It will also increase awareness regarding training, tools, and resources that support implementation, compliance monitoring, and broader understanding.

The Organization of Scientific Area Committees (OSAC) for Forensic Science was created to strengthen the nation's use of forensic science by promoting the use of discipline-specific forensic science standards. To this end, the OSAC drafts standards that are forwarded to Standards Developing Organizations (SDOs) that further develop and publish them. The OSAC also reviews standards and recognizes them on the OSAC Registry, which serves as a central repository of high-quality, consensus-based, technically sound standards.

The legal system—criminal, civil, and administrative—must resolve controversies. Forensic science has long been at the forefront in answering complicated questions brought before the bar of justice. Forensic scientific standards, simply stated, enhance the value and usefulness of forensic science to the legal community. A good forensic science standard not only helps assure high-quality results in the laboratory, but also shows how work performed in accordance with the standard that is both well-grounded in theory and data and that it is presented within the boundaries of “the knowledge and experience of [the expert’s] discipline.” (*Kumho Tire Co. v. Carmichael*, 526 U.S. 137, 148 [1999] [quoting *Daubert v. Merrell Dow Pharms, Inc.*, 509 U.S. 579, 592 [1993]]). Standards address four principal features that are important to the legal systems utility of a given Standard: (1) standards are written as clearly as possible, and without undefined technical terms and symbols, to enable lawyers and judges to grasp the main ideas and requirements; (2) standards describe in detail how the peer-reviewed and readily available scientific literature establishes the validity of the assumptions underlying the scientific tests and the interpretation of test results, (3) standards list the limitations of the tests and results and provide for expressions of the uncertainties in measurements and inferences drawn from them; and (4) standards include recommendations or requirements for the creation and retention of documentation of the test and the contents of reports, including the scientific limitations of the tests and related conclusions or inferences.

Forensic scientific standards developed by practitioners working with other stakeholders address all the questions being asked by courts. Courts are concerned with both technical merit and legal importance. Courts are not able to assess the scientific merit of a standard on their own. Therefore, having a process that reviews whether a Standard makes a case for the validity of the method and legal utility of the kinds of expert opinions that a standard contemplates is invaluable to the decision-making truth seeking function of the court.

During this presentation, updates related to standards development in forensic science will be presented and their legal impact will be discussed. Strategies for implementation and acceptance within the legal community will be addressed. Opportunities for supplemental training related to discipline-specific standards will be presented, as well as additional resources and tools designed to facilitate gap analysis, compliance monitoring, and outreach efforts.

Forensic Science, Standards, Legal

F5 Strengthening Forensic Science Through Independent Verification and Validation: The Path Forward

Marc Canellas, JD, PhD, Office of the Public Defender for Arlington County & the City of Falls Church, Arlington, VA and IEEE-USA AI Policy Committee, Washington, DC*

Learning Overview: Attendees will learn about the meaning, processes, and value of Independent Verification and Validation (IV&V) for the safety and security of our technological society and how forensic science must adopt it to ensure the evidence they generate is reliable and ensure confidence in their evidence.¹

Impact Statement: Modern technology is impeding the ability of the forensic science community to continue its pursuit of justice through truth and evidence. These technologies like probabilistic DNA software or acoustic gunshot detection are complicated and prone to failure and manipulation in new and novel ways.^{2,3} When they fail, innocent people are punished and accused persons are never brought to justice. When they fail, society loses confidence in the legal system and the forensic science community. This presentation will show that adopting the principles of IV&V is the best path forward for the forensic science community to ensure the evidence they generate is reliable and ensure confidence in their evidence.

“Is this the right product to correctly build for its intended use?” That is the fundamental question of IV&V, a foundational process to ensure the safety and security of our technological society from the Department of Defense’s nuclear weapons systems, the Nuclear Regulatory Commission’s regulations of nuclear power plants, to the National Aeronautics and Space Administration’s (NASA’s) manned space systems, and the Food and Drug Administration’s (FDA’s) regulation of medical systems. The Institute of Electrical and Electronics Engineers (IEEE) Standard 1012 is the world’s gold standard of IV&V and developed by IEEE Standards Association, a world-leading standards-setting organization.⁴ IEEE 1012 codifies the requirements for independent technical, managerial, and financial verification and validation for any system likely to cause major injury, loss of safety or security, and to ensure reliability of some of the most complex and safety-critical systems in the world, including at the Department of Defense and NASA.

Despite IV&V and IEEE 1012’s wide acceptance in the science and engineering community, it has not been adopted by the forensic science community when generating evidence. New and novel hardware and software is being deployed all the time, from probabilistic genotyping (DNA) software, breath alcohol measurement devices, and face recognition, to malware detection, license plate readers, and acoustic gunshot detection. Too little time and resources are spent asking whether these systems are the right system built the right way for the intended use. As a result, systems are later found to be biased, flawed, used in improper ways, vulnerable to manipulation by users or attacks from the outside, which undermines confidence in the legal system and the forensic science community.¹⁻³ For the forensic science community to meet its pursuit of justice through truth and evidence, the community must require IV&V.

In reviewing high-profile federal cases regarding DNA software, there are several truths that must be understood in order to apply IV&V properly.⁵⁻⁸ First, all high-risk software must comply with IV&V and evidence used to determine someone’s rights and liberties is clearly high-risk. Second, guidance documents are not standards. Standards, like IEEE 1012, are formal specifications and procedures governed by federal law and required by the Supreme Court to be produced through fair processes and without any conflicts of interest. Third, internal validation is not IV&V. IV&V requires technical, managerial, and financial independence such that none of the tools, people, organizations, or money used to perform the verification and validation have an interest in the outcome. Fourth, reliability requires objective evidence. IV&V requires systems to be evaluated based on studies, outcomes, and statistics, not merely counts of allegedly peer-reviewed articles or of how many political agencies or laboratories adopted the technique.

Ensuring the reliability of evidence used in the legal system is an awesome responsibility. It is one that will be under increasing threat due to the complexities of modern technology. For generations, IV&V has been the foundational process for engineers and scientists to meet their responsibilities for high-risk technology. The forensic science community must do the same.

Independent Verification and Validation, Standards, Practices and Procedures

F6 Giving the Defense Bar a Seat at the Table: The Importance of Ensuring a Defense Perspective in Standard Development in the Firearms Identification Field

Kyla Wells, JD, The Legal Aid Society, Bronx, NY*

Learning Overview: This presentation will offer attendees information about how the Firearms and Toolmarks Consensus Body functions, what steps defense attorneys should take if they are interested in participating in a consensus body, as well as emphasize the importance of the defense bar's perspective being reflected in standard development.

Impact Statement: After attending this presentation, attendees will understand that the lack of uniform standards in the firearms identification field is a contributing factor to the misapplication of this forensic discipline. Attendees will also understand that a willingness by not only practitioners, but also defense attorneys, to participate in establishing standards in the firearms identification field is essential to improve the discipline and thereby prevent wrongful convictions stemming from the admission of faulty forensic evidence in courts.

Hypothesis: The foundational validity of firearm and toolmark examination—a subjective pattern-matching discipline that lacks an adequate empirical basis—has recently come under increasing scrutiny. A major source of criticism is the lack of uniform standards in the field. In 2009, the National Research Council issued a Report, *Strengthening Forensic Science: A Path Forward*, which emphasized the need to regulate the forensic sciences. The Report concluded:

“...Standards and best practices create a professional environment that allows organizations and professions to create quality systems, policies, and procedures and maintain autonomy from vested interest groups. Standards ensure desirable characteristics of services and techniques such as quality, reliability, efficiency, and consistency among practitioners.”

To address not only the lack of standards in the firearms identification field, but across forensic science disciplines, the National Institute of Standards and Technology (NIST) created the Organization of Scientific Area Committees for Forensic Science (OSAC) to develop much-needed standards. OSAC drafts proposed standards, sends them to standards developing organizations, who then further develop and publish the standards. The American Academy of Forensic Science (AAFS) Standards Board (ASB) is an organization consisting of consensus bodies that work closely with OSAC and its subcommittees in standard development. Members of the Firearms and Toolmarks Consensus Body of the ASB have traditionally been police officers, prosecutors, and firearms examiners. However, several defense attorneys have joined to bring a necessary defense perspective. Since joining, the consensus body has worked on developing a variety of standards aimed at moving the discipline forward, such as establishing minimum education requirements for firearms examiners. Through our participation, defense attorneys can serve as a voice for our clients who have long been the victims of faulty forensic “science.”

ASB, Consensus Body, Firearms/Toolmarks

F7 Sniffing Out Crime?: The Science and the Law of Drug Detection Dogs

Dana Delger, JD, Stockholm, Sweden; Michelle Grant, Neighborhood Defender Service of Harlem, New York, NY*

Learning Overview: After attending this presentation, attendees will have an understanding of the basic science and law of drug detection dogs. Attendees will also learn a basic framework for undertaking a challenge to a forensic technique they have not previously encountered.

Impact Statement: This presentation will impact the forensic science community by explaining the current state of the science and law of drug detection dogs, as well as providing a practical understanding of how lawyers should approach this evidence.

There is little question that some animals have superior scenting abilities to humans, and human beings have relied on those abilities for thousands of years, from the truffle hogs of the Roman empire to today's COVID-19 "detection dogs." But just how superior those abilities are, and under what circumstances they can be relied upon (and for which purposes) is a more fraught question, and one that has significant consequence when they are relied on in criminal proceedings.

One such use is that of drug detection dogs, dogs routinely employed by federal and state police authorities with the ostensible ability to reliably and accurately detect the odor of illegal drugs. But available empirical evidence suggests that drug dogs' actual performances fall well short of such claims.¹ This presentation will cover both the science that proponents of drug dog usage point to and where that science falls short, with a particular focus on how such evidence relates to the error rate paradigm put forward by the 2016 President's Council of Advisors on Science and Technology Report.²

Drug dogs may not only be inaccurate but also biased, as research shows their results can be influenced by handler knowledge.³ There is also data showing that drug dogs results may be even more biased when they are engaging with Black, Indigenous, and People Of Color (BIPOC) individuals.⁴ This presentation will cover these issues, contextualizing them against the history of police usage of dogs against particularly Black people.

Courts have largely failed to grapple with these shortcomings, and despite its common use and the many scientific and legal issues it raises, drug dogs remain novel evidence to many attorneys. In addition to covering these failures, this presentation will also look at the evidence from the perspective of an attorney facing a first-time challenge. It will provide a basic framework for how to think through and approach a challenge that would benefit from application to any forensic science.

Drug Dogs, Litigation, Cognitive Bias

F8 Current Scientific Issues for Human Remains Detection Dog Cases in Court: Animal Remains and Residual Odor

Mary Cablk, PhD*, Desert Research Institute, Reno, NV

Learning Overview: After attending this presentation, attendees will be aware of two components pertaining to the validity of Human Remains Detection (HRD) dog evidence being debated in United States courts at present and have a better understanding of the science pertaining to those aspects.

Impact Statement: This presentation will impact the forensic science community in two ways. It will inform the community of contemporary challenges to HRD dogs evidence in court and will inform anyone involved in using HRD dogs as an investigative tool of issues of reliability that may occur and may be later challenged.

HRD canines are commonly deployed to locate human remains evidence in criminal investigations throughout the United States. While the Academy Standards Board is in the process of developing a national certification standard for HRD canines, the skill and reliability of HRD teams varies widely. Regardless of certification, each canine requires assessment for reliability, and the defense has the right to review the records and challenge the training on a canine.¹ The prosecution relies on the HRD dog team's reliability established through certification and training.

Much of the case law pertaining to HRD dogs derives from narcotics and trailing cases, although HRD canine evidence is increasingly called into question in court in the United States. Canine final responses that produce human remains evidence such as an intact decedent, blood, bones, or DNA are generally not an issue in terms of defensibility. When an HRD canine performs a final response and no human remains evidence is located through other forensic processing means, that final response itself may be considered evidence and increasingly is presented in court as such. Here lies the question of reliability, whether the final response is a false positive or is a true positive that cannot be validated via other means.

One challenge to canine evidence in the absence of human remains is the possibility of confusion between human and animal remains, as argued in *Colorado v. Redwine*.² The handler's documentation would be critical to establish the degree to which the canine had been challenged with differentiating animal and human remains, but there are still valid challenges to be had. The counter argument comes from the science, to include studies that have addressed the Volatile Organic Compounds (VOCs) that emanate from animal remains which an expert witness might use in part of the basis of their opinion on the reliability of a canine.³⁻⁵

The other challenge is the likelihood that a final response could be to residual odor of human remains, which would explain the lack of validating evidence using other methods. The issue of residual odor has been argued in numerous cases.^{6,7} Few scientific studies have examined residual odor and canine responses to it leaving the scientific community virtually helpless to weigh in at present beyond establishing that residual odor exists.^{8,9}

Human Remains, Dog, Odor

F9 Firearms Tool Mark Comparison: The 2008/2009 NAS Report, the 2016 PCAST Report, and the AMES Study

John Nixon, MBA, ARC, Bippus, IN*

Learning Overview: This presentation is aimed primarily at jurists who wish to gain an understanding of the challenges and current state of acceptance of the firearms tool mark comparison discipline (often referred to as ballistics). This presentation focuses on the criticisms levelled at the discipline over the past two decades, and the defensive responses from the community of technicians who pay their bills by practicing this discipline.

Impact Statement: Attendees will gain an understanding of critical issues relating to the validity of the discipline of firearms tool mark comparison.

For millennia, humans have invested a tremendous amount of intellectual and physical resources into inventing and developing more effective ways to kill game animals, dangerous predators, and one another. Most game animals can outrun humans, so the development of personal weapons concentrated on launching projectiles that could “outrun” those game animals. When it came to warfare, being able to defeat an enemy with a projectile that had more range and accuracy than that of the opponent was a critical advantage. Projectiles have evolved over time, but essentially comprise sharp spears or arrows, and blunt trauma weapons such as pebbles and small rocks launched from hands and slingshots. The range of these weapons was limited by user strength, and the accuracy by user skill. Over the past couple of centuries, the firearm has emerged as the dominant weapon—it harnesses chemical energy to vastly increase range and, more recently, combined the laws of physics with metallurgy and manufacturing technology advances to launch spinning projectiles that provide excellent accuracy at those extended ranges. Humans now throw metal pebbles over long distances with great accuracy.

Rifles and pistols launch a single projectile that is spin-stabilized to improve accuracy and reduce drag. Most firearms spin the projectile by having a number of helical grooves cut into the interior of the barrel. The longstanding assumption has been that those machined barrels always have machine tool marks, wear defects, and corrosion that will leave discernibly unique (assumed) marks on the bullets pushed through them. Additionally, the cartridge case (typically brass) will collect discernibly unique (assumed) markings from other firearm components, such as the firing pin and the breech face.

Prosecutors have long proffered the discipline in criminal litigation and it had been accepted without challenge by the courts, defense counsel, and jurors. The proposition that all firearms left discernibly unique markings on ammunition components that were discharged in them was accepted as obvious, just as scientists had accepted as obvious, for many centuries, that the Earth was flat. Like the flat Earth theory, the concept of low error rate discernible uniqueness in firearms tool mark comparisons has been unravelling for some years, despite a few diehard proponents.

In the 21st century, astute attorneys began to challenge these assumptions, and with the aid of independent members of the scientific community, reviews were commissioned and challenges mounted. The 2008 and 2009 National Academies of Science Reports were very critical of the discipline, and their publication prompted a wave of “validation studies” by the community of practitioners.^{1,2} The 2016 President’s Council of Advisors on Science and Technology (PCAST) Report cast doubt on the validity of the validation studies, and in the 2017 Addendum to that Report, the PCAST Committee opined that there was only one valid validation study—the AMES study.³⁻⁵ The PCAST committee did note, however, that the AMES study had not been peer reviewed prior to their nod of approval. Subsequent critical review of the AMES study revealed that it was not valid on many levels, and it has been dismissed by courts. The reported false positive error rates of around 1% was too low by a massive margin – inconclusive (“I don’t know”) answers were counted as correct answers—if they are considered incorrect then the false positive error rate increases to 36% . Further, if the 23% of volunteer participants who failed to return their answers are counted as incorrect, then the false positive error rate increases to 50%. More recent studies (one claiming an error rate of zero percent) have also been discredited.

F10 Mixtures and Baskerville Data—The Importance of What Isn't There

Charles Brenner, PhD, DNA-VIEW, Oakland, CA and Human Rights Center, UC Berkeley, Berkeley, CA*

Learning Overview: Incorporating “Baskerville data”—sub-threshold yet unarguably reliable—can turn otherwise strongly inculpatory mixture evidence on its head.

Impact Statement: Evaluation and calculation of possible dropout must be revised to consider Baskerville data.

“Baskerville” refers to the Sherlock Holmes story in which lack of evidence—a dog doing nothing—was evidence. Analysis of a shell casing DNA mixture was presented in a criminal case. The analysis, using a dropout-capable mixture program in the way the vendor recommends, calculated a hefty likelihood ratio of 825 connecting the defendant—call him Baltimore—to the casing. But consideration of the sub-threshold pattern of the data led to two new insights and a likelihood ratio favoring the defendant.

First, the logical reason that sub-threshold signals are unreliable data does not apply to the *absence* of a signal. It is a traditional tenet that the DNA data to be considered for evaluating the evidentiary strength of a DNA mixture should be limited to signals with height above a pre-determined “analytic” threshold rfu value. The motive behind the analytic threshold is to avoid subjectivity and bias in distinguishing real DNA signals from artifacts. The analytic threshold is by definition a level above which data is reliable. Therefore, sub-threshold signals are potentially unreliable, so accepting them risks framing (i.e., manufacturing evidence against) an innocent suspect. But that concern applies only to “data” in the positive sense of a visible signal. Negative data—information that there is no signal—unambiguously and reliably says there is no real signal.

A second, complementary point is that the *lack* of sub-threshold signals (Baskerville data) can be powerful evidence to *free* the accused as it is in the Baltimore case. The issue is dropout or, more precisely, it is computing whether dropout is a good explanation for the observed mixture data. In Baltimore’s case, the answer is “yes” when the Baskerville information is ignored, but “no” under an analysis of the real and complete data. The necessary modification to the dropout calculation is not complicated.

The issue of Baskerville data arises with all mixture software that purports to deal with dropout and that filters the data with a threshold. That includes virtually all of the available continuous and semi-continuous model programs.

An occasionally stated dictum is the wisdom that while sub-threshold information should not be used as inculpatory evidence, it can be used to exclude. How that might be done was never explained until now.

DNA Mixture, Sub-Threshold, Exonerate

F11 A Forensic Analysis of “Gang Cop” Testimony

Sarah Sanger, JD, Sanger, Swysen & Dunkle, Santa Barbara, CA*

Learning Overview: After attending this presentation, attendees will be aware of how to prepare for or challenge “gang cop” testimony based on forensic science principles.

Impact Statement: This presentation will impact the forensic science community by increasing awareness of the need to meet basic forensic science (social science) standards for gang testimony.

Testimony about gangs, which can result in substantial sentencing enhancements, often is delivered by “gang cops” who derive their “expertise” from their time on the job. Sociologists have studied gangs and gang behavior, collecting empirical data and analyzing it according to scientific standards and practices. This presentation examines the scientific validity or lack thereof in “gang cop” testimony.

First, the nature and quality of the empirical data that is used to form the basis for expert opinions does not meet social science standards and practices. Observations of police officers, while interesting, are not neutral. As observers, gang cops are armed combatants who, for the most part, observe complex sociological interrelationships of members of a community from the outside. Even if they interact part of the time with the community in a constructive manner, for instance in community workshops, they are still biased observers. The data will be further distorted by the observers’ bias as members of the prosecution team.

Some efforts to curb the most significant abuses of “gang cop” testimony have been made, but do not address the core systemic problems. For instance, in California, the state Supreme Court in the *Sanchez* case, disallowed a “gang cop” witness from testifying to case-specific facts unless the witness had admissible firsthand knowledge of the facts. Typically, a witness would refer to hearsay information in police reports, Field Interview (FI) cards, or photos that were in the gang “data base.” Prior to *Sanchez*, this testimony would be presented to establish that a particular defendant was a member or associated with a gang.

Excluding this testimony in the *Sanchez* case was a step forward but only addressed part of the issue of the reliability of the data relied upon and introduced through the “gang cop” witness. Data that is not fact-specific to the defendant is still data accumulated by a police officer who claims knowledge of what is happening in a community and within alleged gangs in that community by virtue of work as a police officer. The ability to acquire unbiased knowledge of such facts is significantly impaired.

Second, opinions proffered by the “gang cop” go to the ultimate issues in the case. “Gang cops” generally testify that a defendant is a member of or associated with specific gang, that the gang is involved in criminal activity and, whatever the defendant is alleged to have done in the case at hand, was for the benefit of the gang. Like other expert witnesses, the claim of expertise and title—that of police officer—may carry undue weight in the deliberations of jurors. Yet, the standards usually associated with establishing a foundation for an expert opinion and establishing the scope of that opinion are not applied.

This presentation will conclude by exploring appropriate forensic limitations on “gang cop” expert witness testimony. One potential resolution is to prohibit the testimony as not meeting the foundational standards for an appropriate database from which to derive opinions. Another potential resolution is to prohibit such opinions even if the data could be more objectively curated, by prohibiting expert opinions as being outside of the expertise of such witnesses. This could lead to the elimination of “gang cop” experts. Some jurisdictions have found that “gang cops,” while not qualified as experts, could offer a lay opinion. That re-categorizes the problem, but does not solve it. Neither expert nor lay opinions should be permitted where they are primarily advocacy. Expert opinions on gang issues, whether or not the witness has police experience, should be based on robust empirical data and scientific standards and practices.

Gang, Expert, Sociology

F12 Fire Investigation Experts: Recommendations for Expressing Opinions in Reports and Testimony

Terry-Dawn Hewitt, LLM, McKenna Hewitt, Denver, CO*

Learning Overview: After attending this presentation, attendees will know the issues to be addressed in developing guidelines on how fire investigation experts should express their opinions in reports or testimony. Some of these issues may be informative to experts in other forensic disciplines that rely on the human interpretation and the scientific method to analyze evidence and form opinions.

Impact Statement: This presentation will impact the forensic science community by delivering practical recommendations that have been compiled from a range of studies and publications to provide guidance on how fire investigation experts are best able to express their opinions in a manner that adequately informs fact-finders without exaggerating (even unintentionally) the nature or the certainty of their opinions.

Among the significant findings of the 2009 National Research Council/National Academy of Sciences (NRC/NAS) Report are the critical questions raised about: (1) the extent that particular forensic science disciplines are based on a valid and reliable scientific methodology; and (2) the manner in which forensic science experts express their opinions in reports and in testimony.¹ These issues of scientific reliability and the fair and accurate reporting of opinions are inherently intertwined. After all, how can an expert express certainty in an opinion that is based on a methodology not proven to be valid and reliable? Is it necessary in the interests of justice for an opinion to address limitations in the methodologies employed, the sources of error, or possible bias? In the wake of developments triggered by the NRC/NAS Report, this presentation highlights ways to meet or surpass the challenges of rendering fair and accurate fire investigation expert opinions.

This research was broad, spanning the following sources: (1) the NRC/NAS Report, which recommended that terminology and minimum requirements for information used “in reporting and testifying about the results of forensic science investigations be standardized;” (2) the two main standards for fire investigations, the National Fire Protection Association (NFPA) 921 Guide for Fire and Explosion Investigations, and NFPA 1033 Standard for Professional Qualifications for Fire Investigator; (3) the history of debates recorded during the evolution of NFPA 921 about levels of confidence in experts’ opinions; (4) the work of the National Center for Forensic Science (NCFS) and the Organization of Scientific Area Committees (OSAC) concerning reporting and testimony; (5) the American Association for the Advancement of Science (AAAS) Quality and Gap Analyses for fire investigations; and (6) authoritative publications from other forensic science disciplines dealing with expert opinions.²⁻⁵

There are limits to the relevance of information from other disciplines. For example, the way opinions are expressed by experts in fields where findings can be reduced to statistical probabilities will not apply to fire investigations. However, there are commonalities that allow lessons to be drawn from other disciplines, such as issues of how experts express their opinions and what lay persons (non-experts such as attorneys, judges, and jurors) understand are largely matters of human communication and psychology. Like other fields, there is also a common need to identify and communicate sources of error in analyses. This presentation will summarize the results of this study, providing some practical guidance on how experts in the fire investigation field should express their opinions, communicate their level of confidence, and address limitations or sources of uncertainty.

F13 The History of Bitemark Evidence in America

Christopher Plourd, JD, Superior Court of the State of California, County of Imperial, El Centro, CA*

Learning Overview: After attending this presentation, attendees will understand that judicial acceptance of a forensic technique does not equate to scientific validity.

Impact Statement: This presentation will educate forensic science practitioners and all persons in the legal community as to the future viability of forensic bitemark identification.

Forensic odontology is a branch of forensic science that has its main application in the identification of human remains. However, and less commonly, it has been used in bitemark analysis—namely, the determination about whether a particular defendant made a bitemark. This presentation will focus on the history of forensic odontology as it pertains to bitemark analysis in America. Bitemark analysis in the American judicial system dates back more than 300 years and its validity has, increasingly, become called into question. Post-conviction DNA exonerations over the past two decades have led to inquiries about the scientific validity of bitemark analysis and whether it has a legitimate place in forensic science and in the courtroom.

This presentation will examine the origination, historical development, and acceptance of bitemark evidence in the American judicial system. It will identify and discuss key bitemark cases with an examination of the arguments both for and against the use of such evidence in criminal cases. This presentation will also evaluate the turbulent history of the use of bitemark evidence and, like all lessons that experience teaches, give some predictions as to the viability of the future use of bitemarks as an accepted forensic science discipline.

Bitemark evidence was first used in the American judicial system in 1692. The Reverend George Burroughs was accused of soliciting young women into witchcraft. A significant part of the evidence used to convict him was evidence that he bit his victims. Witchcraft judges readily accepted the presentation of bitemark evidence to substantiate these allegations. Rev. Burroughs was hanged on August 19, 1692. Two decades later, Burroughs was declared innocent, and the colony of Massachusetts compensated his children for their father's wrongful execution. The Burroughs case was the first reported conviction in America based on bitemark identification. Ironically, the Burroughs case was also the first case in America of a bitemark identification exoneration.

Nearly three hundred years later, in 1954, the first bitemark identification case to be reported in an American judicial opinion was the *Texas case of Doyle v. State*.¹ However, it was not until 1979 during the state of Florida trial of serial killer Ted Bundy that forensic bitemark analysis gained national attention. The Bundy case was the functional equivalent of the moon landing for bitemark evidence—a turning point for forensic odontology, marking its acceptance as a legitimate forensic discipline. Over the next 30 years, numerous convictions involving bitemark evidence further cemented bitemark evidence into the legal system as admissible evidence. Some of these same cases, however, were later shown to be erroneous.

In 2009, the National Academy of Sciences (NAS) issued a Report on forensic science raising questions relating to bite mark testimony in a conclusive match."²

In 2016, the Texas Forensic Science Commission recommended a moratorium on the admission of bite mark testimony

Additionally, in 2017, the National Institute of Standards and Technology (NIST) was asked to do a scientific review and issue reports on the validity of DNA mixture, ballistic evidence, and bitemark evidence. The NIST report on the scientific validity bitemark evidence is due to be published by the end of 2021. This presentation will evaluate the report, the basis for its conclusions, and the impact it will have on the use of bitemark evidence in the American judicial system.

Odontology, Bitemark, Validity

F14 Y-Chromosomal Short Tandem Repeat (Y-STR) Testing in Indian Country: The Injustice of Ignoring Y-Chromosomal Variation Within and Among Tribal Communities

J.D. Schmid, JD, Minnesota Board of Public Defense, Duluth, MN*

Learning Overview: After attending this session, attendees will appreciate how Y-chromosomal variation within and among localized Native American subpopulations impacts the statistical weight of a Y-STR haplotype match when the suspect's presumed paternal ancestry is Native American and the relevant events occurred on or near an Indian Reservation. Practitioners engaged in Y-STR testing will be encouraged to avoid using pooled, nationwide data to assign statistical weight when the circumstances described above are present. Researchers will be encouraged to develop and validate regional databases that accurately reflect the Y chromosomal genetic characteristics of Native American subpopulations located in different geographic areas of the United States.

Impact Statement: This presentation will impact the forensic community by bringing awareness to the potential injustice of using a pooled, nationwide Native American database to assign statistical weight to a Y-STR match. It is by now axiomatic that any database used to assign statistical weight to a DNA match must accurately represent the population of potential contributors. A statistical calculation derived from a database that is not representative of the population of potential contributors can mislead stakeholders by exaggerating the significance of a match between a suspect profile and an evidentiary profile.

A pooled database of Native American men living in different geographic regions of the United States does not accurately represent the Y-chromosomal genetic characteristics of localized Native American subpopulations. Population research has observed a high degree of Y-chromosomal variation among Native American men depending on where the samples were taken from geographically. It has also shown that common haplotypes occur much more frequently within localized Native American subpopulations than within subpopulations of the other major ethnic groups in the United States. These observations suggest that match probabilities are, in fact, much higher within localized Native American subpopulations than would be reflected in a nationwide, pooled database.

DNA evidence is so powerful that it can undermine the ends of justice when its significance is not properly understood. Jurors, judges, and attorneys often misinterpret statistical evidence by overestimating the probative value of a match between a suspect sample and an evidentiary sample. Ignoring Y-chromosomal variation within and among Native American subpopulations compounds the risk that jurors will overestimate the significance of a match and incorrectly conclude that the suspect is the source of DNA in an evidentiary sample even when he is not. The increased risk of source misidentification will, in turn, increase the risk that innocent Native American men charged with offenses on or near Indian Reservations will be wrongfully convicted, while the real perpetrators remain in the community.

Y-STR Testing, Native American Subpopulations, Statistical Weight

F15 Understanding Juror Comprehension of Forensic Testimony: Assessing Jurors' Decision Making and Evidence Evaluation

Cassidy Koolmees BS, BA, Florida International University, Miami, FL; Devon LaBat, BS, Florida International University, Miami, FL; Jacqueline Evans, PhD, Florida International University, Miami, FL; Nadja Schreiber Compo, PhD, Florida International University, Miami, FL; Deborah Goldfarb, JD, PhD, Florida International University, Miami, FL*

Learning Overview: Attendees will be provided with information about juror decision-making in cases involving forensic print evidence.

Impact Statement: The current research will provide insight into how jurors perceive forensic evidence testimonial quality and whether jurors need additional support to assess testimonial quality.

Testimony by forensic scientists can have a powerful impact on jurors' perceptions of the guilt or innocence of the accused. At the same time, forensic evidence often relies on highly scientific and technical methods that jurors may have difficulty comprehending. Research suggests that putative jurors struggle with understanding the statistics and technical language used to convey forensic science.¹ Furthermore, jurors often do not interpret forensic evidence in the way that expert examiners intend, such that they can misperceive the strength of the evidence by relying on factors external to the evidence.^{2,3} Although previous work has explored how the content and language used by forensic experts can impact juror decision making, no known study has examined whether jurors are sensitive to testimonial quality.

Recently, the Department of Justice released a Uniform Language for Testimony and Reports document for forensic print examiners. This document included five guidelines that forensic print examiners should follow when creating reports and testifying as an expert witness in court. First, a forensic expert should not claim that two prints came from the same person and from no other person (or to the exclusion of all other persons). Second, a forensic expert should not state that forensic print examination is without error. Third, a forensic expert should not give a conclusion about prints that includes a statistical or numerical degree of probability except when based on relevant and appropriate data. Fourth, a forensic expert should not cite the number of forensic print examinations he or she has done in his or her career as proof of the accuracy of their conclusion in this case. And fifth, a forensic expert should not use the expressions "reasonable degree of scientific certainty," "reasonable scientific certainty," or similar claims of reasonable certainty in either reports or testimony about print evidence. The current study examined whether jurors were sensitive to testimonial quality using these guidelines and explored the impact of testimonial quality on juror decision making and perception of forensic evidence.

Participants viewed and listened to transcripts of a mock criminal trial using language from real-world criminal trials. Trial transcripts included preliminary jury instructions, brief opening statements, direct and cross-examination of witnesses for the prosecution and the defense (including a forensic print examiner), closing statements, and final instructions. Participants were randomly assigned to conditions in a 2 (case fact pattern) x 3 (forensic evidence type: fingerprint, footwear print, tire-print) x 6 (level of forensic testimonial quality) design. Participants were presented with a version of a trial transcript consistent with their randomly assigned condition. After reading and listening to the trial transcripts, all participants were asked to provide feedback as if they were a juror on the case, including: providing a verdict and rating their confidence in their verdict; rating the overall evidence on a variety of measures (e.g., strength, quality, clarity); rating the forensic science testimony on a variety of measures (e.g., strength, quality, clarity); and rating the forensic scientist (e.g., credibility, qualifications, effectiveness).

Data collection is almost complete. Preliminary results indicate that the quality of testimony has no effect on verdict decisions, perceptions of strength of the evidence overall, perceptions of the forensic scientist, or perceptions of the forensic science evidence. This suggests that mock-jurors are not sensitive to low-quality forensic testimony and need additional support to differentiate between low- and high-quality testimony. Legal and policy implications will be discussed.

Forensic Testimony, Juror Decision Making, Print Evidence

F16 Juror Understanding of the Weight of Evidence Presented as a Likelihood Ratio and the Impact on the Deliberative Process

Bess Stiffelman, JD, Law Office of Bess Stiffelman, Los Angeles, CA and Independent Juvenile Defender Program, Los Angeles, CA*

Learning Overview: Attendees will better understand how the lack of intuitive understanding of the weight of evidence presented as a likelihood ratio impacts the deliberative process in criminal trials, and whether this evidence should be limited or recharacterized to prevent miscarriages of justice.

Impact Statement: With the advent and popularity of probabilistic genotyping, software likelihood ratios are becoming an increasingly popular tool for evaluating and presenting the probative value of evidence, particularly in the context of complicated mixtures of DNA. This presentation will help explain how even though likelihood ratios may be appropriate tools when they are used to evaluate evidence in research contexts or as investigative leads, they may not be the best method for communicating the weight of the evidence in criminal trials.

Legal reasoning relies on a different set of foundational concepts than forensic science such that, although the disciplines often interact and rely on one another, they do not always share the same objectives. Although we are all concerned with outcomes and want to minimize wrong decisions while optimizing right ones, our legal system is not merely consequentialist. There are aspirational principles at play as well—symbols of respect and autonomy that lie at the heart of the criminal justice system. As articulated by William Blackstone in the 1760s, our system is founded on the principle that “it is better that ten guilty persons escape than that one innocent suffer.” The presumption of innocence and the corollary burden of proof beyond a reasonable doubt create limitations on what evidence should be heard and how it is presented. Relevant evidence can, and often does, conflict with these principles and is therefore not heard by a jury. These likelihood ratios threaten to undermine those bedrock principles.

A previous article raised some of these concerns about the use of likelihood ratios in the presentation of DNA mixture evidence interpreted using probabilistic genotyping software.¹ J. Buckleton et al. responded with a critique and technical corrections purporting to assuage any such concerns.² This article’s focus on the purely technical aspects, while perhaps appropriate to the discipline of forensic science, nevertheless failed to account for and grapple with the legal principles at play and the larger concern about juror understanding of the weight of evidence communicated as a likelihood ratio. This created an opportunity for a conversation between the legal community and our forensic science colleagues about the competing principles at play, and the impact on the deliberative process.

Likelihood ratios produced by probabilistic genotyping software express the probabilistic relationship between two specific hypotheses that seek to explain the observed characteristics of a given piece of DNA evidence. Although a familiar concept to many here, this is not as easy for the rest of us to understand. As one judge recently described it, probabilistic genotyping is “a combination of forensic DNA techniques, mathematical theory, statistical methods (including Monte Carlo Markov Chain modelling, as in the Monte Carlo Gambling venue), decisional theory, computer algorithms, interpretation, and subjective opinions . . .”³

Intuitively, without an understanding of the probabilistic reasoning at play, likelihood ratios appear to jurors as something that they are not. Thompson and Newman found that “[a] surprisingly high percentage of our participants (about two thirds) indicated that one or both statements consistent with the source probability error were a ‘correct interpretation’ of what the expert said. These fallacious interpretations were not merely matters of semantics—[they] found that they were strongly associated with verdicts and estimates of the probability that the defendant was guilty.”⁴

In order for jurors to properly understand and incorporate a likelihood ratio into their deliberations, Bayesian reasoning must be applied. This requires converting the prior assessment of guilt or innocence into a probability and thus quantifying that prior belief. It is this act of quantifying the prior that creates one of the challenges. This is not how jurors make decisions, and when likelihood ratio evidence is introduced, they are not instructed on Bayesian reasoning. As the Adams Court that considered this in the United Kingdom concluded, “to introduce Bayes Theorem, or any similar method, into a criminal trial plunges the jury into inappropriate and unnecessary realms of theory and complexity deflecting them from their proper task.”⁵ So, we are left with the other option: incorporating the evidence in an intuitive manner, which is how this happens in most trials. This leads us right back to the concern that jurors will be unable to determine the weight of the DNA evidence presented as a likelihood ratio.

Since factfinders in a criminal trial will overvalue likelihood ratio evidence, and DNA evidence is often already given undue weight because of the “CSI effect,” this use of likelihood ratios may lead to miscarriages of justice.

Likelihood Ratio, DNA Evidence , Presumption of Innocence

F17 The Role of Opinions, Probability, and Likelihood Ratios in Forensic Evidence Communication by Experts

Hari Iyer, PhD, National Institute of Standards and Technology, Gaithersburg, MD; Steve Lund, PhD, National Institute of Standards and Technology, Gaithersburg, MD*

Learning Overview: Attendees will become familiar with the distinction between probabilities, which are numerical expressions of personal degrees of belief, and relative frequencies, which report how often an event of interest has actually occurred in real life during a given duration of time. A likelihood ratio, being a ratio of two probabilities, is also a personal assessment and is, in fact, an opinion expressed using a numerical scale. One may, incorrectly, view these personal assessments, expressed numerically, as being rigorous and objective because of the mathematical or statistical tools used to arrive at them. A proper understanding of the information being communicated by an expert, in the form of probabilities or as likelihood ratios, either in their report or during testimony, requires additional information that can help the trier of fact judge the reliability of the expert's testimony. This presentation explains these concepts in detail. No background training in probability or statistics is needed to appreciate the relevance of the information presented.

Impact Statement: This presentation will help the forensic science community better understand the nature of the information presented in reports and/or testimony, using a probabilistic framework, and will enable them to meaningfully evaluate the reliability of expert testimony by focusing on available supporting information rather than based on the expert's credentials alone.

Forensic science experts have the difficult task of communicating their findings, after analysis of forensic evidence, to triers of fact and other decision makers in the judicial system. Ever-increasing technical complexity resulting from scientific advances and cutting-edge practices and challenges associated with the treatment of uncertainty add to the difficulty of communicating accurately and effectively. In many forensic disciplines, experts report their findings in the form of a conclusory opinion. Many forensic scholars argue that it is inappropriate for an expert to offer conclusions, as conclusions are the domain of the decision makers and doing so may suppress meaningful consideration of factors that could lead a decision maker to reach a different conclusion. Instead, it is often argued that experts should summarize their findings by providing a likelihood ratio as the strength of the evidence. This presentation emphasizes that likelihood ratios are opinions too, and concerns related to experts providing conclusions have analogs with experts providing likelihood ratios (or other forms of probabilistic interpretation). Various issues associated with experts using probabilities and likelihood ratios to communicate forensic findings are discussed. Motivated by the notes to FRE 702, alternatives are explored that do not require experts to summarize their findings using an opinion (conclusory or probabilistic) instead focusing on the specialized knowledge that they possess by virtue of their training and experience.

Likelihood Ratio, Probability, Reliability

F18 Should Low Likelihood Ratios (LRs) Be Admissible? Considering the Kinship Problem

Clinton Hughes, JD, Brooklyn Defender Services, Brooklyn, NY*

Learning Overview: This presentation will demonstrate that without a factual and scientific basis for ruling out relatives in a DNA mixture, the elimination of the uninformative range and the unqualified reporting of low LR in forensic DNA analysis threaten to run afoul of the fitness for purpose standard of *Daubert*.¹

Impact Statement: Considering the prevalence of law enforcement searches of family homes and other examples of semi-closed environments where relatives have access, the criminal justice system should not dismiss DNA mixtures of related individuals as some kind of rare outlier when considering low inculpatory LR.

In their 2020 research paper, *Are low LR reliable?*, several leaders in the field of forensic DNA offered context for the 2018 SWGDAM Guideline 3.1, which advised that even low LR should not be considered inconclusive.^{2,3} This study contrasted a closed environment—for example, a crime scene with fewer than five possible donors—with an open environment where anyone with access to the crime scene could be a possible donor. This study claimed that in a closed environment, even low-discriminating LR may be probative. However, this approach ignores a common and predictable scenario of a closed or semi-closed environment—a crime scene such as a family home or family car where related individuals have access. With related individuals as a common issue, it is critical to evaluate the significance of any low LR by ruling out whether a non-contributor relative of the true contributor(s) to a DNA mixture might be falsely associated with that mixture. While non-contributor testing with this common scenario has been disturbingly sparse, a few internal validations of probabilistic genotyping tools have indicated a much higher false positive rate for related non-contributors than with random unrelated profiles.⁴ In certain situations, false positive LR with related individuals can reach into the high quadrillions. Considering the prevalence of law enforcement searches of family homes and other examples of semi-closed environments where relatives have access, the criminal justice system should not dismiss DNA mixtures of related individuals as some kind of rare outlier when considering low inculpatory LR. By reporting low LR without underlying validation, labs are complicit in shifting the burden of proof to defendants to establish that the true contributors are relative[s], rather than requiring the prosecution to rule out a very common exception. This presentation will demonstrate that without a factual and scientific basis for ruling out relatives in a DNA mixture, the elimination of the uninformative range and the unqualified reporting of low LR in forensic DNA analysis threaten to run afoul of the fitness for purpose standard of *Daubert*.¹

Likelihood Ratio, Probabilistic Genotyping, Relatedness

F19 Touch DNA Communication in the Courtroom: Developing Methods for the Effective Communication of Forensic Science Data

Julie Burrill, PhD, Alan Alda Center for Communicating Sciencefor, Stony Brook, NY and King's College London, London, NA, United Kingdom*

Learning Overview: Attendees will hear about novel research results into the content of touch DNA deposits. They will also learn about new methods for scientists to consider when communicating their forensic data to each other, to attorneys, or to juries.

Impact Statement: This work seeks to improve the way that scientists communicate their results and put them appropriately into context for a legal audience. Additionally, the novel touch DNA results presented here will further clarify the cellular and cell-free components as well as the human and non-human DNA content in touch deposits, which has a direct impact on their potential to transfer between people and items.

Forensic science exists to be utilized in a legal setting. Consequently, it is only as valuable as the scientists' ability to communicate their process and results in the courtroom and interpret the meaning of scientific data in context for the fact finder. This can be particularly challenging when conveying complex results with nuanced layers of interpretation such as those from DNA mixtures or low-level samples such as "touch DNA."

Research at the Alan Alda Center for Communicating Science is investigating the relative success of various methods of communicating these scientific complexities in the courtroom. This work includes analysis of existing trends in testimony and report writing and is currently developing and testing new communication strategies for both scientists and attorneys. This presentation will use touch DNA as an exemplar evidence type and explore how to best improve effective communication of novel research and/or casework results. Original research quantifying the relative contributions of cellular and acellular DNA to a potential touch deposit will be presented.

Hand rinses were collected from washed and unwashed hands. Each sample was processed and characterized using newly adapted methods for short DNA fragments. DNA was characterized with traditional Short Tandem Repeat (STR) typing as well as massively parallel sequencing to evaluate degradation patterns and microbial content. Results will be discussed in the context of the current scientific and legal landscape; potential techniques for the dissemination of these data for various target audiences will be presented. The Alda Method combines improvisational theater techniques that help scientists to pay dynamic attention to the needs of their listeners and learn to spontaneously adjust to those needs. This approach integrates techniques to help scientists distill their message, shape compelling stories, create common ground, and use conversational language that fosters genuine human connections. This presentation explores the applicability of this and related approaches to touch DNA results in a courtroom.

Touch DNA, Science Communication, Courtroom

F20 The Application of the OSAC Registry of Standards to the Revised Federal Rules of Evidence Rule 702

Mark Stolorow, MS, MBA, National Institute of Standards and Technology, Special Programs Office, Gaithersburg, MD*

Learning Overview: This presentation will provide an examination of the proposed changes to Rule 702 and the relationship of implementation of the standards on the OSAC Registry to the demonstration of ensuring compliance with those changes.

Impact Statement: This presentation will discuss the relevance and potential impact standards implementation have on the application of the newly proposed amendment and case notes to Rule 702.

In April 2021, the federal Advisory Committee on Evidence Rules (ACER) proposed amendments to the wording of Federal Rules of Evidence Rule 702 which pertains to expert testimony. Briefly, those proposed changes encourage courts to more rigorously adhere to ensuring that “forensic expert testimony is valid, reliable, and not overstated in court.”

Since its official inception in 2014, the NIST Organization of Scientific Area Committees (OSAC) for Forensic Science has advanced the mission of strengthening forensic practice by facilitating the development of technically sound, science-based standards through a formal standard developing organization (SDO) process, by evaluating existing standards published by SDOs for placement onto the OSAC Registry, and by promoting the use of the OSAC Registry approved standards throughout the forensic science community.

How does the implementation of standards on the OSAC Registry impact conformance with the revised Rule 702? This presentation will address the implications.

With the list of OSAC approved standards growing, the community has rightfully turned its attention to the implementation of these standards into the quality systems of forensic laboratories. As of the drafting of this abstract, OSAC has posted 65 standards involving 15 different forensic science disciplines plus interdisciplinary standards. From preliminary national OSAC standards implementation survey results closing in August 2021, more than 100 forensic science service providers have already implemented standards listed on the OSAC Registry into their quality management system documents.

Since September 2020, OSAC has also implemented Scientific and Technical Review Panels (STRPs) to ensure that standards contain processes for determining and reporting measurement uncertainty whenever possible. Standards need to reference supporting scientific literature to provide experts and the courts with foundational documents supporting the validity and reliability of the principles and methods. OSAC aspires for the STRPs to ensure that standards will meet those needs.

What relevance and potential impact does standards implementation have on the application of the newly proposed amendment and case notes to Rule 702? Standards implementation and adherence to those standards in the forensic analysis, reporting and testimony can demonstrate to the courts that the proffered expert opinions are not overstated and comport with nationally approved standards grounded in valid and reliable methodology.

This presentation will provide an examination of the proposed changes to Rule 702 and the relationship of implementation of the standards on the OSAC Registry to the demonstration of ensuring compliance with those changes.

Standards, Federal Rules of Evidence, OSAC for Forensic Science

F21 Medical Biobanks—Different Aims, Same Controversies: How to Approach the Constitutional Lens to Bioethical Dilemmas of Human Rights, Civil Claims, and Solving Crimes

Maria Ciruzzi, PhD, Hospital de Pediatría Prof. Dr. Juan P. Garrahan, Buenos Aires, Buenos Aires, Argentina and Law School, University of Buenos Aires, Buenos Aires, Buenos Aires, Argentina*

Learning Overview: After attending this presentation, attendees will be confronted with the dilemmas and conflicts that the use of medical technology poses in different areas of human behavior, showing that there is no unambiguous answer where we can feel comfortable.

Attendees will also acknowledge the importance being open minded, exercising critical thinking, and dealing with dilemmatic situations in a non-binary world.

Impact Statement: This presentation will impact the forensic and social community by showing key aspects of the important role that law, ethics, and technology are called on to perform in a rapidly changing world under almost omnipotent technology.

“Genetic information” distinguishes between the genetic material itself and the genetic information: the “genetic material” will always be with the person from the first stages of life until the moment of death, while the genetic information is obtained by performing a series of techniques or methodologies that allow the extraction of certain specific data. In this sense, it is affirmed that genetic information is the set of data of genetic origin and nature that is settled on a specific support, it may be a file or a specific information bank.

It should be noted that not all genetic information is private. There is genetic information associated with phenotypic traits, that is, external traits that are public knowledge, such as eye color, height, complexion, etc. The genetic information that deserves protection is that of sensitive management and generally associated with health and predisposition to certain diseases of genetic origin and late onset. That information is private, at least until the first symptoms appear or until the individual intentionally discloses this information.¹

Genetic data could certainly be very useful, but we know that not all that is technically possible as it could be bioethically grounded and/or legally binding.

Millions of human biological samples are stored worldwide for medical research or treatment purposes. These samples are also of enormous potential value to law enforcement, as DNA profiles can be obtained from these samples but for different goals.

This presentation will expose a real medical case as a trigger to compare the different views that may arise from a single biological sample when the objectives differ: medical use, parental responsibility, crimes against humanity, or the resolution of cold cases. Based on this, this presentation will try to assess the interaction between bioethical dilemmas, judicial controversies, protection of human rights, and the exercise of the state punitive power.

F22 Shifting Forensic Science Development From the Organization to the Discipline

Claude Roux, PhD, Centre for Forensic Science, University of Technology Sydney, Broadway, NSW, Australia; Sheila Willis, PhD, Leverhulme Research Centre for Forensic Science, University of Dundee, Dundee, NA, United Kingdom; Celine Weyermann, PhD, Ecole des Sciences Criminelles, Université de Lausanne, Lausanne, VD, Switzerland*

Learning Overview: After attending this presentation, attendees will have a better understanding of forensic science as a discipline and be able to differentiate scientific fundamentals focused on a purpose from a scientific organization focused on means and technologies.

Impact Statement: The presentation will promote and encourage discussions with the community, including judges, prosecutors, defense attorneys, and policy makers, on how ongoing challenges in forensic science may be best addressed by shifting the focus from the organization to the discipline purpose.

Forensic laboratories and services are a mainstay of the criminal justice system across the world. The usefulness of (forensic) science is therefore widely recognized. However, several reports indicate that forensic science usefulness in court remains very limited and is occasionally highly controversial. Different problems have been identified, such as justice miscarriage, backlogs, unreliable scientific process, inadequate training, lack of reference data, etc. However, attempts to solve these issues (i.e., more funding, quality management, bias mitigation, statistics, shared databases) do not seem to have durably solved the forensic science “crisis.” It is argued that some solutions may even have brought further unforeseen problems. For example, distancing scientists from the crime scene may forward independence and decrease bias. Still, it also increases linkage blindness (i.e., the ability to connect different pieces of information in casework, including essential information for subsequent scientific examination).

An alternative path forward is suggested in this contribution by contrasting the forensic science means and purposes under the prism of the discipline (i.e., forensic science) rather than the organization (i.e., practice). Indeed, nowadays, forensic science is mainly viewed as applying science(s) to legal matters and has barely been defined as an academic discipline (at best, it is a subdiscipline of medicine, chemistry, biology, or computer science). Thus, the forensic science development has essentially been driven by organizations (such as, but not limited to, forensic laboratories). It is argued that organizational response to the forensic crisis has focused on improving and standardization of means and processes. However, organizations and processes are highly dependent on the political, economic, and legal structures in which they operate. This may explain why proposed solutions could hardly be efficiently applied transversally to all forensic science models.

Moreover, new tools and technologies are continuously developed by a quasi-infinite number of different scientific disciplines, thus leading to further diversity and fragmentation of forensic science. On the other hand, as a distinct discipline, forensic science can refocus research and development on shared principles and purposes, such as reconstructing, monitoring, and preventing crime and security issues. Scientific research and development must mainly be carried out from within a discipline in a scientific (bottom-up) rather than political or economic (top-down) approach to be relevant and efficient.

This presentation will show how shifting the forensic science focus from means to a purpose provides a basis on which organization (s) and current practice(s) can more adequately evolve, eventually leading to a more impactful and long-lasting improvement of forensic science basic knowledge and subsequently application.

Relevance, Technology, Research and Development

F23 Forensic Science Leading the Fight Against Illicit Pharmaceuticals

Geoffrey Albert-Bolinski, BA, Merck & Co. Inc, West Point, PA; Belen Gonzalez Amoros, MSc, Organon, Jersey City, NJ; Janine Brouillette, MSc, Merck & Co. Inc, West Point, PA; John Douglass, BSc, Merck & Co. Inc, West Point, PA; Stephanie Beer, MSc, MSD Wertheim BioPharma GmbH, Schachen, Luzern, Switzerland; Dorotyia Sallos, MSc, MSD Wertheim BioPharma GmbH, Schachen, Luzern, Switzerland; Christopher Hopkins, MSc, Merck & Co. Inc, West Point, PA; Tony Zook, PhD, Merck & Co. Inc, West Point, PA*

Learning Overview: Attendees will learn about the global health threat of counterfeit pharmaceuticals and how pharmaceutical companies can provide specific expertise in authentication and identification using traditional forensic approaches to partner with law enforcement in an effort to protect public health.

Impact Statement: This presentation aims to build awareness of the global threat of counterfeit pharmaceuticals and how forensic principles and techniques around quality, analysis, and interpretation help support law efforts to mitigate this threat.

Counterfeit medicines and illicit pharmaceuticals are a worldwide problem that have critical public health and safety implications that continue to escalate. Collected intelligence on the subject for calendar year 2020 reported 4,344 unique pharmaceutical counterfeiting, diversion, and theft events, involving 2,451 different medicines, and spanning 137 countries. A historical review of counterfeit events shows a significant increase in counterfeit events involving oncology medicines.¹

The incredible complexity required to authenticate pharmaceutical products highlights the need for brand owners to play a role. Expertise for a company's entire product portfolio that encompasses physical printing and packaging characterization, chemical characterization, unknown compound identification, and even proteomics is crucial. In addition to the analytical requirements, to be able to support legal action, those analytical needs must be paired with the forensic science legal standards of strict chain of custody and evidence management controls, **International Organization for Standardization (ISO)** accreditation standards required for evidentiary data submissions, and expert witness training to testify as subject matter experts.

Merck® has designed and built a global laboratory network that meets these demands and is dedicated to the detection and characterization of counterfeit and illicit medicines. Partnered with health organizations, government agencies, and law enforcement departments, these ISO 17025-accredited labs test for product authenticity and characterize counterfeit or illicit products in an effort to protect patient safety.

A case study involving a counterfeit oncology product will be presented highlighting how the Merck® laboratories were able to use analytical tools and forensic techniques to characterize the counterfeit products and use those characterizations to drive actionable and defensible forensic intelligence. This intelligence developed through laboratory analyses was able to link multiple cases globally to a single organized crime group operating clandestine laboratories that managed a global distribution network of the counterfeit product. Partnerships with key investigators and law enforcement groups led to the arrests and successful prosecution of the organization's leaders and the disruption of the illegal enterprise.

From this success, the Merck® forensic laboratories look for where to go from here by looking for additional traditional forensic techniques that can help drive forensic intelligence and meaningful outcomes like the shared example. Techniques around enhanced protein analysis, stable isotopic signatures, and reverse engineering of counterfeits are beginning to be added into the repertoire in an effort to push the fight against counterfeit and illicit pharmaceuticals.

F24 Court Proceedings During the COVID-19 Pandemic

Julianna Firek, Duquesne University, Pittsburgh, PA; Lyndsie N. Ferrara, PhD, Duquesne University, Pittsburgh, PA*

Learning Overview: After attending this presentation, attendees should better understand how greatly the court system has been affected by the COVID-19 pandemic.

Impact Statement: This presentation impacts the forensic science community by affecting the way courts are run and how testifying may look in the future

Synopsis: As of March 2020, the courts shut down, along with the rest of the world. During this unprecedented time, figuring out a way to continue with legal proceedings was a difficult feat that each court did independently, without universal guidelines. Prior to the pandemic, the court was extremely slow to make changes, but the pandemic forced many quick changes along with significant investment into new courtroom technology. These significant changes are important to document and analyze.

The goal of this research was to collect firsthand accounts of court adaptations and operations throughout the pandemic. Interviews were conducted with various professionals within the court system to gather information on their experiences during the pandemic. Interviews were conducted across different jurisdictions in order to compare the changes each court made. These interviews were conducted via Zoom or in person, and the responses were compared to each other and what was found in literature. This comparison identified challenges confronting the court system as well as elicited unique perspectives specific to different jurisdictions. Courtroom operations were examined in light of legal rights and requirements such as the Sixth Amendment right to a speedy and public trial.

Documenting how the courts adapted is important for future events that may require virtual court as well as for analyzing if operations were effective and fair. As the pandemic continues, court operations continue to adapt. This research provides a retrospective analysis of courtroom operations that shifted to fully virtual proceedings up through re-opening efforts and hybrid models. During the shutdown period, lengthy backlogs continued to increase. Addressing this back log will require a unique and efficient approach in order to ensure every person obtains equal access to justice.

COVID-19, Virtual, Court

F25 Perpetuating the Presumption of Guilt: The Role of Implicit Racial Bias in Forensic Testimony

Janis Puracal JD, Forensic Justice Project, Portland, OR; Aliza Kaplan, JD, Forensic Justice Project, Portland, OR and Lewis and Clark Law School, Portland, OR*

Learning Overview: After attending this session, attendees will have a better understanding of how implicit racial bias can impact forensic opinions and how systems should be reformed to mitigate that risk.

Impact Statement: This presentation will impact the forensic science community by presenting the research on implicit racial bias and how that bias can contribute to wrongful convictions.

Since the murders of George Floyd and Breonna Taylor, conversations around racial bias in the criminal justice system have accelerated. Much of the focus has turned to police reform. The potential for racial bias, however, does not end with the initial stop, search, and arrest. Rather, it can be found throughout our criminal justice system, and forensic testimony is one area that does not get nearly enough attention when it comes to implicit racial bias. Lawyers, judges, and jurors often approach scientific sounding evidence with a predisposition to accept the expert's conclusions, without a critical eye. Experts for the government are often presumed to be neutral and objective witnesses who report the science with no stake in the outcome. Government experts, however, are susceptible to bias, including implicit racial bias, just like the rest of us. These experts who testify in criminal cases may not be reporting "neutral science;" the testimony may be contaminated by implicit racial bias, among other biases, that has colored their conclusions.

Pattern-matching methods—for example, analysis of firearms and tool mark impressions, bloodstains, latent prints, hairs, and footwear and tire impressions—are especially problematic. These methods are inherently subjective, meaning that they rely heavily on the examiner's individual judgment, rather than any objective standard. Even though the examiner may be analyzing, for example, a bullet from a crime scene, that examiner may also be given "irrelevant contextual information," such as the name, race, and background of the lead suspect. Knowing that information can predispose the examiner to believe that the bullet was fired from that suspect's gun, leading to a result-driven opinion about whether the marks on the bullet "match" the marks on test fires from the gun. The human eye will see what it wants to see, and, because there are no objective standards by which to measure the marks, the examiner's conclusions may reflect bias in favor of guilt, rather than a true determination that the marks are, in fact, the same in appearance or sufficient in number.

A number of recent exonerations have raised questions about the role of implicit racial bias in faulty forensic testimony that resulted in a wrongful conviction. This presentation addresses how implicit racial bias can affect forensic testimony and ways to address it before wrongful convictions occur.

Implicit, Race, Bias

F26 The Art of Retrieving Documents From Messaging Apps

John Carney, JD, Carney Forensics, Scandia, MN*

Learning Overview: This presentation will briefly introduce the practice of mobile device forensics and explain why mobile apps are key sources of document evidence. It will explore six questions with attendees that go to the heart of document retrieval from mobile messaging apps based on new technology platforms:

- Which mobile devices must be examined for message and document retrieval?
- What types of messages must be recovered?
- What types of documents are to be retrieved from those messages?
- How much metadata must be collected to provide foundation and authenticate those documents?
- What about recovery of documents and messages subject to spoliation?
- What other message and document sources can be probed when mobile devices are not available?

Impact Statement: The presentation will impact attendees in terms of competence (ability) and performance (action) by showing the expanded definition and range of modern document evidence. It will provide practical advice and effective forensic techniques for recovering documents attached to popular mobile messages found on smart phones and other mobile platforms. It will teach attendees how to preserve the integrity and authenticate messaging and document evidence for admission into the record of federal and state courts. And, it will show credible demonstrative exhibits of document evidence competently retrieved from messaging apps on mobile device platforms to help attendees visualize successful outcomes.

This presentation will focus on effectively using mobile device forensics to recover new and traditional forms of document evidence attached to popular mobile messaging apps used by billions of people worldwide today. The proposition of this presentation is to acknowledge and come to grips with the expanding definition and role of document evidence in the modern world, including government, academia, business, and jurisprudence. This presentation centers on the need for attorneys, paralegals, and investigators to develop new processes and forensically sound techniques for document recovery and forensic collection. The objective is the satisfaction of the rules of evidence to support admissibility of material evidence from billions of smart phones and tablets upon which cases are likely to turn today. Document retrieval from messaging apps is more “art” than science for many legal practitioners in 2022. They lack a viable process capable of producing repeatable and defensible results. They mastered document recovery from emails decades ago, but the retrieval of messages and their documents on new mobile technology platforms elude much of the legal profession. A paralegal will usually start from scratch for each case or each client. They use ad hoc or case-specific methods that often disappoint and produce only screenshots or worse. Ultimately, parties are frustrated and the bench faces admissibility challenges due to forensically unsound recovery or collections.

Mobile Device Forensics, Messaging App Evidence, Document Retrieval

F27 Pandemonium in Social Media: A Collision Course With the Fourth Amendment

Gary McDonald, JD, Dallas County Criminal District Attorney's Office, Dallas, TX*

Learning Overview: The purpose of this presentation is to educate attendees about emerging trends in the collection of location data by social media companies.

Impact Statement: This presentation will impact attendees by helping them understand the Fourth Amendment implication of the collection of this information, the forensic viability, and the commercial uses for which it is collected.

Social media permeates today's electronic world. It is estimated by recent research that adults in the United States use social media in the following percentages: Facebook®—69%, Instagram™—40%, Snapchat™—25%, and Twitter®—23%.¹ Users of these services, by way of example, opt into Terms of Service Agreements that allow the collection of metadata and information, including location information. For instance, Facebook® and Instagram™ are governed by the same Data Policy that includes metadata, location information, usage, and device information, which may be used for a valid business purpose, as described, but may also be accessible to law enforcement in furtherance of criminal investigations.² For other social media companies such as Google®, it has been reported that location information collected was an invaluable tool in the identification of those involved in the Capitol protests on January 6, 2021, and that such information is collected and stored in the Google® Sensorvault, which aggregates location information from a variety of sources.³⁻⁵

After this presentation, attendees will have a deeper appreciation of the sources and uses of such information for corporate and law enforcement purposes—especially as it relates to emerging trends for the forensic use of information, such as in geofences. As the nature and type of information collected increasingly impacts individual privacy, the Electronic Communication Privacy Act of 1986 will be compared to emerging more limited state privacy provisions.⁶ The recently adopted Subchapter (G-1), Texas Code of Criminal Procedure and the California Electronic Communications Privacy Act both restrict law enforcement access to such prospective location information through traditional tools and provide a statutory exclusionary rule, if the information is obtained outside of the state statutory provisions.^{7,8} This shift from federal law, which contains an exclusivity of remedies provision for information obtained through the Stored Communications Act may serve as a trend toward the limitation of the use of such information in forensic science and investigations.⁹

Social Media, Privacy, Location Information

F28 Picture Me Rollin': Personal Privacy in the Land of Automated License Plate Readers

Michael Buresh, JD, Cook County Public Defender, Chicago, IL, USA*

Learning Overview: This presentation will introduce attendees to the popular police mass-surveillance technology of Automated License Plate Readers (ALPRs), high-speed cameras that detect and record every license plate they encounter. While United State police departments spend millions of dollars on ALPRs, only a small fraction of their indiscriminate surveillance proves useful to public safety. Worse yet, these devices are deployed disproportionately in communities of color, leading to terrifying and potentially fatal encounters between armed police and the people of these communities. This presentation will teach attendees the basics of how these devices work, how police use them, how effective they are, and the legal implications of their use.

Impact Statement: This presentation will impact the forensic science community by encouraging consideration of the utility of a mass surveillance technology. Attendees will learn the costs, both financial and human, of indiscriminate surveillance of people's public movements.

ALPRs are high-speed cameras that photograph vehicle license plates in their immediate environment. When an ALPR camera scans a license plate, the camera records an image of the plate, along with the date, time, location, and photograph of the vehicle and its plate. ALPR software then uploads these images of license plates, called "detections" or "plate scans," to a centralized database. ALPRs can be mounted on fixed infrastructure like poles, or mounted on police or other city vehicles.

Police departments contract with third-party companies for access to these companies' databases of ALPR detections. The most prolific ALPR service provider is Vigilant Solutions, which maintains a database called the National Vehicle Location Service (NVLS). Law enforcement agencies can create lists of wanted license plates ("hot lists") in these databases. If a plate is in a hot list at the time it is scanned by an ALPR camera, this is called a "hit." When a hit occurs, the system will notify the law enforcement agency whose reader recorded the hit, as well as the agency who entered the plate into the hot list. Law enforcement clients can also perform historical searches by entering a license plate number into the database and the database will return a list of all instances in which its ALPR cameras detected that plate. Law enforcement agencies can also elect to make their NVLS-hosted detections accessible to other law enforcement agencies. This presentation will present details of law enforcement agencies' use, including statistics obtained via public records requests.

While ALPRs sometimes provide valuable intelligence to law enforcement agencies, this surveillance technology also raises serious privacy and discrimination concerns. Most obviously, these devices conduct constant, indiscriminate mass surveillance of entire communities, regardless of whether any individual is suspected of committing a crime. Further, civil liberties groups, such as the American Civil Liberties Union, the Electronic Frontier Foundation, and the Brennan Center for Justice, have raised concerns about the discriminatory impact of ALPR camera deployment.¹⁻³ In addition to exposing communities of color and other vulnerable populations to over-policing, the discriminatory deployment of ALPR cameras can also signal to those communities that they are unvalued. "Surveillance that disproportionately targets communities of color carries a distinct and cognizable equal protection harm: branding them with a badge of inferiority."⁴ For example, in Chicago, the city's initial deployment of fixed-location ALPR cameras in 2017 focused primarily on Black and brown neighborhoods on the South and West sides of the city.

This presentation will also address the current legal landscape of ALPRs. While most courts that have addressed the issue have found that law enforcement's broad surveillance via ALPRs does not violate individuals' right against unreasonable searches and seizures, most of these decisions were issued before the United States Supreme Court's landmark decision in *Carpenter v. United States*.⁵ In *Carpenter*, the Court ruled that the Fourth Amendment prohibits law enforcement's warrantless tracking of peoples' movements via their cell phones, even when most of those movements occur in public.

Surveillance, Privacy, License Plate

F29 Michael Williams v. Forensic Gunshot Audio Detection: How Unvalidated Forensic Evidence Sent an Innocent Man to Jail

Brendan Max, JD, Cook County Public Defender, Chicago, IL*

Learning Overview: Attendees will learn how police and prosecutors attempt to use unvalidated forensic gunshot audio detection evidence in criminal trials. This presentation will discuss the forensic method employed by ShotSpotter®, Inc. to detect and locate gunshot events in complex urban environments. This presentation will describe the substandard approach taken by ShotSpotter® to validate their forensic method, as well as the inaccurate claims made by ShotSpotter® regarding the performance of their forensic method. Finally, attendees will learn how such unvalidated evidence cost Michael Williams his freedom when he was charged with murder based largely on forensic evidence generated by ShotSpotter®.

Impact Statement: The forensic science community will gain an inside look at the forensic method employed by ShotSpotter®, a method that has undergone very little scrutiny in the forensic science community. The forensic science community will gain new insights into the inadequate attempts by ShotSpotter® to validate their method and will also gain critical knowledge of the bases relied upon by ShotSpotter® when making performance claims about their forensic method. The result of this presentation will be to spur on vital outside scrutiny of the ShotSpotter® forensic method, which has been lacking for many years.

Michael Williams was charged with murder based on evidence generated by the ShotSpotter® forensic method despite the fact that the ShotSpotter® method has never undergone meaningful scrutiny by the forensic science community and despite the fact that the method has never been adequately validated for use in criminal trials. The lack of scrutiny stems, in part, from the fact that most in the forensic science community and the criminal justice system know very little about the ShotSpotter® method and its weaknesses and limitations. While ShotSpotter® has repeatedly issued claims about the performance of their forensic method, such as a false positive rate below 1%, these claims are not scientifically derived and fail to provide an accurate assessment of method performance. This presentation will discuss the ShotSpotter® method, performance claims by ShotSpotter®, and how those claims fail to tell the true story of ShotSpotter® method performance. This presentation will describe how the ShotSpotter® forensic method has avoided scientific scrutiny despite widespread use in the criminal justice system. Through the example of the Michael Williams case, this presentation will describe how police and prosecutors used questionable ShotSpotter® evidence to charge Mr. Williams with murder and incarcerate him for nearly a year before prosecutors decided to dismiss the charges, and will further discuss how prosecutors use their discretion to avoid litigating the reliability and admissibility of evidence generated by the ShotSpotter® evidence. Finally, this presentation will call for more transparency from ShotSpotter® as well as meaningful scrutiny from the forensic science community.

ShotSpotter®, Gunshot, Audio

F30 The Dangerous Creep of Investigative Forensic Techniques Into Criminal Trials

M. Chris Fabricant, JD, Innocence Project, New York, NY*

Learning Overview: The goal of this presentation is to discuss how forensic techniques such as ShotSpotter®, facial recognition technology, cadaver dog evidence, and others that were developed for investigative purposes are beginning to be introduced in court as direct evidence of guilt. More specifically, this presentation will discuss the pressure to introduce at trial forensic evidence that has led to the identity of a suspect—or to other evidence—but has not been scientifically validated, and how the use of such evidence threatens the fair administration of justice.

Impact Statement: This presentation will impact the forensic community by elucidating how novel—often proprietary—techniques are being pushed into court for purposes beyond the intended use of the technology and before scientific validation. For example, ShotSpotter® was developed to direct police to a geographical area to investigate potential gunshots. Courts, however, have admitted ShotSpotter® evidence to prove gunshots were, in fact, fired. As more and more criminal investigations rely on forensics to develop suspects and/or corroborate prosecution theories, there is corresponding pressure to allow juries to hear all the evidence that led to the arrest/indictment. Courts typically make admissibility rulings based on the facts of the particular case and not on how such rulings influence other courts. A single *Daubert* or *Frye* decision can open the floodgates to the unfettered use of technology that is not sufficiently reliable to make life and liberty decisions. Moreover, and equally concerning, unvalidated technologies are being used to justify a level of police intrusion (e.g., providing the basis for a warrant, or creating, in the case of facial recognition, an unduly suggestive identification procedure that becomes the basis for an arrest). In such cases, courts must allow the accused to confront and interrogate these techniques, even when they lurk in the background because they *create* the more traditional evidence that then ends up in court.

DNA exonerations over the past 30 years have demonstrated the unacceptable risk of the introduction of unvalidated and unreliable forensic sciences in criminal trials. Evidence that began as investigative techniques, such as bite mark evidence, were accepted by one court in one case, leading to widespread acceptance by courts across the country—and over 30 wrongful convictions and indictments.¹ Over the past decade, there has been a proliferation of proprietary forensic techniques marketed to law enforcement agencies as infallible. As these techniques come online, there is inevitable pressure by law enforcement to allow juries to hear evidence that may or may not be reliable. Moreover, expert witnesses in these emerging areas often have a financial interest in courts' acceptance of the method. As society becomes ever more dependent—and credulous—of technology, courts must exercise their gatekeeping responsibilities to reject evidence that has not been proven reliable, whether this evidence is the product of the technologies themselves or was obtained using the unreliable technologies and, as such, is similarly suspect. The failure to do so will lead to the same pattern of blind acceptance of unreliable forensics that has resulted in wrongful convictions. This presentation will be an opportunity to learn and discuss how to prevent this cycle from recurring.

F31 A Strict Metrological Approach to the Validity as Applied of DNA Profiling

Veronica Scotti, JD Politecnico di Milano, Milano, MI, Italy; Alessandro Ferrero, MSc, Politecnico di Milano, Milano, MI, Italy*

Learning Overview: After attending this presentation, attendees will have a better understanding of the different uncertainty contributions that may lead to doubts about the reliability of DNA profile extraction and how they should be estimated to assess the validity as applied in each specific case.

Impact Statement: This presentation will impact the forensic science community by presenting a scientifically sound method for estimating the probability that possible errors in the obtained DNA profiles may lead to incorrect decisions.

Validity and reliability of DNA profiling methods have been discussed since the very first application of this method in the forensic field and the discussion has never stopped, mainly because of the number of miscarriages of justice originated by incorrect interpretations of the obtained profiles.¹

This discussion has mainly considered the random match probability and its correct evaluation (especially when cold hits are considered) as the main parameter for assessing the validity of DNA profiling methods.¹ However, it was also proven that the presence of false positive errors may significantly affect the maximum likelihood ratio used to weigh the plausibility of the inclusion hypothesis with respect to the exclusion one.²

Several contributions are available aimed at evaluating the probability of false positive errors, but they are mainly based on the analysis of Quality Assurance (QA) issues detected by the forensic labs.³⁻⁵ While these are interesting contributions, showing that errors are possible, they cannot be applied to each single DNA evaluation and do not consider errors that could not be identified by the QA system. This approach does also neglect two important points:

Most steps in DNA profile extraction require accurate measurement procedures directly related to the material under test (DNA quantification, fluorescence, etc.) or to influence quantities (such as temperature), and measurement uncertainty may affect the final result.

There is a growing request for forensic labs to be accredited according to **International Organization for Standardization (ISO) 17025** standard, that mandatorily requires uncertainty evaluation.⁶

This presentation will discuss these points and how the evaluation of all uncertainty contributions, including those coming from the analysis of QA issues, is expected to provide a reliable estimate of the probability of wrong identification in the specific considered case. Reference to the Amanda Knox case is also considered, since exoneration was based on similar considerations.

Forensic Metrology, DNA Profiling, Validity as Applied

F32 Making Something Out of Nothing: The Inconclusive Fallacy

Kelley Kulick, JD, Santa Clara County Public Defender's Office, San Jose, CA; Mark Perlin, PhD, MD, Cybergenetics, Pittsburgh, PA*

Learning Overview: After attending this presentation, attendees will understand the significance of an “inconclusive” forensic result. They will learn how to prevent the unethical misuse of inconclusive results, promoting relevant and reliable forensic evidence in the courtroom.

Impact Statement: This presentation will impact the forensic community by educating both lawyers and scientists about the ethical considerations and serious risks inherent in the admission of inconclusive DNA results into evidence.

“You can’t get something for nothing”—First Law of Thermodynamics

“ $0+0=0$ ”—Immediate from the Peano Postulates of Natural Numbers

“Nothing will come of nothing”—King Lear, Act I, William Shakespeare

It is well known in science, mathematics, and literature that one cannot create something out of nothing. Adding together an infinite number of zeros still sums to zero. But in forensic science, some lawyers argue that the absence of forensic evidence implies guilt. That “inconclusive” DNA evidence means that the defendant is “included” in DNA evidence. This fallacious reasoning is wrong and dangerous.

The argument goes like this. First, a forensic expert reports that some evidence (DNA, for example) is “inconclusive” for a defendant. Then, an attorney has their expert agree that, based on these “inconclusive” results, the defendant “cannot be excluded” from the DNA evidence. The lawyer goes on to tell the jury that since the defendant cannot be excluded, he “must be included” in the DNA evidence and, therefore, is guilty as charged.

This logical fallacy misapplies the “law of the excluded middle.” The lawyer is incorrectly saying that the defendant must either be “excluded” or “included” from the evidence; there is no other possibility. But there is a third possibility—the evidence is “inconclusive”—and so no “excluded” or “included” determination can be made.

Expressed as a Likelihood Ratio (LR), when an LR match statistic equals one, there is no support in the evidence for a hypothesis (e.g., defendant inclusion) or its alternative (exclusion). Scientists use the logarithm of the LR to express information. The log of 1 is 0. So, there is zero information about inclusion or exclusion. Zero is not a positive log(LR) supporting inclusion, nor is zero a negative log(LR) supporting exclusion. A zero log(LR) means zero information.

Many crime laboratories apply thresholds to their statistical LR results. Even though they calculate an informative match statistic (say, an inclusionary $LR=1,000$, or an exclusionary $LR=1/1,000$), they do not report this LR and instead call the result “inconclusive.” Better science would have them report the LR value, along with an error rate that provides context for the jury (for example, given the chance that someone who didn’t leave their DNA in the evidence would have a match statistic as strong). That helps prevent the unscientific transformation of informative DNA evidence into inconclusive results.

Arguing that “inconclusive” forensic non-results imply guilt is not admissible evidence. An “inconclusive” statement has no probative value—it has no ability to make a relevant disputed point more true or less true. Moreover, Federal Rules of Evidence (FRE) Rule 403 on relevant evidence permits courts to exclude even relevant evidence, should its probative value be substantially outweighed by a danger of unfair prejudice, confusing the issues, or misleading the jury.

This presentation introduces the “inconclusive fallacy,” where lawyers concoct something nonsensical out of nothing forensic. This presentation will illustrate the fallacy’s misuse in recent criminal cases where “inconclusive” arguments harmed justice and will discuss the ethical implications of misleading a jury through non-probative forensic evidence. Practicing trial lawyers need to be aware of this maneuver so they can raise timely objections to vacuous arguments that subvert forensic science.

Inconclusive, Forensic Reporting, Error Rate

F33 The Impact of Post-Traumatic Stress Disorder (PTSD) on the Crime Scene: Expected Results

Donatella Curtotti, PhD, Department of Law, Foggia, Italy; Giovanni Messina, PhD, Foggia, Italy; Francesco Sessa, PhD*, Department of Clinical and Experimental Medicine, Foggia, Italy; Wanda Nocerino, PhD, Department of Law, Foggia, Italy; Fabrizio Vanaria, MD, Department of Medical, Surgical, and Advanced Technologies, G.F. Ingrassia, Catania, Italy*

Learning Overview: After attending this presentation, attendees will have a better understanding of a correct Crime Scene (CS) approach.

Impact Statement: This presentation will impact attendees in terms of competence (ability) and performance (competence put into “action”) in handling the pressure and post-traumatic stress at the CS.

Forensic sciences aim to provide answers to the questions underlying a criminal event, through the examination of the CS. Experts belonging to different forensic branches are called to gather evidence, but the identification of such evidence and how it is linked to the crime is often difficult due to the shortage of specialized personnel, the lack of suitable professional equipment, and the convulsive conditions.¹ In this regard, the emotional implications deriving from the examination of particularly bloody crime scenes should not be minimized.

It has been noted that in repeated activities at the CS, some operators show particular behavioral evidence, manifesting a state of Post-Traumatic Stress (PTS). Repeated exposure to this stress due to the nature of the profession can result in Post-Traumatic Stress Disorder (PTSD). In PTSD, individuals experience extreme terror, helplessness, and pain after witnessing extremely painful and traumatic cases, such as murders, acts of terrorism, and suicides of family members and colleagues, even if they are not directly exposed to harmful or threatening situations.

Stress induces the activation of the Sympathetic Nervous System (SNS) and of the Hypothalamic-Pituitary-Adrenal axis (HPA), modifying a whole series of biological parameters.²⁻⁴ Consequently, the conditions of emotional stress can affect the rational abilities of the operators who intervene in various ways on the crime scene (first aid personnel, first responders, the Crime Scene Investigator [CSI] team), causing cognitive biases that can alter the logical reasoning that must always characterize intervention on the CS.

Due to the centrality of the examination of the CS in the criminal trial, the University of Foggia in collaboration with the Italian Scientific Police, is conducting research (still in the testing phase, to be finished by December 2021) to verify whether the post-traumatic emotional stress disorders of the operators approaching the CS may affect (and to what extent) the results of the investigations conducted, in terms of the efficiency of the results acquired there.

The aim of this paper is to share the preliminary results of this experiment on the stress conditions of operating personnel on CS, distinguishing between first aid personnel, first responders, and the CSI Team.

The verification process was staggered as follows:

Administration of a questionnaire of investigative habits. First, an online questionnaire has been distributed to a selected number of subjects belonging to different professional associations engaged in CSI.

Collection of information on personal experiences of stress and anxiety on the CS. Participants are asked to report on the state of stress, anxiety, and coping mechanisms. To measure stress levels, the Perceived Stress Scale (PSS), the Police Stress Questionnaire (PSQ), and the Distress Thermometer will be used.

Questionnaire elaboration and evaluation of the impact of PTSD on the CS. The following parameters shall be assessed at this stage: emotional intelligence; death anxiety; and PTS. The following dosages are performed at time 0 (time of enlistment), time 1 (after three months), and time 2 (six months), correlating them with the events the subject has witnessed.

Results of the experiment and possible drafting of a standardized operational protocol. According to the response of the experimentation, solutions will be advanced to contain the risk of investigative errors caused by emotional stress. In particular, it will evaluate the opportunity of resorting to the introduction of Standard Operating Procedures (SOPs). The provision of adequately detailed and meticulous standardized procedures could neutralize the dangers deriving from the errors of reasoning of CS operators caused by personal traumatic experiences.

F35 When DNA Lies: One Family's Reckoning With an Erroneous Test Result

Melanie Armstrong, BA, ThroughLine Consultants, Vienna, VA; Tynan Peterson, MA, ThroughLine Consultants, Oakland, CA*

Learning Overview: After attending this presentation, attendees will better understand the power of genetic genealogy and its use in a new context.

Impact Statement: This presentation will impact attendees by sharing a landmark case in which genetic genealogy found the truth despite previous scientific evidence to the contrary.

Genetic genealogy combines autosomal DNA data from at-home DNA tests with traditional genealogical research to determine the level and type of genetic and familial relationship between individuals. Most often used to help identify an adoptee's likely birth parents or the unknown parent of a child of a Non-Paternity Event (NPE), genetic genealogy has also relatively recently been used as an effective crime-fighting tool—helping to identify criminals, exonerate the innocent, and give names to victims of violent crimes, also known as Jane and John Does. While genetic genealogy has been used for years, the rise in popularity of consumer DNA tests continues to increase the effectiveness of this approach. There are more databases and more samples in those databases, making searches easier. They are more popular globally, enabling cross-border and international searches. This explosion of data broadens the range of situations in which genetic genealogy can uncover the truth. The uses of forensic genetic genealogy—genetic genealogy in a legal context—are continuing to evolve. Fertility fraud cases—where fertility doctors have impregnated their patients under false pretenses—are on the rise. In addition, instances of rape and incest—and their perpetrators who fathered children—are being identified for the first time.

The unique case study presented in this session will show how genetic genealogy was used in yet another legal context. Twenty years ago, a custody battle was settled based on the results of a paternity test. A family was torn apart and the child's parentage a complete mystery. Eighteen years later, a genetic genealogy analysis correctly identified the birth father and proved that the long-ago paternity test was wrong. A new paternity test confirmed these results and revealed how the first test was mishandled by the original lab. The family was divided because of human error. In one of the first cases of its kind, the impacted family is pursuing legal action against the two companies responsible for the original test, suing both for negligence "in obtaining, labeling, handling, testing, and reporting tests results." The case is working its way through the legal process.

The implications of this case are vast: credibility and accountability of DNA labs, irreparable damage to families, and legal precedence, to name a few. In this case, there is a strong possibility that another family also received inaccurate results and is still unaware of the mistake. DNA doesn't lie, but to err is human. Genetic genealogy is a powerful investigative tool that can bring the truth to light.

Genetic Genealogy, Forensic Genetic Genealogy, DNA Testing

F36 Cannabis Green Tongue: Anecdotal Science and Legal Fiction

Gerald Feigin, MD, Gloucester Medical Examiner Office, Sewell, NJ; Gil Sapir, JD, MSc, Chicago, IL*

Learning Overview: After attending this presentation, attendees will understand that a “green tongue” is a toxicological and legal fiction for cannabis use.

Impact Statement: The forensic science community will be impacted through anecdotal green tongue’s non-compliance with scientific standards for evidential use.

Police officers use the purported “objective” observation of a dorsal “green tongue,” “green coating,” “green film,” and “green tint” as one of several signs to justify probable cause for arrests in Driving Under the Influence of alcohol or Drugs (DUI/DUID).¹ However, there is no supporting scientific evidence, case law, or authority for it. The “green tongue syndrome” is more of an interest and misuse of police science than actual toxicology. A review of relevant literature provides an anecdotal basis for a green tongue from smoking cannabis.²

Probable cause is commonly defined as: A reasonable ground to suspect that a person has committed, or is committing a crime, or that a place contains specific items connected with a crime.³ Being a marijuana user, by itself, is not reasonable suspicion or probable cause.

A green tongue is caused by food coloring, including FD&C green No.3 or a mix of Blue 1 or Blue 2, Yellow 5, and Food and Drug Administration (FDA) -approved grape skin extract or disease.^{4,5} The most common disease is thrush, a fungal infection, caused by the yeast *Candida albicans* with a minimal faint green color.³

The green component in marijuana is chlorophyll. Chlorophyll is denatured by heat at 60°C and, therefore, cannot stain a tongue green.⁶ The chemical and physical composition of cannabis smoke does not contain chlorophyll.⁷ Tobacco and cannabis do not color the tongue when smoking cigarettes or vaping.⁸ Smoking marijuana will not cause a green tongue.

Law enforcement, Drug Recognition Experts (DRE), and the National Highway Traffic Safety Administration (NHTSA) primarily rely on dated, unreliable, and misquoted articles taken out of context, without supporting authority, to infuse credibility for a subjective cannabis determination. Furthermore, cited literature omits chlorophyll heat degradation. The current February, 2018 Drug Recognition Expert Course manual states, “possible green coating on the tongue” and “a greenish coating on the tongue has been documented in two peer-review articles.”⁹⁻¹¹ Proponents of green tongue identification often employ numerous qualifiers throughout related articles without definitive empirical data, thereby subjecting the content to speculation, conjecture, and unreliability.^{12,13}

DREs through law enforcement and NHTSA are serial anecdotalists. DREs testify that “outward signs that somebody may be under the influence of [marijuana]” include (1) “raised taste buds,” (2) “a green stripe down their tongue,” that “looks like a dull green film on their tongue” and results from “marijuana debris and film in their mouth.”¹⁴

“‘Junk science’ is the mirror image of real science, with much of the same form but none of the same substance.”¹⁵ Junk science or pseudo-science routinely consists of flawed, unreliable, exaggerated, and sometimes fabricated testimony usually founded on questionable methodology.

Law enforcement, NHTSA, and DREs are purveyors of green tongue fiction and irreparable harm. The scientific accuracy and legal reliability of a green tongue for cannabis use is unsubstantiated in current scientific literature. Green film tongue syndrome should be considered pseudoscience or junk science. It cannot be employed or referenced with any aspect of DRE training and law enforcement use. Accordingly, a green film tongue is not a reasonable suspicion or probable cause for a determination of cannabis use.

Green Tongue, Probable Cause, Junk Science

G1 Forensic Odontology—Where We’ve Been, Where We Are, and Where We Are Going: Part 2

David Williams, DDS, Howard County Community College, Columbia, MD*

Learning Overview: At the completion of this presentation, the attendee will be able to apply the Stevens Nonprofit Lifecycles to the Odontology Section and understand the challenges and opportunities for the future.¹

Impact Statement: This is the continuation of a study presented in a 2008 AAFS meeting, with the addition of data from 2021. It will compare the data with a “non-profit lifecycle” model as described by Stevens to help determine, within this hypothetical lifecycle, the stage of the Odontology Section and the potential challenges and opportunities for the future of the Section.¹

Meeting and surpassing the challenges of a modern forensic world requires the support of a strong organization. Continued robust support for the practice of forensic odontology is critical for the science to evolve. The Odontology Section is one of the newer sections in the American Academy of Forensic Sciences, with only 2 of the 11 sections having been composed since the Odontology Section was started in 1970. Stevens proposes a lifecycle for non-profit organizations to aid officers’ and members’ understanding of the development of their organizations, which can move through stages that may include:

- Idea: A solution or vision for a community need has been identified and developed.
- Startup: The organization is out to prove the business’ case by experimenting with program design.
- Growth: This stage focuses on standardizing and deepening programs to meet the needs of constituents and formalizing structures and processes to ensure organizational vitality.
- Maturity: Formal organizational structures and processes have been established.
- Decline: The organization has settled into a prescribed way of doing things, slowly losing touch with clients and resisting the programmatic adaptations necessary to meet changing community needs.
- Turnaround: Organizations are in the process of regaining the market.
- Terminal: When an organization has declined too far, a turnaround is unsuccessful, or a startup never finds its place.

It is critical for members—and particularly leaders—of organizations to understand where in the cycle their organization is so that opportunities are not missed and challenges can be overcome.

This is the extension of a study presented in the 2008 AAFS meeting, with the addition of data from 2021. This presentation will provide the attendee with a comparison of the demographic data of members of the Odontology Section of the American Academy of Forensic Sciences over a 24-year period from 1997 to 2007 and also from 2022. It will additionally outline the areas in the development of forensic odontology and how these developments are related to Stevens’ Nonprofit Lifecycle theory and provide some insight into the potential future developments and challenges that may impact the discipline and what can be done to improve the likelihood of long-term survival.

A convenience sample was taken from the Odontology Section of the American Academy of Forensic Sciences Members’ directory from 1997, 2007, and 2021. The total number of section members, membership status, sex, and state/country of residence were extracted for analysis. The results will be presented so that the attendees will see the changes in the membership of the Section over the past 24 years and help identify challenges to and opportunities for the future of the Section.

Forensic Odontology, Membership, History

G2 Deaths After Tooth Extraction and Treatment in the Dentist's Office in Turkey

Huseyin Afsin, PhD, Bezmialem University, Kocamustafapasa, Istanbul, Turkey; Gulnaz Javan, PhD, Alabama State University, Montgomery, Alabama*

Learning Overview: After attending this presentation, attendees will be able to utilize the data presented in order to evaluate the prevalence of deaths after dental procedures and their corresponding criminal penalties in Turkey.

Impact Statement: This presentation will impact the forensic science community, the prevalence of deaths after dental procedures, and such deaths' legal consequences in Turkey.

Death is a rare occurrence in current dental practice. Despite the correct aseptic precautions taken by dentists, infection can result from various dental procedures such as tooth cleaning and filling, water contamination, and tooth extraction and root canal procedures. Such deaths are the most common emergencies that take place during dental surgery and primarily occur during tooth extraction and dento-alveolar surgery and usually occur in patients with bleeding disorders, allergic reactions, and epilepsy and because of the lack of sterilization of the medical instruments used and/or the lack of practice. Death can be caused by the obstruction of the airways because of a hypersensitivity reaction or an asthma attack, vomit, or swallowing or aspirating foreign objects such as cotton rolls or dental instruments from the operating area. Anaphylactic reactions to drugs used in dental procedures are dangerous and life-threatening pathological conditions that can lead to patient death unless the dentist is specially trained to recognize these conditions and act promptly.

This study examined 18 cases consisting of 11 men and 7 women who died because of dental treatment and whose deaths were reported by the news media. This chain of incidents started at dentists' chairs and ended in death. This study followed victims' treatments and litigation processes. Victims in 14 of the cases were under local anesthesia, 3 were under general anesthesia, and 1 was under chloroform superficial anesthesia. First interventions on 11 victims took place in private dental offices, and 7 took place in public hospitals. Dentists performed the first emergency responses on 14 of the subjects, followed by dental technicians who intervened in 3 cases, and an otolaryngologist who performed the first emergency treatment on 1 of the victims. Of the cases, 5 died because of endocarditis, 5 because of infection (sepsis), 4 because of bleeding, and 4 because of allergic reactions. In 3 cases, the victims died of a cardiovascular event following anaphylactic shock. One died as a result of nose surgery. In one case, although the otolaryngologist who performed the surgery claimed that his patient had died of poisoning from orthodontic braces, this claim was not found credible by the court, and monetary and legal penalties were levied for malpractice. Three dental technicians were given prison sentences ranging from four to five years because of the lawsuit. Dentists and anesthesia technicians who intervened during general anesthesia received monetary and legal penalties for malpractice. Other cases were found to be the result of natural causes.

As dental professionals know, the extraction of teeth can be an especially disturbing and frightening procedure; therefore, some patients prefer general anesthesia for this procedure. It is important that the dentistry practice complies and follows the minimum anesthesia standards while performing these procedures. Dental restorations performed using general or local anesthesia in elderly, disabled, or pediatric patients are not without risk, either. Outpatient dental procedures using general anesthesia are particularly risky for children because they are more likely to experience a lack of oxygen than are adults. There is also always a chance that bleeding will occur after a tooth has been removed. No deaths as the result of bleeding after normal dental surgical procedures have been reported in the literature. However, dental and medical emergency services should be familiar to staff members and available for dealing with these situations. Odontogenic and other acute oral infections can spread rapidly and dramatically. The dentist should therefore know when infections can be treated in the general practice and when the patient will be better served by a referral to a specialist or admittance to a hospital. Dentists should always comply with the routine procedure criteria and, especially, the anamnesis/indication details before and after the intervention.

Forensic Odontology, Death, Emergency

G3 Dental Evidence of the Human Remains of a Slavic Soldier Population Deported to Concentration Camps During World War II

Federica Mele, MD, University of Bari, Bari, BA, Italy; Antonio De Donno, MD, University of Bari, Bari, BA, Italy; Sara Sablone, MD, University of Bari, Bari, BA, Italy; Mariagrazia Calvano, MD, University of Bari, Bari, BA, Italy; Mirko Leonardelli, MD, University of Bari, Bari, BA, Italy; Stefano Duma, MD, University of Bari, Bari, BA, Italy; Enrica Macorano, MD, PhD, University of Bari, Bari, BA, Italy; Valeria Santoro, PhD, University of Bari, Bari, BA, Italy; Francesco Introna, MD, University of Bari, Bari, BA, Italy*

Learning Overview: After attending this presentation, attendees will have a better understanding of the dental health status of soldiers during World War II.

Impact Statement: This presentation will impact the forensic science community by presenting evidence from the dental remains of Slavic soldiers who fought in World War II.

Aims: Dentition is one of the most useful hard tissues in anthropological and forensic analysis because of its resistance to different environmental factors, such as postmortem modification, high temperatures, and other extreme conditions.¹ Teeth provide valuable information about dietary habits, general health issues, and personal identification.² The aim of this presentation was to analyze the postmortem dental records of a collection of 93 skeletal remains exhumed from the ossuary of Bari Municipal Cemetery in Apulia, Italy. These skeletal remains belonged to Slavic soldiers who were deported in 1941 during World War II to two Italian concentration camps and who died in 1946–1947. Subsequently, the bodies were buried in the Monumental Cemetery of Bari, and their human remains were exhumed in 2019 from the ossuary and inventoried in the Institute of Forensic Medicine of Bari.

Methods: A total number of 1,949 teeth were analyzed according to the American Board of Forensic Odontology and the World Health Organization (WHO) methods. The majority of the victims were men (95%) between the ages of 18 and 62 years. The dental evidence of these Slavic soldiers varied among different classes of age and different dental elements.

Results: The results showed the dental health of a population of World War II soldiers—in particular, the high rates of caries (35%), periodontal disease (61%), and dental wear (65%)—according to the high stress levels of the soldiers during the armed conflict and their subsequent deportation. It is well-known that the Holocaust dramatically affected the mental and physical status of the deported subjects and led to significant health consequences. Locomotion and cardiovascular systems were mainly affected, but very few data are reported in the literature about the dental health status of soldiers in concentration camps and of those who died during World War II.³

Conclusions: This is the first study reported in the literature that analyzes the effects of war and deportation on soldiers' oral health status. This analysis also confirmed the usefulness of teeth for anthropological and forensic research because of their high resistance to and preservation despite postmortem modifications and varying environmental factors.

G4 Dental Injuries During General Anesthesia: Risk Management and Forensic Perspectives

Emilio Nuzzolese, DDS, PhD*, University of Turin, Turin, Italy; Giulio L. Rosboch, MD, University of Turin, Turin, Italy; Fabio Innocenzi, MD, University of Turin, Turin, Italy; Davide Santovito, MD, AOU Città della Salute e della Scienza, Torino, Italy; Francesco Lupariello, MD, University of Turin, Turin, Italy

Learning Overview: After attending this presentation, attendees will have an understanding of the risks and causes of dental damages during general anesthetic procedures and how to evaluate accidental versus non-accidental lesions due to negligence.

Impact Statement: This presentation will have an impact on the forensic community by presenting the retrospective analysis of dental injury claims and by offering a possible solution to reduce damage from the forensic analysis of the dental lesion and intubation dynamics via the use of a tailored and 3D-printed splint.

General anesthesia requires an endotracheal intubation performed by an anesthesiologist using a laryngoscope to maintain a patient's airway. In complex cases and in patients with dental vulnerabilities, the oral-tracheal intubation procedure can cause dental lesions. According to Givol, dental trauma and injuries represent the main causes of medicolegal compensation claims after general anesthesia.¹ Retrospective studies evaluate an incident rate of 0.02–0.07% of cases; according to other, prospective studies, the percentage rises to 12.1–25%.^{2–7} The teeth most affected are the upper incisors, followed by the lower incisors.^{8–11} The main injuries to the teeth include subluxations, avulsions, enamel injuries, crown fractures, and root fractures.

This retrospective investigation aims to quantitatively and qualitatively analyze the claims received by the Hospital *Città della Salute e della Scienza* of Turin, Italy, that were made by patients undergoing general anesthesia in the period 2011–2020, with the goal of understanding the dynamics of the traumatic events experienced and finding a possible definitive solution for patients with dental vulnerabilities.

Materials and Methods: In the period from 2011 to 2020, the Hospital received 576 claims for compensation, of which 47 were selected as related to dental injuries. Only 24 were found to be secondary to the oral-tracheal intubation procedure. The sample examined represents all patients treated in elective surgery, aged between 22 and 76 years, who were divided into three age categories: <35 years; 35–60 years; and >60 years. Cases were analyzed to evaluate the responsibility of the anesthetist, the oral condition of the patients, and the compensation paid. An anonymous questionnaire was also delivered to 21 anesthesiologists who were working in the same hospital to evaluate their use or misuse of the standard protective splint supplied.

Results: The patients were distributed according to age: Group A, with patients <35 years of age (8.4% of claims were dental related); Group B, with patients between 35 and 60 years of age (41.6% of claims were dental related); and Group C, with patients >60 years of age (50% of claims were dental related). Claims related solely to dental treatments ranged from €300 to €10100 in those cases of assessed negligence. The teeth most commonly involved were the central and upper lateral incisors (in 87.5% of the cases), the lower incisors (in 12.5% of the cases), and the lower canines (in 4.1% of the cases). The anesthesiologists interviewed confirmed either sporadic use, or even misuse, of dental protective devices in 61.9% of the cases; 66.67% of those surveyed said they would definitely use a protective splint, but that the splint should be thinner and tailored to the individual patient.

Discussion and Conclusions: The forensic analysis of the claims for dental damage highlights that patients' poor oral health is one of the principal causes of dental damage during intubation but that the misuse of the protective device supplied by the hospital is often a contributing factor. Once a dental vulnerability has been identified by the anesthesiologist through the collection of the patient's medical and dental history, a dental visit should be requested to evaluate the dental fitness of the patient.¹² Dentists should treat teeth at high risk of damage (that is, with old restorations or critical periodontal conditions) and/or proceed with a custom-made protective splint for the patient to wear prior to the endotracheal intubation, which would significantly reduce the risk of dental damage.¹³ Per this study, the best outcome in the protection of teeth during tracheal intubation procedures can be achieved by using an intraoral scan of the patient and a custom-made, 3D-printed mouthguard.

G5 The Role of Charting Dental Anomalies in Human Identification

Jayapriya Jayakumar BDS, MSc, University of Dundee, Dundee, Scotland, United Kingdom; Sheila Manica, DDS, MSc, PhD, University of Dundee, Dundee, Scotland, United Kingdom*

Learning Overview: In forensic odontology, the comparative dental analysis of Antemortem (AM) dental records and Postmortem (PM) dental findings completely depends on the reliability of the dental records received. The more accurate, complete, and up-to-date the dental records are, the easier and faster the identification process will be. Unreliable dental records may lead to wrong conclusions when it comes to human identification. It is seen that only strict medicolegal and ethical codes would encourage clinicians to keep adequate dental records of patients. In numerous countries, even though laws on the maintenance of dental records exist, many dentists do not maintain adequate dental records. Through this session, the presenter hopes to create awareness among all attendees (mainly forensic professionals and clinical practitioners) on how dental anomalies can be used for human identification and how the accurate recording of every single feature/anomaly in the oral cavity can, directly and indirectly, impact human identification in the future.

Impact Statement: Although identification using teeth is considered to be one of the easiest, most reliable, and most economical methods of human identification, it is still not utilized up to its potential in several countries. From the survey conducted, it was observed that the awareness of forensic odontology among dentists was exceptional, but that the charting of dental anomalies was poor. This presentation (with the help of autopsy cases as examples) will prove that even a single dental feature/anomaly can help in identification if that feature/anomaly is described correctly in the form of dental charts or recorded in the form of radiographs, photographs, or casts that constitute the AM dental records. As a result of this study, “The Atlas of Dental Anomalies” and “The Scale of Forensic Significance of Dental Features” were designed to aid the charting of dental anomalies and to understand their forensic significance in human identification. This understanding would help create better, more reliable, and more up-to-date dental records that can be used for forensic identification purposes in the future and on a global scale.

An increase in the awareness of dental hygiene among people over the years consequently provoked a significant decrease in the occurrence of dental caries and, thus, a decrease in the number of dental restorations. This improvement of oral health affected the comparative dental analysis using dental treatments for human identification; hence, existing dental features or anomalies could act as unique identifying features. This study evaluated the awareness of dentists on charting dental anomalies using a dental-charting task and addressed the importance of maintaining dental records for forensic and medicolegal purposes. An online survey-based study was conducted of 101 dentists practicing in the South Indian states of Karnataka, Kerala, and Tamil Nadu using Google® Forms. Results showed that clearly visible anomalies such as midline diastema, crowding, and transposition were mentioned by only 11.8%, 22.7%, and 5.9% of the respondents, respectively. In addition, 17.8% misnamed the accessory cusp on a premolar as a Talon’s cusp. The awareness of forensic odontology among dentists was exceptional, but their dental charting needs improvement.

A “Scale of Forensic Significance of Dental Features” was created to interpret the accuracy when recording anomalies and was comprised of three parameters, namely: Incorrect answer (0%), Partially Correct answer (50%), and Accurate answer (100%). The parameters classify different levels of forensic significance of dental findings in human identification. Only a few respondents submitted an Accurate or a Partially Correct answer, and, as a result, an Atlas of Dental Anomalies (www.theatlasofdentalanomalies.com) was created to rectify this poor pattern of dental charting, as the site can be used as study material for dental students, as a checklist for dental nurses and hygienists/assistants, and/or as reference material for dentists (or police, lawyers, or other laypeople). This site not only creates awareness of dental anomalies but also acts as a reminder of the correct terminology for those who tend to misname anomalies. The Atlas of Dental Anomalies along with the Scale of Forensic Significance of Dental Features were designed to improve the charting of dental anomalies and to explain their forensic significance in human identification, which in turn helps create better, more reliable, and more up-to-date dental records that can be used for identification purposes on a global scale.

Forensic Odontology, Dental Anomalies, Human Identification

G6 Smile Selfie Images in Forensic Dental Identification: A Novel Procedure Proposal

Hugues Grégoir, DDS, Université Libre de Bruxelles, Bruxelles, Belgium; Anna Ravera, DDS, Université Libre de Bruxelles, Bruxelles, Belgium; Emilio Nuzzolese, PhD, Università di Torino, Turin, TO, Italy*

Learning Overview: After attending this presentation, attendees will understand how the identification process of human remains can benefit from the supplementary dental information detectable from smile selfie images of missing persons.

Impact Statement: This presentation will have a positive impact on the forensic community by presenting the results of a structured protocol on the visual comparison of images of front teeth by forensic odontologists and dentists and the protocol's application in the field of forensic dental identification.

The collection of postmortem dental evidence from unidentified human remains is fundamental to the initial reconstruction of—as well as to the definitive comparative identification of—those remains.¹ The main challenge of dental identification may be collecting antemortem dental data from dental clinics and hospitals. However, relevant dental data may be available from the family of the missing person by conducting a thorough interview and collecting dental information that is in the home of the missing person or victim, information that could be converted into useful secondary forensic antemortem identifiers. For example, old radiographs or dental devices or orthotics such as a bruxism bite, a sports mouthguard, bleaching trays, and orthodontic retainers are examples of these identifiers. In this regard, a portrait showing the person smiling can provide identifying features that could lead to the comparison of postmortem and antemortem dental data.^{2,3} This study processed smile selfie images for the purpose of introducing a structured protocol as a supplementary tool in forensic dental identification.

Materials and Method: A sample of 253 people was recruited on a voluntary basis. Each person was asked to take a selfie while smiling and showing the front teeth. These images were considered antemortem photos found on a victim's phone or social media profiles; 71 of the 253 people were also asked to take an intraoral picture for the purpose of simulating postmortem pictures. Five odontologists were involved in a blind and random comparison of the images to evaluate the degree of recognition of the 71 images from among the 253 smile selfie images sampled.

Results: The visual comparison had an average recognition of 65.5%. The Shapiro-Wilk test showed normality of the study, and the Student test showed no significant differences among the observations of the operators involved. This study observed that the shift variables of the front upper incisors presented the least differences and that the axis of central and lateral incisor edges—rounded or straight—were the variables most easily identified. Conversely, the offsets of the lateral incisors in relation to their adjacent central incisors were the criteria with the most subjective differences among the operators. The features that were best recognized by all operators were the axes of the front incisors and the shapes of the central upper incisors' edges

Discussion: This analysis demonstrated a recognition rate of more than 50%, which is not sufficient to make this process reliable in a disaster victim identification scenario but is sufficiently reliable for application in single identification cases when also applying the exclusion criteria. The shooting angle of the photographic snapshot and the lens distortion can lead to interpretation errors when teeth do not lie on the sample plane because they are either more lingual or more vestibular. This study recognizes that visual recognition is not a reliable enough method to use in human identification, but that visual recognition can be used as a preliminary sorting tool when dental features, such as diastema, malpositions, rotations, pigmentation, crown morphology, dental piercing, and restorations, are visible on the front teeth.⁴

Conclusion: A selfie picture search on social media should be performed by forensic odontologists as adjunct data in the preliminary reconstructive identification process. Smile selfie pictures can be used in the preliminary search of compatible reported-missing persons as supplementary data and when dental records are not yet available. The proposed protocol and the current state of research on the smiling selfie are showing promising developments when combined with artificial intelligence and facial recognition software.

Selfie Images, Dental Identification, Dental Autopsy

G7 Computer-Aided Dental Identification Using Intra-Oral Scanning Techniques

Lise Malfroy Camine, DDS, MSc, Institut de Recherche Criminelle de la Gendarmerie Nationale, Pontoise, France; Aimé Conigliaro, MSc, Institut de Recherche Criminelle de la Gendarmerie Nationale, Pontoise, France; Gilles Amador Del Valle, DDS, PhD, Nantes University, Nantes, France*

Learning Overview: Attendees will learn the different steps of an innovative protocol for dental surface comparison, with perspectives in forensic identification. The first results of its feasibility study will be exposed.

Impact Statement: This presentation proposes an innovative protocol for individual identification based on comparing dental surfaces obtained by the Intraoral Scanning Technique (IOST), which represents a complementary tool in difficult Disaster Victim Identification (DVI) situations that have limited access to radio-imaging. This method would give experts quantitative decision criteria in little time and with little equipment necessary.

Because of its recent development in dental practice for prosthetic and orthodontic purposes—but also as a medicolegal tool—the IOST represents a growing and promising source of Antemortem (AM) data: It allows for the long-term preservation of dental morphology and satisfying traceability, digital storage, and transfer. For the same reasons, IOST provides promising Postmortem (PM) material that easily saves 3D-colored representations of the teeth, without contact and even in difficult conditions (burnt remains, constraint mouth opening, etc.).

In cases of airplane crashes or explosions, DVI units may face situations in which sound dental elements or fragmentary teeth are found. With limited radiological imaging available, dental identification may rely on the morphological characteristics of teeth, which is mostly a subjective approach. New methods are needed to use these criteria as objective decision tools.

Based on their acquisitions using IOST, a protocol for a computer-aided comparison of dental surfaces in an identification objective is proposed.

In a preliminary study, ten upper molars from the collection of the Forensic Science Laboratory of the French Gendarmerie (IRCGN) were scanned with a Condor® camera and then implemented in the Cloudcompare® software as .ply files. The dental mesh was converted as a pointcloud, and the occlusal surface was sectorized. Each tooth was scanned twice in order to mimic an AM and a PM sample.

The PM specimens were registered on the AM dental surfaces, and the mean point-to-point distance was calculated for match (PM and AM surfaces from the same individual) and non-match (PM and AM surfaces from different individuals) situations. Intra-operator and inter-operator variability of the method was evaluated.

First results demonstrate satisfying repeatability and reproducibility values and statistical differences between matches and non-matches (5% threshold).

Sensitivity/specificity tests are needed, using appropriate samples; and limitations because of fragmentation, attrition degree, and the use of different IOST devices have to be evaluated. Nonetheless, the proposed method shows promising perspectives, with little material or training required and in a short amount of time, making it particularly important in DVI contexts

Intra-Oral Scanning Technique, Dental identification, 3D

G8 A Catastrophic Bus Crash in Hungary—Another Disaster Victim Identification (DVI) Operation

Ajang Armin Farid, DMD, National Bureau of Investigation, Budapest, Hungary

Learning Overview: After attending this presentation, attendees will have learned about a fatal bus crash that occurred in Hungary in August 2021, where the Hungarian International Criminal Police Organization (INTERPOL) Disaster Victim Identification Team was called in to recover, register, and identify victims.

Impact Statement: This presentation will impact the forensic science community by raising awareness that well-trained DVI teams are essential for the welfare of society.

On August 15, 2021, a bus carrying 56 Hungarian tourists was on its way back to Budapest from Croatia. Two bus drivers took turns driving to and from the Croatian coast and were only an hour away from their destination in Budapest when, because of a mechanical issue, the driver lost control of the vehicle, which drifted off the highway, crashed into the pillar of a bridge, and landed on its side in a ditch. Chaos was reported by witnesses before rescue operation teams arrived at the scene and began to revive and stabilize the severely injured passengers. Eight people lost their lives, among them the driver of the bus, who was decapitated. Two others suffered severe injuries, and 46 had minor injuries. Within two hours of the accident, the DVI Interpol Hungary Team was deployed and arrived at the scene to identify and register the victims. Strict INTERPOL protocol was followed and resulted in the identification of all the victims via dental recognition.

Currently in Hungary, plans are underway to expand the contingent of forensic odontologists and to fully train them in DVI INTERPOL protocol. Because of the pandemic, there were no opportunities to meet new recruits in person and/or to establish in-person training courses for them. However, for more than a year now, regular virtual training workshops have been organized and facilitated by the Hungarian DVI Dental Unit's leadership, who have invited specialists from around the world, mostly American Academy of Forensic Sciences (AAFS) members, who have shared with the participants their learning and experiences about various DVI missions. These courses are now being offered to attendees from all continents and continue to be great sources of learning and development.

These training workshops not only offer the highest standards of education in this important field of forensic science—they also help promote a common vision among those working in the field of DVI internationally, especially in Europe.

In overcoming the challenges we face together as one human family, the concepts of accompaniment and assistance are vital in developing our capacities when chartering our own individual path for progress and growth. Great accomplishments are possible in the field of public service through unity of vision and action and ongoing mutual understanding, collaboration, and support.

DVI, Identification, INTERPOL

G9 Dental Identification in a Case of Purposeful Commingling of Remains by a Toronto Serial Killer Operating in the Gay Community of Toronto, 2010–2017: The Bruce McArthur Case

Taylor Gardner, BFS, Ontario Forensic Pathology Service, Toronto, Ontario, Canada; Yolanda Nerkowski, BA, Royal Jubilee Hospital, Victoria, British Columbia, Canada; Robert E. Wood, DDS, MSc, PhD, Ontario Forensic Pathology Service, Toronto, Ontario, Canada*

Learning Overview: After attending this presentation, attendees will have a better understanding of the planning and management required in the death investigation of a highly politicized case involving multiple victims of homicide attributed to a single perpetrator.

Impact Statement: This presentation will impact the forensic science community by emphasizing the importance of interdisciplinary and interagency collaboration in complex death investigations as well as the need to recognize and address the institutional biases inherent in these investigations that further victimize the marginalized communities being served.

Between 2010 and 2017, several men with ties to Toronto's LGBTQ+ neighborhood known as "The Village" went missing. Two consecutive taskforces were created to investigate these disappearances. Ultimately, Bruce McArthur, a 66-year-old self-employed landscaper, was arrested on January 18, 2018. Police, who had been surveilling McArthur, intervened when a potential victim entered his apartment and was found handcuffed to a bed. A search warrant provided access to McArthur's electronic devices, which provided macabre details of the crimes and their aftermath. A total of eight first-degree murder charges were brought following what would become the largest criminal investigation by the Toronto Police Service and support agencies.^{1,2}

Thirty properties previously visited or serviced by McArthur were systematically searched by police and forensic experts during a Canadian winter. Cadaver dogs focused on very large planter boxes at a residence where McArthur stored some landscaping equipment. The planters were brought to the Forensic Services Complex, where several human remains, in varying states of decomposition, were discovered concealed among the plants and soil. An exhaustive search adjacent to the properties revealed further remains.

A multidisciplinary approach, which involved the expertise of forensic anthropologists, pathologists, and odontologists, was required to analyze and identify the bodies. From an anthropology standpoint, the case was complicated because all the victims were of the same sex and because the remains had apparently been purposefully commingled, with some body parts, including two skulls, missing. Eight deceased victims were subsequently identified using a combination of fingerprint, DNA, dental, and skeletal comparisons, often with several means of identification used to identify each individual. Antemortem dental records were obtained for seven of the victims.

Toronto's LGBTQ+ community has had a long-standing history of distrust of the Toronto Police Service. The Bruce McArthur investigation has spurred an external review of how police have handled missing-person cases. Advocates within the community are hopeful that the review will identify the systemic biases that have negatively impacted vulnerable populations, including racial, LGBTQ+, and recent immigrant groups, populations of which McArthur's victims were members.³

The expansive investigation has reinforced the need for interagency cooperation and the need to ensure that adequate numbers of trained individuals can work together in a careful, expeditious manner in marginalized communities.

Forensic Odontology, Identification, Serial Killer

G10 The Digitalization of Dental Arcades in Forensic Dentistry

Nelson Freitas, MS, Scientific Police of the State of Sao Paulo, Sao Paulo, Brazil; Silvia Nuñez, PhD, Daniel Magalhães, PhD, University of Brazil, Sao Paulo, Brazil*

Learning Overview: This work aims to demonstrate the feasibility of using 3D digitization of dental arches as a subsidy for the anthropological examination of human remains.

Impact Statement: The total time to digitize and create each 3D model in dicom format is about five minutes per arc; once the image is collected, it can be compared immediately or sent over the Web from anywhere in the world for analysis and comparison without the need to mobilize human or bone parts.

Introduction: Forensic dentistry deals with the examination and evaluation of the characteristics of intact or fragmented dental arches, among other characteristics. Forensic dentistry is essential for identifying living or deceased individuals with different means of death, which is essential in mass disasters. This work scanned the dental arches of cadavers to compare the forensic dentist's report obtained by the typical physical method and the 3D-imaging method using a 3D scanner.

Methods: To create a 3D image of the dental arch, a 3Shape TRIOS® scanner was used. The total time to digitize and create each 3D model in dicom format was about ten minutes (five minutes per dental arch). An Instituto Médico Legal de São Paulo (IML/SP) dental examiner and specialist was asked to prepare a legal dental report, and the five dicom models were analyzed by the respective professional using a 3Shape 3DViewer.

Results: According to the evaluation of the forensic dentist, by comparing the legal dental report carried out in the five cases to the corresponding 3D-digitized images, it was possible, via image analysis, to determine individual characteristics that could help in the identification process.

Conclusion: The 3D images helped in cases of unknown and/or unclaimed bodies because it was possible to carry out the reconstruction from the 3D digital scanning and send the images obtained to specialized centers for analysis, without needing to forward the remains, thereby substantially minimizing the costs of transport, time, packaging, chain of custody, and preservation of human parts. After the images are sent over the internet, even with a smart phone, they can be analyzed in specialized centers anywhere in the world.

G11 Second Expert Opinion in Human Identification Through a Virtual, Digital, and Remote Dental Autopsy

Emilio Nuzzolese, DDS, PhD*, University of Turin, Turin, Italy; Ymelda Wendy Velezmore Montes, BDS, Universidad Particular Científica del Sur, Villa, Peru; Wassim Rihawi, BDS, Syrian Forensic Odontology Association, Aleppo, Syrian Arab Republic; Khalid Mohamed Khalid BDS, MSc, University of Medical Sciences and Technology, Khartoum, Sudan; Jayasankar Pillai, BDS, Government Dental College and Hospital, Ahmedabad, India; Baig Mirza Humayoun Temoor, BDS, MSc, University of Health Sciences, Punjab, Pakistan; Hemlata Pandey, BDS, MSc, Seth FS Medical College & KEM Hospital, Mumbai, India

Learning Overview: After attending this presentation, attendees will understand the advantages of teleconsultation in forensic odontology when a second opinion on a dental autopsy could be helpful or appropriate.

Impact Statement: This presentation will impact the forensic community by presenting the innovative process of a virtual, digital, and remote dental autopsy.

The principle behind the human identification process is comparing antemortem to postmortem evidence and the findings from the primary identifiers: fingerprint, DNA, and dental data. The collection, analysis, and interpretation of dental information require experienced dentists with a forensic odontology background and knowledge of disaster victim identification. Although forensic odontology is taught in most countries, forensic odontologists are not always available or recruited systematically for the human identification process. Furthermore, when the nationality of the deceased is unknown or in very challenging cases, a second expert opinion could be decisive in the correct interpretation of dental treatments found in the mouth of the deceased.

The process of virdentopsy™ proposed by the Human Identification Laboratory (HIDentiLab) of the University of Turin, Italy, was employed to verify the feasibility and efficacy of transmitting postmortem dental data from human remains in order to obtain a second expert opinion from forensic odontologists situated in Italy¹. “Virdentopsy™” differs from “virtopsy” because the former is based on a different process and workflow, which also includes live streaming.²

Forensic odontologists from India, Peru, Syria, Sudan, and Pakistan performed a traditional dental autopsy, then transmitted the following postmortem dental data to HIDentiLab: photographs, video recordings, and X-ray images of dental arches and skulls.² The data received were analyzed, and a report was elaborated using the biological dental profile of the human remains, inclusive of dental age estimation.

The remote evaluation performed by experts in forensic odontology and disaster victim identification can be a concrete contribution to achieving timely and effective personal identification in those scenarios in which dental identifiers have been collected.³⁻⁶ Examples are the victims of migrations, the unidentified human remains of unknown nationality, and when second expert opinions are needed.⁶

Virtual, digital, and remote dental autopsy broadens the horizon of the forensic casework involving odontologists from various countries without the need for them to be onsite and could become a standard practice for each unidentified dead body recovered or for age estimation. This procedure is a possible solution when forensic odontologists are not available at the mass disaster site, when recovery is needed, or when a second expert opinion is needed to allow for the widening or confirming of dental findings, such as age, habits, and dental treatments, thus reducing bias. This process can be a useful tool in archeology and paleopathology, for training in forensic odontology courses, or when using live streaming smart glasses and augmented reality. Per this work, virdentopsy™ should also be considered a humanitarian forensic odontology tool that can support countries in need of teleconsultations in forensic odontology, given the extremely low cost of the procedure.

G12 Identification Via a Digital 3D-Simulated Dental Cast: A Case Report

John Nase DDS, Philadelphia Medical Examiner's Office, Philadelphia, PA and Dental Forensic Services of Indian Valley, Harleysville, PA;
Christina VandePol, MD, Chester County Coroner's Office, West Chester, PA*

Learning Overview: Attendees of this presentation will learn how to seek the existence of digital casts from the antemortem dental record, obtain those files, manage the dynamic 3D image file, and compare the files to postmortem findings.

Impact Statement: The forensic community will be impacted by this presentation because it will increase awareness of the prevalence of this relatively new dental technology and will teach how to repurpose this technology for forensic dental identification.

The use of digital impression scanners is becoming more prevalent in modern dental practice to replace physical study models of dentition, to fabricate both fixed restorations and removable prostheses, and to perform orthodontics. Traditional plaster casts are often destroyed in the fabrication process, discarded because of the lack of storage space, or simply lost. On the other hand, 3D dental digital files and the resulting 3D-simulated casts produced from these files are generally electronically and systematically stored and can be located and transferred readily. In this case, a thorough examination of the presumed individual's dental records elicited the existence of these files, which were then easily obtained via email from the treating dentist.

This case report details the positive identification of a presumed individual through the comparison of antemortem digital, 3D-simulated study casts to postmortem photographs. Although limited antemortem radiographs existed, the sole use of radiographic comparison for positive identification was hampered because no dental restorations existed and no removable prostheses were recovered. Using a dynamic 3D image file of the dentition, it was possible to exactly match the orientation (head rotation, pitch, and yaw) captured in the photographic evidence collected at postmortem examination. The resulting "still" images from the digital casts were then compared to the postmortem photographs via side-by-side comparisons and digital overlays, which significantly increased the number of concordant points and boosted the level of scientific certainty of a positive dental identification.

Identification, Digital Dental Cast, 3D Scanner

G13 How Scientific Evidence Can Lead to Human Identification Without a Corpse

Luciene Corradi, MS, IMLAR, Belo Horizonte, Minas Gerais, Brazil*

Learning Overview: Attendees will learn how forensic dentistry/forensic anthropology assumes a particular role in the contexts of determination and clarification of facts involved in litigation, leading to its conclusion in cases of human identification.

Impact Statement: This case report will demonstrate how forensic human identification can effectively corroborate the opinion of the police authority in relation to the existence (or not) of facts relevant to the investigation of a crime.

In Brazil, forensic medicine is a tool for police investigations that provides technical information and support for certain case facts and clarifies their criminal character. In the same way, forensic dentistry represents, in specific situations, the only method through which to obtain the factual background of the criminal act, converging to a conclusion of the investigation in which the facts have been determined and penal legislation may be applied according to current Brazilian Criminal Law.

This case report, realized by the Serviço de Odontologia Legal do Setor de Antropologia Forense (SAF) do Instituto Medico Legal de Belo Horizonte, Estado de Minas Gerais, Brasil (Forensic Dentistry of Forensic Anthropology Department of the Legal Medical Institute of Belo Horizonte, Minas Gerais/Brazil), will demonstrate how forensic human identification can effectively corroborate the forming of the “expert opinion” of the police authority in relation to the existence (or not) of facts relevant to the investigation and how it can play a specific role in the context of determination and clarification of the facts involved in litigation, leading to its conclusion.

Case Study: A lower Removable Partial Denture (RPD) was sent to SAF by requisition for anthropologic dental examination. The prosthesis was allegedly found, according to the requisition information, at the locale where the homicide occurred and the corpse was hidden. These facts were determined through the work of the designated police authority and their team, who additionally found that the probable perpetrators of the crime had also placed a dental prosthesis belonging to the victim in a hidden place at the locale. As a further result of the investigation, the police were led to the discovery of a missing person report filed on the same date as the crime. Thus, the police investigation team was able to collect data and characteristics of the missing person, including dental records in the form of radiological images of some of the victim’s teeth. In this case, all of the dental documentation that was found to belong to the missing person was sent (along with the partial denture recovered at the locale of the crime) to be analyzed, with the objective of formulating an expert opinion—after genetic material (on a swab) from the prosthesis as well as from relatives of the supposed victim was collected and analyzed—as to the whether the prosthesis belonged to the supposed victim. There were two prosthetic crowns fixed on the RPD that were studied in radiological images. The comparative study of these images, along with radiological images from the teeth of the dental chart sent, showed that they were absolutely compatible. The result of this comparative dental study in human identification was finalized successfully, permitting the police investigative team to materially conclude that the person was indeed the victim of homicide, even though the body was never found.

Human Identification, Anthropology, Forensic Dentistry

G14 The Role of Dental Pathologies, Anomalies, and Restorations in Forensic Identifications: Its Applications to Ajnala Dental Remains

Jagmahender Singh Sehrawat, PhD, Panjab University, Chandigarh, India; Priyanshi Sood, MSc, Panjab University, Chandigarh, India

Learning Overview: After attending this presentation, attendees will realize the importance of dental anomalies and pathologies and their antemortem record in postmortem examination of the deceased.

Impact Statement: This presentation will impact the forensic science community by informing attendees that dental anomalies, restorations, and pathologies can be valuable adjuncts to the forensic identification of unknown human remains.

Teeth are the hardest and most resistant structures of the human body and retain their unique forensic significance for a comparatively long period of time, even in the worst conditions of taphonomic degradations resulting from biological or chemical destruction. In addition to the unique odontological, molecular, and chemical characteristics of teeth, their dental pathologies and structural anomalies play crucial roles in the forensic identification of unknown human skeletal remains. The idiosyncratic features of teeth, such as staining/coloration patterns, developmental defects, wear and attritions, restorations/implants, cultural modifications, signs of tobacco or nut chewing, occupational stigmas, etc., act as valuable adjuncts to the examination of teeth in forensic or bioarchaeological contexts. Dental pathologies and anomalies may reflect oral hygiene, dietary patterns (such as consumption of sweets, sugar, fats, and proteins), and the socioeconomic, sociocultural, and occupational statuses of an individual. This work presents a brief overview of different dental defects and their putative roles in the forensic identification of unknown human remains.¹⁻³

Variations in shapes, colors, positions, age changes, wear patterns, and restorative work make the human dentition as individual as fingerprints. Dental pathologies can thus reveal the dietary status, population affinity, and ancient or contemporary nature of teeth found in forensic anthropological contexts. Wear pattern can reflect the type of food eaten (fibrous or non-fibrous), the occupation, and the oral activity patterns (like mal-occlusions) of an individual. Dental anomalies are developmental variations (morphology, number, and arrangement of teeth) unique to an individual that are considered crucial for identifying unknown human remains found in forensic or bioarchaeological contexts. The localized insignificant/mild anomalies of restoration, crowding, and spacing give every individual a unique dental identity that may be helpful in forensic identifications. Because of their uniqueness, stability, and low frequency of occurrence in different populations, developmental dental anomalies can assist in cases of postmortem identification.¹ However, dental anomalies can help in human identification only if they were properly stored as antemortem dental records in the form of dental charts, radiographs, photographs, text details, or similar forms.⁴ A dentist's awareness of the forensic value of maintaining antemortem dental records, of state regulations, of the ethical and medicolegal responsibility of the consultant, etc., will determine the records' proper handling and preservation for future use.

The negligible percentage of dental pathologies (wear, caries, and hypoplasia) in Ajnala teeth supported their military affiliation hypothesis. The recruits of the colonial army in 1857 were expected to have sound oral health and hygiene relative to that of the contemporary civilians. Low levels of carious lesions may also imply that the individuals were young and healthy at the time of their deaths. The notched incisors and canines in the majority of studied anterior teeth may result from the fact that the slain sepoys had to break the threads of pork- or beef-greasy cartridges during their military duties and strategic operations. The continuous use of anterior teeth to manipulate threads, nuts, wires, and other instruments by tailors, carpenters, cobblers, electricians, musicians, and other professionals also made them notched.^{5,6} Ancient teeth had comparatively lesser chances of having dental pathologies than the teeth of contemporary, modern populations; the same was corroborated by pathological examination of Ajnala dental assemblage, which again endorses their possible affiliation to soldiers killed in 1857.^{6,7}

In this presentation, different types of dental pathologies, anomalies, and restorations and their possible roles in forensic identifications, with a general reference to Ajnala dental remains, will be discussed.

Forensic Odontology, Dental Anomalies and Pathologies, Ajnala Dental Remains

G15 Odontology Forensic Identification in the Case of a Flash Fire Death

Massimiliano Esposito, MD*, Department of Medical, Surgical and Advanced Technologies, G.F. Ingrassia, University of Catania, Catania, Italy; Lucio Di Mauro, MD, Department of Medical, Surgical and Advanced Technologies, G.F. Ingrassia, University of Catania, Catania, Italy; Giuseppe Cocimano, MD, Department of Medical, Surgical and Advanced Technologies, G.F. Ingrassia, University of Catania, Catania, Italy; Andrea Failla, MD, Department of Medical, Surgical and Advanced Technologies, G.F. Ingrassia, University of Catania, Catania, Italy; Edmondo Scoto, MD, Department of Medical, Surgical and Advanced Technologies, G.F. Ingrassia, University of Catania, Catania, Italy; Angelo Montana, MD, Department of Medical, Surgical and Advanced Technologies, G.F. Ingrassia, University of Catania, Catania, Italy

Learning Overview: The aim of this presentation is to focus on the importance of forensic odontology identification in cases of unidentified cadavers.

Impact Statement: This presentation will impact the forensic science community (consisting of the forensic pathologist, the forensic radiologist, and the forensic odontologists) through a multidisciplinary method of identifying a cadaver, especially in cases of flash fire deaths. In fact, flash fire deaths often make cadavers unidentifiable because of the strength of the flames causing the destruction of soft tissues and organs.

Forensic dentistry, or forensic odontology, is defined as the branch of forensic pathology that analyzes dental remains (whether fragmentary or complete and including all types of dental restorations) from unknown persons or bodies, with the goal of possibly identifying the latter. Indeed, dental identification is an important postmortem identification method. In some cases, it is the only method that can be used to make or refute the identification of unrecognizable corpses because the teeth remain the only parts of the body not destroyed, such as in cases of mass disaster, incineration, or severe decomposition of the corpse.¹ Indeed, flash fire death is an uncommon death related to severe damage that destroys the body. The majority of victims die of the effects of fire in enclosed spaces (for example, a house, an apartment, a room, a barn, a garden shed, an auto, a mobile home, or a ship). Gerling et al. classified the damage induced by fire in three degrees: Grade A—little soft tissue loss, with rupture of the abdominal wall; Grade B—moderate soft tissue loss, especially in the lower extremities, with the opening of the chest and/or abdominal cavities but sparing the head; and Grade C—soft tissue loss in the lower and upper extremities, with the opening of the cranium, sometimes in combination with the opening of the chest and/or abdominal cavities.²

Case Report: In December 2020 in the south of Italy, a burning car was noticed inside a warehouse. Firefighters arrived on the scene, and after extinguishing the flames, they found body remains inside the car. The prosecuting officer consulted the coroner. On the crime scene, the car, completely destroyed, contained an unidentifiable body. External examination of the cadaver revealed a classification of C-grade wounds according to Gerling: The face was unrecognizable, with the opening of the skull, chest, and abdomen, and loss of the lower and upper extremities. At autopsy, it was discovered that the tongue, pharynx, and especially glottis were scorched. The lumen of the larynx, trachea, and main bronchi were thickened, too. In addition, there was soot in the tracheal mucus, a sign of breathing while the fire was in progress.³ Histological examination of the lungs and airways in Hematoxylin and Eosin (H&E) showed elongated cylinder epithelia, elongated cell nuclei, reactive hyperemia in the subepithelial tissue, and peripheral soot particles that resulted from the heat-inhalation trauma.⁴ A forensic dental examination was performed and showed the absences of tooth n.11 and tooth n.12 and an orthodontic appliance of teeth n.13 and n.14. Dental photos of a suggested missing man were analyzed and showed the same characteristics as those of the cadaver. The comparison of the Orthopantomogram (OPT) performed antemortem of the missing person with the postmortem of the cadaver perfectly aligned. Thus, according to the American Board of Forensic Odontology (ABFO), a positive identification (Grade 1) was achieved because of a perfect match between premortem and postmortem dental data.¹

Odontology, Identification, Flash Fire Death

G16 Dental Hygiene Students' Matching Accuracy When Comparing Antemortem Dental Radiographs and Oral Photos to Simulated Postmortem WinID3® Records

Brenda Bradshaw, MS, Old Dominion University, Norfolk, VA; Emily Ludwig, MS, Old Dominion University, Norfolk, VA; Amber Hunt, MS, Old Dominion University, Norfolk, VA; Tara Newcomb, MS, Old Dominion University, Norfolk, VA*

Learning Overview: Attendees will learn about senior dental hygiene students' identification match accuracy with simulated antemortem dental radiographs and oral photographs to postmortem dental charts.

Impact Statement: Forensic odontology educational opportunities are not readily available in dental hygiene formal education, and little is known about the transferability of their skills to assist forensic odontologists during disaster victim identifications. Therefore, this research will fill a gap in the literature about dental hygienists' ability to assist forensic odontologists when needed.

Objective: Matching dental records are one of the most reliable methods for Disaster Victim Identifications (DVI). The aim of this study was to assess the ability of senior dental hygiene students to accurately match simulated cases based on Antemortem (AM) radiographs and oral photos to Postmortem (PM) WinID3® charts as a possible transferrable skill for disaster victim identification, gained during formal education. The study also compared participant accuracy when matching AM radiographs to PM dental records versus AM oral photos to PM dental records.

Methods: Five patient cases (labeled A–E), including a Full-Mouth Series (FMS) of radiographs and a set of five intraoral photos, were selected and de-identified from a dental hygiene care facility's patient records software system to serve as AM images. Researchers created simulated WinID3® dental charts for each case to serve as PM records for comparison. Cases varied in complexity—with cases B and E having less distinctive dental identifiers (for example, no restorations), while cases A and C had similar restorative patterns, and case D consisted of numerous restorations that varied greatly from those of the other cases. A convenience sample of $N=31$ senior dental hygiene students from one institution were presented with a PowerPoint® explaining how to interpret WinID3® dental charts; they then were presented with the five mismatched cases and asked to visually interpret each case to make ten total identification matches: five based on AM digital FMS, with simulated PM WinID3® records, and five based on AM digital photos with PM WinID3® records. Participant match accuracy per image type was assessed for performance differences among radiographic and photographic matching abilities. A researcher-designed Qualtrics post-test asked participants to indicate perceived difficulty and confidence in making matches per image type. SPSS software was utilized for statistical analyses of this Institutional Review Board (IRB) -approved descriptive study.

Results: Participant match accuracy for cases with numerous dental identifiers (cases A, C, and D) ranged from $M=93.5$ to $M=77.4$. Match accuracy declined with cases B and E of less distinctive dental identifiers ($M=58.1$ to 41.9). Participants commonly mismatched case A with C, and case B with E when comparing images to charts. McNemar's chi square revealed no statistical differences in participants' match abilities depending on image type (radiographs vs. photos): $p=.687$ (case A), $p=.388$ (case B), $p=.625$ (case C), $p=1.000$ (case D), and $p=.774$ (case E). Most participants (74.2%) indicated photo matching as more challenging than radiograph matching despite quantitative findings showing that matching performance was not statistically different depending on image type. Most participants (70.9%) indicated experiencing no to slight difficulty when attempting to match radiographs to charts, and 87% indicated slight to moderate difficulty when matching photos to charts. When asked about perceived confidence, 93.5% indicated they were moderately confident that they had correctly matched at least half of the sets.

Conclusions: The results of this study demonstrate that dental hygiene students can accurately match simulated AM images with PM records with confidence. While much research has been performed to validate the uniqueness of dental radiographs, oral photos, and charting for victim identification purposes, this study is innovative because of its focus on assessing the ability of dental hygiene students to accurately match AM and PM records. Forensic odontology educational opportunities are not readily available in dental hygiene formal education, and little is known about the transferability of these skills to assist forensic odontologists during DVI. More research is needed in education and practice when preparing dental hygienists for forensic-based service.

Forensic Odontology, Dental Hygienist, Identification Match Accuracy

G17 Histological and Elemental Markers in Teeth Help Reconstruct Decedent-Specific Lived Experiences

Paola Cerrito, MPhil*, New York University, New York, NY; Bin Hu, MD, New York University, New York, NY; Rachel Kalisher, Brown University, Providence, RI; Shara Bailey, PhD, New York University, New York, NY; Timothy Bromage, PhD, New York University, New York, NY

Learning Overview: Attendees are expected to learn about a novel and easy-to-implement method that could be used to identify, from dental remains, specific life events that may be unique to a decedent.

Impact Statement: Rather than relying on diagnosing visible stress lesions in unidentified skeletal remains, the methods presented here would work toward identifying more specific lifestyle factors that may be unique to a decedent's experience and help determine the decedent's identity. By recognizing signatures of stress at a higher resolution than macroscopic trauma, non-skeletal pathologies (such as systemic illnesses), and reproductive history, this method could help in restoring unidentified victims to their families and loved ones. This research improves the forensic anthropology identification process by presenting an additional method for discerning antemortem information that can not only help establish a positive identification but also limit potential incorrect matches.

This project reports on the utilization of histological and elemental markers contained in dental microstructure to infer decedent-specific lived experiences (trauma, illness, and reproduction). Thousands of long-term unidentified individuals are listed in the National Missing and Unidentified Persons System (NamUs), resulting in what has been referred to as the Nation's "silent mass disaster."^{1,2} A significant portion (56.28%) of the active NamUs unidentified persons cases are comprised of partial (36.6%) or complete (19.68%) skeletal remains.² To address the problem of identifying unidentified individuals, this work tests the hypothesis that dental histology of cementum can be used as a record of an individual's medical and reproductive history. From histological examination of dental remains, this study proposed, for instance, to estimate the number of live births a female has had, the age of her menopause, and the age at which a male reached sexual maturity. This study performed histomorphological analyses of 47 teeth from 15 individuals with known life history events and was able to detect reproductive events and menopause in all females.³ This study also found that stressful events such as systemic illnesses and incarceration were detectable. Using a novel analytical method, this study was able to time all such events with high accuracy (R-squared=0.92). Nonetheless, these promising results are limited because they do not appear to be event-specific: This study could not determine the cause of the stressor from histological analysis alone. This study, therefore, proceeded to measure, via field-emission scanning electron microscopy and energy-dispersive X-ray analysis, major and minor element concentrations across the cementum transects of 34 teeth of a model organism (Rhesus macaques) with the aim of discovering event-specific elemental signatures. The results of this analyses indicate that the relative concentrations of Magnesium (Mg) and Oxygen (O) distinguish ($p < 0.05$) reproductive events from all other physiological states; Sodium (Na) concentrations are significantly altered ($p < 0.05$) in association with skeletal trauma; and Mg, Na, Calcium (Ca), and Phosphorous (P) concentrations provide a unique elemental profile ($p < 0.05$) in association with suckling and weaning. These results suggest that combined histological and elemental evidence may help guide investigators in their attempts to identify missing and unidentified persons. Specifically, these novel methods could be used to identify specific life events that may be unique to a decedent should the medicolegal and investigative system be able and willing to recover such details from next of kin or medical records.

Dental Cementum, Dental Histology, SEM/EDX

G18 The Use of Computer Image Recognition and Interpretation Software (CIRIS) for Automation of Dental Age Assessment: An Update

Kaiming Xu, BSc, Stony Brook University, Stony Brook, NY; Kenneth Aschheim, DDS, Office of Chief Medical Examiner, New York, NY and New York University College of Dentistry, New York, NY; Sakher AlQahtani, PhD, King Saud University Institution, College of Dentistry, Riyadh, Riyadh, Saudi Arabia; Arie Nakhmani, PhD, Electrical and Computer Engineering Department, University of Alabama at Birmingham, Birmingham, AL; Allen Tannenbaum, PhD, Stony Brook University, Stony Brook, NY*

Learning Overview: After attending this presentation, attendees will understand why CIRIS can be used to address some of the concerns raised by the current methods used to assess a forensic age interval by dental means.

Impact Statement: This presentation is the next step in the goal of using these biometric algorithms to create a new population-based data table with a greater degree of granularity. In addition, by using the identical standardized computer algorithm to collect both the population data and the staging of a dental radiograph, any concerns about the accuracy of the staging comparison process can be eliminated.

Forensic age assessment by dental means estimates an individual's chronologic age interval through the scientific evaluation of the individual's dentition and maxillofacial structures. Although numerous methodologies are available, the most common method compares the progressive morphological, developmental changes of the crown, root, and apex of a tooth to known population tables. This assessment is performed by a highly trained forensic odontologist who must make a qualitative assessment of discernible radiographic changes because of progressive mineralization of each tooth. The odontologist must then assign "developmental stages" to each tooth to compare them to suitable population-specific reference data. Because dental age assessment requires skill, training, education, and experience to execute correctly, concerns of inter-operator and intra-operator consistency have been raised.

In 2009, Aschheim, Tannenbaum, and Nakhmani presented to the AAFS a paper on "The Use of Computer Image Recognition and Interpretation Software for Automated Dental Age Determination—A Proof of Concept."¹ The paper's premise was that using CIRIS could interpret visual dental development images. In addition, the software could derive meaningful metric information from the data via an image segmentation system. Improvements in the software, especially for its use in homeland security for real-time facial recognition and automated interpretation of satellite data, have led to a desire to revisit this technology and see whether these improvements could be incorporated into updated software.

Deep learning, which can extract high-level features, is an extremely popular tool in image recognition. It also can be used in teeth staging. With enough training data and a correct hyperparameter, we can use a good model to predict teeth stages. Data augmentation helps when the data number is limited. In imaging, translating, cropping, rotating, flipping, and adding noise can be used to increase the amount of data. Histogram equalization is an image-processing method that increases the global contrast and can solve the brightness problem. Alex Net is used with an augmented training set, and all of the code is written in Python[®] language.

This presentation will expand on the previously presented proof of concept application to determine the computer's ability to accurately discern meaningful biometric data utilizing deep learning. Furthermore, it will evaluate if the newer system can better stage teeth from a dental radiograph for comparison with relevant population-specific reference data.

G21 Deep-Learning-Based Age Estimation From Panoramic Radiographs: Unraveling the Learning Process

Yung-Hsuan Fang, MSc DDS*, Forensic Odontology, KU Leuven, Leuven, Vlaams-Brabant, Belgium; Laurens Ghyselen, MSc, Electrical Engineering, KU Leuven, Leuven, Vlaams-Brabant, Belgium; Jeroen Bertels, MSc, Electrical Engineering, KU Leuven, Leuven, Vlaams-Brabant, Belgium; Jannick De Tobel, PhD, MD, DMD, MSc, Diagnostic Sciences, Radiology, Ghent University, Ghent, Oost Vlaanderen, Belgium; Dirk Vandermeulen, PhD, MSc, Electrical Engineering, KU Leuven, Leuven, Vlaams-Brabant, Belgium; Patrick Thevissen, PhD, DMD, MSc, Forensic Odontology, KU Leuven, Leuven, Vlaams-Brabant, Belgium

Learning Overview: After attending this presentation, attendees will understand which information is used from panoramic radiographs for age estimation by convolutional neural networks.

Impact Statement: This presentation will impact the forensic science community by providing insight into how machine learning algorithms interpret panoramic radiographs for age estimation.

Background: Dental age has been proven to be a good predictor of chronological age, especially in children, for whom the permanent teeth are still developing.¹ In adolescents and young adults, the dental age is still useful as a predictor of chronological age, albeit less accurate and precise than it is in children.² Numerous dental age estimation methods have been described in the literature, both for children, on one hand, and for adolescents and young adults, on the other hand.² Traditionally, the methods are based on staging dental development, which is done by expert observers. Still, inter-observer variability remains, regardless of the observer's experience. To overcome the issue of inter-observer variability, automated dental age estimation methods were developed.³⁻⁷ Vila-Blanco et al. demonstrated that their Convolutional Neural Network (CNN) for age estimation focused on different parts of the panoramic radiograph, depending on the age category of the studied individual.⁷ This grossly corresponds with how human observers interpret the panoramic radiograph: by focusing on the developing permanent teeth in children and on the developing third molars in adolescents and young adults. At the same time, Banar and Bertels et al. showed that their CNN for third molar development staging benefited from background removal as a potential compensatory mechanism for having a limited amount of training data.⁸ Therefore, it can be hypothesized that CNNs for age estimation can be aided by directing their focus inside the panoramic radiograph corresponding to a human observer's approach. Providing the observer with extra information about where to look may increase accuracy and precision by eliminating redundant information.

Purpose: To study the effect of three preprocessing steps of the panoramic radiographs on age estimation performance.

Materials and Methods: A set of 3,266 digital panoramic radiographs was collected retrospectively at *blinded for review*. The study population was between 1 and 24 years old, approximately evenly distributed between both sexes and among all age categories of 1 year.

Two preprocessing steps were conducted by a human observer: (1) cropping the panoramic radiographs to display only a rectangle within the third quadrant, and (2) indicating the long axes of the seven permanent teeth and the four third molars on the panoramic radiographs. Based on those long axes, a third preprocessing step was conducted using the Python OpenCV package: (3) masking all redundant information in the panoramic radiographs, keeping rectangles around the seven permanent teeth and the four third molars. Subsequently, the EfficientNet-B7 CNN pretrained on ImageNet was used in combination with an additional global average pooling layer and two dense layers to predict age.⁹ Age was predicted based either on the original panoramic radiograph or on one of its three preprocessed variants. In each setup, the CNN was tested on the same random subset of 170 subjects. The remainder—for which the number of subjects could vary slightly between the different preprocessing steps because of technical constraints—was used for model fitting, including an internal validation set to monitor convergence.

Results: The mean absolute error equaled 0.95 year using the original panoramic radiograph, 1.15 years using the cropped images, 1.08 years using the images with the long axes, and 1.22 years using the masked images.

Conclusion: Rather unexpectedly, the CNN benefited from being able to consider the original panoramic radiograph. This suggests that significant discriminative information is present throughout the full panoramic radiograph and/or that directing the CNNs' focus using prior human experience could be harmful outside the limited data regime.

G22 Age Estimation Using Third Molar Maturation Based on Demirjian's Criteria

Tanuj Kanchan, MD, All India Institute of Medical Sciences, Jodhpur, Rajasthan, India; Vinay Chugh, MDS, All India Institute of Medical Sciences, Jodhpur, Rajasthan, India; Chugh Ankita, MDS, All India Institute of Medical Sciences, Jodhpur, Rajasthan, India; Vikas Meshram, MD, All India Institute of Medical Sciences, Jodhpur, Rajasthan, India; Rutwik Shedge, MSc, All India Institute of Medical Sciences, Jodhpur, Rajasthan, India, Arun Patnana, MDS, All India Institute of Medical Sciences, Jodhpur, Rajasthan, India; Kewal Krishan, PhD, Panjab University, Chandigarh, Punjab, India*

Learning Overview: After attending this presentation, the attendees will have a better understanding of the use of third molar maturation in human age estimation.

Impact Statement: This presentation will inform the attendees and the forensic science community of the utility of third molar maturation in ascertaining whether an individual has attained the medicolegally significant ages of 16 and 18 years.

Forensic age estimation is one of the most important aspects of human identification. Age estimation is routinely done by assessing the age-related changes that occur in skeletal and dental anatomical regions. Most of the commonly employed methods of age estimation include assessing the epiphyseal fusion of bones and evaluating the extent of maturation of the human dentition. Teeth follow a predictable pattern of eruption and maturation that can be assessed radiographically in the living, thus allowing experts to estimate an individual's age. Third molars develop much later than the other permanent teeth, and this fact can be used to estimate the ages of individuals nearing the legal age of maturity. The ability of third molar maturation when graded using Demirjian's criteria to indicate whether an individual has attained the medicolegal ages of 16 and 18 years has not yet been verified.¹ The present study involved assessing the third molar maturation of 300 individuals (150 males and 150 females) of a training set using Demirjian's scoring system, generating regression models to estimate age using the third molar maturity scores, applying these models on a test set of 40 individuals (23 males and 17 females), and calculating the Mean Difference (MD) and the Mean Absolute Error (MAE) between the chronological and the estimated ages of the test set participants. It was observed that the lowest mean difference and the mean absolute error were observed for the maturation of the left mandibular third molar (MD=1.05 years, MAE=2.09 years). Boxplots generated in the study report that the third molar maturation stages given by Demirjian can identify whether an individual has attained the medicolegally significant ages of 16 and 18 years of age. The present study concluded that age estimated from third molars using Demirjian's criteria can be used to estimate the age of individuals nearing the legal age of majority. This method can be used on its own when other, well-established methods of age estimation cannot be applied or as an adjunct to these methods.

Forensic Odontology, Dental Age Estimation, Third Molar

G23 Magnetic Resonance Imaging for Multi-Factorial Age Estimation Using a Bayesian Approach: A Validation Study in Two Independent Samples

Heleen Coreelman, MSc*, Radiology, Ghent University, Ghent, Oost-Vlaanderen, Belgium; Patrick W. Thevissen, PhD, Forensic Odontology, KU Leuven, Leuven, Vlaams-Brabant, Belgium; Thomas Widek, PhD, Diagnostic and Research Institute of Forensic Medicine, Medical University of Graz, Graz, Steiermark, Austria; University of Graz/Graz University of Technology/Medical University of Graz, Graz, Steiermark, Austria; Martin Urschler, PhD, School of Computer Science, University of Auckland, Auckland, North Island, New Zealand; Elke Hillewig, MSc, Radiology, Ghent University, Ghent, Oost-Vlaanderen, Belgium; Steffen Fieuws, PhD, Interuniversity Institute for Biostatistics and Statistical Bioinformatics, KU Leuven/Hasselt University, Leuven, Vlaams-Brabant, Belgium; Koenraad L. Verstraete, PhD, Radiology, Ghent University, Ghent, Oost-Vlaanderen, Belgium; Jannick De Tobel, PhD, MD, DMD, MSc, Diagnostic Sciences, Radiology, Ghent University, Ghent, Oost-Vlaanderen, Belgium; Vlaams-Brabant, Belgium and Department of Oral and Maxillofacial Surgery, Leuven University Hospitals, Leuven, Vlaams-Brabant, Belgium

Learning Overview: After attending this presentation, attendees will have a better understanding of the validity of Multi-Factorial Age Estimation (MFA) models based on Magnetic Resonance Imaging (MRI) in living adolescents and young adults.

Impact Statement: This presentation will impact the forensic science community by presenting evidence on the validity of MFA models for radiation-free age estimation in the living.

Background: The use of medical imaging for forensic age estimation remains a controversial subject and is often labeled as unethical and imprecise. To prevent exposure of an individual to ionizing radiation, MRI has been proposed as a suitable imaging modality to visualize developing anatomical structures.¹⁻³ Moreover, to increase the accuracy of the point prediction of age, to reduce its uncertainty, and to decrease the chance of an ethically unacceptable error, MFA is preferred.¹ Indeed, two research groups independently demonstrated that age estimation around the age of 18 years should combine data of the third molars, left hand/wrist, and both clavicles.^{3,4} One of these research groups developed MFA models based on Bayes' rule combining MRI data of the third molars, left hand/wrist, and/or both clavicles but reported only on internal cross-validation.⁴ In males, combining all three anatomical sites rendered a mean absolute error equal to 1.36 years, a mean width of the 95% prediction intervals equal to 5.49 years, 94% correctly categorized adults, and 90% correctly categorized minors. In females, the corresponding results were 1.41 years, 5.91 years, 93%, and 91%, respectively. However, external validation is essential before the approach could be used in practice.

Purpose: To externally validate MFA models based on MRI in two independent samples.⁴ This study hypothesized that the original models perform equally well in the external validation samples as reported for internal cross-validation.

Materials and Methods: The relevant anatomical structures were studied in two samples, independent of the sample used in the De Tobel study.⁴ Note that the validity of the models can be studied only if the MRI protocol applied in the validation sample is equal to (or at least very similar to) the MRI protocol applied in the original sample.

In a first validation sample, which will be referred to as the Ghent sample, MRI of the left wrist and both clavicles was prospectively conducted in 108 healthy Belgian Caucasian volunteers (52 males, 56 females), with ages between 16 and 21 years.⁵ In a second validation sample, which will be referred to as the Graz sample, MRI of the third molars, left hand/wrist, and both clavicles was prospectively conducted in 337 healthy Austrian Caucasian males, with ages between 13 and 25 years. Development was staged and age estimation performance was tested, calculating mean absolute errors, 95% prediction intervals and their coverage, and percentages of correctly identified minors and adults.^{4, 6-8}

Results: Because this is ongoing research, no results that confirmed or rejected the hypothesis were available at the time of this submission.

Age Estimation, Magnetic Resonance Imaging, Bayesian Statistics

G24 Ethnic Variations in the Development of Third Molars Between Chinese and Hispanic Children and Adolescents

Jayakumar Jayaraman, PhD, MDS, Virginia Commonwealth University, Richmond, VA*

Learning Overview: Following this presentation, attendees will understand the influence of ethnic variations, particularly between the Chinese and Hispanic populations, in dental development of third molars. This will be presented in a form of a research study that compares the average age at attainment of crown formation stages in the maxillary and mandibular third molars.

Impact Statement: This presentation will impact the forensic community by demonstrating variations observed in third molar development between two distinct ethnic populations. It also emphasizes the importance of using population-specific reference standards for accurate age estimation.

Age estimation is an important procedure in forensic practice, and several studies have shown relatively accurate estimates of age using dental development. The influence of ethnicity on dental development and age estimation has been widely debated.^{1,2} A recent study demonstrated significant differences in dental maturation between Caucasian and Chinese populations, with the latter showing advanced development by over five months.³ Although the relationship between ethnicity and dental development has been well established, such comparison has not been conducted in the Hispanic population.

This study aimed to compare the development of third molars between Chinese and Hispanic children and adolescents. Dental panoramic radiographs belonging to healthy children of Hispanic and Chinese ethnicity were obtained from the archives of teaching hospitals in Hong Kong and Texas, respectively. In total, 600 radiographs for Hispanics and 1,200 radiographs for Chinese children ages 6 to 17 were obtained, comprising an equal number of males and females in each age group. All third molars in the maxillary and mandibular arches were scored according to Demirjian's classification of tooth development stages (A to F) by a single trained and calibrated examiner (JJ). The radiographs were scored in the Microsoft® Access database designed by the Dental Age Research London Information Group (DARLInG). The average Age of Attainment (AoA) for each stage of development, along with the number and standard deviation, were calculated. Statistical significance was set at $p < 0.05$, and an independent sample t-test was used to compare the AoA for individual stages of development for all third molars, independently for females and males in the Chinese and Hispanic ethnic groups. For males, Hispanic children consistently demonstrated advancement in dental development by 0.81 year for maxillary and 0.91 year for mandibular third molars. For females, advancement of 1.16 years and 1.10 years were observed for maxillary and mandibular third molars, respectively, and the differences were statistically significant for all stages and for dentition ($p < 0.05$).

In conclusion, significant advancement in third molar development was observed in Hispanic compared to Chinese children and adolescents. The variations in dental development should be taken into consideration during age estimation procedures, and a population-specific reference dataset is recommended in the considered population groups.

Dental Development, Ethnicity, Third Molar

G25 The Reproducibility of Third Molar Development Stage Allocation on Panoramic Radiographs and Cone Beam Computed Tomographs (CBCT): Comparing Imaging Modalities, Observer Experience, and Observer Calibration

Ahmad Rabah, MSc, DDS, Forensic Odontology, KU Leuven, Leuven, Vlaams-Brabant, Belgium; Mustafa Hayder, MSc, BDS, Forensic Odontology, KU Leuven, Leuven, Vlaams-Brabant, Belgium; Dana Ahmed, MSc, BDS, Forensic Odontology, KU Leuven, Leuven, Vlaams-Brabant, Belgium; Aspalilah Alias, PhD, MSc, DDS, Forensic Odontology, KU Leuven, Leuven, Vlaams-Brabant, Belgium and Faculty of Dentistry, Universiti Sains Islam Malaysia, Kuala Lumpur, Selangor, Malaysia; Steffen Fieuws, PhD, MSc, I-BioStat, KU Leuven, Leuven, Vlaams-Brabant, Belgium; Maximilian Timme, MD, DMD, Institute of Legal Medicine, University Hospital Münster, Münster, Nordrhein-Westfalen, Germany; Patrick Thevissen, PhD, DMD, MSc, Forensic Odontology, KU Leuven, Leuven, Vlaams-Brabant, Belgium; Jannick De Tobel, PhD, MD, DMD, MSc, Diagnostic Sciences, Radiology, Ghent University, Ghent, Oost Vlaanderen, Belgium*

Learning Overview: After attending this presentation, attendees will understand why CBCT is of added value to third molar development stages in adolescents and young adults and how observer variability affects the staging.

Impact Statement: This presentation will impact the forensic science community by providing well-founded argumentations on the preferred imaging modality and the approach to allocate third molar development stages.

Background: The clinical introduction of CBCT allowed obtaining high-quality tooth images in three orthogonal planes, using low radiation doses.^{1,2} Consequently, CBCT is making inroads into medicolegal age estimation.^{3,4} Although tooth development staging techniques were established on Panoramic radiographs (PAN), it is assumed that using them on CBCT provides comparable results. However, the scientific proof is scarce on stage allocation being exchangeable between PAN and CBCT. Franco et al. reported congruent developmental stage allocation results between PAN and CBCT in third molars.³ Nonetheless, the early developmental stages were not studied, and a very small sample was used.³ Similarly, Zirk et al. studied a relatively small sample and obtained inconsistent results comparing the development of the lower right third molar on PAN and CBCT.⁵ Moreover, their conclusions were not supported by the results.⁵

When allocating and comparing stages within and between imaging modalities, observer experience and observer calibration play important roles.⁶ However, to date, the reproducibility of stage allocation among research centers has not been discussed in the literature.

Aim: To study the reproducibility of staging of third molar development within and between imaging modalities (PAN, CBCT) among observers with different experience levels and from different international research centers.

Materials and Methods: In a sample of 449 healthy blinded for review subjects (221 females, 228 males), PANs and CBCTs were retrospectively selected if they were taken on the same day. The subjects were between 7 and 26 years old. Their third molars were staged according to the technique of Köhler et al., independently for PAN and CBCT.^{7,8} At least one expert and one non-expert observer per international research center conducted the staging, with a separate stage allocation for each root. To quantify the agreements between imaging modalities and among observers, the percentages of agreement were reported, as were weighted kappas. Simple kappas quantified the agreements of whether or not a stage could be allocated to the considered root and tooth. The McNemar test was used to verify the differences in stage distributions. To detect systematic differences between imaging modalities and among observers, a Wilcoxon signed rank test was used.

Hypotheses: (1) High reproducibility is achieved in tooth stage allocations on root level between PAN and CBCT. (2) Observers with different levels of experience show congruent results. (3) Observers with different calibrations (i.e., from different centers) show congruent results.

Results: Since this is ongoing research, there were no results available to confirm or reject the hypothesis at the time this abstract was submitted.

G26 Finding John “Little Zion” Doe: When the Science of Forensic Dentistry Proves Itself Above Rational Thinking

Grace Chung, DDS, Clark County Office of the Coroner/Medical Examiner, Las Vegas, NV*

Learning Overview: Attendees will learn how a seemingly small aspect of forensics such as odontology has made significant contributions with years of scientific research—in this case, how an unidentified body can be identified not BY forensic dentistry but BECAUSE of it.

Impact Statement: Forensic sciences are a science because there is a method and systematic approach to its findings. Sometimes what one may think is common sense is contradicted by these sciences. It is easy and likely that the average person would follow what makes rational sense; however, we forensic scientists must trust our own research and studies to push forward what our examination of evidence is telling us. In seeking the truth, the forensic science community may not have the popular opinion, but it often will be the correct opinion. This presentation will hopefully inspire the community to continue becoming experts in their fields to have the confidence to be the non-popular contributor if need be and to show how important it is to have your voice heard.

On May 28, 2021, a body of a young male was found along Route 106 in Las Vegas, NV. Weighing just under 125 pounds and about 4'11" tall, it was evident that the decedent was a young child. The body was immediately transported to the Clark County Coroner's Office, and law enforcement was alerted and began investigations in hopes of securing an identify.

The events that followed were a whirlwind of dynamic information. Evidence was brought in, conclusions were made, then further investigation that depended on those conclusions ensued; yet an entire week went by with no identity for the boy, who now was nicknamed “Little Zion.” The chief forensic odontologist had been called upon to perform a dental autopsy and found himself becoming the leading opposer to challenge the investigators' initial findings.

One mother had seen photos of the boy and claimed him as her son. She told police that her son, along with a half-brother, had been taken by their father and that she had been unable to reach them for a few days. Immediately, chief forensic odontologist was asked to collect dental evidence of that mother's son and to compare it to the decedent's dental record. By now, investigators were already assuming that they knew the identity of the boy and began searching for the father. However, it took only a few minutes of reviewing the dental X-rays of the boy thought to be missing for him to be excluded as the decedent.

It was back to the drawing board on the search for the identify of this child. Based on his height and weight, investigators initially published a search request from the community for a Hispanic boy who was about 10–12 years old. However, the chief forensic odontologist pushed back because his dental age placed him much younger. According to calculations, he would be between 6 and 8 years of age. Although this age range seemed incompatible with the relative size of the body, the science behind dental age assessment is one the chief forensic odontologist urged investigators to follow. They changed their age search to 8–10.

It would be a full week between the time the body was found and when an identification was finally made, which was an enormous burden lifted off the shoulders of all involved with the case. Because unidentified children typically do not stay unidentified for more than 24 hours, the police were desperate, offering up to \$10,000 to anyone able to give them an identity and visiting door-to-door Hispanic families with school-aged boys. They had multiple artists attempting to create sketches of an antemortem portrait, and they finally received an updated and more accurate version from the National Center for Missing and Exploited Children. The identity of the boy was finally made on June 6. His name was Liam Husted, and he was only 7 years old.

Although the final identification was made using DNA, odontology played a major role in re-diverting the investigation when it was heading in the wrong direction. For one thing, once the chief forensic odontologist excluded the initial missing boy as the victim, investigators began searching for him and eventually found him and his half-brother both safe, camping in a remote area with their father. Also, the change of the age interval for the deceased child helped investigators look for younger children when they initially had been looking at a much older population.

Odontology is a branch of forensic sciences that can often be overlooked because of its seemingly small scope. However, as shown in this case, the science of odontology can be used as a reliable resource and can make large contributions to complex cases.

Age Estimation, Unidentified, Child Abuse

G27 Bitemarks That I Have Known

Peter Hampl, BS, DDS; Spokane County Medical Examiner, Spokane, WA, Pierce County Medical Examiner, Tacoma, WA, Disaster Mortuary Operational Response Team, Washington, DC, and Blake Emergency Services, Pyegreave Combs High Peak, United Kingdom*

Learning Overview: It is the intention of this presentation to show the complexities of bitemark analysis and the rarity of human bitemarks of evidentiary value.

Impact Statement: After attending this presentation, it is hoped that a conservative approach to bitemark analysis will be forthcoming.

This presentation is a follow-up to a presentation given at the 2020 American Academy of Forensic Sciences meeting in Anaheim, CA, titled, “Non-Bitemarks I Have Known.”¹ This presentation covers a 40-year period of involvement in pattern injury analysis. In that period, only four cases have come to this study’s attention that were of evidentiary value. Although human bitemark evidence has been under continued criticism over the past 20 years as being unscientific, there is in rare cases very useful evidence observable to the trained odontologist. It is extremely important that the odontologist be conservative and not develop a bias during the investigation of pattern injuries.

Standard scientific methods cannot be used in pattern injury analysis. Neither the odontologist nor anyone else can control or reproduce the numerous factors involved in pattern injuries on human skin. A field of science in which controlled observations cannot be done in order to study cause and effect is called an “observational science.” For example, astrophysics is an observational science in which a person cannot change the movement or any other aspect of the sun, moon, or stars. Similarly, the odontologist must develop his/her opinions based on a sound understanding of dental anatomy, clinical experience, and keen observational skills. With these tools, the odontologist must carefully understand and correctly interpret each and every mark in the pattern injury. The use of the American Board of Forensic Odontology Bitemark Analysis and Comparison Algorithm is a most helpful tool during the odontologist’s investigation of pattern injuries.

Odontology, Bitemark, Observational Science

G28 The Crash of Flight IY 626: Bitemark Identification on Victims' Bodies

Charles Georget, DDS, IRCGN, Pontoise, France; Ing Aime Conigliaro, MSc, IRCGN, Pontoise, France*

Learning Overview: This presentation provides feedback on a Disaster Victim Identification (DVI) mission with specific conditions: a submarine recovery scene with two distinct identification sites and a bitemark analysis applied to the identification of implied taphonomic fauna.

Impact Statement: This presentation will impact the forensic science community by presenting the use of a submarine rescue vehicle for the recovery of air crash victims and the influence of Postmortem (PM) examination conditions on the DVI process. Moreover, it highlights the advantages of pluridisciplinary analysis and close collaboration between two DVI team located 800km from each other.

On June 30, 2009, flight IY 626, operated by Yemenia Airways, crashed into the Indian Ocean during a Saama (Yemen)—Moroni (Comoros) service. It hit the surface of the water while approaching its destination airport. There were 142 passengers and 11 crewmembers on board. Among them were 62 French people and 43 Comorians living in France. The sole survivor was a 13-year-old girl.

On July 4, the United States Air Force located the first fragments of the aircraft after a several-day air-sea rescue operation near Ngazidja Island. The next day, the French *Bureau d'Enquêtes et d'Analyses* (BEA) detected the signals from both flight recorders. The wreckage was lying on the ocean floor at a depth of 1,200 meters. The French Ministry of Defense decided to chart this part of the very steep ocean floor at once, and the French Navy conducted this task until July 23. Then the American submarine rescue vehicle *Remora 6000* recovered the flight recorders. It was not possible to pull out of the water the first bodies and the beacons before August 21.

However, on July 8, 21 bodies and some aircraft debris were recovered near Mafia Island off the coast of the United Republic of Tanzania. It was a surprise because Tanzanian coasts were 800 kilometers away from the crash site. Autopsies could be performed as early as July 10, at Dar Es Salaam (Tanzania).

Both in Tanzania and Comoros, the autopsies revealed PM bitemarks on some of the victims' remains. Some of the bodies recovered on the seashore of Mafia Island had deep and large wounds due to squall bites and smaller and rounder bites originating from unidentified predators.

On Comoros, the videos recorded by the submarine rescue vehicle showed that the fauna were diverse near the A310 wreckage. Crabs and spider crabs were living close to *isistius* (cookiecutter) sharks. The videos allowed the Forensic Science Laboratory of the French Gendarmerie (Institut de Recherche Criminelle de la Gendarmerie Nationale [IRCGN]) to identify the species responsible for the small and round wounds.

The management of this aircraft disaster had distinctive technical, technological, and scientific features. Indeed, for the first time, French authorities resorted to the use of a submarine rescue vehicle and had to deal with two body-recovery areas.

The submarine rescue vehicle resurfaced a Digital Fly Data Recorder (DFDR), a Cockpit Voice Recorder (CVR), and the remains of 68 victims, who were lying at a depth of 1,200 meters. After that, victim identifications were performed at two different sites, located 800 kilometers from each other, under different conditions and at different periods. Eventually, the French DIV determined the origin of PM lesions found on some of the remains.

Identification, Bitemark, Marine Fauna

G29 Bitemarks: Do They Still Exist?

Richard Fixott, DDS, Redmond, OR*

Learning Overview: The goal of this presentation is to discuss the diagnostic criteria for suspected bite injuries, explore how to better train odontologists, and discuss how best to use bitemark evidence.

Impact Statement: This presentation will improve the usefulness of recognizing an injury as a human bite.

There has been much discussion concerning bitemarks and forensic odontology, to the point where some feel there is no value in recognizing or diagnosing an injury as a human bite. Concerns include the scientific basis for identifying a bitemark, disagreements among practitioners, the lack of an error rate, and, most importantly, criminal convictions based partially or solely on bitemark analysis that have been overturned.

Is there a scientific basis for bitemarks? Multiple research projects have consistently demonstrated that a bite administered with sufficient force will create an injury. Patterned injuries can be examined, and a differential or definitive diagnosis that may include or be a human bite can be made. Recognition/diagnosis of an injury as a human bite is part of the mandate to health professionals to report abuse/neglect: the diagnosis/recognition of an injury as a bite may have evidentiary value.

Diagnosis in general is based on examination of the patient, testing, and practitioner experience. A differential diagnosis of an injury as a bite can be based on the diagnostic size, shape, and pattern criteria seen. A definitive diagnosis is based on the same criteria as well as elimination of all other reasonable causes.

Disagreements among practitioners do not mean that a particular diagnosis or medical discipline is invalid. For example, dentists can interpret a radiograph as showing a cervical radiolucency as caries, artifacts, or anatomical features. Because there are disagreements, does it follow that dentists should not be qualified to detect or treat caries? Individual physiological differences will create different responses to the same treatment, test, and/or diagnosis. Different opinions or treatment options are a reflection of physiological differences, not necessarily professional competence, and make the idea of a “bench science” -type of error rate not applicable.

What should be eradicated? Definitely the inclusion of one dentition to the exclusion of all others (which is currently expressly forbidden by the current American Board of Forensic Odontology [ABFO] Standards and Guidelines, DRM Section 3, Page 9) but not the ability to observe and diagnose an injury as a bite. The goal of this presentation is to discuss diagnostic criteria for suspected bite injuries, explore how to better train odontologists, and discuss how best to use bitemark evidence.

Bitemark, Odontology, Diagnosis

G30 Progress on a National Institute of Standards and Technology (NIST) Scientific Foundation Review Assessing Bitemark Analysis

Kelly Sauerwein, PhD, National Institute of Standards and Technology, Gaithersburg, MD; Christina Reed, MS, National Institute of Standards and Technology, Gaithersburg, MD; John Butler, PhD, National Institute of Standards and Technology, Gaithersburg, MD*

Learning Overview: This presentation reports progress on a NIST scientific foundation review examining bitemark analysis.

Impact Statement: The foundational review provides an assessment of the current literature related to bitemark analysis. This report will help promote a better appreciation of the limitations of bitemark analysis among the forensic science community, stakeholders, and the general public.

Bitemark analysis involves three key premises: (1) the uniqueness of human dentition, (2) the ability of bitemark characteristics to be transferred and persist on human skin, and (3) the ability to associate a bitemark to an individual. More than 200 sources (including peer-reviewed articles, books, edited volumes, conference abstracts, and discussions held during a 2019 Bitemark Thinkshop organized by the Center for Statistics and Applications in Forensic Evidence [CSAFE]) were examined as part of this assessment.¹

Relying on a suspect's dentition to associate it with a bitemark pattern found on a victim assumes that the three key premises just mentioned are reliable and true. Support for uniqueness alone, however, has proven difficult. Because the ability to distinguish one human mouth from another is possible using dental records for the purpose of identifying a deceased individual, there currently exists a lack of agreement regarding the specific characteristics for establishing uniqueness when tasked to compare dentition patterns alone. Furthermore, no population frequencies have identified the degree of variation in dental features or included measures of similarity, error, or correlation.^{2,3} Indeed, multiple bites from a single dentition have shown significant distortions such that no two bitemarks from the same mouth appeared the same.⁴ If bitemarks with the same dentition are not reproducible, then doubt about the possibility of unique, individual dental patterns increases.

In addition, this distortion problem hinders the ability to accurately transfer individual characteristics of the biter's dentition to the substrate.⁴⁻⁶ Not only might two bites from the same mouth leave different marks, but any one bite may not reflect the characteristics of the biter because of distortions that can result from bite force, surface area and alignment of the dentition, tooth sharpness, elasticity of the victim's skin, movement during the biting event, and the body's injury response. All of these may prevent an analyst from reliably including or excluding a potential suspect.^{4,7-8} Therefore, a bitemark impression in the skin would not include sufficient detail to make an identification on an individual level. Additionally, current imaging methods may be insufficient because they do not capture all the characteristics necessary for bitemark analysis; for example, these methods cannot determine the force of the bite, the bruising depth, or the movement during the bite.¹ Even under highly controlled experimental conditions, bitemark analysis has shown high levels of variability and incorrect identifications. Bitemarks in cases in which circumstances cannot be controlled are prone to error and unlikely to produce accurate results.

Conclusion: For the past 60 years, repeated calls have been made for fundamental research in bitemark analysis. From this study's analysis, there appears to be a lack of empirical data to support the premise that bitemarks are unique to individuals, that those distinguishing characteristics can be reliably transferred to skin, and that modern methods can compensate for distortions and provide accurate information to exclude or not exclude an individual as the source of a bitemark.

Odontology, Bitemark, Dentition

G31 Stress on Forensic Odontologists

Wassim Mohammad Rihawi, MS, Identification Center, Aleppo, Syrian Arab Republic*

Learning Overview: This presentation will demonstrate the stress forensic odontologists are faced with and the importance of absolute accuracy in their work.

Impact Statement: This presentation will provide enlightenment regarding the hard work of forensic odontologists.

The forensic dentist is no longer interested in treatments and the cosmetic aspect as much as he has engaged in difficult tasks, some of which are stressful to both physical and psychological health. Work pressure on the one hand and accuracy of work on the other hand and long hours sometimes all change the psychology of the forensic dentist ..

One of the most complex tasks of the forensic dentist is the analysis and study of bite marks. At a time when this specialty is new in Middle East countries and specialists have begun to highlight its importance to judicial authorities and the police regarding the need to call the forensic dentist in the event of suspicion of bite marks, an opposite trend began in the United States about the failure of this evidence to be proven, in some cases, as irrefutable evidence in the course of investigations. This would increase pressure on the forensic dentist to not make a mistake when dealing with the perpetrators on the one hand and with the living and dead victims on the other hand.

In some cases, the judge may request evidence that is not completely scientifically supported; this also increases the burden on the specialist to explain that the evidence follows several different circumstances. However, the specialist is obliged to respond to the judge's request, since that request is one of his duties.

Psychological pressure may not only be related to the analysis of bite marks; other tasks are added to it, such as estimating age. What is interesting is that pressures sometimes arise from the environment surrounding the case, if the specialist has some kind of threat to his life or career if his final report is not suitable for their interests.

This presentation will mention some examples that show how risky this profession is and how it requires absolute accuracy in the work, and how it may lead some to thinking about early retirement if matters become more threatening to the safety of this specialist.

Stress, Forensic Odontologist, Hard Work

G32 Hot Off the Press—New Standards and Technical Reports in Forensic Odontology

Kenneth Aschheim, DDS, Office of Chief Medical Examiner, New York, NY; Kathleen Kasper, DDS, Collin, Dallas, and Tarrant County Medical Examiner Offices, Carrollton, TX; Raymond Miller, DDS, Office of the Erie County Medical Examiner, Buffalo, NY*

Learning Overview: This presentation will cover the essential American National Standards Institute (ANSI) requirements for developing standards. In addition, it will illustrate how the Academy Standard Board (ASB) and the American Dental Association (ADA) Standards Committee on Dental Informatics implement those requirements to create forensic odontology standards. It will conclude with a detailed look at the development of ADA TR1077 and ASB BPR 108.

Impact Statement: This presentation will impact the forensic science community by demonstrating how a partnership between forensic science and a Standards Development Organization (SDO) can create consensus-based standards and best-practices documents. These documents aim to delineate policies, procedures, and guidelines that provide a framework for ensuring that the forensic sciences deliver high-quality, reliable, and consistent results.

In 2005, Congress passed the Science, State, Justice, Commerce, and Related Agencies Appropriations Act to “conduct a study of forensic science.” Its goal was to disseminate guidelines that will ensure quality and consistency in using forensic technologies and techniques. The result was the recommendation in 2009 by the National Academy of Sciences to create a “new, strong, and independent entity” outside of the jurisdiction of the Department of Justice (DoJ) to define standards and guidelines for the forensic sciences.

Standards are consensus-based specifications, rules, guidelines, or definitions created using a well-defined review and adjudication process. Historically, Scientific Working Groups (SWGs) were created to develop these documents. One example was the creation in 2011 of the Scientific Working Group on Disaster Victim Identification, which included various forensic disciplines associated with victim identification. However, one of the shortcomings of SWGs was that they follow the formal standards development process.

In 2013, the DoJ created The Organization of Scientific Area Committees (OSAC) to assist in developing these scientifically based documents. OSAC subcommittees were tasked with taking over the work of many of the SWGs, which were subsequently sunsetted. Once these documents were created, SDOs would complete the process by publishing documents that went through vigorous consensus-based rules. In addition, OSAC created a formal registry of independently reviewed and approved SDO-published documents for recommended use by forensic specialties. Both the Forensic Odontology (FO) subcommittee and the Disaster Victim (DVI) subcommittee of OSAC were tasked with handling documents affecting forensic odontology. Since then, numerous documents such as ANSI/ADA 1058–2010 (R2015)—Forensic Dental Data Set and ADA Technical Report No. 1088 Human Identification by Comparative Dental Analysis—have been placed in the OSAC registry.

In 2014, the FO subcommittee formalized a best-practice document to assess a chronological age interval by dental means. The draft document was submitted to American Dental Associations’ Standards Committee on Dental Informatics (ADA SCDI), an ANSI-accredited SDO. ADA SCDI Subcommittee 14—Forensic Odontology Informatics’ Working Group 14.3: Human Age Assessment by Dental Analysis—completed the formal review process. This document was approved as ADA Technical Report No. 1077 for Human Age Assessment by Dental Analysis (ADA TR1077). Its stated goal is to describe best practices for estimating a chronologic age interval of a living or deceased individual by analyzing the human dentition and associated maxillofacial structures.

Also in 2014, SWGDVI was transitioned into the OSAC DVI subcommittee to continue work on a set of documents from various disciplines such as DNA, odontology, anthropology, and others. These documents served as Best Practice Recommendations (BPR) in disaster victim identification. The completed draft documents were then submitted to the ASB, an ANSI-accredited SDO established by the American Academy of Forensic Sciences (AAFS). The ASB’s mission is to create high-quality, science-based consensus forensic standards, guidelines, best-practice recommendations, and white papers for the entire forensic community.

One of those documents would ultimately become ASB BPR 108: Forensic Odontology in Disaster Victim Identification: Best Practice Recommendations for the Medicolegal Authority (ASB BPR 108). This document covers best-practices recommendations as they apply to the forensic odontology section of a mass-fatality incident team and relates to the morgue’s staffing, antemortem, and postmortem data collection, the forensic dental autopsy, and applied technologies. It also includes recommendations for the dental identification and reconciliation processes to ensure consistency and reliability.

Standards, Forensic Odontology, ADA

G33 A Morphometric Analysis of Cone Beam Computed Tomography (CBCT) Images of the Mastoid Process for Sex Determination in the Adolescent Population

Avni Bhula, DDS, MSc*, University of Texas Health School of Dentistry, Houston, TX; Ritu Tiwari, MDS, University of California-Los Angeles, Los Angeles, CA; James Fancher, DDS, PhD, University of Texas Health School of Dentistry, San Antonio, TX; David Senn, DDS, University of Texas Health School of Dentistry, San Antonio, TX

Learning Overview: After attending this presentation, attendees will have a better understanding of the importance of dental radiology techniques in differentiating sexual dimorphism in the adolescent population.

Impact Statement: This presentation will impact the forensic science community by presenting evidence of using dental radiography to measure a cranial feature that displays sexual dimorphism at critical ages.

One of the key features in assessing the biologic profile of an individual is sex. The pelvis and the skull display the greatest levels of sexual dimorphism, the pelvic bone being the most reliable.^{1,2} Following the pelvis, the mastoid process of the temporal bone is the second-most-reliable osteological feature to determine sexual dimorphism.³ The size of the mastoid process is known to show marked sexual dimorphism in adulthood.^{4,5} Currently, it is known that there is no difference in size of the mastoid process of males and females at the pre-pubertal age that allows for sexual dimorphism of skeletal remains. This study aims to assess the age at which sexual dimorphism can be differentiated in adolescents by analyzing the dimensions of the mastoid process from pre-existing CBCT images.

Overall, males present with larger dimensions, more robust cranial and facial features, and greater muscularity. However, female skulls tend to demonstrate gracile features. After the onset of puberty, the difference between males and females becomes clearer, with males developing adult features and females retaining pedomorphic features.⁶ On average, girls begin puberty at ages 10–11 and complete puberty at ages 15–17; boys generally begin puberty at ages 11–12 and complete puberty at ages 16–17.⁷

This study consists of 60 individuals between 10 and 16 years of age. The study sample was derived from the database of the Department of Oral and Maxillofacial Radiology, University of California, Los Angeles. Pre-existing CBCT images taken for clinical purposes were analyzed. Size analysis of the mastoid process performed by two observers was based on linear measurements performed between selected points located on the mastoid process that objectively yielded the largest dimension. Linear measurements were recorded for both right and left mastoid processes and included mastoid height, width, and length.

All analyses were performed using R statistical software (R Core Team 2018) and SPSS version 26. No statistically significant effect was found among age, gender, and mastoid width and length. However, a statistically significant effect of gender was found on age and mastoid height (right height p value=0.017; left height p value=0.047). The intraclass correlation coefficient between the observers for right and left height was 0.96 and 0.97, respectively. In males, the greater the age, the larger the mastoid height beginning during puberty (\approx age 13) from graphic extrapolation. Therefore, from these findings, it may be concluded that the mastoid process may demonstrate dimorphic gender features from the approximate age of 13.

Mastoid Process, Age Assessment, Sexual Dimorphism

G34 Forensic Anthropological Evaluation of Mandibular Remains and Included Furnishings

Nicolina Palamone, DDS, Laboratorio di Antropologia e Odontologia Forense, San Potito Sannitico, Italy; Antonio Della Valle, DDS, Laboratorio di Antropologia e Odontologia Forense, San Potito Sannitico, Italy; Angelica Zenato, DDS, Laboratorio di Antropologia e Odontologia Forense, San Potito Sannitico, Italy*

Learning Overview: With this study, attendees will be able to learn about the forensic anthropological evaluation of human remains that is aimed at personal identification, the tests and techniques conventionally used in this evaluation, and the means and methods used to construct a “biological profile” that identifies the species, race, age (*perimortem*), sex, probable historical and chronological periods, possible life habits, and the social conditions of the individual.

Impact Statement: The impact to the science community of this presentation will be a deepening understanding of the techniques used in the forensic anthropological evaluation of human remains that is aimed at personal identification.

Individual identification represents a central focus of the forensic anthropological analysis of human skeletal remains. Advancements made in recent research include new anatomical areas of interest, technologies, mathematical approaches, and biochemical analysis and techniques, namely, modern-day isotopic investigations on human remains. The use of multi-isotope profiles (e.g., C, N, O, H, S, Sr, and Pb) from multiple body tissues (e.g., teeth, bone) helps predict the likely region of origin of unidentified human remains and provides additional items of evidence for human identification, including a decedent’s possible region of birth, long-term adult residence, history, and dietary choices. Also, the study of funerary furnishings provides details that help contextualize the historical period in which the individual lived.

Individual identification, Biological Profile, Stable Isotope Analysis

G35 Let's Only Use What Really Counts! A New Formula for Age-at-Death Assessment Using Root Translucency

Joe Adserias-Garriga, DDS, PhD, Mercyhurst University, Erie, PA; Anthony Lanfranchi, MS, Mercyhurst University, Erie, PA; Kristine Kortnick, MS, Mercyhurst University, Erie, PA; Douglas H. Ubelaker, PhD, Smithsonian Institution, Washington, DC; Sara C. Zapico, MS, PhD, New Jersey Institute of Technology, Washington, DC*

Learning Overview: Attendees at this presentation will acquire a thorough understanding of how to apply root translucency measurement to age-at-death assessment in order to obtain more accurate results than is possible when this parameter is used in conjunction with other postformation changes.

Impact Statement: This presentation will affect the forensic science community by providing a new formula for dental age assessment using root translucency.

A main contribution of forensic odontologists and forensic anthropologists to forensic investigations is their ability to assess a person's biological profile. A significant component of the biological profile is the age-at-death assessment. Age assessment can assist in narrowing the search possibilities for cases involving missing persons and unidentified decedents. The study of dental tissues has long been considered a very useful tool for age assessment; therefore, several age assessment methods involving dentition have been developed and are widely used. Dental age assessment methods in infants, children, and young adults rely on developmental changes of the dentition, whereas adult dental age assessment methods rely on postformation changes.

Lamendin et al. developed an adult age estimation method based on root transparency and periodontal recession.¹ Their regression formula was successfully applied to the age assessment of individuals between 40 and 70 years old. Later, Prince and Ubelaker evaluated the effects of ancestry and sex and incorporated root height into the equation, thereby developing four new regression formulas for males and females of African ancestry and for males and females of Caucasian ancestry.² In 2018, Adserias et al. adjusted these techniques by demonstrating that 1600 lux was the best light setting for analyzing root translucency.³

However, a frequent concern of researchers and practitioners was the subjectivity in the periodontal recession measurement when applying the methods established by Lamendin et al. and by Prince and Ubelaker.

The aim of this present study is to create a new formula that takes into account just one postformation change: the root translucency, which has been demonstrated to show a good correlation with chronological age. So, periodontal recession (which is considered in the formulas generated by Lamendin et al. and by Prince and Ubelaker) would be taken out of the equation.

Ninety single-rooted teeth from individuals of known age and sex were used for this study. Two observers measured root height, periodontal recession, and root translucency in millimeters. Root translucency was measured applying the 1600 lux. Intra- and inter-observer errors were recorded.

Lamendin and Prince and Ubelaker's formulas were applied to obtain an age estimate. A new formula considering only root translucency was generated, without lowering the accuracy.

Thus, the findings from this research demonstrate that even with only one parameter, it is possible to determine age from uniradicular teeth with similar accuracies (and without using previously established formulas), thereby reducing the subjectivity of the estimates.

Age Assessment, Postformation Changes, Root Translucency

H1 A Triple “Suicide Pact”: A Case Report With a Review of the Literature

Matteo Cecchetti, MD, Health Science Department, Forensic Pathology Section, University of Florence, Florence, Italy; Ilaria Tarozzi, MD, Health Science Department, Forensic Pathology Section, University of Florence, Florence, Italy; Silvia Raddi, MD, Health Science Department, Forensic Pathology Section, University of Florence, Florence, Italy; Silvio Chericoni, PhD, Department of Surgical, Medical, and Molecular Pathology, University of Pisa, Pisa, Italy; Sara Bortolini, PhD, Science and Technology, Free University of Bolzano, Bolzano, Italy; Valentina Bugelli, PhD, Azienda Usl Toscana Sud-Est sede di Grosseto, Grosseto, Italy*

Learning Overview: After attending this presentation, attendees will better understand the role of a thorough analysis of the crime scene, together with an accurate autopsy and appropriate toxicological test in a singular case of a triple suicide consumed within a family nucleus.

Impact Statement: This presentation will influence the forensic science community by providing an interpretation of the relevance of autopsy and crime scene analysis as well as the importance of additional circumstantial information to distinguish between unusual suicide and homicide impacts.

Three bodies belonging to same family were discovered in their apartment. The mother, a 77-year-old woman, was discovered lying on her bed, in her pajamas. The body was cachectic, partially mummified, composed, in the absence of external lesions or blood stains on the soma and nearby. There were no signs of defense or constriction. The clothes were unaltered. No dirt was detected in the environment. At the autopsy, through toxicological tests, the cause of death was attributed to a lethal intake of morphine in an elderly person with terminal cancer. The two other bodies (49-year-old male and 46-year-old female) were found in their bed, with blood stains and the same stab wound in the left lateral cervical region, which cut off the anterior head of the left sternocleidomastoid and damaged the vascular wall of the external jugular vein. On the clothing, there were no signs of discontinuity. The cause of death was therefore determined as acute posthemorrhagic anemia due to venous bleeding, which contributed to the assumption of psychotropic drugs and alcohol, as confirmed by the toxicological data.

In such a scenario, what are the useful elements to distinguish between homicidal and suicidal hypotheses? Numerous scenarios are possible whenever two (or more) individuals are found unexpectedly dead at the same location. The considered hypothesis could be accidents and natural diseases, suicides, or homicides. Suicide pacts usually involve only two victims and are rare, accounting for only 0.6-4% of cases of suicide overall. Joint suicides have often been provoked by serious illness in one or both of the victims, so a review of their recent medical histories may be clarifying. Thorough scene investigation, autopsy findings, as well as toxicological analysis are essential in discriminating between homicide and suicide. From the crime scene, as much information as possible should be obtained on the victim's previous character, including previous psychiatric history, in order to elucidate his or her manner of death. External examination of the body is crucial to discover signs of fighting with defense injuries or lesions on the clothes. In this case, the lack of traumatic injury on mother's body and clothing, as well as the finding of morphine, led to deeming a suicidal purpose that is supported also by the circumstantial elements such as: a recent voluntary discharge from the hospital with the presence of the hospital identification bracelet, end stage neoplastic disease with baleful prognosis, and alcohol intake. The two adult children's bodies, found together in the bed, presented a single-cut wound in the neck without any defense injuries and both were surrounded by abounding blood stains.

The anamnestic-circumstantial elements, suggestive of isolation of the family unit with little, if any, contact with the outside world, the morbidity of the relationship of the sons toward the mother, and the economic difficulties, together with the serious health problems of the mother, account for an overall dynamics of “suicide pacts” most likely motivated by a condition perceived as unsustainable and devoid of possible solutions by the small family unit.

Suicide Pact, Homicide/Suicide, Crime Scene

H2 A Reconstruction of Events, Including a Self- Inflicted Gunshot Wound, Leading to a Fatal Motor Vehicle Collision

Molly House, DO Office of the Chief Medical Examiner, Norfolk, VA; Wendy Gunther, MD, Office of the Chief Medical Examiner, Norfolk, VA*

Learning Overview: After attending this presentation, attendees will better understand how to reconstruct the probable course of events in a motor vehicle crash in which the acutely intoxicated driver sustained a gunshot wound.

Impact Statement: Separation of injuries from gunshot wounds from those sustained in a terminal motor vehicle collision assists in clarifying the cause and manner of death; forensic evaluation of the ballistic and blunt force injuries can allow reconstruction of the events during the interval between gunshot wound injury and death.

A 27-year-old man, with a history of heavy drinking and recent exacerbation of chronic back pain, drove away from an attempted police traffic stop. A low-speed chase ensued, with the vehicle passing through several residential yards before colliding with a tree. The airbags deployed; the unrestrained victim was found dead. Police and emergency medical technicians saw fragmented brain on the dashboard, inconsistent with the mechanism of the crash.

Police identified two rounds, one deformed, on the floorboards beside the driver's seat. A black firearm, pointing upward with hammer cocked back, was found on the floor between the console and the passenger seat. There were unfired rounds in cup holders, and empty liquor bottles throughout the vehicle.

Multiple findings at autopsy were consistent with a vehicle crash. There was significant blunt force trauma to the head (facial fractures), chest, abdomen, and extremities. The lungs exhibited lacerations due to rib fractures and contusions. There was partial transection of the descending thoracic aorta past the subclavian takeoff, associated with dissecting posterior mediastinal hemorrhage, but no hemothorax. The liver had multiple lacerations. There were omental tears and a tear in the gastocolic ligament; hemorrhage surrounded the transverse colon. A duodenal bruise was associated with dissecting hemorrhage between the duodenum and the pancreas and foci of retroperitoneal hemorrhage. The left femur was fractured.

In addition to blunt force trauma, the decedent had a hard contact perforating gunshot wound of the right temple, with exit above the left ear. This correlated to a fatal brain injury. Extensive skull fractures were due to both gunshot wound injury and impact; calvarial and basilar skull fractures were from the gunshot wound; facial fractures that shifted the midline of the face to the left were from blunt trauma. There was also a patterned injury, a C-shaped mark, on the right side of the neck, suggestive of an incomplete circumferential muzzle imprint without a bullet defect.

Postmortem toxicology identified markedly elevated blood and vitreous ethanol, $0.310 \pm 0.017\%$ by weight by volume in blood, and $0.340 \pm 0.019\%$ in vitreous humor. Blood also exhibited marijuana metabolites; vitreous humor showed a trace of isopropanol. No other drugs or drug classes were identified.

Scene and autopsy findings allowed reconstruction of the probable chain of events. The first event was probably the attempted hard contact gunshot wound of the neck, resulting in misfire. It is likely that this occurred while the victim was driving away from the attempted traffic stop; the unfired round found on the floorboard was probably correlated with this gunshot. The second event was the suicidal gunshot wound to the head, which caused death. Given the extent of blunt force injuries, it was unlikely he could have shot himself after the crash. As the blunt force injuries did not have a typical postmortem appearance, there must have been a very short interval between the fatal gunshot wound and the vehicle's collision with the tree. Most likely, he shot himself as he was driving through the last residential yard or just before the collision occurred.

This unusual suicidal gunshot wound death occurred in a decedent who succeeded in driving with a markedly elevated blood ethanol level (characteristic of chronic alcoholism, which carries an increased risk of suicide). Recent "intolerable" exacerbation of his chronic back pain may also have played a role. The fatal gunshot wound probably followed an attempted suicidal gunshot wound to the neck with a misfire. The correlation of history and scene information with laboratory and autopsy findings allowed reconstruction of the probable chain of events and determination of the cause and manner of death.

Motor Vehicle Collision, Suicidal Gunshot Wound, Event Reconstruction

H3 Takayasu Arteritis Involving Coronary Arteries in a Young Black Male: A Case Report and Literature Review

John Hu, MD, PhD, Pinal County Medical Examiner's Office, Florence, AZ*

Learning Overview: After attending this presentation, attendees will appreciate typical pathologic features of Takayasu Arteritis (TA) at autopsy, especially in a pediatric patient.

Impact Statement: The postmortem diagnosis of TA in autopsy highlights the importance of autopsy as a tool to provide critical pathologic findings to clinicians and facilitate early diagnosis and treatment, which may delay the advancement of the disease and improve prognosis of TA.

Background: TA is a rare, chronic, granulomatous, idiopathic vasculitis of large blood vessels. Although it was initially reported mainly in Asia, incidences have been reported worldwide in all ethnicities and age groups. Early diagnosis of TA is challenging in the pediatric population due to its non-specific clinical manifestations and lack of reliable laboratory biomarkers. The differential diagnoses of TA are wide, including other granulomatous vasculitides involving large vessels, sarcoidosis, or tuberculosis or syphilis infections. Clinical intervention often delays advancement of disease and improves prognosis.

Clinical Presentation: Presented is an undiagnosed case of TA in a 17-year-old Black man with no known medical history. The patient had complained of non-specific symptoms of malaise, occasional chest pain, and pain the left shoulder since the age of 15. Laboratory tests were remarkable for slightly elevated immunoglobulin. He began to experience palpitations a few weeks prior to his death and intermittent chest pain five days prior to his death. Cardiac troponin-I was elevated. A urine drug screen was negative for drugs of abuse. He was discharged home after a normal echocardiogram study. He was later found unresponsive and was pronounced deceased shortly after arrival at the hospital. Autopsy showed 50% to 70% stenosis of the proximal portions of the right coronary artery and left anterior descending coronary artery with concentrically thickened vascular walls. The intrathoracic aorta, pulmonary trunk and arteries and their primary branches, proximal portion of the brachiocephalic artery, left common carotid artery, and left subclavian artery showed irregularly raised plaques on the intimal surfaces with markedly thickened arterial walls and moderate reduction of luminal sizes. There was no prominent mediastinal lymphadenopathy. There were no gross nodules in the pulmonary parenchyma. Microscopically, extensive infiltrates comprised of lymphocytes and plasma cells were seen in the large vessels, with thickening of entire arterial walls, including the intima and the junction between the tunica media and adventitia. There was disorganization of elastic fibers. Inflammation also involved the vasa vasorum. There were rare granulomata with multinucleated giant cells in the aortic wall. Intimal fibrosis and inflammatory cells infiltrates also involved coronary arteries with reduced lumina and thickening of the adventitia. The myocardium showed multiple foci of wavy myofibers with necrosis and neutrophils. The cause of death was attributed to acute myocardial infarction due to TA involving coronary arteries. Acid-fast bacilli and Grocott-Gomori methenamine silver stains of the involved aorta were unremarkable. A postmortem nasopharyngeal swab was negative for SARS-CoV-2.

Discussion: The age of the patient in this case, involvement of mainly large vessels, and overall histologic features are consistent with TA. The clinicopathological features of TA in children and young adults often present challenges to early diagnosis. While early clinical features are often non-specific, malaise, fever, chest pain, pain the left shoulder, and elevated troponin-I of unknown etiology in a young man may warrant further work-up, including detailed physical examination and vascular imaging studies. Myocardial infarction is one of the leading causes of death in patients with TA. Early diagnosis and treatment can delay advancement of disease and improve prognosis.

Takayasu Arteritis, Autopsy, Myocardial Infarction

H4 A Fuel Tank Injury In a Fatal Motorcycle Accident

Gianluca Rossi, MD*, University of Turin, Turin, Italy; Giancarlo Di Vella, MD, PhD, University of Turin, Turin, Italy; Marta Moretti, MD, University of Turin, Turin, Italy; Lucia Tattoli, PhD, A.O.U. Città della Salute e della Scienza Of Turin, Turin, Italy

Learning Overview: After attending this presentation, attendees will better understand that some typical lesions can help the forensic pathologist to clarify the dynamics of motorcycle accidents.

Impact Statement: This presentation will impact the forensic scientific community by highlighting the importance of injury around the groin area in victims of motorcycle accidents, known as Fuel Tank Injury (FTI) as one of the few characteristic findings.

Vehicle trauma is the leading cause of death in young people. The collision injury mechanism is the cause of direct impact with a fixed object, another motorcycle, or vehicle. FTIs occur when a motorcycle undergoes a violent deceleration following the impact, leading the driver to slide forward against the tank, handlebars, and steering of the vehicle. The driver creates high peak loads between the rider's pelvis and the motorcycle fuel tank, causing abdominal and groin injuries. The 85% of the pelvic injuries sustained by the patient were due to this type of mechanism.^{1,2} FTIs are comparatively rare even in drivers of motorcycle accidents because they may occur only from a head-on collision. Some reports showed that the FTI was an evidence of the driver, even though the passengers can also suffer from groin injuries.³

A 26-year-old man was riding on a motorcycle with a 600-cc engine (Honda® Hornet®). The motorcycle ran straight into an intersection at high speed and collided with the right-frontal side of a left-turning car. The rider was thrown from the motorcycle onto the roadway by the impact. He was unconscious immediately after the accident and had neither spontaneous breathing nor response on arrival at the emergency department, where he was pronounced dead.

At autopsy, the body showed purple bruising distributed symmetrically over both hips with a partial bowel evisceration through an abdominal lacerated wound, scrotal laceration with exposure of the left testicle, left femur's fracture, and diffuse bruises and abrasions of the head, the trunk, the abdomen, and the four limbs. Multiple rib fractures, thoracic aorta's laceration, intrathoracic herniation of the liver through a diaphragmatic breach, and laceration of the bowel, the spleen, and the liver were also found.

The groin injuries were related to the violent impact with sudden deceleration of the motorcycle, which catapults the rider forward over the saddle. The FTI resulted from gliding and striking of the scrotum and perineum of the rider on the fuel tank during the collision.

For its mechanism, this injury is one of the most useful and important findings of the motorcycle driver and has been described as exclusive to the driver who is sitting behind the fuel tank.³ The occurrence of groin injuries appears to be dependent on the specific dynamics of the collision and on the impact speed.⁴ Therefore, a better knowledge of the FTIs is helpful to understand the dynamics of the event and to discriminate the driver from the passenger, in case this is unknown.

Fuel Tank Injury, Groin Injury, Motorcycle Accident

H5 What Causes the Triad in Diagnosed Abusive Head Trauma (AHT)? Is It the Shaking?

Thomas Young, MD, Heartland Forensic Pathology, LLC, Kansas City, MO*

Learning Overview: After attending this presentation, attendees will reconsider diagnosing subdural hemorrhages, retinal hemorrhages, and encephalopathy as AHT.

Impact Statement: This presentation will impact the forensic science community by demonstrating through media reports that most cases diagnosed as AHT are neither abusive nor traumatic.

This study utilizes news media reports rather than records generated by physicians. Using media reports instead of doctor-generated reports has advantages, including: (1) obtaining access to unprotected information in the public domain, (2) learning points of view that differ from those that typically diagnose AHT; and (3) learning more about the antecedent past events than the consequent medical outcomes. Disadvantages (which may also be advantages) include: (1) obtaining data from medically untrained individuals (yet this may mitigate bias that physicians who study this problem often carry); (2) encountering frequent bias in media reports (yet such bias frequently favors prosecutors who allege abuse and trauma in AHT court cases and not defendants); and (3) learning unverified information from one source (yet multiple media sources showing similar events are compelling).

Internet searches through [google.com](https://www.google.com) using the words “child abuse shaken baby abusive head trauma” yielded 40 media reports of AHT from September 2, 2020, to August 7, 2021. Reports requiring a paid subscription to access them were excluded. All news reports came from 26 states within the United States.

Victim ages were: 3 weeks to 5 months: 24/40 (24 out of 40 reports); 6 months to 11 months: 5/40; 1 year to 3 years: 6/40; > 3 years: 1/40; age not stated (reported as “infant” or “baby”): 4/40. Children who were unresponsive/non-breathing and transported to a hospital: 32/40; responsive/breathing and transported to a hospital: 5/40 (2 of these for onset of seizures, 1 for lethargy and vomiting, 1 for thermal burns); unresponsive with no mention of a hospital: 2/40; referred to a hospital by an outside doctor: 1/40. Reports with no mention of shaking or head impact from any eyewitness: 22/40; with witnessed accidental trauma: 5/40; with trauma resulting from attempting to revive an unresponsive child: 2/40; with shaking admitted to police: 9/40; with shaking and abusive head impact admitted to police: 2/40; with abusive head impact only admitted to police: 1/40; with abusive trauma (not shaking) witnessed by other(s): 2/40; with shaking or abusive impact spontaneously and independently confessed: 0/40. Reports mentioning skull fractures: 5/40; rib fractures: 4/40; arm fracture: 1/40; ankle fracture: 1/40; numerous fractures not further described: 1/40.

Most infants diagnosed with AHT stop breathing, then are resuscitated but die later in the hospital. Bleeding from a rich dural venous plexus that persists until about age 3, bleeding from hypoxic retinal vessels, and the hypoxic encephalopathy that follows a restoration of blood flow result in the AHT triad. As such, this is a hypoxia problem, not an “abusive” or “head trauma” problem.

Infants who die suddenly and unexpectedly in infancy—“crib death” or “Sudden Infant Death Syndrome (SIDS)” —are typically not successfully resuscitated, so there typically is no triad. Alleged perpetrators may admit shaking or AHT to police officers during an interrogation, whether abuse or head trauma really happened. Those later imprisoned for crimes they did not commit did not recognize the damage done by hypoxia and subsequent resuscitation, and neither did diagnosing doctors.

Abusive Head Trauma, Shaken Baby Syndrome, Triad

H6 The Forensic Medicolegal System in Qatar

Ibrahim ElRamahi, MD, Forensic Medicine Center, Doha, Qatar; Khalid BinMarzook, BSc, Forensic Medicine Center, Doha, Qatar*

Learning Overview: After attending this presentation, attendees will have learned about the different facets of the medicolegal system in Qatar and how it differs from other systems.

Impact Statement: This presentation will shed light on the different aspects of the Qatari medicolegal system, which is a combination of the medical examiner system and coroner system that takes into consideration the socio-cultural aspects of the environment it operates within.

Forensic medicine is defined as “the application of medical knowledge to solve legal questions.”¹ It is governed by various legal aspects (that differ from one country to another) that form the medicolegal framework of a country. Appreciating the medicolegal system in Qatar—a system that comprises a combination of both civil and Islamic Shari’a law—can provide a foundation to understanding the medicolegal system in other Arab-Islamic countries.² This presentation will set out to do so by expanding on the details of the system in Qatar.

Qatar is a sovereign country, located on the northeastern coast of the Arabian Peninsula in Western Asia. This Arabian, Islamic country is part of the Gulf Cooperation Council (GCC). Its total area is approximately 11,600km² and its population is estimated to be approximately 2.7 million, with Qatari nationals making up 400,000 only, while the rest of the population is made up of expats from 110 nations.

Forensic medical services in Qatar are provided to the entire population through the Forensic Medicine Center, which is part of the General Administration of Public Security at the Ministry of Interior. Its services can be broadly categorized into two distinct branches. The first relates to medicolegal death investigations, where autopsies are governed by the Autopsy Law.³ The other branch relates to medicolegal cases pertaining to the clinical aspect of forensic medicine, which are governed by the Criminal Law and the Manual of Criminal Procedure.^{4,5} To further analyze the medicolegal system in Qatar, both of these branches will be detailed. The first branch involves medicolegal death investigation cases that are referred to the center for external examination and/or autopsy in collaboration with Hamad Medical Corporation hospitals. These cases can include sudden death, suicide, medical errors, road traffic collisions, fatal abortions, and criminal deaths, among others, which are then classified as either homicidal, suicidal, or accidental. The second branch involves the clinical aspect of forensic medicine and takes place at the clinics of the Forensic Medicine Center. These include physical assaults, sexual assaults, child abuse, medical liabilities, domestic violence, and work-related injuries, among others.

It should be noted that a forensic pathologist is required to attend all death and crime scenes in order to examine the body at the scene and to determine whether further investigation is required. The district attorney then orders an autopsy and further investigation, including bodily samples and imaging techniques. In criminal cases, virtual autopsy does not suffice and the gold standard of a full autopsy is performed. Prior to the submission of the final report, a preliminary report is completed and submitted within ten days in order to assist in the investigation.

A continental, or multifaceted, medicolegal system is vital due to its adaptability and pragmatism. In a system like the Qatari medicolegal system, roles are clearly defined, and procedures are routine. Indeed, improvements are needed to tackle the deficiencies in some aspects, and more practical protocols are required.

Medicolegal Systems, Autopsy, Qatar

H7 Railway Fatalities: A Retrospective Analysis of 21 Years

Christina R. Shreve, BS, County Medical Examiner's Office, El Paso, TX; Mario A. Rascon, MD, El Paso County Medical Examiner's Office, El Paso, TX; Lorenzo Gitto, MD, State University of New York, Upstate Medical University, Department of Pathology, Syracuse, NY*

Learning Overview: After attending this presentation, attendees will have better knowledge regarding railway deaths, including their features and demographics.

Impact Statement: This presentation will impact the forensic science community by presenting relevant information related to railway fatalities, including risk factors and injury patterns.

Railway systems are an important part of the infrastructure of the United States. Because of their large mass, collisions involving trains and motor vehicles/pedestrians can be devastating. Severe blunt force injuries generally result from these collisions. In the United States, there have been over 500 railway-related deaths per year over the past 20 years. The majority of the subjects were trespassing on railroad tracks at the time of their death.¹ Previous studies have shown that young, intoxicated males are often the predominant victims of these collisions.²

It can be challenging to determine the manner of death in railway fatalities. Medical, social, and psychiatric history, along with scene investigation, autopsy findings, and toxicology results are essential in determining whether the death was accidental or intentional.

In the present study, case files from the El Paso County Medical Examiner's Office database were retrospectively reviewed for railway-related deaths over a 21-year period between January 2000 and December 2020. There were no exclusion criteria. The following records were reviewed: autopsy, investigative, police, and toxicological reports, medical records, and death certificates.

A total of 52 cases were found in the database. The ages of the subjects ranged from 2 to 80 years with a mean age of 35.8 years. There were 40 males (77%) and 12 females (23%). The race was White in 51 cases (including Caucasians and Hispanics—98%), and unknown in 1 case (2%). Forty-nine deaths were due to blunt force injuries (94%), 2 deaths were due to decapitation (4%), and 1 death was due to the traumatic amputation of the upper right extremity (2%). The manner of death was accident in 39 cases (75%), suicide in 7 cases (13.5%), and undetermined in 6 cases (11.5%). There were no homicides.

Evaluating railway-related deaths and their risk factors could shed light on ways to help with prevention of these deaths. An analysis of the cases will be performed, including correlation of location of injuries, time of event, toxicology results, scene investigation, and psychiatric, medical, and social history. A thorough discussion of the results will be presented to the attendees.

Forensic Pathology, Railway Fatalities, Train Accident

H8 Pitfalls in Postmortem Computed Tomography

Angela Baldwin, MD, MPH*, Office of Chief Medical Examiner, New York City, NY; Stacia Semple MD, New York Blood Center Enterprises, New York City, NY

Learning Overview: After attending this presentation, attendees will understand that postmortem imaging is best used with caution and always best utilized when in conjunction with autopsy.

Impact Statement: This presentation will impact the forensic science community by reinforcing why autopsy is the gold standard for postmortem detection of cause of death and trauma.

Background: As imaging techniques and technology improve, postmortem imaging has been increasingly utilized in conjunction with traditional autopsies.¹ Scholing et. al demonstrated agreement of the cause of death between Postmortem Computed Tomography (PMCT) and autopsy varied between 46% and 100%, while the amount of injuries detected on PMCT ranged from 53% to 100% compared with autopsy.² The sensitivity of PMCT was increased when combined with postmortem magnetic resonance imaging.³ Much is at stake when legal/criminal determinations are based on postmortem study. Here is presented one case of suspected pediatric trauma-homicide, further underlying the importance of autopsy in conjunction with imaging studies.

Case: A 2-week, 6-day-old term female infant born at 38 weeks gestational age was brought into an emergency department by emergency medical services. One week prior, the infant was evaluated by her pediatrician after multiple episodes of diarrhea, which subsequently resolved two days after the visit. The morning of her death, the infant was reported to be lethargic and was refusing feedings from her mother and grandmother after multiple attempts. In the afternoon, her grandmother retrieved her from where she was sleeping, supine on the couch. The infant had shallow breathing with decreased movement, then became unresponsive in her grandmother's arms. Resuscitative efforts were immediately started. Emergency services arrived and continued resuscitation attempts. Despite all efforts, the infant was pronounced dead upon arrival to the emergency department. A PMCT scan demonstrated displaced-depressed calvarial fracture at the level of the coronal suture, non-displaced right temporal bone fracture, mild depression of the occipital calvarium at the level of the lambdoid sutures bilaterally, and subdural hemorrhage. All other findings were unremarkable. Based on these findings, the child's guardians were questioned by the police. Both denied knowledge of trauma. At autopsy, on external examination, the body was atraumatic, and the scalp without contusions. Internally, overlapping of the parietal skull bones and occipital skull bones at the sutures were noted. The skull and dura were intact. Right parietal intradural patchy petechia as well as parafalcine green-maroon material consistent with aging subacute hemorrhage, also noted. Microscopy revealed rare fibrin-platelet thrombi in the kidneys. Analysis of vitreous humor revealed slight dehydration. Neuropathological examination revealed hypoxic ischemic changes of the brain consistent with sequelae of recent evolving sepsis. Blood cultures failed to grow any organisms, likely due to insufficient sample. Metabolic, toxicologic, molecular, and virology studies were non-contributory. The manner of death was determined to be natural.

Conclusion: While postmortem imaging is informative, it is best utilized in conjunction with autopsy as opposed to substitution. Autopsy remains the gold standard.

Postmortem Imaging, Autopsy, Infant

H9 Disseminated Coccidioidomycosis in the Human Skeleton

Laura Fulginiti, PhD*, Maricopa County Office of the Medical Examiner, Phoenix, AZ; Zachary Michalicek, DO, Maricopa County Office of the Medical Examiner, Phoenix, AZ; Andrew Seidel, PhD, Maricopa County Office of the Medical Examiner, Phoenix, AZ; Katelyn Bolhofner, PhD, Maricopa County Office of the Medical Examiner, Phoenix, AZ; Caroline Cross, MD, Maricopa County Office of the Medical Examiner, Phoenix, AZ

Learning Overview: Attendees can expect to learn how to recognize the skeletal manifestations of *Coccidioides* fungal infections.

Impact Statement: The impact of this presentation will be to inform forensic science practitioners about increasing cases of fungal, bacterial, and infectious processes that go untreated, and result in death.

Coccidiomycosis is a common fungal infection found in the southwestern desert soil of the United States, Mexico, and Central and South America. While 80% of infected individuals are asymptomatic, pulmonary disease is the most common manifestation. In a small percentage of individuals, disseminated lesions are documented and skin, subcutaneous tissue, bone, and brain are targets of the fungus. Reports of Cocci have been increasing since the 1980s and statewide trends reflect this: cases doubled to 10,358 cases from 2014 to 2019, with a surge in 2019. Medical examiner offices have seen an uptick in untreated cases resulting in death. Using two recent cases, this presentation will explore the course of these infections.

An 8-year-old male was found unresponsive by his parents at their shared residence. The mother reported to Emergency Medical Services (EMS) that the child had no illness or trauma, then later added that he vomited the previous night. EMS noted him to have multiple scars and several open wounds, including one bandaged on his forehead, and an open ulcer on his foot. At autopsy, the child was observed to have numerous, irregularly shaped scars all over his body. There were open ulcers on his left foot, right hand, and two on his back. Defects were observed on the forehead, and the back of his head. Two large radiolucent defects were observed radiographically. Upon reflection of the scalp, the occipital defect was filled with soft, pasty, cream-colored material. When the calvarium was removed, a large tumor was observed in the left cerebellar region of the brain. Cultures initially grew *Streptococcus agalactiae*, determined to be a secondary infection. Additionally, the child was in diabetic ketoacidosis due to extreme dehydration.

A 57-year-old female was found decomposed in her residence. Her relevant medical history included lytic left acromion lesion status post-biopsy with pathology demonstrating bone and soft tissue with necrotizing granulomatous inflammation and numerous *Coccidioides* organisms. Laboratory results show positive *Coccidioides immitis* antibody. Medical records review revealed the decedent presented in March 2020 complaining of six months duration pain, weakness, and stiffness in her left shoulder. She also stated she was currently “dealing with valley fever.” At autopsy, postmortem radiographs showed distal acromion with mass-like erosion measuring 3x2x3cm and histology specimens revealed *Coccidioides immitis* spherules in the lung and brain. Family stated that the decedent was normally clean and organized, but that her house looked like it had been ransacked, findings consistent with erratic behavior due to fungus in the brain.

With the advent of novel fungal, bacterial, and viral infections in an era of increased isolation, fear, or lack of access to health care, forensic practitioners are likely to encounter cases more frequently. The Nigerian family in the first case had an aversion to Western medicine and were afraid to leave the home during the COVID-19 pandemic. The father reported that the child suffered from diabetes and had numerous “fatty bumps” and that he (the father) would occasionally incise and drain the contents.

Forensic anthropologists are employed more frequently by forensic pathologists to augment their findings. Recognition, familiarity, and thorough documentation of pathologic conditions that affect bone are crucial for these collaborations. Anthropologists accustomed to seeing lesions in dry bone or, in skeletal or archaeological assemblages, may be confounded when seeing the disease in an active state. Forensic pathologists may be more familiar with the soft tissue changes due to infection, but less familiar with bony lesions produced by the same. Participation by both specialties in these cases will lead to increased familiarity and more comprehensive documentation.

Fungal Infections, Coccidioides, Skeletal Lesions

H10 Scuba Diving Fatalities: A Case Report of a Death Due to a Massive Air Embolism

Valentina Bugelli, PhD, MD, Azienda Usl Toscana Sud-Est, U.O. Medicina Legale, Grosseto, Italy; Silvia Raddi, MD, Health Science Department, Forensic Pathology Section, Firenze, Italy; Matteo Cecchetti, MD, Health Science Department, Forensic Pathology Section, Firenze, Italy; Ilaria Tarozzi, MD, Health Science Department, Forensic Pathology Section, Firenze, Italy; Lorenzo Franceschetti, MD, Department of Medical and Surgical Specialties, Radiological Sciences and Public Health, Brescia, Italy; Gianfranco Simonini, MD, Centro Tecnico della Subacquea, Polignano a Mare, Italy; Davide Machado, MD, Azienda Usl Toscana Sud-Est, UOSD Neuoradiologia, Grosseto, Italy*

Learning Overview: After attending this presentation, attendees will better understand the ultimate contribution of postmortem imaging in scuba diving fatalities.

Impact Statement: This presentation will impact the forensic science community by highlighting the key role of postmortem Computed Tomography (CT) imaging in a scuba diving death, since air embolism is an uncommon cause of death and air bubbles may disappear during autoptic maneuvers.

A 69-years-old male experienced scuba diver with a history of heart attack went with other experienced divers for a dive to a depth of about 37m. Witnesses said that during the ascent, he signaled that couldn't breathe. After the mandatory stop at the depth of 15m, he made the "OK" sign and continued the ascent. On the surface, he was unconscious and unresponsive. His friends pulled him onto the boat and started Cardiopulmonary Resuscitation (CPR) without resuscitation. Postmortem ascertainties were set.

Postmortem total body CT showed air-equivalent attenuation values in several arteries, including anterior and middle cerebral artery as well as vertebrobasilar system (Cerebral Arterial Gas Embolism [CAGE]), supraaortic trunks, cardiac cavities, coronary arteries, and arterial-venous thoraco-abdominal and extremities circulation. No signs of pneumothorax, pneumomediastinum, or subcutaneous emphysema were found.

In the light of radiological findings, the autopsy was set with special techniques to highlight air bubbles in cerebral arteries and sample the gas from heart cavities. Gas inclusions were detected in all arteries of the circle of Willis. The heart floated in water and its cavities were filled with microbubbles. The histological findings excluded that bubbles were a postmortem artifact. The cause of death was identified in massive gas embolism due to decompression sickness.

Technical ascertainment established that all decompression procedures had been respected and diving equipment was well functioning; however, the sintered filter was unclean and the Venturi effect deactivated, resulting in an overall decrease of oxygen rate.

According to annual diving reports, the primary cause of death in diving fatalities is drowning, followed by heart disease. Arterial Gas Embolism (AGE) and severe Decompression Sickness (DCS) represent a small percentage of fatal cases. They are caused by rapid decompression, which leads to the formation of gas bubbles in the blood. They may also depend on diving equipment malfunction.

The autoptic diagnosis of air embolism may be difficult since air bubbles usually disappear during organ extraction maneuvers. In the present case, medical history, witnesses' account, and ascertainment on the equipment placed the differential diagnosis with a cardiac death. However, it was postmortem CT that played a fundamental role in suggesting the presence of arterial gas embolism.

In this way forensic radiology represented a valuable tool to guide the subsequent autoptic procedure and indicate the correct technical approach according to the diagnostic suspect. Postmortem CT confirmed its essential diagnostic significance in scuba diving fatalities, especially providing relevant additional information to direct autopsy and support pathological findings.

Scuba Diving, Air Embolism, Postmortem Computed Tomography

H11 FVIII Expression to Differentiate Vital Hemorrhages From Postmortem Artifacts

Giuseppe Bertozzi, MD, Department of Clinical and Experimental Medicine, University of Foggia, Apulia, Italy; Michela Ferrara, MD, Department of Clinical and Experimental Medicine, University of Foggia, Apulia, Italy; Giovanni Pollice, MD, Department of Clinical and Experimental Medicine, University of Foggia, Apulia, Italy; Stefania De Simone, MD, Department of Clinical and Experimental Medicine, University of Foggia, Apulia, Italy; Santina Cantatore, MLT, Department of Clinical and Experimental Medicine, University of Foggia, Apulia, Italy; Luigi Cipolloni, MD, PhD, Department of Clinical and Experimental Medicine, University of Foggia, Apulia, Italy; Raffaele La Russa MD, PhD, Department of Clinical and Experimental Medicine, University of Foggia, Apulia, Italy*

Learning Overview: The goal of this presentation is to show how the search for vitality markers of soft tissue injuries allowed the forensic pathologist to be moved into a wide spectrum of techniques to reach the correct diagnosis. In this context, immunohistochemical analyses provide evidence that, integrated together, can strongly corroborate the diagnosis of vitality, thus making them mandatory for forensic pathologists.

Impact Statement: This presentation will impact the forensic pathologists community by highlighting the need to establish a pattern of markers that should be routinely performed for the diagnosis of viability of soft tissue lesions, including Factor VIII (FVIII).

Wound age assessment is one of the most challenging issues in forensic pathology. While Red Blood Cell (RBC) infiltration is classically considered a sign of a vital reaction, several studies have shown that extravasation of blood cells can occur even after death and cannot be used as a reliable marker in the diagnosis of wound viability. Indeed, macroscopic artifacts may be related to postmortem Prinsloo-Gordon hemorrhages or hypostatic infiltrations, injuries related to resuscitation, or from macro- and micro-fauna alterations. On the other hand, in the literature, Immunohistochemistry (IHC), an important diagnostic tool in anatomical and surgical pathology, is used less frequently in forensic pathology. Tissue degradation due to postmortem decomposition is believed to be an important limiting factor, although it is unclear what impact this degradation actually has on the validity of IHC staining. According to some authors, autolysis would induce a higher risk of false positives; according to others, the advancement of decomposition would involve a higher risk of false negatives.

In this context, this study aimed: (1) to underpin the importance of histological examination to precisely qualify lesions; (2) to test an immunohistochemical biomarker and, subsequently, a pattern capable of diagnosing vital injuries from postmortem artifacts.

Skin samples collected from selected subjects who died from trauma were analyzed and compared with those of the control. Moreover, as positive control, skin specimens resulted positive to immunohistochemical reaction with antibody anti-CD15 and anti-tryptase.

The results of the present study confirmed the importance of histology as a fundamental tool in order to produce evidence for the diagnosis of the identification of the lesions and, therefore, of the cause of death. Furthermore, different cellular and cytokine expression patterns are associated with antibody positivity, compared to the control case. Furthermore, it is interesting to note the behavior of the immunohistochemical reaction using anti-FVIII antibodies.

Based on the expression of FVIII in wound hemorrhage and data collected from the literature review analysis, although preliminary and limited in number, it seems to suggest the utility of this marker in combinations of multiple markers to achieve vitality diagnosis.

FVIII, Hemorrhage, Vitality

H12 Sudden Death After Contrast Media Administration—Not Always Anaphylaxis: A Workflow for Diagnosis

H13 Evaluating Trends and Demographics of Accidental Drug Deaths in Harris County, Texas, From 2016 to 2020

Varsha Podduturi, MD, Harris County Institute of Forensic Sciences, Houston, TX; Namrata Walia, MD, MHA, Baylor College of Medicine, Houston, TX and UT Health School of Public Health, Houston, TX; Daryl Shorter, MD, The Menninger Clinic, Houston, TX*

Learning Overview: After attending this presentation, attendees will understand the drug trends associated with the most commonly used substances and decedent demographics of accidental drug deaths from 2016 to 2020 in Harris County, TX (which includes the city of Houston).

Impact Statement: This presentation will impact the forensic science community by examining drug trends and the demographics of the population involved within Harris County, TX.

Cases classified as accidents represented 32% to 40% of all the total cases between 2016 and 2020. A significant number of the accidental deaths were related to drug intoxication (ranging from 32%-51%), followed by motor vehicle crashes (ranging from 29-33%). The electronic database from the Harris County Institute of Forensic Sciences (HCIFS) in Houston, TX, was searched for all accidental drug deaths between 2016 and 2020. The following data was collected: cause of death, age, sex, and ethnicity. Each case was evaluated for the substances listed in the cause of death and each intoxicant was subsequently coded in a database that categorized substances in general categories based on its designation within the *International Classification of Diseases, Tenth Revision*, Clinical Modification (ICD-10) system, such as narcotics, psychodysleptics, and sedative-hypnotic drugs, and further subcategorized into more specific categories with specific substance names.

Evaluation of the data showed the total number of accidental drug deaths in Harris County increased from 429 in 2016 to 989 in 2020, which represents an increase of 130%. White males (average of 36.23%), followed by Black males (average of 18.46%) and Hispanic males (average of 17.03%,) were the most impacted by accidental drug intoxications. Among females, White females (15.3%) were more prevalent than Black (7.65%) and Hispanic (3.26%) females.

Hispanic females had the least number of intoxication deaths among the decedent population with 2% or more of the cases. Hispanic males and White females had decreased numbers of drug deaths within their populations. Others (2.07%), including Asians and American Indians, continued to be the least affected.

A review of the data indicated that cocaine is the most frequent intoxicant in fatalities. Accidental drug deaths may involve multiple intoxicants; therefore, a single case may be included in more than one category when describing the number of drug deaths involving specific substances. In the order of prevalence, cocaine, methamphetamine, benzodiazepines, and prescription opioids were commonly detected. Fentanyl and analogs were found in less than 5% of the cases in 2016. However, they were reported in over 30% of cases in 2020. Similarly, methamphetamine was reported in 56 cases in 2016 (13% of cases), compared to 352 cases in 2020 (35.63% of total cases), representing a 174% increase. The use of benzodiazepines has slowly increased over the five-year period reviewed. Conversely, the numbers of cases involving prescription opioids gradually decreased as other drugs such as methamphetamines and fentanyl became more prevalent.

Harris County has continuously experienced record highs among its intoxication deaths, especially within the White male population. The increasing numbers of accidental drug deaths, specifically those related to methamphetamine and fentanyl, require attention. This information can be useful for public health campaigns for targeting groups most at risk. Additionally, the rise of fentanyl analogs emphasizes how critical it is for toxicology laboratories to be able to provide testing to detect these emerging substances.

Toxicology, Drug Deaths, Drug Trends

H14 An Unexpected and Rare Cause of Child Death: A Large Obstructing Fecaloma

Stefania De Simone, DM*, Department of Clinical and Experimental Medicine, University of Foggia, Foggia, Puglia, Italy; Elena Giacani, DM, Department of Clinical and Experimental Medicine, University of Foggia, Foggia, Puglia, Italy; Maria Antonella Bosco, DM, Department of Clinical and Experimental Medicine, University of Foggia, Foggia, Puglia, Italy; Giovanni Gurgoglione DM, Department of Clinical and Experimental Medicine, University of Foggia, Foggia, Puglia, Italy; Michela Ferrara, DM, Department of Clinical and Experimental Medicine, University of Foggia, Foggia, Puglia, Italy; Luigi Cipolloni, DM Department of Clinical and Experimental Medicine, University of Foggia, Foggia, Puglia, Italy

Learning Overview: The aim of this paper is to highlight the importance of the use of immunohistochemical investigation in complex cases. The presented case is a unique case of child sudden death due to an obstructing fecal impaction.

Impact Statement: This presentation will impact the forensic community, showing that as for the cause of death, the systematic application of immunohistochemical investigation is the only tool to obtain more information, especially in this unique case of death by fecaloma. In fact, in the event of sudden death, in the absence of anamnestic and clinical information, the pathologist cannot identify the exact mechanism of death only with the autopsy examination. In this perspective, immunohistochemistry highlights alterations not noticeable by macroscopic or histological observation.

Text: A 9-year-old boy started complaining of severe abdominal pain during the night. The mother of the child called the emergency service, explaining that the child was suffering from intense abdominal pain and diarrhea. She was invited by the doctor to hydrate only the child and to wait until morning. The boy continued to suffer and, at last, he suddenly died at 6.00 a.m. The parents reported that the child had no symptoms in the previous days and did not suffer from any illness. So, being the cause of death was unclear, an autopsy was performed. On external examination, the body did not show external injuries. The abdomen was distended and entirely affected by the putrefactive green stain. Opening the peritoneal cavity, there was a massive expansion of the intestinal loops without apparent necrosis. The intestine was isolated and opened on his anti-mesenteric side. In the lumen of the rectum-sigma, about 18cm from the anus, there was a large hard fecal mass, measuring 7x5.5x4cm. The fecal mass obstructed the lumen. The whole gastrointestinal system contained fecaloid material, while the esophagus was full of blackish fecal-like material. The organs did not show macroscopic alteration. The toxicological tests carried out on blood and urine were negative. The study of the samples of the organs, stained with hematoxylin-eosin, revealed visceral stasis, massive pulmonary edema, and interfascicular edema of the myocardium. The histological examination of the intestinal wall revealed no necrosis. Immunohistochemical analysis was performed using antibodies anti-CD68, MCP-1, TNF α , and COX2. The intestinal wall showed intense positivity for CD68 antibodies on the mucosal side. The other markers were more noticeable on the serous side. The immunohistochemical positivity thus demonstrated the presence of inflammation of the intestinal wall. The inflamed intestinal wall leads to a hydro electrolytic imbalance due to the lack of reabsorption of fluids. These mechanisms contributed to the death of the boy. The sudden death of the child was due to acute heart failure secondary to a hydro electrolytic imbalance caused by intestinal obstruction.

Bowel obstruction is a mechanical obstruction that interrupts the flow of intestinal contents, resulting in proximal bowel dilatation and distal bowel decompression. The progression of obstructions increases the degree of dilatation, causing bowel wall ischemia, necrosis, and even perforation with associated peritonitis and sepsis, necessitating urgent surgery.¹ Causes of large bowel obstruction in children are helminths infection, bezoars (solid masses of indigestible material), congenital abnormal bands, intestinal malrotation, Hirschsprung disease, Meckel's diverticulum, etc.^{1,2}

In the presented case, the cause of the bowel obstruction was a large fecaloma. A Fecal Impaction (FI) is a large mass of compacted stool that is impossible to evacuate spontaneously.³ The distal colon and rectum are the most common sites for fecalomas.⁴ This condition is uncommon in children, the majority of reported cases are in elderly or psychiatric patients.⁵ There are multiple causes of fecaloma formation, but in the described case, the cause is unknown as the parents did not report a history of chronic constipation or other diseases.^{6,7}

Sudden unexpected death depending on gastrointestinal diseases is not common, especially compared to other conditions such as cardiovascular conditions or infection.⁸ In literature, there are not reported cases of infant death due to fecal impaction. Generally, parents describe a history of chronic constipation and abdominal pain. The absence of anamnestic information did not guide the diagnosis of death. The autopsy was crucial to finding the fecal impaction.

H15 Streptococcal Toxic Shock Syndrome: A Cautionary Tale

Meredith Reynolds, MD*, Cook County Office of the Medical Examiner, Chicago, IL; Pouya Jamshidi, MD, Northwestern University Feinberg School of Medicine, Chicago, IL; James Bellis, MS, Ann & Robert H. Lurie Children's Hospital of Chicago, Chicago, IL; Nicole Jackson, MD, MPH, Cook County Office of the Medical Examiner, Chicago, IL; Michael Eckhardt, MD, Cook County Office of the Medical Examiner, Chicago, IL; Pauline Chou, MD, Ann & Robert H. Lurie Children's Hospital of Chicago, Chicago, IL

Learning Overview: Attendees can expect to learn about the signs, symptoms, autopsy findings, and suggested autopsy workup of Streptococcal Toxic Shock Syndrome (STSS).

Impact Statement: This presentation will remind the learner of the existence of STSS, its potential pathogens, complications, and clinical scenario. The autopsy or forensic pathologist will be aware of this disease and its postmortem workup, which may aid in its detection and, where appropriate, notification of public health agencies.

Background: TSS is an acute, severe, toxin-mediated illness resulting from superantigen production by *Staphylococcus aureus* or *Beta-hemolytic Streptococcus*, resulting in rapid onset shock and organ failure.^{1,2} Risk factors include skin wounds, viral infection, or other minor trauma (e.g., sprains, bruises). Clinically, a prodrome of fever, myalgia, chills, nausea, vomiting, and diarrhea may precede hypotension and multisystem organ failure by a period of hours to days.³ Evidence of deep soft tissue involvement, including necrotizing fasciitis or myonecrosis, may appear within 24–72 hours.⁴ The incidence of STSS is increasing in North America and Europe, with a mortality rate of 5–10%.^{1,5}

Case Report: The patient was a previously healthy adolescent female who presented to the emergency department following several days of cough, flank pain, sore throat, nausea, vomiting, and worsening dyspnea and orthopnea. Testing for COVID-19 was negative. She had bilateral pleural effusions, respiratory failure requiring immediate intubation, and acute kidney injury requiring dialysis. Her course was further complicated by development of Acute Respiratory Distress Syndrome (ARDS), necrosis of a hand, pancytopenia, purpura fulminans, Disseminated Intravascular Coagulation (DIC), and septic shock requiring multiple vasopressors. Blood cultures grew Group G Streptococcus, and a diagnosis of STSS was rendered. Despite treatment with antimicrobials and Intravenous Immunoglobulin (IVIg), her status declined and she died.

Autopsy Findings: External examination showed soft tissue necrosis of the hand and purpura fulminans. Microscopic examination of the lungs showed necrotizing pneumonia and Diffuse Alveolar Damage (DAD) with hyaline membrane formation with invasive fungal organisms. Similar fungal organisms were present in sections of the trachea. Other organs showed evidence of ischemia and shock: acute tubular necrosis with cellular casts in the kidneys, centrilobular (zone 3) hepatocyte necrosis of the liver, multiple microscopic infarcts with associated microcalcifications of the myocardium, and ischemic changes in the hippocampal neurons.

Tissue cultures taken of the lung and spleen grew *Candida albicans*, which was morphologically consistent with the invasive fungal organisms noted in the lungs and trachea histologically. Bacterial cultures of the lung and spleen showed no growth of aerobic, anaerobic, or mycobacterial organisms. A viral culture of the spleen was negative. Blood cultures were not performed due to the patient's antemortem positive cultures and treatment with antimicrobials.

Discussion: The causative agent of this patient's case was identified as Group G Streptococcus, which, while not as common as Group A Streptococcus in STSS, has nonetheless been described previously.² The invasive *Candida albicans* was attributed to an opportunistic takeover of normal flora in the setting of sepsis and severe immunocompromise. A nidus of infection was not identified, though this is not necessary for diagnosis and, in many cases, may never be definitively elucidated.⁵

While this patient's case followed the "textbook" STSS sequence of non-specific prodromal symptoms rapidly devolving into septic shock, multisystem organ failure, and DIC with soft tissue necrosis and purpura fulminans, STSS may lack soft tissue involvement and instead mimic other pathologies, including pneumonia, myocardial infarction, peritonitis, or pelvic inflammatory disease.⁴ Cutaneous lesions may also resemble patterned or inflicted trauma.⁶ The fast and furious onset of STSS has the potential to be lethal before a definitive diagnosis is obtained, or before medical care may be sought. Forensic and hospital autopsy pathologists must therefore maintain a high index of suspicion for TSS in the setting of sepsis, with a low threshold for obtaining blood and tissue cultures, performing histologic examination, and, where necessary, notifying public health agencies.⁷

H16 Air Embolism: An Important Autopsy Finding in Gunshot Wounds of the Head Deaths

Xin Zhang, MD, Cook County Medical Examiner Office, Chicago, IL; Michael Eckhardt MD, Cook County Medical Examiner Office, Chicago, IL; Benjamin Soriano, MD, Cook County Medical Examiner Office, Chicago, IL*

Learning Overview: After attending this presentation, attendees will have a better understanding of the frequency, significance, and methods for detecting air embolism in deaths due to a gunshot wound of the head.

Impact Statement: This presentation will impact the forensic science community by emphasizing the significance of identifying air embolism in deaths due to gunshot wounds of the head, including its possible contribution to the mechanism of death and the opportunity it presents for educational purposes and maintenance of competency.

Air embolism occurs as a result of air entering the blood circulation. It is reported that when greater than 50ml air is introduced into the circulation, it may result in pulmonary outflow obstruction.¹ When a large amount of air enters the circulation, it may lodge in the right side of the heart, causing diminished and obstructed outflow of blood from the pulmonary artery, which may contribute to the mechanism of death. The effect of the embolism is determined by the total volume, the speed, and the location of the air embolism.² In a forensic setting, its presence may be investigated in deaths involving open wounds of the neck, chest trauma, childbirth, diving, and certain medical procedures. However, it can also be caused by open head injuries with exposure of the dural sinuses.

Air embolism can be detected by postmortem radiography and can be confirmed by multiple postmortem methods, including needle aspiration from the right heart chambers using a water-filled syringe. Air bubbles emerging from the heart chambers are considered a positive finding.

Gunshot wounds of the head are a common cause of open head injuries in a medical examiner or coroner office setting. This study reports the occurrence rate of air embolism detected by postmortem radiography in deaths due to a gunshot wound of the head, reviews methods to identify the air embolism, and discusses its significance in forensic practice.

A Cook County Medical Examiner Office database search of the 7/1/2020 to 7/1/2021 cases resulted 154 deaths due to a gunshot wound of the head. Cases that had thoracic organ donation and signs of decomposition by visual inspection were excluded from the study; 145 cases were included in the statistical analysis. Anterior-posterior chest X-ray images were reviewed. Air embolism was identified by a radiolucent area in the right heart, typically involving the superior vena cava, right atrium, right ventricle, and in some cases, extending to the pulmonary artery. Thirty of the 145 gunshot wound of the head cases (20.7%) had radiographic evidence of air embolism. Among these cases, only one had craniotomy, four had intravenous and/or interosseous infusion catheters, and the remaining cases had no invasive medical intervention or no medical intervention at all. All decedents included in the statistical analysis were pronounced within 24 hours after being shot, and the examinations were completed by one day after pronouncement. The control group included 2 gunshot wound of the abdomen cases, 11 gunshot wound of the chest cases, and 18 multiple gunshot wounds cases without head injury. The control cases were selected using the same exclusion criteria (no decomposition, no thoracic organ donation). In addition, cases with injury to the heart were excluded. None of the 31 control cases (0%) had radiographic evidence of air embolism.

Conclusion: Air embolism is occasionally observed in head trauma, including deaths due to gunshot wounds of the head. Identification of air embolism on postmortem radiography prior to autopsy is essential to be able to confirm at the time of examination. Familiarization with the phenomenon and its detection methods facilitates forensic pathologists in case documentation and potential forensic implications.

Air Embolism, Gunshot, Head

H17 Anomalous Ligature Materials and Means in Hangings: A Report of Ten Cases

Maria Antonella Bosco, MD, Department of Clinical and Experimental Medicine, University of Foggia, Foggia, Puglia, Italy; Giovanni Gurgoglione, MD, Department of Clinical and Experimental Medicine, University of Foggia, Foggia, Puglia, Italy; Elena Giacani, MD, Department of Clinical and Experimental Medicine, University of Foggia, Foggia, Puglia, Italy; Giovanni Pollice, MD, Department of Clinical and Experimental Medicine, University of Foggia, Foggia, Puglia, Italy; Michela Ferrara, MD, Department of Clinical and Experimental Medicine, University of Foggia, Foggia, Puglia, Italy; Benedetta Baldari, MD, Department of Clinical and Experimental Medicine, University of Foggia, Foggia, Puglia, Italy; Giuseppe Bertozzi, MD, Department of Clinical and Experimental Medicine, University of Foggia, Foggia, Puglia, Italy*

Learning Overview: The purpose of this presentation is to show how the forensic pathologist faces a large spectrum of ligature materials and improvised means employed to commit hanging. It can cause singular ligature marks, thus it is relevant to determine the compatibility between marks and materials/means through an attentive and comparative analysis; the ligature mark vitality through histological and immune-histochemical examinations must be assessed too.

Impact Statement: This presentation will affect forensic pathologists by bringing attention to a complete approach in studying hangings that occurred in anomalous circumstances/performed with unusual means through a careful examination, including a comparative analysis of the ligature mark both with materials and means employed.

Hanging is one of the most common methods used to commit suicide. Homicidal and accidental hangings are rare. Hanging consists of the complete or partial body suspension with a ligature around the neck. Ligature materials can be various; victims may use anything available at that moment. So, in some cases, the victims use unusual means to commit suicide.

The present study is a review of the autopsy reports of ten suicidal hangings observed in the period 2010–2021 at the Department of Forensic Sciences of the University of Foggia, in which the circumstances and the ligature means were different than usual (i.e., ropes, laces, etc.).

Regarding the unusual means used for the hanging, the review pointed out the case of an 82-year-old man that partially suspended himself by a nasal cannula fixed to a metal hook to his kitchen's ceiling; a 24-year-old man found lifeless in his prison cell, hanged with a noose made by cutting a cotton T-shirt into a narrow strip, hooked to a metal window bar; a 26-year-old found hanging with a horse bridle to a ceiling beam of a stable; a 45-year-old found incompletely suspended by two tied shoelaces to his bedroom's door.

Regarding the circumstances in which the hanging happened, the review includes the case of an under-24h-visual-surveillance 46-year-old man, found lifeless in his prison cell, partially hanging with his pant drawstring to the bathroom's window grate; a 50-year-old drug-addict, found partially suspended by two tied bathrobe belts to his room's radiator in a recovery center; a 9-year-old child incompletely suspended with his neck inside the handle of an olive sack; a 30-year-old hanged with the shoulder strap of a gym bag hooked to the top of an emergency call box on a highway; a 47-year-old drug addict, partially hanged with a waist belt to a French window in his bedroom; and a 74-year-old, hospitalized in a psychiatric center, incompletely suspended by a towel to the bathroom's radiator.

In many of these cases, the ligature means had been already removed when the pathologist performed the crime scene investigation because the relatives attempted to rescue the victim by removing the ligature from around the neck. Considering the peculiar materials used to commit hangings, it has been necessary to compare them with the injuries and verify the circumstances of death to exclude different events than suicides.

The study highlights that analysis of the ligature's mark and the histological and immunohistochemical examinations can help to determine the vitality of injuries and the compatibility with the alleged means of hanging. In the ten cases, these elements have been fundamental to reach a differential diagnosis between suicide, homicide, and accident.

Anomalous Ligature Means, Hangings, Suicides

H18 The Use of Forensic Radiology in the Assessment of the Emergency Department Presentation of Near-Hanging Victims in the United Kingdom

Sarah Anastasia Gaier, MSc, Queen Mary University of London, London, England, United Kingdom; Curtis Edward Offiah, MD, Queen Mary University of London, London, England, United Kingdom; Nikolas Petros Lemos, PhD, Queen Mary University of London, London, England, United Kingdom*

Learning Overview: After attending this presentation, attendees can expect to better understand the use of forensic radiology in assessing victims of near-hangings that present to hospital emergency departments with potentially significant head and neck trauma. Attendees will gain insight into the use and varying reliability of easily measurable parameters identified upon presentation in near-hanging victims for management improvement purposes; their use in mortality/morbidity prediction; and acquire important information about hanging as seen through radiology.

Impact Statement: This presentation will impact the forensic science community by raising awareness on the variability of presentations of near-hanging victims, which hinders the development of management and investigation guidelines for such cases. Additionally, the original casework presented herein will add to what is currently known about near-hanging victim presentations and prognoses to help shape such guidelines and highlight the importance of cervical radiology in assessing the gravity of injury sustained.

Hanging is commonly encountered in the forensic setting, where the conventional autopsy and postmortem radiology serve to distinguish from the pattern(s) of injury, suicide, and accidental death from homicide. Hanging is the most commonly employed method of suicide for both men and women in England and Wales, reflecting a global trend.^{1,2} The fatality of hanging is high, but individuals who survive to hospital are termed “near-hanging” victims and may present with numerous signs varying across a wide range of severities.³ While many of these patients will leave the hospital alive and well, in-patient deaths in this population are not uncommon, and others who survive may only do so with a neuropsychological disability. Radiology is a critical tool for the successful investigation and management of these patients.

However, the observed versatility of injury and possible outcomes mean robust guidelines for the treatment of near-hanging victims have yet to be established.⁴ The prediction of mortality and morbidity of near-hanging victims presenting to hospital is important for the patients, but also for their families and friends.

Currently, Glasgow Coma Scale (GCS) score and cardiopulmonary arrest prior to being admitted are the only presenting parameters (excluding what is forensically known about the scene, such as hanging time and drop height) that have been identified in the literature as predictors of mortality. No accurate predictors of morbidity have been established for near-hanging victims.⁵

Objective: This study assesses if presenting parameters (age, sex, presence of a ligature mark, and earliest GCS score) can constitute adequate morbidity/mortality predictors for maximizing the triage, radiological investigation, and medical management of near-hanging victims.

Methods: Computed Tomography (CT) scans of 21 near-hanging victims presenting to hospitals in the United Kingdom were subjected to forensic radiology analysis. Raw data was processed using SPSS to establish the incidence of injury, mortality, and population demographics.

Results: No presenting parameters were deemed dependable predictors of radiologically identifiable injury. A GCS score ≤ 3 was statistically significant ($p=0.044$) and associated with higher mortality. Overall trends indicated increasing age was correlated with an increased risk of injury and death.

Conclusions: Findings of this present study confirm information previously reported in the literature. As presenting parameters are not sufficiently reliable to determine the extent of injury and the prognosis of near-hanging patients, early investigation with CT scanning is recommended in all patients to prevent overlooking potentially devastating injury.

H19 Wound Vitality and the Estimation of Wound- Age Production: New Frontiers Through Immunohistochemistry Investigation

Michela Ferrara, MD, Department of Clinical and Experimental Medicine, University of Foggia, Foggia, Puglia, Italy; Stefania De Simone, MD, Department of Clinical and Experimental Medicine, University of Foggia, Foggia, Puglia, Italy; Giovanni Pollice, MD, Department of Clinical and Experimental Medicine, University of Foggia, Foggia, Puglia, Italy; Giuseppe Bertozzi, MD, Department of Clinical and Experimental Medicine, University of Foggia, Foggia, Puglia, Italy; Santina Cantatore, MLT, Department of Clinical and Experimental Medicine, University of Foggia, Foggia, Puglia, Italy; Raffaele La Russa, MD, PhD, Department of Clinical and Experimental Medicine, University of Foggia, Foggia, Puglia, Italy; Luigi Cipolloni, MD, PhD, Department of Clinical and Experimental Medicine, University of Foggia, Foggia, Puglia, Italy*

Learning Overview: Evaluation of the vitality of soft tissues injuries still represents a challenging topic for forensic pathologists, who aim to estimate wound-age production. This purpose is even harder in cases of corpses in advanced decomposition states. Immunohistochemical techniques are becoming an indispensable aid when the macroscopic investigation is not determining.

Impact Statement: This presentation will impact attendees by showing that the systematic application of the tested techniques could help forensic pathologists to get diagnostic elements in cases, only observed in forensic practice, in which biological materials are not well preserved, but it is mandatory to establish a cause of death and/or the timing of the production of wounds.

This pilot study aims to apply the immunohistochemistry investigations to evaluate the vitality of the lesion by using monoclonal antibodies against CD15 (produced by leukocytes, especially in neutrophils), IL-15 (cytokine secreted by mononuclear phagocytes and some other cells following infection by a virus), tryptase (an enzyme released by mast cells), and glycophorin A (red blood cell transmembrane proteins). Literature data indicate that the quantification of their expression can estimate the age production of a wound. Moreover, in this study, a comparison between the Hematoxylin-Eosin (H&E) staining and immunohistochemistry techniques is also provided to evaluate their potential in identifying “vital” processes, above all in putrefied soft tissues.

The study examined 12 cases in which autopsies were performed some days after death because the corpses were not found immediately. In all these cases, causes/circumstances of death were uncertain (natural vs. unnatural death), and all bodies had lesions and/or mutilations with doubtful relevance regarding the cause of death. In many cases, the putrefaction process was so advanced as to not allow the distinction between vital or not vital injury. Many samples were taken from the edges of the lesions, both in the soft tissues and bones. The samples were fixed in 10% formalin and from each sample were obtained at least five slides. The slides of every case were stained with H&E, CD 15, IL 15, tryptase, and glycophorin A, then observed on the optical microscope. Samples from the bodies’ areas without injuries were taken and stained with the same techniques.

The preliminary results suggest that the immunohistochemical stainings should be routinely applied in cases of corpses with advanced putrefaction phenomenon; even if the radiological investigation is performed, the macroscopic examination is inconclusive, and the H&E staining is not reliable.

Though certainly not conclusive, the experimental application carried out in this study suggests that the use of monoclonal antibodies anti-CD15, anti-IL-15, anti-tryptase, and anti-glycophorin A may be important to diagnose the vitality/not vitality of lesions and to estimate the timing of the production of a wound.

Wound Vitality, Anti-CD15, Anti-Glycophorin A

H20 A Forensic Approach to an Italian Mass Disaster: The Collapse of the Morandi Bridge

Francesca Frigiolini, MD, University of Genova, Department of Legal and Forensic Medicine Genova, Italy; Camilla Tettamanti, MD, PhD, University of Genova, Department of Legal and Forensic Medicine Genova, Italy; Davide Bedocchi, MD, University of Genova, Department of Legal and Forensic Medicine Genova, Italy; Fiorella Caputo, MD, University of Genova, Department of Legal and Forensic Medicine Genova, Italy; Martina Drommi, MD, University of Genova, Department of Legal and Forensic Medicine Genova, Italy; Sara Lo Pinto, MD, University of Genova, Department of Legal and Forensic Medicine Genova, Italy; Anna Roncallo, MD, University of Genova, Department of Legal and Forensic Medicine Genova, Italy; Francesco De Stefano, MD, PhD, University of Genova, Department of Legal and Forensic Medicine Genova, Italy; Francesco Ventura, MD, PhD, University of Genova, Department of Legal and Forensic Medicine Genova, Italy*

Learning Overview: After attending this presentation, attendees will have a better understanding of the importance of involving the forensic science community in mass disaster management.

Impact Statement: This presentation will impact the forensic science community by presenting the organization of the morgue following the mass fatality of the Morandi Bridge collapse.

Mass disasters are generally understood as crisis situations that go beyond a community's ability to recover. They are usually unpredictable and unexpected situations demanding a multidisciplinary and well-coordinated approach. On August 14, 2018, at 11:36 a.m., a 690ft section of the Genoa Morandi Bridge collapsed. Thirty-three vehicles traveling on it fell from an height of 130ft into the river below and the surrounding industrial area. Fifty-eight people were directly involved in the fall: 43 died and 15 were wounded. The death toll was: 29 Italian citizens, 4 French, 3 Chileans, 2 Albanians, 1 Colombian, 1 Jamaican, 1 Peruvian, and 1 Romanian. During the two days following the collapse, the 43 bodies were found either in the fallen vehicles or in the industrial area below the bridge and subsequently taken to the town morgue of Genoa. Immediately after the event, all the medical staff of the Departmental Section of Legal and Forensic Medicine of Genoa cooperated with the Civil Protection Agency, psychologists, and the public prosecutor.

For the victims' identification, the International Criminal Police Organization (INTERPOL) Disaster Victim Identification (DVI) process was used. A postmortem team photographed the victims, collected DNA samples, and took notes of their personal belongings, general physical characteristics, and distinguishing features. Collaborating with the Civil Protection Agency, in charge of the rescue, was fundamental for determining in which vehicle each victim was found and who the passengers of each vehicle were. At the same time, an antemortem team interviewed the victims' relatives who arrived at the morgue. Finally, antemortem and postmortem data were compared to identify potential matches between a found body and a missing person.

Despite the height of fall, all the victims preserved strong identification marks; this allowed the use of visual identification to confidently confirm the identity of all the victims without awaiting the DNA comparison results. The victims were identified in less than 24 hours from arrival at the town morgue. After receiving the authorization of the public persecutor, all bodies underwent a forensic examination to identify the cause of death: in 29 cases, multiple traumatic severe lesions were found and the cause of death was attributed to a polytrauma; in 12 cases, traumatic injuries had forced brain tissue out from the skull, causing a severe craniocerebral traumatism; and finally, in 2 cases, the cause was found to be cervical spine fractures with wide spinal cord involvement.

Seven months after the collapse, in accordance with Italian law, 37 people were evaluated to identify personal injuries related to the event: 15 people were directly involved in the fall and reported predominantly physical damages, while the remaining 22 complained only of psychological damages due to having seen the bridge fall. Personal injuries were detected in 34 cases. After the Morandi Bridge collapse, authorities carried out an extensive investigation that showed the responsibilities of different companies involved in the bridge maintenance.

This presentation brings to light that the combination of a correct forensic approach and the teamwork of different professional profiles is essential to manage mass fatality accidents, both for purposes of criminal investigation and as a moral obligation vis-a-vis the victim's family members. The Morandi collapse also shows that every mass disaster has unique features and requires a tailored approach; this is to be developed through experience, pre-planning, and continuous training.

Forensic Pathology, Disaster Victim Identification, Biological Damage Evaluation

H21 The Death of a Professional Scuba Diver Due to Gas Embolism: An Autopsy Case

Cemyigit Deveci, MD, Department of Forensic Medicine, Faculty of Medicine, Akdeniz University, Antalya, Konyaalti, Turkey; Mehmet Atilgan MD, Department of Forensic Medicine, Faculty of Medicine, Akdeniz University, Antalya, Konyaalti, Turkey; İbrahim Demir MD, Antalya Group Administration, Turkish Council of Forensic Medicine, Antalya, Konyaalti, Turkey; K. Aylin Aksoy, MD, Antalya Group Administration, Turkish Council of Forensic Medicine, Antalya, Konyaalti, Turkey*

Learning Overview: After attending this presentation, attendees will have meaningful insights on radiological and pathological features and autopsic findings in cases of decompression sickness.

Impact Statement: This presentation will impact the forensic science community by providing striking visuals and videos of histopathological, radiological, and macroscopic findings of air embolism within coronary and cerebral vessels.

Gas embolism or decompression sickness is a result of rapid decompression, which gives rise to bubble formation within tissues from dissolved inert gas. When pulmonary barotrauma occurs due to pressure gradient, intra-alveolar gas can penetrate to the intravascular space of pulmonary vessels, then to the systemic circulation through the pulmonary veins. Death can occur either by gas embolism in cerebral or coronary circulations or by cardiac failure due to intraventricular “airlock.”

In this case report, a 37-year-old professional military diver, who lost consciousness during ascent from a deep dive on a training session and died after being unresponsive to cardiopulmonary resuscitation, is presented. After the arrival of the deceased to the morgue, an X-ray of the chest revealed air within cardiac chambers, the carotid artery, and cerebral vessels. Consequently, an autopsy investigation was carried out to establish the exact cause of death. The gross examination of the brain revealed very clear and striking visuals of air bubbles within superficial cerebral veins. Furthermore, the air bubbles were present in superficial cardiac vessels, as well.

Photographic and video documentation was made, and appropriate samples were taken for toxicological and histopathological analysis. Microscopic examinations confirmed the air presence within the cerebral and cardiac vessels, and the pulmonary barotrauma.

Cerebral arterial gas embolism is more likely to happen in scuba divers because of the vertical position of the person during ascension and the tendency of the gas bubbles that are forming within the circulation to float. Cerebral arterial gas embolism presents with loss of consciousness within minutes after the rapid ascension and cardiac arrest that is unresponsive to cardiopulmonary resuscitation. A controlled ascent, therefore, is of utmost importance to avoid rapid decompression “off-gassing” (gas pass from the solution into the vessel lumens because of pressure changes).

The presented case is an excellent visual example of decompression sickness. The findings identified during the investigations carried out, together with the presentation of the condition, made it possible to identify the cause of death as arterial gas embolism due to pulmonary barotrauma. Conclusively, this case highlights the importance of having a systematic approach to scuba-diving deaths to determine the exact cause of death, using available radiological properties, and choosing the appropriate autopsy technique. The forensic practitioner who conducts the autopsy for a scuba-diving fatality should have knowledge and experience about the physiopathology of barotraumas.

Gas Embolism, Decompression Sickness, Autopsy

H22 An Anomalous Origin of Left Coronary Artery With Retro-Aortic Course and Sudden Cardiac Death

Paolo Fais, PhD, Legal Medicine-University of Bologna, Bologna, Italy; Clara Fiorentini, PhD, Legal Medicine-University of Bologna, Bologna, Italy; Gabriele Bronzetti, PhD, Paediatric Cardiology Unit-Cardio-Thoracic-Vascular Department-S. Orsola-Malpighi University Hospital, Bologna, Italy; Arianna Giorgetti, PhD, Legal Medicine-University of Bologna, Bologna, Italy; Guido Pelletti, PhD, Legal Medicine-University of Bologna, Bologna, Italy; Ornella Leone, PhD, Cardiovascular Pathology Unit-Department of Pathology-S. Orsola-Malpighi University Hospital, Bologna, Italy; Susi Pelotti, Legal Medicine-University of Bologna, Bologna, Italy*

Learning Overview: After attending this presentation, attendees will have learned that a comprehensive autopsy, including expert cardio-pathological examination, is of the utmost importance in cases of Sudden Cardiac Death (SCD), especially when cardiac anomalies are classified as uncertain cause of death.

Impact Statement: This presentation will impact the forensic science community because medical malpractice is often claimed in cases of unexplained SCD in young people. Issues related to cardiovascular screening of young athletes and improper resuscitation will be also discussed.

Introduction: Congenital anomalies of coronary arteries are often asymptomatic and may cause death with different degrees of certainty (i.e., “certain, highly probable, or uncertain”). While the anomalous origin of Left Main Coronary Artery (LMCA) from the opposite sinus with inter-arterial course has been reported as a “highly probable” substrate of SCD, when the anomalous origin of LMCA is followed by a retro-aortic course, this association has been reported as “uncertain.”

Case Report: An 8-year-old boy, in apparent good health, suddenly fell on the playground during a football training. His two Basic Life Support Defibrillation (BLSD) -trained coaches promptly performed resuscitation with the help of the emergency medical service telephonic suggestions.

Unfortunately, although an automated external defibrillator was available at the training site (as recommended from the Federation Internationale de Football Association [FIFA]), it was not used. After about 15 minutes, the medical staff arrived on site and declared the boy dead on arrival. At autopsy, LMCA anomalous origin from right coronary sinus of Valsalva with a separate ostium followed by retro-aortic course was observed. In addition, the left coronary artery displayed separate coronary ostium, acute angle takeoff from the aorta, and hypoplasia of its main branches. Microscopic examination revealed multiple foci of recent (days-weeks) ischemic lesions in inflammatory reparative phase, associated with mild multifocal lymphocytic myocarditis.

Discussion: Anomalous origin of the LMCA from the contralateral Valsalva sinus without inter-arterial course is infrequently diagnosed in children and, based on the available data, have been reported as an “uncertain” substrate of SCD. In the present case, the additional described alterations probably concurred to reduce the blood flow in the anomalous vessel, resulting in myocardial ischemia foci and in SCD during exercise. It is also possible that the superimposed mild lymphocytic myocarditis played a role. In this specific case, SCD occurred in a young athlete, despite regular cardiovascular screening tests, including Electrocardiogram (ECG) and echocardiography, which were unsuitable to diagnose such coronary artery anomalies. The forensic evaluation about the cause and the manner of death considered also the modalities of the resuscitation attempts and the claimed malpractice, as often occurs in case of sudden unexpected death in young athletes. Anomalies of coronary artery origin should require case-by-case evaluation, including clinical history, circumstances of death, and results of detailed cardio-pathological examination.¹

H23 Things Are Never What They Seem—A Fatal Injection in a Drug Abuser: Hemorrhagic Shock, Pulmonary Embolism, Fulminant Sepsis, Acute Methadone Poisoning, or Medical Liability? A Case Report

Maria Silvestre, MD*, Interdisciplinary Department of Medicine, University of Bari, Bari, Italy; Serena Corradi, MD, PhD, Interdisciplinary Department of Medicine, University of Bari, Bari, Italy; Andrea Marzullo, PhD, Interdisciplinary Department of Medicine, University of Bari, Bari, Italy; Lucia Aventaggiato, PhD, MD, Interdisciplinary Department of Medicine, University of Bari, Bari, Italy; Alessandro Dell'Erba, MD, PhD, Interdisciplinary Department of Medicine, University of Bari, Bari, Italy; Biagio Solarino, MD, Interdisciplinary Department of Medicine, University of Bari, Bari, Italy; Davide Ferorelli, MD, Interdisciplinary Department of Medicine, University of Bari, Bari, Italy

Learning Overview: After attending this presentation, attendees will have a better understanding of the importance of integrating the circumstantial, clinical, toxicological, and histopathological data in the definition of the cause of death in a drug-related death with contextual copious hemorrhage.

Impact Statement: This presentation will impact the forensic science community by demonstrating that the circumstantial data is not always sufficient to define the exact causal seriation of the death; sometimes it may induce the medical examiner to focus attention on facts and elements secondary to the definition of the cause of death.

The identification of the cause of death derives from the application of a rigorous forensic methodology. In the case submitted, the historical-circumstantial data was indicative of a hemorrhagic shock from probable injury to the brachial artery. The toxicological investigation, however, showed high levels of methadone such as to independently justify the death.

This study presents the case of a 44-year-old man with a history of drug addiction being treated with methadone, found unconscious by his mother on the floor surrounded by a large blood patch. The man was rescued and transported to a hospital where he died a few hours later. The body was subjected to forensic examinations; a lesion of the brachial artery was found. The toxicological examination showed a high level of methadone in the blood (935ng/ml, reference: <10ng/ml).

Methadone is a drug used in heroin detoxification programs. The initial dose in medication-assisted methadone treatment corresponds to 20–30mg once daily and should not exceed 30mg. The maintenance dose range is 80–120mg per day, with dosing adjustments being made over the first week based on withdrawal symptoms.¹ Accumulation of methadone can lead to sedation, respiratory depression, respiratory arrest, and death.² Respiratory depressive effects can also occur at doses below 30mg in non-tolerant subjects.^{3–5}

The death of the subject, according to the autopsy investigations and pathological findings, must relate to respiratory pneumonia of central origin, resulting from the depressive-inhibitory toxic action of the breathing centers due to the action of methadone in the subject with simultaneous blood loss.

The exact identification of the cause and means of death in each case of drug-related death is articulated through a methodological path that considers the circumstantial data, the results of the sector experiment, as well as the laboratory tests, according to what is advocated by the most careful doctrine coroner who recalls how the “diagnosis in terms of acute or chronic toxicity intoxication is a paradigmatic example of the need to correlate anamnestic-clinical data, anatomical-pathological, macro and microscopic findings, and chemical-toxicological findings.”⁶

H24 Sudden and Unexpected Death After an Induced Abortion: Medical Responsibility or a Hidden Cause?

Francesco Lupariello, MD*, Legal Medicine Section, University of Turin, Turin, Italy; Federica Mirri, MD, Legal Medicine Section, University of Turin, Turin, Italy; Fabio Innocenzi, MD, Legal Medicine Section, University of Turin, Turin, Italy; Alessandro Gabriele, MD, Legal Medicine Section, University of Turin, Turin, Italy; Giancarlo Di Vella, MD, PhD, Legal Medicine Section, University of Turin, Turin, Italy

Learning Overview: After attending this presentation, attendees will have a better understanding of occult pheochromocytoma as a cause of sudden and unexpected death in young patients.

Impact Statement: This presentation will impact the forensic science community by presenting the importance of the medicolegal investigation in a case of sudden and unexpected death immediately after a medical procedure.

Pheochromocytoma (PHEO or PCC) is a rare catecholamine-producing tumor originating in the adrenal medulla.¹ Symptoms are due to catecholamines over-production and related to sympathetic nervous system hyperactivity (i.e., hypertension, tachycardia, sweating, headache, pallor) or a mass effect (i.e., abdominal pain or bowel obstruction). Acute crises can be spontaneous or may be triggered by medications, tumor manipulation, or anesthesiology procedures.²

This study reports the case of a 36-year-old woman admitted to the gynecology department to undergo an abortion at seven weeks of gestational age. Obstetric history was positive for three term pregnancies (two normal spontaneous vaginal deliveries and one caesarean delivery). The patient did not report any illness or medication use. At the preoperative anesthesiology evaluation, vital signs were unremarkable. A medical abortion was performed, followed by Dilation and Curettage (D&C) under epidural anesthesia. The D&C lasted five minutes and immediately after the procedure, the patient developed a severe hypertensive crisis with cardiogenic shock. The patient required intensive resuscitation procedures, including inotropic agents and extracorporeal membrane oxygenation. She subsequently developed hepatic failure that led to coagulopathy. A computed tomography scan revealed a previously unknown left perirenal mass. Eventually, the patient died due to multiorgan failure.

An autopsy was ordered to clarify the cause of death and to assess any medical responsibility. At the internal examination, the left mass was found to originate from the adrenal gland; upon gross examination, the cut surface of the mass was diffusely hemorrhagic. Histopathology of samples from the adrenal mass using hematoxylin-eosin stain was suggestive for PHEO.³ The immunohistochemistry analysis on the same samples demonstrated strong and diffuse positivity for chromogranin A in all fields. In addition, a medical inquiry with the woman's relatives revealed that the deceased was affected with hypertension treated with triple-combination therapy. In the light of these findings, death was ascribed to an acute hypertensive crisis caused by an occult adrenal PHEO. PHEO has been referred to as the great mimic because the symptoms are quite common and sometimes it can be suspected only after paroxysmal episodes such as hypertensive crises. Unmanaged and/or undiagnosed PHEO is dangerous and can lead to serious and potentially lethal cardiovascular complications due to the acute massive secretion of catecholamines.⁴ In this case, the patient was affected by an undiagnosed PHEO that triggered a lethal hypertensive crisis during a minimally invasive gynecological procedure under local anesthesia. Medical malpractice was excluded because the tumor was occult and the patient did not report her complete medical history. In conclusion, an unknown PHEO can lead to sudden and unexpected death in young patients. In some instances, the diagnosis of PHEO can only be formulated after a complete medicolegal investigation.

H25 The Walking Dead: A Strange Case of Falls From a Staircase

Mauro Ciavarella*, Hospital Potenza, Potenza, Italy; Natascha Pascale, Hospital of Potenza, Potenza, Italy; Valeria Bruno, Matera Corporate Health Services, ASM Basilicata, Matera, Italy; Maurizio Scarpa, Matera Corporate Health Service, ASM Basilicata, Matera, Italy; Aldo Di Fazio, Hospital of Potenza, Potenza, Italy

Learning Overview: After attending this presentation, attendees will have gained insight into the role of postmortem Computed Tomography (CT) images in the quick interpretation of blunt traumatic injuries, especially when circumstantial data is not available.

Impact Statement: This presentation will impact the forensic science community by demonstrating that a combined classical and new forensic method with the use of Bloodstain Pattern Analysis (BPA) and postmortem CT is important to explain possible falling patterns and manner of death in individuals presenting lesions from falls down staircases without contextual information.

This work presents the case of a 64-year-old female found dead at home. The body was found prone on the middle of the second flight of a double U-shaped staircase with one square landing. At the crime scene, the primary blood pool was found at the bottom of first flight and a swipe pattern of blood was found on the steps of second flight coupled with a small amount of pool blood around the head of victim. The external examination showed extensive laceration and abrasion of the left side of the face (nose, eyebrow, eyelid, cheek) and multiple bruising on the back of the hands and arms. Postmortem CT was performed immediately and showed comminuted fractures of the nasal pyramid, bilateral maxillary sinus, left medial orbital wall, left cheekbone, fractures and dislocation of the middle-lower cervical spine (C4, C6 vertebrae) with fractures of spinal processes and severe deformity of the spinal cord. The autopsy confirmed fractures and revealed perivertebral spine hemorrhage coupled with contusion hemorrhages and transection of the C4 spinal cord. Microscopical examination confirmed the vitality of lesions and revealed massive pulmonary edema and myocardial contraction band necrosis, suggesting an acute condition of spinal shock as the mechanism of death. Toxicological analysis was negative.

Falls down stairs frequently occur within domestic environments. The skeletal blunt force trauma resulting from fatal falls involving stairs is complex. Frequently, it is not possible to understand the cause of the fall and the manner of death just with an external examination. There are multiple ways an individual may fall when stairs are involved.¹ Thus, the importance of a careful combination of the accurate analysis of evidence collected from crime scene and the evidence collected from the forensic pathologist is of the utmost importance.

From the result of the Crime Scene Investigation (CSI), it was apparent that the victim fell onto her face and struck the left side of her face, not on the step where found, but on a flat surface such as the bottom of first flight where the bigger blood pool was found. The postmortem CT quickly suggested that the victim had sustained a severe spinal cord lesion and wasn't able to move from the primary site of impact. Contrary to expectations, the bloodstain pattern analysis showed drag marks called a "swipe pattern" on the steps of second flight, a bloodstain pattern with characteristics that indicated relative motion between the two surfaces. So it was possible to suspect that the victim was dragged downstairs from the primary blood pool found at the bottom of first flight. On the basis of CSI and postmortem CT, it was immediately possible to exclude an accidental fall. The CSI and autopsy findings helped the forensic pathologist in reconstructing the sequence of events. In all probability, the victim was pushed down from a first flight with an impact onto her face against the square landing where the blood pool was found, causing an acute hyperextension injury of the cervical spine, with resultant profound spinal shock and instantaneous death. Later, the suspect tried to push the victim down the second flight of stairs. A suspect was arrested. He admitted that he was guilty.

This case underlines the usefulness of a combined forensic approach to determine the manner in which the death occurred in a case of blunt trauma. In addition to the classical forensic method, the use of BPA and postmortem CT is also important to determine the possible falling patterns from stairs.

Falls, Staircase, Blunt Trauma

H26 Suicides by Barbiturate Intoxication

Joy Edegbe, MD*, Jackson County Medical Examiner's Office, Kansas City, MO; Tiffany Hollenbeck, DO, Jackson County Medical Examiner's Office, Kansas City, MO

Learning Overview: After attending this presentation, attendees will be more familiar with the toxic and lethal effects of barbiturates and the increased incidence of suicides resulting from their use.

Impact Statement: This presentation will impact the forensic community by highlighting the use of barbiturate medications in suicides and examine how the internet and publications are influencing this suicide method.

Background: Barbiturates are a class of sedative/hypnotic drugs used mainly as antiepileptics and for induction of general anesthesia. Some states use them in physician-assisted suicides/euthanasia and for capital punishment via lethal injection. Because of the high risk of overdose and no available antidote to reverse toxicity, their use in clinical practice has been largely replaced by benzodiazepines.¹ Now they are primarily used to anesthetize animals during surgery and euthanize them in veterinary practice.²⁻⁴ Popular media, books, and information on the internet boasts barbiturates provide a peaceful method of suicide, which has led to increased interest in obtaining them from areas where they are less regulated.^{2,3,5,6}

Case 1: A 55-year-old male (a veterinarian) made a 911 call that was traced back to his business address where he was found unresponsive with an intravenous catheter in the right antecubital fossa attached to two bags labeled "Veterinary 0.9% Sodium Chloride Injection" and "Veterinary Lactated Ringer Injection." On the counter near the decedent was a bottle of veterinary euthanasia medication containing pentobarbital sodium and phenytoin sodium. Toxicologic analysis of the blood revealed ethanol, pentobarbital, and phenytoin.

Case 2: A 63-year-old male was found deceased in his residence after law enforcement had received an email from the subject stating there would be a deceased body at his residence. Scene investigation revealed personal documents, books, and letters with Post-it® notes attached expressing who should receive which document. A bottle of sodium pentobarbital was also located on scene with instructions of how to administer it. A plastic cup containing a crushed white substance was located near the subject. Toxicological analysis of the blood revealed pentobarbital and diphenhydramine.

Case 3: A 68-year-old male with a history of chronic obstructive pulmonary disease left his residence after an argument with his wife. When he returned, he reported that he had taken "end of life medication" that he had purchased in Mexico (~30 pills of phenobarbital) with intentions of ending his life. Toxicological analysis of his blood revealed cannabinoids, fluoxetine, norfluoxetine, phenobarbital, bupropion, hydroxybupropion, and ethanol.

Conclusion: Although barbiturates are not used as commonly in clinical practice, they are still used to treat certain conditions and can be obtained from internet orders as well as in veterinary practices.^{1,2,5,7,8} Pentobarbital is a very addictive drug categorized as a Drug Enforcement Administration (DEA) Schedule II substance.⁷ Toxic levels of pentobarbital in the blood range from 8–24mg/L and lethal levels range from 15–241mg/L. Phenobarbital has less addictive potential and is categorized as a DEA Schedule IV substance with toxic levels in the blood ranging from 35–253mg/L and lethal levels ranging from 48–348mg/L.⁹ Toxic/lethal effects of these drugs include airway compromise, cardiovascular collapse, coma, and death.¹ A study was performed on 51 cases in which barbiturates were detected in postmortem blood samples; of these 51 cases, 17 were ruled as suicides in which barbiturate toxicity was the primary cause of death. Within these 17 cases, 14 cases were due to pentobarbital toxicity and 3 were due to phenobarbital toxicity.¹⁰ Although barbiturates are still not commonly used in suicides, with the increasing number of online drug sellers and the accessibility of suicide kits, the number of suicide deaths using barbiturates is on the rise.

H27 An Extremely Rare Case of Hemorrhagic Shock Caused by an Early Post-Implant Saphenous Vein Graft Pseudoaneurysm Rupture

Eleonora Mezzetti, MD*, Institute of Legal Medicine, University of Pisa, Pisa, Italy; Alessandra De Matteis, MD, Legal Medicine and Orthopedics, Sapienza University, Rome Italy; Andrea Scatena, MD, Institute of Legal Medicine, University of Pisa, Pisa, Italy; Andrea Costantino, MD, Institute of Legal Medicine, University of Pisa, Pisa, Italy; Arianna Baronti, MD, Institute of Legal Medicine, University of Pisa, Pisa, Italy; Lavinia Pellegrini, MD, Legal Medicine and Orthopedics, Sapienza University, Rome, Italy; Alice Chiara Manetti, MD, Institute of Legal Medicine, University of Pisa, Pisa, Italy

Learning Overview: After attending this presentation, attendees will have discovered a rare complication of Saphenous Vein Graft (SVG) implantation. In this case, it presented with hemorrhagic shock instead of cardiac tamponade, as would have been expected. SVG rupture may lead to patient death and medical liability claims.

Impact Statement: This presentation will highly impact the forensic sciences community because it demonstrates that surgeons and pathologists have to explore the possibility of an SVG rupture in cases of post-surgical hemorrhagic shock, even if it is an extraordinarily unusual event.

Introduction: The SVG is a natural blood vessel used for surgical revascularization of a coronary. This technique is an authentic life-saving tool, and its use is still widespread today.¹ The procedure involves early and late complications. Late complications include restenosis or occlusion of venous bypass, progressive atherosclerosis of native coronary arteries, graft's aneurysms, intracoronary steal syndrome, coronary arteriovenous fistula, and aortic dissection at the anastomotic site.² Aneurysmal dilatation and pseudoaneurysm degeneration of SVGs have been rarely described in scientific literature.^{3,4} Their rupture occurs in only 8% of cases with catastrophic complications.⁵ In this presentation, a rare case of fatal hemorrhagic anemia after SVG pseudoaneurysm rupture is presented.

Case Report: A 53-year-old man was recovering after a syncopal episode. At the hospital, physicians diagnosed severe aortic stenosis, which required surgical treatment for valve replacement. During the procedure, the patient suffered a sudden episode of Ventricular Fibrillation (VF). The physicians hypothesized that myocardial hypoperfusion was caused by ostial occlusion that occurred during valve implantation. For this reason, the surgeons performed an immediate double bypass through a bilateral autologous SVG. After only four hours, the hemoglobin level dropped inexorably. An echocardiography performed seven hours after the surgery showed a small amount of pericardial effusion. The day after, the patient's clinical condition became critical; no blood transfusion or epinephrine injections could prevent hemorrhagic shock and death.

The Judicial Authority investigated if medical malpractice might be involved and ordered an autopsy. The main issue, in this case, was to understand whether the doctors could have prevented the patient's death.

The autopsy revealed rupture of a pseudoaneurysm in the left coronary graft, which caused massive blood leakage. The pericardium appeared vastly infiltrated and full of clots. Pleural cavities contained massive quantities of blood, respectively 830ccs on the right and 230ccs on the left. Histological examination showed that the fissure of the SVG occurred first in the deepest layer and spread to the more superficial ones. The absence of clinical signs of cardiac tamponade, like it could be logically expected, and the impossibility to instrumentally investigate blood vessels, made clinical diagnosis extremely challenging.

Autopsy investigation allowed assessment of the cause of death: hemorrhagic shock caused by the SVG's pseudoaneurysm rupture. A silent, invisible, and unpredictable time bomb implanted in the patient's chest developed between the explant and re-implantation of the graft. Therefore, necropsy examination was essential to relieve the medical staff and demonstrate that pseudoaneurysm rupture can be an insidious early complication in bypass surgery.

In this report, a rare case of hemorrhagic shock due to SVG rupture soon after the implant is presented. Thanks to the forensic investigation, it has been demonstrated that the pseudoaneurysm rupture complication can occur even a few hours after the surgery and manifest with unusual characteristics. So, this event, even though atypical, should be suspected and investigated in good medical practice. In the same way, pathologists have to consider this event as a possible diagnosis of death in cases of hemorrhagic shock.

H28 “She Don’t Lie, She Don’t Lie, She Don’t Lie—Cocaine!” Homicide, Suicide, or Accident? The Unresolved Question About Drug-Related Deaths

Michele Telegrafo, MD, University of Bari, Bari, Italy; Alessandro Dell’Erba, MD, University of Bari, Bari, Italy; Enrica Macorano, MD University of Bari, Bari, Italy; Maurizio Mastrapasqua, MD, University of Bari, Bari, Italy; Francesco Carravetta, MD, University of Bari, Bari, Italy; Federica Misceo, MD, University of Bari, Bari, Italy; Maria Silvestre, MD, University of Bari, Bari, Italy; Serena Corradi, MD, University of Bari, Bari, Italy; Roberto Maselli, MD, University of Bari, Bari, Italy; Lorenzo Spagnolo, MD, University of Bari, Bari, Italy; Sara Sablone, University of Bari, Bari, Italy*

Learning Overview: After this presentation, attendees will be able to recognize the symptoms and signs of overdose from cocaine ingestion.

Impact Statement: This presentation will impact the forensic science community by presenting evidence from ingestion of a large quantity of cocaine.

A 2017 general population survey on drugs found that a third of the Italian population aged 15–64 years had used a psychoactive substance at least once in their lifetime, and one in ten had done so in the previous year. The majority of consumers are male, although the incidence increased in both sexes. For what concerns cocaine, it is a drug whose use varies from occasional to repeated up to compulsive. Repeated use of cocaine can lead to addiction and other serious harm. Cocaine can be taken in different ways: depending on the chemical-physical form of the substance, it can be inhaled, injected, smoked, or ingested. There is no safe way to take cocaine, since any modality can lead to the absorption of toxic doses, causing serious cardiovascular or cerebrovascular problems and, in some cases, sudden death. Cocaine ingestion, however, is the most unusual form of cocaine intake and it is mainly chosen for national and international transport. The absorption of ingested cocaine already begins in the oral mucosa and continues in that of the gastrointestinal tract. Through the oral route, the substance bioavailability is 30–40%. The maximum duration of effects of an average dose (20–50mg) ranges from 45 to 90 minutes. Several studies have shown the potentially lethal consequences of cocaine packet ingestion.^{1–5}

A 36-year-old Italian man who had suffered from a depressive disorder subsequent to the recent death of his mother was found lifeless on the sofa of his home. The evening before the discovery, after having had dinner and simultaneously drinking a small amount of wine with his father, he had a psychotic crisis with pantoclastic manifestations. Several psychoactive drugs, such as lithium and clomipramine, were found at the crime scene.

At the external examination, a cadaveric rectal temperature of 41.3°C was registered, compared to an ambient temperature of 31.3°C. Moreover, several skin abrasive injuries were identified on the upper and lower limbs, as accidental consequences of the premortem psychotic crisis. During autopsy examination, a circular plastic film was found in the hypopharynx. A series of six other similar plastic films were then identified in the stomach. Toxicological investigations revealed the presence of cocaine equal to 466ng/L (cut-off 10ng/mL), metabolites of cocaine all above the cut-off, and alcohol equal to 0.26g/L in the cadaveric blood. No psychoactive drug (or their metabolites) was found.

Usually, the typical mode of assumption of cocaine is inhalation. The case here presented represents the first documented one in Italy of a fatal overdose resulting from the ingestion of large quantities of cocaine, the toxicity of which has been amplified by the presence of alcohol. The intake of the substance still packaged in its envelopes does not allow a differential diagnosis to be made between the hypothesis of suicide or accidental death that could have been occurred after a failed attempt at concealed drug transport.

Cocaine Ingestion, Toxicology Findings, Psychotic Crisis

H29 Another Case of Femicide? No, That's Another Case of Underlying Sudden Unexpected Death in Epilepsy (SUDEP)

Natascha Pascale, MD; San Carlo Hospital, Potenza, Italy; Mauro Ciavarella, MD; San Carlo Hospital, Potenza, Italy; Valeria Bruno, MD; ASM, Matera, Italy; Maurizio Scarpa, MD; ASM, Atera, Italy; Aldo Di Fazio, MD, San Carlo Hospital, Potenza, Italy*

Learning Overview: After attending this presentation, attendees will understand that SUDEP is still an underestimated and difficult to diagnose cause of death and that it is very important protecting epilepsy through an evaluation of the environmental conditions and periodic medical strictly controls.

Impact Statement: This presentation will impact the forensic science community by showing the crucial importance of a full medicolegal investigation (i.e., clinical history collection, autopsy, and histological and toxicological studies). Furthermore, there is a need to educate officials at all levels about this diagnosis in persons who have epilepsy with no other cause of death.

SUDEP is defined as “the sudden, unexpected, witnessed or unwitnessed, non-traumatic and non-drowning death in patients with epilepsy with or without evidence of a seizure, and excluding documented status epilepticus, in which postmortem examination does not reveal a structural or toxicological cause for death.”¹ The most common pathologic finding in autopsies is pulmonary congestion/edema (~50%); there is no evidence of neurodevelopmental abnormalities, which are often the etiology of epilepsy. While the mechanisms of death in SUDEP are unknown, these discoveries suggest that cardiogenic mechanisms may be involved in the sudden death of these patients. Cardiac and pulmonary pathological abnormalities are frequent among SUDEP cases, most commonly pulmonary edema/congestion and focal interstitial myocardial fibrosis. There are frequent reports of persons dying alone in their sleep. It is assumed that death occurs following a seizure, but since the deaths are often unwitnessed, this is only an assumption. The most important risk factor appears to be poor seizure control.^{2,3}

The present case concerns a 43-year-old Italian woman found dead in her bed, in the prone position, with her face pressed against the pillow. The medical history suggested epileptic disease from infancy under pharmacological treatment, with persistence of episodic seizures, the last of which happened the night before; no other pathology was documented. During the police investigation, the house was found in order. There was also a violent relationship with her husband, who was addicted to alcohol and drugs. An immediate rough examination of the body showed small bruises on the neck, but the case was closed for natural death, without further investigation. A forensic autopsy was performed one month after her death, after the parent's claims to the police of suspicion of homicide committed by the husband of the victim. The corpse was in putrefaction; the external examination showed the signs of old bruises to the arms and neck. The internal examination mainly revealed an absence of injuries and or hemorrhagic infiltrations, while pulmonary edema was found. The brain has not been studied due to advanced autolysis. The heart showed a normal size with early coronary artery atherosclerosis. The evaluation of histological specimens showed cardiac interstitial fibrosis, massive edema of the lungs associated with multi-organ congestion, liver steatosis, and no vital signs in the epidermal lesions. Toxicological analysis were negative.

This case underlines the need to keep attention levels high in the forensic analysis of all so-called “seizure-related deaths” to exclude with certainty the initial suspicion of homicide and to make a final diagnosis of SUDEP.

SUDEP, Forensic Investigation, Differential Diagnosis

H30 The “Pathologic” Mother-Son Bond: An Unusual Case of Matricide With “Overkill”

Cristina Mondello, MD, PhD, University of Messina, Messina, Italy; Gennaro Baldino, MD, University of Palermo, Palermo, Italy; Chiara Stassi, MD, University of Palermo, Palermo, Italy; Cataldo Raffino, MD, Legal Medicine Centre of Inail, Enna, Italy; Alessio Asmundo, MD, University of Messina, Messina, Italy; Elvira Ventura Spagnolo, MD, PhD, University of Palermo, Palermo, Italy*

Learning Overview: After attending this presentation, attendees will understand that matricide is a rare and aberrant event in which the reasons for the murder could be found in the complex and pathological bond between mother and son/daughter.

Impact Statement: This presentation will impact the forensic science community by highlighting a rare case of matricide with “overkill” in which the perpetrators, after killing the mother, plug needles in the face of the cadaver to simulate the punishment his mother inflicted on him when he was a child.

Matricide is among the rarest murder and has always been considered one of the most abhorrent crimes. Studies on matricide by a son highlighted that most perpetrators are single adults with an intense relationship with their mother, a lack of interest in other women, a feeling of social inferiority, and an absent or passive father.¹ These subjects often reported feeling that their mothers were either ambivalent toward them or excessively domineering.

Matricide is classically committed in the victim’s home, and a weapon is usually used, although asphyxia is also common. Moreover, matricide is described as associated with “overkill” in some cases.²

A 73-year-old woman was found dead in her home by police. The police intervened because they were alerted by a neighbor who had heard the woman scream and ask for help. In the house, the young adopted son attacked the agents with a knife; he was then disarmed and arrested. The forensic pathologist performed the crime-scene investigation, which observed a living room mess and the woman’s body lying on the floor covered with furnishings. The preliminary external examination revealed skull and facial trauma and the presence of needles strung in various regions of the face. At the autopsy, the needles were found, respectively: one in the left eye, five in the left zygomatic region, and one in the left mandibular region. Several maxillo-facial fractures and brain hemorrhage were found; moreover, bruises, contusions, excoriations, and lacerations were observed on the body, also at the neck. There were multiple bilateral rib fractures and hemopericardium due to right ventricle laceration.

Based on the forensic investigations (crime scene analysis, circumstantial data, autopsy, and blood pattern analysis), the murder was reconstructed, supporting the extreme violence through which the young men attacked the mother, causing her death from severe trauma to the head and chest.

Even if the literature reported that most matricides suffer from psychotic disorders, especially schizophrenia, this is a rare case in which non-psychiatric illnesses were diagnosed. A “pathological” mother-son bond was described, and the murder reason was brought back to the vexatious dynamics perpetrated by the mother since the son was a child; the mother punished the boy with needles strung in the face. The reconstruction of the mother-son relationship, as well as the life experiences of both, allowed consideration that the murder was a dramatic attempt to “break” the destructive bond among them.

Matricide, Overkill, Mother-Son Bond

H31 Charred Bodies: Homicidal, Suicidal, or Accidental Death? A Case Series

Chiara Stassi, MD*, University of Palermo, Palermo, Italy; Chiara Rizzo, MD, University of Palermo, Palermo, Italy; Gennaro Baldino, MD, University of Palermo, Palermo, Italy; Martina Ciriminna, MD, University of Palermo, Palermo, Italy; Jurij De Francisci, MD, University of Palermo, Palermo, Italy; Cristina Mondello, MD, University of Messina, Messina, Italy; Antonio Micali, MD, University of Messina, Messina, Italy; Cataldo Raffino, MD, INAIL, Messina, Italy; Alessio Asmundo, MD, University of Messina, Messina, Italy; Elvira Ventura Spagnolo, MD; University of Palermo, Palermo, Italy

Learning Overview: After attending this presentation, attendees will have acquired a better insight on the importance of a multidisciplinary approach for the determination of cause and manner of death—homicidal, suicidal, or accidental—when charred bodies are recovered

Impact Statement: This presentation will impact the forensic science community by highlighting the importance of a proper interpretation of the results obtained from different forensic investigations carried out on severely charred bodies in order to correctly determine manner and cause of death, as well as its dynamics when the obtained data are combined with the information provided by specific professional figures in selected cases.

Charring is a process responsible for a wide range of heat-related injuries, which often produce deep destructive transformations of organs and tissues following a prolonged exposure of the body—or parts of it—to temperatures $\geq 300^{\circ}\text{C}$ as a consequence of a combustion process between a fuel and an oxidizer (usually the oxygen in the surrounding atmosphere). Depending on the body parts involved and the temperatures and time of exposure, the destructive effect on human remains can largely vary from localized burns/charred areas to complete incineration. As such, depending on both the fire entity and the extent of the charred body surface, issues may arise concerning: (1) identification, especially when no clothes or personal objects are recovered on cadavers and physiognomic features appear severely impaired; (2) primary cause of death, that is to say whether the fire effects occur before or after death; and (3) manner of death, whose elucidation is of utmost importance in cases of homicide since charring represents a frequent attempt to destroy forensic evidence and prevent the cadaver recovery.

Under the heat effect in cases of extensive charring, skin appears dry and blackish, with burnt or almost absent hair; dehydration is responsible for tissue retraction followed by an overall reduction of the body surface, together with muscle contracture; the consequential extreme flexion of upper and lower limbs lets the cadaver assume a typical “pugilistic” pose. Bones usually undergo the so called “calcination” phenomenon, which makes them more frail, and thus more prone to non-vital fractures and/or amputations; epidural heat hematomas can also be detected as consequence of heat-induced suction due to the volume reduction of the brain. Since these findings, although characteristic, taken alone are almost unspecific, an aid in understanding the manner and dynamics of death must be provided by additional investigations.¹⁻³

To this aim, cause and manner of death have been investigated by a multidisciplinary approach in 21 cases of severely charred bodies. Along with circumstantial data, information on mental health status and autopsy, and whenever possible, additional findings have been provided by: histology, carried out on 14/21 cases, which gave rise to unspecific findings; Computed Tomography (CT) scan, carried out on 17/21 cases in order to detect and eventually characterize internal injuries not related to fire and/or foreign bodies; and toxicological investigations, carried out on 17/21 cases in order to detect either the presence of abuse substances and the levels of blood carboxy-hemoglobin as an indicator of aspiration occurrence before death. A novel investigation, Scansion Electron Microscopy with Energy-Dispersive X-ray (SEM/EDX), was carried out only in case number 3 for the evaluation of both heat-induced bone alterations and metallic residues as indicators of the cadaver recovery site. In 7/21 cases, they rely on an engineer expertise, also revealed fundamental for the comprehension of the dynamics of the event.

The combined interpretation of the different findings thus allowed the statement of 11 cases as accidental deaths, 6 cases as homicidal, and 4 cases as suicidal.

Charred Bodies, Forensic Investigations, Manner of Death

H32 The Immunofluorescence Survey and the Persistence of SARS-CoV-2 After Death

Isabella Aquila MD, PhD, Institute of Legal Medicine, Magna Graecia University of Catanzaro, Catanzaro, Italy; Matteo Antonio Sacco, MD, Institute of Legal Medicine, Magna Graecia University of Catanzaro, Catanzaro, Italy; Maria Manno, MD, Institute of Legal Medicine, Magna Graecia University of Catanzaro, Catanzaro, Italy; Pietrantonio Ricci, MD, PhD, Institute of Legal Medicine, Magna Graecia University of Catanzaro, Catanzaro, Italy*

Learning Overview: After attending this presentation, attendees will have a better understanding of the importance of the use of immunofluorescence as a rapid test to detect the persistence of SARS-CoV-2 infection in cadavers.

Impact Statement: This presentation will impact the forensic science community by presenting evidence of the persistence of SARS-CoV-2 18 days after death in a buried corpse.

To date, over 4.5 million deaths due to SARS-CoV-2 infection have been recorded worldwide.¹ Contagion occurs mainly through the release of droplets, during speech and respiration, and therefore the contact of viral particles with the epithelial surfaces, in particular on the bronchi and conjunctiva.² The analysis of nasal and oro-pharyngeal swabs for the search for viral RNA is the primary tool for detecting the presence of infection through the Reverse Transcription Polymerase Chain Reaction (RT-PCR) method, which is based on the amplification of the traits of genetic material of interest. Its use, even in the forensic field, is recommended by scientific societies and by Italian guidelines.³ The search for the proteins (antigens) of the virus by immunofluorescence is, however, able to prove in cases of positivity, a greater integrity of the viral particles. This is an essential prerequisite to be able to hypothesize the survival of virions.

This study brings knowledge to the international scientific community of the case of the finding of a double positivity to nasopharyngeal swabs, carried out during an autopsy, on the corpse of a man who died 18 days earlier, analyzed with both methods. The man died from the development of massive interstitial pneumonia (also documented on Computed Tomography [CT] images) associated with COVID-19 pulmonary vascular microthrombosis. The peculiarity of the case is that, following the death, the body was never kept in a cold room, but it was buried. The corpse was placed in a body bag inserted into a galvanized wooden crate, in turn contained in a metal casing, and was subsequently exhumed to allow the autopsy. This made it possible to detect the persistence of the viral genetic material (RNA) found on RT-PCR, as well as, above all, of the viral antigens, detected thanks to immunofluorescence, 18 days after death. The assay used is a lateral flow immunofluorescence sandwich assay for the qualitative detection of the SARS-CoV-2 nucleocapsid protein antigen.

This research intends to emphasize the importance of performing nasopharyngeal swabs to be analyzed by immunofluorescence on cadavers with suspected or confirmed COVID-19 infection. This test has, in fact, the advantage of giving a quick answer and, in case of positivity, of identifying the bodies at greater infectious risk. Furthermore, it allows us to formulate hypotheses about the survival time of the virus—an indispensable prerequisite for contagion—in the corpses of infected people at the time of death and stored in ambient temperature conditions.

Forensic Science, Postmortem Swab, Immunofluorescence

H33 Hepatodiaphragmatic Interposition of the Colon: Radiological Evidence and Autopsy Findings in a Case of Chilaiditi Syndrome

Martina Padovano, MD, Department of Anatomical, Histological, Forensic and Orthopaedic Sciences, Sapienza University of Rome, Rome, Italy; Federico Manetti, MD, Department of Anatomical, Histological, Forensic and Orthopaedic Sciences, Sapienza University of Rome, Rome, Italy; Matteo Scopetti, MD, Department of Anatomical, Histological, Forensic and Orthopaedic Sciences, Sapienza University of Rome, Rome, Italy; Alessandro Santurro, MD, Department of Medicine, Surgery and Dentistry, University of Salerno, Salerno, Italy; Paola Frati, PhD, Department of Anatomical, Histological, Forensic and Orthopaedic Sciences, Sapienza University of Rome, Rome, Italy; Vittorio Fineschi, PhD, MD, Department of Anatomical, Histological, Forensic and Orthopaedic Sciences, Sapienza University of Rome, Rome, Italy*

Learning Overview: After attending this presentation, attendees will better appreciate the characteristics of a rare anatomical condition identified as Chilaiditi syndrome through the description of a case of sudden death that occurred after admission to the emergency department.

Impact Statement: This presentation will impact the forensic community through the description of autopsy findings related to a condition of prevalent radiological finding.

Chilaiditi syndrome is a rare condition, caused by an interposition of the colon or small intestine between the liver and diaphragm. The anatomical condition is associated with clinical manifestations; the most frequent presentation is abdominal pain, anorexia, nausea, vomiting, flatulence, constipation, abdominal tension followed by respiratory distress, and, less frequently, cardiac symptoms such as chest pain and arrhythmias. These manifestations are more severe when the subject assumes a supine position, and, only rarely, involve several organs at the same time. Gastrointestinal involvement can be of varying degrees of severity up to the acute abdomen. On the contrary, the anatomical finding in the absence of correlated symptomatology only allows highlighting the presence of the Chilaiditi sign in the absence of a syndromic context.

The present report concerns the death of a 59-year-old man that occurred suddenly a few hours after being admitted to the emergency department for abdominal pain, constipation, sweating, skin pallor, and abdominal distension. During hospitalization, the clinical conditions were substantially stable with normal vital signs; the only relevant evidence was provided by an abdominal Computed Tomography (CT) scan which documented the presence of the previously never-objectified Chilaiditi sign. Despite this, the death was unexpectedly ascertained after a few hours; for this reason, an autopsy was required to establish the cause of death.

The autopsy assessment confirmed the hepatodiaphragmatic interposition of the colon associated with diaphragmatic lifting and visceral adhesions. In addition, an increase in heart volume and weight related to the subject's gender, age, height, and weight, associated with a condition of systemic atherosclerosis, was found. No findings compatible with intestinal occlusive pathology were highlighted. In consideration of the clinical history and autopsy evidence, organ and tissue samples were collected for subsequent histological investigations.

The histological examination revealed the presence of coronary artery disease and widespread interstitial fibrous substitution phenomena in the heart. A modest amount of alveolar edema was also evident in the lungs. The colon wall showed no noteworthy structural changes.

At the end of the investigations, the cause of death was identified as acute heart failure in the context of dilated heart disease associated with coronary atherosclerosis and myocardial interstitial fibrosis.

In conclusion, this presentation offers an extensive anatomical detail of a condition that presents mainly, if not solely radiological, description in the literature. In addition, some autopsy procedural insights are provided for the diagnosis of pathological conditions possibly associated with Chilaiditi syndrome.

Chilaiditi Syndrome, Radiological Evidence, Autopsy Findings

H34 Rare Congenital Diseases and Infant Deaths: Postmortem Investigations of a Case of Fraser Syndrome

Federico Manetti, MD, Department of Anatomical, Histological, Forensic and Orthopaedic Sciences, Sapienza University of Rome, Rome, Italy; Martina Padovano, MD, Department of Anatomical, Histological, Forensic and Orthopaedic Sciences, Sapienza University of Rome, Rome, Italy; Matteo Scopetti, MD, Department of Anatomical, Histological, Forensic and Orthopaedic Sciences, Sapienza University of Rome, Rome, Italy; Alessandro Santurro, MD, Department of Medicine, Surgery and Dentistry, University of Salerno, Salerno, Italy; Paola Frati, PhD, Department of Anatomical, Histological, Forensic and Orthopaedic Sciences, Sapienza University of Rome, Rome, Italy; Vittorio Fineschi, PhD, MD, Department of Anatomical, Histological, Forensic and Orthopaedic Sciences, Sapienza University of Rome, Rome, Italy*

Learning Overview: After attending this presentation, attendees will better appreciate the pathological implications of a rare congenital disease associated with high neonatal mortality: Fraser Syndrome.

Impact Statement: This presentation will impact the forensic community by sharing a multidisciplinary operative methodology that can be adopted in suspicion of genetic diseases involving multiple districts.

Fraser Syndrome is a rare autosomal recessive genetic disorder with an estimated prevalence (Europe) of 1/500,000 births. It is caused by mutations in FRAS1, FREM2, and GRIP1 genes and coding for extracellular matrix proteins also involved in the embryological development, whose mutation is believed to be responsible for a failure in apoptosis. The alterations can affect eye, urinary tract, reproductive organs, craniofacial structures, respiratory systems, heart, digestive tract, and skull, although the most characteristic manifestations of the pathology are cryptophthalmos and syndactyly. In the most severe cases, Fraser Syndrome has a high rate of prenatal or perinatal death, generally due to alterations in the upper aerodigestive tract and the excretory system; otherwise, extended or normal life expectancy have been reported.

The present report concerns the investigations conducted in a case of death in a 6-month-old child affected with Fraser Syndrome.

The analysis of the available clinical documentation revealed that the baby was born premature at the 34th week, due to the presence of ascites, polyhydramnios, anemia, and scarce fetal movements that required caesarean emergency section, following which he underwent invasive ventilation for the presence of respiratory failure. Due to the finding of multiple malformations, physicians suspected Fraser Syndrome. At the sixth month of life, the baby was found unconscious and not responding by the mother and was transported to the nearest emergency room. Despite the timely intervention of the doctors and the resuscitation maneuvers performed for about two-and-one-half hours, death was ascertained.

Postmortem investigations were carried out in order to define the causes of death and specify the conditions suffered by the child with preventive purposes. Prior to invasive investigations, the body underwent both Postmortem Computed Tomography (PMCT) and Postmortem Magnetic Resonance (PMMR).

Multiple pathological findings were observed during external examination, including dysmorphism of the head due to a net increase in posterior diameters, hypertrichosis, bilateral cryptophthalmos with microphthalmia of right eye, ogival palate, single transverse palmar crease at the right hand and two to three toes syndactyly bilaterally. Autopsy was performed according to Letulle technique; given the presence of abundant yellowish milk-like material in the upper airways and the observation of suggestive findings at radiological investigations; trachea and bronchi opening was performed at the autopsy table and revealed the presence of similar material in correspondence of the right main bronchus and the macroscopically explorable branches. The brain and the whole Letulle block were fixed in 10% buffered formalin, while samples of organs' parenchyma for genetic investigations were taken and stored in the freezer at -20°C. The diagnosis of death from bronchoaspiration of food material was confirmed both by the revision of the fixed organs and by histopathological investigations, which revealed the presence of birefrangent material in the airways.

In conclusion, the clinical autopsy and the further investigations carried out made it possible, on the one hand, to obtain with certainty a diagnosis of death and, on the other, to document the typical alterations of a rarely described condition with the desirable repercussions not only for postmortem diagnostics, but also for the clinic on the living.

Fraser Syndrome, Neonatal Deaths, Postmortem Investigation

H35 The Role of Superstitions In Sexual Assault: A Case Discussion

Sarah Al Hinnawi MD, HBT Medical College, Mumbai, Maharashtra, India*

Learning Overview: After attending this presentation, attendees will be aware of how superstitions and blind beliefs make women vulnerable to sexual assault.

Impact Statement: This presentation aims to provide an insight into how superstitions, myths, and beliefs make women fall prey to people who then commit crimes, including sexual assaults.

Superstition refers to any belief or practice that is caused by supernatural causality and which contradicts modern science. The acceptance of superstitions and paranormal healing are claimed by fake shamans and believed by many. It is not only confined to the uneducated but also the educated and developed population.¹ There are various sociological factors—regional beliefs, local population structure, and social influences—as well as the belief in the powers of paranormal beings in solving problems of human beings. People believe that such practices are to be followed silently and not questioned or analyzed on scientific lines. The effect of superstition is seen more among women and in those who are emotionally vulnerable. The practitioners of such faiths even exploit childless women sexually under the pretext of curing their infertility. Lack of education, failures, and domestic problems make domination and sexual harassment added to the woes of women, forcing them into the trap of superstitions.

Counseling centers have also been started to dissuade women in distress to turn to superstitions for solace. It even had to take the death of an activist for the first Act to be passed in the Parliament.² However, education remains the best solution to this.

The present case discusses one such disturbing incident and the various measures that can be undertaken to combat such issues. This presentation also discusses the responsibility and accountability of the society and lawmakers to improve the mindset and imbue rationality and science in the mind of the people.

Superstition, Myths, Sexual Assault

H36 Standards Development Activities in Forensic Medicine

Jason M. Wiersema, PhD, Harris County Institute of Forensic Science, Houston, TX; Keith Pinckard, MD, PhD; Travis County Medical Examiner's Office, Austin, TX

Learning Overview: After attending this presentation, attendees will have a better understanding of the status of discipline-specific standards pertinent to forensic medicine.

Impact Statement: This presentation will impact the forensic science community by creating greater awareness of standards development activities within forensic medicine. It will also increase awareness regarding training, tools, and resources that support implementation, compliance monitoring, and broader understanding.

The Organization of Scientific Area Committees (OSAC) for Forensic Science was created to strengthen the nation's use of forensic science by promoting the use of discipline-specific forensic science standards. To this end, the OSAC drafts standards that are forwarded to Standards Developing Organizations (SDOs) that further develop and publish them. The OSAC also reviews standards and recognizes them on the OSAC Registry, which serves as a central repository of high-quality, consensus-based, technically sound standards.

During this presentation, updates related to standards development in forensic medicine will be discussed, including standards that have been added to the OSAC Registry, OSAC proposed standards, standards published by SDOs and other authoritative bodies that have yet to go through the Registry approval process, and documents currently in development by the Subcommittees of the Forensic Medicine SAC. The subcommittee priorities for upcoming work products and other initiatives will be presented, including opportunities for supplemental training related to discipline-specific standards, and additional resources designed to facilitate gap analysis, compliance monitoring, and outreach efforts.

Forensic Medicine, Standards, OSAC

H37 Standards Development Activities in Wildlife Forensic Biology

Kimberly Frazier, MS, Wyoming Game and Fish Department, Wildlife Forensic and Fish Health Laboratory, Laramie, WY*

Learning Overview: After attending this presentation, attendees will have a better understanding of the status of discipline-specific standards pertinent to the field of wildlife forensic biology.

Impact Statement: The presentation will impact the forensic science community by creating greater awareness of standards development activities in wildlife forensic biology.

The Organization of Scientific Area Committees (OSAC) for Forensic Science was created to strengthen the nation's use of forensic science by promoting the use of discipline-specific forensic science standards. To this end, the OSAC drafts standards that are forwarded to Standards Developing Organizations (SDOs) that further develop and publish them. The OSAC also reviews standards and recognizes them on the OSAC Registry, which serves as a central repository of high-quality, consensus-based, technically sound standards.

During this presentation, updates related to standards development in wildlife forensic biology will be discussed. These include:

- Recent standards that have been added to the OSAC Registry:
- American National Standards Institute/Academy Standards Board (ANSI/ASB) Standard 019, *Wildlife Forensics General Standards*, First Edition, 2019
- ANSI/ASB Standard 029, *Report Writing in Wildlife Forensics: Morphology and Genetics*, First Edition, 2019
- ANSI/ASB Standard 028, *Wildlife Forensics Morphology Standards*, First Edition, 2019
- ANSI/ASB Standard 047, *Wildlife Forensics Validation Standard—Validating New Primers for Sequencing*, First Edition, 2019
- OSAC proposed standards Wildlife Forensics Methods
- OSAC 2021-N-0001, *Wildlife Forensics Method—Collection of Known DNA Samples from Domestic Mammals*

Published standards from the ASB pending Registry approval process:

- ANSI/ASB Standard 046, *Wildlife Forensics Validation Standards—STR Analysis*, First Edition 2019
- ANSI/ASB Standard 048, *Wildlife Forensic DNA Standard Procedures*, First Edition, 2019
- ASB Standard 106, *Wildlife Forensics—Protein Serology Method for Taxonomic Identification*, First Edition, 2020
- ANSI/ASB Standard 111, *Standard for Training in Mitochondrial DNA (mtDNA) Analysis for Taxonomic Identification*, First Edition, 2020
- Documents currently in development at the OSAC or by the ASB:
- Genetic methods to determine an individual of potential hybrid origin
- Criteria for analyzing Short Tandem Repeat (STR) data in forensic wildlife cases when no allelic ladder is available
- Standard for the development and use of in-house sequence databases for taxonomic assignment of wildlife
- Method for geographic assignment of individual animals
- 2021-S-0006 Standard for the Use of GenBank for Taxonomic Assignment of Wildlife
- 2021-N-0001 Wildlife Forensics Method—Collection of Known DNA Samples from Domestic Mammals
- Wildlife Forensics—Standards for Construction of Multilocus Databases

Other highlights:

- Hosted an OSAC Wildlife Forensics Validation Discussion
- Developed several research needs

Wildlife Forensics, Standards, OSAC

H38 Professionals of the Medicolegal Death Investigation Workforce—The State of the Talent Pipeline

Jeri Roper-Miller, PhD, RTI International, Research Triangle Park, NC; Hope Smiley-McDonald, PhD, RTI International, Research Triangle Park, NC; Crystal Daye MPA, RTI International, Research Triangle Park, NC; Kelly Keyes, BS, RTI International, Research Triangle Park, NC; Connor Brooks, MSc, Bureau of Justice Statistics, Dulles, VA*

Learning Overview: After attending this presentation, attendees will have a better understanding of professionals in medicolegal death investigation and the needs associated with improving the workforce pipeline.

Impact Statement: This presentation will impact the forensic science community by presenting general staffing statistics, operations, training, and professional development data within the United States medicolegal death investigation system.

Introduction: In 2019, the United States Bureau of Justice Statistics (BJS) (2017-MU-CX-K052) administered the national Census of Medical Examiners and Coroners' Office (CMEC) to collect 2018 data describing the Medicolegal Death Investigation (MDI) in the United States. In 2017, 450,000 deaths were investigated by Medical Examiner and Coroner (ME/C) offices, accounting for approximately 20% of all deaths; more than 70,000 were overdose mortalities.¹ This was before the 2020 COVID-19 pandemic, which caused an additional 375,000 United States deaths.² The lack of highly skilled and trained MDI professionals, especially board-certified forensic pathologists, persistently and negatively affect the ability of ME/C offices to complete their investigations adequately, in a timely manner, and affordably. Publicly accessible BJS data were analyzed to report on the talent pipeline of autopsy pathologists, death investigators, autopsy technicians, toxicologists, and other professionals in this national census of more than 2,100 ME/C offices.

Objective: To analyze and discuss operational characteristics of ME/C offices in the United States to provide insight for staffing, workload, budget and operations, training, and professional development.

Methods: The 2018 CMEC was conducted during an 11-month period. A census questionnaire was designed and coordinated with forensic expert panel review and piloting of the instrument to select ME/C offices. As a mixed-mode data collection, ME/C responses were received by completed census questionnaires through mail, facsimile, computer-assisted telephone interviewing, and a web-based instrument. Questions and data providing details as to the operation of ME/C offices specific to staffing and the workforce were analyzed.

Results: This study provides insight and context for personnel (salary, certification), budgets, workloads, resources needed, and investigative practices within these ME/C offices. Where possible, the data are presented by type of office and size of jurisdiction, and selected comparisons with the 2004 CMEC administration will be made. The overall number of autopsies has increased since 2004, although the average caseload has gone down slightly. Although it has been estimated that there are about 400–500 forensic pathologists working in the United States, the 2018 CMEC found that this number may be higher.³

Conclusion: Attendees will gain an understanding of talent pipeline, current state of the ME/C workforce, training, and professional development practices within United States ME/C systems. Crucial statistics for the operation and function of our nation's death investigation system is discussed, fully realizing that the current state of staffing needs and workforce deficits is critical to public health and safety.

Medicolegal Death Investigation, Workforce and Talent Pipeline, Medical Examiner and Coroner Systems

H39 Addressing the Future of Forensic Pathology in the Caribbean: The Need for Mentorship Among Caribbean Medical Students

Ann-Marie Ming, BMedSc, Department of Clinical Sciences, Faculty of Medical Sciences, The University of the West Indies, St. Augustine, Trinidad and Tobago; Catherine Morris MD, Department of Pathology, Port of Spain General Hospital, Port of Spain, Trinidad and Tobago; Alfredo Walker, MBBS, Department of Pathology and Laboratory Medicine, Faculty of Medicine, University of Ottawa, Ottawa, Toronto, Canada*

Learning Overview: After attending this presentation, attendees will be able to: (1) define and describe the role of mentorship in medicine in attracting interest in specialty training; (2) describe the state of forensic pathology in the Caribbean and how it can be improved through mentorship; and (3) describe a Caribbean medical student-led initiative that facilitates student mentorship by forensic pathologists.

Impact Statement: This presentation will impact the forensic science community by creating an awareness of the landscape of forensic pathology in the Caribbean as being a largely underrepresented and unrecognized field.

Over the past few decades, there has been an increase in autopsy cases with an inversely proportional forensic pathology workforce within the Caribbean region. Some Caribbean islands have no qualified forensic pathologists to perform medicolegal postmortem examinations, which results in these examinations being performed by the few anatomical pathologists in existence, inclusive of homicides and criminally suspicious deaths. This is not ideal and can lead to errors of interpretation and the potential for miscarriages of justice. The implications of this shortage run the gamut, leading to a backlog of cases, overworked forensic pathologists, delayed legal proceedings, freeing of the accused, distress to family members, an increased incidence of “inconclusive” findings, and overall poor quality of practice.^{1,2}

Several factors account for this shortage inclusive of inadequate exposure to pathology and its subspecialties (such as forensic pathology) in the medical curriculum, misconceptions about the field, a lack of mentorship, the “introvert” personality stereotypes, and the imbalance between the reality of the fields versus the public perception as portrayed on television and in the media.³⁻⁶

Reform in the modern undergraduate medical curriculum has led to a focus on patient-centered approaches that have replaced the traditional subject-based curriculum. Limited pathology courses are therefore spread throughout the preclinical and paraclinical years, which facilitates minimal to no interaction with pathology and pathologists in clinical years and a lack of exposure to surgical pathology and the autopsy with a resultant reduced understanding of and disinterest in pathology.^{7,8}

Within the University of the West Indies, exposure to forensic pathology is limited to observership of autopsies over four days during an anatomical pathology clerkship; with an average of 12 hours of exposure. A forensic pathologist is not guaranteed to be present and either an anatomical pathologist or house officer (post-internship junior doctor) provides instruction to medical students. These factors negatively impact proper exposure to forensic pathology and anatomical pathology and contribute to medical graduates considering careers in the more traditional specialties.

It is well known that the implementation of forensic pathology mentorship programs in medical schools will provide role models and career guidance to address these issues.⁴ Additionally, involvement in a pathology interest group has been associated with medical students who chose a career in pathology.⁹

A survey conducted by the National Association of Medical Examiners' (NAME) Forensic Pathology Training Committee also found that the influence of a professor or mentor and exposure to the field in residency training were the most significant factors that influenced its members to pursue a career in forensic pathology.¹⁰ Mentorship is therefore integral in influencing the choice of career. However, there is a lack of mentoring programs in medical schools in several countries, including throughout the Caribbean.^{11,12}

Conclusion: The Pathology Club of the University of the West Indies was established in August 2020 together with an aligned mentorship initiative, the Caribbean Pathology and Laboratory Medicine Student Initiative (CPALMSI), supported by the Department of Pathology and Laboratory Medicine of the University of Ottawa, where there is a well-established and respected forensic pathology unit. This initiative has served to increase interest in pathology and provide mentorship and career guidance for Caribbean medical students.¹³ Expansion of mentorship initiatives such as the CPALMSI is required to address the shortage of forensic pathologists in the long term.

Forensic Pathology, Caribbean, Mentorship

H40 The Utilization of Blood Smears and Flow Cytometry to Diagnosis Hematologic Malignancies and Triage Cases for Autopsy

Jolee Suddock, DO, Office of the Medical Investigator, Albuquerque, NM; Molly Biggs, BS, University of New Mexico, Albuquerque, NM; Daniel Babu, MD, University of New Mexico, Albuquerque, NM; Clarissa Krinsky, MD, Office of the Medical Investigator, Albuquerque, NM*

Learning Overview: After attending this presentation, attendees will have a better understanding of when to consider undiagnosed hematologic malignancies at autopsy, as well as how to collect blood and bone marrow, prepare smears, and utilize flow cytometry in the postmortem setting.

Impact Statement: This presentation will impact the forensic science community by proposing a protocol for the workup of suspected hematologic malignancies based on a case in which its use was successful. The aim is to improve diagnostic accuracy and aid in triaging autopsy cases.

Neoplasms presenting as unexpected death at autopsy are rare; however, hematologic malignancies have been reported as one of the most common causes.¹ Leukemic processes also often do not form discrete masses, unlike large mass-forming malignancies that can be more readily identified at autopsy or on postmortem imaging. Diagnosis relies upon the examiner's consideration at the time of autopsy. A number of case reports discuss the diagnosis of leukemia and lymphoma at autopsy; however, these diagnoses were primarily made by histologic examination of multiple organs or with the use of an extensive panel of immunohistochemical stains.^{2,3} Flow cytometry has been utilized in forensic medicine in various ways; however, its use in the postmortem diagnosis of leukemia has not been well-established.⁴

In addition to diagnosis, utilization of blood smears and flow cytometry may aid in triaging autopsy cases. If the diagnosis can be accurately made using externally collected blood, a full autopsy may not be necessary. This is of particular benefit to offices that serve cultural and religious groups who request minimally invasive postmortem examinations.

This study presents a case of a 12-year-old girl who died at home. She had malaise, heavy menstruation, epistaxis, and fatigue in the days before her death. Externally she was markedly pale. Medical care was not pursued due to the religious beliefs of the family, and a minimally invasive examination was requested. This prompted the consideration of external examination with collection and evaluation of blood and bone marrow. Utilizing a large-bore needle, bone marrow was aspirated from the iliac crest and heart blood was collected. Smears were prepared on glass slides, allowed to air dry, and stained with Wright-Giemsa. Blood and marrow smears revealed numerous immature cells, prompting hematopathology consultation. Flow cytometry of collected blood identified blasts consistent with B-lymphoblastic leukemia. A full autopsy was completed after discussion with the family, and a lymph node was collected and was also found by flow cytometry to be involved by leukemia.

This case highlights that externally collected blood and bone marrow, with the use of flow cytometry, can aid in cause of death determination and may be used to triage select autopsies. Challenges to establishing protocol for the postmortem workup of hematologic malignancies include the viability of samples, the availability of staining kits and slides, and an association with a laboratory that performs flow cytometry. Future directions include establishing an optimal time frame for viability and evaluating the cost-effectiveness compared to traditional diagnostic methods.

Leukemia, Autopsy, Triage

H41 Histological and Immunofluorescent Imaging of Infant Bridging Veins

Student Neil Harris, MSc, East Midlands Forensic Pathology Unit, University of Leicester, Leicester, Leicestershire, United Kingdom; Emma Cheshire, MS, East Midlands Forensic Pathology Unit, University of Leicester, Leicester, Leicestershire, United Kingdom; Guy Rutt, MD, East Midlands Forensic Pathology Unit, University of Leicester, Leicester, Leicestershire, United Kingdom; Roger Malcomson, PhD, Histopathology Department, Leicester Royal Infirmary, Leicester, Leicestershire, United Kingdom*

Learning Overview: After attending this presentation, attendees will better understand bridging vein microanatomy.

Impact Statement: The diagnosis of Abusive Head Trauma (AHT) can be extremely challenging, with past controversies surrounding the mechanism of injury and the source of subdural bleeding. This presentation aims to provide novel micro-structural information on infant bridging veins from both head injured and non-head injured children to enable sample comparisons and to investigate potential markers of traumatic damage. Ultimately, this study hopes to provide a reliable and easily applicable diagnostic tool to forensic and pediatric pathologists, for the sensitive detection of damaged bridging veins in AHT cases.

Background: Damaged bridging veins are generally accepted by the majority of medical professionals as the source of Subdural Hemorrhage (SDH) in infants that have been subjected to AHT. However, damaged bridging veins can be difficult to visualize during postmortem examinations and on medical imaging such as magnetic resonance and computed tomography. There is also a paucity of information on the typical microanatomy of bridging veins, particularly in the infant population. When observed and photographed during postmortem examinations, some infant bridging veins are very small and extremely delicate.

Since 2013, the East Midlands Forensic Pathology Unit has developed and utilized a novel method for removing the infant calvarium using neurosurgical equipment. This technique leaves the underlying dura mater intact, enabling careful reflection of this membrane to visualize and dissect bridging veins. The Unit has also developed dissection methods using approximator clamps to extract bridging veins with minimized artifactual damage. These techniques have enabled the current microscopy study, detailing the typical microanatomy of infant bridging veins.

Methods: This study used histological, immunohistochemical, and immunofluorescent techniques to detail the typical microanatomy of infant bridging veins, retained with appropriate consent, during non-forensic postmortem examinations. Using specific markers (CD31 and smooth muscle actin), histological stains (Hematoxylin-Eosin [H&E], Masson's trichrome, and elastic Van Gieson's) and auto-fluorescent signals, this study documents the micro-structure of these vessels using light and fluorescent microscopy.

Preliminary Results: Preliminary results suggest that an infant bridging vein is composed of an endothelial lining, which is in close contact to a thin smooth muscle layer. Collagen bundles, surrounding the smooth muscle cells, are the main component of the bridging vein wall. Small amounts of elastin fibers are also noted within the bundles of collagen.

Conclusion: These insights into the typical structure of infant bridging veins will enable future comparisons between blood vessels retained from both AHT and non-AHT cases. It is hoped that these anatomical comparisons will enable the detection of trauma to infant bridging veins.

Bridging Veins, Head Injury, Pediatric

H42 Improving the Postmortem Examination Process Using Complete Body Radiographic Imaging

Clayton Carter, BS, Homer Stryker School of Medicine, Kalamazoo, MI; Jered Cornelison, PhD, Homer Stryker School of Medicine, Kalamazoo, MI; Christine Pink, PhD, Homer Stryker School of Medicine, Kalamazoo, MI; Joyce DeJong, DO, Homer Stryker School of Medicine, Kalamazoo, MI; Joseph Prahlow, MD, Homer Stryker School of Medicine, Kalamazoo, MI*

Learning Overview: After attending this presentation, attendees will have a better understanding of the value, benefits, and efficiency of a whole body imaging system as it pertains to radiologic casework in a medical examiner's office, with special emphasis on foreign body localization, skeletal trauma, and scientific identification of remains. Attendees will also be exposed to a variety of other scenarios and circumstances where whole body imaging provides valuable information, including information vital to the safety of morgue personnel.

Impact Statement: This presentation will impact the forensic science community by highlighting the many benefits of incorporating a whole body imaging system into a medical examiner's office.

For forensic pathologists, there are many tools available to assist with postmortem examinations. An extremely important tool involves the use of medical imaging technologies. Radiologic findings can be invaluable to the forensic pathologist by providing a tool for radiographic identification, revealing foreign bodies, and uncovering significant pathology. Forensic radiology can be traced back to 1898, beginning with plain films used to localize projectiles. Since then, imaging use has dramatically expanded. Radiography can be used to identify subtle fractures, locate foreign bodies, estimate the biological age of individuals, and help determine the ages of various bony injuries. The uses of imaging modalities have expanded, encompassing not only plain films, but also fluoroscopy and Computed Tomography (CT) scanning.

A relatively recent innovation is the complete body radiographic imaging device. The institution of this study, which is a regional medical examiner's office, obtains at least one full-body scanned image for every case, whether a full autopsy, limited autopsy, or external exam. The scanner is capable of providing a complete body radiographic scan and can perform a complete scan in 13 seconds.

Thus, the scanner can provide a complete, uninterrupted view of the full body, allowing for greater ease of examination and tremendous time-saving. If necessary, multiple scans, including regional and anterior-posterior and lateral views, can be taken to aid in the postmortem investigation. Forensic anthropologists at institutions are responsible for ensuring scientific identification when warranted. The complete body scans are of great value when scientific identification is based on comparative medical radiography.

Several complete body imaging cases will be presented that informed or enhanced the postmortem examination. In addition to providing case examples where complete body imaging has provided excellent and efficient information and necessary documentation for cases, additional examples will be presented that highlight other interesting and sometimes extremely valuable and beneficial information afforded by complete body imaging.

Complete Body Imaging, Complete Body Scans, Radiography

H43 Iatrogenic Changes Related to Perimortem Cardiopulmonary Resuscitation (CPR) as Documented by Postmortem Computed Tomography (CT) Scanning

Aneesa Baig, MSc, Queen Mary University of London, London, England, United Kingdom; Curtis Edward Offiah, MD, Queen Mary University of London, London, England, United Kingdom; Nikolas Petros Lemos, PhD, Queen Mary University of London, London, England, United Kingdom*

Learning Overview: Attendees can expect to learn how to determine which findings may be due to resuscitation-related injury as visualized on postmortem radiological imaging. Attendees will also learn the definition of iatrogenic injury and distinguish this from natural postmortem insults using Postmortem CT (PMCT) scanning. In addition, attendees will learn the intricacies found with postmortem imaging as compared with traditional autopsy, as well as the factors that may cause variations in depth and severity of such injury.

Impact Statement: This presentation will impact the forensic science community by demonstrating the power of forensic radiology as an aid for the accurate determination of cause of death. The community will also be exposed to natural postmortem changes and be allowed to visually compare those to Cardiopulmonary Resuscitation (CPR) -related injuries.

Although known as a “life-saving” procedure,” forensic pathologists can often find CPR-related injuries that may or may not be related to the primary cause of death. Injuries sustained during perimortem CPR are inevitable due to its intensive nature. With many cases involving resuscitation resulting in death, this study undertook an investigation that aimed to define iatrogenic changes caused by resuscitation methods. Injuries as a result of CPR are commonly encountered at autopsy, but often are found incidentally. When encountering such injuries, care must be taken to define those caused iatrogenically, as similar injuries can be produced for patients with non-accidental injury or even systemic disease. This study inspected PMCT scans from London cases that had been subjected to perimortem CPR. CT imaging is a minimally invasive investigative technique that requires little to no manipulation of the body. Compared with traditional autopsy, the images produced from PMCT imaging can be easily retained and stored, as well as acting as a powerful evidence tool in medicolegal proceedings. Addressing the fundamental concepts of CPR and establishing the injuries that occur from its improper implementation is explored in this study due to the fact that correctly performing CPR can often minimize the severity of injury occurring during resuscitation. This work further helps distinguish between injuries induced from resuscitation compared to those caused by other severe insults, such as abuse or assault.

There have been, however, numerous studies that report the high efficacy of PMCT imaging, and its successful results in determining the causation of death are consistent with the findings of conventional autopsies, thus casting doubt about the need of PMCT analysis. This work offers an understanding of the injuries sustained from resuscitation techniques based on PMCT analysis and discusses the possibility of the injury contributing to the causation of death of an individual.

Iatrogenic Changes, Postmortem CT Scan, Cardiopulmonary Resuscitation (CPR)

H44 Keeping Up With the Drug/Opioid Epidemic: In-House Testing Program of the King County, Washington, Medical Examiner's Office

Jordan Taylor, MD, King County Medical Examiner Office, Seattle, WA; Richard Harruff, MD, PhD, King County Medical Examiner Office, Seattle, WA; Nicole Yarid, MD, King County Medical Examiner Office, Seattle, WA; Katie Heidere, MSW, King County Medical Examiner Office, Seattle, WA; Celia Simpson, King County Medical Examiner Office, Seattle, WA*

Learning Overview: After attending this presentation, attendees will be able to explain how a medical examiner office can implement in-house testing for drug overdose deaths to expedite death certification and provide timely, useful data to public health and law enforcement agencies.

Impact Statement: This presentation will impact the forensic science community by showing how medical examiners can serve their communities through implementing in-house testing for drug overdose deaths.

The rapid emergence of the drug/opioid overdose epidemic in Washington overwhelmed resources, resulting in extreme delays in receiving toxicology reports. These delays interfered with timely death certification, data collection by epidemiologists, and information provided to law enforcement agencies. As a countermeasure, King County Medical Examiner's Office (KCMEO) initiated "real-time fatal drug overdose surveillance." This presentation reviews the first three full years (2018–2020) of the project.

KCMEO dedicated one medicolegal death investigator, two college student interns, and one statewide Information Coordinator for fatal drug overdose surveillance. KCMEO investigators collected drug evidence at suspected drug overdose death scenes, and KCMEO pathologists selected decedents for in-house testing. Urine from autopsy was tested with a One Step Detect Multi-Panel Forensic test cup, a colorimetric immunoassay dipstick panel of 14 drugs, and a Rapid Response fentanyl test strip. Field portable spectrometers, including Thermo Scientific™ TruNarc™, Rigaku ResQ, and 908 Devices MX908, were used to test drug evidence collected at the scene, and a chemiluminescent immunoanalyzer, Randox® MultiSTAT, was used to screen decedents' blood for 21 analytes. Deaths due to drug overdose were certified based on finding the same drug(s) present in two independent tests, including one from the decedent. Follow-up information was elicited from cooperative family members, and data were provided to law enforcement and public health agencies. All drug deaths certified by this methodology were validated through formal toxicology analysis, and results of drug evidence testing were confirmed by bench laboratory analysis. Data were entered into a Microsoft® Access® database, subsequently migrated to Microsoft® SQL Server linked to the main KCMEO VertiQ database, and analyzed using Microsoft® Excel®.

Over three years, 1,385 drug overdose deaths were certified, 1,092 decedents' blood samples were screened, 1,061 urine samples were tested, and 2,789 tests were performed on drug evidence items from 670 different cases. Drug overdose death certificates were often completed within one day. Overall, the average delay between autopsy and certification of drug overdose deaths decreased from 75 to 31 days. The proportion of all autopsy reports completed in 60 days increased from 55% to 72% and in 90 days increased from 77% to 99%. A collaborative network of local, state, and federal law enforcement and public health agencies was established, and weekly and monthly bulletins were published. To date, 25 of the 39 Washington counties participate in the surveillance project.

Although deaths due to drug overdose continue to accelerate, KCMEO became an active participant in controlling the epidemic by providing timely and usable intelligence informing and evaluating response efforts through this program. The fatal drug overdose surveillance program developed into a collaboration between public health and law enforcement agencies. As the drug/opioid overdose epidemic has been declared a "public health emergency," it is appropriate that medical examiners feel compelled to participate in combating the epidemic. The experience of KCMEO validates such efforts and serves as a model for other offices.

Drug Overdose Surveillance, Postmortem Toxicology, In-House Drug Evidence Testing

H45 An Internal Validation of the ANDE® 6C Expert System for the Analysis of Unidentified Human Remains in a Forensic Laboratory Setting

Mariel Candelario-Gorbea, MS, Puerto Rico Institute of Forensic Sciences, San Juan, PR; Fabiola Fernández-Padín, MS, Puerto Rico Institute of Forensic Sciences, San Juan, PR; Carmen Tirado-Neris, Puerto Rico Institute of Forensic Sciences, San Juan, Puerto Rico*

Learning Overview: Attendees can expect to see the results of the internal validation on Rapid DNA identification performed on several tissue types, including blood, muscle, liver, hair, tooth, and bone samples for the implementation of Rapid DNA as a viable technology for the analysis of Unidentified Human Remains (UHRs) in a forensic laboratory setting.

Impact Statement: The use of a Rapid DNA instrument for the analysis of evidentiary forensic casework samples, with or without human intervention, is not an approved use of this technology at this time. This presentation seeks to help those forensic laboratories that assist a medicolegal client in the identification of unidentified human remains, see the benefits of using this technology for these purposes in an accredited laboratory setting, and explore the possibility of analyzing other types of samples as well.

The Rapid DNA Act (H.R. 510) became United States federal law on August 18, 2017. The approval of this law permits criminal justice agencies and forensic science providers to use Rapid DNA instruments approved by the Director of the Federal Bureau of Investigation for their use in the testing of reference samples without human intervention at police booking stations or in an accredited laboratory setting. However, the use of a Rapid DNA instrument for the analysis of evidentiary forensic casework samples, with or without human intervention, is not an approved use of this technology at this time.

The Forensic DNA-Serology Laboratory of the Puerto Rico Institute of Forensic Sciences (PRIFS) is the only forensic laboratory in Puerto Rico to analyze all forensic cases such as homicides, sexual assaults, and more. Part of the services offered by this laboratory is the identification of UHRs requested by the Medical-Legal Division. These identification cases can take up to 60% of the analyst's time, which could otherwise be used to solve other crimes. The objective of this study was the internal validation of the ANDE™ 6C Expert System for a Modified Rapid DNA Analysis of UHR samples using the I-Chip (Part number A0210001060) designed for forensic samples.

The ANDE™ System consists of automated purification, amplification, separation, detection, allele calling, and Expert System interpretation. The use of a Rapid instrument for identification cases will allow the PRIFS to analyze UHRs and their reference samples in an expedited manner. UHRs not identified or with unacceptable results would later be analyzed using conventional DNA methods and technologies for Combined DNA Index System (CODIS) upload. A total of 114 blood, liver, muscle, buccal, hair, tooth, and fresh and degraded bone samples were analyzed to assess the suitability of the ANDE™ 6C System for use with I-Chips and human intervention as Modified Rapid DNA. Internal validation studies included sensitivity, accuracy/concordance, reproducibility, sample-to-sample contamination, 1:1 and 1:5 mixtures, mock samples, and a certified reference material, focusing on viability for use in the identification UHRs. All samples were run in duplicate for reproducibility. Sensitivity studies included 1µL, 5µL, 10µL, 20µL, 40µL, and 80µL of blood, and blood dilutions of 1:1, 1:4, 1:10 1:20, and 1:100.

The ANDE™ 6C Expert System Disabled Setting with 12 passing autosomal was used, which identifies samples with low DNA and applies a less conservative calling algorithm, allowing one to use and evaluate more data generated by the instrument.

Reproducibility of results averaged at 96% with loci designated as passing loci. Loci designated as not pass was due mostly to complete loci dropout; 99.66% of alleles in passing loci were determined to be true alleles. Dropout of sister alleles in true heterozygote loci was observed in 1.33% of the samples. This phenomenon occurred in loci with less than 6,000 Relative Fluorescence Units (RFU). Thus, 98.67% of homozygote alleles below 6,000 RFU can confidently be considered homozygote alleles. In contrast, 52 out of 149 (35%) heterozygote and Y-chromosome loci deemed as “not passing” demonstrated concordance with reference sample. These internal validation results led to the approval of the ANDE™ 6C Instrument together with the single-use I-Chip consumable performing the FlexPlex™ assay for the analysis of UHR samples in the PRIFS.

Rapid DNA, Unidentified Human Remains, Forensic Laboratory

H46 Forensic Photography—An Invaluable Tool During Forensic Autopsies

Rachael Landrie, BS, Office of the Chief Medical Examiner, Washington, DC*

Learning Overview: After attending this presentation, attendees will learn the process of photo documentation during forensic autopsies as well as how to stage the body and organs in order to capture high-quality forensic images and achieve favorably presentable photographs.

Impact Statement: This presentation will impact the forensic science community by demonstrating invaluable processes regarding forensic photography that can be utilized during forensic autopsies.

A forensic autopsy is performed in a medical examiners or coroner's office and, typically, the autopsy is documented by the forensic pathologist by a written report. The external exam involves documenting the body for any scars, trauma, or disease, as well as identifying features such as hair color and length, tattoos, eye color, etc. Internally, the organs are evaluated for trauma and disease. These findings as well as toxicology and histology are used by the forensic pathologist to determine cause and manner of death and are included in the final autopsy report. Photographs taken at the time of autopsy can serve to further document important and pertinent findings visually.

Frequently, forensic photography is used to provide detailed, visual documentation of forensic investigations, including crime scenes and physical evidence not limited to fingerprints, shoe mark impressions, and shell casings for legal purposes; however, forensic photography can also play an important role in visually recording the body during a forensic autopsy. The body is physical evidence. Photo documentation provides a visual explanation of what is documented in the autopsy report, which may be difficult to describe verbally. As a result, forensic pathologists can review these photos to support their autopsy report and recall detailed information about the case if called to testify in a court of law. Other uses allow for forensic pathology teaching, consultations, and, importantly for attorneys, to present as evidence during court trial proceedings.

With advances in digital technology, capabilities of forensic photography have increased exponentially. Digital photography equipment is more user friendly and affordable, photographic supplies are readily available, and digital photographs are easy to store and display. Through mindful attention to decedent and organ preparation, composition, and basic camera/lighting settings, forensic autopsy photos can be achievable accurately and quickly. Current methods in the use of digital equipment and supplies, basic autopsy photography flow, and examples of acceptable versus unacceptable photographs will be presented to support the significance of photography in the forensic community.

Autopsy, Photography, Pathology

H47 The Logic of Forensic Pathology Opinion

Hans de Boer, MD, PhD, Victorian Institute of Forensic Medicine, Southbank, VIC, Australia and Department of Forensic Medicine, Monash University, Southbank, VIC, Australia; Judith Fronczek, MD, PhD, Victorian Institute of Forensic Medicine, Southbank, VIC, Australia and Department of Forensic Medicine, Monash University, Southbank, VIC, Australia; Charles Berger, PhD, Netherlands Forensic Institute, The Hague, Zuid-Holland, Netherlands and Institute of Criminal Law and Criminology, Leiden University, Leiden, Zuid-Holland, Netherlands; Marjan Sjerps, PhD, Netherlands Forensic Institute, The Hague, Zuid-Holland, Netherlands and Korteweg-de Vries Institute for Mathematics, University of Amsterdam, Amsterdam, Zuid-Holland, Netherlands*

Learning Overview: After attending this presentation, attendees will have a better understanding of how Bayes' theorem can help forensic pathologists provide logically sound and transparent evidence, while staying within their areas of expertise.

Impact Statement: This presentation will impact the forensic science community by discussing the benefits of applying Bayes' theorem and providing advice on how to apply it in forensic pathology.

Evaluating evidence, and providing opinions based on evidence, are subjects of ongoing importance within all forensic sciences. Among others, forensic experts are expected to provide evidence that is based on logically sound and transparent scientific reasoning that honors the boundaries of their area of expertise. In order to meet these objectives, many fields of forensic science explicitly use Bayes' theorem when expressing their opinion. This theorem describes the logically correct way to update probabilities on the basis of observations and is therefore well-suited for forensic evidence interpretation. The benefits are numerous. Among others, it helps expert to stay within their remit, increases the relevance and specificity of the expert opinion, and provides clarity about the roles of the expert and the trier-of-fact.

Making a distinction between "investigative" and "evaluative" modes of operating helps to implement the theorem into daily casework. The distinction between the two recognizes that the amount of information that is available to experts changes over time, and that this affects their roles and the type of statements they can make.

Despite these developments in other fields of forensic science, forensic pathology seems slow to adopt these principles. As a consequence, the majority of forensic pathology reports currently do not meet the objectives stated above. This presentation explores this issue further and suggests a way forward.

This presentation starts with a short introduction into Bayes' theorem and its benefits, followed by a discussion of why its application is actually second nature to medical practitioners. It then discusses the difference between investigative and evaluative opinions, and how they enable the forensic pathologist to apply Bayes' theorem in the different phases of a forensic investigation. Several practical examples will be used to support this presentation.

The overarching aim of this contribution is to advance the implementation of logically correct reasoning and reporting in forensic pathology.

Forensic Pathology, Evidence Interpretation, Likelihood Ratio

H48 Work-Related Fatal Injuries in the Genoa District of Northwest Italy: A Forensic Analysis of the 2011–2020 Decade

Giulia Molinari, MD, Department of Legal and Forensic Medicine, University of Genoa, Genoa, Italy; Martina Drommi, MD, Department of Legal and Forensic Medicine, University of Genoa, Genoa, Italy; Valentina Calamano, MD, Department of Legal and Forensic Medicine, University of Genoa, Genoa, Italy; Rosario Barranco, MD, Department of Legal and Forensic Medicine, University of Genoa, Genoa, Italy; Stefano Errico, MD, Department of Legal and Forensic Medicine, University of Genoa, Genoa, Italy; Francesco Ventura, MD, PhD, Department of Legal and Forensic Medicine, University of Genoa, Genoa, Italy*

Learning Overview: After attending this presentation, attendees will have learned about the occupational-related deaths; a worldwide increasing problem with severe social repercussions. In particular, this presentation aims to bring the attention of the forensic science community to the relevance of deaths that occurred in the workplace and were forensically investigated at the Institute of Forensic Medicine of Genoa from 2011 to 2020.

Impact Statement: This presentation will impact the forensic science community by underlying the aim of providing a forensic and medical-legal framework of fatal accidents during work.

According to the International Labor Organization, an occupational accident is an incident that occurs in the course of work and results in a fatal or non-fatal injury. In the Italian scenario, the first cause of fatal accidents at work includes road accidents, crushing and falls from above, followed by other causes in smaller numbers, including burns, electrocution, suffocation and asphyxiation, drowning, and explosions.

In Italy, the sectors most affected are industry and agriculture, while the prevailing sex is male: in particular for fatal accidents, men are affected ten times more often than women, for a total of 4,197 cases, including 273 deaths. In recent years, the social phenomenon of immigration has also taken on an increasing importance in the field of accidents at work; there is, in fact, an increasing presence of foreign workers in the Italian labor markets, especially the strictly manual labor market, and their increasing involvement in accidents.

The data analyzed for each death shall include the nationality and sex of the worker, the employment performed at the time of death, the year in which the fatal event occurred, the time slot, the day of the week and the month in which the event occurred, the use of personal protective equipment, any medical treatment carried out on the subject (from immediate resuscitation procedures to subsequent hospitalization), the cause of death and the prevalent injuries and, finally, the results of toxicological tests.

This study includes a list of 47 people that have died because of an occupational injury: 46 males and only 1 female. The construction worker/metalworker was the most exposed to fatal accidents (40.5%). In 41 cases (87.2%), the death was related to a major mechanical trauma secondary to precipitation (42.5%), falling objects directly on the body of the victim (38.3%), or pedestrian road investment (6.4%). A fatal head trauma with endocranial hemorrhage occurred in 23 cases (63.4%). In 4 out of 47 cases (8.5%), death was due to a violent asphyxiation mechanism, of which 3 were drowning and 1 was accidental hanging. Finally, the last 2 deaths were caused by an electrocution mechanism.

In conclusion, fatal accidents at work almost exclusively affected men, consistent with national and international cases. However, men are also employed in more dangerous and tiring work tasks, with a higher risk of accident and death, while women are more obedient to safety rules. The work of a construction worker/metalworker remains the one with the greatest risk of accidents at work: often, in fact, they are precarious occupations, carried out by subjects employed in part-time or temporary and contract positions, with rights and safeguards much more limited than those held by the majority of the employed population, despite the high occupational risks.

Moreover, this study highlights the importance of the fact that, although high-income countries, thanks to surveillance, reporting, and survey methods and the changing of legislation over the years, have achieved a reduction in deaths at work, the number of fatal accidents in construction, industry, and shipbuilding remains high.

Work Accident, Fatal Injury, Mechanical Trauma

H49 Diving Accidents and Related Deaths in the Genoa District of Northwest Italy: A Forensic Analysis of the Period From 1968 to 2020

Arianna Balbo, MD, Department of Legal and Forensic Medicine, University of Genoa, Genoa, Italy; Martina Drommi, MD, Department of Legal and Forensic Medicine, University of Genoa, Genoa, Italy; Filippo Spigno, MD, Department of Legal and Forensic Medicine, University of Genoa, Genoa, Italy; Francesca Frigiolini, MD, Department of Legal and Forensic Medicine, University of Genoa, Genoa, Italy; Rosario Barranco, MD, Department of Legal and Forensic Medicine, University of Genoa, Genoa, Italy; Francesco Ventura, MD, PhD, Department of Legal and Forensic Medicine, University of Genoa, Genoa, Italy*

Learning Overview: After attending this presentation, attendees will have learned important aspects about the causes of death resulting from scuba diving accidents during the past 52 years in the City and Province of Genoa (1968–2020). In particular, this presentation will aim to bring the attention of the forensic science community to the relevance of increased fatal accidents brought about by the introduction of easy-to-use scuba diving equipment and the consequent widespread increase of scuba diving activity in the Genoa area.

Impact Statement: The presentation will seek to impact the forensic science community by emphasizing the description of the forensic medical approach in fatal diving accidents based on analyzing the characteristics of the population involved, the circumstantial data, and the outcomes of the investigations performed.

The Province of Genoa, having a mainly rocky coastline, attracts many seashore tourists of many different nationalities. Scuba diving is divided into recreational and technical diving, depending on the time, depth, and breathing mixtures used (pure oxygen, nitrox, trimix). According to literature, most deaths during diving activities are caused by drowning; however, the primary cause of death is different.

The present study included 48 subjects who died because of scuba diving accidents; 44 males and 4 females. All subjects underwent autopsy examination and histological investigations, toxicological screening, and equipment analysis, as applicable. Also analyzed were the characteristics of the population, the circumstances of the event, and the data from the investigations. In 34 subjects, the type of diving was known: 16 recreational and 18 technical.

Regarding the breathing mixture used, 22 subjects used compressed air breathing apparatus, 4 nitrox, 3 pure oxygen, 3 trimix with Enriched Air Nitrox (EAN), 1 trimix, and 1 air with nitrox. Seven subjects were using rebreathers. The dive period, in which the diving accident occurred, is known only in 26 cases: 10 during the descent, 14 during the ascent, and 2 post-dive.

Of the 48 analyzed incidents, 7 were attributed to technical factors and 3 to human error. The histological study showed in 26 subjects predisposing pathological factors; mainly cardiovascular. The most common pathological findings were: polyvisceral congestion (83.3%), pulmonary edema (77.1%), pulmonary emphysema (72.9%), “foamy fungus” (47.9%), rupture of the interalveolar septa (45.9%), conjunctival petechiae (45.9%), and subpleural petechiae (33.3%). In 12 diving-related fatalities (25%), the identified cause of death was exclusively drowning, whereas in the other subjects the primary causes of death were identified in: Arterial Gas Embolism (AGE) following pulmonary barotrauma (27.1%), cardiocirculatory arrest due to heart attack (16.7%) or other causes (8.3%), confined space asphyxia (12.5%), gas intoxication (4.1%), Decompression Illness (DCI) (4.1%), and AGE and DCI combined mechanism (2.1%).

The analysis of the data showed that, in less recent cases, the cause of death was attributable to mechanical asphyxia secondary to drowning. Later, thanks to the improvement of diagnostic techniques and knowledge in the field of diving medicine, according to literature, it was possible to determine the specific primary cause of the diving accident.

In conclusion, from data obtained, fatal accidents could be limited by more accurate medical controls and the introduction of periodic refresher courses. Moreover, this study highlights the importance of the role of medical examiner to clarify the circumstances of death and to allow the continuous increase of safety in the practice of this activity, expanding the knowledge in the field of diving medicine.

Scuba Diving, Fatal Accident, Drowning

H50 An Unusual Gunshot Wound Suicide With Findings Mimicking a Second Entrance Wound

Harrison Moosavi, MD*, Georgia Bureau of Investigation, Decatur, GA, and Augusta, University–Medical College of Georgia, Augusta, GA; Andrew Koopmeiners, MD, Georgia Bureau of Investigation, Decatur, GA

Learning Overview: After attending this presentation, attendees will have a better understanding of the importance of correlating scene findings, investigative details, and autopsy findings for proper interpretation and certification of suicidal gunshot wounds.

Impact Statement: This case will demonstrate an unusual method of suicide by using handguns simultaneously to inflict gunshot wounds of the head, with only one firearm successfully firing, but two wounds being present.

Suicide is the tenth leading cause of death in the United States. In 2019, 50.4% of the 47,511 suicides in the United States involved firearms.¹

The presented case is of a woman who committed suicide by simultaneously holding two handguns against opposite sides of her head.

A 53-year-old woman was found supine in her bed with a .380 semi-automatic handgun in her right hand and 9mm semi-automatic handgun between her left arm and left side of her chest. One spent .380 shell casing was located at the scene. Two unspent 9mm rounds were found on the floor near the bed. Both weapons had multiple unspent rounds in their magazines. Both weapons contained tissue, blood, and head hair on the ends of the barrels.

At autopsy, a contact gunshot wound was identified on the right temple with an associated abrasion consistent with a muzzle imprint, with a bullet track passing through the skull and brain with no associated exit wound. There was a laceration of the left temple with an associated patterned abrasion consistent with a muzzle impression; however, there was no gunshot wound associated with this defect. Per scene photography and investigative information, it was revealed that only the .380 handgun discharged. The cause of death was a gunshot wound of the head.

Suicides involving the use of multiple firearms are uncommon, but not unheard of. Review of the literature and case reports involving multiple firearm suicides usually involve simultaneous gunshots to the head and chest, or head and abdomen.^{2,3} Additional cases of multiple gunshot wound suicides involve defective firearms in which the initial gunshot was insufficient to cause death or incapacitation and subsequent gunshots were fired.⁴ Only one other similar case from 2019 involving simultaneous attempted gunshot wounds of the head with only one firearm successfully discharging was reviewed.⁵ This case represents an unusual circumstance in which the laceration and associated abrasion caused by the head striking the barrel of an unfired handgun mimics a second entrance wound.

This case highlights the importance of correlating scene findings, investigative details, and autopsy findings to allow for proper interpretation and certification of suicidal gunshot wounds.

H51 A Study on the Suicide Statistics Using Sodium Nitrite in Korea Over the Past 10 Years (2011–2020) and on the Identification Method of Sodium Nitrite Using Coloration Reaction Reagents at the Unnatural Death Scene

Jin Yeong Kim, MD, Korea National Police Agency, Seoul, Korea*

WITHDRAWN

H52 A Tale of Two Suicides—Gunshot Wounds to the Occiput

Jiemin Zhou, MD, Office of the Chief Medical Examiner, Baltimore, MD; Zabiullah Ali, MD, Office of the Chief Medical Examiner, Baltimore, MD; Stephanie Dean, MD, Office of the Chief Medical Examiner, Baltimore, MD; J. Laron Locke, MD, Office of the Chief Medical Examiner, Baltimore, MD*

Learning Overview: The goal of this presentation is to alert attendees to not presume manner of death from atypical gunshot wounds of entrance.

Impact Statement: This presentation will impact the forensic science community by highlighting two cases involving self-inflicted gunshot wounds to the back of the head.

Case 1: This 28-year-old man was found prone in the water of the Patapsco River in central Maryland. He had originally texted his girlfriend stating he had a flat tire. The girlfriend then went to the incident location, found the decedent, and alerted emergency services. At the scene, a Glock® 26 was found in the river next to the decedent's head. His truck was in the parking lot with a flat tire. An empty gun holster was attached to the front dashboard. Additionally, the truck appeared ransacked with a wallet on the ground with missing money. A bullet hole was also noted in the tailgate. Against the truck were a spare tire, tire jack, and tire iron.

Autopsy revealed a single contact gunshot wound to the back of the head near the parietal-occipital region. Soot was found on the scalp, subgaleal surface, and underlying bone. An exit wound was located on the left side of the forehead with recovery of projectile fragments along the wound path. Postmortem toxicology testing of the heart blood was positive for alcohol (0.17% w/v).

Further investigation revealed the decedent had a history of drug and alcohol abuse. He had a recent argument with his girlfriend in which he later sent a vague, cryptic text-message to her. The decedent also complained of career-related difficulties. There were no signs of a struggle; nothing was stolen from the decedent; and no other tire tracks were in the parking lot. Based on investigation, the manner of death was ruled a suicide.

Case 2: This 76-year-old man was found rolling in the surf line at Ocean City, MD, when he was then brought ashore. A Ruger® belonging to the decedent was located a short distance away days later by a person searching for metal with metal detector on the beach.

Autopsy revealed a single gunshot entrance wound to the right occipital scalp with gunpowder stippling extending up to ½" from the entrance wound. The bullet did not enter the cranial cavity but did cause subarachnoid hemorrhages and cerebral contusion. Multiple bullet fragments, imbedded in the skull, were recovered; the bullet exited the right occipital scalp, approximately 1" from the entrance wound. The autopsy was otherwise remarkable for immersion changes; heavy and edematous lungs; aqueous fluid in the sphenoid sinus; and findings suggestive of prostate carcinoma. Toxicologic analysis was negative for alcohol and drugs.

Further investigation revealed video recording of the decedent walking to the beach, then disappearing before the next street camera. According to his family, he was "hiding an illness" and had lost 50 pounds in the last six months. In his residence, his cell phone, keys, and all important documents and papers were organized and placed on the kitchen table. Based on investigation, the manner of death was ruled a suicide.

Discussion: Firearms are used in the majority of suicides in males in the United States. Gunshot wounds to the occiput comprise less than 1% of suicides. Staged homicides, such as the arranged scene in Case 1, may further obfuscate the course of events. While the location of the entrance wound may suggest homicide, the importance of a thorough investigation and collection of evidence cannot be overstated in determining the proper manner of death.^{1,2}

Suicide, Self-Inflicted Gunshot Wounds, Back of Head

H53 Deaths Associated With SARS-CoV-2 Vaccination: The Importance of Autopsy

Francesco Sessa MS, PhD*, Department of Clinical and Experimental Medicine, University of Foggia, Foggia, Italy; Massimiliano Esposito, MD, Department of Medical, Surgical and Advanced Technologies, G.F. Ingrassia, University of Catania, Catania, Italy; Monica Salerno MD, PhD, Department of Medical, Surgical and Advanced Technologies, G.F. Ingrassia, University of Catania, Catania, Italy; Cristoforo Pomara, MD, PhD, Department of Medical, Surgical and Advanced Technologies, G.F. Ingrassia, University of Catania, Catania, Italy

Learning Overview: Following this presentation, attendees will understand how the autopsy should be a rule in the causality assessment of fatal cases temporally related to COVID-19 vaccination.

Impact Statement: This presentation will impact the forensic community by providing up-to-date data about the pivotal role of forensic sciences providing scientific evidence to dissolve the doubts of public opinion regarding COVID-19 vaccination.

The current challenge worldwide is the administration of anti-severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) vaccine. To date, the European Community, following the recommendation by the European Medicines Agency (EMA), has authorized the use of four vaccines. The vaccine of the company BNT162b2 (Pfizer®–BioNTech®) was authorized on December 21, 2020; the second mRNA-1273 (Moderna®) was approved on January 6, 2021; the third vaccine, ChAdOx1 nCoV-19 (AstraZeneca®), was approved on January 29, 2021; and the last vaccine is COVID-19 Vaccine Janssen (Johnson & Johnson®), authorized on March 11, 2021.¹⁻⁴

Nevertheless, severe adverse reactions temporally related to vaccine administration have generated diffidence in the population, slowing the European vaccine plan.

This communication aims to analyze the pivotal role of forensic sciences in order to define the causal relationship between Adverse Events Following Immunization (AEFI) and COVID-19 vaccination. To achieve this goal, a literature review was conducted using the following keywords: “COVID-19 vaccination,” “Post-mortem findings,” and “autopsy findings” in different databases (PubMed®, Scopus®, Web of Science®).

Although different fatal events temporally related to the COVID-19 vaccine administration were reported, the postmortem investigation has been performed in a few cases (nine papers have published fatal cases temporally related with COVID-19 vaccine administration, discussing about 16 cases). Based on this data, autopsy is very useful to define the main characteristics of the so-called Vaccine-induced Immune Thrombotic Thrombocytopenia (VITT) after ChAdOx1 nCoV-19 vaccination: the recurrent findings were intracranial hemorrhage and diffused microthrombi located in multiple areas.

Vaccines represent some of the greatest medical and scientific achievements of the modern era. Particularly in the pandemic scenario, a medicolegal perspective on vaccination is very important in order to provide a critical viewpoint. The COVID-19 vaccine administration involves different questions, such as the possibility of side effects, which led to a fairly diffuse suspicion and rejection, especially when a fatal case temporally related to vaccine administration occurs in a young healthy subject. The use of vaccines also poses various ethical and legal problems, including the possibility of conflicts between individual and collective rights.^{5,6}

The great challenge for the scientific community in the fight against COVID-19 is represented by the success of a global vaccination campaign and, in this light, it is important to provide scientific evidence to dissolve the doubt of public opinion. In order to avoid another “Lockdown of Science,” the autopsy should be a rule in the causality assessment of fatal cases temporally related to COVID-19 vaccination.⁷

H54 The Time and Temperature Dependence of Volatile Organic Compounds' (VOCs') Appearance in Autolytic Rat and Pig Liver

Gabrielle Messe, BA, University of New Haven, West Haven, CT; Robert Powers, PhD, University of New Haven, West Haven, CT*

Learning Overview: After attending this presentation, attendees will better understand the potential for VOCs to provide information regarding Postmortem Interval (PMI).

Impact Statement: The goal of this research is to explore the pattern of volatile compound generation as an indicator of time since death during the early stages of decomposition.

The PMI reflects the period between death and the discovery of a body. In some cases, an accurate estimation of PMI may play a significant role in death-related investigations. Current methods for the determination of PMI are primarily subjective and based on observation of the decedent and their surroundings. During decomposition, endogenous enzyme activity produces a number of VOCs characteristic of the process. Much of the available literature describing postmortem production of VOCs is focused on the later periods of decomposition, during which extensive microbial activity produces many of these compounds. This project has focused on the autolytic period that occurs before breaching of the Gastrointestinal (GI) tract, and the extensive microbial colonization of the body that follows, initiating the putrefactive stage of decomposition. This work explores the time- and temperature-dependent relationship between specific volatiles and the potential of such relationships to correlate to a particular range of PMI. In using the ratios of specific target VOCs on a time- and temperature-dependent model, details on the PMI may be elucidated.

Incubations of a rat liver homogenate at two different temperatures (room temperature and 28°C) were conducted for five-day periods, with triplicate aliquots removed at 0, 6, and 12 hours, and at 12-hour intervals thereafter. Headspace/Gas Chromatography/Mass Spectrometry (HS/GC/MS) analysis was used to identify specific compounds generated at each time point. The relative abundance of detected compounds was then plotted against time and temperature. Similar experiments were performed using pig liver.

Compounds of interest in the rat incubations were acetaldehyde, ethanol, acetone, acetoin, and 3-methyl butanal. Ethanol, acetoin, and hexanal were similarly found in pig liver. A linear temporal relationship between Acetone (A) and Ethanol (E) in the room temperature incubation of rat liver was determined, expressed as: $A/E \text{ Ratio} = -0.0104(\text{Time}) + 0.08066$, yielding an $R^2 = 0.97$. Thus, for these compounds, under these specific experimental conditions, the A/E ratio appeared to be highly correlated to PMI for the 24–72-hour incubation period. Acetoin-to-acetaldehyde also appeared to have a linear relationship. In contrast, the hexanal-to-acetaldehyde, and acetone-to-acetoin ratios appeared to be exponential.

Despite the lack of consistency between the apparent nature of the relationship between specific analytes, be it linear or exponential, these findings suggest that the ratio of specific volatiles with different temporal evolution profiles may be useful for the determination of PMI.

Postmortem Interval (PMI), Volatile Organic Compounds (VOCs), Decomposition

H55 A Complex Suicide by Drowning and Stabbing: The First Italian Case Reported in the Literature

Stefano Duma, MD, University of Bari, Bari, Italy; Federica Mele, MD, University of Bari, Bari, Italy; Mariagrazia Calvano, MD, University of Bari, Bari, Italy; Mirko Leonardelli, MD, University of Bari, Bari, Italy; Enrica Macorano, MD, University of Bari, Bari, Italy; Francesco Introna, MD, University of Bari, Bari, Italy*

Learning Overview: After attending this presentation, attendees will have a better understanding of the importance of distinguishing this kind of complex suicide from others or from violent forms of death, such as homicides or accidents.

Impact Statement: This presentation will impact the forensic science community by presenting the first case in Italy of a complex suicide through self-stabbing and drowning.

The term “complex suicide” refers to suicides in which more than one suicide method is applied.¹ In a planned complex suicide, the victim plans different and simultaneous methods of death, to prevent one of them from failing. In an unplanned complex suicide, on the other hand, the victim changes the method because the first one fails or turns out to be too painful.

The case presented is the first Italian example reported in major literature of an unplanned complex suicide achieved through stabbing and drowning by a man with no psychiatric history or alcohol/drug abuse history.

The body was found lying on the front seats of a car, in a field outside the city, near the seaside. The clothes worn by the corpse were intact, wet, and smeared with mud and gravel compatible with the characteristics of the shoreline leading to the sea. Inside the car, a kitchen knife with a serrated blade and a pair of scissors were found, both smeared with dried blood material.

The cadaveric inspection showed multiple superficial stab and cut injuries. The leakage of aqueous-like transparent liquid from the nasal cavities was also found. The external examination of the corpse confirmed the presence of multiple stab lesions, mostly punctiform, some of them triangular in shape and others linear, mostly superficial, located in different body sites: head, neck, chest, and abdomen. None of the internal organs or blood vessels were affected. Numerous superficial linear excoriated lesions were also investigated at the level of the right and left latero-cervical regions of both wrists. There were no outcomes of violent or defensive injuries attributable to the actions of third parties.

At the opening of the thorax, at the level of the left hemithorax, there was extensive hemorrhagic infiltration of the subcutaneous soft tissues and muscle tissues, as well as two infiltrations in correspondence with the sternal manubrium and the left parasternal region. Upon examination of the lungs, these were expanded, heavily congested, with increased volume. On the section surface was observed the leakage of liquid material mixed with air. The blood and urine taken during the autopsy examination were used to carry out toxicological investigations, which gave negative results. The cause of death was attributed to hypothermia in a subject with multiple stab wounds and evidence of incomplete drowning.

The case described above is the third case worldwide and the first case in Italy of complex suicide through self-stabbing and drowning.^{2,3} In cases of suicide, it is necessary to analyze all the evidence, which makes possible to distinguish this kind of sudden/unnatural death from others or from a violent form of death, such as homicide or accident. In these cases, it is mandatory to perform an accurate external examination of the corpse, an autopsy, and lab tests in order to ascertain the cause of death with certainty. Moreover, a multidisciplinary approach including a psychiatric criminological investigation could help in finding the truth of how and why the suicide was prepared.

H56 Spectrophotometric Analysis of Postmortem Lividity: A New Objective Measure to Define Time of Death

Mariagrazia Calvano, MD*, Department of Interdisciplinary Medicine, Section of Legal Medicine, Policlinico di Bari Hospital, University of Bari, Bari, Italy; Antonio De Donno, MD, Department of Interdisciplinary Medicine, Section of Legal Medicine, Policlinico di Bari Hospital, University of Bari, Bari, Italy; Chiara Lauretti, MD, Department of Interdisciplinary Medicine, Section of Legal Medicine, Policlinico di Bari Hospital, University of Bari, Bari, Italy; Ilaria Santoiemma, MD, Department of Interdisciplinary Medicine, Section of Legal Medicine, Policlinico di Bari Hospital, University of Bari, Bari, Italy; Carmelinda Angrisani, MD, Department of Interdisciplinary Medicine, Section of Legal Medicine, Policlinico di Bari Hospital, University of Bari, Bari, Italy; Federica Mele, MD, Department of Interdisciplinary Medicine, Section of Legal Medicine, Policlinico di Bari Hospital, University of Bari, Bari, Italy; Mirko Leonardelli, MD, Department of Interdisciplinary Medicine, Section of Legal Medicine, Policlinico di Bari Hospital, University of Bari, Bari, Italy; Stefano Duma, MD, Department of Interdisciplinary Medicine, Section of Legal Medicine, Policlinico di Bari Hospital, University of Bari, Bari, Italy; Enrica Macorano, MD, Department of Interdisciplinary Medicine, Section of Legal Medicine, Policlinico di Bari Hospital, University of Bari, Bari, Italy; Francesco Introna, MD, Department of Interdisciplinary Medicine, Section of Legal Medicine, Policlinico di Bari Hospital, University of Bari, Bari, Italy

Learning Overview: After attending this presentation, attendees will be aware of a new and innovative method for hypostases objective detection that can reliably define the time since death.

Impact Statement: This presentation will impact the forensic science community by presenting a new instrumental analysis procedure based on a spectrophotometric technique that provides a promising way of interpreting the hypostatic phenomenon with high reliability.

The correct definition of time of death often represents a key to solving judicial cases. However, a problem frequently encountered in medicolegal practice is the difficulty of precisely defining the “Time Since Death” (TSD).¹⁻³ One of the thanatochronological parameters used in forensic medicine is the study of hypostases and their characteristics in relation to the migration and the possibility of using digital compression to highlight the changes they undergo in the different periods after death. However, these are based on non-objective parameters, and are therefore characterized by an intrinsic variability that can compromise their reliability. In fact, as the results of numerous worldwide studies have shown, the current traditional methods of assessment of hypostases for thanatochronological purposes are characterized by numerous limitations and, therefore, they are not conclusive.⁴⁻⁷

The purpose of the present study was to propose a standardized method of objective detection of hypostases, which still represents a weak link in the thanatochronological triad used, thus allowing estimation of time since death with good approximation. To achieve this, the instrument used was based on spectrophotometry in order to analyze only the hemoglobin contribution to skin color, while excluding the role of melanin.^{8,9} This made it possible to analyze a hypostatic area, with a numerical value defined as a measure of the hemoglobin content before and after application of standardized pressure for a defined time interval. The study was conducted on 100 cadavers in various wards. The variables considered in the study were: Hb-pre (mean hemoglobin measure before weight force application); Hb-post (mean hemoglobin measure after weight force application), ΔHb (change in mean hemoglobin measures from before to after weight force application); and red% Hb (percentage reduction in hemoglobin after weight force application, compared to the mean measure of hemoglobin before weight force application).

The data analysis showed statistically significant correlation between the red% Hb value, as the percentage reduction of post-compression hemoglobin, and time, in terms of time since death. This provided a mathematical formula to estimate time since death with good reliability (±4 h, 50 min).

The spectrophotometric technique used has proven to be valid and effective for the evaluation of hypostases, mainly because it can provide the operator with quantitative data for the hemoglobin levels in the skin scans analyzed, a characteristic not found in any other study in the literature to date. This method also applies to the potential for more in-depth evaluation of the biological factors that influence the phenomenon analyzed, essentially with a view to attribute these to specific causes of death. Finally, a potentially revolutionary aspect of the proposed technique that will be evaluated in future studies lies in the possibility of analyzing the cutaneous quantity of hemoglobin also in the skin of subjects of Negroid ethnicity, therefore overcoming this objective limitation in the analysis of hypostases in such cadavers.

H57 The Effect of Multiple Washes and Thread Count on Semen-Stained Sheets

Jenna Hedlich, MSFS, University of Alabama at Birmingham, Birmingham, AL; Jason Linville, PhD, University of Alabama at Birmingham, Birmingham, AL*

Learning Overview: After attending this presentation, attendees will better understand how the weave and thread count of fabric affects the retention of sperm cells and proteins in a semen stain after laundering. Attendees will also learn how sperm cells and other materials were retained following repeated washings up to ten times.

Impact Statement: This presentation will impact the forensic science community by presenting scenarios where semen stains on articles of laundered clothing or bedding after a sexual assault may be difficult to locate, but may still contain sperm cells capable of producing a complete DNA profile.

Since its development, DNA analysis has been the gold standard for crime scene evidence. In cases of sexual assault, DNA evidence such as seminal fluid is extremely valuable. It may be the only evidence left at the scene that can link the perpetrator to the victim. Analysts have explored the possibility of obtaining DNA profiles from biological evidence from stained fabrics that have been laundered.

Successful extractions are dependent on the conditions used when laundering the fabrics. Wash temperature, chemicals and detergents, number of washes, and fabric structure can affect how long a stain remains on a piece of fabric. Previous studies have focused on temperature settings, types of detergents and chemicals, and drying in a machine dryer versus air drying. In general, fluorescence and acid phosphatase are washed away more easily than sperm cells. In this project, semen stains were deposited on bed sheets and laundered. The thread count of sheets were varied along with the number of washes in a washing machine. This study focused on how the weave and thread count of material affects the persistence of a semen stain and how multiple washings diluted the stain until an attempt to obtain a DNA profile failed. Utilizing regular wash and dry cycles simulated what may occur to evidence after a crime and thus could provide information on whether analysts can use articles of clothing or bedding after a sexual assault even if those items have been laundered multiple times. Overall, data indicated that fluorescence could be removed following a single wash, but sperm cells remained following multiple washes.

Laundered Semen Stains, Thread Count, DNA

H58 The First Italian Suicide Death Due to Helium Inhalation: The First Histological Findings and Pathogenesis

Enrica Macorano, MD*, University of Bari, Bari, Italy; Andrea Marzullo, MD, University of Bari, Bari, Italy; Federica Mele, MD, University of Bari, Bari, Italy; Mariagrazia Calvano, MD, University of Bari, Bari, Italy; Mirko Leonardelli, MD, University of Bari, Bari, Italy; Stefano Duma, MD, University of Bari, Bari, Italy; Francesco Introna, MD, University of Bari, Bari, Italy

Learning Overview: After attending this presentation, attendees will be able to recognize the histopathological data of the lungs in deaths caused by helium intoxication

Impact Statement: This presentation will impact the forensic science community by presenting evidence from a combined death's mechanism: helium asphyxia and asphyxia by obstruction of the airway.

Every year in Italy, about 4,000 suicides are documented accordingly to The Italian National Institute for Statistics (ISTAT). Suicide rates are higher among older people; among young people, however, suicide is, in Italy as in the rest of the world, one of the first causes of death.¹ According to the literature, not many cases of suicides by helium gas have been recorded recently. The continued inhalation of helium may induce loss of consciousness within 5-10 seconds and lead to hypoxic death in few minutes.^{2,3} The "procedure" of this suicidal technique, including the so-called "suicide bags," is well described on many easily accessible websites; the above-mentioned bags were indeed used in the first cases reported in literature.⁴ These consist of a kit composed of a plastic bag connected and fixed by a drawstring or adhesive tape to a plastic tube linked to a gas bottle. The plastic needs to be hermetically sealed, so it is usually also fixed tightly to the neck.

A 28-year-old Italian man was found dead in a hotel room. The corpse was lying on the bathroom floor. His head was wrapped in a plastic bag, closed around the neck with a tape, and connected to a 2.2L helium cylinder by a plastic tube. The external examination showed a ligature mark of the skin that resulted from the compression of the neck by the tapes and the elastic. Autopsy revealed only a marked and widespread congestion and cerebral edema, expanded and big lungs, with reddish petechiae bilaterally. On cut-section, the lung parenchyma was pale, with emphysematous-like aspect and a foam-like structure. Based on these findings, death was attributed to a double asphyxiating mechanism: helium intoxication and asphyxia in a confined space due to the plastic bag wrapped around the head. It was not possible to measure the helium concentration in the blood sample because helium can not be detected using standard analysis.

The case presented here is the first case reporting the microscopic data of helium inhalation. Asphyxiation by helium is a very rare occurrence and, per research, only few cases are reported in literature. A combined mechanism is seen in this case: gas asphyxia and asphyxia by obstruction of the airway are both present. The plastic bag alone may have been sufficient to cause asphyxiation even without helium, but the addition of the gas allowed a more rapid loss of consciousness and death.

Asphyxia in a Confined Environment, Helium Intoxication, Combined Death Mechanism

H59 Postmortem Findings in 11 Cases of Deaths Occurring After the Administration of an Anti-SARS-CoV-2 Vaccine

Chiara Franzetti, MD*, Department of Public Health, Experimental and Forensic Medicine, University of Pavia, Pavia, Italy; Sofia Bodini, MD, Department of Public Health, Experimental and Forensic Medicine, University of Pavia, Pavia, Italy; Alessandra Radogna, MD, Department of Public Health, Experimental and Forensic Medicine, University of Pavia, Pavia, Italy; Claudia Carelli, MD, Department of Public Health, Experimental and Forensic Medicine, University of Pavia, Pavia, Italy; Vittorio Bolcato, MD, Department of Public Health, Experimental and Forensic Medicine, University of Pavia, Pavia, Italy; Paola Braga, MD, Department of Public Health, Experimental and Forensic Medicine, University of Pavia, Pavia, Italy; Valeria Prandini, MD, Department of Public Health, Experimental and Forensic Medicine, University of Pavia, Pavia, Italy; Gulnaz Javan, PhD, State University Department of Physical Sciences and Forensic Science Programs, Montgomery, AL; Silvia Visonà, MD, PhD, Department of Public Health, Experimental and Forensic Medicine, University of Pavia, Pavia, Italy; Matteo Moretti, MD, Department of Public Health, Experimental and Forensic Medicine, University of Pavia, Pavia, Italy; Luca Morini, PhD, Department of Public Health, Experimental and Forensic Medicine, University of Pavia, Pavia, Italy

Learning Overview: The goal of this presentation is to describe and explain the macroscopic and microscopic postmortem findings in 11 individuals who died following administration of the anti-SARS-CoV-2 vaccine.

Impact Statement: This presentation will impact the forensic science community by underlying the key role of postmortem investigations in the clarification of disorders related to the SARS-CoV-2 vaccine to improve vaccine safety.

During 2020 and 2021, the global pandemic of COVID-19 has resulted in high death rates and acute and chronic morbidity worldwide. Large-scale anti-SARS-CoV-2 vaccination campaigns brought hope that the spread of this virus could be controlled; to date, the European Community, following the recommendation by the European Medicines Agency, has authorized the use of four vaccines: Pfizer®-BioNTech® “Comirnaty,” Johnson & Johnson® “Janssen,” Moderna® “Spikevax,” and AstraZeneca® “Vaxzevria.”^{1,2} During the pharmacovigilance phase, for millions of people who received the new vaccines, mild side effects, such as fever or pain at the injection site, were frequently reported; however, in sporadic cases, severe side effects were also reported.

In this study, as well as in other reports in literature, most of the deaths occurred shortly after the vaccine administration and were due to thrombosis and its consequences; therefore, it is important to ascertain if administration of the abovementioned vaccines, with particular individual susceptibility, could cause alterations in blood aggregation and coagulation, leading to a fatal outcome.³

Materials and Methods: This study has been conducted on 11 subjects who died from February to July 2021 after administration of anti-SARS-CoV-2 vaccines. The subjects were between 18 and 86 years-old, 7 females and 4 males: 4/11 (36%) died after receiving the Vaxzevria (after the second dose), 7/11 (64%) after the Comirnaty (3/7 after the first dose; 4/7 after the second one). Death occurred within 1 hour to 16 days after the administration of the vaccine.

Each subject underwent a forensic autopsy at the Legal Medicine Unit of the University of Pavia, followed by histological examination. Samples taken from the brain, heart, lungs, liver, spleen, kidney, blood vessels, and thrombi (if present) were routinely fixed in 10% formaldehyde solution for at least 24 hours and stained with hematoxylin-eosin.

In addition, an immuno-histochemical staining was performed: anti-CD42 and anti-PF4 antibodies were used to observe alterations of platelet aggregation; anti-I-CAM and anti-V-CAM antibodies were used to observe initial inflammatory responses, leading to pro-coagulative pathways. In addition, immuno-histochemistry results were compared to those of five unvaccinated subjects, deceased before April 2019, not exposed to the SARS-CoV-2 virus.

Conclusions: The epidemiological surveillance of the population has shown that vaccination programs have been successful in significantly reducing mortality and morbidity rates from SARS-CoV-2. The deaths occurring after the vaccine administration require a deep investigation in order to identify the mechanisms of death, the relation with vaccination, and the factors involved in possible individual susceptibility. These questions are of paramount importance to identify people with increased risk to develop severe adverse reactions, and hence to allow the patient's safety in the context of global vaccination programs.

SARS-CoV-2, Vaccination, Immunohistochemistry

H60 Postmortem Computed Tomography (PMCT) in Luxembourg: A Retrospective Analysis

Thorsten Schwark, MD, Laboratoire national de santé, Dudelange, Esch, Luxembourg and Medical University of Graz, Graz, Styria, Austria; Martine Schaul, MD, Laboratoire national de santé, Dudelange, Esch, Luxembourg; Vincent Lens, MD, Centre Hospitalier de Luxembourg, Luxembourg; Andreas Schuff, MD, Laboratoire national de santé, Dudelange, Esch, Luxembourg*

Learning Overview: After attending this presentation, attendees will have an overview of the use of PMCT in Luxembourg, including typical indications and strengths and weaknesses of the method.

Impact Statement: This presentation will affect the forensic science community by sensitizing forensic pathologists to the importance and benefit of PMCT by presenting typical applications, examination indications, and findings complementing autopsy results as well as selected case presentations.

PMCT was implemented in the routine work at the Institute of Legal Medicine in Luxembourg in January 2018. Since then, out of a total of 339 autopsies performed until July 31, 2021, 88 PMCTs (corresponding to 26 percent of autopsy cases) have been realized. Selection of cases to be scanned was based on the recommendations of the German Society of Legal Medicine (DGRM) on PMCT indications.¹ CT scans were evaluated by a clinical radiologist, and radiological diagnoses were compared with autopsy results.

The predominant indications for PMCT were traffic accidents (50 % of all PMCTs), followed by (suicidal or accidental) falls from great heights (20 %), and gunshot and stab wounds (11 % and 8 %, respectively). Less frequent reasons for a CT scan prior to autopsy were putrefaction, explosions, sudden death of infants or children, suspicion of medical malpractice, and homicidal strangulation.

Overall, a good agreement between radiological diagnosis and autopsy results was observed. As expected, CT was superior to autopsy, particularly in detecting gas or foreign bodies in vessels and tissues, and in detecting bony injuries (facial fractures, non-displaced cervical spine fractures, fractures of transverse processes of vertebral bodies, fractures of hand and foot skeleton, pelvic fractures). Classic autopsy, on the other hand, more reliably detected soft tissue, visceral organ, and vascular injuries (liver and spleen ruptures, aortic ruptures).

In conclusion, PMCT is a useful adjunct to conventional autopsy—particularly with regard to the detection of osseous lesions and foreign bodies. A CT indication according to Fischer et al. was established in about one-quarter of Luxembourg autopsy cases.¹

The presented report clearly illustrates the benefit of PMCT prior to autopsy in certain cases.

PMCT, Forensic Radiology, Autopsy

H61 Congenital Rib Abnormalities: A Presentation of Two Case Studies and a Literature Review

Gregory Dickinson, MD*, Office of Chief Medical Examiner, New York City, NY; Hannah Jarvis, MRCS, Harris County Institute of Forensic Sciences, Houston, TX; Angela Soler, PhD, Office of Chief Medical Examiner, New York City, NY; Julie Fleischman, PhD, Harris County Institute of Forensic Sciences, Houston, TX

Learning Overview: After attending this presentation, attendees will have a better understanding of the incidence and characterization of congenital rib abnormalities and their association with disease.

Impact Statement: This presentation will impact the forensic science community by presenting two case studies of congenital rib abnormalities and a review of the literature.

Congenital rib abnormalities are rare in the general population, with an estimated incidence of up to 0.6%, and are most often identified by radiographic imaging. They are generally categorized as bifurcated ribs with duplication of articulating ribs at the sternum, rib fusions resulting in a reduction of articulating ribs at the sternum, and rib foramen with a well-circumscribed round to oval intercostal space.^{1,2} Bifurcated ribs (Luschka's bifurcated rib) are more common in males than females and occur most frequently in the third and fourth ribs on the right side.

Rib fusions most commonly involve ribs 1 and 2 and can be fused anteriorly or posteriorly.^{2,3}

Case 1: A 59-year-old man with a history of substance use was found decomposing in his locked apartment with multiple empty methadone bottles at the scene. At autopsy, there was marked atherosclerosis of the left anterior descending coronary artery. The cause and manner of death is currently pending further investigation to rule out acute intoxication.

At autopsy, the left fifth rib was bifurcated at the anterolateral position, forming two distinct and separate sternocostal joints, with normal attachment and crowding on the left side of the sternum.

Case 2: A 3-month-old female infant was found unresponsive after bed-sharing with her mother. The infant was markedly below growth percentiles for age. It was not possible to determine the exact mechanism of death, and the cause of death was certified as Unexplained Sudden Death (Intrinsic and Extrinsic Factors identified). The manner of death was Undetermined.

At autopsy, the anterior halves of the bodies of right ribs 1 and 2 were fused, resulting in a single sternal end and costal cartilage for the fused ribs. The bone fusing the rib bodies was continuous and consistent in morphology. The contour of the ribs and their attachments to the spine were grossly normal.

Congenital rib abnormalities are rare and are likely underreported. A query of the Infant Injury Database (IID), a database containing soft tissue and skeletal findings from 868 infants and children (≤ 5 years old) autopsied at the Harris County Institute of Forensic Sciences since 2010, identified only two cases using qualitative terms, including "fused," "joined," and "bifid."⁴ Congenital rib abnormalities are generally considered benign anomalies but have been associated with Gorlin-Goltz syndrome along with multifocal basal-cell carcinoma of the skin, odontogenic keratocyst, facial abnormalities (frontal and temporoparietal bossing, hypertelorism, and mandibular prognathism), bilateral ovarian fibromas, and cardiac fibromas due to a mutation of the PTCH gene found on chromosome 9q in an autosomal dominant pattern.⁵

H62 A Forensic Investigation of Fatal Myocardial Infarctions—A Gender-Wise Comparison, Autopsy Findings, and Biological Rhythms: A Study From Greece

Konstantinos, Katsos, MD, PhD, Department of Forensic Medicine and Toxicology, Medical School, National and Kapodistrian University of Athens, Athens, Attiki, Greece; Evmorfili Zouzia, MD, MSc, 1st Intensive Care Clinic, Evangelismos General Hospital, Medical School, National and Kapodistrian University of Athens, Athens, Attiki, Greece; Konstantinos Moraitis, PhD, Department of Forensic Medicine and Toxicology, Medical School, National and Kapodistrian University of Athens, Athens, Attiki, Greece; Dimitrios Vlachodimitropoulos, MD, PhD, Department of Forensic Medicine and Toxicology, Medical School, National and Kapodistrian University of Athens, Athens, Attiki, Greece; Nikolaos Goutas MD, PhD, Department of Forensic Medicine and Toxicology, Medical School, National and Kapodistrian University of Athens, Athens, Attiki, Greece; Chara Spiliopoulou, PharmD, MD, PhD, Department of Forensic Medicine and Toxicology, Medical School, National and Kapodistrian University of Athens, Athens, Attiki, Greece; Emmanouil Sakellidis, MD, MSc, PhD*, Department of Forensic Medicine and Toxicology, Medical School, National and Kapodistrian University of Athens, Athens, Attiki, Greece

Learning Overview: Attendees can expect to learn about gender-wise analysis of fatal myocardial infarctions that represent the most common cause of death in the developed countries.

Impact Statement: In Greece, a forensic practitioner is required by law to perform autopsies in many non-violent deaths, including many elderly deaths. Traditionally, autopsies provide reliable data for morbidity and mortality. This study sample can serve as the basis for further analysis to permit adaptation of more efficient preventive health policies.

Fatal Myocardial Infarctions (MI) represent a significant part of sudden-unexpected death cases referred for autopsy.¹ Gender-wise comparison of such cases, based on autopsies, has not previously been attempted in Greece. Demographic characteristics of the deceased, autopsy findings, and study of the biological rhythms may provide tools for better understanding of such cases.

Cases of MI-related deaths, examined during 2010–2017, were included in the study sample (827 cases in total). Medical history was obtained through hospital records, police information, and interviews with the relatives of the deceased.

Statistical analysis was performed using Stata/MP 13 (Stata Corp) and IBM® SPSS Statistics Version 20 (IBM). Statistical significance was defined as a 2-sided P value of <0.05. Pearson chi-square test and Student's *t*-test were appropriately used for comparison among categorical and continuous variables. The assessment of seasonal variation of fatal MIs was accomplished via two methods (chi square goodness of fit and Rayleigh test).

Regarding the social characteristics of cases, the mean age of males was lower than that of females (64.1 ± 14.657 vs. 70.8 ± 14.423 $p < 0.001$). Marriage was encountered more frequently among males (58.5% vs. 37%, $p < 0.001$). Females were more frequently widowed (32.6% vs. 7.6%, $p < 0.001$); 30% of males vs. 14.9% of females were employed; $p < 0.001$. 50.9% of males and 15.6% of females were retired.

Regarding the death conditions, females were more likely to die within their residence compared to males (53.6% vs. 42%, respectively; $p = 0.005$). Furthermore, death inside a hospital was also more likely to occur among females (42% vs. 34.15%, respectively; $p = 0.049$). On the other hand, a male predominance regarding deaths in public spaces was noted (24% vs. 4.4%, respectively; $p < 0.001$). A fatal MI was more like to occur during physical activity among males (69.8% vs. 59.7%, respectively; $p = 0.010$) and it appears that more females died while abed/sleeping (40.3% vs. 30.2%; $p = 0.010$).

Symptoms prior to the event were reported more frequently among females (73.8% vs. 62.7%; $p = 0.024$). No significant differences were observed as far as it concerns the mean duration of symptoms prior to the fatal MI between the two genders (Males: 3.86hrs [SD=8.556] vs. females: 3.29hrs [SD=5.519]; $p = 0.589$).

The gender-wise comparison of cardiovascular risk factors (smoking, diabetes mellitus, dyslipidemia, family history of coronary artery disease, hypertension, alcohol consumption, history of prior MI) showed significant differences only for the following factors, which were more common among males: smoking (males 54.2% vs. females 35.3%; $p < 0.001$), alcohol consumption (males 13.5% vs. females 6%; $p < 0.008$) and history of prior MI (males 18.3% vs. females 7.2%; $p = 0.001$).

Significant stenosis (>70%) in left anterior descending branch was more common among males (63.2% vs. 40.3%; $p < 0.001$) while significant stenosis in the left circumflex or the right coronary artery appeared more often among females (44.1% vs. 28.7%; $p < 0.001$) and (46.9% vs. 27.6%; $p < 0.001$), respectively. Males suffered from significant three-vessel disease more often than females (33.3% vs. 17.1%; $p < 0.001$). MI with Non-Obstructive Coronary Arteries (MINOCA) (defined as non-obstructive CAD<50% in all vessels) was more common among females (32% vs. 10.1%; $p < 0.001$).

Myocardial scar evidence was more common among males (54.6% vs. 39.8%; $p < 0.001$).

Monthly distribution of male cases appeared to be uniform using both chi-square goodness of fit and Rayleigh tests ($p = 0.204$ and $p = 0.095$). Regarding females, chi square goodness of fit demonstrated a non-uniform distribution of deaths (increase during April, decrease during June) in the case of monthly distribution ($p = 0.003$); however, Rayleigh test did not yield the same result ($p = 0.758$).

Gender-wise differences observed in the autopsy sample provide useful information that should be taken under consideration within the primary care settings. Cooperation between medical specialties is essential for the reevaluation of current preventive health policies.

H63 The Determination of Manner of Death When Evaluating Intent: An Examination of Two Cases of Brodifacoum Adulteration of Synthetic Cannabinoids

Libby Aronson, MD, Cook County Medical Examiner, Chicago, IL; Michael Eckhardt, MD, Cook County Medical Examiner, Chicago, IL; Dan Isenschmid, PhD, NMS Labs, Horsham, PA; Kristin Escobar Alvarenga, MD, Cook County Medical Examiner, Chicago, IL*

Learning Overview: This presentation examines autopsy findings in cases of Brodifacoum Adulteration of Synthetic Cannabinoids (BASC), discusses the manner of death, and examines how intent behind actions impacts the practice of forensic pathology.

Impact Statement: While several prior publications have focused on the clinical impact of Synthetic Cannabinoid-Associated Coagulopathy (SCAC), few have examined the forensic implications of this outbreak. This presentation reviews epidemiologic data of postmortem cases of SCAC, identifies autopsy findings of BASC in two cases within the Cook County Medical Examiner's Office (CCMEO), and explores the manner of death based on the circumstances of each case.

From May 2017 through October 2018, an outbreak of SCAC was recognized, with tests indicating BASC. These "superwarfarins" are warfarin derivatives commonly found in rodenticides. They have greater potency than warfarin and can cause internal hemorrhage and death.

National Medical Services (NMS) received 31 total cases of brodifacoum toxicity during this timeframe, including 7 cases additionally positive for other superwarfarins. NMS identified 19 positive samples from clinical entities and 12 positive postmortem samples. Clinical samples originated from referral labs, which may not reflect the actual patient locations. Clinical samples were sent from Illinois (5), Minnesota (5), Virginia (4), Utah (3), and Florida (2). Postmortem samples originated from Illinois (5), Wisconsin (5), and Maryland (2).

The 12 brodifacoum-positive postmortem cases ranged in age from 22–46 years, with a median and mean age of 33 years. Ten cases were male and 2 had no reported gender. Two cases from Illinois were positive for other superwarfarins. Ten of the 12 postmortem samples were tested for the presence of synthetic cannabinoids; 7 were positive for FUB-AMB and/or FUB-AKB-48.

The CCMEO autopsied two cases of BASC. In the first case, there was massive retroperitoneal hemorrhage without a definitive source of bleeding and no evidence of trauma. The cause of death was non-traumatic retroperitoneal hematoma due to brodifacoum toxicity with recent synthetic cannabinoid use. The manner was ruled "accident."

In the second case, autopsy findings included minor healing abrasions of the scalp with no underlying trauma to the skull or brain. Internally, a thin subarachnoid hemorrhage was present; sectioning demonstrated multiple foci of intraparenchymal and intravascular hemorrhage. This case was certified as complications of brodifacoum toxicity with recent synthetic cannabinoid use. The manner was ruled "undetermined."

The CCMEO policy is to certify most drug overdose deaths as accidents, as the decedent's intent was intoxication, not death. In some cases, clear suicidal intent with elevated drug levels can help determine the manner as suicide. In rare cases, the intent of the drug dealer may also influence the determination of manner.

Despite both cases involving young men self-administering adulterated synthetic cannabinoids, the circumstances surrounding the deaths were different. The first case was received at the beginning of the outbreak and was ruled "accident." There were no indications of suicidal intent and no implication of intentional poisoning and thus CCMEO policy was followed. The second case was received later in the outbreak, after multiple incidents were reported. The decedent suspected that he was intentionally sold BASC. While this information was relayed to the CCMEO investigators, it was not reported to the police and no arrests were made. Due to the suspicious circumstances, the manner of death was ruled undetermined as the allegation of the decedent could not be overlooked.

General Statement of Conclusion: To date, there is no explanation for the origins of the BASC and the intent behind the adulteration is unknown. Determination of manner of death is challenging when the circumstances surrounding the incident are not fully elucidated. In such cases, manner of death should be based on all available information, considering not only the actions, but the intent behind them as well.

Brodifacoum, Cannabinoids, Manner

H64 A Study of Post Severe Traumatic Brain Injury (sTBI): Pathological and Radiological Diffuse Axonal Injury (DAI) Changes

Meenakshi Sharma, MSc*, All India Institute of Medical Sciences, New Delhi, India; Dipin Sudhakaran, MD, All India Institute of Medical Sciences, New Delhi, India; Arulselvi Subramaniam MD, All India Institute of Medical Sciences, New Delhi, India; Kangana Sengar, DNB, All India Institute of Medical Sciences, New Delhi, India; Shivanand Gamanagatti, MD, All India Institute of Medical Sciences, New Delhi, India; Vaishali Suri, MD, All India Institute of Medical Sciences, New Delhi, India; Rajesh Malhotra, MD, All India Institute of Medical Sciences, New Delhi, India; Sanjeev Lalwan, MD, All India Institute of Medical Sciences, New Delhi, India

Learning Overview: After attending this presentation, attendees will have a better understanding about the role of histopathology to ascertain the cause, survival time, and manner of death resulting from an intentional assault or accident. This is especially important where malicious head injury is suspected and the circumstantial data are contradictory or unknown by the pathologist.

Impact Statement: This presentation will impact the forensic science community by helping in ascertaining survival time and the degree of mechanical forces that developed during the traumatic event where malicious head injury is suspected, thereby evaluating the authenticity of statements made by the alleged perpetrator.

Introduction: DAI emerged as the most common and important pathological features of TBI and is considered as one of the main causes of unconsciousness in post-traumatic cases with the absence of detectable intracranial lesions on Computed Tomography (CT). This study assists in identifying the entire spectrum of brain injury, through pathological examination of the brain after postmortem.¹⁻³

Aims and Objectives: to study post sTBI pathological and radiological DAI changes, and to compare the sTBI induced pathological and radiological DAI changes with non-TBI and control cases.

Materials and Methods: Sixty-four postmortem brain tissues from different sites (corpus callosum, thalamus, brain stem, and cortex) were collected from patients who died due to sTBI; 24 non-TBI samples of brain tissue and 12 control samples from individuals without any injury were also collected.

Patients whose Glasgow Coma Scale (GCS) score was ≤ 8 at the admission and whose age were above 18 years with positive CT findings were included in the study. Brain tissue was collected in 10% formaldehyde for pathological analysis after informed consent from the legally authorized representative of the patient.

The CT scan reports were analyzed for the presence of hematoma, contusion, fracture, and mass effect/mid line shift, which further classified according to Rotterdam CT classification.⁴ CT images were analyzed from the Picture Archiving and Communication System (PACS) to calculate the DAI score.⁵ After routine Hematoxylin-Eosin (H&E) staining and Immunohistochemistry (IHC) staining for β APP, microscopic changes were graded according to hypoxic changes, infarction, gliosis, axonal swellings, infarction, neovascularization, lipid laden macrophages, gemistocytic astrocytes, congestion/edema, hemorrhage, and vascular changes.⁶ IHC of β APP was graded according to granular changes, axonal swellings, retraction bulbs, and presence of bands.^{7,8}

Results: The average age of the patients is 39 years for the sTBI group, 33 years for the non-TBI group, and 36 years for the control group. Among the sTBI group, 61% of the patients have a GCS score of ≤ 4 . The male/female ratio (55/9) was in the sTBI group. The mode of injury was motor vehicle collision for 75.6% cases, followed by fall in 21.9%. According to collision type, rear impact crash was maximum with 28.6% followed by side impact crash of 22.5% in the sTBI group compared to the non-TBI group. In CT brain findings, hemorrhage is 79.3%, cerebral contusion is 55.9%, and subdural hematoma 49.1% was found to be significant.

Rotterdam CT score was found to be significant in the sTBI group compared to the non-TBI group with a maximum grade 2 score (i.e., 49.1%). DAI score was non-significant in the sTBI group compared to the non-TBI group with a maximum grade 1 score (i.e., 45.3%) followed by grade 3 in 34.0%.

The H&E and β -APP scores were found to be significant in the sTBI group compared to the non-TBI and control groups. According to the survival time of the patient, the H&E score is maximum median (min.-max.) 11 (9-13) and was found to be significant in >10 days group compared to 0-6hrs, whereas β -APP scoring was able to identify axonal injury changes even at 0-6hrs following TBI.

Conclusion: DAI lesions are histopathological and neuroimaging hallmarks of DAI. CT imaging is quick, non-invasive, widely available, and has few contraindications, at the same time not sensitive to subtle DAI. Some patients with relatively normal CT scans may have significant unexplained neurological deficit. DAI changes were seen more in histology as compared to CT findings. β -APP serve as a gold standard for diagnosis of DAI. Forensic pathologists predominantly rely on gross findings to diagnose TBI; histological slides and paraffin blocks can serve as forensic evidence.

H65 A Fatal Snap: Death by Extrinsic Percussion of the Neck

Andrea Costantino, MD, University of Pisa, Pisa, Tuscany, Italy; Alice Chiara Manetti, MD, University of Pisa, Pisa, Tuscany, Italy; Eleonora Mezzetti, MD, University of Pisa, Pisa, Tuscany, Italy; Arianna Baronti, MD, University of Pisa, Pisa, Tuscany, Italy; Paola Santoro, MD, University of Rome La Sapienza, Roma, Lazio, Italy; Lavinia Pellegrini, MD, University of Rome La Sapienza, Roma, Lazio, Italy*

Learning Overview: Given autopsy and histological data, this case highlights the importance of differential diagnosis between hypoxia from full-thickness tracheal rupture or fatal percussion of the cervical nerve bundle.

Impact Statement: This presentation will have a strong impact on the scientific community because it shows a unusual case of death by neck percussion, which is rare in the general population.

Introduction: Atypical neck compression is a form of asphyxia in which the fatal mechanism results from a combination of different pathophysiological mechanisms, such as respiratory, vascular, and nervous.¹ However, in cases where the impact on the neck is particularly severe, resulting in high kinetic energy transfer, death derives from percussion rather than compression of respiratory structures. Deaths from percussion are rare, being described mostly in professional athletes.² In addition, very violent blows can also cause significant injury to organs located in the neck loggias, such as tracheal total rupture.³⁻⁵ In this work, a case of unusual death by extrinsic percussion of the neck is presented.

Case Report: A 43-year-old woman was on summer vacation with her boyfriend. As she passed by a garden closed to the public, she decided to take a photo. The woman clung with all her weight to a three-meter concrete beam suspended between two false columns, causing the structure to collapse. The beam broke in several places and fell on the victim, who was hit on the head, neck, and chest. Despite immediate resuscitation efforts, the woman died shortly after impact. Autopsy was requested by the judicial authority to clarify the cause of death. Externally, the woman exhibited typical signs of Morestin's ecchymotic mask, as well as rhinorrhagia, oral bleeding, bruising, and extensive ecchymotic-escharotic complexes. A characteristic excoriated ecchymotic complex in the form of a rail was observed on both the neck and chest, compatible with the profile of the concrete bar. Autopsy revealed several lesions, such as a subarachnoid hemorrhage, a mandible multifragmentary fracture, and amyletic cervical vertebral fractures. Key elements to establish the cause of death were full-thickness rupture of the trachea and esophagus, as well as significant hemorrhagic infiltration of the right cervical neurovascular bundle. These autopsy findings, together with the absence of typical vital signs of tracheal injury, such as blood in the airways or cervical subcutaneous emphysema, led pathologists to conclude that death was immediately caused by atypical ab extrinsic percussion of the neck. Stimulation of reflexogenic areas, such as sensory branches of the superior laryngeal nerve or carotid sinus, determined the onset of cardiac inhibitory phenomena, which, together with asphyxia mechanisms caused by compression on the neck, brought about sudden death. These conclusions were further supported by histological examination, which showed significant hemorrhagic infiltration of the right neurovascular bundle and the absence of pulmonary intra alveolar hemorrhage. This report presents an unusual case of death from cranio-cervical-thoracic polytrauma, with several major injuries, such as full-thickness rupture of the trachea, and minor ones, such as hemorrhagic infiltration of the cervical nerve bundle.

Polytrauma, Ab Extrinsic Neck Percussion, Asphyxia

H66 A Case of Traumatic Internal Carotid Artery Dissection: A Rare Event With Devastating Consequences

Giacomo Visi, MD*, University of Pisa, Pisa, Italy; Eleonora Mezzetti, MD, University of Pisa, Pisa, Italy; Andrea Scatena, MD, University of Pisa, Pisa, Italy; Aniello Maiese, MD, University of Pisa, Pisa, Italy; Paola Santoro, MD, Sapienza University, Rome, Italy; Alessandra De Matteis, MD, Sapienza University, Rome, Italy; Massimiliano Dell'Aquila, MD, Sapienza University, Rome, Italy

Learning Overview: This report is about a case of Traumatic Internal Carotid Artery Dissection (TICAD), a condition usually diagnosed when cerebral damage has already occurred. Thus, even if it is rare, a prompt diagnosis is essential. This case highlights the importance of the adoption of a TICAD screening strategy in cases of blunt traumas, especially when a motor vehicle is involved.

Impact Statement: This presentation will have a great impact on the forensic sciences community because it demonstrates the need to establish screening guidelines for the diagnosis of TICAD, which unfortunately are not yet in place.

Introduction: Internal Carotid Artery Dissection (ICAD) occurs when a false lumen is created by the blood penetration into the arterial wall because of internal elastic lamina discontinuation. About 20% of cerebral infarctions in the young adult population are due to ICAD.^{1,2} Both extracranial and intracranial carotid arteries could be involved, and the pathophysiological mechanism could be spontaneous (SICAD) or traumatic (TICAD). Carotid injuries could complicate the 0.32% of cases of general blunt trauma, and it seems that the percentage increases in severe multiple traumas. When TICAD occurs, a direct or indirect cervical injury is usually described and is often related to motor vehicle accidents.³⁻⁵ Unfortunately, it is frequently diagnosed when neurological symptoms have already occurred leading to permanent neurological impairment or even death.^{6,7} In blunt carotid injury, morbidity is estimated at up to 80% and mortality up to 40%.^{7,8} Specific TICAD screening guidelines are missing. Nevertheless, TICAD should be taken into consideration in the case of a young adult or middle-aged patient involved in severe blunt trauma. Herein, a rare case of TICAD is presented.

Case Report: A 54-year-old man with an unknown medical history was involved in a car accident while driving a car, manifesting a transient sudden loss of consciousness shortly after. The first medical evaluation revealed acceptable vital parameters, frontal skin abrasion, and foot crush injuries with exposed fracture. An X-ray examination also showed two vertebral fractures (one at the right arch of C1 vertebra and the other at D10 vertebra's body) and multiple left pulmonary contusions. No ischemic or hemorrhagic brain injuries were present and surgery for the foot fracture was planned. Two days later, the neurological situation changed as the patient could not move the left upper limb, and a brain Computed Tomography (CT) scan plus CT angiography revealed a right posterior cortico-subcortical temporo-parietal insular ischemic lesion with median shift caused by a right ICAD with almost completed lumen obstruction. A revascularization procedure was not indicated, and the physical examination showed left hemiplegia, right-sided head deviation, right eye divergent strabismus, bilateral reactive miosis, Cheyne-Stokes respiration, and drowsiness. The day after, a brain CT scan showed ischaemic lesion progression. A decompressive hemicraniectomy and a partial temporal lobectomy were performed, but the neurological status deteriorated further until brain-death was declared. The forensic autopsy revealed humble adventitial hemorrhagic infiltration of the right ICA slightly below the carotid bifurcation. The right common, internal, and external carotid arteries were sampled, and the histological examination confirmed the presence of intramural hematoma with intimal and media laceration, and a thrombus into the lumen.

H67 The Hazard of Grabbing a Quick Bite: A Case of Fatal Choking on Ham

Arianna Baronti, MD*, Section of Forensic Pathology, Department of Surgical Pathology, Medical, Molecular and Critical Area, Institute of Legal Medicine, University of Pisa, Pisa, Tuscany, Italy; Andrea Costantino, MD, Section of Forensic Pathology, Department of Surgical Pathology, Medical, Molecular and Critical Area, Institute of Legal Medicine, University of Pisa, Pisa, Tuscany, Italy; Andrea Scatena, MD, Section of Forensic Pathology, Department of Surgical Pathology, Medical, Molecular and Critical Area, Institute of Legal Medicine, University of Pisa, Pisa, Tuscany, Italy; Giacomo Visi, MD, Section of Forensic Pathology, Department of Surgical Pathology, Medical, Molecular and Critical Area, Institute of Legal Medicine, University of Pisa, Pisa, Tuscany, Italy; Zoe Del Fante, MD, Dept. of Anatomy, Histology, Legal Medicine and Orthopedics, "Sapienza" University of Rome, Rome, Latium, Italy; Lavinia Pellegrini, MD, Dept. of Anatomy, Histology, Legal Medicine and Orthopedics, "Sapienza" University of Rome, Rome, Latium, Italy; Silvia Romano, Dept. of Anatomy, Histology, Legal Medicine and Orthopedics, "Sapienza" University of Rome, Rome, Latium, Italy

Learning Overview: Although fatal food asphyxia is not so unusual, it is relatively uncommon among healthy adults. This case highlights the need to not exclude the hypothesis of fatal food asphyxia in lower-risk individuals and, at the same time, the importance of ruling out all of the possible alternative causes of death.

Impact Statement: This presentation will impact the forensic science community by showing an unusual case of fatal asphyxia that occurred in a man with no risk factors for food inhalation. In such cases, the forensic pathologist plays a key role in establishing the real cause of death.

Introduction: Fatal asphyxiation by a foreign body is not as rare as expected. According to the National Safety Council of the United States, foreign body inhalation represents the fourth-leading cause of accidental death.¹ Several studies demonstrated that food represents the most common type of foreign body implicated.² Fatal choking predominantly occurs in infants and small children because of their oral exploration behavior and uncoordinated swallowing reflex.^{3,4} Conversely, it is relatively unusual in adults, due to the larger diameter of the airways, and mostly involves fragile people such as elderly or neurologically impaired people.^{5,6} In this report, a case of a healthy middle-aged man who choked on 30g of unintentionally inhaled ham is presented.

Case Report: A 42-year-old man was eating his meal during lunchtime when he suddenly manifested dyspnea and dry heaves. His colleagues did not understand what was happening until he feebly asked for help since he was choking. They immediately called the emergency service and performed the Heimlich maneuver. The emergency personnel found the patient cyanotic and in cardiac arrest; despite rescue attempts, he died. A necropsy investigation aimed at establishing the cause of death and whether earlier health treatment would have saved the man was performed. External examination showed a single petechial hemorrhage in the conjunctiva and hematic staining in the oral cavity. Internal examination revealed the presence of 30g of sliced ham that completely occluded the airways from laryngeal aditus to the tracheal bifurcation. The bolus was molded to the shape of the obstructed airways. Lungs showed subpleural petechiae. At the histological investigation, signs of acute pulmonary emphysema were found. Autopsy excluded any concomitant disease and toxicological analysis was negative. There was no sign of trauma. Witnesses' description of death circumstances corroborated the hypothesis of mechanical asphyxia. For these reasons, it was concluded that this was an infrequent case of fatal food asphyxia in a healthy adult due to accidental food aspiration. It was possible because of the special characteristics of the food bolus. In fact, some food items pose a greater choking hazard due to their size, shape, or texture, becoming dangerous also for lower risk individuals. The investigation, also based on the perused documentation, allowed the exclusion of the health care professionals' liability.

H68 Massive Insulin Injection: A Rare Case of Suicide

Paola Santoro, MD, Department of Anatomy, Histology, Legal Medicine and Orthopedics, Sapienza University of Rome, Rome, Italy; Andrea Costantino, MD, Inst. of Legal Medicine, Dept. of Surgical Pathology, Medical, Molecular and Critical Area, University of Pisa, Pisa, Italy; Arianna Baronti, MD, Inst. of Legal Medicine, Dept. of Surgical Pathology, Medical, Molecular and Critical Area, University of Pisa, Pisa, Italy; Eleonora Mezzetti, MD, Inst. of Legal Medicine, Dept. of Surgical Pathology, Medical, Molecular and Critical Area, University of Pisa, Pisa, Italy; Umberto De Gennaro, MD, Department of Anatomy, Histology, Legal Medicine and Orthopedics, Sapienza University of Rome, Rome, Italy; Alice Chiara Manetti, MD, Inst. of Legal Medicine, Dept. of Surgical Pathology, Medical, Molecular and Critical Area, University of Pisa, Pisa, Italy; Fabio Del Duca, MD Department of Anatomy, Histology, Legal Medicine and Orthopedics, Sapienza University of Rome, Rome, Italy; Lavinia Pellegrini, MD, Department of Anatomy, Histology, Legal Medicine and Orthopedics, Sapienza University of Rome, Rome, Italy*

Learning Overview: Suicide by insulin represents a challenging diagnosis for forensic pathologists; therefore, a high level of suspicion needs to be maintained for clues that insulin may be involved, requiring complete autopsy investigation and a toxicological and histological analysis with correlation to circumstantial evidence.

Impact Statement: This presentation will impact the forensic science community because of the rarity of this manner of death, in consideration of the difficult determination of insulin in biological samples, especially in the postmortem setting.

This presentation aims to discuss a rare case of suicide by massive insulin injection. Suicidal insulin overdose is an unusual cause of death, often undervalued due to non-specific autopsy findings.

Analysis of insulin overdose is a challenging task in forensic pathology because of the complexities in toxicological analysis. It is therefore essential to prove the role of such a substance as the cause of death by performing a thorough toxicological, histological, and immunohistochemical analysis. Accidental fatal insulin overdose is the most common manner of death, followed by suicide, and very rarely homicide.

Insulin is a hormone that regulates glucose blood concentration. Proinsulin molecules consist of two chains along with a connecting peptide (C-peptide) before secretion. Exogenous insulin administration is able to suppress secretion of C-peptide and to diagnose hypoglycemia induced by exogenous insulin, it is necessary to test serum C-peptide concentration. Insulin administration should be meticulously managed since it could lead to severe hypoglycemia, coma, and even death. The mechanism of death linked to insulin overdose is hypoglycemic encephalopathy, which can damage irreversibly the central nervous system. The normal glucose concentration of blood is 3.9–7.1 mmol/L; when the blood glucose concentration is lower than 2.2 mmol/L, the glucose concentration in brain tissues is close to zero. Several studies show that myocardium is not sensitive to hypoglycemia and can normally work under such conditions, thus explaining why there are no evident pathologic alterations in the hearts of deaths by insulin overdose.

Postmortem analysis of insulin is challenging because of the rapid occurrence of decompositional changes and blood hemolysis after death. It is impossible to determine whether hypoglycemia was the cause of death based on postmortem glucose levels. Such difficulties emphasize the pivotal role of crime scene investigation in the evaluation of insulin-related deaths.

This report presents the unusual case of a 55-year-old Caucasian female found dead at home. At the crime scene investigation, there were no signs of forced entry into the victim's apartment and no signs of violence were found on the deceased body. The victim was found lying on the bed, fully dressed, and close to her feet, three empty insulin pens were found. A further pen, not used, was found after moving the dead body. Six handwritten letters were found, confirming the suicidal purposes of the woman.

During the autopsy, no macroscopic pathological findings were found in the major organs. Blood, humor vitreous, urine, bile samples, and major parenchymal organs were taken for toxicological and histological analysis, respectively. Histological analysis was inconsistent, except that neuronal degeneration was conspicuous in the cerebral cortex and basal ganglia of the brain. Toxicological analyses were negative for drug abuse and alcohol intake, thus revealing the presence of acetone, the simplest and smallest ketone body, insulin metabolites.

Insulin, Suicide, Acute Intoxication

H69 When Chronic Venous Insufficiency Becomes a Life-Threatening Condition: A Case of Fatal Hemorrhage From a Varicose Veins' Ulcer

Zoe Del Fante, MD, Dept. of Anatomy, Histology, Legal Medicine and Orthopedics, Sapienza University of Rome, Italy; Arianna Baronti, MD, Inst. of Legal Medicine, Dept. of Surgical Pathology, Medical, Molecular and Critical Area, University of Pisa, Pisa, Toscana, Italy; Eleonora Mezzetti, MD, Inst. of Legal Medicine, Dept. of Surgical Pathology, Medical, Molecular and Critical Area, University of Pisa, Pisa, Toscana, Italy; Alice Chiara Manetti, MD; Inst. of Legal Medicine, Dept. of Surgical Pathology, Medical, Molecular and Critical Area, University of Pisa, Pisa, Toscana, Italy; Fabio Del Duca, MD*, Dept. of Anatomy, Histology, Legal Medicine and Orthopedics, Sapienza University of Rome, Italy Silvia Romano, Dept. of Anatomy, Histology, Legal Medicine and Orthopedics, Sapienza University of Rome, Italy

Learning Overview: This case is unusual because the cause of the blood loss was not immediately evident at the crime scene, whereas the huge amount of blood all over the place may induce suspicion of a violent crime. In such cases, the skin ulcer may be very tiny. Therefore, the forensic pathologist needs to carefully look for it while evaluating the body. The aim of this presentation is to emphasize the role of a complete and accurate corpse inspection and to provide a complete overview of the needed examinations.

Impact Statement: This presentation will impact the forensic science community since it illustrates a possible event that each pathologist may encounter in his/her career. Attending this presentation, attendees will have improved their knowledge about such suspicious forensic scenarios.

Chronic Venous Insufficiency (CVI) of the lower limbs is a common condition in Western countries.¹ The pathogenesis of CVI and associated Varicose Veins (VVs) is related to valve reflux and incompetence.² Possible complications of these conditions are skin ulceration and ulcer rupture. Ulcer rupture could be spontaneous or a consequence of mild/trivial traumas.³ In such cases, a large amount of blood around the victim may lead to the hypothesis of violent death, whereas the real cause of death usually is hemorrhagic shock due to the spontaneous bleeding from the ulcer. Therefore, the forensic pathologist has to distinguish between natural or violent death, which is not always obvious. Even if blood loss is a frequent scenario, the diagnosis of hemorrhagic shock is not easy to prove, and often is a diagnosis of exclusion.⁴⁻⁶ Herein, the case of a woman found dead in a pool of blood with no apparent traumatic lesions is presented.

Case Report: A 90-year-old woman, who lived alone, was found dead at her home. The corpse was slumped on the toilet bowl with a huge blood stain on the floor. A closer look at the body revealed a stain of blood running down her left leg, as well as a blood-soaked towel tied around it. There were many bloody footprints in the bathroom and other rooms. A judicial autopsy was performed to establish the cause of death and exclude the hypothesis of a crime. The external examination showed pale skin and mucous membranes, abundant blood staining of the lower limbs with a point-like solution of continuity, with telangiectasias on the nearby skin, located on the mid-lateral aspect of the left leg, 34cm above the calcaneus. A careful squeezing of the lesion resulted in leaking of some blood drops. There were no other traumatic lesions. The internal examination revealed pale organs. Histologic studies were undertaken on formalin-fixed tissue from all organs, showing non-specific morphological findings (hemorrhage and parenchymal necrosis) consistent with "shock organs." The left leg skin lesion was also sampled. The histological examination showed a segment with removal of the epidermis and dermis with consequent deep dermis exposure. Additionally, diffuse chronic atrophic skin changes were seen. Toxicological screening was negative. The complete autopsic procedure and histological examination of organ tissues excluded any alternative cause of death, so eventually the death was attributed to hemorrhagic shock.

Varicose Veins, Ulceration, Fatal Hemorrhage

H70 Death by Arterial Injury: Two Unusual Cases of Sharp Force Fatalities

Lavinia Pellegrini, MD, Sapienza University, Rome, Italy; Fabio Delduca, MD; Sapienza University, Rome, Italy; Paola Santoro, MD, Sapienza University, Rome, Italy; Andrea Costantino, MD; University of Pisa, Pisa, Italy; Giacomo Visi, University of Pisa, Pisa, Italy; Giacomo, MD, University of Pisa, Pisa, Italy; Alice Chiara Manetti, MD, University of Pisa, Pisa, Italy*

Learning Overview: In the reported cases, a great number of peculiarities were observed: unusual location of the injuries, armpit in the first case and lower leg in the second; manner of injuries, accidental fall in Case 1 and stabbing in Case 2; cause of death, massive blood loss owing to a single artery injury in both cases.

Impact Statement: This presentation will impact the scientific community by showing how only a complex investigative approach, with correct interpretation of circumstances of death, in conjunction with a detailed autopsy examination (both macroscopic and microscopic) along with toxicological analysis, represents the best practice for the discrimination of such unusual deaths.

Fatalities due to sharp force trauma may be homicidal, self-inflicted, or accidental, and they represent 10-20% of clinical forensic examinations. Moreover, homicide by sharp force (stabbing) is one of the most common in European countries, involving generally domestic or interpersonal conflict. Wounds to the head, limbs, hands, neck, or back are consistent with homicide, while injuries affecting the anterior part of the trunk, the neck, or forearms, are predictive of suicide.

This presentation aims to discuss two rare cases of sharp force fatalities, showing how forensic pathology methodology, including death scene investigation, autopsy examination, and toxicological analyses, are pivotal to detect the manner of death. These two rare cases deal with an accidental event and a murder.

The first is about a complete transection of the axillary artery caused by an accidental stab injury on the right armpit of a 57-year-old man. The event dynamics relate to a fall on a piece of sharp glass. Toxicological analysis was extremely meaningful, as it proved the presence of alcohol in blood (2.56g/L), urine (3.55g/L), and gastric (2.48g/L) fluid samples.

The second case deals with another atypical death of a 41-year-old man: a single stab wound on the leg causing a 0.5cm linear full-thickness lesion of the anterior tibial artery. The cause of death was attributed to massive external blood loss owing to the right anterior tibial artery lesion, following a scissor stabbing.

Sharp Force Injuries, Arterial Lesion, Accidental Death

H71 Postmortem Degradation of Porcine Skeletal Muscle Proteins During a Heat Wave in Northern Germany

Janine Geissenberger, MSc, University of Salzburg, Salzburg, Austria; Jens Amendt, PhD, Goethe-University of Frankfurt, Hesse, Germany; Fabio C. Monticelli, PhD, University of Salzburg, Salzburg, Austria; Peter Steinbacher, PhD, University of Salzburg, Salzburg, Austria; Stefan Pittner, PhD University of Salzburg, Salzburg, Austria*

Learning Overview: With this presentation about postmortem protein degradation in different outdoor conditions and research regarding postmortem protein decomposition for Postmortem Interval (PMI) estimation, attendees will gain information about an innovative method to determine the time since death—a crucial topic in forensics.

Impact Statement: A precise determination of the time since death is of high importance in forensic routine. Further research in this field is required in order to expand the prevailing range of applications in forensic PMI estimation. Especially, analysis of muscle protein degradation has shown its potential to contribute to according mid- and long-term delimitations in practice. This publication will improve our understanding on postmortem protein degradation in realistic outdoor conditions in particular.

A most precise determination of the PMI is one of the major tasks and a continuous challenge in forensic routine. An innovative approach—based on the biochemical analysis of protein degradation patterns—has been developed that contributes to expand the prevailing range of applications in forensic PMI estimation. In particular, specific time points of degradation events of certain proteins provide reasonable markers for PMI delimitation. Nevertheless, considerable research is yet required to increase our understanding of protein decomposition and how it is affected by individual and environmental factors in order to provide a broad applicability of this method.

Following the scientific method, it is first required to exclude as many influencing factors as possible—for example by investigating postmortem protein degradation under controlled (and) standardized conditions. Previous studies/experiments showed predictable results of protein degradations patterns at different ambient temperature settings in a controlled environment. In a next step, it is important to apply the method in natural outdoor conditions in order to investigate the robustness of this method toward certain environmental influences.

Therefore, a field study was conducted using five pig carcasses, left to decompose under natural environmental conditions until full skeletonization. Muscle samples of the M. biceps femoris were collected daily, processed via Sodium Dodecyl Sulphate-Polyacrylamide Gel Electrophoresis (SDS-PAGE) and degradation patterns of selected proteins were identified by Western blotting. Unexpectedly, the planned sampling period turned out to be in the middle of a heat wave with temperatures significantly beyond average, allowing unique insights into degradation events under these (increasingly frequent) circumstances.

Due to the high ambient temperatures and substantial insect activity, the cadavers decomposed within only few days, allowing sufficient tissue sampling only until day 7. Results of the protein analysis interestingly showed that some proteins remained stable over the sampling period, while others displayed complete degradation of the native form, in part accompanied by distinct degradation products at defined PMI phases. This study provides evidence that muscle protein degradation patterns compare well between results from standardized experiments and this field study, despite extreme conditions.

Together with data from previous experiments at different ambient temperatures, results are expected to provide additional data to establish a reliable model of postmortem protein degradation for time since death estimation.

Protein Degradation, PMI, Environment

H72 A Cocaine-Related Left Ventricle Rupture: A Case Report

Gabriele Licciardello, MD*, Legal Medicine, Department of Medical, Surgical and Advanced Technologies, G.F. Ingrassia, University of Catania, Catania, Sicily, Italy; Federico Privitera, MD, Legal Medicine, Department of Medical, Surgical and Advanced Technologies, G.F. Ingrassia, University of Catania, Catania, Sicily, Italy; Massimiliano Esposito, MD, Legal Medicine, Department of Medical, Surgical and Advanced Technologies, G.F. Ingrassia, University of Catania, Catania, Sicily, Italy; Edmondo Scoto, MD, Legal Medicine, Department of Medical, Surgical and Advanced Technologies, G.F. Ingrassia, University of Catania, Catania, Sicily, Italy; Sabrina Franco, MD, Legal Medicine, Department of Medical, Surgical and Advanced Technologies, G.F. Ingrassia, University of Catania, Catania, Sicily, Italy; Aldo Liberto, MD, Legal Medicine, Department of Medical, Surgical and Advanced Technologies, G.F. Ingrassia, University of Catania, Catania, Sicily, Italy

Learning Overview: The goal of this paper is to examine the contribution of cocaine abuse in a rare case of heart rupture.

Impact Statement: This presentation will impact the forensic science community through the provision of a proper autopsy technique, a complete toxicological analysis, and a histological examination, in order to describe the correlation between the role of acute consumption of cocaine and cardiac rupture in cocaine abuse.

Cocaine, an alkaloid extracted from the leaves of coca, is a sympathomimetic drug that mainly determines effects on the central nervous system and cardiovascular tone. Cardiovascular complications are among the most common and dangerous adverse effects of cocaine abuse and include cardiac arrhythmias, hypertension, acute myocardial infarction, infective endocarditis, ventricular dysfunction, dilated cardiomyopathy, hypotensive shock, and stroke.¹ This presentation describes a cardiac death of a cocaine chronic abuser. An accurate autopsy, macroscopic, microscopic findings, and toxicological analysis confirmed that cocaine had a crucial role in the cause of death. The habitual use of cocaine is likely to be the main feature of the histological heart changes. The acute intake of cocaine induced an increase of circulating catecholamines, with a consequent increase of inotropism and chronotropism ending in a massive ventricular rupture.

Case Report: A 56-year-old man was found dead on the street in the early morning. The body temperature was 100.4°F (38.5°C), the environmental temperature was 60.8°F (16.5°C), hypostasis moved completely to the newly dependent zones, and rigor mortis was absent. At external examination, no lesions were found. A complete autopsy was performed. Anatomical dissection by single planes was performed.² The heart postmortem examination showed a pericardium blood collection of 510ml and a full thickness tissue lesion of 3.5 x 3cm at the posterior wall of the left ventricle, which exposed the ventricular cavity and the papillary muscles. The histological investigation of heart samples showed diffuse areas of myocardial scarring, contraction band necrosis, perivascular fibrosis, colliquative myocytolysis, myofiber breakup, severe coronary sclerosis with critical stenosis of the anterior descending coronary artery, with up to 95% occlusion of the vascular lumen.³ Consequently, to verify the presence of xenobiotic substances, toxicological investigations were performed. The ratio (brain/blood) between the concentration of cocaine found in the brain (772.3ng/ml) and in blood (364.4ng/ml) was approximately 2.1, and affirmed that there was a recent consumption (15 minutes) of cocaine. The concentrations of cocaine detected (ng/ml), in the samples examined, are: urine 1,007.4, gastric contents 2.183, lung 261.4, liver 673.3, and kidney 721.4. The concentrations of BEG detected (ng/ml), in the samples examined, are: blood 140.8, urine 111.3, gastric contents 111.6, brain 95.9, lung 626.7, liver 637.3, and kidney 164.2. A hair sample was analyzed, too, and allowed to assess the chronic abuse of cocaine (cocaine concentration 38.7ng/ml, BEG concentration 4.7ng/ml). Conclusions: cocaine increases systemic blood pressure, heart rate, and contractility—the major determinants of myocardial oxygen demand. Concurrently, cocaine induces coronary vasoconstriction, thereby limiting oxygen delivery to the heart. This vasoconstriction occurs both in normal and diseased segments of artery but its effects are more pronounced in diseased segments. This vasoconstriction results from alpha-adrenergic stimulation coupled with endothelial endothelin (vasoconstrictor) production and nitric oxide (vasodilator) reduction.

This case serves as a reminder that in cases of heart rupture, a meticulous postmortem examination (proper autopsy technique, a complete toxicological analysis, and histological examination) and a careful history search for substance abuse is fundamental, in order to achieve a correct postmortem diagnosis.

Cocaine, Acute Intoxication, Heart Rupture

H73 Ischemic Heart Disease Due to Intramyocardial Amyloidosis and Undiagnosed Plasma Cell Myeloma

Nicole Stanley, MD*, University of Utah, Salt Lake City, UT and Utah Office of the Medical Examiner, Taylorsville, UT; Erik Christensen, MD, Utah Office of the Medical Examiner, Taylorsville, UT

Learning Overview: This presentation will inform attendees that occlusion of intramural small vessels by amyloid in the setting of systemic amyloidosis is a known, but infrequently encountered, cause of ischemic heart disease that should be considered in decedents with a clinical history strongly suggestive of ischemic heart disease but without epicardial coronary artery disease or known risk factors.

Impact Statement: Awareness of this entity will broaden the differential diagnosis in these rare but challenging cases of apparent ischemic heart disease, leading to correct identification and certification of cause of death, as well as providing timely answers for families and treating clinicians.

Greater than 90% of cases of ischemic heart disease, including angina pectoris and myocardial infarction, are attributed to obstruction of the epicardial coronary arteries by atherosclerotic lesions, which often progress slowly over time in patients with known risk factors that include obesity, hypertension, elevated cholesterol, smoking, diabetes, and family history positive for myocardial ischemia.¹ In rare cases, however, ischemic heart disease can occur in individuals without clinically apparent coronary artery disease or known risk factors.

Described here is a case of sudden death in a 61-year-old man with a 15-month history of exertional chest pain, diminished exercise tolerance, and fatigue. He was an avid runner, a non-smoker, and had no history of hypertension, hyperlipidemia, diabetes, or known family history of heart disease. Cardiac workup eight months prior to his death included an **Electrocardiogram** (EKG) showing atrial fibrillation with rapid ventricular response and incomplete left bundle branch block, echocardiogram showing a minimally diminished left ventricular ejection fraction that resolved on conversion to normal sinus rhythm, and left heart catheterization showing large, widely patent coronary arteries. He was heard moaning in the night and was subsequently discovered unresponsive by his family. Autopsy confirmed the absence of significant atherosclerosis in the major coronary arteries. However, the myocardium showed a mottled appearance, and multiple foci of acute and subacute myocardial infarction were identified on microscopic examination. Diffuse amyloidosis with luminal narrowing was identified in the intramural small vessels, highlighted by Congo Red special stains. Diffuse vascular amyloidosis was also identified in the lungs, liver, kidneys, spleen, thyroid, small bowel, and skeletal muscle. Finally, there was diffuse infiltration of the bone marrow by atypical, CD138-positive plasma cells. The cause of death was thus listed as ischemic heart disease due to amyloidosis of intramyocardial arteries, due to plasma cell myeloma.

Occlusion of intramural small vessels by amyloid in the setting of systemic amyloidosis is a known, but infrequently encountered, phenomenon. Furthermore, it is difficult to diagnose in the clinical setting and is most often discovered at autopsy or explantation.² Intramyocardial small vessel amyloidosis should be considered in decedents with a clinical history strongly suggestive of ischemic heart disease but without epicardial coronary artery disease or known risk factors.

Ingrassia, University of Catania, Catania, Italy; Monica Salerno, MD, Legal Medicine, Department of Medical, Surgical Sciences and Advanced Technologies G.F. Ingrassia, University of Catania, Catania, Italy*

Learning Overview: After attending this presentation, attendees will be able to focus the importance of external examination, of autopsy findings, and of the effects of contribution of small and big fauna to postmortem change and artifacts.

Impact Statement: During this kind of crime scene investigation, it is important to accurately discriminate the presence/absence of self-defense injuries on the deceased body, the amount of blood present in the scene, the presence of paw prints deriving from animal's paws, accessibility to the pets/wild animals, and between antemortem and postmortem wounds.

The discovery of decomposed bodies in a domestic setting is not an uncommon occurrence. Many animal species are members of this food chain. However, postmortem animal scavenging of their owner is not commonly reported but can occur when the main predisposing factors are social isolation, pets living free in the house, and a medical condition causing sudden death.¹ Postmortem animal activity is an important step in incorporating protein, fat, and carbohydrates in corpses to the food chain. Outdoor corpses may be attacked by many predacious and scavenger animals and exposed to complete destruction, and the bones and belongings of the dead person may be scattered all over a large area due to postmortem animal activity. Indoor corpses may be attacked by pets, domestic dogs, cats, ants, and rodents during the postmortem period.² Frequently, the face, hands, and legs are destroyed by postmortem animal interference as they are unclothed and thus easily accessible.³

Case History: A 76-year-old male was found dead in his house in an advanced state of decomposition. The house was in poor hygienic condition, and there was garbage and feces of probable canine origin everywhere on the floor. No blood was found at the scene. He was lying supine on the kitchen floor: the neck and head were exposed, while the chest and the lower part of the body were covered with a gym suit. The external examination showed a general mummification of tissues coexisting with an almost complete skeletonization of the viscerocranium with a complete absence of the teeth, tongue, and upper airways. The eyeballs and nasal cartilages were absent. Despite the skeletonization of the viscerocranium, the ears were only partly removed, and the scalp of the neurocranium had an increased consistency and hair. During the site inspection, the officers found a small dog, likely responsible for the scavenging. The next day a Computed Tomography (CT) scan evaluation was performed, which excluded traumatic head and bone lesions. A complete autopsy was performed one week after the discovery. While the brain was completely absent, the heart, lungs, and abdominal organs were reduced as the state of putrefaction advances with a massive and diffuse larval infestation. According to the postmortem changes, the time between the death and the recovery of the body was about 45–60 days. Histological examination of the wound edges on the face showed no obvious vital reaction. Toxicological analysis of the blood showed no significant alcohol levels or any other toxic substances.

Postmortem Damage, Predators, Skeletalization

H75 A Multidisciplinary Investigation of a Corpse Found at the Sea, With Particular Focus on the Use of Barnacles for the Estimation of the Time Spent in Water

Marco Torrisi, MD, Department of Medical and Surgical Sciences and Advanced Technologies, GF Ingrassia, University of Catania, Catania, Sicily, Italy; Fabrizio Vanaria, MD, Department of Medical and Surgical Sciences and Advanced Technologies, GF Ingrassia, University of Catania, Catania, Sicily, Italy; Manuela Coci, MD, Department of Medical and Surgical Sciences and Advanced Technologies, GF Ingrassia, University of Catania, Catania, Sicily, Italy; Paola Magni, MD, PhD, Forensic Science, Murdoch University, Murdoch, WA, Australia; Cristoforo Pomara, MD, PhD, Department of Medical and Surgical Sciences and Advanced Technologies GF Ingrassia, University of Catania, Catania, Sicily, Italy*

Learning Overview: The goal of this paper is to present the multidisciplinary investigation performed on a unknown corpse found in water. The corpse was in advanced state of decomposition and the study of barnacles led to the estimation of the Postmortem Interval (PMI).

Impact Statement: This presentation will impact the forensic community by informing attendees of the importance of a multidisciplinary forensic approach and the use of barnacles for PMI estimation.

Human remains can be found in water environments for multiple reasons such as accident, natural or mass disasters, homicide, and suicide. The characteristics of aquatic environments are many and varied and all unique in terms of biological, chemical, and physical properties. The decomposition process and the colonization of the remains are strictly related to these characteristics. As any other forensic medical investigation, when a corpse is recovered from an aquatic environment, primary tasks are the confirmation of the personal identification, the determination of the cause of death, and the estimation of the time since death (PMI).

To date, considering the difficulties in the evaluation of postmortem changes, several studies have suggested the use of aquatic organisms, such as macroinvertebrates and algae in both freshwater and saltwater environments, to aid in the estimation of the PMI. In particular, for cases that occurred in seawater, the analyses of the barnacles (Crustacea: Cirripedia) colonizing the remains and the clothes and the objects associated with it have proven to be able to provide important information both on the provenance of the corpse and the PMI. The present casework reports the multidisciplinary investigation performed on a corpse recovered in the Strait of Sicily in the Mediterranean Sea. The corpse was found in an advanced stage of decay, partially skeletonized and dismembered, with diffuse adipocere. Goose barnacles (*Lepas anatifera* L.; Crustacea: Cirripedia: Pedunculata) were found colonizing the items connected with the corpse (a watch, a single sock, and a shoe), the teeth, the exposed bones, and, for the first time, were also observed attached directly on the corpse's skin. A complete medicolegal investigation comprehensive consisting of a Computed Tomography (CT) scan and diatom-test allowed ascertainment of the cause of death by drowning, while the use of barnacles and oceanographical data were used to estimate the floating time and the journey traveled by the corpse. The DNA profile of the subject was uploaded in the official international databank; however, at present the identity of the subject remains unknown. Despite this case being still open, the multidisciplinary approach to this complex investigation should be used as a guideline for future similar cases.

Postmortem Investigation, PMI, Barnacles

H76 Bodies in a Pool of Blood: Murder or Natural Death?

Ingrassia, University of Catania, Catania, Sicily, Italy*

Learning Overview: The aim of this presentation is to prove that an accurate crime scene investigation, external examination, and autopsy is essential in case of sudden death due to the rupture of varicose veins.

Impact Statement: The purpose of this presentation is to consider, in crime scene investigations characterized by large bloodstains, the rupture of venous varices as the cause of death. Therefore, it is crucial to perform a detailed external examination of the lower limbs and a complete autopsy.

Varicose veins are tortuous and pathologically dilated vessels, due to the chronic increase in intraluminal pressure and the weakening of the supporting vessel wall.¹ Venous reflux originates from a connective tissue disorder or from the failure of the venous valves, which results in retrograde flow and stasis of venous blood in terminal branches of veins.

Some of the typical symptoms of chronic venous insufficiency include aching, itching, swelling, and heaviness in the legs, which can progress to skin changes and ulceration. There may be lower limb bleeding if a very superficial and friable vein is involved.²

Case Report: This presentation describes three cases of sudden death due to the rupture of varicose veins. In Case 1, a 61-year-old overweight male was found at home; the crime scene was characterized by some large bloodstains on the floor, rooms, and corridor, with some shoe print marks. The corpse presented a blue color of both lower limbs, related to a venous insufficiency. In the left foot, at 0.39 inches (1cm) inferiorly from the lateral malleolus, there was a bleeding round-shaped skin laceration, with a diameter of 0.11 inches (0.3cm). Case 2 was a 48-year-old male with congenital malformations in the chest, found in his room by his parents, surrounded by an extended blood area. The corpse presented an accentuation of the subcutaneous venous district that appeared purple with tortuous course and a cutaneous bleeding laceration on the extreme distal of left leg. Case 3 was an 83-year-old female undertreated with oral anticoagulants, found once again in a pool of blood. The external examination showed an irregular-shaped skin laceration measuring 0.27x0.59 inches (0.7x1.5cm) in the lateral side of the right leg. In Cases 1 and 2, a complete lower limb dissection was performed; malleolar regions showed: dorsal metatarsal veins, dorsal cutaneous venous arch, lateral marginal vein, small saphenous vein, and lateral dorsal cutaneous nerve. In Case 1, the muscular heads were detached from the distal insertion and overturned to allow the isolation and study of the vascular-nervous component (anterior artery and anterior tibial vein, a superficial peroneal nerve, and deep peroneal nerve). In Case 2, a hydraulic test was executed in the blood vessel below the skin lesion of the left leg; after clamping the interested vein tract, a syringe of water was administered into the vein, and liquid loss was observed from the blood vessel.

Rupture of Varicose Veins, Sudden Death, Large Bloodstains

H77 An Unusual Suicide Using a Screwdriver: A Case Report

Bayan Alzumaili, MD, Department of Pathology, Molecular and Cell Based Medicine, Icahn School of Medicine at Mount Sinai Hospital, New York, NY; Kristen Landi, MD, Office of Chief Medical Examiner, New York, NY; Avneesh Gupta, MD, Office of Chief Medical Examiner, New York, NY*

Learning Overview: After attending this presentation, attendees will be aware that the presence of multiple weapons at the scene necessitate careful examination of the wounds' entrances, tracks, and exits.

Impact Statement: The impact of this presentation is that screwdrivers, although non-lethal most of the time, can be used as a method of suicide.

Suicide by sharp force to the neck is relatively uncommon, and complex suicide using more than one method is rare. Screwdrivers are unusual weapons for suicide. Herein is described a case of a middle-aged male with history of depression, valvular heart disease, and methadone use, who was found face down in a pool of blood in his locked apartment. At scene were a blade knife with dried blood and a bottle of soap spilled on the floor. In the kitchen, open boxes of naloxone were seen, along with a white powder. There were three empty methadone bottles found on the bed. There were suicide notes found on the bed and in the kitchen. The decedent had a sharp force stab wound on the right side of the neck that penetrated up to the strap muscles. The wound on the midline of the neck had a screwdriver embedded in the wound track with a hilt mark. This stab wound had sharp margin and angled ends, consistent with a stab injury from a knife. The lower margin of the wound showed some irregularity of the sharp margin, which probably represents an additional injury created by the screwdriver. The stab wound(s) penetrated the anterior neck, the tongue, and came out into the oral cavity and penetrated the palate of the upper jaw with the tip of the screwdriver embedded within the roof of the hard palate. The tongue showed three stab wound tracks with a star shape (screwdriver) wound on the right-side angle of the tongue, and two teardrop wounds (knife) on the right anterior and posterior tongue. There were corresponding wounds on the pharynx in the midline of the upper jaw (corresponding to the star-shaped screwdriver), and teardrop wounds on the right side of the pharynx. The track wounds stopped at the roof of the upper hard palate and did not penetrate the skull cavity or injure the brain. Postmortem toxicology showed methadone (1447ng/ml) and fentanyl (0.24ng/ml). Death was attributed to combined methadone intoxication and exsanguination of blood from the neck and tongue, caused by the knife and the screwdriver stab wounds, with preexisting heart disease and fentanyl intoxication as a contributing factor. This study describes the first case of combined knife and screwdriver stab wounds using the same point of entry and resulting in multiple paths.

Suicide, Multiple Stab Wound, Screwdriver

H78 Post-Vaccination Myocarditis and Thrombosis: Monitoring Strategies and Impact on the Vaccines' Benefit-Risk Assessment

Giulio Perrone, MD, Department of Health Promotion, Mother and Child Care, Internal Medicine and Medical Specialties, Section of Legal Medicine, University of Palermo, Palermo, Italy; Clio Bilotta, MD, Department of Health Promotion, Mother and Child Care, Internal Medicine and Medical Specialties, Section of Legal Medicine, University of Palermo, Palermo, Italy; Corinne La Spina, MD, Department of Health Promotion, Mother and Child Care, Internal Medicine and Medical Specialties, Section of Legal Medicine, University of Palermo, Palermo, Italy; Vanessa Milazzo MD, Department of Health Promotion, Mother and Child Care, Internal Medicine and Medical Specialties, Section of Legal Medicine, University of Palermo, Palermo, Italy; Giuliana Malandrino, MD, Department of Health Promotion, Mother and Child Care, Internal Medicine and Medical Specialties, Section of Legal Medicine, University of Palermo, Palermo, Italy; Valeria Provenzano, MD, Department of Health Promotion, Mother and Child Care, Internal Medicine and Medical Specialties, Section of Legal Medicine, University of Palermo, Palermo, Italy; Daniela Guadagnino, MD, Department of Health Promotion, Mother and Child Care, Internal Medicine and Medical Specialties, Section of Legal Medicine, University of Palermo, Palermo, Italy; Mario Spanò, MD, Department of Health Promotion, Mother and Child Care, Internal Medicine and Medical Specialties, Section of Legal Medicine, University of Palermo, Palermo, Italy; Walter Pitingaro, MD, Department of Health Promotion, Mother and Child Care, Internal Medicine and Medical Specialties, Section of Legal Medicine, University of Palermo, Palermo, Italy; Mattia Palmeri, MD, Department of Health Promotion, Mother and Child Care, Internal Medicine and Medical Specialties, Section of Legal Medicine, University of Palermo, Palermo, Italy; Valeria Tullio, PhD, Department of Health Promotion, Mother and Child Care, Internal Medicine and Medical Specialties, Section of Legal Medicine, University of Palermo, Palermo, Italy; Stefania Zerbo, PhD, Department of Health Promotion, Mother and Child Care, Internal Medicine and Medical Specialties, Section of Legal Medicine, University of Palermo, Palermo, Italy; Antonina Argo, PhD, Department of Health Promotion, Mother and Child Care, Internal Medicine and Medical Specialties, Section of Legal Medicine, University of Palermo, Palermo, Italy*

Learning Overview: This presentation will inform attendees of the impact of mass vaccination during the COVID-19 pandemic and its adverse effects.

Impact Statement: This presentation will impact attendees by presenting what is known of the autaptic and histological findings concerning post-vaccination death.

Introduction: The COVID-19 pandemic has made it necessary to shorten the time of research because of its high transmissivity. Two types of vaccines were developed with two different technologies: viral vector and messenger RNA (mRNA). Thrombosis and myocarditis are considered the most frightening complications of these vaccines.¹⁻⁴

Materials: Case 1: A 45-year-old female with abdominal pain was hospitalized 12 days after the administration of the first dose of viral vector vaccine. The Computed Tomography (CT) scan revealed a splenic-mesenteric-portal thrombosis and the laboratory tests highlighted a severe thrombocytopenia without predisposing factor. Case 2: A 61-year-old female suffering from hepatic cirrhosis and renal failure was found dead the morning after the second dose of mRNA vaccine; it was a case of sudden death because of the absence of detectable signs or reported symptoms. Case 3: A 63-year-old male, suffering from diabetes mellitus, hypertension, bronchopulmonary chronic obstructive disease, and schizophrenia was found dead less than three days after the first dose of mRNA vaccine.

Results: Case 1: Autaptic and histologic findings confirmed a mesenteric, hepatic, pancreatic, and splenic venous thrombosis. Case 2: The autopsy and the histologic exams only revealed the presence of acute pulmonary edema. Case 3: The autopsy and the histologic exams showed pulmonary thromboembolism, aortic thrombosis, and myocarditis.

Discussion: The post-vaccination myocarditis and thrombosis currently remain the most frightening adverse effects observed during the mass anti-COVID-19 vaccination. It is already possible to outline a few differences between the two complications, although the final epidemiological-statistical results are still waited upon completing the vaccination campaign. Myocarditis was observed most frequently following the administration of mRNA vaccines' second dose, as opposed to thrombosis mainly occurring following the first dose of viral-vector vaccines, less often following mRNA vaccines, as the Case 3 illustrates. Myocarditis further involved more male subjects younger than 30 years, although it can also afflict elderly subjects, such as in Case 3; thrombosis had a female prevalence and a high age heterogeneity. The median time to onset of symptoms was three days for myocarditis, and 8-16 days (viral vector vaccine) or <3 days (mRNA vaccines) for thrombosis. It is assumed that the mRNA could be considered as antigen by the immunological system activating an innate and acquired immune response with a consequent proinflammatory cascade developing the myocarditis.

There would seem to be an immune-mediated mechanism at the base of thrombosis, with antibodies against the complex PF4-polyanions as protagonists. A genetic predisposition is hypothesized in both cases. Myocarditis showed a basically positive outcome in contrast to the high mortality of thrombosis; for this reason, the diagnosis and therapy of myocarditis can be made at the moment of hospitalization and modulated according to the specific case. The thrombosis' poor prognosis requires an early diagnosis and specific monitoring strategies put in place between the third and tenth day following the vaccination through the monitoring of platelets and antibodies.

The benefit-risk assessment for both types of vaccines demonstrated a positive balance, independent of age or gender, because of the positive outcome of myocarditis and the low thrombosis' incidence (approximately 1:100.00/1.000.000). The results of autaptic exams were awaited to evaluate vaccine-related mortality and exclude the cases in which vaccination was only the context of the event, such as in Case 2.

Conclusion: Further studies and final epidemiological data are awaited to verify the positive balance of the benefit-risk assessment for both types of COVID-19 vaccine, the incidence and mortality rate of post-vaccination cardiomyopathy and thrombosis, and their long-term impact. The current lot suggests that monitoring and prevention strategies for the thrombosis could be useful during the mass vaccination for COVID-19 with both types of vaccines.

Vaccine Adverse Effects, COVID-19 Vaccination, Vaccine-Related Complications

H79 Sudden Cardiac Death and Thymic Hypertrophy: A Recurrent Cycle in Medicine

Simona Nicoli, MD, University of Bari, Bari, Italy; Marcello Benevento, MD, University of Bari, Bari, Italy; Giampiero Bottari, MD, University of Bari, Bari, Italy; Simona Nicoli, MD, University of Bari, Bari, Italy; Cristina Elena Rosa Caterino, MD, University of Bari, Bari, Italy; Francesco Clemente, MD, University of Bari, Bari, Italy; Biagio Solarino, PhD, MD, University of Bari, Bari, Italy*

Learning Overview: After attending this presentation, attendees will appreciate the importance of the extensive heart examination in sudden unexpected deaths and will also have a short review concerning the “myth” of thymic death.

Impact Statement: This presentation will encourage further in-depth studies concerning the relation between thymic hypertrophy and cardiovascular pathology by the forensic science community.

Sudden cardiac death is a major public health issue worldwide. The exact incidence rate of sudden cardiac death in young adults remains unclear and is generally thought to be underestimated. The most common mechanism of a cardiac arrest leading to sudden death is abrupt ventricular fibrillation because of an underlying cardiovascular disease.¹

This presentation reports the case of a 24-year-old man, with a silent personal and familiar medical history, who suddenly collapsed in a restaurant during dinner with workmates. The man did not smoke and was an amateur soccer player; he was 172cm tall and weighed 78kg.

Toxicological examinations were negative. Immunological examines excluded anaphylactic shock. The autopsy did not show macroscopic lesions, but the extensive study of the heart's conduction system along with specific histological examinations detected atrioventricular node fibrosis. The fibrosis has been pointed out using Masson's Trichrome stain.

Furthermore, the autopsy drew attention to the 13cm wide hypertrophic thymus. The histological examinations of the thymus did not relieve any structural alteration. In the past, thymic hypertrophy was considered a cause of sudden death and part of some nosographic entities like status lymphaticus or thymic asthma.^{2,3} The so-called “thymic death” remained consigned to the history books until 2017 when a Chinese study⁴ reclaimed the hypothesis of the correlation between thymic hypertrophy and sudden death through an immunological point of view.⁴

Sudden unexpected death remains a big issue for pathologists and requires full autopsy and ancillary exams to be carried out. The present case reported infrequent heart disease, with any known underlying cause, and thymic hypertrophy. Is this a coincidence? Should the myth surrounding the “thymic death” be re-examined?

Sudden Cardiac Death, Atrioventricular Node Fibrosis, Thymic Death

H80 A Rare Case of Sudden Death Due to Endomyocardial Fibrosis in Italy: A Differential Diagnosis With Other Causes of Restrictive Cardiomyopathy

Chiara Rossetti, MD, Department of Medicine and Surgery, University of Insubria, Varese, Varese, Italy; Giacomo Belli, MD, Department of Public Health, Experimental and Forensic Medicine, University of Pavia, Pavia, Italy; Paola Braga, MD, Department of Public Health, Experimental and Forensic Medicine, University of Pavia, Pavia, Italy; Lorenzo Franceschetti, MD, Department of Medical and Surgical Specialties, Radiological Sciences and Public Health, University of Brescia, Brescia, Italy; Cesare Garberi, MD, Department of Biotechnology and Life Science, University of Insubria, Varese, Italy; Mario Picozzi, MD, Department of Biotechnology and Life Science, University of Insubria, Varese, Italy; Jutta Maria Birkhoff, MD, Department of Biotechnology and Life Science, University of Insubria, Varese, Italy*

Learning Overview: This presentation allows attendees to acquire more information about endomyocardial fibrosis, especially regarding its macroscopical and histological characteristics.

Impact Statement: Attendees will be impacted by being informed that in sudden death, a detailed and complete differential diagnosis could be very important, including any uncommon pathology.

Endomyocardial Fibrosis (EMF) is an uncommon restrictive cardiomyopathy leading to congestive heart failure. The disease is characterized by deposition of fibrous tissue in the endocardium and, to a lesser extent, in the myocardium, usually affecting the apical region of the right or left ventricle, or both. It is most common in regions with high air humidity within tropical countries, in particular, in the eastern and central regions of Africa. Rare cases were native Europeans who stayed in tropical countries for a long period of time. Endomyocardial fibrosis frequency has a bimodal peak at age 10 and age 30. The majority of studies do not show any difference between the sexes.

In this case, a 45-year-old Indonesian woman was admitted to an Italian hospital with nausea, vomiting, abdominal pain, and tachyarrhythmia. Atrial fibrillation was found at Electrocardiogram (ECG) and blood tests showed mild hepatic function alterations. Thoraco-abdominal echography and Computed Tomography (CT) showed bilateral pleural effusions, ascites, and hepatomegaly. Physical conditions and laboratory results worsened rapidly, followed by multi-organ failure. Systolic and diastolic functions of the left ventricle were found to be strongly compromised at US. Death occurred 28 hours after admission.

An autopsy was performed to clarify the cause of death. It showed jaundiced skin, bilateral pleural and pericardial effusions, ascites, mild cardiomegaly, ventricular endocardial fibrosis, a thrombus in tight junction to the left ventricular wall, and hepatic necrosis.

Histological investigations revealed a massive endomyocardial fibrosis, easily detected through Hematoxylin-Eosin, Verhoef-Van-Gieson, Azan-Mallory stain. Congo Red stain was also performed and was negative. Toxicological investigations were negative; the paracetamol level was under the therapeutic range. Pneumococcal, EBV, CMV, HBV, HCV, and HIV antigens and bacterial cultures on blood samples were all negative.

The cause of death was a global cardiac dysfunction caused by a restrictive cardiomyopathy in an Indonesian woman affected by an undiagnosed and asymptomatic endomyocardial fibrosis. In particular, differential diagnosis between other causes of restrictive cardiomyopathy (amyloidosis, endocardial fibroelastosis) have been excluded.

Endomyocardial Fibrosis, Autopsy, Sudden Death

H81 Formalin-Fixed Paraffin-Embedded (FFPE) Extraction of DNA From Tumor Samples: A Revolutionary Breakthrough

Kelly Burns, BS*, Ohio Northern University, Ada, OH; Dennis DeLuca, PhD, Ohio Northern University, Ada, OH

Learning Overview: The goal of this presentation is to inform attendees as to how important DNA extraction from formalin-fixed material will be for forensic science.

Impact Statement: Previous studies have been performed on FFPE DNA extraction; however, those samples were specifically non-tumor samples. This presentation looks at the efficacy of this extraction method of tumor samples. This is important for forensics since tumors are a part of normal tissue. This study is to compare tumor tissue to normal tissue.

Extraction of formalin fixed tissues would be an extraordinary advancement in DNA for the forensic science community. An extremely beneficial impact it creates is FFPE extraction, which can recover vital DNA that was previously unrecoverable, such as cases where tissue was previously scarce and degrading and needed fixation.^{1,2} Recovery is invaluable for these unknown or extremely uncommon DNA samples.

There have been previous techniques on non-tumor specimens, such as prostate biopsies, liver, brain, and other autopsy samples.³ These studies led to the question of FFPE DNA extraction from tumor blocks originating from differing organ samples to determine the efficacy of said technique. So far, DNA extraction is entirely possible; however, further testing is still needed to determine the best methods and techniques for a complete, successful extraction.

In this presentation, the FFPE QIAGEN® tissue kit was used for extraction of the DNA, and results were taken from multiple tumor blocks with sources from colon and kidney samples taken from both St. Rita's and Lima Memorial hospitals in Lima, OH.⁴ As of present, Reverse Transcription Polymerase Chain Reaction (RT-PCR) was used to determine positive or negative extractions as well as sex to look for contamination between different gendered blocks of the same tumor. The results showed a positive DNA sample for both the male and female extractions with 17.5985nm/μL and 376.194nm/μL of DNA extracted, respectively.⁵ Further testing and extractions are still needed to determine efficacy, yet the current data yields promising results for future developments.

FFPE, DNA, Extraction

H82 Chronic Mineral Oil Aspiration: A Case of Exogenous Lipoid Pneumonia

Valeria Prandini, MD*, Department of Public Health, Experimental and Forensic Medicine, University of Pavia, Italy; Chiara Franzetti, MD, Department of Public Health, Experimental and Forensic Medicine, University of Pavia, Italy; Gianmarco Di Palma, MD, Department of Public Health, Experimental and Forensic Medicine, University of Pavia, Italy; Paolo Musto, MD, Department of Public Health, Experimental and Forensic Medicine, University of Pavia, Italy; Alessandra Radogna MD, Department of Public Health, Experimental and Forensic Medicine, University of Pavia, Italy; Silvia Visonà, MD, PhD, Department of Public Health, Experimental and Forensic Medicine, University of Pavia, Italy; Luca Morini, PhD, Department of Public Health, Experimental and Forensic Medicine, University of Pavia, Italy; Matteo Moretti, MD, Department of Public Health, Experimental and Forensic Medicine, University of Pavia, Italy

Learning Overview: After attending this presentation, attendees will be able to identify peculiar macroscopic and histopathologic findings associated with lipoid pneumonia.

Impact Statement: This presentation will impact the forensic science community by improving the ability to identify a rare form of interstitial pneumonia, combining anamnestic and clinical data with histological findings.

Lipoid pneumonia is an unusual form of interstitial pneumonia characterized by the presence of lipid drops in macrophages and throughout the pulmonary parenchyma. Depending on the source of the lipid/oil in the respiratory tract, its etiology can be endogenous (bronchial obstructions such as those caused by neoplasms) or exogenous (aspiration of animal fats or vegetable/mineral oils). Due to its rarity and its insidious clinical presentation, characterized by non-specific respiratory symptoms and radiological findings, the diagnosis of lipoid pneumonia may be challenging in both clinical and postmortem settings.^{1,2}

Case Report: An 83-year-old man, living in a care facility since 2012, with an history of cognitive impairment, Parkinsonism, dysphagia, and diabetes mellitus developed symptoms of a lower airways infection in November 2020. Therefore, an antibiotic (cephalosporin) was added to the man's usual medications, which consisted of an oral anticoagulant, antidiabetic drugs, a neuroleptic sedative, and a mineral oil as a laxative. Despite the given therapy, his symptoms progressively worsened over the following weeks; for this reason, different antimicrobial agents were administered (fluoroquinolones) and the patient tested negative twice for SARS-CoV-2. On the last days of December, signs of pulmonary edema and cardiac failure were detected; all therapeutic efforts were unsuccessful, and the death was declared a few hours later.

Postmortem examination revealed pleural and pericardial effusion, right-heart dilation, bullous pulmonary emphysema, yellowish mucus in the tracheobronchial tree, pulmonary edema, and parenchymal consolidation of the lower lobes. All the collected organ samples were formalin fixed and paraffin embedded, then stained with Hematoxylin-Eosin (H&E). In the site of the pulmonary consolidation, histological findings showed large fibrotic areas interspersed with cystic spaces surrounded by macrophages containing globules of lipid material, dilated capillaries, and fibroblasts. In addition, an organizing exudate composed of numerous granulocytes, plasma cells, and lymphocytes was observed.

The macroscopic and histologic postmortem findings allowed identification of the cause of death as a respiratory failure resulting from acute on chronic pulmonary alterations, which could be attributed to lipoid pneumonia. The etiology of this condition may be ascribed to the continuous aspiration, due to the man's dysphagia, of small droplets of mineral oil, chronically taken for laxative purposes.³

H83 Tell Me What You Ate and I'll Tell You When You Died

Fabio Policino, MD, PhD, University of Naples Federico II, Naples, Campania, Italy; Emanuele Capasso, MD, PhD, University of Naples Federico II, Naples, Campania, Italy; Pierpaolo Di Lorenzo, University of Naples Federico II, Naples, Campania, Italy; Serena Dei Medici, MD, University of Naples Federico II, Naples, Campania, Italy; Mariagrazia Marisei, MD, University of Naples Federico II, Naples, Campania, Italy; Gianluca Auriemma, MD, University of Naples Federico II, Naples, Campania, Italy; Massimo Niola, University of Naples Federico II, Naples, Campania, Italy*

Learning Overview: This presentation aims to highlight the importance of tanatochronology.

Impact Statement: This presentation will impact the forensic science community by presenting evidence on the importance of the gastric content study in order to establish the time of death and the role of different eating habits.

Assessing the correct timing of death is one of the biggest priorities in forensics, being of great interest when determining and identifying an eventual liability in someone's death. It is made harder when bodies are kept at a controlled temperature in cold rooms. The study of gastric content is, hence, crucial.

The following work will analyze and discuss the case of a 76-year-old male, found dead on the morning of November 27, 2017, at a residence in southern Italy by his son at 9.30 a.m. Although noticing the total absence of vital signs, the son called the emergency number. The ambulance arrived at 12:40 p.m., after the intervention of the police. The son eventually made a statement against the emergency department, stating that an immediate intervention at the time of the first call would have saved his father. No investigation on the spot was performed. In order to replay a judicial question, it was essential to identify the time of death, so the autopsy was performed.

The external cadaveric examination showed fixed hypostases, consensual with the supine lying, resolution of the corpse rigidity, and body temperature lower than the ambient one, compatible with the permanence of the corpse in the cold room. Autopsy revealed bilateral pulmonary congestion, heart concentric increase, and dilated aortic lumen with atheromatous alterations, in particular at the level of the aortic ascending tract. The cause of death was identified in the fissuring of the vascular intima of the ascending aorta with consequent onset of arterial thromboembolic phenomena. The stomach was filled with abundant poltaceous material with corpuscular elements, including fragments of mollusks and vegetables in the absence of appreciable free liquid content. Toxicological analyses excluded the presence of xenobiotic substances involved in death.

In this case, not being able to base the thanatochronological evaluation on classic cadaveric phenomena, the study of the gastric contents and its emptying was helpful. The gastric emptying variables are therefore correlated to quantity and quality of food eaten.¹⁻³ Generally, abundant solid meals leave the stomach after the liquid component, and higher calorie meals leave the stomach slower. Easily digestible solid meals leave the stomach between three and five hours, while abundant solid meals leave between five and eight hours.

In the present case, the gastric content was abundant without free liquid content. So, in consideration of the quantity and complexity of the gastric contents and of scientific data concerning gastric physiology, it was possible to conclude that the death occurred within 5–8 hours from the end of the meal. Moreover, the presence of fragments similar to mollusks and vegetables led to the belief that the gastric content was compatible with that deriving from a lunch or more likely a dinner, according to the most common eating habits in the birthplace of the deceased (Naples), of his residence, and the discovery of the body.

In any case, even in the hypothesis that the death occurred very late with respect to the interval indicated above (up to about 5.30), a timely intervention by the 118 health workers following the first phone call, the deceased would have been dead at least four hours anyway. As a result, not only studying the gastric content crucial to determine the time of death in absence of other elements but also knowing the cultural differences among eating habits and geographical areas made it possible to refer a meal to a certain time of the day.

Learning Overview: After attending this presentation, attendees will be aware of an unusual kind of electrocution caused by low-voltage electric current and of the hazardousness of smart phone use in bathtubs.

Impact Statement: This presentation will impact the forensic science community by explaining the importance of an integrative and multidisciplinary approach in cases of death by suspected electrocution.

Death from electrocution is caused by the passage of electric current through the body. It can cause a wide range of injuries, local or systemic, or even death, depending on several specific characteristics, such as amperage, voltage, and frequency. Every electrical device, under certain circumstances, can cause electrocution, even an apparently harmless mobile phone. Although for most people picking up the phone anytime is as natural as breathing and it is regarded as one of the most run-of-the-mill, low-risk things we can do, actually it is not always true.^{1,2}

In a small city in northern Italy, a 32-year-old man was found dead in his bathtub after an electrical blackout. The emergency response team could only confirm the death. The body was naked and presented an intense rigor mortis. Furthermore, the man's mobile phone, still plugged to the main electricity circuit via a power cord and an extension cord, was found immersed in the water of the bathtub. A forensic investigation was requested by the prosecutor in order to clarify the cause and manner of death. A site inspection and a forensic autopsy were performed, during which tissue samples and biological fluid were taken in order to carry out histological and toxicological investigation. Sections of skin lesions, collected with a ceramic scalpel, were analyzed using suitable histological staining (Hematoxylin-Eosin [H&E] and Perls' staining), then Scanning Electron Microscope (SEM) equipped with Energy Dispersive X-Ray Spectroscopy (EDS).^{3,4} Moreover, an engineer was asked for additional consulting in order to better define the dynamic of the event. At external examination, circumscribed and superficial burns with a central zone of pallor were detected; they involved the right arm, the right hand, and the trunk. Here they were characterized by a striped-shaped lesion, extended from the right chest to the ipsilateral inguinal area, ending in a figured, rectangular burn with a size of 20 x 8cm (this lesion matched well with the phone found in the bathtub). At autopsy, the morphological findings were non-specific. Several petechiae were detected on conjunctiva, the oral cavity, heart, and lungs, together with diffuse visceral congestion. The histological examination of the skin lesions revealed the typical microscopic picture of a current mark. The diagnosis of electric mark was supported by Perls' staining and by the SEM analyses, which revealed metallic particles on the skin sample. Toxicological analysis conducted on the blood was negative. Furthermore, the engineering investigation found that the phone charger was counterfeit and did not meet safety regulation standards. In particular, the isolation was not sufficient to prevent an electric shock. On these bases, it was possible to conclude that the cause of death was an accidental electrocution.

To correctly identify this type of death, the integrated use of different tools is recommended, such as macroscopic observation, H&E, and iron-specific staining, and SEM analysis. Most importantly, every electronic device found on the scene should be considered as a potentially fatal source of electricity and properly investigated, asking for engineering consulting.

Electrocution, SEM, Accidental Death

H85 Drowning at Home: Risk Factors and Prevention in Adults

Adrienne Aardema, BS, Western Michigan Homer Stryker M.D. School of Medicine, Kalamazoo, MI; Theodore Brown, MD, Western Michigan Homer Stryker M.D. School of Medicine, Kalamazoo, MI; Joseph Prahlow, MD, Western Michigan Homer Stryker M.D. School of Medicine, Kalamazoo, MI*

Learning Overview: Attendees of this case series presentation will learn about the risk factors, autopsy signs, and prevention strategies of at-home drownings.

Impact Statement: This case series will impact the forensic community by showing that certain risk factors in adults are associated with at-home drownings, exploring autopsy findings in drownings, and suggesting prevention strategies for vulnerable patient populations.

Drowning occurs when submersion of the nose and mouth in water causes respiratory impairment. Since the volume of water required for drowning only needs to be enough to submerge the nose and mouth, there are multiple ways to drown at home. When filled with water, bathtubs, sinks, toilets, and buckets all pose potential risks. Drowning prevention is most commonly discussed with pediatric populations, but adults with certain medical and psychiatric conditions also have an increased risk of drowning. The risk of drowning increases when a patient is incapacitated in some way, whether through intoxication, seizure, syncope, cardiac arrhythmia, psychiatric illness, or other methods.^{1,2} The identification of risk factors and patterns in drownings can inform prevention strategies.

This presentation will examine five cases of drownings. The decedents range in age from 22 to 76 years old, and all are found deceased at home. The locations of these drownings include two bathtubs, a toilet, a pan, and a kitchen sink. The contributing causes include drug use, epilepsy, cardiovascular disease, schizophrenia, and Parkinson's disease. This presentation will explore the multiple risk factors for drowning, describe the autopsy findings associated with drowning, and discuss prevention strategies related to these cases.

One of the goals of forensic pathology is to identify patterns in mortality to further knowledge and to aid public health measures for prevention. Autopsy findings that indicate drowning, but are not necessarily universally present, include foam in the airway, lung hyperinflation, increased lung weight, and watery stomach contents.³ Since the autopsy findings for drowning are non-specific, careful examination of the scene is important for accurate determination of the cause of death. There are multiple risk factors for drowning, including drug use, seizures, cardiac conditions, and psychiatric conditions, and patients with these factors should be educated on prevention strategies.^{1,2} Strategies to prevent at-home drownings can include using showers instead of bathtubs, not leaving uncovered collections of water at home, and preventing vulnerable states of unconsciousness. By examining the patterns of at-home drownings, recommendations for prevention can be targeted to at-risk patient populations.

H86 The Differential Diagnosis Between Accidental Injury and Fatal “Shaken Elderly Syndrome”: Insights From a Case Report

Valentina Bugelli, MD, Azienda USL Toscana Sud-Est, Grosseto, Italy; Ilaria Tarozzi, MD, University of Florence, Florence, Italy; Matteo Cecchetti, MD, University of Florence, Florence, Italy; Arturo Abruzzese, MD, Santa Chiara Hospital, Pisa, Italy; Francesca Iannaccone, MD, Department of Surgical Pathology, Medical, Molecular and Critical Area, Institute of Legal Medicine, University of Pisa, Pisa, Italy; Marco Di Paolo, MD, Department of Surgical Pathology, Medical, Molecular and Critical Area, Institute of Legal Medicine, University of Pisa, Pisa, Italy*

Learning Overview: After attending this presentation, attendees will be aware that intracranial hemorrhages in elderly people may suggest fatal physical abuse.

Impact Statement: This presentation will impact the forensic science community by contributing to highlight the importance of a multidisciplinary approach to make differential diagnosis between accidental craniocerebral injuries and abusive head trauma in the elderly. This will increase awareness of medicolegal implications of the clearly underestimated elder abuse phenomenon.

An 82-year-old woman was found at home unconscious and unresponsive to the application of painful stimuli. Her nephew called an ambulance, reporting she had accidentally fallen, so the woman was taken to the emergency department. As multiple contusive lesions were present, on suspicion of physical abuse, the judicial authority was informed. A Computed Tomography (CT) scan identified bilateral subdural hematoma and left subcortical cerebral hemorrhage. No indication of neurosurgical treatment was given. Four days after unsuccessful intensive care, brain death was pronounced.

The autopsy performed three days later showed the presence of multiple excoriations and polychromatic bruises associated with macroscopic hematic infiltrate, mostly distributed among the head, thorax, arms, and legs. It showed a single hematoma of the inner aspect of the scalp, no fracture of the skull, bone callus on anterior arch of four ribs, and a mesenteric-ileal hemorrhagic area. After formalin brain fixation, the presence of bilateral subdural hemorrhage of about two centimeters (maximum thickness) and left temporo-occipital subcortical cerebral hemorrhage was confirmed. Basic histological examination using hematoxylin-eosin stain showed heterogeneous chronology of cutaneous lesions (from 4-5 days to 14-16 days before death) and different components of subdural hematoma (one dating 4-5 days before death, the other dating 16-18 days before death). Histological examination of the other organs was non-contributory.

Cause of death was classified as brain dysfunction due to large subdural hemorrhage. Since no coagulative disorders as well as spontaneous intracranial hemorrhages (such as intracerebral hemorrhage) were present, a traumatic origin of subdural hematoma was identified. According to the lack of signs of direct head trauma and the chronological correspondence between chronic subdural hemorrhage and the arms' bruises, subdural hemorrhage was considered the result of bridging veins rupture due to brain acceleration in the skull secondary to violent shaking.¹

“Shaken Baby Syndrome” is extensively described in literature, but intracranial findings of characteristic abusive head trauma are not limited to pediatric patients. When shaking as a traumatic mechanism is used in elderly people, it can be hard to differentiate abusive intracranial findings from spontaneous ones.^{2,3} Further studies are needed to identify effective and appropriate diagnostic criteria for “Shaken Elderly Syndrome,” particularly focusing on differences between spontaneous subdural hemorrhages and those due to shaking.

Shaken Elderly Syndrome, Subdural Hematoma, Elder Abuse

H87 A Fatal Case of Delayed Post-Tonsillectomy Hemorrhage: Potential Medicolegal Implications

Rasmey Thach, DO, William Beaumont Army Medical Center, Department of Medicine, Fort Bliss, TX; Lorenzo Gitto, MD, State University of New York, Upstate Medical University, Department of Pathology, Syracuse, NY*

Learning Overview: After attending this presentation, attendees will have a better knowledge of the frequency and significance of post-tonsillectomy complications, their outcomes, and potential medicolegal implications.

Impact Statement: This presentation will impact the forensic science community by presenting a peculiar case report in which the autopsy findings and the clinical evidence helped clarify the possible medicolegal issues involved in a fatal delayed Post-Tonsillectomy Hemorrhage (PTH) in a pediatric patient.

Tonsillectomy is one of the most common surgical procedures worldwide. Although it is considered routine surgery, several complications may happen. Among these, PTH is the most common and significant complication. The vast majority of PTH is generally easily managed, but life-threatening bleeding may rarely occur.

According to the literature, PTH represents a significant portion of malpractice claims against surgeons. Potential technical errors during the surgery represent the most common compliant. However, in cases with unintentional outcomes, questions arise about the surgical indication. Both surgical mistakes and the absence of a clear indication for surgery are considered medical errors, and medical malpractice can occur.

Presented here is the case of a 2-year-old Caucasian child with a history of severe Obstructive Sleep Apnea (OSA). A rhinolaryngoscopy examination revealed grade IV tonsillar hypertrophy. A sleep study revealed numerous, severe episodes of obstructive apnea with moderate/severe desaturations. The clinical scenario was consistent with severe OSA, and tonsillectomy was indicated.

Surgery was performed without intra-operative or early post-operative complications. The patient was discharged after 24 hours of uneventful observation in the hospital. A follow-up visit was performed six days after the surgery and did not reveal any complications or abnormalities. Approximately 36 hours after the follow-up visit, the patient experienced profuse hematemesis and loss of consciousness. He was immediately transferred to the local emergency department by ambulance, but he died during the travel. A medical malpractice lawsuit was filed against the hospital, primarily against the surgeon and the attending physician who performed the follow-up visit after the tonsillectomy. Thus, the legal authority ordered a medicolegal autopsy.

The autopsy revealed features of wound healing grossly in the tonsillar bed bilaterally, with evidence of fresh hemorrhage in the left tonsillar bed where an absorbable stitch was properly located. Dissection of the pharynx revealed possible involvement of the ascending palatine artery, in the context of healing process and artifacts due to the recent surgery. The lungs showed focal areas of possible blood aspiration. The digestive tract was filled with dark blood starting from the stomach and extending up to 160cm within the small bowel. Grossly normal, clear bowel content was present in the terminal ileum and colon. No other abnormalities were detected.

The forensic expert was asked to comment about potential medical errors and malpractice. A multidisciplinary approach was required to answer the questions asked by the legal authority. The approximate time of bleeding was roughly estimated based on the autopsy finding and a review of the clinical medical literature. Moreover, a thorough evaluation of the clinical history, documents, and guidelines allowed comment about the treatment's appropriateness and indication to the surgery.

A thorough discussion of the case from pathological, medicolegal, and clinical points of view will be presented to the attendees.

Forensic Science, Tonsillectomy, Medicolegal Implications

H88 Disseminated Fungal Infections at Forensic Autopsy

Amy Lorber, AB*, Western Michigan University, Homer Stryker MD School of Medicine, Kalamazoo, MI; Joseph Prahlow, MD, Western Michigan University, Homer Stryker MD School of Medicine, Kalamazoo, MI

Learning Overview: After attending this presentation, attendees will have a better understanding of the types of situations where disseminated fungal infections may be evident at autopsy, as well as the pathologic findings in such cases.

Impact Statement: This presentation will impact the forensic science community by highlighting several cases where disseminated fungal infections were found in cases presenting for medicolegal death investigation.

Fungal infections are an increasing source of morbidity and mortality worldwide with multiple factors contributing to their rise. One critical factor is a growing number of immunocompromised or transiently neutropenic patients due to hematopoietic stem cell and solid organ transplants, as well as the rising use of immune-modifying therapies.^{1,2} Climate change and our growing population are influencing the prevalence of endemic fungi and human exposure to them. Diagnostic tools for identifying fungal disease have rapidly advanced, including genetic testing through Polymerase Chain Reaction (PCR) and other molecular techniques.¹ However, symptoms of fungal infection are often non-specific and may mimic other infections or other disease, so correct diagnosis may be delayed and only occur after other work-up has failed.³ To diagnose and treat fungal infection requires awareness of fungal disease features. The public health threat of fungal infection is best addressed by increasing understanding and recognition of these diseases and risk factors.³ To this end, this study reports three cases of death due to fungal infections occurring in a Midwest United States medicolegal death investigation office.

In the first case, a 22-year-old White female, with a history of Noonan syndrome and a seizure disorder present from childhood, was discovered deceased in her home without any history of acute preceding illness. At autopsy, she was discovered to have evidence of chronic disseminated histoplasmosis, with granulomatous inflammation affecting her lungs, lymph nodes, spleen, kidney, and liver. The disseminated fungal infection was considered incidental.

The second case concerns a 24-year-old Cambodian male with a recent history of being “extremely ill,” but who had reportedly declined medical care. He had a history of marked weight loss and night sweats. He was reported to have a history of possible tuberculosis; however, according to records, his cultures never grew. He experienced a fatal cardiorespiratory arrest at his home. At autopsy, microscopic examination of the lungs showed diffuse granulomatous inflammation along with mixed inflammatory cell infiltrate with special stains positive for fungal organisms. There was also granulomatous inflammation in the lymph nodes, spleen, kidney, liver, pancreas, and thymus. Additionally, his skin showed fungal ulcerations. He was determined to have diffuse, systemic blastomycosis, which was considered the Cause Of Death (COD).

The final case involves a 59-year-old White female with a history of immunosuppression due to a bilateral lung transplant for the treatment of idiopathic pulmonary fibrosis. She was also suffering from chronic transplant rejection and was awaiting second transplant. She was found deceased in her home from apparent massive hemoptysis due to pulmonary hemorrhage from invasive aspergillosis with associated vascular wall necrosis.

Fungal diseases may have a diversity of presentation, from relatively asymptomatic to fatal, and disease can occur in a wide range of patients. These cases may be difficult to correctly diagnose or differentiate from other infectious agents; hence, the absence of diagnosis in these patients prior to their deaths.⁴ These examples demonstrate an opportunity for improvement in treatment of fungal disease, through increased awareness and suspicion of fungal infection, especially with changing environmental conditions, worldwide human migration, and increasing immunosuppressed patients. Pathologists can be instrumental in diagnosing fungal infections, providing important feedback to clinicians when such cases are not identified during life.

Fungal, Infection, Mycoses

H89 Krönlein Shots and Pseudo-Krönlein Shots

Christopher Ramos, MD, Western Michigan University, Homer Stryker MD School of Medicine, Kalamazoo, MI; Joseph Prahlow, MD, Western Michigan University, Homer Stryker MD School of Medicine, Kalamazoo, MI; Elizabeth Douglas, MD, Western Michigan University, Homer Stryker MD School of Medicine, Kalamazoo, MI*

Learning Overview: After attending this presentation, attendees will be familiar with the forensic pathology eponym term “Krönlein shot” as it pertains to certain firearm-related injuries. In addition, attendees will be introduced to a new term, “pseudo-Krönlein shot,” which refers to non-firearm traumatic brain injuries which simulate true Krönlein shots.

Impact Statement: This presentation will impact the forensic science community by introducing a new term, “pseudo-Krönlein shot,” to describe expulsion injuries of brain hemispheres occurring in non-firearm trauma situations.

The terms “Krönlein’s shot” and “Krönlein shot” are eponyms used in forensic pathology to describe the expulsion of an intact brain hemisphere (or both hemispheres) in high-velocity firearm injuries of the head.¹⁻³ The phenomenon is named for the famous German surgeon Rudolf Ulrich Krönlein, who first described brain evisceration from a military rifle wound in 1899.¹⁻³ Krönlein shots typically occur with high-energy contact-range gunshot wounds of the head, such as occur with shotguns or high-velocity rifles. This study presents several classic cases of Krönlein shots, then presents a series of non-firearms related traumatic deaths that demonstrate cerebral hemisphere expulsion injuries similar to what occurs with Krönlein shots. The moniker “pseudo-Krönlein shot” is suggested for such injuries.

Pseudo-Krönlein shots may occur in a variety of traumatic situations, including those involving blunt force/deceleration/crushing injuries, sharp force/chop injuries, and explosion injuries. Examples of each of these scenarios will be presented. Blunt force/deceleration/crushing injury cases include motor vehicle collisions, a skydiving incident, and a crane accident. An example of sharp force/chop injury involves an airplane propeller. An example of an explosion injury involves an incident involving a tire blowing off of the rim of heavy construction machinery.

Although described as being “rare” by some authors, firearm-related Krönlein shots are encountered relatively frequently in busy medical examiners offices in geographic regions where firearms are common. Such injuries are especially common in contact wounds of the head using shotguns or high-velocity rifles; however, similar shots can occur with contact wounds using high-energy handguns, as well as non-contact wounds involving high energy weapons, such as high-velocity rifles or shotgun slugs. Expulsion injuries of entire cerebral hemispheres, or substantial portions thereof, are classic findings, with brain segments typically being found relatively close to the body. Pseudo-Krönlein shots demonstrate similar expulsion injuries of the brain; however, the brain segments may be a considerable distance from the body, compared to those produced by firearms, depending on the underlying forces responsible for the injuries.

Krönlein Shot, Firearms, Mimics

H90 Mutual Homicide Including Immediate Revenge Homicide by Two Unrelated Assailants Utilizing One Sword

Wendy Gunther, MD, Office of the Chief Medical Examiner, Norfolk, VA; Molly House, DO, Office of the Chief Medical Examiner, Norfolk, VA*

Learning Overview: After attending this presentation, attendees will review and become familiar with external and internal wounds consistent with mutual homicide (fatal stabbing with immediate revenge homicide) with a single weapon utilized by two assailants.

Impact Statement: Recognition of mutual homicide with one weapon can conserve police investigation resources; characteristics of injuries can support police inquiry with autopsy evidence. Difficulties with transporting a decedent with the sharp force object in place should be overcome in order to permit optimal evaluation of the second decedent.

Deaths of two unrelated persons after mutual combat, utilizing the same sharp force weapon, are rare. This presentation describes mutual homicide by two unrelated decedents, utilizing one weapon; the death of the second person may be described as an immediate revenge homicide.

Emergency medical services were called for two severely injured victims in the same mobile home community. The unrelated decedents lived on adjacent lots and had a history of arguments. On the day of death, the 66-year-old man, who had acquired a 39½" (100cm) "samurai sword," challenged the 19-year-old man; the older man cut the younger man on the leg before stabbing him in the chest through the ribs, liver, right hemidiaphragm, and right lung. Witnesses said the combatants were briefly scuffling on the ground. Autopsy evidence (cuts on the volar surfaces of fingers of both hands) supported the contention that the younger man pulled the blade out of his body himself. Before dying, he impaled the older man with the sword, through the chest wall, right lung, heart, esophagus, descending aorta, left lung, and left eighth rib. Both combatants became unresponsive. Death ensued for the older man before Emergency Medical Services (EMS) arrival, and for the younger man shortly after arrival in the emergency department.

At autopsy, the younger man showed limited emergent medical intervention, including endotracheal intubation and intravenous and intraosseous catheterization. A postmortem chest X-ray showed profound leftward tracheal shift with right hemopneumothorax. Autopsy documented the stab wound and extremity cuts as described. Natural pathology was limited to a benign follicular adenoma of the thyroid gland. Postmortem toxicology was negative for drugs or alcohol.

The older man presented with the "samurai sword" in place, wrapped in a second body bag. 28" (~70cm) of hilt and blade protruded at an angle from his chest; slightly more than 11" (28cm) remained in the body; a cardboard protector beneath the body prevented the protruding tip from enlarging its 3/8" (~1cm) partial exit. He had no other injuries. X-rays demonstrated the weapon clearly. Autopsy demonstrated the wound path, along with gastric pouch blood, hemothorax, hemopericardium, and visceral pallor. Natural pathology included hypertensive and atherosclerotic cardiovascular disease, emphysema with an unsuspected right lung malignancy, and cirrhosis of the liver with steatosis. Postmortem toxicology was negative for drugs; the blood alcohol was 0.159% by weight by volume.

Autopsy findings assisted the police in corroborating the story and determining that no further investigation was required into the deaths of either the older man who initiated the attack or the younger man who succeeded in an immediate revenge homicide. The Commonwealth attorney declined prosecution. Both cases were closed on completion of the police and autopsy investigation.

Multiple homicides occurring in one event are often domestic. "Mutual combat" has been utilized as an alternative description for domestic violence, also not usually lethal.² Brawls are episodes of combat between multiple, often unrelated participants; the term does not imply lethal outcomes. These deaths occurred between unrelated victims without domestic violence and were committed using one sword; they are best described as mutual homicides, including an immediate revenge homicide.

H92 Woman-to-Woman Sexual Violence: A Case Discussion

Sarah Al Hinnawi, MD, HBT Medical College, Mumbai, Maharashtra, India*

Learning Overview: After attending this presentation, attendees will be aware of the lesser-known entity of woman-to-woman sexual assault.

Impact Statement: This presentation aims to provide an insight and create awareness into the lesser-known and even lesser-understood entity of female-to-female or lesbian sexual assault.

The term “sexual assault” is used to refer to any unwanted contact and behavior that is perceived to be of a sexual nature and which takes place without consent. It has been used here as an umbrella term to represent the different ways women may refer to their experiences. Even in the Lesbian/Gay/Bisexual (LGB) population, surveys conducted focus on male-perpetrated rape of victims who are female. Because of deeply rooted assumptions about gender role and notions about the maternal and caregiving nature of women, it is commonly assumed that women are incapable of inflicting violence on another person. Women tend to assume they are safe or at a significantly reduced risk of being sexually violated when in the company of other women.¹

The lack of recognition of women as offenders is reflected widely in various statistics worldwide. Due to homophobia and discrimination, the women generally do not come forward. There may also be a strong need for unity and holding onto same-gender relationships leading to concealment of the rape incident.² It may also be difficult for women to frame criminal charges against female perpetrators, due to the different legal definitions of rape between countries and criminal jurisdictions. There is also a lack of same sex resources.³ Further research is needed to understand the motivations and ramifications of sexual violence between women. Service providers should be educated about the possibility of same-sex sexual violence and ways to help survivors to recover from the trauma, connect with others, and confront multiple oppressions.

H93 Fatalities Due to the February 2021 Winter Storm in Harris County, Texas

Noah Reilly, DO*, Harris County Institute of Forensic Sciences, Houston, TX; Varsha Podduturi, MD, Harris County Institute of Forensic Sciences, Houston, TX; Hannah Jarvis, MBBS, Harris County Institute of Forensic Sciences, Houston, TX

Learning Overview: After attending this presentation, attendees will have learned about fatalities in Harris County, TX, during the February 2021 winter storm.

Impact Statement: This presentation will impact the forensic science community by providing an overview of the deaths encountered during a major winter storm.

During this timeframe, there is an average daytime high of 39°F and low of 25°F.¹ Due to the lack of cold weatherization of the independent Texas power grid and the inability of Texas to import electrical power from the national power grids, 91% of Harris County residents lost power at some point during the week.² The freeze also caused water pipes to malfunction, leaving 65% without running water.² Reviewed here are 41 fatalities during the storm that were examined at the Harris County Institute of Forensic Sciences from February 12 to February 23, 2021.

Hypothermia is clinically defined as a core body temperature of less than 95°F. The postmortem diagnosis of hypothermia is a challenge as many of the findings are non-specific. The most commonly reported are gastric petechiae (Wischnewski spots), cherry-red lividity, excoriation of the nose, ears, and hands, and acute hemorrhagic pancreatitis. Scene investigation and circumstances are key to the diagnosis.

Of the 41 fatalities, 23 were autopsied, 13 were externally examined, and 5 were reported but not examined. Causes of death included hypothermia, carbon monoxide poisoning with hypothermia ($n=5$), and one blunt trauma case. All manners of death were accident. Twenty-five decedents were male, 16 were female, and the average age was 62 years old, with age ranging from 7 to 100 years old. Their ethnicities were White ($n=17$), Black ($n=16$), Hispanic ($n=7$), and Asian ($n=1$). Thirty-five deaths were on scene and 6 were hospital deaths (interval to death ranging from 2 minutes to 16 hours after arrival). Deaths of those with fixed residences was much greater ($n=31$) than those that were homeless ($n=10$). Average axillary temperatures of the bodies on scene were 63.6°F and ranged from 41°F to 90.6°F. The most common co-morbidity was hypertension ($n=15$). The most common autopsy findings were Wischniewski spots in the stomach ($n=12$, 30%). The presence of ethanol on postmortem blood analysis was the most common toxicology finding ($n=11$, average: 0.175g/dL).

Hypothermia is a major preventable cause of mortality during severe storms, and global climate change will likely make these weather events more common. The prolonged loss of electrical power infrastructure can lead to improper use of portable generators or indoor grilling for heating purposes increasing the risk of carbon monoxide exposure. The risk of hypothermia in vulnerable groups, such as the elderly, is also much greater. Identification of these groups and correct classification of these deaths by medical examiners are important for public health data, targeted education, and intervention.

Hypothermia, Forensics, Autopsy

H94 COVID Testing and Postmortem Interval

Breanna Cuchara, MS, DC Office of the Chief Medical Examiner, Washington, DC; Francisco J. Diaz, MD, DC Office of the Chief Medical Examiner, Washington, DC*

Learning Overview: After attending this presentation, attendees will understand the procedure of testing for COVID-19 on postmortem cases. Attendees will gain a better understanding of the viability of the virus.

Impact Statement: This presentation will impact the forensic science community by encouraging other medical examiner's offices to test their decedents for COVID-19 to minimize the exposure to their staff. This is of great importance when considering variants and the exposure rate on scenes and in the office.

Between January 2020 to April 2021, there have been approximately 578,520 deaths due to the coronavirus in the US.¹ According to the National Association of Medical Examiners, there is no uniform way of investigating COVID-19 deaths by medical examiners.² These deaths are traditionally not under the jurisdiction of the medical examiner. Each office will vary on their response to COVID-19 deaths.

The Washington, DC, Office of the Chief Medical Examiner (OCME) has taken jurisdiction over all COVID-19 deaths that occur in the District and performs testing on decedents suspected of having it. If it is reported to the investigator that the decedent has had COVID-19 symptoms or was recently exposed, it is documented in the case synopsis. An X-ray is then completed. If the medical examiner is suspicious, a nasopharyngeal swab or lung swab (during autopsy) is taken from the decedent and sent to the DC Public Health Laboratory.

This study reviews the postmortem intervals between pronouncement time of death, time of testing, location of death, and more. DC OCME has swabbed 347 decedents for COVID-19 from March 2020 through April 2021. It has been determined that 56 cases came back positive. It was found that about 60% of decedents died at home, 17% at a hospital, 9% outside, 8% at a nursing home, and 3% at a shelter or hotel. Approximately, the decedents were pronounced on an average of 35.8 hours prior to being swabbed for COVID-19. It was also found that decedents were transported and placed in the freezer 29.9 hours before being swabbed. Interestingly, decedents were last seen alive, on average, four days before swabbing, with one decedent in a moderate stage of decomposition.

This research provides statistical data that the coronavirus is potentially still active even when being exposed to a harsh, cold environment (i.e., the freezer) and to decomposition changes. Depending on the circumstances surrounding the death, it is advised to test decedents for COVID-19 to decrease risk of exposure to staff members. This will help to obtain accurate numbers pertaining to COVID-19 deaths.

COVID-19, Pandemic, Autopsy

H95 SARS-CoV-2 Active Replication in Cadavers

Francesca Cazzato*, Section of Legal Medicine, Department of Health Surveillance and Bioethics, Università Cattolica del Sacro Cuore, Rome, Italy; Simone Grassi, Section of Legal Medicine, Department of Health Surveillance and Bioethics, Università Cattolica del Sacro Cuore, Rome, Italy; Alessandro Alfonsetti, Section of Legal Medicine, Department of Health Surveillance and Bioethics, Università Cattolica del Sacro Cuore, Rome, Italy; Massimo Zedda, Section of Legal Medicine, Department of Health Surveillance and Bioethics, Università Cattolica del Sacro Cuore, Rome, Italy; Paola Cattani, Institute of Microbiology and Division of Clinical Microbiology, Catholic University of Sacred Heart, and Department of Laboratory Sciences and Infectious Diseases, Fondazione Policlinico Universitario A. Learning Overview: After attending this presentation, attendees will have a better understanding of the actual biological risk related to SARS-CoV-2 infection both in Forensic autopsy Cases (FCs) and in Clinical autopsy Cases (CCs).

Impact Statement: This presentation will impact the forensic science community by presenting evidence of SARS-CoV-2 active replication in cadavers and of the persistence of high viral loads even several days after death. The key message will be that, despite the exposure, full compliance with guidelines and safety standards can guarantee health preservation in the autopsy room.

During the ongoing pandemic, autopsies have represented and represent a valuable tool to assess the cause of death in patients affected by SARS-CoV-2 infection, providing data of great epidemiological and research interest.¹⁻⁴ However, the actual biological risk of the pathology staff during autopsies on SARS-CoV-2-confirmed cadavers has not been precisely assessed, albeit some evidence on the persistence of relatively high viral loads after death has been reported.^{5,6}

This study performed microbiological testing on the postmortem swabs of 17 FCs and 12 CCs admitted to the Fondazione Policlinico Universitario Agostino Gemelli IRCCS in Rome, Italy. All CCs died during hospitalization, while only 7/17 FCs died in a hospital. Swab samples were collected from the nasopharyngeal tract and/or lungs of cadavers (registering the interval of time between death and sample collection) and, every two weeks, naso-pharyngeal swabs were also performed on all the dissectors. On the postmortem samples, this study performed a multiplex real-time Polymerase Chain Reaction (PCR) to detect three SARS-CoV-2-specific genes (RdRP, S, and N), a gene of the Sarbecoronaviruses (E), and an in-house real-time PCR assay to detect subgenomic messenger RNAs (mRNAs) (intended as indicators of viral active replication). Hence, this study quantified viral load. It was found that, albeit the mean postmortem interval was higher in FCs than in CCs (5.93 days vs. 2.25 days), the mean viral load of FCs was higher than that of CCs (1.02 1011 copies/mL vs. 6.52 108 copies/mL). Moreover, in 13/29 cases, evidence of active replication was found. These findings confirm the persistence of significant viral loads even several days after death. Moreover, there was a statistically significant (p-value <0.05) relationship between death without hospitalization and the presence of active viral replication. This study did not find a statistically significant relationship between swab site and detection of subgenomic mRNAs.

In the light of scientific literature and these results, full compliance with guidelines to contain biological risk in the autopsy room must be considered critical. In fact, following these guidelines and operating in a Biosafety Level-3 (BSL-3) autopsy facility, in this team there were no cases of infection among the dissectors.

SARS-CoV-2, Viral Replication, Viral Load

H96 The Postmortem Persistence Time of Sars-CoV-2 Virus: An Analysis of a Case Series

Isabella Aquila, MD, PhD, Institute of Legal Medicine, University Magna Graecia of Catanzaro, Catanzaro, Italy; Matteo A. Sacco, MD, Institute of Legal Medicine, University Magna Graecia of Catanzaro, Catanzaro, Italy; Pietrantonio Ricci, MD, PhD, Institute of Legal Medicine, University Magna Graecia of Catanzaro, Catanzaro, Italy*

Learning Overview: After attending this presentation, attendees will understand the possibility of postmortem persistence of the SARS-CoV-2 virus.

Impact Statement: This presentation will impact the forensic science community by demonstrating the results of an operative protocol with postmortem swabs performed on a case series.

Introduction: Postmortem activity of the SARS-CoV-2 virus has been poorly studied. From a social and cultural point of view, the absence of these data led the institutions, preventively, to prohibit the funerals of infected bodies and initially to reduce the number of COVID-19 autopsies.¹ However, very few studies have evaluated the virus persistence in the body. The presentation proposes an operational protocol with the execution of postmortem swabs to understand the persistence time of the virus based on the time from death.

Materials and Methods: The sample included 25 patients who died at the COVID-19-Center-Mater Domini of Catanzaro with incoming diagnosis of positivity to the SARS-CoV-2 test.

The period of hospitalization, medical records, comorbidities, and cause of death were analyzed for each patient. Nose-pharyngeal, oropharyngeal, and endo-bronchial swabs (only in autopsy cases) were performed postmortem at serial timings starting from the moment of death up to 24 hours (0-2-4-6-12-24hrs). The swabs were subjected to one-step Real-Time Reverse Transcription Polymerase Chain Reaction (rRT-PCR) with Cycle threshold (Ct) values, using as targets the gene markers for the E, RdRp (RNA-dependent RNA polymerase), N proteins of the virus. In some cases, this method was combined with the use of immunofluorescence technology for the rapid detection of the N antigen (nucleocapsid protein) in order to verify the presence of both viral antigens and RNA.

Results: The analysis of the results of the swabs showed a variable trend in positivity in relation to the time elapsed since death. In particular, postmortem permanence of the SARS-CoV-2 virus in the corpse in about 52% of cases was detected. Repetition of the swab over time showed that there was a positivity in the various timings examined, with 12/25 cases still positive 24 hours after death. The persistence of the virus did not show correlations with the comorbidities from which the patients were affected or with specific cause of death. None of the health care workers involved in autopsies tested positive for the swab.

Discussion: The proposed protocol demonstrates that death is a biological phenomenon which, despite abiotic processes, may not inactivate the virus in the corpse even beyond 24 hours after death. In particular, the positive result of the swabs demonstrates the possibility of the virus to survive for a long time in the corpse. The data obtained allow us to hypothesize resistance of the pathogen to postmortem changes in temperature and acid-base balance.

By virtue of the results obtained, the choice not to expose the COVID-19 corpses appears to be acceptable and scientifically valid. From a health point of view, the choice not to carry out autopsies is now not scientifically supported, although an expert team with safe autopsy rooms and suitable devices is needed. An increase in autopsies is desirable in order to investigate the pathogenetic mechanisms of the virus on humans for diagnostic, therapeutic, and preventive purposes.

Forensic Science, SARS-CoV-2, Postmortem Swab

H97 Ventilated Postmortem Imaging of COVID-19-Related Lung Disease With Clinicopathologic Correlation

Nadia Solomon, MD*, Yale University School of Medicine, New Haven, CT; Inga Melvinsdottir, MD, Yale University School of Medicine, New Haven, CT; Shin Rong Lee, MD, PhD, Yale University School of Medicine, New Haven, CT; Roxanne Wadia, MD, Yale University School of Medicine, New Haven, CT; Savannah Gisriel, MD, MPH, Yale University School of Medicine, New Haven, CT; Donald Turbiville, MD, Yale University School of Medicine, New Haven, CT; Declan McGuone, FRCPath, MBBCh, Yale University School of Medicine, New Haven, CT; S. David Hudnall, MD, Yale University School of Medicine, New Haven, CT; Albert Sinusas, MD, Yale University School of Medicine, New Haven, CT

Learning Overview: After attending this presentation, attendees will have a better understanding of the potential applications of radiology to death investigation and the type of information/data that may be extracted through radiologic-pathologic correlation.

Impact Statement: This presentation will impact the forensic science community by demonstrating that ventilated Postmortem Computed Tomography (PMCT), combined with limited autopsy, can provide insight into the pathophysiology of COVID-19-related lung injury and the differences between COVID-19 and non-COVID-19 injury.

The emergence of the COVID-19 pandemic inadvertently revealed an opportunity to expand the application of forensic imaging methodologies. COVID-19, caused by SARS-CoV-2, is associated with lung injury, Acute Respiratory Distress Syndrome (ARDS) and high mortality.^{1,2} Early in the pandemic, the virulence of COVID-19 and its mechanisms of transmissibility were incompletely understood, resulting in variable recommendations for protective measures and anxiety in those in and out of the health care setting. Autopsy—a vital part of cause-of-death investigation—was suspended in many hospitals around the world due to the inherent risk of disease exposure, resulting in a loss of potential data and a delay (if not a void) in understanding of the disease pathophysiology and mortality.³ Albeit necessary at the time to protect health care workers, the resultant deviations from standard practices highlight the need to explore supplemental techniques for Postmortem (PM) investigation, such as PM imaging for characterization of COVID-19 and non-COVID-19 lung disease, which may help explain why studies evaluating ARDS secondary to COVID-19 and comparing it to non-COVID-19 ARDS have reported mixed findings and conclusions, including the potential for various phenotypes along a spectrum of COVID-19-related lung disease.⁴⁻¹⁴ While published reports describe PMCT findings in COVID-19 patients, PMCT may inform on disease pathophysiology, particularly when combined with ventilation studies, pressure flow analysis, and autopsy findings.

Two female patients who required ventilation for respiratory failure were examined: one died of complications of COVID-19, and the other died from cerebral hemorrhage, but not before developing ventilator-associated pneumonia. Both patients underwent PMCT within 48 hours of death (Discovery 570c NM/CT, GE Healthcare), imaged at Positive End-Expiratory Pressures (PEEP) of 0, 10, 20, and 30cm H₂O. Using 3D Slicer software, the lungs were isolated and segmented by degree of aeration: over-inflated (<-1000 to -901 HU, 95% aeration); well-inflated (HU -900 to -501 HU, 70% aeration); and poorly inflated (-500 to -101 HU, 30% aeration). Targeted autopsies were conducted.

Quantitative analysis of PMCT showed that total aerated lung volumes normalized by height were lower at rest (0 cm H₂O) in the COVID-19 patient compared to the non-COVID-19 patient. Concordantly, normalized lung weights were greater in the COVID-19 patient (807.2g/m vs. 629.9g/m). Pathology demonstrated congestion, acute fibrinous organizing pneumonia, and scattered accumulations of neutrophils within smaller airways and alveoli in the COVID-19 patient, and occasional foci of intra-alveolar edema and hemorrhage in the non-COVID-19 patient. PMCT-derived pressure-volume curves showed relatively increased lung compliance in the COVID-19 patient.

This study reports a novel comparison of ventilated PMCT findings in a COVID-19 and non-COVID-19 patient with autopsy findings. Although the COVID-19 patient demonstrated edematous lungs with lower aerated volumes at rest, lung compliance was preserved if not increased, a surprising finding consistent with some *in vivo* studies showing intriguingly high lung compliance in COVID-19-related ARDS.

Gemelli IRCCS, Rome, Italy

Learning Overview: After attending this presentation, attendees will have a better understanding of the role of the PMCT in cases of confirmed/suspected SARS-CoV-2-related deaths.

Impact Statement: This presentation will impact the forensic science community by presenting the evidence of a correlation between radiological and histopathological findings in cadavers with microbiological evidence of SARS-CoV-2 infection and a previous clinical diagnosis of COVID-19.

Since the first wave of the SARS-CoV-2 pandemic, Computed Tomography (CT) has been proposed as primary diagnostic tool for COVID-19 cases. The most common pulmonary CT findings in these patients are bilateral lung involvement with ground-glass opacity, thickened interlobular septa, vascular enlargement, air bronchogram, bilateral lower lobe involvement, and complete consolidation of both lungs.¹ PMCT imaging has been proposed as a screening method for SARS-CoV-2 infection before autopsy and has been employed in forensic investigations of confirmed/suspected SARS-CoV-2-related deaths.²⁻⁶

The aim of this study is to compare the thoracic PMCT imaging and the histopathological findings in eight cadavers with microbiological evidence of SARS-CoV-2 infection and clinical diagnosis of COVID-19. Cadavers underwent a PMCT, then a full forensic autopsy with histopathological examination. At thoracic PMCT, in 50% of cases and in 25% of cases, respectively, a massive consolidation and crazy-paving pattern were found that corresponded to severe lung COVID-19 disease at the histopathological analysis. In 25% of cases, lung PMCT showed limited upper ground-glass opacities due to hypostasis. The cause of the death in 75% of cases was a cardiorespiratory failure with serious pulmonary histopathological signs of COVID-19, while in the 25% of cases histopathological analysis revealed non-specific COVID-19 lung alterations (then, the cause of death was not attributed to SARS-CoV-2 infection).

In forensic science, thoracic PMCT can improve diagnostic sensitivity in cases of SARS-CoV-2 lung impairment.⁷ Lung PMCT sensitivity is enhanced by the natural contrast caused by air; however, a possible bias of this radiological technique is represented by hypostases, which can appear as areas of greater opacity, frequently of the ground-glass type, distributed in lower regions of the lungs.⁸ That being said, at PMCT, cadavers with a diagnosis of COVID-19 usually have suggestive lung alterations (massive and bilateral consolidations, “crazy-paving pattern,” upper areas of ground glass opacity in the context of hypostatic ground glass opacity in both lungs) that can be differentiated by hypostases. However, despite the improvements given by this emergent radiological approach, the gold standard for postmortem studies of SARS-CoV-2-positive cadavers is still represented by autopsy and histopathology.^{2-4,6} Therefore, in SARS-CoV-2-positive cadavers, evidence of a good correspondence between the lung involvement revealed by PMCT imaging and that found at histopathological analysis (as reported in this study) can be important for forensic practice.

Finally, these findings highlight the importance of performing thoracic PMCT when data of SARS-CoV-2 infection are available, suggesting that, in future, this technique could become a useful and reliable tool to attribute the cause of death to severe lung COVID-19 disease.

H99 COVID-19-Associated Myocarditis at Autopsy

Charles Rohrer, MD*, University of Wisconsin Hospitals and Clinics, Madison, WI; Adam Bailey MD, PhD, University of Wisconsin Hospitals and Clinics, Madison, WI; Erin Brooks MD, University of Wisconsin Hospitals and Clinics, Madison, WI

Learning Overview: After attending this presentation, attendees will better understand the histologic spectrum, significance, and frequency of Severe Acute Respiratory Syndrome Coronavirus-2 (SARS-CoV-2) -associated myocarditis at autopsy.

Impact Statement: This presentation will impact the forensic science community by aiding autopsy pathologists in diagnosing, characterizing, and interpreting the likely significance of myocardial inflammation in COVID-19 deaths.

While the respiratory complications of COVID-19 have been well- publicized, an increasing body of evidence suggests associated cardiac injury may also play a role in morbidity and mortality. There are multiple ways by which SARS-CoV-2-associated myocardial injury may occur, including myocarditis. Reports regarding the incidence of COVID-19-associated myocarditis range widely, however, from 3–55%.^{1,2} Additionally, the composition of the myocardial inflammatory infiltrate appears variable, and the potential contribution of myocarditis to death is unclear.¹

A retrospective search was performed of the electronic autopsy database at the University of Wisconsin Hospitals and Clinics, utilizing search terms “COVID” and “SARS,” yielding 209 cases. Report review revealed 23/209 (11%) to have had positive nasopharyngeal SARS-CoV-2 Polymerase Chain Reaction (PCR) testing antemortem, postmortem, or both. COVID-19 was determined to be the cause of death in 10/23 (43%) cases and incidental in the remaining 13. Two of the incidental cases were external examinations only. Of the 21 cases in which internal examination was performed (including procurement of cardiac histologic sections), myocarditis with associated myocyte necrosis was present in 3/21 (14%); in 2/21 (10%), a rare small focus of interstitial lymphocytic inflammation without associated myocyte necrosis was found. All myocarditis cases arose in patients who ultimately died of COVID-19. Immunohistochemical staining for CD68 (macrophage marker), CD3 (T lymphocyte marker), and CD20 (B lymphocyte marker) was performed to better characterize the cellular infiltrate in the myocarditis cases and highlighted a relative macrophage predominance with lesser numbers of lymphocytes. A few scattered neutrophils could also be seen. It has been proposed that migration of infected pulmonary macrophages and/or transient viremia are the mechanisms by which SARS-CoV-2 myocarditis may arise.³

In terms of distribution, myocarditis was limited to the right ventricle in two cases. As the lungs are the major organ targeted by SARS-CoV-2, it is suspected that the right ventricle may be at greater risk of impairment/failure than the left, in cases of myocarditis. The remaining myocarditis case was fulminant involving both ventricles as well as the atrioventricular node. *In Situ* Hybridization (ISH) for SARS-CoV-2 spike and nucleocapsid RNA was positive within cardiomyocytes in the fulminant myocarditis case; testing is on-going in the remaining two cases. In 2/3 cases of SARS-CoV-2-associated myocarditis diagnosed at autopsy, both patients appeared to have been improving with stabilized ventilatory requirements prior to precipitous cardiorespiratory collapse.

Encouraging autopsy in such scenarios may thus assist in elucidating the cardiac sequelae of COVID-19 infection. Ultimately, definitive diagnosis of myocarditis requires histologic examination of tissue in order to exclude differential cardiac diagnoses (e.g., stress-induced cardiomyopathy).

H101 Died From or Died With COVID-19? The Application of Frailty Scores in the Assessment of Causality in 41 Autopsy Cases in Elderly Community Settings

Martina Zanon, MD*, University of Trieste, Trieste, Italy; Martina Montanaro, MD, University of Trieste, Trieste, Italy; Francesca Sinopoli, MD, University of Trieste, Trieste, Italy; Matteo Dri, MD, University of Trieste, Trieste, Italy; Davide Radaelli, MD, University of Trieste, Trieste, Italy; Carlo Moreschi, MD, University of Trieste, Trieste, Italy; Stefano D'Errico MD, PhD, University of Trieste, Trieste, Italy

Learning Overview: Attendees to this presentation will consider the opportunity to integrate autopsy findings with a clinical score of frailty in the assessment of causality in the elderly population with SARS-CoV-2 disease living in community settings and affected by multiple severe comorbidities.

Impact Statement: The aim of this presentation is to validate the methodological approach used to establish the causal relationship between SARS-CoV-2 infection and death in the elderly population.

In the first half of 2020, a new form of coronavirus spread around the world starting from China. The elderly were the population most affected by the virus around the world, in particular in Italy, where more than 90% of the deceased were people over 65 years of age.¹ In elderly populations living in community settings who died in the few weeks in the first wave of the COVID-19 pandemic in Italy, establishing the causal role of COVID-19 infection was extremely difficult due to the multiple and severe comorbidities and the early “lockdown” of autopsies.²⁻⁶ In this scenario, the criteria proposed from the health authorities were inconsistent in the forensic field.

This study proposed the results of 41 autopsies performed from the beginning of May to the beginning of June 2020 in the elderly population living in residential care homes who died in the first few weeks of the first wave of the COVID-19 pandemic with positive swab for virus SARS-CoV-2. Demographic and clinical information were extracted for each subject from their personal records. Postmortem examination was performed many weeks after death (38 days average) and included a multiple swabs panel (oropharyngeal, nasopharyngeal, tracheal, bronchial, and rectal), macroscopic and microscopic examination of tissue samples by routine, and immunohistochemical stainings. Samples for electron microscopy were also collected with surprising results.

The subjects included in this study were 14 men and 27 women; each one was a guest of a nursing home in the city of Trieste. Mean age was 90 years and mean postmortem interval was 38 days, with bodies preserved in different conditions, from cold rooms to refrigerated rooms. Comorbidities were represented by walking impairment/bed rest syndrome (86%), followed by severe cognitive impairment (56%), ischemic heart disease (50%), Chronic obstructive pulmonary disease (COPD) (43%), chronic kidney failure (33%), arrhythmogenic heart disease (26%), hypertension (23%), neoplastic disease with dissemination (23%), diabetes mellitus (13%), and congestive heart failure/valvulopathy (10%). Swabs were analyzed by real time Polymerase Chain Reaction (PCR) and resulted positive in 34 cases (83%). In 53% of cases, acute respiratory failure was indicated as the cause of death, and diffuse bronchopneumonia was observed in 46% of these, 23% in association with diffuse alveolar damage. In 37% of cases, acute cardiovascular failure in ischemic heart disease was indicated as the cause of death, and diffuse bronchopneumonia was observed in 20% of these. Ten percent of deaths were related to cancer, sepsis, and digestive hemorrhage. The Geriatric Index of Comorbidity (GIC) based on the severity of the diseases was used to measure the frailty and vulnerability associated with aging decline to “weigh” the degree of (forensic) causality of death with COVID-19 infection.⁷ The probability of a causal relationship was high in 16% of cases, moderate in 14% of cases, low in 47% of the cases, and a certain alternative cause of death, regardless of the outcome of the swab, was found in 23% of the cases.

This presentation introduces a new methodological approach in the forensic assessment of the causality integrating collected autopsy findings with the GIC and alerts pathologists to the importance of a complete postmortem examination in certain or suspected COVID-19-related deaths.⁸⁻¹⁰ A brief discussion is also reserved regarding the positivity of swabs collected with a mean postmortem interval of 38 days.

COVID-19, Cause of Death, Elderly

H102 Pediatric SARS-CoV-2 Infection in the Forensic Setting

Rebecca Folkerth, MD, Office of Chief Medical Examiner, New York City, NY; Michelle Stram MD, MSc, Office of Chief Medical Examiner, New York City, NY; Dimath Alyemni, MD, MPH, Office of Chief Medical Examiner, New York City, NY; Michael Greenberg, MD, Office of Chief Medical Examiner, New York City, NY; Avneesh Gupta, MBBS, Office of Chief Medical Examiner, New York City, NY; Amanda Krausert, MD, Office of Chief Medical Examiner, New York City, NY; Lauren Mecca, MD, Office of Chief Medical Examiner, New York City, NY; Sophia Rodriguez, MD, Office of Chief Medical Examiner, New York City, NY; Jay Stahl-Herz, MD, Office of Chief Medical Examiner, New York City, NY*

Learning Overview: Attendees will recognize and cite the elements of the spectrum of SARS-CoV-2 infection among children in the forensic setting.

Impact Statement: Forensic pathologists may encounter and thus must be aware of SARS-CoV-2-infected infants presenting as “Sudden Unexpected Infant Death (SUID),” as well as cardiovascular collapse in SARS-CoV-2-infected school-age children with underlying medical conditions.

Complete forensic investigation of unexpected deaths in infancy and childhood includes microbiologic testing for underlying infectious causes. Since March, 2020 (the era of COVID-19), nasopharyngeal swabbing for SARS-CoV-2 was added to supplement the routine screening for other viruses such as enterovirus, respiratory syncytial virus, rhinovirus, and others known to cause pediatric deaths. Over a 16-month period (through June 2021), eight non-traumatic pediatric cases (newborn through age 18 years) were referred to this study’s office, with antemortem (in emergency department) and/or postmortem results positive for SARS-CoV-2. The cases distributed into two groups: (1) infant deaths ($n=4$, ages 7 weeks to 4 months); and (2) school-age children ($n=4$, ages 5-15 years).

All infants were found unresponsive after a sleep period and in unsafe sleeping environments (i.e., as SUID); attempted resuscitations were unsuccessful. Of the infants, one had sickle cell disease, and he and his parents had influenza-like symptoms in the week prior to death; at autopsy, he had platelet and fibrin microthrombi in the lungs and interstitial pneumonitis. Another had been treated at birth for presumed congenital syphilis but had no recent illness (certified as undetermined cause and manner of death). One infant had “recent rhinitis” but died with evidence of positional asphyxia (manner of death, accident). Neuropathologic examination was notable in one infant for perivascular vacuolization and gliosis, as well as sparse perivascular lymphocytes, similar to changes in adults with COVID-19.¹

All four school-age children had at least one underlying medical condition (e.g., obesity, metabolic disease, and/or autism) and presented with influenza-like illnesses; three had laboratory findings of multisystem inflammatory syndrome upon testing in the emergency setting. Two children collapsed and died before admission, and the other two were hospitalized, receiving mechanical ventilation and Extracorporeal Membrane Oxygenation (ECMO). One of the hospitalized children developed a complication of ischemic stroke ipsilateral to the ECMO cannula (total hospital course, 11 days), and the other required abdominal surgery for an ingested foreign body (total hospital course, 4 days); the latter child also had co-infection with adenovirus.

Autopsy findings in the school-age children included acute lung injury/pneumonia ($n=3$), with microthrombi in one. One child had a body-mass index of 45.8, with diabetic ketoacidosis, cardiac hypertrophy, and fatty liver disease; he also had co-infection with adenovirus. One hospitalized child had coronary and cerebral arteritis and aortitis, resembling Kawasaki disease. The other hospitalized child had known neuronal storage disorder, also with an enlarged fatty liver. Nervous system findings were particularly interesting: all had subtle evidence of meningoencephalitis, focally involving the brainstem, as reported in adults with COVID-19.¹ Of note, two children had heretofore unreported histologic evidence of autonomic/peripheral nervous system involvement by mononuclear inflammation, raising an additional possible neurologic contribution to cardiovascular (autonomic) collapse.

In conclusion, SARS-CoV-2 may present very differently in infants (more “SUID-like”) than in older children, who, as in the adult population, often have underlying medical conditions predisposing to fatal outcomes, and may also have co-infection with a second virus. Kawasaki-like findings may occur in a subset. Neuropathologic changes in children resemble those in adults. Additional analysis of the peripheral/autonomic nervous system of children with COVID-19 would be of interest in understanding the propensity for cardiovascular collapse/sudden death in the population coming to forensic autopsy.

COVID-19, Sudden Unexpected Death in Infancy, Sudden Unexpected Death in Childhood

H103 Overdose Analysis in a Year of COVID-19 in Orange County, California

Kelly Keyes, BS, RTI International, Research Triangle Park, NC; Chelsea Brown, MA, Orange County Sheriff Coroner, Santa Ana, CA*

Learning Overview: After attending this presentation, attendees will understand how the COVID-19 (also called SARS-CoV-19 or Coronavirus disease 2019) pandemic affected overdose rates at a large coroner's office, specifically Orange County, CA.

Impact Statement: This presentation will impact the forensic science community, especially those involved in medicolegal death investigations, by presenting information on how a pandemic affected rates of death in cases not directly related to the pandemic, focusing on overdose deaths, from March 2020 when lockdown from the pandemic began, until a year later in March 2021.

Early in the pandemic, there was much publicity about anticipated effects of the pandemic and associated lockdowns on the population and mental health. As the pandemic progressed there was much information released about the skyrocketing rates of overdose deaths during this time frame. Unfortunately, we still remain too deep in the crisis to fully understand any long-term effects on our populations, including on mental health, financial stressors, and other changes in people's lives, but we do have information available on those dying in this initial year of the pandemic.

This presentation aims to examine the potentially indirect consequences of the pandemic on death rates at a medicolegal death investigation office; consequences that in addition to the burden of increased deaths directly attributed to the virus, adds significantly to the workloads of the staff at these medical examiner and coroner offices. The added workload is felt at all levels of the office, from records to investigation to autopsy. Along with other indirect pandemic deaths (such as pandemic-related suicides and natural deaths complicated by lack of treatment during the pandemic), this presentation will focus on increased overdose deaths within the jurisdiction. This presentation will also briefly address all classifications of death, including traffic-related fatalities and deaths by suicide, during this time frame as well.

This presentation will include comparisons to rates from the prior five years to examine the relationship of potential trends. Analysis will be done on various age groups, races, and genders. This presentation will also look at the specific substances that the cause of death is attributed to, types of substances (licit vs. illicit, when it is known), manners of death for these overdose cases, as well as locations of injury.

This presentation can serve as a guideline for potential future resource allocation in times of pandemic, as well as serve a public health role for future evaluation to save lives should we as a nation again be faced with such challenges. This presentation can also be used by medicolegal death investigators to have heightened awareness of death rates during a pandemic.

Medicolegal Death Investigation, COVID-19, Overdose

H104 A Year of Mandatory, Universal COVID-19 Postmortem Testing in San Francisco: Lessons Learned

Rand Miyashiro, MA, City and County of San Francisco, San Francisco, CA; Willi McFarland, MD, PhD, Department of Public Health, City and County of San Francisco, San Francisco, CA*

Learning Overview: After attending this presentation, attendees will have a better understanding of the utility, processes, and likely outcomes of universal postmortem testing mandates in response to pandemic situations such as COVID-19.

Impact Statement: This presentation will impact the forensic science community by providing a case study for the how, when, where, who, and why of universal postmortem testing in the event that such public health mandates are implemented for future surges of COVID-19 or during similar emerging pandemics. Findings may help pathologists develop guidance for -19 postmortem test orders where testing capacity is limited. This includes a greater understanding of COVID-19-positive persistence of greater than three days postmortem.

The City and County of San Francisco is the only United States health jurisdiction to have required universal postmortem COVID-19 testing, per research. The rationale for the mandate was to: (1) help protect first responders and persons working in funeral-related services; (2) identify missed cases of COVID-19, including those without symptoms, for contact tracing; (3) understand who is at highest risk for death due to COVID-19; and (4) provide the public with information on the COVID-19 epidemic. The mandate was in effect from June 2020 through June 2021, a period covering peak mortality and transmission. By emergency order of the county Health Officer, all decedents were required to be tested and positive results reported to the Department of Public Health. To assist the community in meeting this requirement, San Francisco implemented a specialized Decedent Testing Unit (DTU), in collaboration with the medical examiner, to rapidly respond to the COVID-19 testing needs of all locations where deaths occurred, including facilities with limited postmortem testing capacity. Based on under 3,000 tests and just under 90 positive results, this order has shown that COVID-19 was detected in many cases when tested 72 hours or more after death. During a year of testing, positivity rates ranged from 0–14% using a 14-day rolling average. Positive cases included asymptomatic as well as symptomatic decedents who had not sought medical attention. The detection of otherwise undiagnosed cases, primarily in at-home and hospice deaths, confirmed the concerns of first responders, such as emergency medical staff, who were proponents of the program. This presentation will discuss testing among place-of-death locations (e.g., hospitals, homes) and compare the percentage of positive decedents against the relative frequency of place of deaths within San Francisco and California.

Complementing well-documented COVID-19 mortality rates occurring in hospitals and skilled nursing facilities, this presentation will present positive rates for homes, outdoors, and other locations of death. The utility of test orders in situations where a decedent was or could be double tested (hospitals and the medical examiner) will also be discussed.

Conclusion: Review of results from a year-long county-wide health order mandating universal COVID-19 postmortem testing showed that decedent-positive cases came from more places of death and were detected postmortem for much longer periods than anticipated.

COVID-19 Testing, Postmortem Testing, COVID-19 Postmortem Persistence

H105 The Challenges in the Disposal of COVID-19- Deceased Bodies in Mumbai, India

Manoj Parchake MD, Seth GS Medical College & KEM Hospital, Mumbai, Maharashtra, India*

Learning Overview: Forensic experts will learn the challenges faced while disposing of the COVID-19 deceased bodies in a highly populated city like Mumbai.

Impact Statement: This presentation will impact the forensic community by demonstrating how the challenges were overcome while disposing of the COVID-19 deceased bodies in a highly populated city like Mumbai.

On December 31, 2019, the China Health Authority alerted the World Health Organization (WHO) to several cases of pneumonia of unknown etiology in Wuhan City in Hubei Province in central China. The cases had been reported since December 8, 2019, and many patients worked at or lived around the local Huanan Seafood Wholesale Market, although other early cases had no exposure to this market. On January 7, a novel coronavirus, originally abbreviated as 2019-nCoV by WHO, was identified from the throat swab sample of a patient. This pathogen was later renamed as Severe Acute Respiratory Syndrome Coronavirus 2 (SARS-CoV-2) by the Coronavirus Study Group and the disease was named Coronavirus Disease 2019 (COVID-19) by the WHO.

The COVID-19 pandemic impacted almost every country on Earth. The current status of COVID-19 cases as per WHO are 216,303,376 and deaths are 4,498,451. In India, the current status of COVID-19 cases and deaths as per WHO is 32,737,939 confirmed cases of COVID-19 with 438,210 deaths. The current status of Covid-19 in Mumbai is total confirmed cases 7, 43,832 and 15,976 deaths, among which 13,617 deaths occurred in individuals above 50 years of age.

Challenges while disposing of the COVID-19 deceased bodies are securing isolation wards for COVID-19 deceased bodies. Problems were faced while shifting COVID-19 deceased bodies from wards to morgues, providing separate mortuary cabinet to preserve the deceased bodies in morgues, and hospitals having to follow government guidelines such as necessary documentation for the disposal of dead bodies. Initially, there was hesitancy of health workers to provide service to dead body disposal. There was a lack of sufficient mortuary cabinets to preserve the Covid-19 dead bodies initially. Challenges were faced while handing over the bodies of COVID-19 decedents to police and relatives. Difficulties were faced on the death of COVID-19 patients or quarantine patients at home. There were difficulties in tracing the relatives of the COVID-19 deceased. Also there was the impact of lockdown, which affected the disposal of Covid-19 deceased. There were long waiting periods for the disposal of COVID-19 deceased bodies for electric cremation at the cemetery in the city. There were challenges in handling the relatives at funeral sites and environmental cleaning.

All these challenges were tackled efficiently by government authorities. For the future, there is a moving morgue concept providing trailer trucks with air-conditioning that can be procured at various morgues to handle the COVID-19 deceased bodies. These trailer trucks can be moved to another hospital as per requirement, which can be very cost effective to the government.

Challenges, COVID-19-Deceased Bodies, Mumbai

H106 Challenges in Managing Dead Bodies With COVID-19 in Indonesia

Yudy Yudy, MD, Cipto Mangunkusumo National Hospital, Central Jakarta, Jakarta, Indonesia; Klarisa Salim, MD, Buleleng General Hospital, Bali, Indonesia; Denys Alim, MD, Cipto Mangunkusumo National Hospital, Central Jakarta, Jakarta, Indonesia*

Learning Overview: After attending this presentation, attendees will better understand the management of infectious dead bodies in Indonesia.

Impact Statement: This presentation will impact the forensic science community by giving an update on challenges in managing dead bodies with COVID-19 in Indonesia.

As of August 30, 2021, the COVID-19 pandemic has infected almost 217 million people and killed around 4.5 million people worldwide since its first discovery in December 2019 in Wuhan, China.¹ The COVID-19 pandemic in Indonesia has already infected around 4 million people and resulted in 132 thousand deaths.² This increasing death toll poses another threat aside from the fact that health care facilities and the system is on the verge of exhaustion and burnout.

In Indonesia, people who have died with COVID-19 will undergo a specific protocol, as the Indonesian Ministry of Health mandates, before the deceased can be buried in the cemetery. In general, the deceased will be cleaned and disinfected, then wrapped in plastic before being put inside a wooden coffin and being sealed tightly by using another plastic on the outside of the coffin. This procedure is done in a special room for dead body preparation and is done by trained funeral staff using personal protective equipment level 3. During the protocol process, the family cannot be with the deceased because of the risk of infection.³

Despite several efforts that the government has made during the pandemic, there is always a slight discrepancy with the peoples' expectations. This is indeed bound to happen because of the diverse background and multicultural nature of Indonesian people. The biggest challenge from managing dead bodies with COVID-19 is the uncooperative families who refuse to let their loved ones undergo the protocol. Eastern culture is still strongly attached in Indonesian people that the deceased must be held in a religious ceremony for the afterlife. So if they abide by the protocol, then the deceased cannot be given the religious ceremony before burial. Another challenge also rises from the limited burial ground, so the government was forced to make a public burial ground for all dead bodies with COVID-19, and there are also challenges in filling out the death certificate correctly. All of these challenges have led to improvements in the dead body management system in Indonesia, despite many shortcomings.

COVID-19 Pandemic, Dead Bodies Management, Indonesia

H107 Estimating the Postmortem Interval (PMI) Using Decomposition Scoring Systems: A Comparative Study

Valentina Bugelli, MD*, Azienda USL Toscana Sud Est, Grosseto, Italy; Silvia Raddi, MD, Health Sciences Department-Legal Medicine Section, University of Florence, Florence, Italy; Matteo Cecchetti MD, Health Sciences Department- Legal Medicine Section, University of Florence, Florence, Italy; Ilaria Tarozzi, MD, Health Sciences Department-Legal Medicine Section, University of Florence, Florence, Italy; Sara Bortolini, PhD, Faculty of Science and Technology, Free University of Bolzano, Bolzano, Italy; Carlo Pietro Campobasso, MD, PhD, Department of Experimental Medicine (Dept. E.M.) School of Medicine, University of Campania, Vanvitelli, Napoli, Italy

Learning Overview: After attending this presentation, attendees will better understand the predictive reliability of quantitative methods of scoring decomposition used for estimating post-fatal interval

Impact Statement: This presentation will impact the forensic science community by it showing limitations and advantages of decomposition scoring procedures for estimating PMI.

Estimating time since death, commonly referred to as PMI, is a crucial task in every death investigation. Unattended deaths or decomposed bodies are usually the most challenging cases for pathologists and anthropologists commonly requested to estimate the PMI. An accurate estimate of PMI may corroborate witness statements, support the credibility of other physical evidence, drive decisions on the allocation of investigative resources, and serve as evidence for subsequent prosecutorial action. Several quantitative methods of scoring decomposition have been suggested for bodies found in aquatic and terrestrial environments. Among them, two approaches are worth of mentioning: Total Body Score (TBS)/Accumulated Degree Days (ADDs) and Total Decomposition Score (TDS)/ADDs. Megyesi et al. introduced first a point-based system for the main three anatomical regions (i.e., head and neck, trunk, limbs) to produce a TBS that is a reliable quantitative value representing the relationship between decomposition and ADDs.¹ This approach has been recently improved by Gelderman et al. who developed an up-dated decomposition scoring method called TDS based on six decomposition stadia for each body region and two different formulas for indoor and outdoor cases.²

In the present study, TBS and TDS have been applied on forensic cases with established known PMI. This obtained PMI was then compared with the PMI estimated by using the entomological method for bodies colonized by insects. The sample study was represented by 11 bodies in total (5 females and 6 males) with an age range from 29 to 86 years, mostly discovered indoors (6 out of 11 cases). The range of presumptive PMI was from a minimum of ten days up to about two years. The bodies showed different stages of decay: four bodies were in active decay stage, five were pre-skeletonized, and two were partially mummified. The series of cases were divided into three groups according to the PMI: shorter than 50 days (four cases), between 50 and 100 days (five cases), longer than 100 days (two cases).

For PMI shorter than 50 days, entomology provided an accurate estimation in three out four cases and underestimated in one case. TBS provided an underestimation of the PMI in three cases, and an overestimation in one case up to 23days (1775,23ADD). TDS underestimated the PMI in two cases up to 12days (129,6 ADD) and overestimated the PMI in another two up to 9 days (129,6 ADD). For the five cases with PMI between 50 and 100 days, the distances between the PMI estimates and the real PMI were shorter than the distances found in other cases, although all three methods provided an underestimation of the PMI. For the two cases with PMI longer than 100 days, none of the three methods was reliable. In conclusion, according to these results, the entomological method provided a fairly accurate estimate of the minimum PMI for cases with PMI below 50 days. TDS resulted in being much more reliable than TBS and entomology in estimating PMI between 50 and 100 days.

These results suggest that using the entomological method together with TDS can increase the predictive accuracy in the estimation of PMI, especially in PMI <100 days.

Postmortem Interval (PMI), TDS (Total Decomposition Score), TBS (Total Body Score)

H108 A Long-Term Study of Decomposition at a Tropical Taphonomy Facility: 2013–2021

David Carter, PhD*, Chaminade University of Honolulu, Honolulu, HI; Alexis Peterson, BS, City and County of Honolulu Department of the Medical Examiner, Honolulu, HI; Adam Orimoto, MS, Honolulu Police Department, Honolulu, HI; Agathe Ribereau-Gayon, PhD, Université du Québec à Trois-Rivières, Trois-Rivières, Quebec, Canada; Carlos Gutierrez, PhD, True Forensic Science, Santiago, Santiago, Chile; Katelynn Perrault, PhD, Chaminade University of Honolulu, Honolulu, HI

Learning Overview: Attendees can expect to be presented the first comprehensive overview of pig decomposition at a tropical decomposition site, including the extent, frequency, and timing of common postmortem processes.

Impact Statement: This presentation will impact the forensic science community by demonstrating that the analysis of a long-term taphonomy database can improve our understanding of decomposition at a given site while stimulating research and applications suitable for use with human remains.

Taphonomy is influenced by several variables that can cause significant variation in the extent, frequency, and timing of postmortem processes. An improved understanding of this variation is the primary goal of decomposition studies. Variation associated with taphonomy in tropical climates is very poorly understood because relatively few decomposition studies have been conducted in the tropics. To address this gap in knowledge, a series of nine carcass decomposition studies were conducted at Chaminade University of Honolulu from 2013–2021. Pig (*Sus scrofa domesticus*) carcasses, three per study, were decomposed on the soil surface or a weighing frame placed on the soil surface. Carcasses weighed approximately 35kg at death and were killed using a range of methods, including electrocution, bolt gun, and exsanguination. Carcasses were placed at the decomposition site within two hours of death and decomposition was monitored for 14 days. Measurements included total body score, mass loss, skin pH, skin temperature, skin oxidation reduction potential (Eh), larval mass pH, larval mass temperature, larval mass Eh, ambient temperature, and ambient relative humidity. All data were compiled and analyzed to identify processes and trends associated with the decomposition of carcasses at the site. The Köppen-Geiger climate classification of the site is Tropical Savanna.

The site is 90m above sea level with mean annual precipitation of 700mm, most of which occurs in the autumn and winter (October–March). The site is rocky with silty clay soil dominated by guinea grass (*Megathyrsus maximus*). Only the small Asian mongoose (*Herpestes javanicus*) has been observed scavenging.

A number of postmortem processes and trends were observed consistently regardless of season:

- All carcasses were a warm temperature (~40°C), slightly acidic/neutral (5.0–7.5pH), with little to no available oxygen (-400–+200 millivolts: Eh)
- All carcasses were patently bloated within 24 hours postmortem
- All carcasses supported patent fly larval masses within 3 days postmortem
- All fly larval masses migrated from carcasses within 10 days postmortem
- All carcasses lost 75% of their mass within 10 days postmortem
- Other postmortem processes were observed less frequently: 80%–abdominal rupture
- 60%–limb disarticulation 53%–rib exposure
- 40%–mandible disarticulation (17% on weighing frame, 56% on soil)
- 13%–complete loss of soft tissue

The current data show that the long-term analysis of taphonomy data can improve our understanding of decomposition by facilitating the identification of common processes and trends. For example, the decomposition of pig carcasses at the current site can be described as rapid, regardless of season. Bloating was patent within 24 hours postmortem. Color changes and fly larvae were well established within three days postmortem. The temperature, pH, and Eh of carcasses indicated an ideal habitat for microbial and larval activity. Carcasses lost ~75% of their mass and entered advanced decay within ten days postmortem. Carcasses tended to rupture between days 3–9 postmortem but the exposure and disarticulation of the skeleton was less predictable. A complete loss of soft tissue was atypical. Although these data are not necessarily representative of human taphonomy, they have stimulated a number of research projects in partnership with human decomposition facilities and medicolegal death investigation agencies.

Taphonomy, Carcass, Tropics

H109 A Longitudinal Study of Human Decomposition Across Summer and Winter in Quebec, Canada

Agathe Gayon, PhD*, Université du Québec à Trois-Rivières (UQTR), Trois-Rivières, Quebec, Canada and International Centre for Comparative Criminology, Montreal, Quebec, Canada; Shari Forbes, PhD, Université du Québec à Trois-Rivières (UQTR), Trois-Rivières, Quebec, Canada and International Centre for Comparative Criminology, Montreal, Quebec, Canada

Learning Overview: Attendees can expect to be presented the first longitudinal study of human corpses in a cold, continental climate in Quebec, and to learn which taphonomic patterns to expect in this environment across various seasons.

Impact Statement: This presentation will impact the forensic science community by contributing to fill a gap in the current knowledge base on the biological impact of a cold, continental climate on the patterns and rates of decomposition of human corpses and by providing the first frame of reference for forensic taphonomy in Quebec.

Background and Aims: The reliability of current methods to measure the decomposition of human remains and estimate the Postmortem Interval (PMI) such as Total Body Score (TBS) and mass loss is influenced by a range of variables. This can include those linked with the environmental and climatic conditions that may undermine the accuracy of the postmortem conclusions presented to the investigators and to court.¹⁻³ It is therefore essential to ensure that the approaches used in forensic taphonomy are underpinned by robust evidence-based data.

However, there is a gap in the current knowledge base on how cold, continental climates can impact the decomposition process and the patterns of mass loss of human remains and how these may affect our ability to estimate PMI accurately. This study aimed to address this gap in the knowledge through an experimental approach and in so doing, producing a baseline for forensic taphonomy in Quebec.

Materials and Methods: An experiment was carried out at the site for Research in Experimental and Social Thanatology (REST), the first human decomposition facility in Canada.⁴ REST is located within a mixed woodland area near Trois-Rivières (Mauricie) in Quebec, which has a humid continental climate according to the Köppen-Geiger climate classification. This type of climate implies significant temperature variations across seasons, with cold, snowy winters, and hot, humid summers.

The bodies of ten adult donors donated through the Université du Québec à Trois-Rivières (UQTR) Body Donation Program were analyzed in this study. The selection of donors consisted of five males and five females, ranging from 55 to 93 years old (median age=72). The donors were all deposited undressed, in a supine position, on the soil surface. All corpses were protected by cages to limit animal scavenging.

A combination of qualitative and quantitative approaches derived from the published literature was used to analyze the patterns and rates of decomposition in real time. The following data were collected from and around the donors:

Endogenous data: visual evaluations of the degradation of soft and hard tissues, internal temperature, entomological activity.

Exogenous data: ambient temperature, ambient humidity, soil surface temperature, freeze-thaw-dry of soil (soil moisture measured through calculating dry matter).^{5,6}

Results and Impact: The results indicate that the distinct combination of heat and humidity over the summer in Quebec led to desiccation of the remains, associated with differential decomposition, which created a protective “shell” that delayed external decomposition. The results from the winter indicate that decomposition progresses during winter, resulting in desiccation of the remains before the typical progression of decomposition stages, such as bloat and active decay. These findings highlight that the taphonomy approaches such as TBS that are currently available may not be suitable for Quebec’s climate, which may introduce uncertainty in PMI estimations.

The results of this study will contribute to strengthening the conclusions that pathologists and forensic anthropologists present to investigators or to the court in Quebec, including in cases that involve missing people from indigenous communities, which have been a pressing issue across Canada. Ultimately, this study will facilitate establishing comparisons with other geographical areas with comparable climates, including in the United States (e.g., the Maritimes, Newfoundland, eastern North Dakota to Maine).

H110 Smelling, Searching, and Sabotage: How Two Carrion Insects Compete for Decomposing Remains

Jennifer Rhinesmith-Carranza, BS*, Texas A&M University, College Station, TX; Jeffery Tomberlin, PhD, Texas A&M University, College Station, TX

Learning Overview: This presentation will describe the findings from a suite of experiments conducted using *Lucilia sericata* blow flies and *Nicrophorus vespilloides* carrion beetles that explored their effects on volatile profiles of remains and their resource preferences. The results have potential implications for how the entomological pre-colonization interval for remains and its relationship with time of colonization estimation assumptions and Postmortem Interval (PMI) inferences are interpreted.

Impact Statement: This presentation will impact the forensic science community by highlighting some of the variability that exists in the entomological phases of decomposition, focusing on the pre-colonization interval. Attendees will better understand how insects of forensic importance locate and interact with remains and the variability associated with these interactions as related to estimating the time of colonization.

Resource location, evaluation, and acceptance by necrophagous insects are complex behaviors influenced by a combination of biotic and abiotic factors. How these factors govern resource-related behaviors of these insects is important in forensic science due to their influence on how Time Of Colonization (TOC) calculations as related to the PMI are determined. Human remains are a nutrient-dense resource pulse in the larger ecosystem that are utilized by insects. They are ephemeral, patchy resources, lasting between a few days and a few weeks or longer.^{1,2}

Because of this variability and their nutritive value, there is intense competition among necrophagous insects for detection, location, and use.³ Volatile Organic Compounds (VOCs) play an integral role in resource location by these insects and can also provide information about the quality and suitability of a resource conditional to insects' needs. Accordingly, it is crucial for insects to employ efficient mechanisms to process public information, such as volatile olfactory cues, in order to alter behavior (such as searching strategies) to maximize fitness.⁴

The common green bottle fly, *Lucilia sericata* (Diptera: Calliphoridae), is the most common *Lucilia* species in the United States and, as a primary colonizer, its presence on remains can be used to determine TOC as related to PMI.⁵ Similarly, the carrion burying beetle, *Nicrophorus vespilloides* (Coleoptera: Silphidae), has a palearctic distribution and is commonly found in cooler climates where they are considered a top competitor with these blow flies for small carrion.⁶ Blow flies are known to "seed" their offspring's environment with commensal microbes, which, by nature, could alter the VOC profile of the remains, which could decrease competition with other species (i.e., change succession trajectory); *N. vespilloides*, moreover, show extensive carcass preparation that includes covering the resource in oral and anal secretions that contain a number of antimicrobial and antifungal compounds that could, similar to the blow fly, also alter the VOC profile and shift arthropod succession patterns.⁷⁻⁹ As primary colonizers with significantly different resource use strategies, *L. sericata* and *N. vespilloides* provide an interesting model system in which to explore carrion use and effects on intra- and inter-specific competition and how these effects may influence colonization intervals and, thus, the relation of these intervals to PMI estimations.

This presentation will report results from a suite of experiments exploring the effects of: (1) *L. sericata* and *N. vespilloides* interaction with remains on the associated volatile profiles, (2) prior insect colonization and carcass age on adult *N. vespilloides* resource preference, and (3) prior insect colonization and carcass age on adult *L. sericata* resource preference in order to further our understanding of their detection, assessment, acceptance, and use of carrion and how that may influence the pre-colonization interval, which could have significant effects on how we view TOC estimations in forensic entomology.¹⁰

Entomology, TOC, Postmortem Interval (PMI)

H111 Pre-Colonization Data Improves Larval Age Estimations With Human Remains

Charity Owings, PhD*, University of Tennessee, Knoxville, TN; Hayden McKee-Zech, MS, University of Tennessee, Knoxville, TN; Erin Patrick, MS, University of Tennessee, Knoxville, TN; Sarah Schwing, MS, University of Tennessee, Knoxville, TN; Thomas Delgado, MS, California State University-Chico, Chico, CA; Dawnie Steadman, PhD, University of Tennessee, Knoxville, TN

Learning Overview: After attending this presentation, attendees will understand that even the best methods for estimating the time since death can be refined to increase accuracy. Attendees will learn about the first systematic attempt to quantify a previously understudied portion of the postmortem interval (the pre-Colonization Interval [pre-CI]) and how such data can be used to improve standard entomological time-since-death estimations.

Impact Statement: This presentation will impact the forensic science community by revealing a new method that can significantly decrease error in time-since-death estimations.

Forensic entomology currently represents one of the best approaches for estimating the minimum Postmortem Interval (PMI_{MIN}) in medicolegal death investigations.¹ However, basic information regarding the period between death and insect colonization (i.e., the pre-CI) is lacking, and validation of standard estimation methods are rare²⁻⁷. Currently, no reference datasets for the pre-CI exists, though the inclusion of such data in a standard entomological estimation could improve accuracy.⁸ The goals of this project were two-fold: (1) generate a baseline pre-CI dataset covering a range of ambient temperatures, and (2) examine the impact of using pre-CI data in conjunction with a larval age estimation on estimation accuracy. It was hypothesized that the addition of the pre-CI would increase estimation accuracy.

For the generation of the reference pre-CI dataset, $N=62$ human donors were placed unclothed on the ground surface at the Anthropology Research Facility (ARF), University of Tennessee from February 2019 to July 2021. Observations for initial oviposition were made at least once a day. Accumulated Degree Hours (ADH) for the pre-CI were calculated from regional weather data.⁹ Pre-CIs were grouped into six temperature bins: 0-10°C, 10.1-15.0°C, 15.1-20.0°C, 20.1-25.0°C, 25.1-30.0°C, and >30.0°C.

For larval age estimations, $N=33$ human donors were sampled for blow fly larvae according to standard procedures, and blow fly species were identified using dichotomous keys.¹⁰⁻¹² Only larvae collected within 5,000 ADH of placement were used as accuracy decreased to 0% beyond this point. Estimations were made for each sampling timepoint, species, and development stage present in a sample. Two reference datasets per species (when possible) were used to generate estimations. The hypothesis that the estimated age was equal to the Time Of Placement (TOP) of each donor was tested. The average ambient temperature for the estimated exposure time was used to select the appropriate pre-CI for each sample. The mean pre-CI was then added to the maximum value of the estimated age range. An estimation was considered accurate if the true TOP was bracketed by the estimated range. Estimation accuracies before and after adding pre-CI data were analyzed via a non-parametric Wilcoxon Signed Rank Test.

The inclusion of temperature-specific pre-CI data in larval age estimations resulted in significantly higher estimation accuracy compared to those that excluded pre-CI data ($P=0.002$). This translated to an 8% increase in overall accuracy (53% vs. 61%), with improvement of 21 underestimations from 13 donors. Improvements in estimation accuracy were not impeded by blow fly species, temperature, season, or any other environmental factors.

These results suggest that including temperature-specific pre-CI data to a standard larval age estimation decreases the likelihood of underestimating the true TOP, thereby increasing overall accuracy. This research represents the first attempt to systematically quantify the pre-CI with a large population of human remains over an extended period of time. This preliminary dataset also represents the largest effort to test and improve standard entomological estimation methods using human remains. Validation of the pre-CI dataset will continue with a larger population of human donors at the ARF.

Forensic Entomology, Postmortem Interval (PMI), Colonization

H112 Successional Changes in the Entomological, Bacteriological, and Fungal Communities During the Decomposition of Swine Carcasses

M. Denise Gemmellaro, PhD, Kean University, Union, NJ; Rachel Domke, BA, Kean University, Union, NJ; Kristina Kovalska, Kean University, Union, NJ; Amanda O'Connor, Kean University, Union, NJ; Olivia Pate, Kean University, Union, NJ; Gloria Raise, Kean University, Union, NJ; Nicholas Lorusso, PhD, University of North Texas, Dallas, TX; Maria Shumskaya, PhD, Kean University, Union, NJ*

Learning Overview: Attendees will have the opportunity to learn about the communities of insects, bacteria, and fungi observed in different body regions of domestic pig (*Sus scrofa domesticus*) carcasses undergoing different stages of decomposition. Past work has established the succession of different groups of organisms during the process of decomposition of deceased organisms; this study intends to assess changes in the community assemblage of three different groups of decomposers (insects, bacteria, and fungi) and how each of these groups may influence each other. Attendees will also be able to learn how successional changes in decomposition can be applied to forensic investigations, specifically in the estimation of the minimum Postmortem Interval (mPMI).

Impact Statement: This presentation will enrich existing knowledge in the forensic science community regarding processes of decomposition, ecological succession, and their use in forensic investigations. The successional changes in entomological, bacteriological, and mycological communities noted during this study may provide reference information useful in forensic investigations involving a decomposing dead body.

One of the most common questions during forensic investigations is the estimation of the PMI, also known as the time of death.¹ In the past few decades, the application of forensic entomology has aided significantly in the estimation of the mPMI or Time of Colonization (TOC).²

Studies focused on the successional patterns of non-arthropod taxa on decomposing remains can also be helpful in forensic investigations; analyses of the microbial community and the fungal community present on decaying substrate during the different stages of decomposition have indeed shown a predictable pattern of species that can help the assessment of the PMI.^{3,4} In this study, the successional changes of the entomological, bacteriological, and fungal communities during the decomposition of domestic pig (*Sus scrofa domesticus*) carcasses were investigated.

Twelve pig carcasses were exposed to the elements in a field in central New Jersey during the summer and allowed to decompose. Insects, bacterial swabs, and tissue samples for fungi were collected for each stage of decomposition. Fungi and bacteria communities were sampled from three different body regions (mouth, thorax/abdomen, and genitals/rectum) and were then identified using 16S rRNA and ITS gene sequencing, respectively. Immature insects (eggs and larvae) collected from the carcasses were reared to adulthood under lab conditions to morphologically identify the species using available dichotomous keys. The results of this study show changes in the community assemblages across the different stages of decomposition. The observed changes are in line with previous observations reported in relevant literature and appear related to the physical and biochemical changes occurring during decay. While the field of microbiological and fungal succession is still young and more research needs to be conducted before it can become truly applicable in forensic investigations, the results of this study do enrich our current knowledge of entomological, microbial, and fungal successional patterns during decomposition.

With growing datasets from studies of this type, this study intends to provide the forensic science community with additional data that can be used as reference in the estimation of mPMI in forensic investigations.

Decomposition, Succession, Postmortem Interval (PMI)

H113 A Characterization of Volatiles Produced by Five Aerobic Postmortem Bacterial Species

Kyle Furuta, BSFS, Laboratory of Forensic and Bioanalytical Chemistry, Chaminade University of Honolulu, Honolulu, HI; Julianne Byrne, BSFS, Laboratory of Forensic and Bioanalytical Chemistry, Chaminade University of Honolulu, Honolulu, HI; Cynthia Cheung, MSFS, Laboratory of Forensic and Bioanalytical Chemistry, Chaminade University of Honolulu, Honolulu, HI; David Carter, PhD, Laboratory of Forensic Taphonomy, Chaminade University of Honolulu, Honolulu, HI; Katelynn Perrault; PhD*, Laboratory of Forensic and Bioanalytical Chemistry, Chaminade University of Honolulu, Honolulu, HI

Learning Overview: After attending this presentation, attendees will be able to identify key volatiles produced by postmortem microorganisms and explain how volatiles develop over time.

Impact Statement: This presentation will impact the forensic community by linking key bacterial species to major components of decomposition odor. These chemical signals may act as key molecules for insect attraction, scent-detection canine alerts, or as targets for future sensor devices targeting decomposition odor.

Volatile Organic Compounds (VOCs) are compounds with an appreciable vapor pressure, and in combination can produce complex odor profiles. These compounds have vast probative potential because they are associated with several types of physical evidence, such as accelerants, drugs, currency, and decomposing remains. Postmortem VOCs are currently becoming of particular interest for possibilities in aiding medicolegal death investigations.

Postmortem VOCs may have great potential in the location of clandestine graves and estimation of postmortem interval. Postmortem microorganisms are also of great interest. They represent a major component of the postmortem food web because they contribute directly to the decomposition of remains and help to attract other decomposers. Individual VOCs can be attributed to postmortem microbial species studied in isolation according to recent studies. This experiment was conducted to characterize the VOCs released by *Curtobacterium luteum*, *Vagococcus lutrae*, *Bacillus subtilis*, *Ignatzschineria indica*, and *I. ureiclastica* using comprehensive Two-Dimensional Gas Chromatography-quadrupole Mass Spectrometry/Flame Ionization Detection (GC×GC-qMS/FID).

VOCs were collected from the headspace above each species incubated on standard nutrient agar in a laboratory setting and monitored over a period of five days. The objectives of this research were to provide longitudinal profiles for each individual microbial species and begin a database of microbial VOC data for comparison to future decomposition odor studies.

Of the data collected, hundreds of VOCs were detected. The standard nutrient agar emitted a complex VOC profile itself, requiring compounds of interest from bacteria to be identified by means of abundance comparison. A feature selection process was performed to identify peaks of interest for each species.

- 18 VOCs of interest were detected in *B. subtilis*, with a large number of aromatics, nitrogen-containing compounds, and halogenated compounds.
- 19 VOCs of interest were detected in *C. luteum*, with a nearly equal distribution across the detected compound classes.
- 21 VOCs of interest were detected in *V. lutrae*, with the fewest compound classes represented of all microbes tested. Aldehydes, esters, and ethers were absent from this species, whereas these were typically present for other species.
- 8 VOCs of interest were detected in *I. indica*, which were largely comprised of aromatic and polysulfide compounds.
- 25 VOCs of interest were detected in *I. ureiclastica*, which were largely contributed by aromatics, ketones, and alcohols.

Although the number of VOCs of interest identified after the feature selection reduced the number of compounds to around 20 compounds per species, the total number of unique compounds detected across the entire research study was 55. This count represents compounds that were differentiated from control samples of blank agar. The list of VOCs of interest provides insight into the origin of postmortem VOCs and typical temporal trends that may be observed given minimal species interaction and/or competition. The combination of numerous bacterial species exploiting a cadaveric resource can create an additive VOC profile that is more challenging to interpret in complex mixtures. The current study will serve to provide foundational data of the key VOCs contributed by each species, which has not been well understood in past decomposition odor research. This will also lay a foundation for future studies looking at VOC production when species are combined with one another to better understand how these bacterial species interact over cadaveric resources.

Forensic Taphonomy, Postmortem Microbiology, Volatile Organic Compounds (VOCs)

H114 Determining Human Identity From Leeches

Veronica Cappas, BS, The Pennsylvania State University, University Park, PA; Reena Roy, PhD, The Pennsylvania State University, University Park, PA*

Learning Overview: Attendees can expect to learn how human DNA profiles can be obtained from an annelid using direct amplification.

Impact Statement: The impact of this presentation will be manifested in the DNA analyst's ability to generate human DNA profiles from unlikely evidence such as an annelid using direct amplification.

Leeches are worms commonly found in water and can suck blood from a human host. These worms carry an anticoagulant, known as hirudin, in their salivary gland. These annelids have suckers, they conceal their cutting plates that hook onto human flesh, and after making a 2mm incision, they can then ingest from 5mL to 15mL blood from one human. If a perpetrator disposes of a victim's body in a river, stream, or pond, the leeches in the pool of water can hook onto the suspect's body. Once they are gorged with blood within about 30 minutes, they can fall off in the nearby area. In addition, they can help with identification of a victim or determine if a body had been in a certain area of the water. Therefore, they can become a valuable source of evidence for the forensic scientists.

The Roy research group has previously determined human identity from *Anopheles stephensi* mosquito blood meals using COPAN® microFLOQ® Direct swabs and PowerPlex® Fusion 6C System to identify Short Tandem Repeat (STR) DNA profiles. Massively parallel sequencing was also performed on the blood from the midgut of the same mosquitoes. In this current study, a similar approach was taken to identify human STR profiles from blood meal ingested by leeches. North American medicinal leeches were obtained from a commercial source, and blood from male and female donors were fed to individual leeches. After a certain period of time, each leech was frozen quickly, then dissected. Once blood was identified in the midgut with presumptive test, the presence of human blood was confirmed with various biological tests. After that, the tip of one swab was used to collect a minute amount of blood from the midgut area of each worm. These swabs, containing the human blood on their tips, were then used for direct amplification and STR profiles were determined using PowerPlex® Fusion 6C PCR amplification reagents. Known blood samples (reference samples) were also amplified using the COPAN® microFLOQ® Direct swabs and analyzed similarly. The Applied Biosystems™ 3130xl Genetic Analyzer was used for capillary electrophoresis. GeneMarker® HID V3.0.0 software was used for analyzing the STR profiles.

Complete and concordant profiles, consistent with the reference profiles of the donors of blood, were obtained from the midgut of the leeches using the above method. The results of this study indicate that COPAN® microFLOQ® Direct swab is an excellent way to amplify blood directly, even when the blood has been ingested by leeches. Complete STR profiles can be generated within a very short period using these swabs and the PowerPlex® Fusion 6C PCR amplification kit. Since only a minute quantity of blood is required, this method of collection and amplification is an excellent procedure for obtaining human identity from minute amounts of blood ingested by leeches and similar organisms. Research is being pursued to include sequencing of the blood from the leech midguts in order to obtain additional information about the human donors.

Direct Amplification, Human Blood, Leeches

H115 2022 Jay Dix Day Lecture Series

Michael Graham, MD, St. Louis University, St. Louis, MO and Office of the Medical Examiner, City of St. Louis, MO; Joseph Prahlow, MD, Western Michigan University, Homer Stryker M.D. School of Medicine, Kalamazoo, MI; Andrew Baker, MD*, Hennepin County Medical Examiner's Office, Minneapolis, MN; Jonathan Hayes, MD*, Office of the Chief Medical Examiner of the City of New York, New York City, NY; Joyce deJong, DO*, Western Michigan University, Homer Stryker M.D. School of Medicine, Kalamazoo, MI; James Gill, MD*, Connecticut Office of the Chief Medical Examiner, Farmington, CT*

Learning Overview: Attendees can expect to learn how and why deaths related to previously specified topics occur. Attendees will learn a systematic approach to the evaluation of such deaths that can easily be implemented in their daily practices.

Impact Statement: Attendees will receive a comprehensive review of what causes and contributes to deaths related to the previously specified topics. They will be able to systematically evaluate deaths in which the previously specified topics may have played a role that they encounter in their daily practices.

Electricity is a ubiquitous entity in our lives. Some of it is intentionally generated to provide power and some of it originates as a force of nature (lightning). Interaction between humans and electricity is common and typically has no untoward effects. However, under some conditions this interaction may result in morbidity and/or mortality. Multiple causes, mechanisms, and contributory factors play a role in injury and deaths involving electricity. Understanding and evaluating injuries and deaths in which electricity may have played a role requires basic knowledge of electricity and how it affects various biological vital functions. Recognition of injuries and deaths caused by electricity is particularly important because of implications regarding the safety of others. This lecture will provide a comprehensive review of these issues.

Firearm fatalities are a major cause of non-accidental morbidity and mortality in the United States. Multiple factors and mechanisms are involved in producing firearm injuries. Understanding and evaluating firearm injuries requires a basic understanding of how these injuries are produced and how to distinguish them from other types of trauma. This lecture will provide a comprehensive review of these issues.

Human life requires the uptake and utilization of oxygen along with the release of metabolic waste. Failure of these processes leads to asphyxia. Proper evaluation of asphyxial deaths requires knowledge of the entities that cause asphyxia, pathophysiologic mechanisms, asphyxia death scenarios, and factors that contribute to death. This lecture provides comprehensive discussion of the investigation of deaths that may involve asphyxia.

There are multiple factors that can play a role in deaths that are temporally related to participating in and, occasionally, while being a spectator at sporting or other recreational activities. This lecture will review several issues that arise in the context of investigating deaths that occur in relation to sports/recreational events. Understanding factors that are involved in these deaths also helps in instituting safety measures to protect participants and spectators.

The past three decades have seen an impressive expansion in the range of drugs available for abuse. The psychedelic revolution of the 60s spilled over into the 70s and 80s with the advent of “designer drugs” like Ecstasy (MDMA), joined in the 90s and 00s by the increased abuse of psychoactive drugs like ketamine and GHB, and, more recently, by the proliferation of powerful derivatives of the analgesic agent fentanyl and stimulants such as methamphetamine. A second pattern of expanded drug use involves increase in consumption in rural areas poorly served by the traditional distribution network for cocaine and heroin. The heartland of America has seen explosive growth in the use of methamphetamine, whether prescribed, homegrown, or cartel-distributed, and in diversion and abuse of prescription medication. Many of the drugs responsible for causing deaths are abused because of their sedating and/or stimulating properties. These substances are commonly used in characteristic scenarios and have somewhat stereotypical death scenarios. Recognition of the patterns of abuse of traditional and novel toxicants helps in assessing the role, if any, of these agents in particular deaths. This lecture will provide a comprehensive review of pharmaceutical and non-pharmaceutical toxicants in the context of investigating deaths.

Forensic Pathology, Pathology, Death Investigation

H116 The National Center for Forensics—Forensic Workforce Development

Danny Milner, MD, ASCP, Chicago, IL; Joseph Dizinno, DDS, George Mason University, Fairfax, VA; Anthony Falsetti, PhD, George Mason University, Fairfax, VA; Amie Ely, JD, NAAG, Washington, DC; Robert Kurtzman, DO, Montana State Medical Examiner's Office, Billings, MT*

Learning Overview: After attending this presentation, attendees will understand the current barriers (real or perceived) for trainees to choose, successfully complete, and matriculate as forensic pathologists in the United States. Further, attendees will be able to explain multiple solutions/approaches to decreasing/removing these barriers to increase the forensic workforce.

Impact Statement: This presentation will impact the forensic science community by presenting work being conducted through the National Center for Forensics by the American Society of Clinical Pathology (ASCP) in collaboration with George Mason University on increasing forensic pathology workforce.

The National Center for Forensics was established through a competitive grant funded by the National Institute of Justice (NIJ) for the purpose of providing scientific and technical learning opportunities for the medicolegal community specifically targeted for medical students, and focused on underserved rural areas; providing forensic science and legal training, information, and support to law enforcement, district judges, and other appropriate criminal justice agencies; and developing, consolidating, and providing access to resources and opportunities for education, training, and best practices in the forensic science community, structured to benefit current and future practitioners in the field. This work includes an overall goal of increasing the pathology workforce through feasible, practical interventions.

The current forensic pathology workforce of approximately 500 board-certified forensic pathologists does not meet the current need in the United States of at least 1,200. This work conducted a literature and existing resources review, created structured questions across four areas, and completed nine focus groups using a diverse set of individuals from inside and outside of the practice of forensic pathology. Using the existing information and insights from focus groups, this work identified barriers in forensic pathology for medical students, residents, fellows, and practicing pathologists. These barriers include salary gaps, microaggressions, debt ratios, and workplace support/resources. This study hypothesized several potential solutions to combat these barriers that need to be tested for impact. From this work, working groups are to be formed with the intention of launching an additional global survey with the final results being feasible interventions focused on the specific barriers described.

Forensic Pathology, Workforce, Focus Groups

H117 The National Center for Forensics—The Medical Examiner's Role

Robert Kurtzman, DO, Montana Forensic Science Division Medical Examiner's Office, Billings, MT; Dan Milner, MD, American Society for Clinical Pathology, Chicago, IL; Anthony Falsetti, PhD, George Mason University, Washington, DC; Joseph DiZinno, DDS, George Mason University, Washington, DC; Amie Ely, JD, National Association of Attorneys General, Washington, DC*

Learning Overview: After attending this presentation, attendees will understand the medical examiner role with the National Center for Forensics and the concept of a coordinated state medical examiner's office/county coroners function utilizing a "coroner liaison."

Impact Statement: This presentation will impact the forensic science community by presenting work being conducted at the Montana State Medical Examiner's Office (MTMEO) in coordination with the state's 56 county coroner offices to promote consistent, timely, and cost-effective death investigation.

The National Center for Forensics was established through a competitive grant funded by the National Institute of Justice (NIJ) for the purpose of providing scientific and technical learning opportunities for the medicolegal community specifically targeted for medical students and focused on underserved rural areas; providing forensic science and legal training, information, and support to law enforcement, district judges, and other appropriate criminal justice agencies; and developing, consolidating, and providing access to resources and opportunities for education, training, and best practices in the forensic science community, structured to benefit current and future practitioners in the field.

Fifty-six county coroner offices investigate death in Montana which is the fourth-largest state in the United States and has a population of approximately 1,040,000. When a Board-Certified Forensic Pathologist (BCFP) is needed to perform a postmortem examination, coroners utilize the MTMEO. The MTMEO lost all state medical examiners in July 2015. Following restructure, the MTMEO was staffed with four full-time BCFPs, two full-time autopsy assistants, and two part-time autopsy assistants working in two regional offices as of April 2019. The concept of a "coroner liaison" was contemplated to facilitate collection of consistent, timely death investigation from coroners for the BCFPs with an online Medicolegal Death Investigation (MDI) reporting system known as the Montana Death Case Management System (MTDCMS). The system, first implemented in December 2019, includes an Application Platform Interface (API) with the state's Vital Statistics Bureau for automated death certificate completion, purportedly the first such system operating in the United States.

The system, MTDCMS, is currently utilized by 39 of 56 county coroners with a desired goal of 100% utilization and is supported by recent legislation. With the NIJ grant, the concept of a full-time, American Board of Medicolegal Death Investigation (ABMDI) -certified coroner liaison came to fruition and was hired and began work August 2021. The addition of the coroner liaison has made an immediate impact to facilitate improved information collection; improve MTDCMS utilization by coroners and lessen the burden of information collection and MTDCMS promotion otherwise performed by BCFPs. The coroner liaison assists with development of forensic training with BCFPs for coroners and frees time dedicated to medical student training. As of this writing, two medical students have served a four-week rotation designed to promote interest in pursuing a career in Forensic Pathology (FP). Additional rotations have been scheduled. Thus far, students have expressed an interest in FP and long-term results will need to be tracked.

In summary, the MTMEO serves a large rural state in partnership with 56 county coroners with a small, cost-effective staff to promote uniform death investigation utilizing a state-wide online MDI reporting system facilitated with a coroner liaison. The MTMEO encourages and provides opportunities for medical students and stakeholders in forensic science to experience death investigation in a state system that serves mostly rural communities and better understand the challenges and opportunities that exist in that environment.

Coroner Liaison, Medical Examiner, Death Investigation

H118 Gunshot-Related Fatalities in the Pediatric Population: A Retrospective Study From the Cook County Medical Examiner's Office

Lorenzo Gitto, MD, State University of New York, Upstate Medical University, Department of Pathology, Syracuse, NY; Ponni Arunkumar, MD, Cook County Medical Examiner's Office, Chicago, IL*

Learning Overview: After attending this presentation, attendees will better understand the prevalence and features of firearm-related deaths in the pediatric population.

Impact Statement: This presentation will impact the forensic science community by adding information about a topic rarely discussed in the current forensic literature.

Deaths due to gunshot wounds are commonly encountered by forensic pathologists worldwide. While the generic features of firearm fatalities are classically described in the forensic literature, only scant information can be found regarding pediatric deaths due to gunshot wounds. Although most deaths occur in young adults or adults, a minor population of young children is also affected. This study reports a series of pediatric deaths due to gunshot wounds from a large metropolitan area.

The Cook County Medical Examiner's Office files were searched for deaths due to gunshot wounds between January 2016 and December 2020. This study considered the general definition of "pediatric population" as subjects between 0 and 18 years. The age was then subcategorized into multiple age groups. Only cases in which gunshot wounds were the primary and immediate cause of death and a clear and reliable manner of death was reported were included in the study. Delayed complications of gunshot wounds were excluded. Information regarding the cases was obtained from the investigative reports, the autopsy reports, and toxicological studies.

A total of 513 pediatric deaths due to gunshot wounds were found in the Cook County Medical Examiner's Office database. After excluding cases of delayed complication of gunshot wounds, 498 cases met the study criteria. The study population included 451 males and 47 females, with a mean age of 16 years; 378 subjects were African American, 95 were Latino, 24 were Caucasian, and 1 was Asian. The manner of death was homicide in 454 cases, suicide in 35 cases, undetermined in 7 cases, and accident in 2 cases. A single gunshot wound was observed in 259 cases, while multiple gunshot wounds were present in 239 cases; 405 deaths occurred in the city of Chicago, while the remaining 93 occurred in other cities.

This study will illustrate distinct features of pediatric deaths due to gunshot wounds. Compared to gunshot wounds deaths in adults, those involving the pediatric population may be more challenging. In this study, different age groups highlight the patterns of injury, the manner of death, circumstances of the event, and other aspects in this specific population. A thorough discussion of the results will be presented to attendees.

Forensic Science, Gunshot Wound, Pediatric

H119 Human Fatalities Caused By Dogs: A 17-Year Retrospective Study in Harris County, Texas, and New York City, New York

Hannah Jarvis MBBS, MRCS, Harris County Institute of Forensic Sciences, Houston, TX; Gregory Dickinson, MD, Office of Chief Medical Examiner of the City of New York, New York, NY*

Learning Overview: After attending this presentation, attendees will gain an understanding of the circumstances, autopsy findings, toxicological results, and epidemiological patterns of human fatalities caused by dogs.

Impact Statement: This presentation will impact the forensic science community and public health communities by providing insight into human fatalities caused by dogs to promote public health safety campaigns and help forensic pathologists evaluate fatalities.

There are approximately 300,000 emergency room visits and up to 13,000 hospitalizations due to dog bite injuries every year in the United States. Dog bite-related fatalities are rare and account for approximately 18 deaths per year in the United States. Texas has one of highest incidence rates of dog bite-related fatalities in the United States. Most of these deaths are in children, occur on the owner's property, by the family's own dog, and involve pit bull-type dogs.¹

This study reviews the case files of all fatalities related to injuries caused by dogs over a 17-year period in Harris County, TX, and New York City, NY, to study the circumstances, autopsy findings, toxicological results, and epidemiological patterns of these fatalities.

The electronic databases of the Harris County Institute of Forensic Sciences and Office of Chief medical Examiner of the City of New York were searched for all fatalities related to dogs between 2003 and 2021.

Of the 23 fatalities, 13 were male and 10 were female, and the average age was 37.5 years, ranging from 16 days to 80 years old, with seven cases being 4 years of age or younger. Most were White ($n=10$) and three were homeless people. Half of the injuries ($n=12$) occurred within a residence. Where known, the dogs involved in the deaths were mostly pit bull-type dogs ($n=6$). The most frequent location where the attacks occurred were Houston, TX, ($n=6$) and the borough of Brooklyn in New York City, NY ($n=3$). Attacks frequently occurred in the winter ($n=6$); and between 4:00 p.m. and 5:00 p.m. ($n=3$) or 9:00 p.m. to 10:00 p.m. ($n=3$). Toxicological analysis revealed illicit substances (cocaine and methamphetamine) and ethanol in six cases.

Eighteen cases underwent autopsy examination and five cases underwent external examination only. The most commonly injured body regions were the extremities ($n=17$) and head ($n=14$). Some of the notable injuries included skull fractures (open and closed), cervical spine fracture with spinal cord injury, other fractures (forearm and ribs), vascular injuries (radial and carotid artery, internal jugular vein), crush injury (larynx), and visceral lacerations (lung, heart, liver). Deaths with no survival interval ($n=12$) were due to multiple blunt and sharp force injuries caused by dog bites or a sudden cardiac arrhythmia during the attack ($n=1$); and those with a survival interval ($n=10$; range 2 days to 19 years) were due to infective complications, including one case of rabies meningoencephalitis, or pulmonary thromboemboli complicating remote injuries of the lower extremities. Twenty-one cases were certified as Accident as the manner of death; one case was certified as Natural (rabies meningoencephalitis); and one as Homicide (neonate).

It is important for a forensic pathologist to be able to identify these injuries as being caused by a dog and not criminal assault and to recognize the patterns. Studies show the rate of deaths from injuries due to dogs is increasing, and are seen frequently in children.¹ Most dog owners are not aware of factors that increase the risk of dog bites, and public safety campaigns should be promoted. A collaborative and multidisciplinary approach is necessary to try to prevent these fatalities.

H120 Homeless Mortality Reporting by the King County, Washington, Medical Examiner's Office: Impact and Importance

Nicole Croom, MD, MPH*, King County Medical Examiner's Office, Seattle, WA; Richard Harruff, MD, PhD, King County Medical Examiner's Office, Seattle, WA

Learning Overview: After attending this presentation, attendees will be able to describe homeless mortality reporting by the King County Medical Examiner's Office (KCMEO) and how it serves public health and the affected community.

Impact Statement: Recognizing that homelessness is a national crisis, this presentation shows how death investigation systems can provide unique data informing and evaluating community responses.

Introduction: On any given night in the United States, there are roughly 567,715 Individuals Experiencing Homelessness (IEH).¹ The number of IEH has decreased by 12% overall since nationwide data collection began in 2007 but has been steadily rising since 2018, as measured by Point-in-Time Counts (PITC), indicating that recent events have reversed progress in eliminating homelessness.¹ Federal health statistics do not count the number of IEH deaths.¹ To fill this gap, the non-profit National Health Care for the Homeless Council began monitoring IEH mortality in 2019.¹ Unfortunately, only 2% of United States counties report decedent housing status.^{2,3} Extrapolating data from reporting cities to the national PITC, the Council estimates that between 17,500 and 46,500 IEH deaths occurred in 2018, though this may be an underestimate due to non-standardized definitions of housing status.^{2,3}

KCMEO serves a population of about 2.3 million of which 11,751 are IEH as estimated by the 2020 PITC; a 5% increase in homelessness compared to the 2019 PITC.^{4,5} Since 2010, KCMEO has compiled homeless mortality data and shares this information with community stakeholders. This presentation reviews KCMEO's homeless death reporting, analyzes IEH mortality in King County from 2010-2020, evaluates how this data serves community responses in combating the homelessness crisis, and encourages other death investigation offices to participate in standardized data collection measuring IEH mortality.

Methods and Materials: During the period of this study, 2010–2020, medicolegal death investigators recorded housing status for jurisdictional deaths using standardized criteria developed in conjunction with Public Health–Seattle and King County, Healthcare for the Homeless program. The data were entered into KCMEO's VertiQ database along with demographics, death certificate information, and narrative accounts describing each death. Quantitative data for this presentation were analyzed using Microsoft® Excel®. Qualitative data came from interviews with community stakeholders who use homeless mortality data.

Results: Between 2010 and 2020, KCMEO assumed jurisdiction on a total of 27,583 cases, with an overall annual increase of 87% over this period. Over this period, there were 1,346 deaths of IEH; the proportion of IEH death out of the total varied from 2.2% to 7.6%, with the maximum in 2018. Of IEH deaths, the average age was 49 years, 19% were female, and 74% were given the racial categorization of White. Manners of death were Accident in 46%, Homicide in 4.5%, Natural in 37%, Suicide in 6.8%, and Undetermined in 5.5%. Acute drug intoxications accounted for 80% of those certified Accident and 37% of total IEH deaths. Cardiovascular disease was the most common cause (36%) of IEH deaths certified Natural. Interviews found that community stakeholders use mortality data for a variety of purposes, including health care coordination and management, evaluation of outreach efficacy, next-of-kin notification, and to "raise up the dignity of the dead."

Conclusion: This study demonstrated important differences in mortality among the homeless compared to the general population investigated by KCMEO. These data represent an important metric for public health and community groups responding to the homelessness crisis. Considering that only 2% of counties report mortality data for IEH, death investigation systems have an opportunity to participate in the response by collecting and reporting housing status data of decedents.

Individuals Experiencing Homelessness, Mortality Review, Program Evaluation

H121 An Analysis of Two Decades of Intimate Partner Femicide-Suicide in Turkey

Nüket Paksoy Erbaydar, MD, PhD, Hacettepe University Medical Faculty Department of Public Health, Ankara, Turkey; Nilufer Dilara Ar Mutlu, MSc, Hacettepe University Medical Faculty Department of Public Health, Ankara, Turkey; Aysun Balseven Odabaşı, MD, PhD, Hacettepe University Medical Faculty Department of Forensic Medicine, Ankara, Turkey; Mehmet Cavlak, MD, Hacettepe University Medical Faculty Department of Forensic Medicine, Ankara, Turkey*

Learning Overview: Attendees of this presentation will learn about the term murder-suicide, the increasing rates of Intimate Partner Female Murder-Suicide (IPF-S) incidents in the media news broadcast in Turkey, and the characteristics of the victims and perpetrators of the incidents.

Impact Statement: This presentation will impact the forensic science community by identifying the methods that perpetrators use to kill and commit suicide, the characteristics of the victims, and the perpetrators of the incidents.

IPF-S is an understudied subgroup of homicide-suicide deaths. There is limited research handling IPF-Ss in the Eastern Mediterranean region. This study aimed to evaluate the characteristics of IPF-Ss that occurred in Turkey between 2000 and 2019. The IPF-Ss ($n=226$) were extracted from electronic news stories. This study collected data about victims, perpetrators, their relationships, and the incidents of murders and suicides. Descriptive statistics were calculated, and logistic regression analysis, mortality rates, and the proportion of IPF-S in femicides calculation were conducted, showing that 13.3% of the femicides ($n=1,699$) were IPF-Ss. The IPF-Ss were increasing in five-year intervals, which were highest in the 2015–2019 period (62.5%). The victims were married in 48.2% of the cases, 56% were younger than 35; while the perpetrators were married in 51.3%, and older than 40 in 52.6% of the cases. In 42.0% of the cases, the perpetrators were living together with the victim. Most (79.2%) of the cases were in urban settlements, and perpetrators used firearms in 84.1% of the femicides. Firearms were a more common method in cases where IPF-Ss were planned ($OR=2.98$), when the IPF-S method was the same ($OR=29.6$), and when the perpetrator committed suicide ($OR=7.82$).

Homicide/Suicide, Femicide, Violence Against Women

H122 Influencing Factors on Postmortem Protein Degradation for Postmortem Interval (PMI) Estimation: A Systematic Review

Angela Zissler, Department of Biosciences, Paris-Lodron University of Salzburg, Salzburg, Austria; Walter Stoiber, Department of Biosciences, Paris-Lodron University of Salzburg, Salzburg, Austria; Janine Geissenberger, MSc, Department of Biosciences, Paris-Lodron University of Salzburg, Salzburg, Austria; Peter Steinbacher, PhD, Department of Biosciences, Paris-Lodron University of Salzburg, Salzburg, Austria; Fabio Monticelli, Department of Forensic Medicine, Paris-Lodron, University of Salzburg, Salzburg, Austria; Stefan Pittner, PhD, Department of Forensic Medicine, Paris-Lodron University of Salzburg, Salzburg, Austria*

Learning Overview: This presentation provides an overview of the research on influencing factors on forensic postmortem protein degradation, discusses limitations and the current state of knowledge, and addresses future perspectives and important open research questions.

Impact Statement: Estimation of the PMI is of critical importance in forensic routine, but often extremely difficult. Novel techniques to contribute to the current methodic spectrum are certainly required, but information on influencing factors is scarce. This presentation highlights the immense importance of this issue for PMI estimation and provides the basis for targeted future research.

Background: A most precise estimation of the PMI is a critical and yet extremely difficult task in forensic routine. In the past decades, biochemical analysis of tissue decomposition, especially protein degradation, has become of significant interest in this regard.

While there is evidence for the breakdown of specific proteins in a number of different tissues, little is published on (possible) individual and environmental influencing factors, despite the striking importance of this issue for the application in casework. This literature review aims to investigate the current state of knowledge and the future perspectives of influencing factors on postmortem protein decomposition for the use in forensic PMI estimation.

Objectives: This study provides a systematic review of the literature to evaluate the current research status of influencing factors on protein degradation-based PMI estimation. Focus was set on characteristics of internal and external influencing factors and the respective susceptibility and/or robustness of protein degradation.

Method: A systematic literature search up to December 2020 was conducted on the effect of influencing factors investigated in the context of postmortem protein degradation in the tissues of animals and humans using the scientific databases PubMed® and Google® Scholar, as well as the reference lists of eligible articles.

Results: This work identified ten studies investigating a total of seven different influencing factors in degrading tissues/organs of humans and animals using six different methodological approaches. Although comparison of study outcomes was hindered by the high variety of investigated factors, and by high risk of bias appraisals, it was evident that the majority of the influencing factors concerned affected protein degradation, thus being able to modulate the precision of protein degradation-based PMI estimation.

Conclusion: The results clearly highlight the need for a thorough screening for corresponding factors to enable the introduction of appropriate correction factors and exclusion criteria. This seems especially relevant for the protein degradation-based study of human PMI to increase the reliability and precision of the method and to facilitate a broader applicability in routine forensic case work.

PMI Estimation, Protein Degradation, Influencing Factors

H123 Postmortem Computed Tomography (PMCT) in Unwitnessed Choking: A Case Report and Retrospective Review of Seven Cases of Airway Obstruction

Michael Harrell, MD, Office of the Medical Investigator, Albuquerque, NM; Lauren Decker MD, Office of the Medical Investigator, Albuquerque, NM*

Learning Overview: After attending this presentation, attendees will have a better understanding of the utilization of Postmortem Computed Tomography (PMCT) in triaging witnessed and unwitnessed (suspected) choking deaths.

Impact Statement: This presentation will impact the forensic science community by correlating findings from multiple autopsies with PMCT where the cause of death is choking. The aim is to improve the autopsy triage process by utilizing PMCT findings to determine the most appropriate examination type.

Choking is broadly defined as a form of asphyxia in which the internal airways are blocked; the manner of these deaths is most commonly classified as accident. Choking-related deaths may prove to be a diagnostic dilemma when triaging for autopsy. At the Office of the Medical Investigator, triage of suspected choking relies on scene evidence to guide the type of examination. Generally, witnessed chokings, including bystander or first responder testimony of the event, require an external examination. If the event is not witnessed, an autopsy is performed to confirm the presence of an obstructing bolus and rule out an alternative cause of death.

PMCT has proven invaluable in evaluating the pharynx and airways for the presence of foreign material.^{1,2} For example, a 54-year-old man with a history of unspecified intellectual disability, hypertension, diabetes mellitus type 2, and remote aspiration pneumonia was found unresponsive in the living room of his group home. Emergency medical services were contacted, and no resuscitative efforts were performed given obvious signs of demise.

PMCT demonstrated abundant obstructive isoattenuating and hypoattenuating foreign material within the oropharynx, hypopharynx, proximal esophagus, trachea, and in the right and left mainstem bronchi immediately distal to the carina. Autopsy revealed the body of an adult male with no significant injuries. A large food bolus completely obstructed the hypopharynx, with abundant smaller food particles throughout the proximal airways, consistent with findings on PMCT. Other natural disease included cardiomegaly, atherosclerotic disease, nephrosclerosis, and steatosis. The cause and manner of death were certified as choking, accident.

A retrospective review of unwitnessed, adult choking deaths with findings at autopsy that underwent PMCT was performed at the Office of the Medical Investigator, in Albuquerque, NM, from 2018 to 2021. This review revealed seven cases, including the aforementioned case. All seven cases had PMCT findings that correlated with gross findings at autopsy. Six of the seven cases had large, obstructing foreign material in the hypopharynx, identified both grossly and by PMCT. One case had only distal airway foreign material that was less readily identified on PMCT. All cases had underlying conditions that predisposed to choking, including intellectual disability, dementia, substance intoxication, intracranial masses, remote stroke, and edentulousness.

Given the gross and PMCT correlations in this review and the referenced material, imaging should be considered informative in decision making regarding autopsy triage of witnessed and unwitnessed choking deaths. This may be advantageous for cultural and religious groups requesting minimally invasive examinations, or those with a marked food burden by PMCT as well as a condition that predisposed to choking. Further investigations would include correlative studies with larger sample sizes, especially involving children and decedents with decomposition changes.

Autopsy, Choking, Accident

H124 The Status of Internal Neck Structures in Violent Compression of the Neck: A Ten-Year Autopsy Study

Nilesh Tumram, MD, Government Medical College, Chandrapur, Maharashtra, India*

Learning Overview: After attending this presentation, attendees will be able to recognize the status of internal neck structures in violent compression of the neck, particularly the damage caused by it.

Impact Statement: This presentation will impact the forensic science community by creating understanding of damages caused by violent compression of the neck. Autopsy findings such as contusion, tears, and hemorrhages in internal neck structures like oropharynx, laryngopharynx, and larynx in cases of fatal compression of neck can be of important medicolegal significance. Presented is such a study that highlights its occurrence and its possible significance to correlate with such incidences.

Fatal compression of the neck due to strangulation, hanging, throttling, etc. are typical forms of suicidal, accidental, and homicidal deaths. External injuries such as ligature mark, periligature injuries, abrasion, contusion over the neck, and internal injuries like hyoid bone fracture, thyroid cartilage fracture, neck muscle hematoma, etc. are utilized to opine regarding the antemortem nature of fatal compression of the neck. However, sometimes the above findings may be minimally present. In such cases, some other findings occurring due to compression of the neck can also be very useful and additive for opining in such incidences.^{1,2}

Out of total 30,310 autopsy cases occurring in a period of ten years at the autopsy center, this work has studied 280 cases of violent compressions of the neck. Apart from the autopsy findings such as ligature mark over the neck, dribbling of saliva, hemorrhages over the neck muscles, fractures of the hyoid and thyroid cartilage, injuries occurring in the internal neck structures like the oropharynx, laryngopharynx, and larynx were studied. Such findings can be useful for commenting on the antemortem nature of such cases together with the other established findings in such cases. Also, such findings can become significant if there are minimal or no findings available in cases of fatal compression of the neck.

In postmortem examination of victims of hanging, ligature strangulation, and throttling who exhibited relatively sparse external findings of significance, a unique and apparently less-described patterned hemorrhage within the oropharynx, laryngopharynx, and larynx can become crucial. In cases where strangulation is suspected as well as other potentially important violent neck compressions, a detailed inspection of these structures may provide invaluable information.

Violent Compression of the Neck, Internal Neck Structures, Autopsy

H125 A Comparison of Findings Identified at Traditional Invasive Autopsy and Postmortem Computed Tomography (PMCT) in Suicidal Hangings

James Lyness, MB, BCh, The State Pathologist's Department, Institute of Forensic Medicine, Belfast, Northern Ireland, United Kingdom and University of Leicester, Leicester, England, United Kingdom and Queen's University of Belfast, Belfast, Northern Ireland, United Kingdom; Anthony Collins, MB, BCh, Royal Victoria Hospital, Belfast, Northern Ireland, United Kingdom; Guy Rutty, MB, University of Leicester, Leicester, England, United Kingdom and East Midlands Forensic Pathology Unit, Leicester, England, United Kingdom; Jane Rutty, PhD, MSc, De Montfort University, Leicester, England, United Kingdom and University of Leicester, Leicester, England, United Kingdom*

Learning Overview: Following this presentation, attendees will have a better understanding of the efficacy of PMCT to detect pertinent findings in cases of suspected suicidal hanging.

Impact Statement: This presentation provides an evidence base for the use of PMCT in cases of suicidal hanging, which is a common case type referred for medicolegal autopsy throughout the world.

The reports of the invasive autopsy and PMCT images were reviewed in 50 cases of suspected suicidal hanging referred to the State Pathologist's Department, Belfast, during an 11-month period. The Traditional Invasive Autopsy (TIA) examinations included an external examination and full internal examination completed by a consultant forensic pathologist. The PMCT images, which included the head, neck, chest, abdomen and pelvis, were reported by a consultant radiologist. The pathologist and radiologist were both blinded to the findings of the other modality. A Cohen's Kappa coefficient (K) was subsequently calculated to assess the agreement between the TIA and PMCT across a range of pertinent findings. This demonstrated perfect agreement with the identification of a ligature (K=1.00) and a strong level of agreement for the identification of a ligature suspension point (K=0.832). However, there was only a minimal level of agreement for the overall ligature mark (K=0.223). In addition, PMCT demonstrated a weak level of agreement for fractures of hyoid bone (K=0.555) and thyroid cartilage (K=0.538), but the invasive autopsy was shown to not be infallible as three probable fractures were identified on PMCT only. Furthermore, the TIA was shown to be superior in the identification of intramuscular and laryngeal fracture-related hemorrhage/bruising. In contrast, PMCT was superior to TIA in the identification of gas deposition within the body, including subcutaneous emphysema and fracture-associated gas bubbles. However, this study would question the usefulness of these findings, particularly in decomposed bodies. Finally, although not a primary study objective, there was overall good correlation between the natural disease and trauma identified elsewhere in the body during the TIA and PMCT, with only a few minor discrepancies reported.

The study demonstrated that PMCT can assist the investigation of suspected suicidal hangings, but the accuracy of many findings is limited, and the technique should not be used in the absence of, at the very least, a detailed external examination completed by an experienced autopsy pathologist.

Hanging, PMCT, Autopsy

H126 An Autopsy Study of Anthropometric Measurements and Indices of Obesity and Their Relationship With Coronary Artery Atherosclerosis in a South Indian Population

Francis Nanda Prakash Monteiro, MD, DNB, A.J. Institute of Medical Sciences and Research Centre, Mangalore, Karnataka, India; Student Shyna Quadras, Stony Brook University, Stony Brook, New York, NY; Tanush Shetty, MD, Father Muller Medical College, Mangalore, Karnataka, India*

Learning Overview: After attending this presentation, attendees will appreciate the relationship between anthropometric obesity measurements and coronary atherosclerosis; gain a better understanding of gender differences with respect to these measurements and indices; and find out if these measurements are coronary artery specific.

Impact Statement: The impact of this study lies in its findings that anthropometric measurements/indices of obesity can be used to identify high risk cases of atherosclerosis at an early stage. Early detection and appropriate preventive or corrective measures can then be instituted to reduce the associated cardiac morbidity and mortality.

The association between human physique and morbidity and mortality resulting from coronary artery disease has been studied extensively over several decades. Multiple studies have also been done on the correlation between grade of atherosclerosis, coronary artery diseases, and anthropometrical measurements.¹⁻⁴ However, the number of autopsy-based studies drastically reduces this number. While in living subjects, it would be expensive, difficult, and even harmful to subject them to imaging modalities like Computed Tomography (CT) scans and procedures involving contrast media to study mild atherosclerosis, no such harm is encountered in autopsied cases.⁵

This autopsy-based study was aimed to correlate the anthropometric measurements and indices of obesity such as Waist Circumference (WC), Hip Circumference (HC), Body Mass Index (BMI), and Waist Hip Ratio (WHR) with the degree of atherosclerosis in the Right Coronary Artery (RCA), main branch of the Left Coronary Artery (LCA), and the Left Anterior Descending Artery (LADA) in 95 South Indian origin victims of both sexes between the ages of 18 and 75 years. The grading of atherosclerosis was done according to criteria suggested by the American Heart Association. The study also analyzed the correlation of the anthropometric measurements and indices of obesity with the number of coronaries affected.

All the anthropometric measurements and the derived indices were found to be significantly correlated to each other in both the sexes except for the age, which is found to have a significant correlation only with the WHR. In both the genders, a severe degree of atherosclerosis was commonly observed in LADA, followed by LCA and RCA. The grade of atherosclerosis in RCA is significantly related to the WHR in males. The grade of atherosclerosis in LCA and LADA is significantly related to the WHR in females. Significant relation was observed between the grade of atherosclerosis in RCA and WC and WHR, and between the grade of atherosclerosis in LADA and HC in males. Significant relation was observed between the grade of atherosclerosis in RCA and WC and WHR, and between the grade of atherosclerosis in LADA and HC in females.

Based on these findings, people with anthropometric measurements suggestive of mild atherosclerosis can be advised to modify their lifestyles, along with decreasing their exposure to other risk factors. This study also further underscores the importance of forensic medicine and autopsies as the best means of obtaining information related to cardiac changes.

Atherosclerosis, Obesity, Coronaries

H127 A Tale of Unrelenting Chest Pain: The “Short” Versus the “Tall”

Robyn Parks, MD, Los Angeles County Department of Medical Examiner-Coroner, Los Angeles, CA*

Learning Overview: After attending this presentation, attendees will be reminded of the importance of completing genetic variant testing in thoracic aortic dissections to detect underlying congenital connective tissue disorders that may impact surviving family members.

Impact Statement: This presentation will impact the forensic science community by presenting two cases of ruptured thoracic aortic dissections with underlying, previously unknown, congenital connective tissue disorders and serve as a reminder of the importance of genetic variant testing and close family communication.

A 38-year-old man without diagnosed medical conditions or illicit drug use complained of chest and back pain. He visited an urgent care and was advised to follow-up at an emergency room, but never sought additional care. One week later he was found unresponsive in the bathroom by his roommate, who subsequently called 9-1-1.

Paramedics arrived and pronounced death at the scene. Autopsy revealed a 74-inch, 154-pound man (body mass index 19.8kg/m²) with an arm span of 77 inches (height/arm span ratio: 1.04), and positive thumb sign. Internal examination revealed hemopericardium (600cc), left greater than right hemothorax (400cc versus 25cc), large hematoma surrounding the proximal aorta, and aortic root dilatation (5.5cm at the sinus of Valsalva, aortic root Z-score 8.06).¹ Cardiac examination revealed a nearly circumferential intimal tear of the ascending aorta with an associated full thickness defect, 1.5cm distal to the aortic valve without aortic valve involvement. On the day of autopsy examination, the findings, diagnosis, and potential for an underlying genetic condition were explained to the family. The Aortopathy and Connective Tissue Disorder Panel was ordered through Invitae Corporation and returned with a heterozygous pathogenic variant in FBN1, which is associated with autosomal dominant Marfan syndrome and related conditions. These results were immediately relayed to family members and the potential for first-degree relatives to receive free testing for this variant was explained. The cause of death was certified as cardiac tamponade due to ruptured thoracic aortic dissection due to Marfan syndrome (FBN1 heterozygous pathogenic variant), and the manner of death listed as natural.

A 29-year-old man without diagnosed medical conditions, illicit drug use, or alcohol use, who was known to not seek out routine medical care, was awoken from sleep with chest and mid-upper back pain. He drove himself to the emergency department where he was diagnosed with kidney failure and possible pleuritic pain, prescribed prednisone, and discharged. His symptoms persisted and, three days later, his father heard a “thud” from his son’s bedroom, where he found him on the floor. 9-1-1 was called and he was instructed to perform lay-person cardiopulmonary resuscitation until paramedics arrived, at which time death was pronounced at the scene. Autopsy revealed a 66-inch, 211-pound man (body mass index 34.1kg/m²) without external trauma. Internal examination revealed hemopericardium (800cc) with an aortic dissection coursing from the proximal ascending aorta with right coronary artery ostium involvement, distally along the length of the aorta and involved bilateral common iliac arteries. Additionally, the organs were extremely friable with extensive lacerations of the liver attributed to bystander cardiopulmonary resuscitation efforts. Similar discussions with family occurred, and the same panel was sent to Invitae. A heterozygous-likely pathogenic variant in COL3A1 associated with autosomal dominant Ehler-Danlos syndrome was detected. The cause of death was certified as cardiac tamponade due to ruptured thoracic aortic dissection due to congenital connective tissue disorder (heterozygous COL3A1 likely pathogenic gene variant).

These cases highlight the spectrum of connective tissue disorders and the importance of medical examiners/coroners pursuing genetic variant testing, along with emphasizing close family communication to ensure appropriate clinical follow-up for surviving family members.

Aortic Dissection, Connective Tissue Disorder, Marfan Syndrome

H128 Restraint-Related Asphyxia, Excited Delirium, and Drugs: The Role of Counterfactual Causation in Assessing the Cause of Death in Custody

Michael Freeman, PhD, Maastricht University, Maastricht, Limburg, Netherlands and Oregon Health & Science University School of Medicine, Portland, OR and Faculty of Forensic and Legal Medicine, Royal College of Physicians, London, England, United Kingdom; Ellen Strommer, MPH, Maastricht University, Maastricht, Limburg, Netherlands*

Learning Overview: The goal of this presentation is to describe a framework for systematic analysis of deaths in custody, when both intoxicants and restraint are present, in the context of evolving research.

Impact Statement: This presentation will impact the forensic science community by presenting an evidence-based format for assessing the role of restraint in causing an in-custody death. This will be accomplished by first describing a counterfactual framework for evaluation of evidence, in which the pivotal question is what was the risk of death in the absence of the restraint? Next, the evidence of risk associated with all plausible and substantive competing causes is quantified and compared as a ratio (i.e., restraint versus all other putative causes). The result can be presented in the form of a ratio of risks that can control for the potential role of cognitive bias in the assessment.

In custody deaths that occur in the context of restraint or the use of force present unique difficulties for the investigation of manner and cause of death. This is particularly true because the mechanism by which restraint can cause death is typically asphyxia, and the amount of force or restraint necessary to result in sufficient asphyxia in an individual to trigger a cardiopulmonary arrest is widely varied and dependent on the physiologic respiratory requirements of the individual prior to the initiation of the restraint, the nature and duration of the restraint, and the physiognomy and cardiorespiratory fragility of the restrained subject.

There is a body of literature that exculpates restraint as a cause of asphyxia and sudden death. This literature supports a complementary theory, which depends on the dual supposition that the death can occur spontaneously due to Excited Delirium (ExDS), a condition that leaves no evidence at autopsy, and at the same time rejects restraint-related asphyxia as a plausible cause of death due to the results of experiments performed on volunteers.

A recent review of the world literature on ExDS, as well as the literature describing simulated restraint experiments, has not only cast doubt on the validity of the ExDS diagnosis, as well as the scientific quality and generalizability of the experiments to the investigation of any real-world death, but demonstrated a direct dose-response between the nature (severity) of the restraint and the likelihood that a diagnosis of ExDS will be fatal (odds of death are 7.4 times greater when manhandling occurs, 10.7 times greater when the individual is handcuffed [and prone], and 50 times greater if the prone person was also hog- or hobble-tied).¹ These findings indicate that ExDS has been used historically to describe deaths when aggressive restraint has been used, which has had the (intentional or unintentional) effect of exculpating the restraint, as well as the individuals responsible for the restraint, as the cause of death.

There are currently no methods of quantifying the effects of restraint, in terms of asphyxial or cardiopulmonary arrest risk, in any given decedent after the effect. In part, this is due to the fact that by the time an agitated or delirious individual is restrained, their oxygen needs are already substantially increased over a resting state, and thus a lesser degree of restraint is required to result in physiologically meaningful hypoxia or asphyxia.

Counterfactual reasoning is a technique for evaluating the “but-for” probabilities within a causal investigation. In a death investigation, the approach asks the question, “Had the investigated adverse exposure not occurred, what is the likelihood the decedent would have died at the same point in time?” In the context of a restraint-related death, the cumulative risk of death from non-restraint-related explanations, including the presence of illicit drugs, alcohol, coronary artery disease, anomalous cardiac vasculature, i.e., can be estimated using methods and data forensic epidemiologic methods and data.

The risks can be quantified using available epidemiologic and other data, yielding an estimate of the death risk to the decedent in the absence of the restraint. This presentation will describe methods for obtaining such risks and comparing them to the risks associated with various means and duration of restraint, so that the resulting ratio of restraint risk versus all other risks can be estimated to provide a semiquantitative conclusion regarding the strength of a causal association between the restraint and the death in a specific investigation.

Death in Custody, Counterfactual Causation, Restraint-Related Asphyxia

H129 Prone Restraint Cardiac Arrest: A Comprehensive Review of the Scientific Literature and an Explanation of the Physiology

Alon Steinberg, MD, Community Memorial Hospital/Western University, Ventura, CA*

Learning Overview: There is current controversy regarding the role of positional asphyxia as the primary factor for restraint-associated mortality. Some authors state that prone restraint position has no significant physiologic effects and that in prospective epidemiological studies, prone position has been shown to be safe. Other authors have described significant physiologic effects and retrospective epidemiological studies have shown that occurrence of death in prone position is not uncommon.

Impact Statement: This presentation will review scientific literature articles on the impact of prone restraint on respiratory physiology and cardiac output and will learn why a certain population of agitated subjects are at risk of death from prone restraint.¹ This is an important topic to understand as, ultimately, it is the forensic scientist who determines the cause of death in an often litigious case. This presentation will further educate the forensic science community regarding the possible causes of death in prone restraint. This presentation will lead to awareness, important discussion/debate, and further future study.

Deaths occurring among agitated or violent individuals subjected to physical restraint have been attributed to positional asphyxia. Restraint in the prone position has been shown to alter respiratory and cardiac physiology, although this is thought not to be to the degree that would cause asphyxia in a healthy, adult individual. This review identifies and summarizes the current scientific literature on prone position and restraint, including experiments that assess physiology on individuals restrained in a prone position. Some of these experimental approaches have attempted to replicate situations in which prone restraint would be used. Overall, most findings revealed that individuals subjected to physical prone restraint experienced a decrease in ventilation and/or cardiac output in prone restraint.

Metabolic acidosis is noted with increased physical activity, in restraint-associated cardiac arrest and simulated encounters. A decrease in ventilation and cardiac output can significantly worsen acidosis and hemodynamics. Given these findings, deaths associated with prone physical restraint are not the direct result of asphyxia but are due to cardiac arrest secondary to metabolic acidosis compounded by inadequate ventilation and reduced cardiac output. As such, the cause of death in these circumstances would be more aptly referred to as “prone restraint cardiac arrest” as opposed to “restraint asphyxia” or “positional asphyxia.”

Police Custody Death, Restraint Physiology, Positional Asphyxia

H130 Prone Restraint Cardiac Arrest

Victor Weedn, MD, JD, Office of the Chief Medical Examiner, Baltimore, MD; Alon Steinberg, MD, Cardiolog Associates Medical Group, Inc., Centura, CA; Pete Speth, MD; Wenonah, NJ*

Learning Overview: After attending this presentation, attendees will understand the physiology of prone restraint cardiac arrests.

Impact Statement: The forensic pathology community should be aware of prone restraint as a cause of death in in-custody deaths.

The National Association of Medical Examiners (NAME) has promulgated a position paper on Deaths in Custody, but does not discuss causes of death.¹ Much of the literature has focused on mechanical asphyxia or excited delirium as the cause of these deaths.² Vilke et al. have claimed that prone restraint is not dangerous, but more recently, Steinberg has refuted this claim.³⁻⁵ Presented are two cases that demonstrate the danger of prone restraint.

The first case involved an obese 51-year-old male subject (BMI 39.7). The subject used drugs (PCP/TCP, cocaine, and methadone), began “acting weird,” and cut his hand when he broke a ceramic plate on the kitchen counter. This woke up his brother-in-law, who then controlled him. When the police arrived, the brother-in-law was standing over the subject. The police quickly handcuffed the subject with his hands behind his back and shackled his legs, turned him on his side, and attempted to calm him. The subject continued to writhe and yell. Emergency Medical Services (EMS) was called and upon arrival, strapped him face down to a spine board, then placed him on a wheeled stretcher with the placement of further straps and loaded him into the ambulance. He became unresponsive during this time or immediately thereafter. He was turned supine and Advanced Cardiac Life Support (ACLS) measures were begun. He was found to be in bradycardia, then asystole, and later Pulseless Electrical Activity (PEA). He was transported to the hospital and was successfully resuscitated, but he never regained consciousness and was declared brain dead a week later.

Autopsy revealed an enlarged heart (650gms) and encephalomalacia. Cardiovascular consultation revealed hypertrophy, biventricular dilatation, and circumferential left ventricular subendocardial necrosis consistent with a reperfusion injury, but no significant coronary artery disease.

The second case involved a 54-year-old male subject (BMI 26.5) who, after using PCP and in an intoxicated state, sexually assaulted an elderly woman in front of her son. The son wrestled the subject down with the subject on top of him in a chest-to-chest position, where he held the subject prone with his arms over his neck and shoulders until he stopped struggling and the police arrived. Upon arrival, the police noted that the subject was unresponsive and without a pulse. The police began Cardiopulmonary Resuscitation (CPR) until EMS arrived.

Upon arrival, the EMS noted hyperthermia and continued the CPR using a Lucas chest compression device and began ACLS measures. The subject continued with PEA and asystole until a pulse was regained. He was transported to the hospital. **Electrocardiogram (EKG)** showed a T-wave inversion and a right bundle branch block; laboratory testing showed increasing Troponin levels. He remained comatose, and was declared brain dead a week later. Autopsy revealed minor injuries consistent with the struggle. Cardiovascular consultation revealed a 360gm heart with a focal reperfusion necrosis, moderate dysplasia of the AV nodal artery, and mild coronary atherosclerosis. Neuropathology consultation revealed acute hypoxic injury with tonsillar herniation.

Both cases involved subjects using PCP, who were restrained in a prone position, which would result in decreased ventilation and an inability to blow off Carbon Dioxide (CO₂). There was also a decrease in cardiac output by increasing intrathoracic pressure and decreasing venous return. This study believes this led to arrhythmias of PEA and asystole and death. Despite the assertions of Vilke et al., these cases appear to confirm the dangerousness of prone restraint and support the notion of prone restraint cardiac arrest.

Prone Restraint Cardiac Arrest, In-Custody Deaths, Police-Involved Deaths

H131 The Role of Mast Cells in Deaths Associated With Fatal Asphyxia: An Immunohistochemical Study Utilizing the CD117 Marker

Raghvendra Shekhawat, MD*, All India Institute of Medical Sciences, Jodhpur, Rajasthan, India; Vikas P Meshram, MD, All India Institute of Medical Sciences, Jodhpur, Rajasthan, India; Meenakshi Rao, MD, All India Institute of Medical Sciences, Jodhpur, Rajasthan, India; Tanuj Kanchan, MD, All India Institute of Medical Sciences, Jodhpur, Rajasthan, India; Rutwik Shedge, MS, All India Institute of Medical Sciences, Jodhpur, Rajasthan, India; Rahul Panwar, All India Institute of Medical Sciences, Jodhpur, Rajasthan, India; All India Institute of Medical Sciences, Jodhpur, Rajasthan, India

Learning Overview: Attendees will get a better knowledge of the essential role of Mast Cells (MCs) in acute hypoxia. Asphyxia patients had significantly more CD117+ MCs than controls, especially near arteries in the peri-alveolar and peri-bronchial regions. This may assist in identifying instances of acute asphyxial death that may go undetected otherwise.

Impact Statement: This presentation will educate attendees and members of the forensic science community about MCs' usefulness in acute hypoxia. This research discovered that asphyxia victims had significantly more CD117+ mast cells than control subjects, especially in the peri-alveolar and peri-bronchial regions next to arteries. Asphyxia results in a rapid and extensive enrollment of peri-bronchial and peri-alveolar mast cells in the lungs, which is facilitated by explicit chemotactic soluble macrophage-derived substances. CD117+ MCs indicate a twofold increase in peri-bronchial MCs in asphyxial deaths. Thus, these results establish the essential role of MCs in acute hypoxia, a finding that merits further study since it may assist in the detection of instances of acute asphyxial death that would otherwise go undetected.

Asphyxia-related deaths have always been a challenging task in the specialty of forensic pathology. Asphyxia-related deaths account for a significant fraction of the cases handled by forensic pathologists.

Asphyxia is the second-leading cause of mortality after mechanical damage.¹ Cases of death resulting from pressure effects on the neck and chest where soft tissue injuries are limited or non-existent can lead professionals to an erroneous conclusion; apart from helpful macroscopical signs (e.g., strangulation mark, cyanosis, petechial hemorrhage, and lung edema), recent literature indicates that prolonged asphyxia is sufficient to induce an increase in MCs.² Inflammatory cells migrate from the bone marrow to the lungs, aiding in the diagnosis of fatal asphyxia death. HIF-1 α , a key regulator protein, is released from lung tissue capillaries during catastrophic hypoxia circumstances, as previously demonstrated in Immunohistochemistry (IHC) research.³

The present study analyzed lung samples from 164 medicolegal autopsy cases, including 57 asphyxia/hypoxia deaths and 107 controls (non-asphyxia deaths). Peri-bronchial, peri-vascular, and peri-alveolar MCs were detected using CD117 antibody, and the average of MCs in each of these locations was noted in each case. The results indicated a statistically significant increase in peri-bronchial and peri-alveolar MCs in fatal asphyxia deaths, including those caused by hanging, drowning, or postural asphyxia. Peri-bronchial MCs in lung sections of asphyxial deaths were in the range of 0.2–5.4, and in non-asphyxial samples were in the range of 0.0–2.2. Peri-alveolar MCs in lung sections of asphyxial deaths were in the range of 0.0–0.6, and in non-asphyxial samples were in the range of 0.0–0.2. This data suggest that MCs play an important role in fatal hypoxia-related mortality, and CD117 may be a reliable marker for the detection of MCs in asphyxial deaths. It is worth mentioning that asphyxial fatalities induced by hanging, drowning, or postural asphyxia generate significant findings regarding the number of CD117+ MCs.⁴ These findings were shown to be statistically significant. It could be very beneficial to forensic pathologists tasked with differentiating fatal asphyxia fatalities from other causes of death.

H132 A Suicidal Transnasal Hunting Crossbow Bolt Head Shot: A Case Report

Wolf Schweitzer, MD, Zurich Institute of Forensic Medicine, University of Zurich, Switzerland; Michael Thali, MD, Zurich Institute of Forensic Medicine, University of Zurich, Switzerland; Christina Herbst, MD, Zurich Institute of Forensic Medicine, University of Zurich, Switzerland; Lars Ebert, PhD, Zurich Institute of Forensic Medicine, University of Zurich, Switzerland; Rilana Baumeister, MD, Zurich Institute of Forensic Medicine, University of Zurich, Switzerland; Garyfalia Ampanozi, MD, Zurich Institute of Forensic Medicine, University of Zurich, Switzerland; Ni Jian, MD, Zurich Institute of Forensic Medicine, University of Zurich, Switzerland; Stephan Bolliger, MD, Zurich Institute of Forensic Medicine, University of Zurich, Switzerland*

Learning Overview: Head injuries that appeared to be specific to a crossbow bolt were identified using Postmortem Computed Tomography (PMCT).

Impact Statement: The relevant injuries in this case benefited greatly from PMCT and the way it did will be discussed in this presentation.

Case: A 31-year-old man was found dead inside his firmly locked flat on the second floor after he had been missing for several weeks. His body appeared to lie on the floor, with a hunting bolt stuck in a wooden cupboard door above him as if shot with him sitting down.

Next to him, a crossbow with a longish wooden branch close to the crossbow trigger, indicating an ostensibly used trigger mechanism. Upon first inspection, the head appeared to exhibit a single penetrating injury to the left occipital region. Clothing and the remainder of the skin of the body appeared without perforating defect or injury. Consistent with a considerable degree of postmortem decomposition, the body lacked most facial and frontal scalp skin, whereas these soft tissues appeared severely degraded but only partly revealing the bone underneath.

The body was admitted to the Institute of Forensic Medicine for identification and for injury clarification using PMCT. The extended inspection of the premises revealed several handwritten pages that were interpreted as a suicide note and even contained the indication that a crossbow shot through a facial orifice may be attempted. The crossbow identified was a hunting crossbow. The bolt that was retrieved contained a round bolt shaft of around 45cm in length and 9mm in diameter. The single arrow tip was about 2mm thick, and its triangular shape was up to 26mm wide at its widest location. The tip mount appeared damaged, and soft metal wire appeared to have come partly undone. The partly fractured hard plastic straight fletching structures were arranged at symmetric 120-degree angles around the shaft circumference and protruded from the shaft surface by up to 12mm, with no apparent index/cock. PMCT showed slit-like comminuted defect fractures of the left sphenoid bone, matching the bolt arrow in extent and vertical orientation, as well as matching the fletching. There was a penetrating skull fracture with outward beveling and attached fracture fragments that were outwardly angled. The defect measured about 33.6 x 13.1mm; it contained additional outward pelleting laterally of 4–6mm each, matching the dimensions of the bolt fletching. The overall fracture constellation was different from a typical firearm injury in that the bone defects of the left sphenoid and left occipital bone matched a vertically oriented arrow, and there were subtle fractures matching the fletching of the arrow even at what was determined as the skull exit injury.

Discussion: Fatal crossbow injuries are rare. While literature suggests that crossbow shots and firearm injuries may appear similar at least to a degree, this case provided differentiating features in fracture appearances. The overall setting of this case was that of a suicide, and the overall setting did not allow for many other serious hypotheses to be supported. The literature documents many cases with bolts *in situ*. Now seeing as how crossbows can be purchased without a license and given their serious injury potential, not only suicides but accidents and homicides may have to be expected. In cases of bolts placed adjacent to a body or in case of missing bolts, the burden on investigation and evidence may be considerably higher, so learning from what appears to be situationally “validated” cases such as this seems legitimate and relevant. In this case, PMCT appeared to be of great value.

Virtopsy, Postmortem Computed Tomography, Crossbow

H133 Bad Manners: Suicide by Starvation

Debra Berry, MD, MS, Denver Office of the Medical Examiner, Denver, CO; Sterling McLaren, MD, Denver Office of the Medical Examiner, Denver, CO; Ian Puffenberger, MD, Denver Office of the Medical Examiner, Denver, CO; Meredith Frank, MD, Denver Office of the Medical Examiner, Denver, CO; James Caruso, MD, Denver Office of the Medical Examiner, Denver, CO*

Learning Overview: After attending this presentation, attendees will understand the mechanism and manifestations of death due to starvation and appropriately address the challenges of determining manner in such cases.

Impact Statement: This presentation encourages attendees to consider the pathologic presentation of starvation as a mechanism in an unnatural death.

Medical examiner offices provide a unique insight into epidemiologically significant local trends, emerging social and environmental threats, and the psychosocial health of the community.¹ This study presents an unusual case of suicide by starvation in an otherwise healthy 51-year-old male.

Scene investigation of the decedent's residence revealed a well-stocked pantry and refrigerator. There were no readily apparent signs of illicit drug use or prescription medications. The decedent's laptop had a browser open with "fumes in bag suicide" typed in the search engine, though no gas tank was found in the residence and there was no bag around the head or deposited near the decedent's body. Numerous handwritten notes were present with expressions of suicidality and suggested attempts at water deprivation. Surviving family members endorsed concerns for the decedent's current suicidal ideations, citing the previous suicide of his twin sibling and numerous recent social and economic stressors, as well as confirming that the decedent's temperament aligned with this protracted means of suicide by starvation—his mother characterized his personality as determined and stoic. The autopsy findings reflected the known manifestations of starvation: a markedly low Body Mass Index (BMI) of 12.7kg/m² and organ weights approximately 20–50% less than expected with preservation of brain weight at 1,490 g.² No mass lesions, neoplastic processes, or systemic inflammatory diseases were identified by gross or microscopic examination. A basic forensic toxicological panel performed on postmortem femoral blood was negative for ethanol, common drugs of abuse, and select therapeutic medications. Vitreous fluid analysis demonstrated a pattern consistent with hypertonic dehydration, with a sodium level of 160mmol/L, chloride of 120mmol/L, potassium of >20mmol/L, creatinine of 4.2mg/dL, and urea nitrogen of >100mg/dL.^{3,4}

The scene investigation, family history, and social factors heavily contributed to the forensic interpretation in this case, along with negative toxicological results. Caloric insufficiency in adults can arise due to natural causes (e.g., cachexia in the setting of chronic disease) or non-natural causes, as seen in cases of psychiatric disease, elder neglect, torture, or politically motivated food refusal (i.e., hunger strikes), and the attribution of manner of death reflects this diversity.^{1,5} Recognition of the antemortem behaviors, autopsy findings, and social circumstances surrounding death by starvation is crucial in attaining a holistic and accurate cause and manner of death.

Starvation, Suicide, Manner of Death

H134 Suicide and Mental Health: Observations From a Coroner/Medical Examiner Office

Nicole Panzica, University of Alabama-Birmingham, Birmingham, AL; Brandi McCleskey, MD, University of Alabama-Birmingham, Birmingham, AL*

Learning Overview: After attending this presentation, attendees will have a better understanding of the purpose of death certificates and the lack of their contribution to vital mental health statistics.

Impact Statement: This presentation will impact the forensic science community by assessing the lack of mental illness documentation on death certificates in cases of suicide at a coroner/medical examiner office.

Overall, the medical community (and likely the community at large) considers a diagnosis of mental illness as a condition that carries a significant risk of suicide ideation, attempt, and completion.¹ However, vital health statistics are often derived from death certificates that rarely include a mental health diagnosis. Researchers would benefit from obtaining data from the primary source, such as the coroner and/or medical examiner's office that investigates the majority of these deaths, but the current medicolegal death investigation system does not allow for this to occur easily. Standardization of death certification practices overall would improve the quality of mortality data; this is especially true in cases of suicide where assessing the true impact of mental illness would benefit clinicians, patients, and families.

Suicide is a manner of death that is captured as a structured field on the death certificate as one of only five options. Causes of death, listed in Part I of the death certificate, capture events that directly resulted in the death. Part II of the death certificate is used to collect information on contributing factors to death; although it is very uncommon for mental health diagnoses to be listed. One study concluded that only 5.5% (124) of death certificates had any information in Part II.² The aim of this project was to utilize a primary data source, like a coroner/medical examiner office's database, to investigate those individuals who died of suicidal means and present observatory details regarding the prevalence of mental illness (namely Post-Traumatic Stress Disorder (PTSD), depression, bipolar disorder, and others) reported in these deaths.

The database at the Jefferson County Coroner/Medical Examiner's Office (JCCMEO) in Birmingham, AL, was queried for decedents with a manner of death of suicide between January 2013 and May 2021. Demographic information, circumstances surrounding death, and reported history of mental illness were collected from case information within the database. Information from the scene, including witness accounts and interviews with family and friends at the time of the death, were obtained from narratives written by medicolegal death investigators.

A total of 757 deaths certified with a manner of death as suicide were identified. The overwhelming majority were due to the use of a gun (68%, $n=513$), followed by hanging (18%, $n=137$). A small percentage (2%, $n=14$) of the decedents had a reported history of PTSD, 43% ($n=325$) had a reported history of depression, and 6% ($n=44$) of bipolar disorder. In total, 50.6% of the decedents had a reported history of some sort of mental illness. However, none of this information was captured on the death certificate, which highlights the severely compromised ability to accurately study the association of mental illness and suicide.

Future studies will include comparing witness and family reports of mental illness with available medical records. Additionally, a strategy will be developed for future coroners/medical examiners to consider listing a mental health diagnosis in Part II of the death certificate. This information will also help better inform our clinical colleagues of the association of mental illness and suicide when treating their patients.

Suicide, Mental Illness, Death Certification

H135 Web-Enabled Suicide Using Sodium Nitrite: An Old Forensic Challenge in New Clothes

Monica Concato, MD*, University of Trieste, Trieste, Italy; Davide Radaelli, MD, University of Trieste, Trieste, Italy; Michela Peruch, MD, University of Trieste, Trieste, Italy; Martina Zanon, MD, University of Trieste, Trieste, Italy; Lara Consoloni, MD, University of Trieste, Trieste, Italy; Alessandro Manfredi, MD, University of Trieste, Trieste, Italy; Giovanna Bettoli, University of Nottingham Medical School, Nottingham, United Kingdom; Riccardo Addobbati, IRCCS Burlo Garofolo, Trieste, Italy; Stefano D'Errico, MD, PhD, University of Trieste, Trieste, Italy

Learning Overview: This presentation will recontextualize intentional sodium nitrite poisoning and provide attendees with the tools to increase awareness of clinicians and forensic colleagues to the challenges presented by methemoglobinemia in patients and in the postmortem period.

Impact Statement: This presentation will provide new impetus to collect further, good-quality evidence regarding sodium nitrite and methemoglobinemia in the postmortem period in order to build a body of knowledge that will aid in future forensic analyses.

Suicide by sodium nitrite ingestion has been long described as a rare fatality.¹ However, the portrait of the last couple of years appears to be different due to a worldwide increase of cases.²⁻¹¹

This presentation describes the case of an 18-year-old man who intentionally ingested an unknown quantity of sodium nitrite together with antiemetic medication. In the same period, two other suspected cases of self-poisoning with sodium nitrite occurred in Italy. As previously seen in the literature, instructions for the suicidal procedure were found on the Internet⁷.

Autopsy findings revealed an asphyxial pathophysiological mechanism of death through cyanotic changes of the nails, as well as internal signs of asphyxia such as subepicardial and subpleural petechiae, pulmonary emphysema, and congestion of the lungs. Toxicological analysis showed a concentration of summed nitrite and nitrates of 1,400 µmol/L in the blood sample collected immediately after death and a concentration of methemoglobin of 27.7% in the blood sample collected during autopsy, performed 36 hours after death.

Both sodium nitrite and methemoglobin analysis pose a challenge for forensic sciences. The rapid oxidation of the salt and the particular characteristic of the blood in the postmortem period can lead to false negatives.^{5,12} After death, methemoglobin can both decrease due to the action of enzyme MetHb-reductase or bacterial contamination, and increase because of decomposition of the body or auto-oxidizing phenomena.^{3,13,14} Blood sample storage conditions such as temperature, quality of blood, preservative, and time between sampling and the analysis can all influence the validity of the measurement^{5,13,14}

In this case, autopsy was performed 36 hours after death; the actual storage conditions of the body were not known. Blood was conserved in sodium fluoride and potassium oxalate and was left at room temperature for six hours after collection before freezing. As already described in previous works, the percentage of methemoglobin in this blood sample was lower than the values indicated as fatal in the existing literature.^{3,5} With current knowledge, the absolute amount of methemoglobin could not be used to determine the cause of death by itself; it is necessary to confirm the diagnosis through the concentration of sodium nitrite and nitrate in the blood. Much more effort should be addressed in this topic to best inform both clinicians and forensics specialists.

II Schema Mode Work, Limited Reparenting, and Empathic Confrontation in Solution-Focused Therapy (SFT) in the Treatment of Forensic Late Adolescent Patients With Antisocial Personality Disorders Who Committed Offenses and in Precautionary Measures in the Community

Melania Lugli, PhD, Science and Method, Reggio Emilia, Italy; Davide Bregoli, PhD, Fattoria Sociale Dosso Sant'Andrea, Brescia, Italy*

Learning Overview: The goal of this presentation is to demonstrate how the Schema Therapy Model can represent a very effective approach to treat forensic late adolescent patients with antisocial personality disorders or significant pathological cores of personality.

Impact Statement: With this type of psychotherapeutic approach, it is also possible to treat patients and the forensic population who have been, until recently, considered very difficult and sometimes impossible to treat with more traditional psychotherapeutic techniques of first and second generation. This presentation will impact the forensic science community by helping attendees be able to communicate the strong points of the Schema Therapy Model. They will bypass the limits of Standard Cognitive Behavioral Therapy in the treatment of late adolescent forensic patients affected by antisocial personality disorder or other types of personality disorders who committed various types of offenses and crimes.

Introduction: This presentation takes as its thesis the confirmed effectiveness of the Schema Therapy Model for the forensic population with severe dysfunctional coping modes and late adolescent patients who have committed offenses. The Schema Therapy Model was adapted by D. Bernstein, A. Arntz et al., to meet the specific requirements of the forensic population. These patients are often affected by severe personality disorders and are characterized by significant fluctuating emotional states. SFT treats these states with the aim of integrating them through limited reparenting and empathic confrontation techniques. Recent research suggests that standard cognitive and behavioral approaches are only of limited effectiveness in forensic patients with personality disorders. SFT may represent a very effective psychotherapeutic approach for late adolescent forensic patients with antisocial personality disorders.

Results: Schema Mode Work, limited reparenting, and empathic confrontation, used as the core of SFT practice in the treatment of more severe personality disorders, confirm their effectiveness in personality disorders in forensic settings and late adolescence. The Schema Mode model was expanded to include new dysfunctional coping modes, bully and attack, predator, paranoid over-controller, self-aggrandizer, and conning and manipulative personality traits that appear to be particularly frequent in late adolescent and adult forensic patients with antisocial personality disorders.

Schema Modes often play themselves out in a predictable pattern. In some instances, these temporal sequences of unfolding dysfunctional coping modes may help to explain the events leading up to and culminating in the committing of crimes and offenses (robbery, mafia crimes, assaults, drug dealing, attempted murder, theft, illegal carrying of arms, etc.). SFT principles and methods have been integrated into each phase of treatment from the start to the completion. The goal of forensic ST is to reduce the patient's reliance on maladaptive coping modes by breaking through the patient's emotional detachment to access and heal their "vulnerable child mode".

During psychotherapy, the empathic confrontation with patients' dysfunctional coping modes, such as paranoid over-controller, bully and attack, and conning and manipulative modes, and limited reparenting with imagery rescripting technique used in past-present emotional bridge exercises, showed their effectiveness in the treatment of patients and in strengthening their functional ways. This allowed the patients to re-enter society in a shorter time and to make good use of therapy by modeling themselves on increasingly adequate, balanced, and healthy behaviors.

At the end of the psychotherapy, the frequency of activation of early maladaptive schemas was diminished, much as the frequency of activation of dysfunctional coping modes. These results were also demonstrated by the scores obtained by the Young Schema Questionnaire and the Short Mode Inventory administered in the post-treatment phase.

Conclusion: SFT for adolescent forensic patients and in particular for patients diagnosed with antisocial personality disorder confirm how this psychotherapy approach, its core techniques, and the importance attributed to the therapeutic relationship is very effective for this type of patient. Mostly, the mode work with bully and attack and paranoid over-controller modes allowed the patients to achieve improvements in their lives and in the forensic context. The ongoing research into this model will provide more insight into the mechanism that explains the apparent effectiveness of SFT in forensic personality disorder patients, including some psychopathic patients.

Adolescent, Antisocial Personality Disorder, Schema Therapy

12 Housing Conservatorship: New Paradigm or Unfunded Boondoggle?

Michael Cheng, MD, University of Southern California Institute of Psychiatry, Law, and Behavioral Science, Los Angeles, CA*

Learning Overview: The goals of this presentation are to: (1) summarize California Welfare and Institutions Code (WIC) §5450, which establishes a “Housing Conservatorship;” (2) review the primary purposes of this legislation; (3) discuss the evidence and opinions for and against the “Housing Conservatorship” statute; and (4) examine the current state of implementation of this pilot program.

Impact Statement: This presentation will analyze California WIC §5450, a recent law that establishes a new kind of conservatorship targeting individuals with serious mental illnesses and substance use disorders, who have had eight or more involuntary psychiatric detentions in a 12-month period. This presentation will review the implementation of the “Housing Conservatorship” pilot program and its role in treating individuals with serious mental illness and substance use disorders.

In 2019, 151,000 Californians were homeless, 23% of whom were severely mentally ill, and 17% of whom had a chronic substance abuse disorder.¹ Officials across the state have struggled to meet the needs of homeless individuals with untreated mental illness and substance use disorders who decline services for housing or treatment. California civil commitment laws under the Lanterman-Petris-Short (LPS) act allow for individuals with a mental illness who are “gravely disabled” (unable to provide food, clothing, or shelter for themselves) to be placed under a conservatorship.^{2,3} The conservator is empowered to decide treatment and housing for the conserved individual (conservatee).³

Officials in San Francisco, CA, perceived two flaws with LPS conservatorship: (1) although it allows chronic alcohol use as a criterion for determining grave disability, other substance use is not considered; and (2) it requires a series of involuntary psychiatric holds in the hospital prior to the individual being conserved.⁴ The ineligibility of other substance use as a criterion for determining grave disability was problematic given that methamphetamine-related diagnoses exceeded alcohol-related diagnoses by a greater than 2:1 ratio among individuals presenting to psychiatric emergency services in San Francisco.⁴ Individuals with substance use disorders were frequently detained for psychiatric treatment. However, after receiving a short period of involuntary treatment, they no longer met grave disability criteria under LPS and thus could not be conserved. They would decline voluntary treatment, only to re-present involuntarily to psychiatric emergency services when they were gravely disabled in a state of intoxication and psychiatric decompensation.⁵

Scott Weiner, State Senator from San Francisco, introduced and passed Senate Bill 1045 (SB-1045) in 2018, and Senate Bill 40 (SB-40) in 2019. These established a pilot program authorizing the counties of San Francisco, Los Angeles, and San Diego to implement a “Housing Conservatorship.”^{6,7} Supporters hoped this form of conservatorship would end the revolving door of involuntary psychiatric detention, psychiatric stabilization, refusal of services, continued substance use, and psychiatric decompensation.

Opponents argued that California WIC §5450 expanded the number of conservatees without providing additional funding for supportive housing, mental health services, or substance use treatment.^{4,5} Homeless and disability rights advocates voiced concerns about infringements on civil liberties. They asserted that Assisted Outpatient Treatment (AOT), a form of court-ordered outpatient treatment, could encourage individuals to engage with treatment while respecting patient autonomy.^{4,5}

To date, only San Francisco has started implementing “Housing Conservatorships.”⁸ San Diego and Los Angeles Counties withdrew from the pilot, citing difficulties such as the need for a centralized database to track the number of times a particular individual has been placed on a psychiatric hold.^{9,10} As San Francisco implements this recently enacted conservatorship, it remains to be seen whether it emerges as a new paradigm for treating severe mental illness and substance use in the chronically unhoused population or ends as an unfunded boondoggle.

Conservatorship, Homelessness, Substance Use

I3 From Neomycin-Bacitracin-Polymyxin to Sexually Transmitted Diseases (STDs): The Significance of Interpretation and Attentiveness When Treating Developmentally Disabled Patients With Severe Mental Illness

Yasmine Razi, BS*, Western University of Health Sciences, College of Osteopathic Medicine of the Pacific, Pomona, CA; Davin Agustines, DO, Olive View-UCLA Medical Center, Sylmar, CA

Learning Overview: This report seeks to highlight the importance of attentiveness among health care workers to be able to interpret the sometimes confusing requests of patients.

Impact Statement: Patients with concomitant severe mental illness and intellectual disability struggle to get adequate medical care given their inability to advocate for themselves as a result of their cognitive disorganization and limited vocabulary. This presentation will seek to expand the forensic community's awareness of the importance of recognizing subtle cues from intellectually disabled individuals that may identify indicators for abuse and trafficking.

Health care disparities for people with mental illnesses, due to a variety of factors including access and quality of care provided, result in poor health outcomes and often premature death.¹ Evidence also suggests that many patients suffer from a dual diagnosis of psychiatric disorders, such as schizophrenia and intellectual disabilities.² Such individuals are all the more vulnerable and often do not receive the help they need due to their mental health and behavioral problems.³ What's more, systemic reviews of patients who have suffered from human trafficking suggest that many suffer from mental illnesses and have longer psychiatric admissions.⁴

Ms. A, a 20-year-old homeless female with unknown psychiatric history was brought to a psychiatric emergency department by police after being found in a driveway mumbling to herself incoherently. Ms. A was eventually transferred to an inpatient psychiatric ward for further stabilization with psychotropic medications. Over time, she began using words to communicate, experienced less auditory hallucinations, and was less frequently seen responding to internal stimuli. Around one month post-admission, as the patient was pre-rounded on by medical students, she mumbled in a low voice "Can I get Neosporin®?" Upon further questioning, she indicated it was requested for use "down there," pointing to the genital region and mumbling "Someone cut me down there." When questioned by whom, when, and why she was cut, the patient remained selectively mute and then asked again for Neosporin®. Her knowledge of the word Neosporin® as well as her body language and decision not to disclose further information was concerning. This suspicion was what prompted the rounding medical student to look further into the request. Fortunately, the patient agreed to physical examination by the attending physician who observed vaginal and anal lesions. This led to a gynecology consult where Sexually Transmitted Disease (STD) testing was suggested, given observations and suspected risky sexual behavior with numerous partners, as this patient, suffering from schizophrenia, tried to fend for herself on the streets. Often, such patients are victims of human trafficking. Upon testing, the patient's HIV and Hepatitis panel were non-reactive, but she was diagnosed with chlamydia, gonorrhea, HPV anogenital warts, and syphilis. An outpatient cryotherapy appointment was made to address the warts, while the other diagnoses were treated onsite. The infectious disease team that was consulted indicated that a lumbar puncture was necessary, which later resulted negative for neurosyphilis. Ms. A was also scheduled for outpatient labs for repeat HIV and Rapid Plasma Reagin (RPR) in one and three months respectively. During this process, the Department of Public Health was consulted regarding the patient's previous STD diagnoses and treatments and was later notified of her current reportable diagnoses.

In conclusion, from a simple request for Neosporin, this patient was consulted by two different medical teams, diagnosed with four sexually transmitted diseases, treated for three of them inpatient, and arranged for three outpatient appointments for both treatment and further diagnostic testing. Her status as a possible victim of human trafficking was also reported to the appropriate authorities.

Thus, careful attention must be made to terms and requests made by psychiatric patients, particularly when they are in reference to medications or symptoms seemingly unrelated to their psychiatric diagnosis. By doing so, health care providers can provide holistic care by addressing medical concerns that may have in fact stemmed from the patient's lack of opportunities given their mental illness. Increased awareness can also help identify indicators for abuse and trafficking that can then be used to help the victims.

Severe Mental Illness, Neurodevelopmental Disability, Attentiveness

I4 A Case of Neonaticide With Homicidal Defenestration of the Child

Bernat-Noël Tiffon Nonis, PsyD*, Universitat Abad Oliba, Barcelona, Spain

Learning Overview: The novice assistant can learn, retain, and implement psychological evaluation techniques in juvenile homicide cases. The experienced assistant can implement new or renewed insights into the methodology of psychological evaluation techniques in cases of homicides perpetrated by minors.

Impact Statement: The impact that can influence the forensic scientific community is to illustrate the psychology and/or psychopathology of a singular case of homicide perpetrated by a new mother with her baby only a few minutes old.

Introduction: When a parent kills their own child, it is known as filicide. Such a criminological situation always originates a great social, legal, and media impact.¹⁻⁴ Calzada et al. consider “as neonaticide the death of a child in the first 24 hours.”⁵

Case: The proven facts in the case of a 19-year-old woman were, as drafted and stated in the body of the sentence, as follows: “. . . at an unspecified time, but between the afternoon and the evening, she gave birth in the bathroom of her home to a female baby that came to breathe autonomously; and immediately after the birth, she threw it out of the bathroom window that overlooks an inner courtyard of the property from a height of 74.97 feet. As a result, the newborn suffered severe polytrauma with the destruction of vital brain centers, which caused her death.”

Discussion: From the legal point of view and as stated in the sentence, the jury considered as proven that the baby was thrown and defenestrated by the defendant from the window. From the psychological point of view, and as a result of the psychometric examination carried out, the personality profile of the victim is compatible with a personality characterized by an acute and singular fragility, weak and sensitive psychoemotional instability, avoidant-dependent-melancholic, which weakens in situations interpreted subjectively and paranoidly as critical and/or acute.

Conclusion: This study describes a singular case of neonaticide of a young mother with a dysfunctional personality and suffering from an acute psychoemotional instability. It is difficult to describe psychologically what was the mother’s will to perpetrate the acts since only the victim knows what her most intrinsic motives were.

As it is clear from the sentence, all the experts who testified regarding the psychological state of the victim agreed that the victim did not present any type of serious mental disorder for which she could benefit from an exonerating circumstance or an attenuation of the criminological penalty. Thus, and following the ruling of the sentence, this meant the consideration of being the responsible author of the crime of murder with the aggravating circumstance of kinship to the penalty of 20 years of imprisonment. Likewise, in order to develop preventive strategies in cases of neonaticides and filicides, it is notoriously difficult to establish and apply due to the heterogeneous dynamics between the perpetrator and the victim.⁶

Neonaticide, Filicide, Personality Disorder

I5 A Homicidal Outburst and Preservation of the Corpse at Home

Bernat-Noël Tiffon Nonis, PsyD*, Universitat Abad Oliba, Barcelona, Spain

Learning Overview: After attending this presentation, the novice assistant will have learned, retained, and be able to implement psychological evaluation techniques in homicide cases. The experienced assistant will be able to implement new or renewed insights into the methodology of psychological evaluation techniques in cases of homicides.

Impact Statement: The impact that can influence the forensic scientific community is to illustrate the unique psychology and/or psychopathology of a perpetrator who, after murdering his ex-partner, suffered from Borderline Personality Disorder (BPD), and kept his corpse buried for some ten months in his own home.

Case: The patient was a 55-year-old single man with no children and no known psychopathological clinical history who was in a companion relationship with a woman who had been his previous affective-emotional partner in the past. Due to their financial situation and the woman's needs, who was affected by BPD, he decided to take her into his home in order to help her with her basic needs for daily life. Their relationship was characterized by continuous interpersonal conflicts, the result of the psychic dysfunction of BPD suffered by the woman.

In one of these frequent discussions that used to periodically characterize the dynamics of the couple, and as a result of a sharp and heated argument in which the reported was subjected to strong psycho-emotional pressure with the presence of frequent insults, humiliation, and psychological abuse (and even physically slapping him, pulling his hair, and causing scratches) for which he felt subjected by her, he decided to kill her in a psychological state of rapture.

According to the words of the reported (now victimizer), “. . . *the situation was impossible and unsustainable*” so that “*in the heat of the argument, he does not remember if she tried to cover herself or if she did anything to defend herself from the ax that he took and with which he hit her two or three times.*” He added that “*he does not know if she died on the spot, but he does know that he left the victim's body in the shower tray for two or three hours.*”

After committing the crime, he proceeded to bury the victim's body in his own home and, after 24 hours, he reported her disappearance to the police. The assailant kept the victim's body buried in his home over a ten-month time frame until it was finally discovered through the police geolocator.

Discussion/Conclusion: The description of the case illustrates the situations in which a subject affected by BPD can originate in the usual dynamics of his interpersonal relationships characterized by the presence of continuous conflicts and arguments.

On this occasion, the (double) victim of BPD and crime was a subject who, due to the continuous and periodic level of conflict, was seized by negative emotions and the frustration of the moment. The low threshold of patience made him break his inhibitory mechanisms of behavior to materialize in a harmful psycho-emotional outburst with a fatal outcome.

The experienced assistant can implement new or renewed insights into the methodology of psychological evaluation techniques in cases of homicides perpetrated by victims of BPD.

Burial of Corpse at Home, Borderline Personality Disorder, Outburst

I6 Death Due to Autoerotic Practices: Evidence for Diagnosis Resulting From a Systematic Review

Salvatore Rocuzzo, MD*, Department of Medical, Surgical and Advanced Technologies G.F. Ingrassia, University of Catania, Catania, Sicily, Italy; Giuseppe Li Rosi, MA, Department of Medical, Surgical and Advanced Technologies G.F. Ingrassia, University of Catania, Catania, Sicily, Italy; Federico Giuseppe Patanè, MD, Department of Medical, Surgical and Advanced Technologies G.F. Ingrassia, University of Catania, Catania, Sicily, Italy; Fabrizio Vanaria, MD, Department of Medical, Surgical and Advanced Technologies G.F. Ingrassia, University of Catania, Catania, Sicily, Italy; Cristoforo Pomara, MD, Department of Medical, Surgical and Advanced Technologies G.F. Ingrassia, University of Catania, Catania, Sicily, Italy

Learning Overview: After attending this presentation, attendees will have a better understanding of autoerotic death phenomenon.

Impact Statement: This presentation will impact the forensic science community by presenting evidence resulting from a systematic review on the topic and useful to establishing the diagnosis of autoerotic death.

Autoerotic death is defined as “accidental death that occurs during individual, usually solitary, sexual activity in which some type of apparatus that was used to enhance the sexual stimulation of the deceased caused unintended death.”¹ An important point in cases of autoerotic death is that the manner of death is accidental.

In this context, autoerotic asphyxia death refers to “fatal episodes that result from asphyxia, thus maintaining the distinction from rarer cases involving quite different mechanisms” and represents the predominant manner and mechanism of the reported cases of autoerotic death.¹ Specifically, autoerotic asphyxia is defined by the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5)* as a particularly dangerous form of masochism, which is considered a paraphilic disorder, associated with transvestism in a substantial proportion of fatal cases, which is at risk of accidental death while practicing.² Historically, it is documented that prostitutes have been experts in sexual asphyxiation for a long time. During the Victorian era in London, men could satisfy their sexual urges through controlled hangings in the “Hanged Men’s Club.”³ The origin of this practice was traced to the Celts, but early accounts have also been found in various ethnic groups, including the Eskimos, Southeast Asians, and Yaghans of South America.^{4,5}

Other less common autoerotic deaths, sometimes referred to as “atypical” because asphyxiation is not a feature, include deaths due to electrocution, hemorrhagic shock, and fatal air embolism.⁶⁻⁹ The diagnosis of autoerotic death is not always so simple, especially in the absence of typical death scene characteristics.

The goal of this presentation is to describe forensic features involved in autoerotic death cases, focusing on life and environment of the victim, the circumstances of death, and autopsy findings that may be effective in the determination of the manner of death in equivocal cases and to highlight the most common causes of death. Finally, this review proposes a practical medicolegal approach to support the forensic professionals in making diagnosis in the hypothesis of such cases and, therefore, to distinguish accidental, suicidal, and homicidal death.

Paraphilic Disorders, Autoerotic Deaths, Crime Scene Investigation (CSI)

17 A Five-Year Review (2016–2020) of Intimate Partner Homicides at the Harris County Institute of Forensic Sciences

Jennifer L. Ross, MD*, Harris County Institute of Forensic Sciences, Houston, TX

Learning Overview: After attending this presentation, attendees will have a better understanding of the incidence and demographics of Intimate Partner Homicides (IPH) over a five-year period (2016–2020) at the Harris County Institute of Forensic Sciences in Houston, TX.

Impact Statement: This presentation will impact the forensic science community by comparing, over a five-year period within Harris County, TX, the number of IPH, the demographics of both the victim and perpetrator, the type of weapon(s) used, and the incidence of suicide and/or injury/death of others at the time of the homicide.

IPH make up a subset of deaths due to domestic violence. Domestic violence homicides can be subdivided into non-IPH (parent, child, sibling, other family member, third party to current/former intimate partner, and roommate) and IPH (current/former spouse, current/former intimate partner). A recent study showed rates of IPH are increasing.¹ It is well known that males are far more likely to be both perpetrators and victims of homicide and that women have a higher rate of victimization than offending. Black women are two-and-a-half times more likely to be killed by an intimate partner than White women.² A previous study found that both sexes employ firearms most often with nearly three-quarters of male offenders and nearly half of females using a firearm.¹

The incidence of IPH, victim and offender demographics, victim-offender relationship, and weapon used were reviewed from deaths due to domestic violence over a five-year period (2016–2020) at the Harris County Institute of Forensic Sciences. The percentage of IPH cases out of all homicide cases has increased slightly from three percent in 2016, four percent in 2017, three percent in 2018, five percent in 2019, and five percent in 2020. The cases have similar results as other studies, with females more commonly victims, Blacks more common as both victims and perpetrators, and firearms as the most common weapon used. The results are important for the local community as they can lead to improved prevention efforts.

Domestic Violence, Intimate Partner Homicide, Harris County

18 Homicides Committed by Delusional Patients in the Early 20th and 21st Centuries: A Study Conducted in a French Secure Unit

Eloise Provoost, MD, Paris Center Psychiatry Unit, Paris, France*

Learning Overview: The aim of this presentation is to provide an analysis of psychotic homicide and identify the clinical features of delusions that lead to that type of homicide. Attendees will have a better understanding of the characteristics of homicides committed by delusional patients.

Impact Statement: This work completes available data by describing two groups from different centuries and exploring delusional themes. This presentation will impact the forensic sciences by improving the understanding of psychopathology of psychotic homicide.

Homicides committed by delusional patients are the object of a rich scientific literature, which puts the risk of such acts occurring into perspective when analyzing the offenders' sociodemographic and clinical characteristics.¹⁻⁵ However, few articles detail the themes and mechanisms underlying those patients' delusions.

To help bridge that gap, a retrospective descriptive study was conducted in a French secure unit, including two samples of delusional homicidal patients; one from near present day (2015–2019) and one from nearly a century ago (1910–1914). This study considered similarities observed in the literature (such as patients' sociodemographic profile, clinical data, and acting-out dynamics), but also explored the characteristics of delusion (such as theme, mechanisms, conviction to the delusion, and societal influence).

In the 2015–2019 sample, the typical patient profile was: single male (31.5 years old on average), without child, unemployed, and with psychiatric history (56.6%). A comorbidity of substance-use disorder was predominantly present (83.3%). Most patients suffered from schizophrenic disease (83%) with non-systematized delusions exhibiting multiple themes in 80% of cases. Four principal types of delusion were observed: persecutive (100%), mystical (43.3%), megalomaniac (30%), and bodily (30%). The mechanisms were interpretative, hallucinatory, and intuitive. There was a societal influence in 23.3% of the cases (most often terrorist acts). The acting-out characteristics were: no premeditation (70%), homicides committed in the victim's home, overkill (40%), knife use (80%), and no staging (in 86.6%). The victims were extra-familial in 62% of cases and intra-familial in 32% of cases (more often the parents).

The 1910–1914 historical sample revealed several differences compared to the near present-day sample: patients were older, more often married, and employed. There were more diagnoses of chronic delusional disorder (30%). Persecutory delusion was constant (100%) and the other delusional themes were the "intimate relationship" type (50%), jealousy, erotomanic, and the bodily type (40%). The crime was more often committed with firearms (60%). Strangers were rarely victimized (9%); among intra-family victims (36.4%), uxoricides and fratricides were the only ones documented.

Considering the homicides from a preventive point of view, clinicians will be able to identify the key features of risk displayed by some of them. However, additional studies are useful to reinforce these findings and to further investigate the possibilities of prevention.

19 Hair Toxicology Identifies Greater Substance Use Than Self-Reported in High-Risk Youth Enrolled in the Adolescent Brain Cognitive DevelopmentSM (ABCD) Study

Natasha Wade, PhD, University of California-San Diego, La Jolla, CA; Vanessa Diaz, BS, University of California-San Diego, La Jolla, CA; Susan Tapert, PhD, University of California-San Diego, La Jolla, CA; Krista Lisdahl, PhD, University of Wisconsin-Milwaukee, Milwaukee, WI; Marilyn Huestis, PhD, Thomas Jefferson University, Philadelphia, PA; Frank Haist, PhD, University of California-San Diego, La Jolla, CA*

Learning Overview: After attending this presentation, attendees will have learned how pre-adolescent and adolescent youth hair toxicology results relate to self-reported substance use and acute toxicology results.

Impact Statement: The results of this study indicate underreporting of substance use in youth at risk for substance use participating in a healthy development study.

Aim: A primary aim of the longitudinal ABCD Study[®] is to document substance use onset, patterns, and sequelae across adolescent development. As intentional and unintentional misreporting of substance use obscures meaningful relationships, objective measurement is needed. Hair toxicology tests provide objective historical substance use data, but are rarely investigated in youth. Here, objective hair toxicology results are compared with self-reported substance use in youth.

Methods: A literature-based substance use risk algorithm identified 696 ABCD Study[®] participants for hair sample collections between baseline and two-year follow-up (spanning ages 9–13 years) for laboratory analysis. Chi-square and *t*-tests assessed differences between participants' demographics, positive and negative hair tests, and self-reported drug use.

Results: Hair testing confirmed 121 of 696 (17%) hair samples positive for one or more substances (9.1% amphetamines, 5.3% cannabis, 1.9% cocaine, 3.6% cotinine, 1.4% alcohol, .3% opiates). Ninety-nine 9–13 year-old children were positive for one, 17 for two, 3 for three, and 2 were positive for four drug classes. Considering prescribed medications, 74 participants (11%) had positive hair tests incongruent with self-report. Participants with positive hair tests underestimated use via self-report ($p < .001$), and participants with negative hair tests reported more sipping of alcohol than those with positive hair tests ($p < .001$). Positive hair tests were more common in males ($p = .009$), and those with lower parental education ($p < .001$), lower income ($p < .001$), and non-married parents ($p < .001$). No participants with positive results self-reported recreational substance use consistent with toxicology results.

Conclusions: An alarming 11% of tested samples in 9 to 13 year-olds were positive for at least one unreported substance of abuse, suggesting underreporting in this population when participating in a national healthy development study. The scale of underreporting cannot yet be calculated given the selective way samples were prioritized for assay due to budgetary constraints. Expanded toxicology testing is key to characterize onset of substance use in studies of youth.

Children, Substance Use, Hair Toxicology

I10 Death of a Doppelgänger: A Peculiar Case of Homicide

Caterina Bosco, MD*, Legal Medicine Section, University of Turin, Turin, Italy; Lucia Tattoli, PhD, S.C. Legal Medicine, Hospital A.O.U. Città della Salute e della Scienza, Turin, Italy; Cristiano Barbieri, MD, Dipartimento di Medicina Legale e Sanità Pubblica, Università degli Studi di Pavia, Pavia, Italy; Gabriele Rocca, MD, Department of Health Sciences, University, Genoa, Italy; Ignazio Grattagliano, PsyD, Dipartimento Di Scienze Della Formazione, Psicologia, Comunicazione, Università Aldo Moro di Bari, Bari, Italy; Giancarlo Di Vella, PhD, Legal Medicine Section, University of Turin, Turin, Italy

Learning Overview: After attending this presentation, attendees will better understand the Doppelgänger phenomenon (or heautoscopy) in a case of atypical first-episode psychosis.

Impact Statement: This presentation will impact the forensic science community by showing that delusional mood (also known as *Wahnstimmung*), as a prodromal feature of an impending psychotic illness, can be dangerous if not properly recognized.

The Doppelgänger phenomenon involves the experience of a direct encounter with one's self, characterized by: (1) the perception of a figure having identical physical features with one's self; or (2) the apprehension that the perceived figure shares the same personality and identity. The Doppelgänger not only looks like the same person, it is his double. The perceptual element is usually a hallucination, though occasionally there is a false perception of an actual figure that may be involved. This phenomenon has been described in individuals with overwhelming fear, severe anxiety or intoxication, epilepsy, and in the transition between sleep and wakefulness.¹ It has also been reported in major psychoses. The fear of imminent death often precedes the Doppelgänger experience.²

This report presents a case of a 30-year-old man, Mr. XY, who was stabbed to death at the gym by Mr. XY, his "double". The aggressor and his victim, although not related, shared both name and surname, same age, professional activity, and place of work. Moreover, they attended the same sport center but barely knew each other.

A week before the homicide, the attacker, who had no history of psychiatric disturbance, had returned to live at home with his parents and sister, appearing more introverted and socially isolated in the aftermath of the separation from his girlfriend. One night he began to rant nonsense things and to be fixated on certain facts that happened on TV, mentioning international conspiracies. He revealed to his mother that he was afraid of being spied on by neighbors and that his family was in danger. Furthermore, he had perceived as a sort of "intuition" that her sister "had got pregnant, following a rape" perpetrated by the victim. His sister, while admitting having met him once through mutual friends, denied both a romantic relationship and the alleged pregnancy. The family consulted a general practitioner, who identified only a "depressive state" and prescribed benzodiazepines. The day before the agreed appointment with a psychiatrist, the murderer went to the gym and, as he crossed paths with the victim, killed him by stabbing him in the chest with a 25cm-long diving knife. The subsequent psychiatric evaluations in prison were suggestive of a psychotic condition.

This case is very unique in the scientific literature. In the most serious psychotic forms, the theme of the "double" calls into question not only the dissociative processes involved in the etiopathogenesis of the disorder, but also bio-psycho-social elements, as well as personal data that made the victim and the aggressor "identical."

In the context of such psychopathological functioning, the delusional mood (*Wahnstimmung*) that precedes the development of delirium is a sort of gateway to an impending psychotic illness, referring to delusional awareness or mood (atmosphere). In psychosis, splitting is the main theme and this influence was seen as an evil, foreign, apocalyptic, and unknown side that is no more recognized as belonging to itself also in the physical sense.³ In such a situation, the only way to survive is the suppression of the one's own double as a defense against the disorganization of the self.

Psychosis, Doppelgänger, Homicide

I11 Strangulation and Drowning: Homicide or Suicide?

Andreana Nicoletta Maria Maglito, MD, Legal Medicine, Department of Medical, Surgical Sciences and Advanced Technologies, G.F. Ingrassia, University of Catania, Catania, Italy; Giuliana Pennisi, MD, Legal Medicine, Department of Medical, Surgical Sciences and Advanced Technologies, G.F. Ingrassia, University of Catania, Catania, Italy; Federica Ministeri, MD, Legal Medicine, Department of Medical, Surgical Sciences and Advanced Technologies, G.F. Ingrassia, University of Catania, Catania, Italy; Francesco Amico, MD, Legal Medicine, Department of Medical, Surgical Sciences and Advanced Technologies, G.F. Ingrassia, University of Catania, Catania, Italy; Giuseppe Li Rosi, MA, Legal Medicine, Department of Medical, Surgical Sciences and Advanced Technologies, G.F. Ingrassia, University of Catania, Catania, Italy; Aldo Liberto, MD, Legal Medicine, Department of Medical, Surgical Sciences and Advanced Technologies, G.F. Ingrassia, University of Catania, Catania, Italy*

Learning Overview: The aim of this presentation is to focus on the crime scene investigation, autopsy findings, and histological studies to make the differential diagnosis between complex suicide and homicide.

Impact Statement: This presentation shows a rare type of complex suicide carried out by a combination of drowning and self-strangulation. The purpose of this case report is to focus the forensic community on the importance of a meticulous crime scene investigation and autopsy finding to establish the manner of death as suicide or homicide.

Text: The term “*complex suicide*” refers to a form of suicide in which more than one self-injurious action using different methods is applied.¹ A challenging task for forensic pathologists is being able to distinguish a complex suicide from a homicide. Therefore, circumstantial data, a meticulous crime scene investigation, a complete autopsy, and a histological study to search for signs of vitality of the lesions are fundamental.

Case Study: A 39-year-old woman was found dead floating in a water collection tank with a rope wrapped six times around her neck. An empty bottle of alprazolam and a kitchen knife were found near the collection tank. The external examination showed a ligature mark of the neck, a plume of froth at the mouth and nostrils, and eye and face petechiae. No other injuries were visible on the body. A Computer Tomography (CT) scan showed no traumatic injury. A complete autopsy was performed two days after her death. Cervical and thoracic organs were dissected with Gohn’s technique (en bloc). Froth and water were found in the tracheobronchial tree. No other significant findings were observed during the autopsy. Histological examination of all organs samples was performed using Hematoxylin-Eosin (H&E) staining. Lung samples showed acute emphysema, endoalveolar edema, and phytoplankton on phase-contrast microscope. Samples of vascular-nerve bundles of the neck and samples of sternocleidomastoid muscle showed no significant findings. Toxicological findings in blood samples included: alcohol 0.20g/l and alprazolam 138.6ng/ml. A plasma concentration range of alprazolam higher than 40ng/ml can be associated with central nervous system depressant effect.² After a few days, the police investigation found out that the victim suffered from depression and that she left a notebook in which she wrote her last wishes. Thanks to that complementary information, no signs of victim’s resistance on the body, and the results of the autopsy, the manner of death was established as primary complex suicide.

Complex Suicide, Drowning, Mechanical Asphyxia

I12 A Massive Suicidal Ingestion of Flurazepam and Lamotrigine: A Case Report

Alessandro Santurro, MD, Department of Medicine, Surgery and Dentistry, University of Salerno, Salerno, Italy; Federico Manetti, MD, Department of Anatomical, Histological, Forensic and Orthopaedic Sciences, Sapienza University of Rome, Rome, Italy; Matteo Scopetti, MD, Department of Anatomical, Histological, Forensic and Orthopaedic Sciences, Sapienza University of Rome, Rome, Italy; Martina Padovano, MD, Department of Anatomical, Histological, Forensic and Orthopaedic Sciences, Sapienza University of Rome, Rome, Italy; Maria Chiara David, PhD, Ministry of the Interior, Department of Public Security, Health Central Directorate, State Police, Rome, Italy; Antonio Grande, MD, PhD, Ministry of the Interior, Department of Public Security, Anti-Crime Central Directorate, Scientific Police Service, Rome, Italy*

Learning Overview: After attending this presentation, attendees will better understand the main autoptotic and toxicological findings in a case of suicide due to massive ingestion of antiepileptics (flurazepam and lamotrigine).

Impact Statement: This presentation will impact the forensic science community by addressing the possible synergistic effect of lamotrigine and flurazepam at supratherapeutic concentrations.

A 47-year-old man with a previous diagnosis of major depressive disorder, a history of substances abuse, and multiple suicide attempts was found dead in his own house, lying on his back next to the table of the dining room. Police and rescuers found two bottles of water and an empty glass on the table and abundant (more than 60) white and blue tablets, both on the table and on the floor. They did not further specify the type of substance. In consideration of the described findings, a judicial autopsy was ordered by the prosecutor to determine the causes of death and highlight any criminal conduct. Medicolegal investigation started approximately 72 hours after the discovery of the corpse.

At the external examination, the body was 170cm in height and 110.0kg in weight. The face and clothing were diffusely smeared with abundant white, bluish, and yellowish pultaceous material from the nasal orifices and oral orifice. Minute granular formations and larger fragments referable to parts of tablets could be detected.

At the internal examination abundant cerebral edema was revealed. The opening of the airways allowed detection of abundant reddish foamy material and hyperemia of the mucous membranes; lungs were increased in weight (834g the left and 936g the right), and showed edema and vascular congestion at the examination of parenchyma. The stomach contained 280cc of whitish pultaceous material, analogous to that found on the face and clothing, with the presence of finely granular residues.

Toxicological investigations were carried out on peripheric blood, bile, urine, gastric content, and major tablet fragments found on the clothes. This research made it possible to identify the presence of lamotrigine and flurazepam in all the studied matrices. Blood concentrations of the two substances ($>2\mu\text{g/mL}$ for flurazepam and $>50\mu\text{g/mL}$ for lamotrigine) were above the lethal threshold described for each; positivity to benzoylecgonine was also detected in blood, urine, and bile.

Antiepileptic massive ingestion for suicidal purposes may pose serious life-threatening conditions. The use of lamotrigine as well as that of flurazepam for suicidal purposes is a rare occurrence and only rarely described in the international scientific literature; their association, on the other hand, has never been reported before.^{1,2} In the described case, the cause of death was related to the cardiovascular effects and the depressive effects on the central nervous system, resulting from a state of acute exogenous intoxication with a possible synergistic effect of lamotrigine and flurazepam.

Antiepileptic Overdose, Lamotrigine, Flurazepam

I13 Massive Sigmoid Volvulus: An Unexpected and Deadly Twist

Matteo Scopetti, MD, Department of Anatomical, Histological, Forensic and Orthopaedic Sciences, Sapienza University of Rome, Rome, Italy; Federico Manetti, MD, Department of Anatomical, Histological, Forensic and Orthopaedic Sciences, Sapienza University of Rome, Rome, Italy; Martina Padovano, MD, Department of Anatomical, Histological, Forensic and Orthopaedic Sciences, Sapienza University of Rome, Rome, Italy; Alessandro Santurro, MD, Department of Anatomical, Histological, Forensic and Orthopaedic Sciences, Sapienza University of Rome, Rome, Italy; Paola Frati, PhD, Department of Anatomical, Histological, Forensic and Orthopaedic Sciences, Sapienza University of Rome, Rome, Italy; Vittorio Fineschi, MD, PhD, Department of Anatomical, Histological, Forensic and Orthopaedic Sciences, Sapienza University of Rome, Rome, Italy*

Learning Overview: After attending this presentation, attendees will be able to better appreciate the features of an unusual and life-threatening abdominal complication of some psychiatric disorders.

Impact Statement: This presentation will have an impact on the forensic science community by reporting the postmortem diagnosis of a massive sigmoid volvulus and secondary intestinal obstruction as a cause of unexpected death. After attending this presentation, attendees will be able to better appreciate the features of an unusual and life-threatening abdominal complication of some psychiatric disorders.

The volvulus of the sigmoid colon represents a rare condition in which an intestinal tract wraps around itself or its mesentery, resulting in closed-loop obstruction of the involved tract. In adults, it represents the third cause of the obstructive syndrome, with greater frequency in subjects suffering from comorbidities such as chronic constipation, diabetes mellitus, neurologic disorders, and previous abdominal surgery. The diagnostic suspicion is necessary when the subject presents with symptomatology consisting of abdominal pain, distention, and constipation, but the clinical presentation depends on the duration and degree of colon torsion. It is necessary to carry out an early diagnosis by means of radiological and endoscopic examinations and promptly treat this condition, as it is potentially life-threatening. Indeed, complications of sigmoid volvulus include hemorrhagic infarction, perforation, septic shock, and death. The data relating to the mortality rate are not unique, but it is possible to group them in an overall range from 14% to 45%.

This report presents the unwitnessed death of a 45-year-old man, which unexpectedly occurred at his home. From the clinical history collected by the relatives, it emerged that the subject was suffering from an unspecified psychiatric pathology pharmacologically treated with olanzapine, which included obsessive behaviors such as refractoriness to defecation. Therefore, a clinical autopsy was required to establish the cause of death.

At external examination, the corpse did not show any noteworthy alterations except for abdominal distention. In the autopsy phase, at the opening of the peritoneal cavity, an unexpected and important subversion of the regular anatomy was noticed; in detail, the loops appeared extremely extended and difficult to mobilize. Analyzing the distal tract, sigma appeared considerably increased in size and rotated on its mesentery, as to describe a volvulus, with subsequent massive distension of remaining intestinal tract. Fecal content of the colon was extremely copious (895g) and presented pultaceous consistency; after abundant washing, it was possible to macroscopically identify the ischemic suffering of the wall in the absence of perforation.

In conclusion, this presentation aims to share a pathological finding rarely described in this age group by forensic pathologists who approach unexpected natural deaths. This condition, although far from usual, can be facilitated by many common conditions and must therefore be considered both by the forensic pathologist and the clinician facing a case of intestinal obstruction.

Sigmoid Volvulus, Bowel Obstruction, Gastrointestinal Death

I14 Work-Related Stress Among Medicolegal Death Investigator Professionals: Sources of Stress, Health Outcomes, and Protective Factors

Jennifer Rineer, PhD*, RTI International, Durham, NC; Crystal Daye, MPA, RTI International, Durham, NC; Sean Wire, MA, RTI International, Durham, NC; Kelly Keyes, BS*, RTI International Durham, NC

Learning Overview: Through this session, attendees will learn: (1) how different aspects of work affect mental and physical health among Medicolegal Death Investigator (MDI) professionals, (2) the impact of COVID-19 on work-related stress and work-based supports, (3) how work-related stress varies by respondent and agency characteristics, (4) personal and work-based resources that mitigate the negative effects of work-related stress, and (5) the evidence-based recommendations for MDI professionals and their employing organizations.

Impact Statement: MDI professionals, including MDIs, autopsy pathologists, and forensic scientists, are routinely exposed to stressful and traumatic events and materials. This impacts their own well-being and their ability to efficiently complete their investigations, collaborate within the criminal legal system, and interact with families of decedents.¹⁻³ Yet, relatively little is known about how stress and trauma impact these professionals and how to improve their well-being. This national study is a critical first step in better understanding which aspects of work most affect MDI professionals' well-being and what individuals and organizations can do to better support the mental and physical health of this workforce. This instrument was developed in collaboration between the research team and members of the American Board of Medicolegal Death Investigators and the International Association of Coroners & Medical Examiners. The survey was fielded in April–July 2021. Over 950 MDI professionals participated in the survey. Approximately 75% of respondents identified as MDIs, but many other job roles were represented among participants, including photographer, autopsy pathologist, forensic toxicologist, and forensic analyst.

Preliminary analyses show that top stressors include dealing with distressed family members, working more than 24 hours in a row to complete work assignments, lack of understanding from political stakeholders or community leaders, and suicide among members of this workforce. Common themes from an open-ended question on sources of stress are lack of support from supervisors, inadequate compensation/resources, and lack of work breaks/time off. Prior to this session, comprehensive analysis of the survey data will be completed. This presentation will share survey findings and discuss practical implications on the following topics:

- The extent of reported work-related stress among MDI professionals and its specific sources
- Health and wellness indicators, including burnout, depression, anxiety, sleep, and post-traumatic stress disorder
- The extent to which work-related stress and work-based supports have been affected by COVID-19
- Differences in stressors and outcomes based on respondent and agency characteristics
- Personal and work-based resources for mitigating the negative effects of work-related stress, such as coping self-efficacy and organizational stress management offerings

This presentation will provide evidence-based recommendations for individuals in this workforce and their employing organizations and discuss the next phase of this project: the development, implementation, and evaluation of a stress-reduction mobile app for MDI professionals. This session will conclude with an opportunity for Q&A and interactive discussion on this critical topic of workforce health.

I15 Prison Gangs, Validation, and Mental Health

Dean De Crisce, MD, New York University, New York, NY; Eleanor Vo, MD, Omdesala Psychiatric Services, Ewing, NJ; Corina Freitas, MD, SUNY Upstate, Syracuse, NY; Jessica Morel, DO, The Pavillion, Fayetteville, NC*

WITHDRAWN

I16 Copping Crazy and Getting Off: What Do You Need to Know About the Insanity Defense?

George David Annas, MD, MPH*, Forensic Psychiatry Consulting, LLC, Syracuse, NY; Corina Freitas, MD, MSc, MBA, Freitas and Associates, LLC, Baltimore, MD

Learning Overview: After attending this presentation, attendees will have obtained knowledge regarding: (1) the history of the insanity defense, what it is, and what it means from a practical standpoint; and (2) the aspects of certain fact patterns of offenses that suggest a defendant has a strong case for such a defense.

Impact Statement: After attending this presentation, attendees will learn and/or improve skill in: (1) analyzing a defendant for an insanity defense (forensic mental health practitioners); (2) determining when to explore an insanity defense and when not to (defense attorneys); (3) determining how to approach when to prosecute a defendant who has a serious mental illness (prosecuting attorneys); (4) preserving evidence in a potential insanity case vs. other cases (Law Enforcement Officers [LEOs]); and (5) what not to do when questioning a suspect whom you believe is mentally ill (LEOs).

Despite being a part of jurisprudence since at least as far back as the second century AD, the concepts surrounding the criminal defense of “Insanity” continue to elude so many in our society. Some see it as simply an excuse for criminal behavior and others as something that mental health professionals “invented.”

This presentation will address the truth about the insanity defense from its origins in history to the modern era. Included will be the press’ and general public’s common misconceptions about the defense, as well as the reality for such defendants who are “successful” in the defense. Also addressed are the frequent misunderstandings among members of the legal profession. What are the practical aspects that prosecutors and defense attorneys need to be aware of? What pieces of evidence are important to preserve if investigators determine this will be a likely defense by the suspect?

Included in this presentation is a forensic psychiatrist who has been involved in multiple insanity cases and who will discuss the common mistakes and deficiencies among analyses within and without the forensic mental health field. This presentation will include aspects from actual cases that will serve as key teaching points for expert witnesses and attorneys, as well as LEOs.

Forensic Psychiatry, Behavioral Evidence, Insanity Defense

I17 The Emotional State of Sexual Assault Survivors Regarding Legal Proceedings: Analysis of Connotation in Online Forums

Haruka Mori*, George Mason University, Fairfax, VA

Learning Overview: After attending this presentation, attendees will have a better understanding of the psychological experiences of sexual assault survivors following legal proceedings.

Impact Statement: This presentation will impact the forensic science community by presenting evidence from two online forums that demonstrate the emotional struggles of sexual assault survivors.

The psychological experience of sexual assault survivors is one of the most important factors to take into consideration when regarding legal proceedings. However, a systematic catalog of survivors' emotional states following legal proceedings and victim notifications has not yet been established.

Campbell et al. evaluated a victim-centered, trauma-informed victim notification protocol by categorizing survivors' reactions to notification and their decisions regarding reengagement with the criminal justice system.¹ They, however, did not consider the internal psychological changes of survivors. In other words, even if survivors were feeling deeply hurt on the inside, they may not have been able to express their feelings outwardly. In order to understand the internal conflicts of survivors regarding the criminal justice system, it is necessary to listen to the real voices of survivors.

In this study, qualitative text analysis of contents posted in two online public forums for sexual assault survivors was performed. Contents were extracted from two different thread categories: "Why you didn't report it" and "Status updates" starting from November 7, 2002, and June 30, 2020, to June 30, 2021. The datasets were obtained from threads of certain topics where people were most likely to discuss their experiences in victim notifications and legal procedures.

The data were analyzed using text analysis software, KH coder. The KH coder takes as inputs raw data and performs statistical analysis functionalities.^{2,3} In this particular study, three modes of qualitative text analysis were performed: word frequency analysis, co-occurrence networks, and correspondence analysis.

Ninety-eight and three hundred twenty posts were included from "Why you didn't report it" and "Status updates," respectively. Word frequency analysis found that when sexual assault survivors discussed their experiences on the internet, they tended to use negative, trauma-based language rather than positive, forward-looking language. Co-occurrence analysis identified that negative connotative words were often associated with institutions such as hospital and counseling where survivors were likely to verbalize their experiences. Correspondence analysis identified the consistency in the writing tendencies of the survivors, which included many words associated with negative emotions.

The findings from the content analysis were that victims used negative connotations when talking about their experiences with the legal system. Words associated with negative emotions were found to be used in conjunction with other negative words such as "cry," "panic," and "afraid," clearly indicating the psychological burden in survivors of sexual assault. At the same time, it became clear that the words expressing the survivor's psychological stress were frequently used when a survivor talked about her/his own experiences and struggles regarding legal proceedings.

This present research brings to light the tremendous psychological distress brought by legal proceedings among sexual assault survivors. Further investigation of survivors' psychological impact following victim notifications about their old cases and legal proceedings is needed to avoid unnecessary re-traumatization of survivors.

Sexual Assault, Forensic Medical Examination, Criminal Justice System

I18 Suicide Trends in Adults and COVID-19: A Retrospective Analysis in Georgia

Jenna Aungst, BS*, DeKalb County Medical Examiner's Office, Decatur, GA and Georgia State University, Atlanta, GA; Brinley Bowen, MPH, Mercer University, Atlanta, GA

Learning Overview: Attendees will increase their understanding of how adult suicides trends have fluctuated during the COVID-19 pandemic in both urban and rural communities. This will inform attendees for the purposes of disaster response efforts, policy development, and resource allocation to better serve vulnerable populations.

Impact Statement: The goal of this study is to emphasize the critical role of forensic science during times of crisis, particularly amid workforce shortages and resource limitations. As government and public health agencies seek to address emerging threats, increasing awareness of how disaster and economic downturns impact mortality has become increasingly important during the era of COVID-19.

The onset of the COVID-19 pandemic affected every facet of life in the United States, including suicide rates. As the tenth-leading cause of death nationwide, suicide continues to pose a substantial public health threat to high-risk populations.¹ This presentation demonstrates how the mental health of urban and rural communities has been impacted by the pandemic and, consequently, the corresponding effect this has had on the medical examiner/coroner system in the state of Georgia.

This study examined suicide cases involving decedents ages 18 years or older during a two-year period between 2019 and 2020. In accordance with the Georgia Death Investigation Act (O.C.G.A. § 45-16-24), these cases were investigated by the appropriate medical examiner or coroner's offices in DeKalb, Hall, Henry, Rockdale, and White counties.

Despite strict isolation and quarantine measures implemented in the city of Atlanta, urban suicide rates decreased by 30.9% over the course of the pandemic. Comparatively, rural suicide rates remained relatively constant amid relaxed COVID-19 restrictions. This disparity could be attributed to factors such as lower socioeconomic status, mental health care stigmatization, and fewer resources in rural areas.² Suicide impulsivity, indicated by the absence of a suicide note or disclosure of intent, increased by 14.1% in urban areas and decreased by 21.0% in rural areas. Despite a nationwide increase in firearm sales during the height of COVID-19, urban firearm-related suicides decreased 41.1% with a corresponding 8.0% increase in firearm-related homicides.³ While both groups experienced an increase in suicides involving intimate partner problems, urban suicides tended to involve financial and job problems, whereas rural suicides involved health-related problems (most commonly cancer and chronic pain). While the pandemic presented the opportunity for many individuals to strengthen their interpersonal relationships, COVID-19 exacerbated relationship decline in those experiencing disproportionate chronic stress, which may have contributed to the increased incidence of intimate partner-related suicide.⁴ In urban areas with lockdown-induced closures, the most substantial increase in suicides occurred in the food and beverage industry (83.3%), while sales and government experienced notable declines (87.9% and 72.7%, respectively). In rural areas, decedents in the entertainment, education, and construction industries were more likely to commit suicide throughout the pandemic, although no particular industry experienced an increase in suicides.

In the setting of the COVID-19 pandemic, this study explores the implications of prolonged stress and how suicide mortality reflects health care disparities in urban and rural communities.

Learning Overview: After attending this presentation, attendees will have a better understanding of the importance of the reunification and reintegration of psychiatric services after Law 81/2014 and the possibility of their collaboration with other social agencies is intended to end the stigma that is attached to the criminal justice system and also to raise the standard of care.

Impact Statement: This presentation will impact the forensic science community by presenting evidence from the treatment for socially dangerous mentally ill people and marginalized people in need of psychiatric treatment that should respect their rights and dignity and should be aimed to their reintegration.

The Law Number 81 May 30, 2014, that established in Italy one or more Residences for the Execution of Security Measures (REMS) as replacements for High Security Hospitals (Ospedale Psichiatrico Giudiziario [OPGs]) in each region of the country for socially dangerous Not Guilty by Reason of Insanity (NGRI) offenders, has followed after more than 40 years the closure of psychiatric hospitals (Ospedale Psichiatrico, OP). A unique community following the public therapeutic model supported the reintegration of all mentally ill patients, offenders or not, back into their family and society under the auspices of the Department of Mental Health (Dipartimento di Salute Mentale, DSM).¹ A REMS is a residential community that is integrated into the larger community model of general psychiatry.² By December 2020, there were 620 inpatients in Italy's 31 active REMSs, 80 of whom were women.³ A REMS is an exceptional measure, which must end as soon as possible and provide care and security to those subjects who suffered from a severe mental illness at the time of the crime who did not have criminal responsibility or had diminished criminal responsibility, but present a high level of social danger. The analysis on REMS therapeutic activities demonstrated a combination of pharmacological, rehabilitative, and psychotherapeutic treatments.³ With regard to the reintegration of outpatients with mental illness who have committed crimes, this study took into consideration the reality of the Puglia region (region is the first administrative body of the state) from January 2018 to December 2018. In Puglia (four million inhabitants), there are two REMS (38 beds total), but currently there are also seven forensic facilities (residential communities dedicated to forensic inpatients, [CRAP dedicate]) with ten beds each with another 70 forensic inpatients on conditional release (Libertà Vigilata). The median length of stay of inpatient treatment was 11.3 months in REMSs. After discharge from the REMS, some patients continue the treatment in the forensic communities on conditional release for longer periods (median length of stay, 22.7 months). Women occupied 10–12% of the regional secure beds. In 84.6% of cases, all samples committed a crime against a person and 15.4% a crime against property. Common diagnoses were schizophrenia (42.3%) and other psychotic spectrum disorders (30.7%) with bipolar disorder (7.7%) cases. Substance use disorder was present in 15.4% of all cases.

The municipalities have made themselves available to a project in collaboration with the health services for the social and occupational recovery of forensic outpatients. The municipalities can promote some socio-work recovery projects for the mentally ill in collaboration with the mental health services and in the same way can proceed for patients up to 50 years of age discharged from REMS and forensic facilities, selected by the DUNDRUM Toolkit 4 currently being validated in Italy.

I20 DUNDRUM: An Italian Validation Project

Donatella La Tegola, PhD, PsyD*, University of Bari, Bari, Italy and Forensic Facilities Group, Metropolis, Molfetta, Italy; Harry Kennedy, MD, Central Mental Hospital, Dublin, Ireland; M. Davoren, MD, Central Mental Hospital, Dublin, Ireland; Fulvio Carabellese, JD, Department of Medical Sciences and Neurosciences, University of Siena, Siena, Italy; Lia Parente, PsyD, Section of Criminology and Forensic Psychiatry, Department of Internal Medicine, University of Bari Aldo Moro, Bari, Italy; Viola Ferrante, TRP, Forensic Facilities Group, Metropolis, Molfetta, Italy; Ilaria Rossetto, MD, REMS Researchers, Italy; Gabriele Mandarelli, MD, Section of Criminology and Forensic Psychiatry, Department of Internal Medicine, University of Bari Aldo Moro, Bari, Italy; Francesco Spadaro, MD, Section of Criminology and Forensic Psychiatry, Department of Internal Medicine, University of Bari Aldo Moro, Bari, Italy; Domenico Montalbò, MD, Section of Criminology and Forensic Psychiatry, Department of Internal Medicine, University of Bari Aldo Moro, Bari, Italy; Michele Bruno, MD, Section of Criminology and Forensic Psychiatry, Department of Internal Medicine, University of Bari Aldo Moro, Bari, Italy; Luigi Paparella, TRP, Forensic Facilities Group, Metropolis, Molfetta, Italy; Marika Leozappa, PsyD, REMS Researchers, Italy; Giusi Lombardo, PsyD, REMS Researchers, Italy; Giuseppe Nicolò, MD, REMS Researchers, Italy; Felice Francesco Carabellese, MD, Section of Criminology and Forensic Psychiatry, Department of Internal Medicine, University of Bari Aldo Moro, Bari, Italy

Learning Overview: After attending this presentation, attendees will have a better understanding of the importance of risk assessment and needs assessment for therapeutic security in an Italian forensic treatment model through a structured professional judgment based on the use of internationally validated scales and tools.

Impact Statement: This presentation will impact the forensic science community by presenting evidence from the predictive assessment of the level of therapeutic safety for patients with mental disorders who are offenders at risk of violence and recidivism in the Italian forensic context, profoundly changed after Law 81/2014.

The DUNDRUM Toolkit is an assessment tool consisting of four different scales (Structured Professional Judgment Tools for Admission, Urgency, Treatment Completion, and Recovery Evaluation Triage) used with forensic patients for evaluation and treatment purposes.¹

The DUNDRUM, like other tools such as the HCR-20, also recently validated in Italy, among the most used in the literature for assessing the risk of violence and recidivism in convicted subjects, is commonly used for Structured Professional Judgment (SPJ).^{2,3} SPJ is increasingly recognized as an effective way to improve the quality, consistency, and transparency of the decision-making process regarding the safe treatment of patients with mental disorders who committed crimes and are at risk of violent acts.

Considering the utility of this tool, which is flexible and broad in its scope of application, especially in a forensic treatment model such as the Italian one aimed at rehabilitation, it lends itself well to the assessment of the level of therapeutic safety and security for forensic patients with mental disorders and for planning treatment and the assessment of treatment appropriateness and effectiveness.

This original tool was made available to the mental health departments that coordinate Residences of Execution of Security Measures (REMS), the forensic facilities that replaced high-security hospitals in Italy after their closing, as well as forensic psychiatrists and researchers validating it for the Italian population and the Italian health system.⁴ For the validation of the DUNDRUM toolkit in Italy, following translation, a preliminary phase was carried out aimed at training the researchers involved. A person specially trained in Dublin at the Central Mental Hospital where the instrument was developed has provided training through a series of monthly meetings for a total of five meetings for the representatives of Italian REMS and other forensic facilities.

In the next phase, the largest possible number of patients included in the Italian REMS was enrolled out of the total of over 600 hospitalized, after obtaining their written consent to the research.⁵ For the purpose of validation, it was expected to enroll no less than 200 patients. At the same time, a series of anamnestic, clinical, and criminological data was acquired through the compilation by the researchers of a specially constructed form. Periodic checks on the progress of patient enrollment were also provided through comparison with all researchers involved. The research was approved by the Ethics Committee of the University Hospital of Bari. All data will be processed by the group of researchers who designed the tool.⁶ The first research data will be presented at the American Academy of Forensic Sciences (AAFS) conference.

121 The Differences Between Readmitted and Non-Readmitted Women in an Italian Forensic Unit: A Retrospective Study

Ilaria Rossetto, MD, PhD, Sistema Polimodulare di REMS Provvisorie, Castiglione delle Stiviere, Italy*

Learning Overview: After attending this presentation, attendees will have a better understanding of the importance of the ongoing research on individual risk and protective factors as well as risk assessment tools on conditionally and unconditionally released female inpatients and the value of studies that consider genders separately.

Impact Statement: This presentation will impact the forensic science community by presenting the variables linked with readmission in Italian forensic psychiatric services for socially dangerous mentally ill women.

The main objective of this study was to compare Readmitted (RW) and Non-Readmitted (NRW) female psychiatric patients after being conditionally or unconditionally released from Italian inpatient forensic psychiatry services in order to identify variables that were significantly linked with readmission.

This study included all patients who were discharged from the female Residences for the Execution of the Security Measure (REMS) of Castiglione delle Stiviere from January 2008 to June 2015 who were not readmitted until December 31, 2018. In addition, data were collected on female patients who were discharged from the same REMS before 2008 and readmitted from January 2008 and December 2018. A key finding of this study was that the readmission into a female REMS was positively associated with the presence of Substance Use Disorders (SUD) and a primary diagnosis on Axis II. To a lesser extent, younger age, being unconditionally discharged when first released, having had a shorter length of inpatient stay, and having committed a crime against property for the first REMS admission were also variables that were apparently linked with readmission. The present research continues the previous research on gender-specific mentally ill offenders.¹ Hence, the decision was made to proceed separately with a sample of men-only offenders and another of women-only offenders. For all these reasons, young female patients with personality disorders and substance use disorders should perhaps remain longer in REMS and be released with conditions. In most European countries, the length of stay depends on the clinical condition and risk assessment, with some exceptions when the courts set a maximum length of stay at the outset, as in Italy.² All factors listed above influence the risk assessment.³

Finally, from integrating these findings into the increasing international literature on conditional release and considering the recent changes in the Italian forensic treatment model, this study recommends continuing research on individual risk and protective factors as well as risk assessment instruments on conditionally and unconditionally released inpatients with genders studied separately.⁴

I22 A Psychopath in the House: How Digital Media Is Used to Exploit Even the Safest Homes

Jessica Morel, DO, Fayetteville, NC; Vivian Shnaidman, MD, Princeton, NJ; Anna-Renee Labak, Enfield, CT*

Learning Overview: The goal of this presentation is to discuss various ways in which digital media enters into forensic psychiatric evaluations and also how digital media investigations may uncover forensic psychiatric issues. Through updates on current crime statistics and various case discussions, this presentation will explore how digital media can be used to exploit the mentally ill as well as how psychopaths and sociopaths may use digital media to find victims.

Impact Statement: This presentation is designed to help the forensic sciences community understand the interface with digital media and forensic psychiatry. As technology continues to develop, the mentally ill are finding victims online and becoming victims to predators. Forensic evaluators are discovering elements of digital media influence in their case assessments and litigation.

Digital media is a growing forensic field as technology is frequently changing and expanding. Society used to assume that their homes were where they were safest. However, as criminals find new ways to exploit technology, investigations are leading back to the home. Cases may be presenting with more and more evidence that encompasses the expertise of forensic psychiatry just as digital media is affecting psychiatric treatment on a daily basis. Oftentimes, the digital media investigators and psychiatrists do not have the opportunity to interface on these cases and the two interpretations of data meet in the court room.

Many in society do not understand the psychological underpinnings of sociopaths and psychopaths, with their similarities and distinctions, nor do they separate these offenders from other individuals with mental health diagnoses that are more likely to be victims. With society turning more and more to technology and social media for personal interactions, we are unwittingly inviting perpetrators into our homes and personal lives. Young adults in particular may have superior skills in using technology, but they lack judgement and are often impulsive, resulting in exploitation. Older adults, on the other hand, can be naïve to the ways in which digital media may be used to attain personal information and exploit finances. With more recent isolation of society due to COVID-19 lockdowns, digital media investigations are becoming more relevant than ever. Potential victims are going online to find interpersonal connections they once found at work and in social activities. Meanwhile, perpetrators are finding and developing new platforms to access their victims at home.

Equally important to acknowledge is the very important evidence that digital media may provide when the perpetrator is deceased or at large. We are starting to see cases play out in the news before they hit the court room due to the wide availability of some digital media platforms such as social media pages, security cameras, and text messages. This presentation will also address the negative impacts that misinterpretations have on cases due to the ease of digital media editing or selection bias by news stations. It is important that we as investigators bear in mind that our first impression may not encompass the whole picture, and we should remain vigilant in our investigations to explore the data further. Digital media data investigations are an asset to our cases, and we should ensure the dissection of this information through thorough psychological interviews and criminal investigations where possible.

Psychopath, Sociopath, Digital Media

I23 Virtual Reality as a Treatment Medium for Sex Offenders

Jacob Pourat, MD*, USC Institute of Psychiatry and Law, Los Angeles, CA

Learning Overview: After attending this presentation, attendees will: (1) understand how Virtual Reality (VR) is currently being utilized in the field of mental health care, and (2) be able to critically appraise the potential uses, benefits, and limitations in using VR in sex offender treatment.

Impact Statement: This presentation will impact the forensic science community by comparing traditional forms of assessing and treating deviant sexual interests with new and theoretical VR methodologies.

VR is a computer-generated simulation that allows people to interact with a 3D and seemingly real virtual environment. VR has been recently introduced into medicine, where it is currently being used for both training and treatment. For example, VR is now being utilized to treat patients with neuromuscular conditions by simulating fun and engaging activities to increase engagement with physical therapy. In the mental health field, VR is more commonly utilized to provide simulated exposure therapies for post-traumatic stress disorder, anxiety disorders, and specific phobias.^{1,2} More recently, VR technology is gaining recognition in forensic mental health with the potential to be more prevalent as a treatment tool.³

When looking at objective measures in sex offender treatment, a substantial body of research shows that deviant sexual interest is a key element in explaining sexual offending behaviors and one of the strongest risk factors for sexual reoffending.^{4,5} This in turn places immense importance on accurately assessing sexual interest for treatment aimed at reducing the risk of reoffending. Penile Plethysmography (PPG), which measures blood flow to the penis as a proxy for sexual arousal, is often used for identification of deviant sexual interest. PPG is used by exposing people to sexually arousing stimuli, most commonly 2D pictures and/or sounds. In one study, researchers found that VR has the potential to improve on the ability to identify deviant sexual interests compared to other tools that use simpler imagery.^{6,7}

VR may enhance the current state of sexual offender treatment. VR has the capability to place sex offenders in different, customizable environments that resemble real-life scenarios and settings (e.g., beaches, parks, grocery stores) while simulating specific interactions with virtual characters. For example, a person who is known to be attracted to minors could be placed in a simulated park to assess how they react to the presence of virtual children. VR can also be combined with other tools commonly used for identifying sexual interest, such as PPG.⁸ As a treatment medium, VR has the potential to be used in psychotherapy with the goal of teaching self-identification of deviant cognitions, self-regulation of behavior, and relapse prevention. Furthermore, by using 3D simulated characters, VR circumvents the ethical and legal issues posed by using real imagery to elicit sexual arousal.³ Even though there are multiple potential benefits of using VR in the forensic setting, it is also important to consider its limitations, such as the lack of research and standardization in using VR in forensic treatment and the high initial cost to incorporate VR for treatment purposes.

Virtual Reality, Sex Offender, Treatment

I24 From Online Personas to Mass Murderers: The Incel Ideology and the Struggles of Mental Health

Eva Ip, BS*, British Columbia Institute of Technology, Burnaby, British Columbia, Canada

Learning Overview: The learning objectives of this presentation are for attendees have a better understanding of what an involuntary celibate (incel) is, how they have developed into an extremist group over the years, and why there needs to be a push for more research to be conducted on this community.

Impact Statement: This presentation aims to impact the forensic science community by presenting research that was collected from inside incel web-based forums, which was able to produce unexpected but astonishing results.

Incels are individuals who are part of a virtual community of isolated men who do not have a sexual life and collectively see women as the cause to their problem of celibacy.¹ In the online communities they frequent, topics of feminism and women are often subjected to hostility and violent threats.

There have been multiple instances throughout history where incels have executed attacks to gain a sense of notoriety and postmortem fame among their online communities; an infamous example was Elliot Rodger, a 22-year-old man who committed a mass murder in Isla Vista in 2014, where he killed 6 individuals and injured 13.² Rodger stated that he committed this act as a response to the hardship he faced in losing his virginity. Sexual shame is often associated with traditional masculinity, heavily suggesting that misogynistic men are more likely to be vulnerable to risk factors. The increased rate of suicide deaths, psychosis, violence, and incarceration in men is significantly higher when they experience this shame.³ However, little research has been conducted on the mental health aspect of an incel and the role that it plays leading up to mass attacks toward the greater population.

This research investigated whether there are underlying mental health factors that contribute to an incel's antagonism toward women and if it ultimately leads to them committing a mass attack. The study applied an exploratory research design as it used secondary research from various academic databases and open-source queries. The data that was collected focused on using web-based discussion boards from Reddit.com and Incels.net in which eight variables were coded. The posts and the comments corresponding were observed over a six-month time frame to reduce any potential bias from the researcher.

The results indicated a strong connection between mental health factors and the antagonism an incel feels toward women and demonstrates where future research could build on what was found to strengthen that connection.

Group Aggression, Extremism, Mental Health

I25 3D Interactive Lineups Improve Eyewitness ID Accuracy

Heather Flowe, PhD*, University of Birmingham, Edgbaston, United Kingdom

Learning Overview: After attending this presentation, attendees can expect to learn: (1) the key lineup procedures that are in use worldwide to identify criminal suspects; (2) key memory theories concerning eyewitness identification; and (3) the latest research on 3D interactive lineups, which significantly increase the identification of guilty suspects and reduce the identification of innocent suspects.

Impact Statement: The forensic science community will be impacted by learning about the potential for new and low-cost technology to improve criminal investigations.

In many countries (including the United States), criminal identification lineups consist of static photographs. Lineup members are shown from the shoulders up, facing forward, even if a witness viewed the perpetrator from a different angle at the time of the crime (e.g., profile view). This study tested whether a novel interactive lineup procedure increases identification accuracy compared to traditional lineup procedures. This study also examined whether witnesses would spontaneously rotate the lineup faces to match the angle in which they saw the perpetrator and, if so, whether this is associated with increased identification accuracy. In tests conducted with 3,000 participant witnesses, this study found that identification accuracy, the ability to differentiate guilty from innocent suspects, is significantly increased when witnesses can view the lineup members at the same angle as they saw the perpetrator commit the crime.¹ Moreover, this study found in tests with 10,000 participants from around the world that identification accuracy is significantly increased compared to the traditional static frontal pose lineups.² Interactive lineups also increase accuracy in other race identifications compared to traditional procedures. Faces are 1.4 times more likely to be misidentified if they are of a different race than the person making the identification and own race bias is a leading cause of erroneous eyewitness identification. These errors are reduced significantly in interactive lineups. Interactive lineups are proving to be a valuable tool for increasing identification accuracy. Interactivity has also been found to boost forensic face-matching accuracy, in both typical as well as superior face recognizers.³ More information about research on interactive lineups can be found in the latest issue of *Scientific American*.⁴

J1 The Department of Justice Uniform Language for Testimony and Reports (ULTR) For Forensic Document Examination (FDE)

Carl R. McClary MS, U.S. Department of Justice, ATF, Atlanta, GA*

Learning Overview: Attendees will learn what the Questioned Document sections of Department of Justice (DOJ) forensic science laboratories have published to be used as reporting and testimony language. Attendees will also gather ideas for terms and definitions for their own opinions on common source.

Impact Statement: This presentation will impact the forensic science community by providing the most updated information on what the DOJ has done to standardize testimony and reporting language across its forensic laboratories. Attendees will learn what, specifically, the examiners within the DOJ Questioned Document (QD) community are currently using to communicate the results of examinations within the discipline. Attendees will learn the five primary conclusions, with bases and reasons included, that are being utilized within the QD sections. These conclusions are based on previously published standardized opinion terminology found within the Scientific Working Group of Forensic Document Examiners (SWGDOC) standard T01-13.

The DOJ has developed and published standardized opinion language for various disciplines within its forensic science laboratories. These laboratories reside in the following agencies: Drug Enforcement Agency (DEA), the Federal Bureau of Investigation (FBI), and the Bureau of Alcohol, Tobacco, Firearms and Explosives (ATF). These documents are provided as guidance for scientific statements when drafting reports or testifying. Currently, 14 disciplines have approved language for reporting and testimony.

Representatives from both DOJ laboratories offering Forensic Document Examination (FDE) services collaborated on a QD working group that convened over a period of two years, meeting both in person and virtually, to gain consensus on the number of terms and definitions used in describing FDE opinions. Because the primary sub-examination of FDE is handwriting and hand printing comparisons, the scheme of opinion levels focuses on accommodating these examinations. However, other examinations, such as paper fracture match, typewriting, and hand stamp (rubber stamp) examinations, can be applicable to the ULTRs. The nine-level standardized opinion terminology widely used served as the basis for the working group. The process also took into consideration language from Bayesian processes, current disparate levels and language in use in the two laboratories, and standardized ULTRs from other disciplines. The FDE ULTR was published on July 5, 2021.

The final product of the working group, below, reflects an easily usable compilation of opinion levels (terms) providing five primary opinions to cover the circumstances of many FDE examinations. Within the two qualified levels is language that can be expanded, if necessary, to reflect the strength of those qualified terms.

Source identification (i.e., identified)—an examiner's conclusion that two or more bodies of writing were prepared by the same writer. The examiner would not expect to see the same combination of characteristics repeated in a body of writing by another writer.

Support for common source—an examiner's conclusion that two or more bodies of writing may have been prepared by the same writer.

Inconclusive—an examiner's opinion that no determination can be reached as to whether two or more bodies of writing were prepared by the same writer or by different writers.

Support for different sources—an examiner's conclusion that two or more bodies of writing may not have been prepared by the same writer.

Source exclusion (i.e., excluded)—an examiner's conclusion that two or more bodies of writing were not prepared by the same writer. Bodies of writing exhibit different handwriting characteristics and no significant limitations or circumstances, such as an alternative writing style or skill level.

Questioned Document Examination, ULTR, Common Source

J2 Classification of Handwriting Using Pen Pressure Patterns

Yoko Seki MA, National Research Institute of Police Science, Kashiwa, Chiba, Japan*

Learning Overview: After attending this presentation, attendees will understand the effectiveness of pen pressure data acquired online in the classification of handwriting.

Impact Statement: This presentation will impact the forensic science community by presenting the experimental procedures and the classification results of handwriting classification experiments using online data.

The development of information technology has greatly changed our ordinary lives. The environment surrounding writing and writing materials has changed greatly. Writing with a finger or a stylus pen on a tablet instead of writing with a pen on paper, especially in the case of signing, has become more and more popular.

The number of forensic handwriting examination cases in which handwritten evidence is acquired online has been increasing, along with the widespread use of various online writing systems. As such, the necessity for the development of forensic handwriting examination methods for online data processing has also grown.

In this presentation, visualization and synthesis of dynamic information on writing acquired online were attempted using a “pen pressure map,” where the pen pressure change pattern was expressed on the pen tip trajectory in three colors. A Convolutional Neural Network was used for writer classification experiments with online and offline data.

Handwriting classification experiments using LeNet were conducted. Online and offline data of four categories of Kanji characters written by ten Japanese adults five times each were used for the experiments. Three samples per writer per category were used for the training data, and the remaining two samples were used for test data. Four categories of characters were combined in a fixed order to be a Japanese person’s name, and the character string of the name was used for the experiments. Any sample of the same category of the same writer in either training or test data was combined following the fixed order. So, 81 (the fourth power of three) samples of training data and 16 (the fourth power of two) of test data were obtained per writer. Online data were processed as follows: online image data of each sample were acquired by drawing the pen tip trajectory; the pen pressure value data were processed using the pen pressure change between two measuring points; and the pen pressure change data between the two points were expressed on the trajectory in three colors, that is, blue (pen pressure increasing), yellow (pen pressure unchanged), and red (pen pressure decreasing). Classification experiments were done on both online and offline data.

Classification results showed greater than 0.95 accuracy, precision, recall and F-measure scores obtained for both online and offline data. Nearly the same correct ratio was obtained in handwriting classification using both online and offline data. This suggests the possibility of handwriting classification using samples written on a tablet may be the direction of future handwriting identification.

Handwriting Classification, Pen Pressure, Convolutional Neural Network

J3 Contemporary Studies Via Chemometric and Spectroscopic Techniques for the Investigation of Questioned Documents

Vishal Sharma, PhD*, Institute of Forensic Science & Criminology, Panjab University, Chandigarh, UT, India

Learning Overview: The detection of written as well as computer-generated document forgeries has always been a challenging task for Forensic Document Examiners (FDEs). With the aim of supporting the examination processes, Diffuse Reflectance Spectroscopy Ultraviolet Visible (DRS-UV-Vis) Attenuated Total Reflectance/Fourier Transform Infrared (ATR/FTIR), and Schottky Field Emission-Scanning Electron Microscopy with Energy Dispersive X-ray Spectroscopy (FE-SEM/EDS) are explored as tools to analyze handwritten ink as well as toner-printed documents. Various handwritten and laser-printed documents from various sources were produced and analyzed through these analytical techniques.

Impact Statement: This research will be useful for FDEs as it provides objective results, and most of the methods are non-destructive in nature. Moreover, the chemometric methods increase statistical confidence in the results, which is highly desired in this field. Moreover, in the future, it is quite possible to create a database of additional inks and toner samples for the identification of unknown inks.

The techniques used in present day analysis of handwritten documents include UV-Vis, ATR/FTIR, and FE-SEM/EDS. In the present research, handwritten and laser-printed documents obtained from various sources were analyzed.^{1,2} The obtained spectral data was then used for applying chemometric models for their classification, discrimination, and characterization.³ The samples from the laser printer and photocopier machines were also studied for their morphological features, elemental profile, and multivariate analysis. The evaluation of SEM images and spectra allowed for discrimination among the samples and classification of toners as having different sources of origin. The application of multivariate analysis was conducted for developing a model of classification for both inks as well as toner samples solely based upon their similarities and dissimilarities in composition. Hierarchical cluster analysis discriminated ink and toner samples in the form of groups based on their chemical makeup. Further cross-validation was conducted for assessing the capabilities of developed Principal Component Analysis (PCA) and linear discriminant analysis models for the examination of inks and toners from an unknown origin.

Toner, Chemometric, Questioned Documents

J4 Indentations Developed on Three Reams of Paper Using an Electrostatic Detection Device (EDD)

Rafal K. Turek, MS, IRS, Chicago, IL; Martin Shlaymoon, PhD*, IRS, Chicago, IL

Learning Overview: After attending this presentation, attendees will have a better understanding of the possible origin of the indentations that can be made on paper before it reaches the user.

Impact Statement: This presentation will impact the forensic science community by presenting the marks and other features created on paper during the paper manufacturing process.

Repetitive indentation patterns were developed with the EDD on reams of 8.5" x 11" paper from the same manufacturer. Three different brands of paper were sampled.

The indentations that appeared on these reams included:

- A pair of scuff marks on the front of the first sheet of each ream.
- Diagonal lines appeared on the front of the first and fifth sheets of two of the reams, and parallel waves appeared on the third ream.
- A mirror image of the diagonal lines appeared on the reverse of the fifth and sixth sheets of two of the reams, and a mirror image of the parallel waves appeared on the third ream.

The above indentations repeat throughout the ream every n+6 sheets, indicating that the ream has been comprised of paper from six different rolls during the sheeting process. There were scuff marks on sheets of each ream, but the appearance of the marks (the size, shape, and distance between them) are what differed from ream to ream. Each of the examined reams of paper consisted of 504 sheets (not 500 as appeared on the label), which is consistent with the fact that the ream is made up of six rolls (because 504 is divisible by 6, but 500 is not).

These indentations are assumed to have been produced during the paper manufacturing and conversion process, where larger rolls are reduced in size and assembled into reams. The differences suggest they could be produced at different plants or mills or under different machinery configurations.

This presentation should make examiners aware that indentations can occur not only from the handling of a document by a user, or from the business machines used in its printing, scanning, or copying, but also from the paper stock itself, created during the manufacturing process. This presentation will show the indentations found and attempt to explain their likely sources.

J5 Assessing the Dependency Structure Between Shape Codes for Forensic Handwriting Data

Cami Fuglsby, MS*, South Dakota State University, Brookings, SD; Kayla Moquin, BS, FBI Laboratory | RSU, Quantico, VA; Christopher Saunders, PhD, South Dakota State University, Brookings, SD; Danica Ommen, PhD, Iowa State University, Ames, IA; Michael Caligiuri, PhD, University of California, San Diego, La Jolla, CA; JoAnn Buscaglia, PhD, FBI Laboratory | RSU, Quantico, VA

Learning Overview: Attendees will gain an understanding of how to compare certain feature sets stemming from the output of an automated handwriting identification system and how the comparison relates to the dependencies between features of handwritten characters.

Impact Statement: This presentation will impact the forensic science community by investigating how certain handwriting features correlate and how those features interact with a scoring method. This may have an impact on future studies on automated handwriting data pertaining to score development or assumptions on the amount of information contained within a handwritten document.

Automated handwriting identification systems typically use a complex set of algorithms to extract the feature sets from a given handwriting sample. For example, in the original CEDAR-FOX system, the features could be grouped into macro- and micro-feature sets.^{1,2} Other systems, such as the FLASH ID® and Handwriter, tend to extract different sets of features based on the orientation of the segmented writing.^{3,4} For the FLASH ID® system, the orientations of segmented writing are referred to as shape codes. In recent work, a set of pairwise scoring rules, known as the Vector-Of-Counts (VOC) method, has been developed that can be decomposed across the shape codes that have been observed in a given pair of documents.⁵ An important aspect of understanding how the FLASH ID® system works for pairwise comparisons is to find the relationship between shape code-specific VOCs and their corresponding correlations with an omnibus VOC. In effect, the greater the correlation between the subcomponents of the omnibus score, the less effect adding in the second subcomponent will have on the omnibus score; ideally, the omnibus score will be constructed in terms of independent subcomponents so that, in any given comparison, there is an understanding of why a given score is observed.

To study this relationship, a class of new statistical regression techniques developed in Caligiuri, and extended in Tang, will be used to provide a statistically rigorous characterization of the dependency between different VOC-shape code pairwise similarity scores.^{6,7} These new statistical techniques are based on using least squares methods on the set of all pairwise comparisons between writers and account for the new dependency structure between the comparisons.

The results of the regression models will be explained and presented in terms of the original observed writing samples with a focus on the graphical display of the shape codes, score development, and resulting findings.

J6 Standards Development Activities Related to Forensic Document Examination

Kevin P. Kulbacki, MS, KDX Forensic Consulting, LLC, Chicago, IL*

Learning Overview: After attending this presentation, attendees will better understand the status of discipline-specific standards pertinent to the field of forensic document examination.

Impact Statement: This presentation will impact the forensic science community by creating greater awareness of standards development activities related to document examination. It will also increase awareness regarding training, tools, and resources that support implementation, compliance monitoring, and broader understanding.

The Organization of Scientific Area Committees (OSAC) for Forensic Science was created to strengthen the nation's use of forensic science by promoting the use of discipline-specific forensic science standards. To this end, the OSAC drafts standards that are forwarded to Standards Developing Organizations (SDOs) that further develop and publish them. The OSAC also reviews standards and recognizes them on the OSAC Registry, which serves as a central repository of high-quality, consensus-based, technically sound standards.

During this presentation, standards development updates related to forensic document examination will be discussed. These include: (1) OSAC proposed standards (Scope for Expertise in Forensic Document Examination, Standard for Forensic Examination of Handwritten Items, Forensic Document Examination Terms and Reference, Standard for the Preservation and Examination of Charred Documents, and Standard for the Examination of Liquid Soaked Documents); (2) published standards from the Academy Standards Board (ASB) that have yet to go through the Registry approval process (Standard for the Examination of Documents for Alterations, Standard for the Examination of Documents for Indentations, and Standard for the Examination of Stamping Devices and Stamp Impressions); and (3) documents currently in development at the OSAC or by the ASB (Standard for Minimum Training Requirements for Forensic Document Examiners, Standard for the Examination of Mechanical Checkwriters, Standard Guide for Initial Evidence Assessment of Questioned Document Evidence, Standard for the Expression of Conclusions in Handwriting Evidence, Standard Test Methods for the Comparison of Writing and Inkjet Inks, Standard for the Examination of Dry Seals, and Standard for the Collection for Known Writing), and other highlights. Opportunities for supplemental training related to discipline-specific standards will be presented, as well as additional resources and tools designed to facilitate gap analysis, compliance monitoring, and outreach efforts.

Questioned Documents, Standards, OSAC

J7 The Accuracy and Reliability of Forensic Handwriting Examiner Decisions

Linda Eisenhart BS, MBA*, FBI Laboratory, Quantico, VA; R. Austin Hicklin, PhD, Noblis, Reston, VA; Brian Eckenrode, PhD, FBI Laboratory, Quantico, VA; Peter J. Belcastro, Jr., MA, FBI Laboratory, Quantico, VA; Ted M. Burkes, BS, FBI Laboratory, Quantico, VA; Connie L. Parks, MA; Noblis, Reston, VA; Meredith DeKalb Miller, MFS, Chicago, IL; Joann Buscaglia, PhD, FBI Laboratory, Quantico, VA; Michael A. Smith, PhD, FBI Laboratory, Quantico, VA

Learning Overview: Attendees will learn about the results of a large-scale Handwriting Decision Analysis (Black Box) Study, including accuracy, error rates, reproducibility, and repeatability of handwriting decisions and what factors impact these rates.

Impact Statement: This presentation will enable forensic document examiners to answer questions regarding what factors impact the accuracy and reproducibility of the decisions, including those related to the examiner and those related to the samples.

This Handwriting Decision Analysis (also known as Black Box) Study was designed and conducted by the Federal Bureau of Investigation (FBI) Laboratory, Ideal Innovations, and Noblis. The design of this study was based on the FBI Laboratory-Noblis latent print examiner black box study, and in consideration of comments made in two United States Reports: the 2009 National Academy of Sciences Report, *Strengthening Forensic Science in the United States: A Pathway Forward* and the 2016 Report from the President's Council of Advisors on Science & Technology (PCAST) titled *Forensic Science in Criminal Courts: Ensuring Scientific Validity of Feature-Comparison Methods*.¹⁻³

Participation for this study was limited to practicing handwriting examiners who had performed casework within the past two years. A pre-test survey was completed by each participant to gather information about their education, training, experience, certification, and day-to-day work. Participants were asked to perform a total of 100 comparisons of paired handwriting samples, each containing one sample of questioned writing and up to five pages of writing from a single known subject. In an effort to represent the wide range of evidence encountered in casework, a diversity of handwriting samples was selected. The test samples included a range of styles of handwriting (i.e., cursive, hand printing, and mixed), content (e.g., addresses, a few sentences, predefined London or CEDAR letters, or freeform text), known writing samples containing the same or different wording, as well as varying amounts of questioned and known writing. Note that this study was limited to the comparison of handwritten documents and did not include the comparisons of signatures. Great effort was taken to provide participants with test packets that were relatively challenging, both for mated and non-mated pairs.

Using an online platform, participants were provided with high-resolution digital images that could be downloaded for comparison. The participants used this platform to respond to predefined questions that included the conclusion, limitation(s), assessments of comparability and variation within questioned and known writing samples, perceived difficulty of the comparison, and most influential characteristics that were used in making their decisions. Participants were given five conclusions to choose from, including definitive opinions (written by and not written by), qualified opinions (probably written by and probably not written by), and no conclusion. The study resulted in 7,213 trials from 86 handwriting examiners on 180 distinct comparisons of questioned and known handwriting.

This presentation will provide the results of the study, including the accuracy, reproducibility (inter-examiner variation), and repeatability (intra-examiner variation) of decisions made by forensic handwriting examiners. This presentation will expand upon the results provided at the 2021 AAFS meeting by presenting the factors that did (or did not) impact the accuracy of the decisions in this study, including those related to the examiner (such as training or experience) and those related to the samples (such as quantity of writing, comparability of content, limitations, or style of writing).

Handwriting, Error Rate, Black Box Study

J8 Expert Disclosure Requirements in the Federal Rules of Civil Procedure and the Federal Rules of Criminal Procedure

Jan Seaman Kelly, BA, Forensic Dynamics LLC, Las Vegas, NV*

Learning Overview: Attendees will have a clear understanding of the differences between Rule 26 in the Federal Rules of Civil Procedure and Rule 16 in the Federal Rules of Criminal Procedure and the impact of the 1993 revisions that were designed to expedite the litigation process.

Impact Statement: This presentation educates the forensic science community on the differences between Rule 26 of the Federal Rules of Civil Procedure and Rule 16 of the Federal Rules of Criminal Procedure. Understanding the requirements that Rule 16 and Rule 26 place on expert witnesses highlights the importance of meeting the requirements, since the failure to do so will result in exclusion of that portion of the witness testimony.

Rule 26 of the Federal Rules of Evidence Civil Procedure was revised and went into effect on December 1, 1993. This revision was controversial as it required parties in a lawsuit to exchange certain information at the beginning of the litigation, including the disclosure of the expert's written report. The Supreme Court's intent for Rule 26 was to encourage openness between the involved parties during the early stages of the dispute as a means to improve the efficiency of the federal judicial process. The Court's intent was three-fold: (1) early discovery benefits both sides to focus on the discovery needed and to facilitate trial or settlement preparation; (2) assists the parties to determine whether or not depositions will be necessary; and (3) requires the parties to share information as well as have a clearer idea of document requests. These three benefits were designed to avoid disputes between attorneys and to accelerate the exchange of basic information. Compliance with Rule 26 in the Federal Rules of Civil Procedure occurs when the expert's written report has been disclosed.

Compliance with Rule 16 in the Federal Rules of Criminal Procedure is not as laborious as Rule 26 in the Federal Rules of Civil Procedure. Under Rule 16, the expert is not required to draft nor to submit a report prior to testifying in court. However, the expert is required to provide a written summary of testimony that includes the issued opinion, the basis and reasoning for each opinion, and the qualifications of the witness.¹⁻⁴

Attendees will have a clearer understanding of the differences between Rule 26 in the Federal Rules of Civil Procedure and Rule 16 in the Federal Rules of Criminal Procedure and the impact of the 1993 revisions designed to expedite the litigation process.

Rule 26, Rule 16, Litigant

J9 Institutional Prejudice by the Courts Involving Certain Opposing Handwriting Opinions

Thomas W. Vastrick, BS, Apopka, FL; Jan Seaman Kelly, BA, Forensic Dynamics LLC, Las Vegas, NV*

Learning Overview: After attending this presentation, attendees will be aware of certain prejudices held by triers of fact against indeterminate and highly qualified opinions. In addition, attendees will learn practices that can mitigate these prejudices.

Impact Statement: This presentation will bring to light a recognized concern of inequitable consideration by courts of highly qualified or indeterminate conclusions. This inequity can conceivably result in “incorrect decisions on culpability or liability,” as noted by the Forensic Handwriting Examination and Human Factors report.¹ It is distinctly hoped that this presentation will contribute to a lesser chance of such injustice within our court system.

The discipline of forensic document examination in the United States has primarily utilized a series of opinion terms since an effort to standardize terms was first introduced many years ago. This presentation delves into user reaction to instances in which there are opposing opinions of varied qualifications/confidence levels/likelihoods. There have been instances in which differing opinions have been misrepresented in litigation and indeterminate opinions have been the source of minimization or outright mockery. Discussions among examiners show that it has become apparent that this problem is far reaching.

In 2016, a study of forensic document examiners who have provided indeterminate opinion testimony in court was conducted. Forty-seven forensic document examiners from around the world responded to the survey, noting that testimony of indeterminate opinions was provided in 519 instances: 245 in criminal court, 178 in civil court, 1 United Nations tribunal, 1 immigration hearing, 12 military hearings, 62 juvenile hearings, 8 bench trials, 2 administrative hearings, 3 *Daubert* hearings, and 7 depositions. In 103 of these instances, an indeterminate opinion was the sole opinion provided.

There are multiple reasons why a forensic document examiner appropriately provides indeterminate opinions. Oftentimes, these reasons include severe examination limitations or conflicting data in which neither associative nor dissociative support is compelling.

Concern has arisen as to how indeterminate and highly qualified opinions are viewed in court. One reference, quoted in the Forensic Handwriting Examination and Human Factors report from the National Institute of Standards and Technology (NIST) states, “The findings suggest that jurors tend to over-value some attributes of forensic science expert testimony and under-value other aspects. The most persistent finding is that jurors rely heavily on the ‘experience’ of the testifying expert and the expert’s asserted certainty in conclusions.”¹ The Human Factors report also notes two additional studies supporting that jurors prefer unambiguous testimony that is strongly worded, ultimately providing this ominous warning, “These findings are a concern because if jurors and others give greater credence to strong opinions that might not be as well reasoned or well founded as more complex, qualified opinions, they may make incorrect decisions of culpability or liability.”¹

There are steps that can be taken by the forensic document examiner to counter this bias. These steps include: (1) clearly denote qualifications; (2) detail the methodologies used and directly denote the industry standard reference step by step; detail, with images, the limitations imposed on the examination; (4) provide the raw data in detail; (5) address alternative hypotheses in as much detail as the initial opinion; and (6) provide substantial detail in an easy-to-understand court presentation, complete with proper illustrations.

J10 The Manual Reconstruction of Shredded Documents

Meg OBrien, MS, USSS, Washington, DC*

Learning Overview: After attending this presentation, attendees will have an understanding of the basic steps of reconstructing shredded document evidence, as well as the time-consuming nature of these cases.

Impact Statement: This presentation will impact the forensic science community by presenting cases involving shredded documents outside the normal scope of paper documents with machine-printed or handwritten text.

Shredded documents are collected from various places and in different types of investigations. The manual reconstruction of shredded documents is a time-consuming process. Imagine being provided multiple jigsaw puzzles, then told to combine all the pieces into one pile, throw away the boxes, and then put the puzzles together. That is essentially how a shredded document case is worked.

The basic steps of a shredded documents case are: (1) sorting, and (2) reconstructing. Sorting is performed based on characteristics such as paper color, directionality of shred, presence of handwriting or machine printing, and font style and color, among other features. Reconstruction of documents can be hindered if multiple versions or copies of documents are included.

The goal of reconstructing shredded documents is to provide information for investigators. This information is needed in a timely manner, but the reconstruction of shredded documents is a time-consuming project. The quantity and size of shred are just two factors that can affect the time needed by the forensic document examiner. An additional factor that affects how long a case takes includes a primarily remote work schedule while evidence must remain in a secure facility, such as a laboratory.

Questioned Documents, Shredded Documents, Document Reconstruction

J11 Electrostatic Detection Apparatus (ESDA): Something Old, Something New

Larry A. Olson, MFS, IRS National Forensic Laboratory, Chicago, IL*

Learning Overview: After attending this presentation, attendees will have a better understanding about: (1) what indentations artifacts may occur when using the ESDA2 or ESDA2/B, and (2) how to use the ESDA2 for examining bound materials.

Impact Statement: This presentation will impact the forensic science community by: (1) reminding document examiners how business machines may cause indentations on paper documents, (2) revealing that ESDA artifacts/defects may cause what appear to be indentations, and (3) reintroducing some possibly long-forgotten instructions from the original ESDA device.

This presentation is in two parts. The first part, Something New, deals with the ESDA2 or ESDA2/B creating artifacts that were mistaken for indentations on papers being examined. In recent years, this study had developed a specific pattern of voids (six columns of white dots) in the ESDA lifts of documents examined in several fraud investigation cases. The most obvious common denominator in the cases was that prior to the submission of the documents, the investigators had made copies using the Automated Document Feeder (ADF) on their copiers. The same pattern occurred on documents passed through the ADF of the laboratory's copier (because the agency had a service-wide contract for the same make and model). After much research and exhaustive correspondence with the copier manufacturer, the origin of the pattern appeared to point to the copy imaging process, where a bar of LED lights in two columns (roughly the same dimensions as the voids) illuminated the document as it passed through the ADF. The other (unconscious) common denominator, however, was that it was the lab's ESDA2 and ESDA2/B that were used in developing the indentations. It was found that a colleague at another lab had experienced the same phenomenon, which turned out to have been caused by an excessive vacuum being pulled through the ESDA platen.

Another instance of an ESDA2 artifact being mistaken for indentations on a document was the result of the softness of the metal used in the platen. In another lab, the spine of a bound notebook being examined embossed the ESDA platen, and the embossing was reproduced on ESDA lifts and initially assumed to be indentations from a document.

The second part of this presentation, Something Old, is a revisiting of possibly forgotten procedures on examining bound books for indentations. These procedures were described in the original ESDA operating instructions but were not included in manuals for the ESDA2.^{1,2} One method requires placing the entire book on the platen with a sheet of metal foil under the sheet being examined to conduct the electric charge. Another method involves positioning the book against the instrument so that only one sheet is on the platen. Younger examiners who have never worked with the original ESDA may be unaware of these methods, although they work equally well on the ESDA2 or 2/B and are, additionally, non-destructive to the book.

Indentation, ESDA, EDD

J12 Exploring Digital Capture and Comparison of Indented Writing Developed With an Electrostatic Detection Device

Mark Goff, BA, Michigan State Police, Lansing, MI*

Learning Overview: This presentation evaluates various methods of digitally capturing writing indentations developed using an Electrostatic Detection Device (EDD), the subsequent comparison of these images to the source writing to show source attribution, and an overview of the applicable areas of the American National Standards Institute/ Academy Standards Board (ANSI/ASB) Standard 044, Standard for Examination of Documents for Indentations, First Edition, 2019.

Impact Statement: After attending this presentation, attendees will have an understanding of the options available for the digital capture and comparison of writing impressions developed with an EDD, methods for conducting comparisons of the digitally captured images, and the applicable current Forensic Document Examination standard.

Multiple methods of digital image capture were tested with varying degrees of success. These methods included: scanning the developed indentations on the platen of an EDD with an inverted Contact Imaging Sensor (CIS) flatbed scanner; a Charge-Coupled Device (CCD) flatbed scanner; and digital photography, using a 22 mega pixel digital camera and a 50 mega pixel digital camera. These imaging methods were compared to physical lifts of the same developed indentations. Scanning with a CCD scanner and digital photography showed results comparable to indentations preserved with a physical lift. Photography of EDD-developed writing indentations showed an increase in efficiency for the forensic document examiner when compared to the time and effort related to the physical encapsulation of the developed image and production of an EDD lift.

The second half of this presentation will provide an overview of the methods of comparison for digital images of EDD-developed indentations to source writing with a raster graphics editing program. This presentation will conclude with an overview of the applicable standards and how they relate to the digital capture and comparison of EDD-developed indentations.

The digital capture and comparison method proved to be a quick and viable way to show source attribution for writing impressions developed with an EDD.

EDD, FDE, Standards

J13 An Objective Inter-Comparison of Trash Mark Constellations From 50 Photocopiers Utilizing Manual and Automated Detection Methods

Linda Eisenhart, BS, MBA, FBI Laboratory, Quantico, VA; Joseph C. Stephens, MFSF, FBI Laboratory, Quantico, VA; Jocelyn V. Abonamah, MFS, District of Columbia Office of the Chief Medical Examiner, Washington, DC; Paige Riley, ORISE/FBI Laboratory, Quantico, VA; Brian Eckenrode, PhD, FBI Laboratory, Quantico, VA; Colbey Ryman, Noblis, Arlington, VA*

Learning Overview: The goal of this presentation is to demonstrate the foundational validity of trash mark comparison methods through empirical, objective data. By harnessing this objective data, forensic scientists can define and apply mathematical calculations and statistical approaches to make the analysis more transparent and reproducible.

Impact Statement: This presentation will impact the forensic science community by outlining a method to move trash mark examinations toward pre-defined decision criteria and data analyses. This presentation will detail the results of an inter-comparison of the trash mark constellations from 50 known photocopiers using a novel, objective method. This method also provides an improvement in efficiency, especially when numerous known machines with multiple functions are being compared to one or more questioned documents.

Trash marks are individual characteristics observed on printed, scanned, or photocopied documents that result from permanent or transient defects on the glass platen, slit glass, photosensitive drum, or lid of office machines. When multiple trash marks resulting from the platen are present, a pattern—or constellation—can be recognized and used for source attribution of questioned documents. Trash mark examinations have been employed in forensic laboratories for decades, yet the method remains relatively untested and relies on training, experience, and anecdotal information to support its validity. This study generated and harnessed objective data to empirically test one of the foundational theories for assessing source attribution of photocopied documents: if trash marks are present in sufficient quantity and/or quality, no two machines will exhibit a constellation of trash marks that is indiscriminate from another. In this study, objective trash mark location and size data was generated for 50 known photocopiers using both a traditional and a novel automated detection method. Intermachine comparisons were conducted using a custom variant of the Hausdorff distance to generate a quantitative assessment of how similar or different the 2,450 pairs of trash mark constellations from this study were. This presentation will report the results of the inter-comparison of the trash mark constellations of 50 photocopiers using both traditional and automated detection methods.

Defect Marks, Photocopy, Printing

J14 Barcodes: Basics and Cases

Carolyn Bayer-Broring, MFS, Homeland Security Investigations Forensic Laboratory, McLean, VA; Elaine Wooton, MFS, Homeland Security Investigations Forensic Laboratory, McLean, VA*

Learning Overview: Barcodes appear in the casework of forensic document examiners in a variety of forms and formats. The forensic document examiner needs to be prepared not only to understand the purpose a barcode serves on the document being examined, but also how to examine the barcode, make minor repairs to damaged barcodes, and extract the information necessary to assist in assessing the legitimacy of that document.

Impact Statement: By attending this presentation, attendees will have an understanding of the purpose and function of barcodes on documents and will be able to explain the outcomes of examinations in which barcodes are interrogated.

Barcodes are ubiquitous and, for the most, part innocuous. However, the use of barcodes in security documents brings the assessment of questionable versions under the purview of the forensic document examiner. Fortunately, equipment developed for laboratory examination of documents includes software to decode barcodes. This allows examiners to undertake the most common activity regarding barcodes, which is determining if the information in a barcode matches the information printed on a security document.

While the software allows for assessments without a lot of knowledge about the type of barcode being assessed, examiners should have a basic knowledge of barcodes so they can describe them and explain the agreement or disagreement between the barcode and the printed information. Basic expertise in this area includes knowledge of the history of barcodes, various types of barcodes, uses for barcodes, as well as barriers or issues with barcode interrogation.

A brief historical overview includes the initial use of barcodes for tracking rail cars, followed by grocery scanning, inventory tracking (commercial and military), and, finally, the widespread use of various barcode versions, including the best known—the QR code.

The simplest way to categorize barcodes is as “1D” or “2D.” 1D barcodes are simple and typically hold a very small amount of data. They are formulated by converting numbers or characters into the elements of a barcode font. Individuals who work with 1D barcodes can often read them as if they were written in their native language. 1D barcodes may contain a short inventory control number or point to an inventory system. 2D barcodes, such as the PDF-417, Data Matrix, and QR code, can contain extensive information depending on the number of rows and columns they include. They are encoded with complex software and incorporate various levels of error correction, so they can be decoded even if they are damaged.

To date, there have been a handful of cases at the laboratory in which barcodes played a significant role. A summary of those cases will be presented and include: identification of fraudulent forms due to the presence of identical 1D barcodes, reconstruction of damaged PDF-417 and Code 39 barcodes, and documentation of mismatches between postal barcodes and correspondence.

Barcodes, PDF-417, QR Code

J15 Forensic Methods to Detect the Presence of Hidden Messages

Kirsten Tate, BS, Federal Bureau of Investigation, Quantico, VA*

Learning Overview: Attendees will learn about methods of concealing a secret message in a written letter, as well as methods of identifying these hidden messages.

Impact Statement: This presentation impacts the forensic science community by bringing awareness to the existence of secret messages that are difficult to detect and by introducing research on a new approach to detecting hidden messages in a larger body of text.

People who commit crimes have plenty of reason to share secrets, and they often resort to various forms of secret writing to accomplish this. The field of forensic cryptanalysis seeks to identify and break these encoded messages in order to reveal their true meaning. *Concealments* are one such method often used by criminals to exchange secret messages without attracting the attention of law enforcement. In a letter-based concealment, the letters of a secret message are systematically scattered throughout a larger body of text. The cover text might be something seemingly innocuous, but the intended recipient of the message is able to extract the correct letters to spell out the secret message.¹ It can sometimes be difficult for a forensic cryptanalyst to determine whether a concealment is present in a given message, since it is hidden within this larger body of “normal” text. However, it has been observed anecdotally that writers of concealments typically write in a different style than they would otherwise. Indeed, recent research has shown that when a person is writing a concealment, their writing style does in fact change from the writer’s natural style. In addition, this phenomenon can be quantified using techniques from a field of statistics called authorship attribution.²

A recent study showed that writers tend to change their sentence length significantly when writing concealments, and they also tend to use different vocabulary and sentence structure than they would otherwise. This novel result can be used to compare a suspected concealment against other writing samples from the same author in order to determine whether a concealment is likely to be present.³ This development provides forensic cryptanalysts with a new tool to use when analyzing a possible concealment. This presentation will introduce concealments as a method of secret writing and show how authorship attribution can be used to identify them.

Cryptanalysis, Secret Writing, Statistics

J16 The Forensic Document Examiner Forum

Karen Nobles, MFS, Forensic Document Services, LLX, Pensacola, FL; Carl R. McClary, MS U.S. Department of Justice, ATF, Atlanta, GA; Samiah Ibrahim, BSc, BA, Canada Border Services Agency, Ottawa, Ontario, Canada*

Learning Overview: After attending this presentation, attendees will have access to new and different ideas, opinions, and methods to consider when approaching questioned document problems in the laboratory. These ideas and methods will represent experiences from different countries and cultures.

Impact Statement: The impact of this presentation on the forensic science community will be the open exchange of ideas and viewpoints. As scientists, we often learn as much from another's thought processes and experiences as we do from books. The younger examiners can benefit from the experiences of the more-experienced examiners, and those experienced examiners can benefit from seeing new and novel viewpoints.

The concept of the Forensic Document Examiner Forum is not new to the Questioned Document community. This format was first utilized at the Southeastern Association of Forensic Document Examiners (SAFDE) meetings in the early 1990s as a method of opening discussion on certain topics of interest to the members. At these meetings, there was a discussion starter on subjects upon which there may have been disparate opinions. Through forums of this type, there have been many lively discussions on controversial topics. Not all discussions must necessarily be centered on difficult issues facing forensic document examiners. Discussions may also focus on the attendee's thoughts and interpretations of quotes from recognized texts in the field. Other discussions could begin with the conclusions and opinions of some of these famous authors in criminal and civil cases of notoriety, both past and present. This type of forum, one which is presented with international viewpoints, is an excellent way to poll attendees about their preferences on examination methods, conclusions, court testimony, or the current standards in the field.

Discussion, Methods, Conclusions

J17 A Type of Forgery in a Forensic Document Recently Seen in Turkey: A Case Report

Dilara Oner, PhD, Istanbul, Turkey; Berna Senel Eraslan, Istanbul University-Cerrahpasa, Istanbul, Turkey; Gursel Cetin, PhD, Istanbul University-Cerrahpasa, Istanbul, Istanbul, Turkey*

Learning Overview: This presentation will ensure that attendees are informed about a method of preparing forged documents that is frequently used today and that is likely to become more widespread in the future.

Impact Statement: Though forensic document examiners may know that a genuine signature from one document can be placed on another document for fraudulent purposes, this method of forgery may not be encountered often in casework. This presentation will demonstrate a case where this method of forgery was used and how it was detected.

A common form of forgery in recent years is to have a person sign a fake receipt for cargo that has been received through a fake distributor. The person signs in a “window-shaped” section with the rest of the document concealed. When the front paper is later removed, a blank paper with the signature on the bottom is revealed for the criminal to insert a deed or similar text to make the signer financially liable.

In the presented case, expert witnesses were asked by the court whether the signatures on a questioned deed belonged to the debtor. The signatures belonged to the debtor; however, it was determined that the promissory note was not the original promissory note paper. There was a 1mm difference between the right and left edges, the lower edge was not a preprinted cut, and there were traces of glue in a rectangular shape around the debtor’s signature. In this case, the plaintiff debtor claimed that the deed was fake, and his petition mentioned an unexpected, suspicious parcel in the form of a gift. This background information helped to guide the examination to include the whole document, rather than just a signature comparison.

The presented case has a twofold significance. First, it is necessary for the public to know that such a form of forgery exists and to pay attention to what is being signed, especially when receiving unexpected merchandise. Second, it reminds the expert to consider and examine the whole document.

Forgery, Forensic Questioned Document Examination, Forged Promissory Note

J18 Fraudulent Backdating and Writing Sequence in Questioned Documents

Mohamed Awadalla, PhD, Forensic Lab, RAK Police, Ras Al Khaymah, UAE*

Learning Overview: After attending this presentation, attendees will have discovered an explanation for how to systematically study the problems of falsely given dates of documents and forged writing sequences.

Impact Statement: This presentation will impact the forensic science community by introducing a comprehensive study of one of the problems facing Forensic Documents Examiners (FDEs) and inform attendees as to how to find solutions to these problems.

Sequential backdating of a document is considered an important type of examination conducted by an FDE. Documents can be backdated to make them appear as though they were issued or signed earlier; thus, the examiner must attempt to determine the sequence of preparation of the document. The signature may be genuine, but the date was altered. This study classified factors that affect sequential dating into two main approaches: static and dynamic. The static approach includes all stable factors, meaning those facts that cannot be changed and relate to the document's history, such as writing ink, writing instruments, stamps, and paper. The dynamic approach addresses changeable factors and are subdivided into factors related to the state of the writer at the time and those related to the document condition. This presentation will review sample cases from casework as illustrations and will present a recommendation regarding examinations.

Document Backdating, Writing Tools, Writing Circumstances

J19 Forensic Handwriting Examination Education and Training Curriculum Development: Making the Ideal Real

Mara Merlino, PhD*, Kentucky State University, Frankfort, KY; Veronica B. Dahir, PhD, University of Nevada-Reno, Reno, NV; Charles Edwards, MA, University of Nevada-Reno, Reno, NV

Learning Overview: Attendees will learn how to apply academic concepts and methods to create education and training programs that incorporate best practices identified by stakeholder organizations such as the National Institute of Standards and Technology (NIST), Organization of Scientific Area Committees (OSAC), and Forensic Science Education Programs Accreditation Commission (FEPAC). Attendees will participate in applying these concepts to the education and training program format demonstrated in the 2021 NIST publication titled *Forensic Handwriting Examination and Human Factors: Improving the Practice Through a Systems Approach*.¹

Impact Statement: This presentation will impact the field of Questioned Document Examination by applying a multidisciplinary approach, including academic and practitioner perspectives, to the task of creating a standardized training program as recommended by stakeholders such as NIST, OSAC, FEPAC, and other relevant stakeholder organizations.

Over the past 20 years, stakeholders in the forensic science enterprise have been engaged in discussions about the reliability and validity of the methods and procedures used by forensic practitioners. These discussions have included recommendations for the content of forensic science education programs, calls for standardized and empirically based education and training based on academic models, and recommendations and examples of the format and content of such education programs.

This presentation will be an interactive demonstration and discussion of how these goals may be addressed through interdisciplinary collaborations between subject matter experts in education and curriculum development and professional document examiners. According to FEPAC, the training program structure should delineate learning objectives, instructor qualifications, requirements for students, and performance goals. Periodic assessments and competency testing should be included. The training program syllabus should be detailed enough to ensure that all these components are clearly understandable and empirically measurable.

Core elements of training programs should include both ethics training and standards of conduct; training in effective verbal and non-verbal communication skills, with attention to evidence handling, the legal environment, and rules of evidence; laboratory policies and operating procedures; and safety practices. Some suggested discipline-specific elements include relevant literature to impart key knowledge about this history of the discipline and the current state of knowledge in the field, including validation studies for methods and procedures, statistics, and training on instrumentation.

These topics will be discussed in the context of the education and training model published in the 2021 publication titled *Forensic Handwriting Examination and Human Factors: Improving the Practice Through a Systems Approach*.

Attendees will engage with presenters in deconstructing these broad elements of a training and education program and suggesting possible program goals, learning outcomes, and benchmarks for demonstrating trainee competence.

Training, Education, Questioned Documents

J20 Revealing the Deposition Order of Optically Indistinguishable Blue Ballpoint Pens Using Mega Electron-Volt-Secondary Ion Mass Spectrometry (MeV-SIMS) Coupled With Multivariate Analysis

Marko Barac, MSc*, Ruđer Bošković Institute, Zagreb, Croatia; Andrijana Filko, MSc, Forensic Science Centre "Ivan Vučetić", Zagreb, Croatia; Zdravko Siketić, PhD, Ruđer Bošković Institute, Zagreb, Croatia; Marko Brajković, MSc, Ruđer Bošković Institute, Zagreb, Croatia; Andrea Ledić, MSc, Forensic Science Centre "Ivan Vučetić", Zagreb, Croatia; Iva Bogdanović Radović, PhD, Ruđer Bošković Institute, Zagreb, Croatia

Learning Overview: After attending this presentation, attendees will be acquainted with the capabilities of an accelerator-based mass spectrometry technique called MeV-SIMS, which is unconventional in the context of forensic questioned document examination.

Impact Statement: This presentation will impact the forensic science community by demonstrating the power of solving a problematic case with MeV-SIMS in the determination of deposition order of two very similar ballpoint pens when the standard optical techniques fail.

Today, most official documents, such as contracts or testaments, which are often the subject of counterfeiting, are produced with commercially available printers. On such documents, a stamp impression or signatures using different types of pens are also applied. The places where such writing tools intersect may reveal if the document is original or was modified in any way after the moment it was produced. Various techniques have been introduced in forensic work to solve the problem of intersecting lines. A comprehensive review of different methods that have been used so far was given in the work of e Brito et al.¹ It was emphasized that optical methods that are non-destructive, fast, and easy to apply will probably remain prevalent in the daily forensic work and that the need for other analytical techniques, which are more expensive and complicated to perform, sometimes destructive and time consuming, would appear in more complex cases where the information obtained from optical methods is inconclusive and not sufficient to give a proper answer.

Recently, accelerator facilities around the world have started to use heavy energetic ions for excitation of secondary molecular ions from the sample surface—an Ion Beam Analysis (IBA) technique called MeV-SIMS. In the field of forensic examination of questioned documents, the technique has demonstrated success in determining the deposition order of fingerprints and inks on paper.² In the case of intersecting lines made by blue ballpoint pens, the deposition order of all studied combinations was determined with success.³ The situation was not so clear in some cases when deposition order of inkjet inks in combination with other writing tools was studied.⁴ Here, some cases were solved by combining MeV-SIMS with the Particle-Induced X-ray Emission (PIXE) technique which, contrary to surface-sensitive MeV-SIMS, provides information from deeper layers.

In the present work, intersections of several very similar ballpoint pens were studied using optical non-destructive techniques (microscopic and infrared luminescence) that are standardly applied for questioned documents examination in the Forensic Science Centre "Ivan Vučetić" and MeV-SIMS that is applied at the Ruđer Bošković Institute. Obtained results were compared and discussed. An emphasis is placed on the ability of MeV-SIMS in combination with multivariate analysis to distinguish two very similar ballpoint pen inks and determine their deposition order. These cases appear to be problematic to Forensic Science Centre "Ivan Vučetić" using any optical method at hand. MeV-SIMS also provides chemical information about the studied writing tools, which is an added value and can be also applied to differentiate the two writing tools in question.

Forensic Document Examination, Optical Techniques, MeV-SIMS

J21 Hyperspectral Imaging and Gray Value Analysis of Porous-Tipped Pen Samples Composed of Unknown Inks

Clarra Moore BS, Sam Houston State University, Huntsville, TX; Patrick Buzzini, PhD, Sam Houston State University, Huntsville, TX*

Learning Overview: After attending this presentation, attendees will understand how to apply gray value analysis and hyperspectral imaging to the analysis of porous-tipped pen ink strokes and blended ink samples.

Impact Statement: This presentation will impact the forensic science community by providing questioned document examiners with an objective, non-destructive image analysis method to analyze porous-tipped pen samples.

Porous-tipped pens are a low-researched area within questioned documents. Analytical methods used to analyze porous-tipped pen samples range from video spectral comparisons to thin-layer chromatography to Raman spectroscopy. Chemical analytical methods typically require destructive sample preparation. Image analysis is an objective approach that can provide numerical information without damaging the document. Hyperspectral Imaging (HSI) and gray value measurements are two such methods. HSI can be achieved with a simple Video Spectral Comparator (VSC). Images are obtained using a range of wavelengths and are then stacked to create a data cube. A spectrometer is then used to obtain the spectral information from each pixel within the 3D data cube. Thus far, HSI has been used to discriminate between ballpoint and gel ink samples and has proven to be an advantageous addition to visual examination of pen inks. While there is little information on the application of HSI to porous-tipped pens, the art history and conservationist field commonly uses HSI to identify colorant components of historically or culturally significant documents and pieces of art. Gray value measurement analysis has much less research. Applying the program ImageJ, images obtained using Infrared (IR) filters can be further analyzed more objectively than solely using visual examination. IR absorbance and luminescence of pen inks are useful characteristics for discrimination between samples, and gray value measurement is an additional application that should be further explored. A section of the image is selected in the software, and each column is an average of the grayscale values, or the amount of light on a scale from 0 to 255, from each row. Gray value analysis has been found to be useful for discriminating between porous-tipped pen ink stroke samples; however, analysis for blended samples needed further improvement.¹

This current project aims to propose an improved method of gray value analysis that has been established by Moore and Buzzini, while also incorporating HSI to the analysis of unknown porous-tipped pen ink stroke and blended ink samples.¹ The goal of this project is to use gray value analysis and HSI to determine the composition of unknown porous-tipped pen samples. A volunteer was given access to a collection of porous-tipped pens and instructed to write the same statement three times using three different inks of their choosing. This volunteer was also instructed to create a blended ink sample of their own choosing using up to six pens of their choosing. These blind samples were then compared with porous-tipped pen standard samples created on Whatman® filter paper using visual examination, gray value analysis, and HSI. Based on the visual examination, the hypothesized standard pen ink samples were used for further comparisons. Images were obtained using eight different light filters of the VSC. Images obtained using IR absorbance and luminescence were further analyzed using gray values analysis in ImageJ. HSI reflectance spectra was obtained using the software provided by the VSC instrument used.

Questioned Documents, Ink Analysis, Image Analysis

J22 Indented Writing Examinations: Rubber Stamp Image Transfers

James A. Green, BS, Eugene, OR*

Learning Overview: Attendees will learn about unusual rubber stamp images recovered with the use of an electrostatic detection device.

Impact Statement: The information presented will make the forensic document examiner community aware of a potential misinterpretation of evidence recovered with the use of an electrostatic detection device.

Electrostatic detection devices, used by forensic document examiners, are well known for their ability to recover indentations from documents. The impressions are usually the result of the pressure generated from pen strokes written upon a document placed above another document. However, images are occasionally captured that are not simply the result of pen pressure, but are due to other types of paper fiber disturbances.

This presentation is related to an uncommon type of non-impact indented writing recovered during casework. An indentation image was recovered of a rubber stamp impression made on a page positioned on top of the questioned document during shipping. The vivid image was surprising because it was not a concentrated pressure impression common to pen stroke indentations nor was it due to indentations from one page affecting the following page through friction.

Research duplicated the results. Several rubber stamp impressions using various stamps and inks were made on separate pages. Each stamped page was then placed over a blank page, using various paper types, and mailed across the country. Upon their return, the blank pages were processed with an electrostatic detection device. Several stamp images became clearly discernable. The transfers were subsequently determined to be caused by the inks' chemical components. The results further established images obtained from an electrostatic detection device are not restricted to common paper fiber disturbances associated with the pen pressure of writing.

Indented Writing, Rubber Stamps, Document Examination

J23 Dating Watermarks

Jane A. Lewis, MFS, Milwaukee, WI*

Learning Overview: After attending this presentation, attendees will develop an understanding of how to effectively visualize and decode the dates of watermarks on documents. Forensic Document Examiners (FDEs) will be shown practical methods to find paper industry contacts who can provide valuable watermark dating information for use in casework.¹⁻⁴

Impact Statement: This presentation will impact the forensic science community by focusing awareness on how papers used in everyday business could contain watermarks. These watermarks may contain date codes that can be deciphered by FDEs with the aid of paper industry technical support.

The work of FDEs includes a variety of paper documents such as wills, trusts, quit claim deeds, personal guarantees, employment agreements, and real estate documents that may be genuine or fraudulent. If these questioned paper documents contain watermarks, the FDE must attempt to decipher the manufacturer's date of fabrication code, if one is incorporated. Watermarks are created at the wet end of the papermaking process by a dandy roll that typically contains wires on a cylinder with designs or printing to move the wet paper fibers away to create a watermark on the paper at the end of the process. Watermarks are visualized with transmitted light or simply holding the paper up to a bright light. Paper makers include watermarks in good-quality papers for the beauty of the designs and, in many instances, to date the paper. Watermark examples with date codes will be displayed.

Common paper industry directories of paper mills, paper manufacturers, and dandy roll makers from years ago have disappeared or changed to online formats. Paper companies and dandy roll makers have changed and consolidated over the years. Access to the latest paper industry directories for FDEs who occasionally need paper manufacturer information in casework can be difficult. The available directories come at a hefty price tag more suited for a large paper company to pay than a forensic scientist.

In two recent cases, watermarks were discovered on a questioned will, trust, and an agreement. The watermarks were visualized with transmitted light from a light box and a video spectral comparator. Two of the watermarks contained date codes and one did not. Watermark images and date codes will be illustrated. An internet search of the watermark company names revealed the paper manufacturers. Contact with a dandy roll maker in one case provided the date-coded year of manufacture of one watermark image. In another case, the papermaker's technical group provided the dating information after receiving an image of the watermark. Paper laboratories in Wisconsin and Georgia are good sources of information about paper manufacturers and dandy roll makers in the United States. Date coding information from the paper industry is proprietary and may be shared at their discretion. Approaching the paper technical workers in a professional way can produce their completely optional cooperation. Dating watermarks in casework is possible with the assistance of paper and dandy roll manufacturers.

Watermark, Forensic Document Examination, Paper

J24 Digital Image Processing for Determining Edge and Feature Detection for Pattern Recognition on the Shroud of Turin

Janis Winchester, MS*, Fort Myers, FL

Learning Overview: After attending this presentation, attendees will have a better understanding of the importance of pattern recognition of possible symbols or letters given low-contrast image enhancement.

Impact Statement: This presentation will impact the forensic science community by providing information regarding determining edge characteristics of the visual impression on a document.

As an overview, the field of pattern recognition provides insights useful in forensic examinations, where there is a growing emphasis on digital documents. For example, the visual identification of a letter form is characterized by certain features. This process may be applied to letter formation where there is low-contrast digital information as described in, “Which Parts Determine the Impression of the Font?”¹

Some definitions are provided for the attendees:

Pattern recognition—can be either “supervised,” where previously known patterns can be found in a given data, or “unsupervised,” where entirely new patterns are discovered.²

Perception “may be subjective and our eye-brain system is very efficient in supplying the missing information in order to make sense out of any pattern we can see.”³

Pareidolia, as noted in the *Merriam-Webster Dictionary*, “is the tendency to perceive a specific, often meaningful image in a random or ambiguous visual pattern.”⁴

The goal of this research is to evaluate digital imaging that provides the greatest information for pattern recognition on documents, such as the Shroud of Turin.

K1 Phenibut, You Say What? A Phenibut and 2-Methyl AP-237 Overdose in a Sober Living Facility

Robyn Parks, MD, Los Angeles County Department of Medical Examiner-Coroner, Los Angeles, CA; Sarah Buxton de Quintana, MS, Los Angeles County Department of Medical Examiner-Coroner, Los Angeles, CA; Juan Carrillo, MD, Los Angeles County Department of Medical Examiner-Coroner, Los Angeles, CA*

Learning Overview: After attending this presentation, attendees will understand the history and methods of detection for phenibut and have an awareness of drug-related deaths in sober living facilities, despite multiple negative drug tests during admission.

Impact Statement: This presentation will impact the forensic science community by presenting a case of a drug-related death in a sober living facility as a result of phenibut and 2-methyl AP-237.

A 29-year-old man with a history of benzodiazepine and gabapentin abuse, chronic gastrointestinal issues, back pain, and depression was found unresponsive at a sober living facility by his roommate. While normally introverted, the week prior to death the decedent was really chatty. The evening prior, the decedent appeared drowsy, so the roommate helped him into bed. When the roommate awoke in the morning, he noticed bloody purge emanating from the decedent's nose. 9-1-1 was called, naloxone was administered without improvement, and death was subsequently pronounced on scene. The sober living supervisor noted that residents undergo weekly drug testing and the decedent tested negative two days prior to his death.

Autopsy revealed mild pulmonary edema (right lung, 700 grams; left lung, 575 grams), left ventricular hypertrophy (1.7cm), and multinodular goiter. In-house comprehensive toxicology examination of blood revealed 2-methyl AP-237. Medical evidence was tested to help guide further toxicological analysis. A white powder collected at the scene revealed 4-phenyl-2-pyrrolidinone, and pill fragments collected from the small intestine during autopsy revealed 4-phenyl-2-pyrrolidinone, menthol, and nicotine. 4-phenyl-2-pyrrolidinone is an acidic compound and was not detected on an in-house comprehensive panel of blood specimens, which does not include an extraction for acidic drugs. Further research revealed this is the cyclic product of phenibut (β -phenyl- γ -aminobutyric acid) that is created at high temperatures.

Toxicology from NMS Labs and the Center for Forensic Science Research and Education laboratory confirmed the presence of phenibut (77,000ng/mL) and 2-methyl AP-237 (5,800ng/mL), respectively. 2-methyl AP-237 is classified as a novel synthetic opioid with central and peripheral analgesic activity.

Phenibut is a central nervous system depressant that is not available for clinical use in the United States or most European countries. It was developed in the Soviet Union in the 1960s to treat insomnia, alcohol withdrawal, and anxiety. It was reportedly valued for its high tranquilizing effects during Russian space flights and is currently marketed as a nutritional supplement and mood enhancer, as it provides a sense of euphoria, reduced anxiety, and hypnosis. Drug tolerance has been reported to develop within a couple weeks of its use. It is purchased online by most users and cannot be readily detected, as there are no blood or urine tests available for commercial diagnosis. The levels detected in the decedent's blood were 22 times that of an average plasma concentration detected after a single, 250mg dose and 2.6 times that of a comatose woman.¹⁻³

The cause of death was certified as combined effects of 2-methyl AP-237 and phenibut toxicity and the manner of death was listed as accident.

This case highlights the importance of collecting paraphernalia and apparent drugs during scene investigation as well as emphasizing the impact of a thorough examination of the gastric and intestinal contents for potential pill fragments, which may aid in toxicologic analysis of blood specimens in unconventional drug-related deaths.

Phenibut, Drug-Related Deaths, Sober Living Facility

K2 Fentanyl Analogs in Dried Plasma Spots (DPS): A Novel Technique

Kintress Watson, MS, Arkansas State Crime Laboratory, Little Rock, AR and Sam Houston State University, Huntsville, TX; Kaitlyn Palmquist, PhD, Sam Houston State University, Huntsville, TX and Harris County Institute of Forensic Sciences, Houston, TX; Madeleine Swortwood, PhD, Sam Houston State University, Huntsville, TX*

Learning Overview: After attending this presentation, attendees will better understand the use of Dried Plasma Spots (DPS) for the detection of fentanyl analogs.

Impact Statement: This presentation will impact the forensic science community by providing attendees with a novel DPS technique for the detection of fentanyl analogs.

Blood and urine are common biological matrices for drug detection in forensic toxicology, but the disadvantages of both matrices may cause individuals to be unwilling to participate in drug sampling. An alternative matrix for drug detection that offers minimally invasive collection and small sample sizes must be explored. DPS offer many advantages over common biological matrices and have potential to become suitable matrices for drug detection in forensic settings. There are limited studies that assess drugs of abuse in DPS. This study aimed to extract 13 fentanyl analogs from DPS.

The analytes of interest were methoxyacetylfentanyl, acetylfentanyl, acrylfentanyl, 4-ANPP, fentanyl, furanylfentanyl, para-fluorofentanyl, cyclopropylfentanyl, cis-3-methylfentanyl, carfentanil, butyrylfentanyl, 4-FIBF, and valerylfentanyl. A solvent extraction was optimized to isolate the analytes from Noviplex™ plasma preparation cards. This method was chosen to eliminate equipment cost and lengthy sample preparation. The assessed parameters of the solvent extraction included solvent type, solvent volume, internal standard placement, and blood sample volume. Neat standards and non-matrix controls were also evaluated in order to assess drug movement through DPS layers onto the plasma disc and to determine if whole blood hinders drug transfer compared to blood plasma samples. Briefly, whole blood was fortified with drug standards and 50µL was added onto the Noviplex™ cards. The blood spots were allowed to dry for 3min before the top layers were peeled away and discarded. The plasma discs were air dried for ten minutes before inserting into microcentrifuge tubes with deuterated internal standard and extraction solvent. Tubes were vortexed, sonicated, and dried under nitrogen. Samples were reconstituted in 25µL mobile phase and analyzed using a previously developed method on an Agilent® Technologies 1290 Infinity liquid chromatograph coupled to an Agilent® Technologies 6530 Accurate Mass Time-of-Flight (LC/qTOF) mass spectrometer operated in targeted acquisition mode.

Samples were best extracted using 1mL of 1% formic acid in a 50:50 methanol-acetonitrile solution. The extraction method was partially validated according to Academy Standards Board (ASB) forensic toxicology validation guidelines. The calibration ranges were 1–100ng/mL for all analytes. The limit of detection and lower limit of quantification for all analytes were 1 and 5ng/mL, respectively. Most analytes displayed unacceptable bias and precision at medium (40ng/mL) and high-quality (80ng/mL) control levels. In addition, large matrix effects were observed and extraction recoveries ranged from 5–7%.

This research introduces a novel technique for extracting fentanyl analogs from DPS using a simple extraction technique and robust instrumentation. While additional extraction optimization should be explored to increase recovery, analytical sensitivity may be suitable for overdose cases. DPS present the ability to serve as an alternative, novel matrix for future forensic toxicology applications.

Fentanyl Analogs, LC/qTOF, Dried Plasma Spots (DPS)

K3 Simultaneous Determination and Quantitation of Five Synthetic Cathinones in Postmortem Blood and Urine by Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS)

Yun-Chen Tsao, MS, Institute of Forensic Medicine, Ministry of Justice, New Taipei City, Taiwan; Chao-Ching Huang, MS, Institute of Forensic Medicine, Ministry of Justice, New Taipei City, Taiwan; Hsiu-Chuan Liu, PhD, Institute of Forensic Medicine, Ministry of Justice, New Taipei City, Taiwan; Ray H. Liu, PhD, Department of Criminal Justice, University of Alabama at Birmingham, Birmingham, AL; Dong-Liang Lin, PhD, Institute of Forensic Medicine, Ministry of Justice, New Taipei City, Taiwan*

Learning Overview: Concerned with frequent reports on abuse and deaths pertaining to overdose of synthetic cathinones, an effective LC/MS/MS method was developed for the analysis of five common synthetic cathinones (N-ethylpentylone, dibutylone, mephedrone, MDPV, and methedrone) in postmortem specimens to help determine victims' causes of death.

Impact Statement: Effective detection and identification of NPS in the laboratory facilitates data collection helpful to the formation of supply reduction and health intervention strategies.

Methods: For method evaluation, 1mL drug-free blood (or urine samples), fortified with 50–1,000ng/mL of the five analytes of interest along with respective deuterated internal standards, were used for the liquid-liquid extraction process, first with the addition of 2mL 1.5 M Na₂CO₃/NaHCO₃ (pH 9.5) buffer for alkalization. Extraction was performed with 3mL dichloromethane:1,2-dichloroethane:*n*-heptane:ethyl acetate mixture (1:1:1:1, v/v). The extract was evaporated and reconstituted, then injected into the LC/MS/MS system. Chromatographic separation was performed at 50°C using an Agilent® ZORBAX® SB-Aq column (100mm × 2.1mm, 1.8µm particle). The mobile phase was consisted of water (0.1% formic acid) and methanol (0.1% formic acid) at a flow rate of 0.28mL/min. Mass spectrometric analysis was performed using electrospray ionization in positive-ion Multiple Reaction Monitoring (MRM) mode. The same protocol was applied to the analysis of case specimens.

Results: The protocol described above was evaluated and found to achieve the following analytical parameters for blood samples: (1) average extraction recovery range: 73.3–108.5%; (2) average matrix effect ranges: 90.3–149.0%; (3) intraday and interday precision ranges (percent CV): 0.95–12.6% and 1.46–10.9%; (4) intraday and interday accuracy ranges: 96.7–105.9% and 98.2–103.2%; and (5) calibration linearity (r^2), detection limit, and quantitation limit: >0.999, 0.2–0.5ng/mL, and 0.5ng/mL, respectively. The corresponding parameters achieved for urine samples were as follows: (1) 74.5–91.8%; (2) 82.5–113.6%; (3) 0.56–9.81% and 1.35–11.3%; (4) 88.6–105.3% and 95.2–102.6%; and (5) >0.999, 0.5ng/mL, and 0.5ng/mL, respectively. This protocol was found effective for the analysis of these synthetic cathinones in postmortem samples. In 2020, blood specimens from cases were found to contain at least one of these five synthetic cathinones with the following mean concentrations (µg/mL) and number of cases: N-ethylpentylone (0.46; *n*=6); dibutylone (0.36; *n*=8); mephedrone (0.73; *n*=57).

Conclusions: Synthetic cathinones played a significant role in fatalities and were often abused simultaneously with ketamine, PMMA, and sedative drugs in Taiwan. With no or limited understanding on these substances' toxicity, addiction potential, and withdrawal symptoms, growing use of New Psychoactive Substances (NPS) is certainly a critical public health issue. Effective detection and identification of NPS in the laboratory facilitates data collection, helpful to the formation of supply reduction and health intervention strategies.

New Psychoactive Substances, Synthetic Cathinones, Postmortem Toxicology

K4 Trazodone-Related Deaths in Taiwan From 2011 to 2020: A Report on 591 Fatalities

Yun-Chen Tsao, MS, Institute of Forensic Medicine, Ministry of Justice, New Taipei City, Taiwan; Chao-Ching Huang, MS, Institute of Forensic Medicine, Ministry of Justice, New Taipei City, Taiwan; Hsiu-Chuan Liu, PhD, Institute of Forensic Medicine, Ministry of Justice, New Taipei City, Taiwan; Professor Ray H. Liu, PhD, Department of Criminal Justice, University of Alabama at Birmingham, Birmingham, AL; Dong-Liang Lin, PhD, Institute of Forensic Medicine, Ministry of Justice, New Taipei City, Taiwan*

Learning Overview: Trazodone is an antidepressant medication used for the treatment of major depressive disorder, anxiety disorder, and alcohol dependence. Since trazodone is often present in postmortem specimens from accidental, suicidal, and homicidal poisoning cases, an effective Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) method was developed and applied to the analysis of this compound in postmortem samples to aid in determining the causes of death.

Impact Statement: These epidemiological data reveal important information related to the circumstances and usage of trazodone in Taiwan.

Methods: Postmortem blood specimens were routinely screened for trazodone using liquid-liquid extraction (by a Toxi-tubes® A protocol), followed by Gas Chromatography/Mass Spectrometry (GC/MS), LC-ion-trap/MS, and Liquid Chromatography/quadrupole Time-Of-Flight/Mass Spectrometry (LC/qTOF/MS) methodologies (including an automated library search step) developed earlier in the laboratory. Positive specimens were confirmed for trazodone and quantified by LC/MS/MS using trazodone-d₆ as the internal standard. This method has been validated and found to achieve 0.005 µg/mL as the limit of quantitation. Complete autopsy records for these 591 cases were reviewed and analyzed against analytical findings to reveal key epidemiological data.

Results: Among the 32,140 forensic autopsy cases that took place during the period (2011–2020) included in this retrospective study, specimens collected from 591 cases were found to contain trazodone. Yearly distributions of these trazodone-positive cases were: 2020, 33; 2019, 38; 2018, 34; 2017, 60; 2016, 92; 2015, 69; 2014, 81; 2013, 54; 2012, 67; and 2011, 63. Among these 591 fatalities, the mean age was 49.0 (ranging from 21 to 91) and 61.4% were male ($n=363$). The manners of death for these cases were 46.5% accident ($n=275$), 24.2% suicide ($n=143$), 18.1% natural death ($n=107$), 7.3% uncertainty ($n=43$), and 3.9% homicide ($n=23$); while the causes of death were 38.2% intoxication—including single and multiple drugs ($n=226$), 26.6% hypovolemic and neurogenic shock ($n=157$), 21.7% drowning or other asphyxia ($n=128$), 11.0% cardiogenic shock ($n=65$), and 2.5% charcoal-burning suicides or fire disaster ($n=15$). Blood trazodone concentrations ranged from 0.01 to 97.0 µg/mL; mean concentrations (with respect to manner of death) were 0.94, 3.21, 0.28, 1.38, and 1.24 µg/mL for accident, suicide, natural death, uncertainty, and homicide cases, respectively; mean concentrations (with respect to cause of death) were 2.56, 0.30, 1.07, 0.45, and 2.44 µg/mL for intoxication, hypovolemic and neurogenic shock, drowning or other asphyxia, cardiogenic shock, and charcoal-burning suicides or fire disaster, respectively. Alcohol, sedative drugs, and antidepressant drugs were the most common companion compounds presented in trazodone-related cases. Alcohol was detected in 208 cases (35.2%) and the numbers of cases found to contain other drugs were: 149 for flunitrazepam (25.2%); 147 for clonazepam (24.9%); 132 for morphine (22.3%); 122 for codeine (20.6%); 99 for estazolam (16.8%); 96 for zolpidem (16.2%); 87 for quetiapine (14.7%); 71 for acetaminophen (12.0%); and 65 for methamphetamine (11.0%).

Conclusion: Trazodone was commonly found in blood specimens collected from Taiwanese forensic autopsy cases; 61.4% of these 591 fatalities occurred during the 2011–2020 period were male, while the mean age was 49.0. Among these trazodone-positive cases, the most common manner of death and cause of death were accident (46.5%) and intoxication (38.2%), respectively. These epidemiological data reveal important information related to the circumstances and usage of trazodone in Taiwan.

Trazodone, Postmortem Toxicology, Epidemiology

K5 A Study on the Characteristics of New Psychoactive Substances (NPS) in Korea From 2014 to Recent Years

Byungsuk Cho, National Forensic Service, Wonju, Gangwon-do, Korea; Junghyun Kim, National Forensic Service, Wonju, Gangwon-do, Korea; Hyewon Baik, National Forensic Service, Wonju, Gangwon-do, Korea; Yujin Park, National Forensic Service, Wonju, Gangwon-do, Korea; Jongsook Rhee, National Forensic Service, Wonju, Gangwon-do, Korea; Eunmi Kim, National Forensic Service, Wonju, Gangwon-do, Korea*

Learning Overview: After attending this presentation, attendees will understand the recent status of NPS in Korea and the detection of synthetic cannabinoids in the hair of drug users.

Impact Statement: This presentation will provide the forensic community with the NPS trends in Korea and data from the detection of synthetic cannabinoids in the hair of drug users from 2014 to recent years.

In 2020, the number of drug offenders in Korea was about 18,000, which was double the number compared to 2010. In this regard, the number of drug-related cases in the National Forensic Service (NFS) was about 68,000 in 2020, a 2.4-fold increase compared to 2014. The first appearance of NPS in Korea was in 2009, and the number of NPS detected in cases at that time was only 8; however, the number was 184 in 2019, a 24-fold increase compared to a decade ago. The government introduced the “Temporary Narcotics Designation System” in 2011 and began to preemptively regulate NPS. Despite all that, the simple reconstruction (producing process) of NPS allows for a large number of NPS that evade the drug law. In this study, the status of NPS abuse in Korea was investigated, focusing on NPS that were detected in hair of drug users from 2014 to recent years.

As of June 2021, a simultaneous analytical method was established using Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) for 25 synthetic cannabinoids and 27 of their metabolites in hair samples. From 2014 to May 2021, a total of 19 synthetic cannabinoids were detected in the hair of drug users. Annual detection cases ranged from 4–64 cases, and the highest was in 2020 with 64 cases. Among the detected NPS, AB-CHMINACA was the most detected with 43 cases, followed by 4F-MDMB-BUTINACA (32 cases), 5F-ADF (27 cases), JWH-210 (20 cases), 5F-MDMB-PICA (20 cases), AMB-FUBINACA (16 cases), and MDMB-4en-PINACA (14 cases). In particular, MDMB-4en-PINACA first appeared in Korea in 2021 and is estimated to be a major NPS of abuse in the future. It was found that one type of NPS used to be solely used; however, unlike in the past, it is now common that two or more NPS are being used in a mixed form. In addition, it used to take at least a year for another new drug to come to market, but now NPS gain popularity more quickly and change more frequently.

In order to prove the use of NPS, it is important to develop an analytical method from biological samples, which is usually carried out in four steps: information collection, Reference Standard Material (RSM) and metabolites obtainment, method development and validation, and application to authentic samples. It takes a long time to obtain RSM, making it difficult to develop analytical methods. Considering the characteristics of NPS being used at an exceptionally fast rate, the government needs to introduce a fast track system to shorten the time required to secure RSM and provide budgets to secure research personnel and high-resolution equipment.

New Psychoactive Substances (NPS), MDMB-4en-PINACA, Fast Track System

K6 Death Via Ingestion of Zinc Phosphide

Erin Spargo, PhD, NMS Labs, Horsham, PA; Beth Slaybaugh, MPS, NMS Labs, Horsham, PA; Lindsay Cheeseman, BS, NMS Labs, Horsham, PA; Lee Blum, PhD, NMS Labs, Horsham, PA*

Learning Overview: After attending this presentation, attendees will be familiar with the effects of zinc phosphide poisoning in the context of a presented case report, including autopsy and toxicological findings.

Impact Statement: This presentation will impact the forensic community as attendees will be better prepared to interpret postmortem findings from zinc phosphide poisonings.

A Be On the Lookout (BOLO) was issued for a 28-year-old White male after he made suicidal statements to local law enforcement. Employed as an exterminator, he was found deceased in the driver's seat of his work truck. His statements indicated that he had consumed gopher poison. Multiple containers of "Mole and Gopher Bait," containing zinc phosphide, were found near the body.

An autopsy revealed both internal and external decompositional changes. Except for the heart, examination of the organs and tissues was performed *in situ*. Congested, collapsed parenchyma were observed in the lungs. Various biological specimens were collected; the medical examiner did not collect gastric contents due to the potential toxicity of the sample. Liver, femoral blood, vitreous fluid, and urine were submitted to the laboratory.

Liver homogenate was screened via Enzyme-Linked Immuno-Sorbent Assay (ELISA) for 12 drugs/drug classes and headspace gas chromatography was used to screen for alcohols. Confirmation testing for cannabinoids was performed using Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS). Blood was analyzed for zinc via Inductively Coupled Plasma/Mass Spectrometry (ICP/MS). The sample was diluted with a solution containing the internal standard, then introduced into the ICP/MS for analysis.

The results of the testing showed the liver homogenate was positive for delta-9-THC with 1,800ng/g delta-9-carboxy THC. Zinc was identified in the blood at a concentration of 1,400µg/dL (14mg/L); for reference, in one study, postmortem blood zinc concentrations in non-poisoned individuals ranged from 4.0–8.7mg/L.¹

Zinc phosphate exhibits its toxicity by the creation of phosphine gas when the material interacts with the acidic, aqueous gastric fluid. The gas is rapidly absorbed, interfering with the respiratory cycle of cells, causing oxidative tissue damage. Symptoms observed after ingestion can be multiphase. Initially, toxicity manifests primarily as gastrointestinal discomfort, with symptoms including nausea, vomiting, and diarrhea. This can be followed by a symptom-free period. Ultimately, multi-organ failure occurs, with cardiopulmonary injury the primary cause of early death. There is no known antidote, resulting in a high mortality rate. Limited toxicological data are available regarding deaths due to zinc phosphide ingestion. Case reports are not generally supported by toxicological findings and often rely on a case history of ingestion.

The medical examiner ruled the cause of death as zinc phosphide ingestion, supported by the presence of the poison near the body, notes of suicidal intent, congested lungs, and an elevated concentration of zinc in the blood.

Forensic Toxicology, Zinc Phosphide, Postmortem

K7 Profiling Trace Element Contaminants of Toxicological Interest in Commercially Available Cannabidiol (CBD) Tincture Oils

Tom Gluodenis, PhD, Lincoln University, Lincoln University, PA; Robert Thomas, BS, Scientific Solutions, Gaithersburg, MD; Marjanii Walton, Lincoln University, Lincoln University, PA*

Learning Overview: Attendees of this presentation will learn: (1) the prevalence of heavy metal contamination for the currently regulated metals (Mercury [Hg], Lead [Pb], Cadmium [Cd], and Arsenic [As]) in commercial CBD oils, (2) whether sufficient evidence exists to support expansion of the list of regulated metals, and (3) the effectiveness of current attempts at industry self-regulation.

Impact Statement: Heavy metals contamination/poisoning is often overlooked given the chronic nature of its affects. This presentation will highlight concerns regarding the potential for heavy metals poisonings as identified through a “market basket” study of readily available CBD consumer products.

Background: There is legitimate concern over the rise in chronic health issues related to metals contamination in CBD-infused products. Hemp, a hyperaccumulator plant, boasts the high biomass, long roots, short life cycle, and genetic structure ideally suited for absorbing and accumulating heavy metals. The situation is exacerbated by the popularity of these products. Sales to United States consumers in the form of pharmaceuticals, dietary supplements, foods, and other consumables are expected to grow >20% annually and reach ~\$25 billion dollars by 2025. As demand outpaces supply, hemp plants are being sourced from outside of the United States and, in some cases, from countries having questionable environmental policies. Yet despite these facts, the regulatory environment is highly fragmented with inconsistent product standards and testing protocols from one state to another.

Objectives: The objective of this study was to document the trace metal profile in a sampling of commercially available full spectrum CBD tincture oils with the aim of:

- identifying and quantifying metal contaminants of toxicological interest
- assessing truth in labeling relative to those metals that are regulated
- assessing the adequacy of the scope of state-mandated heavy metals testing requirements

Methods: A “market basket” study of 18 hemp oils was conducted. The samples were full-spectrum CBD oils having a potency of 25–50mg/mL CBD and naturally flavored (although this was not possible with all producers). Variables that could not be controlled given the guidelines presented include method of solvent extraction (supercritical fluid vs. ethanol extraction), final solvent (Medium Chain Triglycerides [MCT], olive oil, or hemp oil), and the source of the hemp from which the CBD was derived.

Samples were prepared using microwave digestion with each batch, including a digestion blank and Quality Control (QC) standard followed by Inductively Coupled Plasma/Mass Spectrometry (ICP/MS) analysis for > 40 elements. Three replicate digests of each sample were analyzed. Three different lots of material were purchased so that temporal (i.e., lot-to-lot variation) could be studied.

Results: The majority of elements monitored, including Hg, As, and Cd, were either below the limit of quantification or below regulated levels. Only the samples diluted in hemp oil were found to contain levels of Manganese (Mn) as high as 0.73 +/- 0.06ppm. For reference, the Food and Drug Administration (FDA) has established that the Mn concentration in bottled drinking water should not exceed 0.05ppm, and the World Health Organization (WHO) drinking water quality guidelines for Mn are 0.4ppm. At least two samples were found to contain elevated levels of lead, 1.59 +/- 0.14ppm and 3.64 +/- 0.08ppm, nearly 3 to 7 times state-regulated levels of lead in cannabis products. The published certificate of analysis for the sample containing 1.59ppm of lead indicated that the lead concentration was below the regulated level at the time the product was tested. The published certificate of analysis for the sample containing 3.62ppm of lead did not indicate that any metals testing was performed on the final product.

Conclusion/Discussion: The potential exists for heavy metal contamination in consumer products, despite current regulations that can be ambiguous and fragmented. A question exists as to whether the elevated lead levels identified are the result of the biomass, contamination of the product by the packaging material, or poor testing protocols. Additional assessments regarding lot-to-lot reproducibility and any identified correlations between geography, potency, CBD extraction method, etc. will be presented.

Cannabidiol, CBD, Metals

K8 A Toxicological Analysis of Methadone and Oxycodone in Decomposition Fluid and Liver Tissue From Decomposed Bodies

Kaitlin Collura, MD, PhD, Office of the Chief Medical Examiner Maryland, Baltimore, MD; Jack Titus, MD, Office of the Chief Medical Examiner Maryland, Baltimore, MD; Stephanie Dean, MD, Office of the Chief Medical Examiner Maryland, Baltimore, MD; Rebecca Phipps, PhD, Office of the Chief Medical Examiner Maryland, Baltimore, MD*

Learning Overview: After this presentation, attendees will have gained an understanding of the limitations of postmortem toxicological analysis and will have learned about a possible new method for postmortem drug testing.

Impact Statement: This presentation will impact the forensic science community by presenting evidence that decomposition fluid may serve as a suitable specimen for postmortem toxicological analysis.

The Centers for Disease Control and Prevention report that over the past 20 years, nearly 841,000 people have died from a drug overdose in the United States. In 2019 alone, there were 70,630 deaths attributed to a drug overdose.¹ Deaths from drug overdose represent an enormous public health burden and continue to contribute to the increasing caseloads of forensic pathologists. As a result, postmortem toxicological analysis is an essential part of the autopsy investigation and is required for an accurate determination of cause of death.

Postmortem toxicological analysis is most commonly performed on blood, liver, and urine specimens.² In the case of decomposed bodies, though, the availability of these preferred specimens for analysis is often limited. Ketola and Kriikku recommend using skeletal muscle for postmortem toxicological analysis when blood is not available.³ However, it is difficult to produce a homogeneous specimen for toxicological analysis from muscle tissue. As a result, drug extraction can be arduous and accurate determination of extraction efficiency cannot be made with certainty. In addition, there is substantial sample site variability in drug concentrations derived from muscle tissue.⁴ Lastly, while there is considerable literature on the quantitative analysis of drugs in liver tissue, there is limited information on the interpretation of quantitative drug analysis in muscle tissue.

Despite the challenge of toxicological analysis of limited specimens from decomposed bodies, the need for testing remains. Thus, novel approaches for overcoming this challenge must be developed. This study sought to determine whether decomposition fluid, an often-abundant and easily acquired specimen in decomposed remains, could be utilized for postmortem toxicological analysis. Specifically, this study asked whether methadone and oxycodone could be qualitatively and quantitatively detected in both liver tissue and decomposition fluid from decomposed autopsy specimens.

This study assessed drug levels in decomposition fluid and liver tissue from decomposed remains over a 15-year period from a total of 680 autopsy cases. Drug levels were assessed using an alkaline liquid-liquid extraction with quantitation by gas chromatography with nitrogen phosphorus detection. Confirmation of drug levels was performed using gas chromatography/mass spectrometry. In 103 autopsy cases, methadone was detected in both decomposition fluid and liver tissue, with an average ratio of distribution of 1:12.7 (decomposition fluid: liver) and a standard deviation of 16.3. In 29 autopsy cases, oxycodone was detected in both decomposition fluid and liver tissue, with an average ratio of distribution of 1:1.5 (decomposition fluid: liver) and a standard deviation of 2.4. There were no cases where methadone or oxycodone were detected alone in decomposition fluid or liver tissue. These results demonstrate that methadone and oxycodone can both be detected in decomposition fluid and liver tissue and that decomposition fluid is a suitable specimen for postmortem toxicological analysis from decomposed autopsy remains. Further studies are ongoing to assess the applicability of decomposition fluid toxicological analysis for additional drugs and metabolites.

K9 The Effects of Ethanol on GABA Catabolism: Succinyl Semialdehyde Dehydrogenase

Natalia Gabrys, BS, University of New Haven, West Haven, CT; Robert Powers, PhD, University of New Haven, West Haven, CT*

Learning Overview: After attending this presentation, attendees will have a better understanding of the metabolism of the inhibitory neurotransmitter γ -aminobutyric acid (Gamma-Aminobutyric Acid [GABA]), and the effect of ethanol on GABA catabolism.

Impact Statement: This presentation will impact the forensic science community by presenting a possible mechanistic explanation for some aspects of the GABA-nergic Central Nervous System (CNS) depressant effect of ethanol. This knowledge may help forensic toxicologists and pathologists understand the toxic response of ethanol in Drug-Facilitated Sexual Assault (DFSA), postmortem, and impaired driving cases.

Currently, ethanol is one of the most popular drugs of abuse, more so than either tobacco or marijuana. Ethanol is commonly encountered in many forensic toxicology cases, including DFSA, postmortem, and impaired driving cases. Ethanol can exacerbate the toxicity of other drugs that may be present by causing a greater depressant effect in the CNS. Despite its popularity, regularity, and importance in forensic toxicology casework, the mechanism of action for ethanol is not completely understood.

In the CNS, GABA is the primary inhibitory neurotransmitter and acts as a CNS depressant. When released by inhibitory neurons, GABA acts as an agonist of two GABA receptor types (GABAA and GABAB; activating chloride and potassium channels, respectively). GABA-Transaminase (GABA-T) and Succinyl Semialdehyde Dehydrogenase (SSADH) represent the first two enzymatic steps associated with the catabolism of GABA.

This research is directed toward the function of ethanol as a possible competitive inhibitor of SSADH. Because of the structural homology between the C1 and C2 carbons of ethanol and the C3 and C4 carbons of GABA, it is reasonable to conclude that ethanol could occupy the enzymatic active site of both SSADH and GABA-T. Such inhibition would be expected to increase the half-life of the substrate GABA, exacerbating CNS inhibition contributing to the characteristic CNS depression associated with ethanol consumption.

A commercially available enzymatic assay was adapted for evaluation of ethanol-based inhibition of GABA metabolism via a series of substrate-velocity experiments. This assay allowed for the determination of kinetic parameters using K_m (Michaelis-Menten coefficient) and V_{max} (maximal reaction rate). Initial experiments indicated that competitive inhibition was present at physiologically relevant concentrations (e.g. $<0.2\text{g/dL}$) and is concentration dependent. Maximal velocity of the enzyme assay was unaffected by the addition of various concentrations of ethanol, and enzyme affinity for GABA decreased, with a corresponding increase in K_m . The inhibitory effect of ethanol on SSADH suggests a potential role for this process as a component mechanism of the CNS depressant effect of the drug.

GABA, Ethanol, Enzyme Kinetics

K10 The Effects of Storage Time, Adverse Storage Conditions, and Lab Exposure on Blood Alcohol Concentrations

Ruby Liliedahl, BS, Sam Houston State University, Huntsville, TX; Tifani Parker, MS, Texas Department of Public Safety, Houston, TX*

Learning Overview: After attending this presentation, attendees will have learned about the effects of storage time, adverse storage conditions, and laboratory exposure on the Blood Alcohol Concentration (BAC) of blood tubes containing sodium fluoride as a preservative.

Impact Statement: This presentation will impact the forensic science community by providing further support to counter the common defense challenge of ethanol production in blood tubes due to storage time, storage conditions, or exposure to microorganisms in the laboratory.

In 1973, Blume and Lakatua reported the production of ethanol in a blood tube that contained 1% sodium fluoride.¹ In 1989, Chang and Kollman also reported this issue.² Defense lawyers often cite these publications when challenging the findings of a blood alcohol analyst in court, arguing the result is a falsely elevated BAC. Since these publications, multiple studies have investigated this issue; many of these studies under acceptable laboratory conditions, such as refrigerating blood tubes. This study focused on whether ethanol production could occur when conditions are not ideal. This study was conducted in the Houston Laboratory of the Texas Department of Public Safety. All blood tubes contained 1% sodium fluoride with BACs varying from 0.000 to 0.3,217g/100mL, which originated from a proficiency test provider. A Shimadzu® Gas Chromatography/Flame Ionization Detector (GC/FID) was used for the analysis.

The first part of this study examined storage time. Blood tubes stored between 2014 and 2021 in a refrigerator were each analyzed for the current BAC in July 2021. The BACs from July 2021 were compared to the original BACs reported when the tubes were first analyzed in the laboratory. No ethanol production occurred during the time the tubes were stored, which encompassed a range of months to years.

The second part of this study examined temperature and was conducted while the laboratory was undergoing air conditioning repair. As such, temperatures in the laboratory rose above the normal room temperature. Fifty percent of the blood tubes were left on the benchtop while the other 50% were stored in the refrigerator. The BACs from this part of the study were compared to the BACs collected from the first part of the study. No ethanol production occurred after more than ten days of storage under either storage condition.

The third part of this study examined whether areas of the laboratory contained microorganisms that, once in the blood tube, could produce ethanol. The samples used for this portion of the study were the previously refrigerated blood tubes. Blood tubes were exposed to swabs from various areas of the laboratory. One pair of blood tubes were allowed to remain open next to each other in the biohazard cabinet for ten minutes. Two replicates of each sample were made: one was left on the benchtop and the other was stored in the refrigerator. The BACs from this part of the study were compared to the BACs after the second part of the study. No ethanol production was detected after a week of storage.

Significant ethanol loss was only detected for samples from the first and third parts of the study. These results support the hypothesis that unusual temperatures and adverse laboratory exposures that may occur are unlikely to result in any ethanol production.

Ethanol, Blood Alcohol Concentration, Storage Conditions

K11 In Vitro Metabolic Profile of the New Synthetic Opioid Bucinnazine by Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS)

Karissa Resnik, MS*, Virginia Commonwealth University, Richmond, VA; Emanuele Alves, PhD, Virginia Commonwealth University, Richmond, VA and Oswaldo Cruz Foundation, Rio de Janeiro, Brazil

Learning Overview: After attending this presentation, attendees will understand the main phase I and phase II metabolites of bucinnazine, a new synthetic opioid.

Impact Statement: This presentation will impact the forensic science community by describing the metabolic processes of a new synthetic opioid.

Bucinnazine, also known as AP-237, is a synthetic opioid recently discovered in seized heroin samples in the United States and in Europe.¹ It was first synthesized in the late 1960s and has been used for the treatment of cancer-associated chronic pain in China for many years.² Bucinnazine is one of the most potent compounds among the series of piperazines, which also include other relevant compounds, such as MT-45, AD-1211, and 2-methyl-AP-237, a methylated derivative of bucinnazine. Bucinnazine is considered a μ -selective opioid, binding primarily to the μ -opioid receptor.³ However, bucinnazine also may share several characteristics with other piperazines, which act primarily on dopamine, serotonin, and norepinephrine neurotransmission.⁴ At present, bucinnazine is not scheduled in the United States, as it is not a therapeutic choice for the treatment of pain. Nevertheless, with the advent of the crypto currency and the easy access of substances on the Darknet, bucinnazine is a real threat to the public health.⁵

The metabolic profile is an important tool for the development of analytical methods for the screening of emerging synthetic opioids, as the metabolites act as biomarkers of previous use. Little information describes the bucinnazine metabolites, with *p*-hydroxylation being the main metabolic pathway.⁶ Despite previous studies, little research has been completed on bucinnazine metabolism.

The aim of this study was to identify the *in vitro* phase I/II metabolites of bucinnazine by using pooled rat liver microsomes. Bucinnazine hydrochloride was incubated at 37°C for one hour with Sprague-Dawley rat microsomes for phase I metabolites. For phase II, UDPGA was added to an aliquot of the resultant phase I solution, and the mixture was incubated at the same conditions for an additional one hour. Analyses were carried out using Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) and Direct Analysis in Real-Time-Time-Of-Flight/Mass Spectrometry (DART®-TOF/MS). The DART®-TOF/MS analysis was performed for the untargeted screening of the metabolites' exact masses. For this analysis, a capillary tube was dipped in a methanolic solution of the obtained metabolites and introduced into the helium stream of the DART®-TOF/MS. For identification of the metabolites, LC/MS/MS analysis was performed. A volume of 2 μ L was injected onto a Shimadzu® LC/MS/MS 8050 system equipped with a Poroshell HPH C18 column with a gradient mobile phase consisting of 5mM ammonium formate and 0.1% formic acid in water as mobile phase A, and 100% methanol as mobile phase B. A flow rate of 0.500mL/min and a dwell time of 1ms was applied. Fentanyl-d5 was used as the internal standard. The ion transitions for bucinnazine and fentanyl-d5 were 273 *m/z* \rightarrow 117 *m/z* and 273 *m/z* \rightarrow 91 *m/z*, and 342 *m/z* \rightarrow 105 *m/z* and 342 *m/z* \rightarrow 188 *m/z*, respectively.

Both phase I and phase II metabolites, including the monohydroxy metabolites, were detected. This confirms *p*-hydroxylation as the main metabolic pathway of bucinnazine. The method was successfully applied to urine samples of patients suspected of previous bucinnazine use. Given the increase in illicit bucinnazine cases in the United States, a deeper understanding of its metabolites as biomarkers is important for the development of reliable identification strategies to detect bucinnazine misuse cases.

K12 The Validation of a Screening Method for 700+ New Psychoactive Substances (NPS) in Authentic Urine by Liquid Chromatography/Triple Quadrupole/Mass Spectrometry (LC/QqQ/MS)

Rebecca Smith, MS, Florida International University, Miami, FL; Anthony DeCaprio, DPhil, Florida International University, Miami, FL*

Learning Overview: After attending this presentation, attendees will understand the potential implications of a screening method including 700+ NPS in forensic toxicology.

Impact Statement: This presentation will impact the forensic community by providing a comprehensive screening method that is high throughput and reliable for the analysis of NPS in human urine.

In forensic toxicology, the most common techniques for screening of licit and illicit drugs are immunoassays and Gas Chromatography/Mass Spectrometry (GC/MS). These methods screen for compounds using specific target structures and chemical properties and are well established for routine drug analysis. However, NPS typically have structural modifications that can result in false positive and negative detections using these techniques. Newer techniques such as LC/QqQ/MS allow for less sample preparation, increased sensitivity, analysis of biological samples without derivatization, and separation of small, polar, and non-volatile compounds. Consequently, LC/QqQ/MS holds many advantages for screening of NPS.

This research reports the validation results for an LC/QqQ/MS dynamic Multiple Reaction Monitoring (dMRM) method for 713 NPS and other drugs in urine using a dilute-and-shoot approach. The method was then applied for screening of several hundred authentic urine samples obtained from a drug testing laboratory. Method validation was completed using reference standards, including deuterated standards, obtained from Cayman Chemical as a neat solid or as a solution. Sixteen mixtures, each containing 25–70 analytes, were created based on the structure of the compound, retention time, drug class, and transitions that were previously collected by LC/QqQ/MS and incorporated into an in-house database (Agilent® PCDL). Mixtures were designed to minimize co-elutions and reduce interferences for reliable identification and analysis of the compounds. Validation parameters were based on the Organization of Scientific Committees (OSAC) recommendations and parameters that were chosen as most applicable for screening validation included bias, carryover, Limit Of Detection (LOD), and ion suppression/enhancement. LODs for all analytes ranged from 0.002 to 0.169ng/mL, which are below levels typically reported for NPS in human specimens.

The validated method was used to screen for NPS in authentic urine specimens that were collected in 2013–2014 and stored at -20°C. Urine samples were collected from individuals in addiction treatment and pain medication monitoring programs and were supplied de-identified. Samples were processed using a dilute-and-shoot method in which 100µL of sample was added to 500µL of High-Performance Liquid Chromatography (HPLC) water. Urine samples were analyzed with and without glucuronidase treatment. Numerous positive detections of NPS, including synthetic cathinones and cannabinoids, and other licit and illicit compounds, were determined in these specimens, indicating that the method may have value as a comprehensive NPS screen in forensic toxicological analysis.

Method Validation, New Psychoactive Substances, Forensic Toxicological Screening

K13 Gender Differences in Driving Under the Influence (DUI) of Psychoactive Drugs: A Systematic Review and Meta-Analysis

Guido Pelletti, MD, PhD*, Department of Medical and Surgical Sciences, Unit of Legal Medicine, University of Bologna, Via Irnerio, Bologna, Italy; Clara Fiorentini, MD, Department of Medical and Surgical Sciences, Unit of Legal Medicine, University of Bologna, Via Irnerio, Bologna, Italy; Camilla Fontana, MD, Department of Medical and Surgical Sciences, Unit of Legal Medicine, University of Bologna, Via Irnerio, Bologna, Italy; Arianna Giorgetti, MD, Department of Medical and Surgical Sciences, Unit of Legal Medicine, University of Bologna, Via Irnerio, Bologna, Italy; Rafael Boscolo-Berto, MD, Section of Anatomy, Department of Neuroscience, University of Padova, Padova, Italy; Rossella Barone, Department of Medical and Surgical Sciences, Unit of Legal Medicine, University of Bologna, Via Irnerio, Bologna, Italy; Paolo Fais, MD, PhD, Department of Medical and Surgical Sciences, Unit of Legal Medicine, University of Bologna, Via Irnerio, Bologna, Italy; Susi Pelotti, MD, Department of Medical and Surgical Sciences, Unit of Legal Medicine, University of Bologna, Via Irnerio, Bologna, Italy

Learning Overview: After attending this presentation, attendees will have a better understanding of the prevalence of Driving Under the Influence (DUI) of psychoactive drugs in male and female drivers.

Impact Statement: This presentation will impact the forensic science community by presenting the first systematic review and meta-analysis on gender differences in DUI drivers.

As observed in epidemiological studies, and in particular in two recent studies, a higher percentage of drivers positive for drugs of abuse are normally found in males, while medicines are more frequently found in females.¹⁻³ However, scientific literature shows that studies are heterogeneous in sample size, inclusion criteria, or characteristics of the analyzed population, limiting the strength of the resulting evidence.

This study performed a broad systematic search of papers reporting toxicological results on selected matrices (blood, serum, plasma, saliva) showing gender differences.⁴ Meta-analysis of random effects estimates was performed to investigate the change in the overall effect size (by Cohen d standardized mean difference test). Mann Whitney U test was performed to test for differences between gender. From the more than 5,000 records identified, after exclusion of duplicates and title/abstract screening, 613 papers were included for full-text analysis. Four hundred fifteen papers were excluded because they lacked original toxicological results, 131 because the gender differences were not considered, and 25 because only data on alcohol were reported.

A total of 27 papers were included, and the total population sample consisted in 100,485 drivers (70,110 men and 30,321 women). The meta-analysis showed a significant higher prevalence among men for cocaine (1.8% vs. 0.9%; $p<0.001$), delta-9-tetrahydrocannabinol (3.5% vs. 1.6%; $p<0.01$), and amphetamine-like drugs (1.2% vs. 0.6%; $p<0.01$), as expected. Surprisingly, no differences were observed in the use of opiates (2.3% vs. 2.2%; $p=0.45$) and benzodiazepines/Z-drugs (2.9% vs. 3.7%; $p=0.52$). This systematic review and meta-analysis shows that, contrary to the extraordinary amount of epidemiological analysis performed on drivers, only a few studies differentiate the prevalence between male and female drivers, not allowing the comparison and analysis of aggregated data. This can lead to an underestimation of the influence of gender in DUI phenomenon or complicate the evaluation of the results as observed for medications, which did not show significant differences despite several studies indicating their higher prevalence in females. The primary goal in the future will be to collect data of DUI drivers following shared and homogeneous methodologies in order to allow for the analysis of larger aggregated samples, which can be used for targeted prevention and enforcement efforts, as well as monitoring evolving trends.

Forensic Toxicology, Driving Under the Influence, Gender

K14 A Gas Chromatography/Tandem Mass Spectrometry (GC/MS/MS) Determination of Ethyl Glucuronide (EtG) on Real Hair Samples and a Medicolegal Evaluation of Alcohol Use and Abuse

Sara Gariglio, BS, Università degli Studi di Torino, Torino, Piemonte, Italy; Maria Chiara David, PhD, Ministry of the Interior, Department of Public Security, State Police, Roma, Lazio, Italy; Alessandro Mattia, PS, Ministry of the Interior, Department of Public Security, State Police, Roma, Lazio, Italy; Vincenza Liviero, PhD, MD, Ministry of the Interior, Department of Public Security, State Police, Roma, Lazio, Italy; Clementina Moschella, Ministry of the Interior, Department of Public Security, State Police, Roma, Lazio, Italy*

Learning Overview: After attending this presentation, attendees will have an insight on an application of an innovative and solid GC/MS/MS method for the evaluation of EtG on medicolegal cases, which were provided to this study for research purposes.

Impact Statement: This presentation will impact the forensic science community by outlining a connection between toxicological analysis on conventional matrices and medicolegal evidence, using the analysis of EtG to provide further information about a subject's history in alcohol use and abuse.

EtG is a minor non-oxidative ethanol metabolite, resulting from the enzymatic glucuronidation of ethanol in the liver.^{1,2} This small molecule can be detected in several body fluids and tissues for variable intervals of time after ethanol ingestion. Furthermore, there is a growing interest in its use in epidemiological studies in order to investigate drinking patterns and correlation to chronic disease and mortality. Currently, the consensus of the Society of Hair Testing (SoHT) describes that concentration of EtG in hair is expected to be above a cut-off value of 30pg/mg for chronic heavy drinkers, corresponding to a daily ethanol intake >60g.³

The evaluation of EtG on keratinic matrices to investigate the history of alcohol use and abuse in an individual is not usually carried out to assess the cause of death. It can, however, provide extremely valuable information for the investigation when the case is one of legal relevance.

For EtG analysis, the specimen was decontaminated by washing with organic solvents, then dried and finely shredded in 1–2mm fragments; 50mg of sample was then put overnight in 2mL of water with an appropriate concentration of internal standard EtG-d5. The supernatant was purified with cationic bed Solid-Phase Extraction (SPE) and derivatized with MSTFA before analysis in Gas Chromatography-Electron Ionization-Triple Quadrupole (GC-EI-QQQ).

In this study, female subjects whose toxicological analysis had been requested following autopsy to help determine cause of death were considered. On both subjects, a high value of alcohol had been found in conventional matrices such as central and peripheral blood, vitreous humor, urine, and gastric content. Therefore, it was interesting to analyze whether these values may be the result of a sporadic assumption of alcohol or coherent with an alcoholic behavior. For this reason, EtG analysis was carried out on hair samples, both on a full-length sample to determine an average concentration in the months before death and on multiple segments to evaluate the history of alcohol consumption over time.

Alcohol Abuse, EtG, Hair Samples

K15 The Adulteration of Powder Milk (Lactogen-1) With Lambda-Cyhalothrin Causing the Death of a Baby Girl: A Case Study

Hafiz Faisal Usman, MS, Forensic Toxicology, Punjab Forensic Science Agency, Lahore, Punjab, Pakistan; Muhammad Imran, MPhil, Forensic Toxicology, Punjab Forensic Science Agency, Lahore, Punjab, Pakistan; Asif Raza, MPhil, Forensic Toxicology, Punjab Forensic Science Agency, Lahore, Punjab, Pakistan; Muhammad Amjad, PhD, Punjab Forensic Science Agency, Lahore, Punjab, Pakistan; Mohammad Ashraf Tahir, PhD, Punjab Forensic Science Agency, Lahore, Punjab, Pakistan*

Learning Overview: After attending this presentation, attendees will have a better view of the forensic toxicologist's contribution in solving cases with unknown causes of death.

Impact Statement: This presentation will provide a guide for the analysis of the most challenging exhumation specimens. Forensic toxicologists regularly analyze blood, urine, and tissue specimens, but exhumed specimens with varying degrees of putrefaction pose a greater analytical challenge.

Case History: A one-month-old baby girl had severe shortness of breath and seizures after consuming a Nestlé® product (lactogen-1) and was taken to a hospital. However, she did not survive. Cardiopulmonary arrest was declared as a cause of death. After religious rituals, she was buried, but her father questioned the quality of powder milk. Due to the matter of suspicion, police collected the packet of remaining powder milk and a water bottle used for dilution of milk. A portion of the milk was sent to Nestlé® for quality testing. Nestlé's® laboratory testing indicated the presence of excessive amounts of calcium chloride, sodium, and potassium in the milk. The victim's father requested through the court of law an exhumation and postmortem of his child. After 75 days of burial, the victim's body was exhumed. The body was in an advanced stage of putrefaction due to the hot and humid weather in Pakistan. The abdominal cavity material was the only biological sample available for toxicological analysis. The abdominal cavity material along with suspected powder milk was sent to a forensic toxicology laboratory for analysis.

Results and Conclusion: Systematic toxicological analysis was done for poisons like metal phosphide and cyanide. Gas Chromatography/Mass Spectrometry (GC/MS) analysis was performed for drugs and pesticides after extraction with the modified Quick, Easy, Cheap, Effective, Rugged, and Safe (QuEChERS) technique. Toxicological analysis revealed the presence of lambda-cyhalothrin (insecticide) along with phenytoin (an anti-seizure drug that may be used during treatment) in the abdominal cavity material. Lambda-cyhalothrin was also found in powdered milk, which was ingested by the baby girl. Per research, this is the first time a fatal poisoning of lambda-cyhalothrin in an exhumation sample has been reported.

Lambda-Cyhalothrin, Lactogen, Exhumation

K16 The Determination of Commonly Encountered Drugs (Pheniramine, Diphenhydramine, Lidocaine, Norketamine, Ketamine, Tramadol, Chlorpheniramine, Dextromethorphan, Pyrimethamine, and Chloroquine) in Biological Specimens Using a Modified Quick, Easy, Cheap, Effective, Rugged, and Safe (QuEChERS) Technique

Najam Ud Din, MS, Forensic Toxicology, Punjab Forensic Science Agency, Lahore, Punjab, Pakistan; Muhammad Imran, MPhil, Forensic Toxicology, Punjab Forensic Science Agency, Lahore, Punjab, Pakistan; Muhammad Amjad, PhD, Punjab Forensic Science Agency, Lahore, Punjab, Pakistan; Mohammad Ashraf Tahir, PhD, Punjab Forensic Science Agency, Lahore, Punjab, Pakistan*

K17 Exo-THC: The Impact of Isobars on Cannabinoid Testing for Seized Drug and Toxicology Cases

Edward Zumaeta, MS, Palm Beach County Sheriff's Office, West Palm Beach, FL; Kelvin Morales-Colon, MS, Palm Beach County Sheriff's Office, West Palm Beach, FL; Ilene Alford, MS, Palm Beach County Sheriff's Office, West Palm Beach, FL; Nicholas Tiscione, MS, Palm Beach County Sheriff's Office, West Palm Beach, FL*

Learning Overview: After attending this presentation, attendees will understand the potential impact of delta **9-Tetrahydrocannabinol** (D9-THC) isobars on testing of cannabinoids by Gas Chromatography/Mass Spectrometry (GC/MS) for seized drug and Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) for toxicology cases.

Impact Statement: This presentation will impact the forensic science community by informing drug chemists and toxicologists on the potential impact of isobars on cannabinoid identification.

Introduction: Delta-8-THC (D8-THC) is a minor constituent in cannabis plants, but the extraction and synthesis of D8-THC is increasing with the availability of Cannabidiol (CBD). D8-THC metabolizes in the body following the same metabolic pathway as D9-THC, resulting in Delta-8-hydroxy-THC (D8-OH THC) and Delta-8-carboxy-THC (D8-COOH THC) metabolites. D8-THC can be synthesized from CBD in solvent with the addition of catalysts. The conversion process from CBD is unpredictable and can form byproducts that are not found naturally in cannabis. One such minor byproduct found in cannabis vape oil liquid is delta-9,11-THC (exo-THC).^{1,2} Cannabinoid isobars have very similar mass spectra and may be difficult to separate chromatographically.

Objective: Evaluate possible interferences caused by exo-THC, D8-THC, Delta-10-THC (D10-THC), and Delta-6a,10a-THC (D-6a,10a-THC) with D9-THC target analytes for seized drug analysis of plant material and extracts by GC/MS and toxicology analysis of blood specimens by LC/MS/MS. The D8-THC metabolites D8-OH THC and D8-COOH THC were also included for the LC/MS/MS toxicology method.

Methods: Seized drug analysis was conducted on an Agilent® 7890 GC with 5977 MS with a HP-5MS (30m X 0.25mm I.D., 0.25µm film) column with helium at a constant flow of 2mL/min. The temperature program began at 255°C, held for 3.5min, ramped at 30°C/min to 280°C and held for 0.9min for a total run time of 5.23min. Extract analysis included a post run at 325°C of 5min.

Toxicology analysis was conducted on a Shimadzu® Prominence XR LC system with a Sciex® 3200 QTrap tandem MS and a Phenomenex PS C18 2.6µm (50 X 2.1mm) column at 50°C. An eight-minute gradient LC program at 0.6mL/min was utilized with mobile phase A (LC/MS water) and mobile phase B (LC/MS methanol) both with 0.1% formic acid. The gradient program is presented in Table I. The calibration range was from 1 to 100ng/mL for D8-THC, D9-THC, D10-THC, CBD, CBN, and delta-9-hydroxy-THC, and 5 to 500ng/mL for delta-9-carboxy-THC. Stable isotope internal standards were used for all analytes except D10-THC, which used D8-THC-d9.

Results: The seized drug GC/MS method was able to chromatographically resolve all cannabinoids listed above. Baseline resolution was not obtained for D6a,10a-THC with D9-THC, which would preclude quantitative or semi-quantitative analysis of D9-THC if D6a,10a-THC was also present. Seven cannabinoid vape oil liquids submitted for analysis containing D8-THC were evaluated for the presence and relative abundance of exo-THC. Exo-THC was a minor component and had less than a 5% relative abundance compared to D8-THC.

For toxicology analysis by LC/MS/MS, D8-COOH THC was not fully resolved from delta-9-carboxy-THC, which may impact accurate quantitation. Although fragmentation was similar, the ratio of monitored ion pairs (Multiple Reaction Monitoring [MRM] ratio) was different and would not result in misidentification. Hydroxy-delta-8-THC co-eluted with hydroxy-delta-9-THC, but yielded a different MRM ratio. This would preclude the identification of either isobar metabolite when present in a mixture. Exo-THC co-eluted with D9-THC and had an identical MRM ratio, which would lead to misidentification if present alone and falsely elevated concentrations of D9-THC if present in a mixture. Delta-6a, 10a-THC, and D10-THC co-eluted and had the same mass fragmentation. Delta-8-THC, D9-THC, and D10-THC were resolved sufficiently to enable accurate quantitation.

Conclusion: Analysis of vape oil liquids by GC/MS is effective for resolution and identification of cannabinoid isobars that may be difficult to differentiate by LC/MS/MS. Although exo-THC could not be differentiated from delta-9-THC by LC/MS/MS due to its extremely low relative amount in vape oils, it is not likely to be present in any detectable amount in biological specimens. An effective partnership between toxicology and seized drug laboratories can aid in determining the risk of cannabinoid isobars being present in biological specimens that may not be differentiated by LC/MS/MS toxicology analysis.

Delta-8-THC, Exo-THC, LC/MS/MS

K18 An Unusual Case of Accidental Phosphine Inhalation in Pakistan

Muhammad Amir Nadeem, MPhil, Forensic Toxicology, Punjab Forensic Science Agency, Lahore, Punjab, Pakistan; Muhammad Mubasher, MPhil, Forensic Toxicology, Punjab Forensic Science Agency, Lahore, Punjab, Pakistan; Muhammad Imran, MPhil, Forensic Toxicology, Punjab Forensic Science Agency, Lahore, Punjab, Pakistan; Muhammad Amjad, PhD, Punjab Forensic Science Agency, Lahore, Punjab, Pakistan; Mohammad Ashraf Tahir, PhD, Punjab Forensic Science Agency, Lahore, Punjab, Pakistan*

Learning Overview: The objective of this work is to highlight the increasing trend of phosphine poisoning in Pakistani society.

Impact Statement: This presentation will impact forensic toxicologists by presenting a case study involving suspicious deaths of family members due to ingestion of biryani (rice) poisoned with phosphine. Identification of phosphine in antemortem and postmortem biological specimens is of paramount importance in determining the cause of suspicious deaths, especially in Pakistan.

Phosphide tablets are an easily accessible, cheap poison commonly used as an insecticide and wheat pill poison. Phosphides (aluminum phosphide and zinc phosphide) are commonly used as insecticides and rodenticides. Phosphine is increasingly used as a homicidal and suicidal poison in the Pakistani community.

A family consisting of five children and their aunt, a resident of Baluchistan, traveled from Quetta, Pakistan, to Karachi, Pakistan, via train. After their arrival in Karachi, they stayed at a rest house and ate biryani (rice) purchased from a nearby restaurant. After eating biryani, they slept. In the early morning, all children were found unconscious and their aunt had severe vomiting. All were taken to a nearby hospital. All children died within an hour and their aunt also later expired in the hospital. Their antemortem and postmortem samples were taken and submitted to the Punjab Forensic Science Agency (PFSA) for analysis of suspected poisons.

Samples were extracted using a modified Quick, Easy, Cheap, Effective, Rugged, and Safe (QuEChERS) extraction technique and run on an Agilent® Gas Chromatograph coupled with a Mass Spectrometer (GC/MS) for identification of any suspected drug/poison in the samples submitted. To rule out phosphine poisoning, samples were aliquoted into headspace vials and a small amount of zinc dust along with 2mL of 6.0 N sulphuric acid was added. These vials were then crimped and heated in the oven at 70°C for 5 minutes, then 0.5mL of headspace was manually injected into Gas Chromatograph/Nitrogen Phosphorous Detector (GC/NPD) equipment.

GC/MS analysis did not PROVIDE any clue for suspected poisons in any of the submitted samples. However, phosphine analysis using GC/NPD revealed the presence of phosphine in blood samples of two victims, urine samples of four victims, and stomach contents of one victim.

There is a dire need to regulate the sale, availability, and purchase of this potent poison (phosphine). Moreover, detection of phosphine in urine specimens of all four victims revealed that urine is an ideal sample for toxicological screening. In this particular case, initially, it was suspected that all family members died due to eating rice; therefore, the owner of the hotel from where the rice was purchased was arrested. However, when toxicological analysis discovered the presence of phosphine in antemortem and postmortem samples, further investigation was performed. It was found that the rest house in which the family stayed had been fumigated with phosphine a day before their stay.

Phosphine, Poisoning, GC/NPD

K19 An Analysis of Cannabis Exposure and Oxidative Stress Biomarkers in Exhaled Breath Condensate and Oral Fluid

Meena Swaminathan, MS, Florida International University, Miami, FL; Anthony P. De Caprio, Florida International University, Miami, FL; Anamary Tarifa, Florida International University, Miami, FL*

Learning Overview: The goal of this work is to present a Liquid Chromatography/Triple Quadrupole/Tandem Mass Spectrometry (LC/QqQ/MS/MS) method for detecting a variety of cannabis exposure and oxidative stress biomarkers in Exhaled Breath Condensate (EBC) and OF (OF) matrices.

Impact Statement: This presentation will impact the forensic science community by presenting a reliable analytical method for detection of major and minor cannabinoids and metabolites in the alternative specimen matrices EBC and OF.

Many states in the United States continue to legalize medicinal and recreational cannabis. As a result, there is a growing need in forensic toxicology to investigate cannabis biomarkers that can differentiate between recent/long-term use and licit/illicit consumption, be sampled with relative ease, and, ultimately, correlate with impairment. Furthermore, clinicians are interested in determining whether inhalation of recreational/medicinal cannabis can exacerbate or provide protection from oxidative respiratory stress following exposure.

EBC and OF are alternative, non-invasive matrices that hold promise for identification of cannabis exposure biomarkers. OF is currently being explored as a matrix for cannabis exposure analysis. However, there are currently no reports on the use of EBC for this purpose, although other drugs have been reported to be detected in this matrix. EBC is an aqueous specimen consisting of condensed water vapor, volatiles, and non-volatile components and has several potential advantages for cannabis biomarker detection, including ease of collection and the presence of a wide variety of volatile and non-volatile analytes, metabolites, and markers of respiratory stress.

In this study, selected cannabis and oxostress analytes were spiked into blank EBC and OF and analyzed by LC/QqQ/MS/MS. A total of 20 major and minor cannabinoids, acid precursors, and metabolites were targeted for analysis based on detection reported in human specimens, compounds identified in recreational and/or medicinal cannabis, and availability of standards. Seven internal standards were included for quantitation analysis. Five commonly monitored respiratory oxidative stress biomarkers were also selected for analysis: 8-isoprostane, 8-oxo-7,8-dihydroguanine, 8-oxo-7,8-dihydro-2'-deoxyguanosine, 4-(methylnitrosoamino)-1-(3-pyridyl)-1-butanone, and 4-(methylnitrosoamino)-1-(3-pyridyl)-1-butanol.

An Agilent® 1290 Ultra High-Performance Liquid Chromatography (UHPLC) coupled to a 6470 LC/QqQ/MS/MS with positive and negative mode Electrospray Ionization (ESI) was utilized for this work. Chromatographic separation was achieved using a Zorbax® 120 EC-C18 column (3.0 x 100mm, 1.8µm) and a step gradient elution with an aqueous mobile phase (A) of 5mM ammonium formate with 0.1% formic acid in water and an organic mobile phase (B) of 0.1% formic acid in 75% acetonitrile and 25% methanol. ESI parameters were optimized to the mobile phase composition of choice, and dMRM parameters including MRM transitions, collision energy, and fragmentor voltage were optimized to effectively analyze both the cannabis and oxidative stress biomarkers in a single run time of 26 minutes.

The method was successful in identifying all analytes, including the difficult to separate Δ^8 -THC, Δ^9 -THC, cannabidiol, cannabichromene, and cannabicyclol. Limit of Detection (LOD) and Limit Of Quantitation (LOQ) for the target cannabinoids and oxidative stress biomarkers ranged from 1 to 10ng/mL and 7 to 18ng/mL, and from 0.13 to 54ng/mL and 0.38 to 164ng/mL, respectively. Future studies will utilize the method to explore cannabis exposure and oxidative stress biomarkers in a human cohort of cannabis smokers with different exposure characteristics.

Cannabinoids, Exhaled Breath Condensate, Oxidative Stress

K20 A Quantitative Analysis of Cannabinoids in Exhaled Breath Aerosols by High-Performance Liquid Chromatography/Electrospray Ionization-Tandem Mass Spectrometry (HPLC/ESI-MS/MS)

Cheryle Beuning, PhD*, National Institute of Standards and Technology, Boulder, CO; Adam Friss, PhD, National Institute of Standards and Technology, Boulder, CO; Kavita Jeerage, PhD, National Institute of Standards and Technology, Boulder, CO; Tara Lovestead, PhD, National Institute of Standards and Technology, Boulder, CO; Cinnamon Bidwellm PhD, University of Colorado, Boulder, CO

Learning Overview: This presentation will describe the process of establishing methods to quantify cannabinoids in exhaled breath aerosols.

Impact Statement: This presentation will impact the forensic science community by raising and answering critical questions about how to accurately measure cannabinoids in exhaled breath aerosols. Reliable methods to determine recent use are a critical need for law enforcement.

With the rise in states decriminalizing adult recreational cannabis, there is a need to understand how to measure cannabinoids in biological matrices, and how those concentrations may be related to intoxication. Studies that try to correlate intoxication to cannabinoid concentrations have investigated cannabinoids present in *OF*, sweat, urine, and blood.¹ However, a link to delta9-Tetrahydrocannabinol (Δ^9 THC) and its metabolites, 11-OH- Δ^9 THC and 11-COOH- Δ^9 THC, has yet to be established. Unlike ethanol, which is abundant in breath, and reliably quantified in a single exhalation, cannabinoids are sparse in breath. However, cannabinoids are lipid-soluble and can be exhaled in aerosols after inhalation of cannabis products. Devices designed to capture breath aerosol particles have been manufactured and breathing maneuvers to increase aerosol production have been investigated.^{2,3} Chronic cannabis users can give Δ^9 THC negative breath samples prior to smoking, and Δ^9 THC levels increase, then gradually decrease after smoking, where the window of Δ^9 THC detection can be up to three hours after consumption.^{4,5} A recent study tried to correlate Δ^9 THC concentrations in the breath to blood after smoking, but inter-individual variability needs to be addressed, such as the variability in the amount of particles that one person can produce versus another.⁵

This pilot study investigated the presence of cannabinoids in exhaled breath aerosols collected with an impaction filter device consisting of a wide mouthpiece followed by three parallel collectors. Aerosols were collected prior to and post *ad libitum* consumption of smoked cannabis according to a National Institute of Standards and Technology (NIST) and University of Colorado-approved Institutional Review Board (IRB) protocol. Participants were instructed to follow a low-lung-volume breath hold breathing maneuver for 12 exhalations to increase aerosol production.³ Breath samples were collected at a baseline session, prior to use, and approximately one hour post use. Blood cannabinoids were monitored to verify compliance with study protocols. One strength of this study was the innovative observational design developed at the University of Colorado, in which experienced cannabis users consume a specific legal market product formulated directly by the dispensary. While initial breath samples were screened for ten cannabinoids and metabolites, this presentation will focus on quantitation of Δ^9 THC, 11COOH- Δ^9 THC, and cannabinol (CBN, a degradation product of Δ^9 THC). Method development for the quantification of un-derivatized cannabinoids in breath samples by HPLC/ESI-MS/MS, including analyte extraction, concentration, and the use of process-matched calibrators will be described. Limits of quantification of cannabinoids down to hundreds of pg/mL were achieved with sensitive multi-reaction monitoring and MS/MS, but varied by molecule. Inter-individual variability is also discussed, as well as the presence of 11COOH- Δ^9 THC in some samples, not previously observed in other breath studies.^{4,6,7}

Cannabis, Breath Aerosols, Mass Spectrometry

K21 A Sensitive Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) Method for the Simultaneous Quantification of 32 Drugs in Oral Fluid

Kayla Marschke, BS, John Jay College of Criminal Justice, New York, NY; Marta Concheiro, PhD, John Jay College of Criminal Justice, New York, NY

Learning Overview: After attending this presentation, attendees will have a better understanding of how to extract and quantify 32 drugs in *OF* in driving under the influence cases by LC/MS/MS.

Impact Statement: This presentation will impact the forensic science community by providing a new analytical tool for the fast and sensitive detection of 32 drugs in *OF* including cannabis, opioids, stimulants, and benzodiazepines.

Due to the increasing interest by legislature and law enforcement for roadside *OF* testing, the need for toxicology laboratories to develop for methods of confirmation in *OF* has risen. *OF* analysis offers benefits to roadside testing and Driving Under the Influence of Drugs (DUID) cases investigation because of the quick, non-invasive sample collection and the correlation to blood as being a filtrate of it.

A sensitive method was developed for the simultaneous detection of a panel of 32 drugs in *OF* collected by the Quantisal® device. The analysis was performed by LC/MS/MS. The target drugs chosen for the method were based on the recommendations by the Toxicology Subcommittee of the National Institute for Standards and Technology's (NIST's) Organization of Scientific Area Committees (OSAC) for DUID cases. Additional substances were included based on the drug prevalence in the New York City region. The method tested for the following drugs: delta-9-Tetrahydrocannabinol (THC), amphetamine, methamphetamine, 3,4-Methylenedioxymethamphetamine (MDMA), 3,4-Methylenedioxyamphetamine (MDA), cocaine, benzoylecgonine, cocaethylene, carisoprodol, meprobamate, zolpidem, alprazolam, clonazepam, 7-aminoclonazepam, lorazepam, diazepam, nordiazepam, oxazepam, temazepam, codeine, 6-monoacetylmorphine (6-AM), buprenorphine, fentanyl, hydrocodone, hydromorphone, methadone, morphine, oxycodone, oxymorphone, tramadol, ketamine, and Phencyclidine (PCP).

Quantisal® collection devices collect 1mL of sample *OF*, for a 1:4 dilution in buffer. In the analysis, this study employed 1mL of the *OF*-buffer mixture, which contains 0.25mL of neat *OF*. The *OF*-buffer samples were prepared by Solid Phase Extraction (SPE) using Strata™ X 33um polymeric reversed phase SPE cartridges. Samples were eluted using dichloromethane: 2-propanol (75:25, v/v) and treated with 1% hydrochloric acid in methanol before evaporation to avoid amphetamines loss. The samples were reconstituted using 0.1% formic acid in water: acetonitrile (95:5, v/v) and injected into the LC/MS/MS.

LC/MS/MS in positive electrospray mode was used for the detection of drugs in *OF*. Two Multiple Reaction Monitoring (MRM) transitions were acquired for each analyte. The mobile phases employed were 0.1% formic acid in water (A) and acetonitrile (B). A reversed phase chromatographic column, Kinetex® C18 100 x 2.1 mm with particle size 1.7um, was used for separation, and the total run time was 15min. The Limits Of Quantification (LOQ) ranged from 0.5 to 5ng/mL, depending on the compound. LOQ was 0.5ng/mL for fentanyl, amphetamine, methamphetamine, MDMA, cocaine, cocaethylene, carisoprodol, meprobamate, zolpidem, tramadol, ketamine, and PCP; LOQ was 1ng/mL for THC, alprazolam, clonazepam, 7-aminoclonazepam, lorazepam, diazepam, nordiazepam, oxazepam, temazepam, and methadone, 6-acetylmorphine; 2ng/mL for buprenorphine; 5ng/mL for codeine, hydrocodone, hydromorphone, morphine, oxycodone, oxymorphone, benzoylecgonine, and MDA. The linearity range was from the LOQ to 500ng/mL. The method is currently being fully validated following the recommendations of Academy Standards Board. This method can pose useful for toxicology labs planning to add *OF* screening and confirmation as states expand roadside *OF* testing.

Oral Fluid, LC/MS/MS, DUID

K22 The Detection of Gabapentin in the Human Umbilical Cord

Amy Racines, MS, USDTL, Des Plaines, IL; Andre Sukta, MSFS, USDTL, Des Plaines, IL; Joseph Jones, PhD, USDTL, Des Plaines, IL*

Learning Overview: After attending this presentation, attendees will have learned about the prevalence of gabapentin abuse within the neonatal population.

Impact Statement: This presentation will help the community appreciate the prevalence of gabapentin abuse in the neonatal population.

Background/Introduction: Gabapentin is an anti-convulsant and is used to treat neuropathic pain. It is a less-addictive alternative to opioids; however, abuse and addiction still occur and have been increasing since the early 2000s. Gabapentin has been shown to cross the placenta and accumulate in the fetal compartment, resulting in a higher rate of pre-term births, lower birth weights, and neonatal abstinence syndrome. Early identification of newborns exposed to gabapentin *in utero* is vital for proper treatment and better neonatal outcomes.

Objective: The objective of this study was to develop and validate a method for the detection of gabapentin in umbilical cord tissue using a Laser Diode Thermal Desorption/Tandem Mass Spectrometry (LDTD/MS/MS) screening analysis and a Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) confirmation analysis.

Methods: Umbilical cord (0.5grams) in acetonitrile was homogenized in a NextAdvance Bullet Blender™ Homogenizer. The specimens were centrifuged, and the supernatants were subjected to a solid phase extraction procedure. The dried extracts were reconstituted with a methanol:deionized water solution containing 100µg/mL of EDTA. Extracts were then spotted into a LazWell™ 96 Plate and dried prior to analysis on the LDTD/MS/MS. Presumptive positive specimens were confirmed through a second aliquot (0.5g) homogenized in acetonitrile. The supernatant was filtered prior to analysis by LC/MS/MS.

Results: All validation criteria followed the American National Standards Institute/ Academy Standards Board (ANSI/ASB) Standard 036, First Edition, Standard Practices for Method Validation, published in 2019. The LDTD/MS/MS analysis had a cutoff of 10ng/g, with a limit of detection of 3ng/g. Both the extracts and dried LazWell™ plates were stable for 48 hours, and no carryover or obvious interferences were observed during the validation. Significant ion suppression, however, was observed. Authentic specimens ($n=70$) were analyzed, and presumptive positive specimens were forwarded to LS/MS/MS for confirmation.

The confirmation method was validated with a cutoff of 10ng/g and a limit of detection of 0.2ng/g. Precision and accuracy was challenged at 4ng/g, 12.5ng/g, and 100ng/g, and results were acceptable. Extracts were stable for up to seven days, and no obvious interferences, significant matrix effect, or carryover were observed. Linear range was determined to be between 4ng/g and 50ng/g. All presumptive positive authentic specimen analyzed ($n=3$) showed 100% correlation with the screening analysis.

Discussion/Conclusion: An increasing number of newborns have been exposed to gabapentin *in utero*, and a crucial aspect of helping these babies recover is early identification. The validated method described here allows early and accurate identification of prenatal exposure to gabapentin, allowing for early intervention and more successful outcomes.

Gabapentin, Umbilical Cord, LDTD

K23 Comparative Biotransformation of New Psychoactive Substances by Human Liver Microsomes, Electrochemical Oxidation, and *In Silico* Analysis

Leonardo Maya, BS, Florida International University, Miami, FL; Anthony DeCaprio, PhD, Florida International University, Miami, FL*

Learning Overview: Attendees will obtain a better understanding of the biotransformation of selected New Psychoactive Substances (NPS) via different *in vitro* methods.

Impact Statement: This research explores alternative *in vitro* metabolomic approaches to assist in the identification of appropriate metabolites for NPS monitoring in forensic toxicological screening and confirmation.

NPS refers to a category of newly modified or synthesized drugs designed to mimic Central Nervous System (CNS) pharmacological effects associated with more classical illicit substances. Using simple or complex changes to core structures, synthesis of NPS can result in a variety of physiological effects as well as yielding a wide array of metabolic products. Human Liver Microsome (HLM) studies are one of the most common *in vitro* assays performed to predict phase I metabolism of drugs. However, these may not encompass the full panel of metabolites that may be generated in human subjects. To better understand and develop metabolomic data for NPS, other methods must be explored.

This study takes a multidimensional approach on phase I metabolism of two synthetic cannabinoids, JWH-018 and 5F-APINAC. Utilizing traditional HLM, Electrochemical Oxidation (ECO), and *in silico* tool (MetaSite), phase I metabolism was assessed. Previous published data has shown metabolomic spectra of the older generation NPS JWH-018 via HLM. However, there is little information regarding the *in vitro* metabolism profiles of 5F-APINAC via HLM, and essentially none for ECO and *in silico* methods. Also, the efficacy of the various *in vitro* methods featured in this study have yet to be comparatively assessed.

The metabolic assays conducted in this study allowed for the screening and confirmation of parent JWH-018 and 5F-APINAC as well as their metabolites. A total of ten metabolites were produced for JWH-018. The *in vitro* assays performed on 5F-APINAC yielded a total of 15 metabolites. Metabolites were categorized based on mono-, di-, trihydroxylation, and dealkylation, among other phase I biotransformations commonly seen in *in vivo* studies. Results initially produced via HLM were compared with the ECO methods and MetaSite data. Through this comparative assessment, metabolites similar to those previously found in literature were matched, along with the discovery of several metabolites not previously reported. These results suggest that ECO and *in silico* analysis of oxidative metabolites may be useful complements or alternatives to HLM for comprehensive profiling of NPS metabolites in forensic toxicology.

Forensic Toxicology, New Psychoactive Substances (NPS), *In Vitro* Biotransformation

K24 Method Development for Drug Court Samples

Kourtney Steen, MSFS, University of Alabama at Birmingham, Birmingham, AL; Elizabeth Gardner, PhD, University of Alabama at Birmingham, Birmingham, AL*

Learning Overview: After attending this presentation, attendees will better understand the Jefferson County Drug Court program, the extraction method utilizing DPX® tips, the data related to emerging drugs, and identifying certain drugs through two derivatizing agents.

Impact Statement: This presentation will impact the forensic science community by providing mass spectral data, discussing the importance of derivatization to separate co-eluting compounds, and an extraction method that uses DPX® tips to conduct Solid-Phase Extraction (SPE) manually.

This project is in collaboration with the Jefferson County Drug Court system. The Drug Court program is available in Jefferson County, AL, for youths and adults to help offenders with felony drug offenses. Individuals can have their cases dismissed once they complete the rehabilitation program. There are three phases to the program in which random drug tests are conducted through a color code system where they are being screened weekly, bi-weekly, and monthly.¹ The program is completed once the individual has received a clean drug test for 90 days. The objectives of this project were: (1) ongoing random confirmation of drug court urine results, and (2) identifying new drugs as they enter the community.

The method used to identify drugs in the urine samples provided was through SPE, using commercially available pipette tips loosely packed with solid-phase sorbent contained by two solvent permeable frits (DPX® tips). DPX® tips are generally used for high-volume robotic systems.² In this case, they are used manually, as one extraction method that can be used for acidic, basic, and neutral drugs.

Urine samples were loaded onto the sorbent and rinsed with distilled water (d-H₂O). Neutral and acidic drugs were extracted with acetonitrile. Basic drugs were extracted with dichloromethane:isopropyl alcohol: NH₄OH (78:20:2). The extracts were dried under Nitrogen (N₂), dissolved in ethyl acetate:methanol (80:20), and analyzed by Gas Chromatography/Mass Spectrometry (GC/MS). Derivatization was necessary for certain drugs. Derivatization is used to separate co-eluting compounds. It helps to create a better chromatography with sharper peaks, larger masses, and often longer retention times. Opioids, benzoylecgonine, and THC-COOH were derivatized with N,O-Bis(trimethylsilyl)trifluoroacetamide (BSTFA). Amphetamines were derivatized with Heptafluorobutyric Acid (HFBA).³

The Jefferson County Drug Court screens the urine samples for amphetamines, barbiturates, benzodiazepines, cannabinoids, cocaine, fentanyl, methadone, heroin, buprenorphine, and creatinine. As part of the method development, 22 drug court samples were analyzed. Of the samples, 11 were negative for drugs of abuse. Of the remaining half, presumptive testing by the Drug Court found most of the samples were positive for opiates, benzodiazepines, amphetamines, cannabinoids, cocaine, and fentanyl. With the analysis of the mass spectra, this study confirmed the positive cases. This study was also able to find drugs not identified by the current Drug Court panel, including xylazine and escitalopram. Xylazine is a veterinary anesthesia. Escitalopram is a Selective Serotonin Reuptake Inhibitor (SSRI).

Solid-Phase Extraction, GC/MS, DPX Tips

K25 The Determination of 67 Analytes in Oral Fluid by Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS)

Kennedy Plude, BS, University of Kentucky, Lexington, KY; Amy Kinkennon, PhD, Keystone Laboratory, Asheville, NC; Phillip Bost, MS, Keystone Laboratory, Asheville, NC; Matthew McGreevy, BS, Keystone Laboratory, Asheville, NC; James Bourland, PhD, Keystone Laboratory, Asheville, NC*

Learning Overview: This presentation will discuss the validation, benefits, and limitations of a precise and accurate method for the quantitative determination of 67 analytes in *OF* using LC/MS/MS. These analytes include benzodiazepines, amphetamines, opiates, opioids, stimulants, hallucinogens, THC, cotinine, antidepressants, opiate agonists, muscle relaxants, anticonvulsants, antipsychotics, and antitussives.

Impact Statement: This presentation will impact the forensic science community by displaying a validated method and linear range for drug testing various clinical and forensic analytes in *OF*. There is a wide array of analytes tested in this method over various drug classes.

Hypothesis/Proposition/Objective: This method was developed and validated to expand the laboratory's *OF* testing menu.

Methods: A 96-well solid phase extraction procedure was used to extract 300µL of *OF* samples consisting of 1:3 neat *OF*: Quantisal™ buffer. Samples were spiked with a deuterated internal standard mix prior to extraction. After wash steps and drying the columns, the analytes were eluted with elution solvent into a 96-well collection plate. After evaporating the eluent to dryness, samples were reconstituted in an aqueous solution of 3% methanol in water. The samples were injected into an LC/MS/MS to separate the analytes based upon their solubility in the stationary and mobile phases. The column effluent was directed into heated electrospray ionization source, which ionizes the analytes as they elute. During the method development stage, all analytes were infused using the molecular weight of each compound in positive ionization mode as the precursor ion. These pre-selected precursor ions were selected in the first quadrupole and fragmented in the second quadrupole (collision cell) by an inert gas collision. The fragment ions were selected in the third quadrupole. The combination of retention time, precursor/product masses, and fragment pattern allowed for the qualitative identification of the analytes. The area of each non-deuterated analyte to deuterated analog ratio permits for the quantification of each analyte. The ratios are compared to a six-point calibration curve that brackets each analyte cutoff and demonstrates the linear range of the assay.

Summary of Results: This method was validated for quantitative results of all 67 analytes that includes four analytical measurement ranges varying from 0.5–25ng/mL, 1–50ng/mL, 2.5–125ng/mL, and 12.5–625ng/mL. The calibration curves had coefficient of determination values greater than 0.99 to determine the linear range. The accuracy showed the results of each calibrator were within the 80–120% of the target concentration after 20 injections per calibrator. The precision study has five concentrations that were tested at 75% of the cutoff, 125% of the cutoff, 2 times the cutoff, 40% of the Upper Limit Of Linearity (ULOL), and 80% of the ULOL.¹ No analytes had a percent accuracy deviating outside 80–120% after 40 injections of each concentration were examined. Carryover of the method was determined for each analyte by 20 injections of the highest concentration calibrator followed by a blank injection and was less than 2%. During the analyte interference study, the percent recovery was accepted if it was within 90–110% of the target. This study showed that pregabalin has major ion suppression when pseudoephedrine is present. Normalized matrix factor equation was used to determine that no biological matrices affected this method.

K26 When Being Positive Is Enough—Unlocking Child Abuse in a Non-Disclosing Child Via Toxicological Hair Testing: A Case Study

Jessica Volz, DNP, Adventist HealthCare Shady Grove Medical Center, Rockville, MD*

Learning Overview: After attending this presentation, attendees will understand how toxicology testing of hair and collaboration among disciplines in cases of non-verbal/non-disclosing children suspected of being abused or neglected can provide critical information for safety planning and legal proceedings.

Impact Statement: This presentation will impact the forensic science community by demonstrating how toxicology testing of hair can be utilized to support child safety through the elimination of plausible and innocent explanations, even when expert opinions differ.

This case study is of a non-verbal/non-disclosing child suspected of being sexually abused by a secondary relative and whose hair toxicology testing revealed ingestion of cocaine. This testing was utilized as a litigation tool to eliminate argument leading to child protection intervention that would have not been otherwise possible.

Toxicological testing of hair samples is not often used in the acute hospital setting. The limitations of this testing are generally cited as the primary reason for this. However, there is some evidence to support consideration of this testing after the age of 34 months.¹ Though toxicological testing of hair may have significant limitations, this case study supports the argument that there is a time and place for it when investigating cases of potential abuse or neglect in non-verbal or non-disclosing children.

In this case, a non-disclosing preschool-aged child with an unremarkable physical examination presented in the hospital setting for a child sexual abuse examination. Despite the lack of findings in the physical examination, the clinician sent blood, urine, and hair for toxicology testing. Blood and urine testing returned with no substances detected. After a negative hair wash, testing of the hair shaft revealed the child's hair was positive for cocaine and benzoylecgonine.

Consultation between two toxicologists and the hospital clinician concluded that there were differing opinions on the number of exposures and the amount of cocaine ingested to produce this result. There was consensus that it could not be determined if the ingestion was intentional. However, the presence of cocaine and the metabolite benzoylecgonine indicated that the child had ingested cocaine and was at minimum supportive of neglect. Superficially, this opinion might be dismissed as useless due to its ambiguity. However, despite this challenge, the science supported the opinion that cocaine and benzoylecgonine were present. For this reason alone, it was cited by the primary litigator as the linchpin that resulted in a settlement that was in the best interest of the safety of the child.

Toxicology Testing, Child Abuse, Cocaine

K27 Electrochemical and Density Functional Theory (DFT) Studies for Fentanyl and Fentanyl Analogs

Ling Wang, PhD, Florida International University, Miami, FL; Gustavo Murilo Alves, BS, University of São Paulo, São Paulo, SP; Sevdie Dogruer, BS, Florida International University, Miami, FL; Bruce McCord, PhD, Florida International University, Miami, FL*

Learning Overview: This presentation will describe the development and application of electrochemical approaches for the presumptive determination of fentanyl and fentanyl analogs, as well as the computational analysis with DFT. Information provided will include the optimized detection methods, the comparison between experimental and calculated spectra, and the data analysis for multiple analytes.

Impact Statement: This presentation will impact the forensic community by demonstrating the electrochemical approaches in the presumptive screening of fentanyl analogs and opioids. The new methods can rapidly distinguish opioids and fentanyl analogs.

The abuse of opioids has been a critical issue to the public health for years. With the appearance of new fentanyl analogs, the overdose rates of opioids continue to bloom. Current screening methods, such as immunoassay, have difficulty detecting the full range of opioid analogs due to a wide variety of structural variations. This study has been working on alternative screening methods. Electrochemical approaches, including square wave voltammetry and cyclic voltammetry, quickly distinguish the group of fentanyl analogs from other opioids with lower cost and easier operations. Both screening approaches are convenient for point-of-care analysis and laboratory tests.

The electrochemical approaches utilize the Screen-Printed Electrodes (SPE) and Phosphate Buffered Saline (PBS) buffer. Solid drugs were dissolved in the buffer solutions, then dropped on electrodes and analyzed via a CHI instrument with an energy range of 0.5–1.8eV. The **Square Wave Voltammetry (SWV)** spectra identify fentanyl analogs from mixtures with the optimized condition for individual drugs, such as fentanyl, cocaine, heroin, opioids, amphetamines, and adulterants. Electrochemical approaches are less sensitive than instrumental methods, however, its operation and preparations are easier for untrained staff. To understand the cross-reaction of fentanyl analogs and impurities as well as the metabolites, DFT calculations displayed the energy changes and pathways from parent drugs to metabolites.

The electrochemical method permits a rapid, easily operated presumptive test for opioids with different benefits. When the method is coupled with other screening methods, such as surface-enhanced Raman spectroscopy as was done in the laboratory, the method can be orthogonal to mass spectrometry and sufficiently sensitive to detect compounds at toxicologically relevant levels. As a result, it should be particularly useful for the screening of opioids and other novel psychoactive substances.

Fentanyl Analogs, Surface-Enhanced Raman Spectroscopy, Square Wave Screening Test

K28 The Stability of Ethanol in Oral Fluids Samples Using the Quantisal® Collection Device

Mairin Higgins, BS, Arcadia University, Glenside, PA; Kelvin Barnes, BS, Immunalysis, Pionoma, CA; Heather Harris, MFS, JD, Arcadia University, Glenside, PA; Karen Scott, PhD, Arcadia University, Glenside, PA*

Learning Overview: After attending this presentation, attendees will be able to evaluate the stability of ethanol in *OF* samples, collected using the Quantisal® collection device, in different temperature environments after several months of storage.

Impact Statement: This presentation will impact the forensic science community by determining the most optimal temperature and storage environment for the stability of ethanol in *OF* samples.

Ethanol is the most widely used drug in most societies. Driving under the influence of alcohol is a problem internationally that can be deterred by random roadside testing. Ethanol, a Central Nervous System (CNS) depressant, negatively impacts an individual's ability to drive by causing poor reaction times, causing lapses in judgement and impairing motor coordination. Blood has been the preferred matrix for drug and alcohol testing, but collection is an invasive process and results in delays in obtaining samples. *OF* is an alternative testing matrix with a rapid turnover and a non-invasive collection technique. Concentrations of ethanol in *OF* are comparable to ethanol concentrations in blood once equilibrium has been reached.

The Quantisal® collection device is used for collecting *OF* samples to be used for *OF* drug testing. This device utilizes a collection pad to be placed under the tongue to collect *OF*. The collection devices can be used anywhere to collect approximately 1mL ($\pm 10\%$) of *OF* for screening, confirmation, and repeat testing. The collection devices utilize approximately 3mL of buffer to stabilize drugs that may be within the *OF* collected.

This research aims to determine the impact of temperature environments, storage environments, and authenticity of samples on stability of ethanol through monitoring the concentration of ethanol over a six-month time span. Temperature environments include a freeze/thaw cycle, a freezer, refrigerator, room temperature, and oven set to 37°C. Storage environments include samples retained within the Quantisal® device as well as samples transferred to Eppendorf® tubes and glass tubes with stoppers. Both spiked and authentic samples were used to study stability.

Ethanol-positive samples, both spiked and authentic, were analyzed in triplicate using Enzyme-Linked Immuno-Sorbent Assay (ELISA) and Headspace/Gas Chromatography/Mass Spectrometry (HS/GC/MS) in parallel. ELISA offers high-sensitivity, rapid analysis of samples. HS/GC/MS instrumentation was used for confirmation of ethanol concentrations in spiked and authentic samples. Temperatures in each environment were monitored using a temperature logger. The oven temperature was held at 37°C, the room temperature was an average of 22°C, refrigerator temperature was found to be an average of 2°C, and the freezer environment was -12°C on average.

Samples were tested at set time increments over a six-month span: t_0 , $t_{day 1}$, $t_{day 2}$, $t_{day 3}$, $t_{day 7}$, $t_{day 14}$, $t_{day 30}$, and every 30 days for the remaining time frame. Storage temperature of the samples impacted the stability of ethanol in samples. Stability of samples remained fairly constant over the first four testing times, regardless of temperature environment. Parafilm was effective at sealing Eppendorf® tubes in an elevated temperature environment to keep ethanol concentrations stable. Samples stored in glass tubes with rubber stoppers remained stable for a longer period than those in plastic Eppendorf® tubes. Samples stored in cooler environments were more stable than those at room temperature and in the oven.

Stability, Oral Fluid, Ethanol

K29 The Development of a Method for the Extraction and Analysis of Fentanyl and Alprazolam From Dermestid Beetles, Larvae, Casings, and Frass

Stephanie R. VanLysebettens, BA*, Arcadia University, Glenside, PA; Stephanie Rainer, MSFS, Rutgers University, New Brunswick, NJ; Lorna Nisbet, PhD, Anglia Ruskin University, Cambridge, Cambs, United Kingdom; Karen S. Scott, PhD, Arcadia University, Glenside, PA

Learning Overview: Those who attend this presentation will be able to utilize the proposed extraction method followed by Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) analysis to determine the presence of fentanyl and alprazolam in beetles, casings, larvae, and frass.

Impact Statement: This presentation will impact the forensic science community by utilizing Dermestid beetles to determine the presence of drugs in decedents who may be void of other tissues for analysis.

Insects play a crucial role in the determination of postmortem intervals of decaying bodies. Extensive studies have been conducted on *Diptera: Calliphoridae*, but little on *Coleoptera: Dermestidae*. Studies on *Diptera* larva have shown that consumption of a decedent with drugs in their system transfers that drug into the insect.¹⁻⁶ The ability to use Dermestid beetles comparably to blow flies would allow evidence to be obtained from a carcass much later in the cycle of decay as beetles do not arrive until approximately nine days after death.

Drugs focused on in this study included fentanyl and alprazolam. These drugs were chosen because of the increasing opioid epidemic in the United States and around the world. Alprazolam is a benzodiazepine that is often used in conjunction with opioids to heighten effects. As benzodiazepines are Central Nervous System (CNS) depressants and fentanyl is an opioid analgesic, the combination can cause respiratory depression and an increased death rate.

Prior to the study a main colony was developed starting with 500 larvae containing an unknown combination of *D. ater*, *D. lardarius*, and *D. maculatus*. From this colony, three replicates were pulled, each containing four separate breeding colonies. Drugs were introduced to the beetles through a food matrix consisting of an 18:1 ratio fish meal and brewer's yeast supplemented with 10% casein powder. Breeding colonies were fed a negative control or food matrix spiked with one of the two drugs of interest. Homogenization using a Biotage® OMNI Bead Ruptor 24 and wash procedures of the beetles, casings, larvae, and frass were performed prior to extraction using Solid-Phase Extraction (SPE). All samples were injected into a SCIEX™ API 3200 LC/MS/MS with Shimadzu® HPLC system. An Agilent® InfinityLab Poroshell 120 EC-C18 column was used (3.0 x 100mm, 2.7-Micron, 1,000bar with Column ID). Product ions for alprazolam were monitored at 281.3 and 205.2 m/z and for fentanyl at 188.1 and 105.0 m/z. Deuterated internal standards for both drugs were also used.

Both drugs were successfully detected from the various matrices collected and in some cases, a dose-dependent response was observed. Dermestid beetles and their associated waste products are useful toxicological tools when conventional samples are no longer available due to adverse conditions at the scene of a drug-related death.

K30 Validation of a Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) Method for 23 Fentanyl Analogs in Oral Fluids

Nicole Haase, BS*, Duquesne University, Pittsburgh, PA; Erin Divito, PhD, MolecularDx, Windber, PA; Frederick Fochtman, PhD, Duquesne University, Pittsburgh, PA and MolecularDx, Windber, PA; Haley Berkland, MS, Duquesne University, Pittsburgh, PA and MolecularDx, Windber, PA; Ashley Trouten, BS, Duquesne University, Pittsburgh, PA; Stephanie Wetzell, PhD, Duquesne University, Pittsburgh, PA

Learning Overview: The goal of this presentation is to demonstrate an LC/MS/MS method development and validation study for analyzing whole blood and OF for 23 fentanyl analogs. Detection limits between the two matrices will be compared.

Impact Statement: This presentation will impact the forensic science community by showing the value of OF as a non-invasive toxicologically important matrix when other matrices are not available or when non-invasive sample collection is preferred.

Currently, synthetic opioids, including fentanyl analogs, are the leading cause of overdose deaths in the United States.¹ New fentanyl analogs are being made regularly and are used to avoid classification as illegal, policy restrictions on manufacturing and/or detection in standard drug tests.² Fentanyl analogs are drugs designed to mimic the pharmacological effects of fentanyl. Fentanyl is a highly potent pain reliever that produces effects such as euphoria, drowsiness, sedation, pain relief, etc.³

Due to the small detection window in OF, blood or urine samples are often utilized in forensic laboratories, but the benefit of testing OF is that it requires non-invasive sample collection and is not easily contaminated.⁴ In this study, a rapid LC/MS/MS method was developed and validated for analyzing OF for 23 fentanyl analogs. Samples were prepared by phospholipid depletion and protein precipitation using 200µL of either whole blood or OF and 1% acetic acid in acetonitrile. Separations were completed using an Agilent® ZORBAX® Eclipse XDB-C18 (2.1x100mm) with a Vanquish™ Ultra High-Pressure Liquid Chromatography (UHPLC) System. Gradient elution was performed with 0.1% formic acid in water and acetonitrile. Identification and quantitation were conducted with a TSQ Endura™ Triple Quadrupole-Mass Spectrometer (QQ-MS) operating in selective reaction monitoring mode. This LC/MS/MS technique combines low complexity sample preparation with the selectivity and sensitivity of LC/MS/MS.

This method was validated in whole blood and OF. Validation studies consisted of precision, accuracy, ion suppression/enhancement, analyte recovery, analyte stability, dilution integrity, matrix interferences, and cross-panel interferences. Limit Of Quantitation (LOQ) are typically 0.05ng/mL with an analytical measurement range reaching 20ng/mL. Validation results show that analytes are detected in OF at significantly lower LOQs than can be achieved in whole blood.

This method allows for the detection of fentanyl analogs in OF. This can help to determine overdose cases and can be implemented in routine drug testing or Driving Under the Influence (DUI) cases. With the constant rapid increase of overdose cases involving fentanyl analogs, it is important to have a quick and efficient way of detecting opioids in various matrices.

LC/MS/MS, Fentanyl Analogs, Oral Fluid

**K31 An Investigation of Structural Features on the Binding of Synthetic Cannabinoids to the CB1 Receptor:
A Computational Study of the JWH Compounds**

Krishna Chaturvedi, PhD, The University of Mississippi, University, MS; Caroline Spencer, PhD, STI Electronics Inc., Madison, AL; Pankaj Pandey, PhD, The University of Mississippi, University, MS; Robert Doerksen, PhD, The University of Mississippi, University, MS; Murrell Godfrey, PhD*, The University of Mississippi, University, MS

Learning Overview: After attending this presentation, attendees will understand the interactions between JWH synthetic cannabinoids and the active-state CB1 receptor.

Impact Statement: This presentation will provide a better understanding of key features of JWH compounds with specific CB1 receptor residues through molecular docking and all-atom molecular dynamics simulation. The knowledge of these critical interactions and structural features of JWH compounds will help forensic chemists to design and predict novel structures of JWH synthetic cannabinoids.

To date, there have been two cannabinoid receptors identified, CB1 and CB2. The cannabinoid receptor 1 is the most abundant G protein-coupled receptor present in the Central Nervous System (CNS) and is also found in the immune system and peripheral organs.¹ **Δ^9 -Tetrahydrocannabinol** (Δ^9 -THC) and synthetic cannabinoids interact with CB1 receptors and cause “psychoactive effects,” functioning as CB1 receptor agonists. JWH compounds and other synthetic cannabinoids are seen under the brand names of “Spice,” “K2,” “herbal incense,” “Cloud 9,” and many more. They have become an important area of research in the forensic science community due to their drug abuse potential and their unpredictable toxicity.²

In the present study, an active-state CB1 X-ray crystal structure was used to design novel JWH-virtual compounds by understanding the ligand-receptor interactions between the CB1 receptor and the JWH synthetic cannabinoid family using docking, binding free-energy calculation, and all-atom Molecular Dynamics Simulations (MDs).

The binding free-energy data revealed that the carbonyl group between the naphthalene and the indole and the length of the N-linked alkyl chain were two important structural characteristics that influence the predicted CB1 activity. Increasing the length of the alkyl chain on the naphthalene of JWH-XXX compounds led to better predicted binding affinity with the CB1 receptor. The MD (100ns) analysis results showed that virtually designed new JWH compounds and selected JWH compounds fit well into the active site of the CB1 receptor and formed stable and strong hydrophobic interactions with the key residues: Phe170, Phe174, Phe177, Phe189, Leu193, Phe200, Phe268, and Trp279. Identifying the key interactions between the synthetic cannabinoids and the CB1 receptor is a step toward a better understanding of the effects of these drugs, including toxicity and potential for abuse and the design of new analogs.

Synthetic Cannabinoid, CB1 Receptor, Molecular Modeling

K32 A Comparison of Meconium, Synthetic Meconium, and Urine by High-Performance Liquid Chromatography (HPLC) and Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) in the Simultaneous Detection of Illicit Drugs and Metabolites

Shannon Palladino, MPS*, Pennsylvania State University, University Park, PA; William Campbell, PhD, Pennsylvania State University, University Park, PA

Learning Overview: Attendees can expect to learn about the value of using meconium in the determination of maternal drug use and/or exposure, extraction procedures used for various biological matrices and the LC/MS/MS method development involving a broad panel of different drugs of abuse. Overall, attendees should gain an understanding of the influence of different matrices (urine, meconium, and synthetic meconium) on LC/MS/MS quantitative analysis of a drug panel of interest to forensics.

Impact Statement: This presentation would be novel in its comparison of urine, meconium, and synthetic meconium from a toxicological perspective supported by validated LC/MS/MS methods. Such an evaluation would confirm or deny the viability of synthetic meconium as an alternative to natural meconium, which could potentially reshape how research is conducted on meconium in the future.

The toxicological determination of drugs, environmental toxins, or other agents that can be passed from mother to child *in utero* is of great relevance in clinical and forensic settings, with drugs of abuse being of particular interest for forensic implications. In order to properly treat a neonate possibly suffering from the effects of fetal drug exposure and to propose the correct legal course of action, the substance or substances in question must be determined and quantified. Matrices like blood and urine are commonly used in toxicological practices and studies, but when determining *in utero* drug exposure, meconium has emerged as an ideal biological matrix. Not only does meconium allow for non-invasive collection, but from an analytical perspective, it has a long window for drug accumulation, allowing for detection with higher sensitivity and specificity than most other matrices.¹⁻³

However, for research purposes, meconium can be a problematic material to work with due to difficulties in obtaining samples and due to privacy and confidentiality issues. That is why this project will focus on the comparison of meconium to synthetic meconium. Synthetic alternatives to biological matrices pose great opportunities in performing clinical and toxicological assessments, and there has been little research done on its potential as a valid substitute for real meconium.⁴

An LC/MS/MS method has been developed to separate and quantitate a panel of 41 drugs of abuse, including stimulants, opiates, benzodiazepines, barbiturates, cannabinoids, and their metabolites. Because there is scarce information about a direct comparison between meconium analysis and urinalysis—a standard practice in clinical testing—this method will also be applied to urine alongside meconium, synthetic meconium, and water. This research aims, through method validation and statistical analysis, to reach a preliminary conclusion about the comparability of synthetic meconium to natural meconium for use in LC/MS/MS method development and research in comparison to urine as a reference matrix.

Meconium, Liquid Chromatography Tandem Mass Spectrometry (LC/MS/MS), Drugs of Abuse

K33 Standards Development Activities in Forensic Toxicology

Marc LeBeau, PhD, Federal Bureau of Investigation Laboratory, Quantico, VA*

Learning Overview: After attending this presentation, attendees will have a better understanding of the status of discipline-specific standards pertinent to the field of forensic toxicology.

Impact Statement: The presentation will impact the forensic science community by creating greater awareness of standards development activities pertinent to forensic toxicology. It will also increase awareness regarding training, tools, and resources that support implementation, compliance monitoring, and broader understanding.

The Organization of Scientific Area Committees (OSAC) for Forensic Science was created to strengthen the nation's use of forensic science by promoting the use of discipline-specific forensic science standards. To this end, the OSAC drafts standards that are forwarded to Standards Developing Organizations (SDOs) that further develop and publish them. The OSAC also reviews published standards and recognizes them on the OSAC Registry, which serves as a central repository of high-quality, consensus-based, technically sound standards.

During this presentation, updates related to standards development in forensic toxicology will be presented. These include:

Recent standards that have been added to the OSAC Registry (ANSI/ASB 017: *Standard Practices for Measurement Traceability in Forensic Toxicology*; ANSI/ASB 036: *Standard Practices for Method Validation in Forensic Toxicology*; ANSI/ASB 053: *Standard for Report Content in Forensic Toxicology*; and ANSI/ASB 037: *Guidelines for Opinions and Testimony in Forensic Toxicology*)

OSAC Proposed Standards:

Published standards from the Academy Standards Board (ASB) that have yet to go through the Registry approval process (ANSI/ASB 054 *Standard for Quality Control Programs in Forensic Toxicology Laboratories*; ANSI/ASB 119 *Standard for the Analytical Scope and Sensitivity of Forensic Toxicological Testing of Blood in Medicolegal Death Investigations*; ANSI/ASB 120 *Standard for the Analytical Scope and Sensitivity of Forensic Toxicological Testing of Blood in Impaired Driving Investigations*; ANSI/ASB 121 *Standard for the Analytical Scope and Sensitivity of Forensic Toxicological Testing of Urine in Drug-Facilitated Crime Investigations*)

Documents currently in development by the ASB (ANSI/ASB 055: *Standard for Breath Alcohol Measuring Instrument Calibration*; ANSI/ASB 098: *Standard for Mass Spectral Data Acceptance in Forensic Toxicology*; ANSI/ASB 113: *Standard for Identification Criteria in Forensic Toxicology*; ANSI/ASB 153: *Standard Practices for Proficiency Testing for Forensic Toxicology Laboratories*; ANSI/ASB 156: *Guidelines for Specimen Collection and Preservation in Forensic Toxicology*; ANSI/ASB 152: *Standard for the Minimum Content Requirements of Forensic Toxicology Procedures*)

Documents currently being drafted at the OSAC (*Standard Practices for Evaluating Measurement Uncertainty of Quantitative Measurements in Forensic Toxicology*; *Guidelines for Performing Alcohol Calculations in Forensic Toxicology*; *Standard for Breath Alcohol Instrument Specifications*; *Standard for Education and Training of Forensic Toxicology Personnel*; *Quality Management Systems in Forensic Toxicology Laboratories*; *Standard Method for Blood Ethanol Identifications and Quantitations*; *Standard Practices for Continued Education in Forensic Toxicology Laboratories*; *Standard for the Accreditation of Forensic Toxicology Laboratories*)

Priorities for new documents or work products and other highlights:

Opportunities for supplemental training related to discipline-specific standards will be presented, as well as additional resources and tools designed to facilitate gap analysis, compliance monitoring, and outreach efforts.

Forensic Toxicology, Standards, ASB

K34 The Rise of the “Cannabisomers”

Tiara Evans, MS, Armed Forces Medical Examiner System, Dover Air Force Base, DE; Joshua Seither, PhD, Armed Forces Medical Examiner System, Dover Air Force Base, DE; Jessica Knittel, MS, Armed Forces Medical Examiner System, Dover Air Force Base, DE; Erin Karschner, PhD, Armed Forces Medical Examiner System, Dover Air Force Base, DE; Jeff Walterscheid, PhD, Armed Forces Medical Examiner System, Dover Air Force Base, DE*

Learning Overview: After attending this presentation, attendees will be familiar with the steps needed to differentiate delta-8 and delta-9-Tetrahydrocannabinol (THC) from each other and other THC isomers. Attendees will also understand the importance of confirming the presence of delta-8 and delta-9-THC in forensic casework.

Impact Statement: This presentation impacts the forensic science community by raising awareness about the growing trend of detecting delta-8-THC, either with or without delta-9-THC, and how it can interfere with confirmation, reporting, and interpretation.

In the past few years, there has been increasing interest in expanded phytocannabinoids analysis. Previously, the presence of delta-9-THC and/or its metabolites in biological fluids indicated exposure to cannabis or cannabis products. More recently, cannabinoid analysis challenges involve the investigation of Cannabidiol (CBD) product usage, determination of THC and metabolite origins from cannabis or synthetic dronabinol, and separation of delta-8-THC, which can obfuscate delta-9-THC identification.

It is well-known that the acid catalyzed intramolecular cyclization of CBD can yield various proportions of delta-8-THC and delta-9-THC, which is influenced by the type of acid, solvent, temperature, and incubation time. Delta-8-THC is available to consumers in edible products, syrups, vaping oils, concentrates, and infused flour. A mixture of delta-8 and delta-9-THC and their carboxylated metabolites are often seen in routine laboratory analysis. If the analytical methods are not sufficient, these isomers may overlap and interfere with acceptable reporting criteria.

A Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) method was developed to resolve delta-8-THC, delta-9-THC, and their carboxylated metabolites. Unfortunately, at the time of development an 11-hydroxy-delta-8-THC reference standard was not available; therefore, it was not included in this analytical method. With consumer products now containing delta-6a,10a and delta-10-THC, it was important to characterize additional THC isomers that may interfere with the analytical method. Using the developed method, delta-6a,10a and delta-10-THC did not interfere with delta-8 and delta-9-THC, as these variants eluted outside the Multiple Reaction Monitoring (MRM) acquisition windows of the targeted analytes.

Since the beginning of 2021, delta-8 THC and/or delta-8-THCCOOH have been confirmed in over 25 human performance and postmortem cases. Without an adequate method of isomer separation, these cases would not be able to be reported to requesting authorities. After altering the chromatography parameters, improved peak resolution allowed for accurate determination of these two species in routine analysis. Authentic case examples presented will include delta-9-THC combined with low but reportable delta-8-THC, delta-8-THC with delta-9-THC absent or below reporting limits, and the more commonly encountered mix of roughly equal delta-8 and delta-9-THC results. It is important to note how these various situations may affect the acceptance criteria for reporting evidence of cannabinoid use.

This presentation will examine representative data and discuss solutions to THC isomer separation. If proper analytical techniques are not available, it is possible to overlook or misinterpret evidence of cannabinoid exposure. The United States military maintains a zero tolerance policy against using cannabis products to maintain safety, health, and mission readiness in the workforce. These cases underscore the need for vigilance when evaluating casework with proper confirmatory testing to reveal significant findings such as delta-8-THC and metabolites.

Delta-8-THC, Delta-9-THC, LC/MS/MS

K35 Impaired Driving Cases With Clonazepam

Nicholas B. Tiscione, BS, Palm Beach County Sheriff's Office, West Palm Beach, FL*

Learning Overview: After attending this presentation, attendees will increase their competence in the interpretation of, and need for, clonazepam testing in impaired driving investigations.

Impact Statement: This presentation will impact the forensic science community by outlining the increasing incidence, polypharmacy, and a case report of clonazepam in impaired driving investigations.

Introduction: Novel benzodiazepines have been increasing in seized drug submissions. Clonazepam has become one of the most frequently detected compounds in counterfeit alprazolam tablets. Clonazepam is a high-potency benzodiazepine that requires sensitive instrumentation and methods for detection in blood and urine specimens and may also require including the metabolite 8-Aminoclonazepam (8-AMC) to detect its use.¹ In 2019, 16 novel and non-routine benzodiazepines, including clonazepam, were added to the urine and blood Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) confirmation methods. In 2019 and 2020 only 9% and 8%, respectively, of immunoassay-positive benzodiazepine cases were not able to be confirmed. From January 1 to May 10, 2021, 24% of positive blood and urine specimens were not able to be confirmed. For cases from April 1 to May 10, 2021 that percentage was 37%, demonstrating a rapidly increasing trend. Revalidation was conducted to add 8-AMC to the scope of testing and decrease the quantitation range of clonazepam in blood from 5–100 to 1–20ng/mL.

Methods: For all driving under the influence of drugs blood cases, a volatile analysis was followed by an 11-panel Enzyme-Linked Immuno-Sorbent Assay (ELISA) and basic extraction with scan Gas Chromatography/Mass Spectrometry (GC/MS). Urine specimens were tested with a 9-panel ELISA and a basic extraction with scan GC/MS. All positive results were confirmed with GC/MS and/or LC/MS/MS, and/or LC with high-resolution MSMS. The ELISA cutoff for benzodiazepines using clonazepam as the target was 10ng/mL for blood and 25ng/mL for urine. The limit of quantitation for clonazepam and Limit Of Detection (LOD) for 8-AMC was 1.0ng/mL for blood by LC/MS/MS. The LOD for clonazepam and 8-AMC in hydrolyzed urine by LC/MS/MS was 20 and 100ng/mL, respectively.

Results: Since updating the blood (~1.5 months) and urine (~2.5 months) confirmation methods, 8-AMC was the most frequently identified benzodiazepine in blood and urine specimens submitted for impaired driving investigations. In urine, 8-AMC was identified in 14/44 cases (32%) and was second only to carboxy **Tetrahydrocannabinol** (carboxy-THC) (52%). Of note, the parent clonazepam was only identified in three urine specimens during the same period. In 26 blood cases tested since the method update, 8-AMC was identified in 10 (38%) with clonazepam identified in 8 (31%). For blood cases, 8-AMC was second only to fentanyl (50%) for the most commonly identified drug. Seven blood cases with quantitative results for clonazepam ranged from 2.9 to 19ng/mL.

Other drugs were identified in the vast majority of the clonazepam cases. In blood cases since 2019, 14 of the 15 positive cases (93%) also contained another drug. The most common combinations of other active drugs in the blood cases were opioids (87%), stimulants (60%), and other benzodiazepines (47%). In one blood case where 8-AMC was the only compound identified, officers observed impairment consistent with a Central Nervous System (CNS) depressant. The driver crashed into a line of cars stopped at a red light at a high rate of speed after being observed having difficulty maintaining his lane and driving too slowly on the roadway. The driver was observed to have problems maintaining balance, slow, thick slurred speech, and some difficulty following instructions.

Discussion/Conclusion: The incidence of clonazepam in impaired driving investigations has increased dramatically in 2020. In one blood case where 8-AMC was the only compound identified, impairment to driving ability and normal faculties consistent with a CNS depressant was observed. Detection of this potent benzodiazepine requires sensitive methods and/or inclusion of the metabolite 8-AMC. Other drugs were identified in the vast majority (93%) of the cases in this jurisdiction.

Clonazepam, 8-Aminoclonazepam, DUID

K36 Gabapentin in Driving Under the Influence of Drugs (DUID): An Update

Jolene Bierly, MSFS, NMS Labs, Horsham, PA; Ayako Chan-Hosokawa, MS, NMS Labs, Horsham, PA*

Learning Overview: After attending this presentation, attendees will better understand the current prevalence and impact of gabapentin in DUID cases.

Impact Statement: This presentation will impact the forensic science community by detailing the current prevalence and impact of gabapentin in DUID cases.

Introduction: Gabapentin has been approved by the Food and Drug Administration (FDA) for adjunctive therapy in the treatment of epilepsy and neuralgia, but is increasingly being prescribed for multiple off-label uses, including insomnia, anxiety, migraine, and as an adjunct in pain management. Side effects include somnolence, dizziness, ataxia, nystagmus, and fatigue. There are previous reports of impaired driving attributed to gabapentin.¹ This group previously reported on the prevalence of gabapentin in DUID casework submitted to NMS Labs from 2015–2017. During that time, gabapentin testing was only available via a targeted Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) test. This work documents the changes in gabapentin prevalence in DUID cases since its inclusion in the Tier II DUID testing panel in 2020.

Method: Gabapentin was included in the laboratory's Tier II DUID expanded panel in 2020. The expanded panel includes a Liquid Chromatography/Time-Of-Flight/Mass Spectrometry (LC/TOF/MS) screen plus an Enzyme-Linked Immuno-Sorbent Assay (ELISA) panel. Gabapentin is currently screened via the ELISA (Reporting Limit [RL] of 5.0mcg/mL) and confirmed via LC/MS/MS (RL 1.0mcg/mL). Antemortem blood specimens submitted for testing via the drugged driving test panel between January 2020 and June 2021 were reviewed. Cases where gabapentin testing was canceled for any reason were excluded.

Results: Between January 2020 and June 2021, there were 2,890 Tier II DUID expanded panels ordered. Gabapentin screened positive in 229 of these with an overall positivity rate of 7.9%; 219 cases confirmed gabapentin with a mean \pm Standard Deviation (\pm SD) and range of 9.9 ± 7.1 mcg/mL (1.6–63mcg/mL). Polypharmacy was common with 95% of gabapentin cases confirming positive for at least one other drug. Common drug class combinations include gabapentin with opioids (54%), cannabinoids (42%), and stimulants (42%). There were 11 gabapentin-only cases between 2020 and March 2021. Mean \pm SD and range of gabapentin concentrations in those cases were 10 ± 7.2 mcg/mL (2.4–28mcg/mL). A review of those cases revealed “erratic driving” was the most commonly reported driving behavior.

Conclusion: This review found an overall gabapentin positivity of 7.9% in DUID cases since January 2020. The mean and median concentrations of gabapentin were significantly higher than those reported in therapeutic use of trough plasma gabapentin concentrations of 2.6mg/L following a dose of 900mg/day, and an average concentration of 4.8mg/L in patients receiving 1,800mg/day, sampled randomly. Significant impairment to driving and human performance was observed in gabapentin-only cases. Approximately 95% of the cases in this review involved gabapentin in combination with other drugs.

Gabapentin, Drugged-Driving, Human Performance Toxicology

K37 An Assessment of the National Safety Council's Tier 1 and Tier 2 Scope Recommendations in Authentic Driving Under the Influence of Drugs (DUID) Cases

Grace Cieri, BS, CFSRE, Willow Grove, PA; Amanda Mohr, MSFS, CFSRE, Willow Grove, PA; Melissa Fogarty, CFSRE, Willow Grove, PA; Barry Logan, PhD, NMS, Horsham, PA*

Learning Overview: After attending this presentation, attendees will be able to evaluate the prevalence of drugs detected in suspected DUID cases that are comprehensively testing and aligned with the scope recommendations for routinely detected and more esoteric drugs developed by National Safety Council's Alcohol, Drugs and Impairment Division Committee (NSC-ADID).

Impact Statement: This presentation will impact the forensic science community by providing an evaluation using comprehensive broad scope testing on authentic DUID cases, offering a highly comprehensive insight into the etiology of the problem in the United States. This information will benefit the criminal justice system by providing a more accurate picture of the drugs contributing to DUID, and the appropriate scope for contemporary drug testing scopes that can be used to update the NSC-ADID recommendations. This process will also provide better support for the drug recognition program and higher quality consolidated data for epidemiological studies and public policy.

Over the past decade, there has been an increase in the legalization of recreational drugs, use of Novel Psychoactive Substances (NPS), and prescription and over-the-counter drugs contributing to impaired driving becoming a larger problem and public health threat. Added to this problem is the scope of testing used by some laboratories, the practice of stop-limit testing, and the lack of standardization between laboratories. These factors have led to the under-reporting of drugs that are not routinely screened for as well as the not detecting emerging drugs such as NPS.

Discarded and deidentified blood samples submitted for analysis in suspected DUID cases were analyzed for the study. Two independent liquid-liquid extractions were performed to analyze for basic drugs and for synthetic cannabinoids. Borate buffer (1 mL, 0.1 M, pH 10.4) was added to blood (0.5 mL), followed by the addition of N-butyl chloride/ethyl acetate (70:30 v:v, 3 mL). For the synthetic cannabinoids and their metabolites, blood (0.5 mL) was basified with TRIS HCL (1.0 M, pH 10.2) and extracted with methyl tert-butyl ether (3 mL). Samples for both extractions were dried to completion and reconstituted in initial mobile phase (200 µL).

Both extracts were analyzed using a SCIEX™ TripleTOF® 5600+ Liquid Chromatography/quadrupole Time-Of-Flight (LC/qTOF) coupled with Shimadzu® Nexera Ultra High-Performance Liquid Chromatography (UHPLC). A reverse phase gradient of ammonium formate (1 mM, pH 3) and methanol/acetonitrile (50:50) with Phenomenex® Kinetex C18 analytical column (50 mm x 3.0 mm, 2.6 µm) was used on both sample types with the corresponding gradient for the basic and synthetic cannabinoid methods. The basic drug panel library contains over 900 drugs and metabolites, and the synthetic cannabinoid panel contains over 300 drugs and metabolites. Both libraries are updated regularly as new drugs are identified.

To date, 694 samples have been analyzed and processed on both the basic drug screening panel and the synthetic cannabinoid panel. The results were divided into three categories: Tier I, referring to drugs routinely tested for in laboratories; Tier II, compounds laboratories may or may not elect to include these in their screening process; and NPS, which is a subcategory under Tier II.

Results for Tier I included methamphetamine ($n=108$; 15.6%) followed by amphetamine ($n=107$; 15.4%), fentanyl ($n=91$; 13.1%), cocaine ($n=48$; 7.0%), and alprazolam ($n=27$; 3.9%). Ethanol was found in 231 cases at an average concentration of 0.156 (± 0.07) g/100 mL (median 0.152 g/100 mL) with a range of 0.11–0.610 g/mL. Delta-9-Tetrahydrocannabinol (THC) was found in 352 cases with an average concentration of 8.8 (± 10) ng/mL (median 5.6 ng/mL). Tier II drugs were identified with less frequency. Diphenhydramine was identified in 35 cases, followed by cyclobenzaprine ($n=24$; 3.5%), hydroxyzine ($n=24$; 3.5%), and trazodone ($n=20$; 2.9%). Results for NPS are 8-aminoclonazepam in 21 cases, followed by etizolam ($n=11$; 1.6%) and fluorofentanyl ($n=11$; 1.6%).

The findings from this evaluation suggest the most recent recommendations for NSC-ADID Tier I and Tier II drugs are appropriately aligned based on prevalence and frequency with which these drugs are detected in DUID casework samples. From the results to date, only the following compounds included in Tier I have not been detected: meprobamate, alpha-hydroxyalprazolam, and oxymorphone.

Impaired Driving, Toxicology, Drugs

K38 The Use of Statistical Models to Evaluate Signs of Cannabis Impairment During Drug Recognition Expert (DRE) Evaluations

Karen Woodall, PhD, University of Toronto, Mississauga, Ontario, Canada; Rachel Ram, BSc, University of Toronto, Mississauga, Ontario, Canada; Reed Holland, York Regional Police Service, Aurora, Ontario, Canada*

Learning Overview: After attending this presentation, attendees will have learned which indicators used by DREs are significant for determining cannabis impairment using different statistical models.

Impact Statement: This presentation will impact the forensic community by providing statistical support for observations frequently used by DREs to identify cannabis-impaired drivers.

Objective: To evaluate suspected drug impaired driving cases where the DRE's observations were confirmed by toxicology analysis as cannabis-only, polydrug-cannabis, and cannabis-negative cases to identify which observations are associated with impairment resulting from recent cannabis use.

Background: The scientific merit of the DRE's is often questioned during legal proceedings due to limited scientific literature that demonstrates the DRE evaluation's sensitivity to cannabis impairment. Research evaluating DRE examinations found that officers were often accurate in identifying the drug category; however, the false negative rate for cannabis was higher than other drug classes.¹ Published literature evaluating the association between DRE metrics and cannabis impairment has compared the prevalence of these observations between individuals impaired by cannabis and non-impaired subjects and concluded that eyelid tremors, rebound dilation, dilated pupils, and elevated blood pressure are associated with cannabis impairment.²⁻⁴ This study investigated data from impaired driving investigations where DRE observations and urine toxicology results were evaluated to see if statistical modeling could predict cannabis-positive and cannabis-negative cases.

Methods: One hundred ninety-one DRE evaluations and corresponding urine toxicology results were evaluated to create two statistical models: a binary model, which distinguishes between cannabis-positive and cannabis-negative cases; and a multinomial model, which distinguishes between cannabis-positive, polydrug-cannabis, and cannabis-negative. Decision trees and logistic regression were used to create the statistical models, resulting in four models: (1) binary decision tree; (2) multinomial decision tree; (3) binary logistic regression; and (4) multinomial logistic regression. Cross-validation was conducted to assess the accuracy and performance of each model.

Results: The binary decision tree classified cannabis-positive and cannabis-negative cases with 81.68% accuracy using three variables: first using eyelid tremors, then muscle tone, and rebound dilatation. The presence of eyelid tremors and rebound dilation were good predictors of cannabis-positive cases. The multinomial decision tree classified cannabis-only, polydrug-cannabis, and cannabis-negative cases with 70.16% accuracy using three variables: first with eyelid tremors, rebound dilation, and number of cues observed during the Walk And Turn (WAT) test. In the presence of eyelid tremors, <2 cues WAT predicted cannabis-only cases whereas ≥ 2 cues predicted polydrug-cannabis cases. Binomial logistic regression (81.48% accuracy) differentiated positive and negative cases using eyelid tremors ($p < 0.001$), lack of convergence ($p < 0.001$), rebound dilation ($p < 0.001$), Horizontal Gaze Nystagmus (HGN) ($p < 0.01$), and muscle tone ($p < 0.05$). Eyelid tremors, lack of convergence, rebound dilation, and normal muscle tone increased the odds of a case being cannabis-positive, whereas presence of HGN and rigid muscle tone increased the odds of a case being cannabis-negative. The multinomial regression model was 70.37% accurate and did not produce statistically significant indicators to distinguish between cannabis-only and polydrug-cannabis cases.

Conclusion: The results from this study provides statistical evidence that eyelid tremors and rebound dilation are the most robust observations that DRE's use when determining if there was recent cannabis use regardless of if the subject was impaired by cannabis alone or a combination with other drugs.

Cannabis, Drug Recognition Evaluation, Impairment

K39 Evaluating Cannabinoid Interference and Drug Stability in Oral Fluid for Driving Under the Influence of Drugs (DUID) Testing

Jasmine Maxwell, MSFS, University of Alabama at Birmingham, Birmingham, AL; Elizabeth Gardner, PhD, University of Alabama at Birmingham, Birmingham, AL; Curt E. Harper, PhD, University of Alabama at Birmingham, Birmingham, AL and Alabama Department of Forensic Sciences, Hoover, AL*

Learning Overview: After attending this presentation, attendees will have a better understanding of potential novel cannabinoid interference and the stability of cannabinoids in Oral Fluid (OF).

Impact Statement: This presentation will impact the forensic science community by presenting data on analyte and matrix interference on a cannabinoid OF assay with novel cannabinoids. This presentation will provide knowledge to the forensic science community about cannabinoid stability in authentic OF case specimens.

The Scientific Working Group for Forensic Toxicology (SWGTOX) method validation guidelines provide instructions on how to evaluate interference and stability. It is important that laboratories continuously monitor method performance, potential new interferents (e.g., isomers, metabolites), and analyte stability. The collection device, buffer, analyte chemical properties, and storage conditions are all factors in the stability of drug concentrations in OF.

OF drug testing is efficient due to its easy, fast, minimally invasive, gender-neutral collection. The applications of drug testing originated in workplace, probation, and pain management facilities, but now include use in DUID and postmortem investigations. OF can be used to establish probable cause at the roadside using devices such as the Dräger DT5000 or the Abbott® SoToxa and for laboratory evidentiary confirmation in DUID cases. Alabama has recently passed a new law, SB258, which gives OF tests the same “implied consent” legal standing as breath and blood test to detect alcohol and drugs after an arrest.

A previously validated liquid-liquid extraction for delta-9-Tetrahydrocannabinol (Δ^9 -THC), 11-Hydroxy-delta-9-Tetrahydrocannabinol (Δ^9 -THC-OH), delta-9-Tetrahydrocannabinol Carboxylic acid (Δ^9 -THC-COOH), Cannabidiol (CBD), Cannabinol (CBN), and Cannabigerol (CBG) followed by analysis using an Agilent® 6460 Triple Quadrupole Tandem Mass Spectrometer was used for this study. OF samples were collected using Quantisal™ collection devices from DUI subjects. Novel cannabinoids (6aR,9S)- Δ^{10} -tetrahydrocannabinol, (6aR,9R)- Δ^{10} -tetrahydrocannabinol, 9R- Δ^6 a,10a-tetrahydrocannabinol, 9S- Δ^6 a,10a-tetrahydrocannabinol, delta-8-Tetrahydrocannabinol (Δ^8 -THC), delta-8-Tetrahydrocannabinol Carboxylic acid (Δ^8 -THC-COOH), and 11-Hydroxy-delta-8-Tetrahydrocannabinol (Δ^8 -THC-OH) were evaluated for target interference with previously validated analytes listed above. Suspected negative OF specimens from volunteer subjects were evaluated for matrix interferences. Previously analyzed and simulated casework specimens were evaluated for stability at various time points up to two years.

Mobile phase A was 5mM of ammonium formate with 0.1% formic acid in water and mobile phase B was 0.1% formic acid in methanol. An Agilent® Poroshell 120 EC-C18 column (2.1 x100mm, 2.7 micron) was used. The LC gradient originally started with 50% mobile phase B for 1 minute, increasing to 65% B at 5 minutes, increasing to 95% B at 8 minutes, and holding at 95% B for 2 minutes. The modified method begins with 70% mobile phase B for 1 minute, increasing to 80% B at 4 minutes, and increasing to 99% B at 10 minutes, which resulted in baseline resolution of Δ^9 -THC, Δ^8 -THC, and (6aR,9R)- Δ^{10} -THC. Fourteen expectorate samples and one Quantisal™ sample had no interference in the blank matrix study. Thirty-two previously analyzed authentic specimens, collected from subjects in drug rehabilitation in Jacksonville, FL, were re-analyzed after two years (\pm two weeks) of storage at 4°C. All cases were previously positive for Δ^9 -THC. Upon reanalysis, 100% of cases were still positive at comparable concentrations. Preliminary analyses suggest effective stability of the Quantisal™ buffer over that time period.

Laboratories should evaluate their current methodology for potential interferents from novel cannabinoids, specifically Δ^9 -THC isomers and their metabolites. With the surge in Δ^8 -THC products throughout the United States, it is imperative that toxicological analyses have specificity to detect Δ^8 -THC and its metabolites. OF cannabinoid stability should also be evaluated over the expected testing time frame in the laboratory. This study has highlighted a cannabinoid OF method with suitable stability in Quantisal™ buffer and lack of interference.

Oral Fluid, Cannabinoids, Interference

K40 The Development and Validation of an Analytical Method for Ten Novel Designer Benzodiazepines in Blood Using Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS)

Pucheng Ke, PhD, U.S. Army Medical Department Student Detachment, Fort Sam Houston, TX and Houston Forensic Science Center, Houston, TX; Sara Dempsey, PhD, Houston Forensic Science Center, Houston, TX; Peter Stout, PhD, Houston Forensic Science Center, Houston, TX; Dayong Lee, PhD, Houston Forensic Science Center, Houston, TX*

Learning Overview: After attending this presentation, attendees will learn a practical LC/MS/MS-based analytical method for selected designer benzodiazepines.

Impact Statement: This presentation will impact the forensic science community by providing information on an analytical method for selected designer benzodiazepines.

Background/Introduction: Designer benzodiazepines have become a rapidly growing group of novel psychoactive substances abused in the U.S.¹ They have created significant challenges for forensic toxicology laboratories in detection and confirmatory testing. In addition, they have created loopholes in regulation and legal proceedings due to the unestablished Drug Enforcement Administration (DEA) classification status. Emerging illicit production and use of designer benzodiazepines have drawn increasing interest and attention from the forensic toxicology community.

Objective: The purpose of this research was to develop and validate an analytical method to reliably detect and quantify prevalent designer benzodiazepines in human blood using LC/MS/MS. The analytes were selected based upon recent designer benzodiazepine prevalence in the United States and cross-reactivity with the benzodiazepine Enzyme-Linked Immuno-Sorbent Assay (ELISA) currently used in this study's laboratory.¹

Method: The method was validated in accordance to the Academy Standards Board (ASB) Standard 036 (2019). The quantitative testing panel includes α -hydroxyetizolam, clonazepam, flualprazolam, deschloroetizolam, flubromazepam, desalkylflurazepam, etizolam, and declazepam. Adinazolam and flubromazepam are for qualitative analysis.

Following addition of internal standards (etizolam-d3 and temazepam-d5) in the specimen, analytes were extracted by a solid phase extraction utilizing CEREX® CLIN II column. Analytes were separated with an Agilent® 1290 Infinity II LC equipped with a 2.1x50mm, 2.7 μ m C18 column. Detection was performed using an Agilent® 6470B QQQ system with Electrospray Ionization (ESI) in positive mode and dynamic Multiple Reaction Monitoring (MRM).

Results: All analytes showed high ELISA cross-reactivity (135%–607%) at 20 g/mL. Calibration curves for quantitative analysis achieved R² values >0.99. LC/MS/MS run time was 5.5 minutes with analytes eluting between 2.1 and 3.5 minutes. Limits of Detection/Limits Of Quantitation (LODs/LOQs) for all ten analytes were 0.5ng/mL. A dynamic range of 0.5 to 100ng/mL was established for quantitation. All eight analytes for quantitative analysis showed acceptable %bias and %CV within $\pm 20\%$ at 1.5, 10, and 80ng/mL. No significant carryover was observed following samples containing the analyte up to 250ng/mL for all ten analytes. Dilution integrity was challenged with dilution factors of 2, 5, and 10. Average quantitation %bias was <20% with each dilution factor for all eight analytes. Matrix interference and ionization suppression/enhancement from multiple blank human blood samples and exogenous substances were evaluated. No significant interference was observed, except for deschloroetizolam coeluting with alprazolam. Both punctured and unpunctured samples stored inside LC/MS/MS multi-sampler at 4°C showed acceptable stability for at least 72 hours.

Conclusion/Discussion/Future Applications: The overall results demonstrated a reliable analysis of several emerging designer benzodiazepines in human blood. Once the method is approved for casework, the laboratory plans to apply the method to case samples that previously screened positive by ELISA but confirmed negative for traditional benzodiazepines. The development of the method for urine specimens is currently in progress.

K41 Quantitation of Synthetic Cannabinoid, 5F-MDMB-PICA, and its Metabolites in Authentic Human Biological Samples using Liquid Chromatography Tandem Quadrupole Mass Spectrometry (LC-QQQ-MS)

Sara Walton, MS, CFSRE, Willow Grove, PA; Alex Krotulski, PhD, CFSRE, Willow Grove, PA; Donna Papsun, MS, NMS Labs, Horsham, PA; Barry Logan, PhD, NMS Labs, Horsham, PA*

Learning Overview: After attending this presentation, attendees will be able to describe the method for quantitating the synthetic cannabinoid 5F-MDMB-PICA and assess concentrations in human samples.

Impact Statement: This presentation will impact the forensic toxicology community by providing methodology for the quantitation of a prevalent synthetic cannabinoid, 5F-MDMB-PICA, and showcasing authentic quantitative human data for this synthetic cannabinoid and its metabolites.

Synthetic cannabinoids, also called “K2” or “Spice,” are Novel Psychoactive Substances (NPS) and these drugs are constantly evolving. Varying chemistries and structures of this class and their recreational use provide challenges for forensic toxicologists. 5F-MDMB-PICA is a potent CB₁ receptor agonist first detected in Europe in 2016. This drug has subsequently been identified in the drug supply in the United States throughout 2021, at times being the most prevalent synthetic cannabinoid detected. As the popularity of synthetic cannabinoids increases, the need for sensitive methodology to determine concentrations in human biological samples is of great importance to assess the degree of exposure.

A sample preparation and extraction procedure were developed and validated. The method included 5F-MDMB-PICA and several of its metabolites (5F-MDMB-PICA 3,3-dimethylbutanoic acid, 5OH-MDMB-PICA, 6'-OH-5F-MDMB-PICA, 2COOH-MDMB-PICA, and 4OH-5F-MDMB-PICA 3,3-dimethylbutanoic acid). 5F-MDMB-PICA-D5 and 5F-MDMB-PICA 3,3-dimethylbutanoic acid-D5 were used as internal standards. The calibration range for 5F-MDMB-PICA was 0.5 to 500ng/mL, and the calibration range for the metabolites was 1 to 500ng/mL. Samples (0.2mL) were prepared using an acidic liquid-liquid extraction with 5% phosphoric acid in water and an extraction solvent consisting of hexane, ethyl acetate, and MTBE (80:10:10 v:v:v).

Quantitation was performed using a Waters® Xevo TQ-S micro LC/QqQ/MS. Chromatographic separation was achieved on an Agilent® InfinityLab Poroshell 120 EC-C18 (3.0 x 100 mm, 2.7µm) under gradient elution. Mobile phase compositions were 0.1% formic acid in water and 0.1% formic acid in methanol. The flow rate was 0.4mL/min, injection volume was 5µL, and column temperature was 30°C. Authentic samples suspected of containing 5F-MDMB-PICA were obtained for analysis from NMS Labs. Samples were collected as part of for-cause forensic investigations and were deidentified prior to use; however, demographic data were still available.

Quantitative analysis was performed on blood (n=44), serum/plasma (n=2), urine (n=7), vitreous fluid (n=10), bile (n=1), and gastric contents (n=1). Samples were collected between 2018 and 2019. The case types were primarily postmortem, but Driving Under the Influence of Drugs (DUID) and clinical cases were also included. Cases originated from 12 states. 5F-MDMB-PICA was qualitatively identified in 17 blood samples and quantitatively confirmed in 23 blood samples. Blood concentrations of 5F-MDMB-PICA ranged from 0.5 to 6.2ng/mL (mean: 2.2 ± 1.7ng/mL, median: 1.4ng/mL). All DUID cases (n=4) had concentrations between 0.5 and 1ng/mL.

5F-MDMB-PICA 3,3-dimethylbutanoic acid was confirmed in 44 blood samples ranging from 1.7 to 272ng/mL (mean: 39 ± 61ng/mL, median: 17ng/mL). 5OH-MDMB-PICA (n=23, mean: 6.4 ± 9.2ng/mL, median: 3.5ng/mL, range: 1–46ng/mL), 4'-OH-5F-MDMB-PICA 3,3-dimethylbutanoic acid (n=24), and 2COOH-MDMB-PICA (n=1) were also identified in the blood samples.

5F-MDMB-PICA was also confirmed in urine (n=6), serum/plasma (n=2), vitreous fluid (n=5), bile (n=1), and gastric contents (n=1, 36ng/mL). 5F-MDMB-PICA was discovered alongside other synthetic cannabinoids (4F-MDMB-BINACA), classic cannabinoids (THC), benzodiazepines, stimulants, and therapeutic drugs.

5F-MDMB-PICA is a prevalent synthetic cannabinoid and was confirmed at low ng/mL concentrations. Two primary metabolites, 5F-MDMB-PICA 3,3-dimethylbutanoic acid and 5OH-MDMB-PICA, were also identified and show the need for sensitive instrumentation and a wide calibration range. 5F-MDMB-PICA is still being identified in 2021, and the presence of 5F-MDMB-PICA with other synthetic cannabinoids, such as 4F-MDMB-BINACA, shows the need for continued research on these newly emerging drugs.

Toxicology, Human, Overdose

K42 An Explanation and the Impacts of a Class-Wide Ban on Synthetic Cannabinoids: What Does the Future Hold for This Already Challenging Novel Psychoactive Substances (NPS) Subclass?

Alex Krotulski, PhD, CFSRE, Willow Grove, PA; Judith Rodriguez Salas, MSFS, CFSRE, Willow Grove, PA; Amanda Mohr, MSFS, CFSRE, Willow Grove, PA; Barry Logan, PhD, NMS Labs, Horsham, PA*

Learning Overview: After attending this presentation, attendees will be able to assess the impacts of a class-wide ban on synthetic cannabinoids and how this could affect forensic casework and testing.

Impact Statement: This presentation will impact the forensic science community by expanding knowledge of synthetic cannabinoids as it relates to legislation, nomenclature, and emerging drug trends.

Synthetic cannabinoids make up the most structurally diverse subclass of NPS and, as such, are undoubtedly the most challenging analytical targets for forensic scientists. Analytical challenges arise due to chemical diversity compared to more traditional drugs and NPS subclasses, compounded by the need for high instrumental sensitivity due to increasing potencies. Reporting and interpretation are also challenging due to inconsistent naming conventions and lack of published data regarding pharmacology, toxicity, and drug concentrations. Remaining abreast of current knowledge for synthetic cannabinoids requires constantly evolving expertise.

Through the NPS Discovery program, the non-profit Center for Forensic Science Research and Education (CFSRE) tracks the emergence of new synthetic cannabinoids through both conventional and non-conventional data sources. Since 2018, this laboratory has employed aggressive sample-mining and data-mining workflows via Liquid Chromatography/quadrupole Time-Of-Flight/Mass Spectrometry (L/-qTOF/MS) to discover new synthetic cannabinoids on the recreational drug market and to monitor trends with respect to drug positivity and proliferation. The largest source of data remains the analysis of authentic forensic toxicology samples, followed by drug materials and clinical samples. In addition, this study's scientists review drug use forums and online gray market vendor websites to gather intelligence about next-generation NPS.

In May 2021, China announced new national legislation that included the class-wide scheduling of synthetic cannabinoids based on core structural features—a move that surprised most in forensic science circles. While core-structure scheduling is not a new concept (e.g., fentanyl and its analogs), this announcement differed in that its purpose was to control an entire subclass of drugs rather than an individual structurally related family. Synthetic cannabinoids were structurally outlined under the regulation based on combined core/linker moieties and further defined by head and tail constituents. Core/linker structures included commonly encountered indoles and indazoles, as well as gamma-carboline, cyclohexylphenols, and others. Tail constituents included varying length hydrocarbons, both substituted and unsubstituted, as well as heterocyclic groups. Head constituents included a large variety of substituted and unsubstituted groups. The effective date for this legislation was listed as July 2021.

In Q1 and Q2 2021, MDMB-4en-PINACA, 5F-MDMB-PICA, ADB-BINACA, and 4F-MDMB-BICA were the most prevalent synthetic cannabinoids identified in forensic casework in the United States. Of these four, 5F-MDMB-PICA was the only drug to be explicitly scheduled by the Drug Enforcement Administration as of August 2021. However, all four drugs are covered under the new Chinese ban: MDMB-4en-PINACA and ADB-BINACA are indazole derivatives while 5F-MDMB-PICA and 4F-MDMB-BICA are indole derivatives. By June 2021, this study's laboratory had already identified a synthetic cannabinoid that would not be covered by the ban: 5F-AB-PFUPPYCA. In the next few months, online reviews of gray market vendors showed the gradual disappearance of variants that were included under the outlined legislation and the emergence of those that could be considered "legal," including a series of MDA-19 (BZO-HEXOXIZID) analogs. In August 2021, tentative identifications of the pentyl and 5-fluoropentyl analogs of MDA-19 were reported (or BZO-POXIZID and 5F-BZO-POXIZID by systematic nomenclature, respectively).

National and international drug control policies can impact the presence and prevalence of NPS on recreational drug markets. Due to recent actions, the synthetic cannabinoid subclass will require increased monitoring over the coming months as new drugs emerge with the goal of evading class-wide bans. Forensic toxicologist must continue research and evaluation of these substances, especially as pharmacology and toxicity are unknown.

Synthetic Cannabinoid, Legislation, Toxicology

K43 The 2021 Novel Psychoactive Substance (NPS) Landscape: The New, the Nuanced, and the Long-Haulers

Donna Papsun, MS, NMS Labs, Horsham, PA; Alex Krotulski, PhD, CFSRE, Willow Grove, PA; Barry Logan, PhD, NMS Labs, Horsham, PA and CFSRE, Willow Grove, PA*

Learning Overview: After attending this presentation, attendees will be able to describe the 2021 NPS landscape encountered in forensic toxicology casework.

Impact Statement: This presentation will impact the forensic sciences by providing an up-to-date snapshot of emerging substances.

NPS are generally characterized as those that have emerged on recreational drug markets since the mid-2000s, whether newly synthesized or repurposed from past scientific research, and/or substances that are being used in a differing manner from original intended use. The NPS landscape is in a constant state of flux as new substances enter the market and old, newly controlled, and/or those out-of-favor exit. These challenges require substantial resources in monitoring and investigating new substances, implementing new or modified testing protocols, and disseminating information.

To provide a comprehensive and current snapshot of the 2021 NPS landscape, all blood cases reporting synthetic stimulants/hallucinogens, Synthetic Cannabinoids (SC), Designer Benzodiazepines (DBZD) and/or Novel Synthetic Opioids (NSO) for the first seven months of 2021 were queried from a large reference laboratory. Reports with more than five cases are listed below.

Synthetic stimulants, along with SCs, historically were the two main classes of NPS, with several generations of substances emerging since the mid-2000s. Eutylone continues to be the current dominant synthetic stimulant, accounting for over 95% of the synthetic stimulant/dissociative blood reports. For SCs, 5-fluoro-MDMB-PICA accounted for 48.2% of reported blood cases. MDMB-4en-PINACA and 4-fluoro-MDMB-BINACA accounted for 32 and 8.9%, respectively.

There has been an increase in number and variety of DBZD. In total, 15 different DBZD (with 3 metabolite pairs) have been reported in the first seven months of 2021. Etizolam, which was first reported to the European Union (EU) Early Warning System in 2011, accounted for over 62% of blood DBZD cases, along with its metabolite alpha-hydroxyetizolam. Flualprazolam, flubromazolam, clonazolam/8-aminoclonazolam, and bromazolam account for 15.9, 9.4, 6.0, and 2.9% of DBZD blood detections, respectively. Diclazepam/delorazepam, flubromazepam, and bromazepam account for 1.2, 0.9, and 0.7%, respectively.

NSOs, due to their significant threat to public health, have garnered a significant amount of attention since 2016. Despite core structure scheduling enacted for fentanyl analogs, many of these substances continue to be detected, although on an infrequent basis. Butyrylfentanyl, valeryl fentanyl, and para-fluorobutyrylfentanyl were reported less than 13 times each, while a number of other fentanyl analogs were reported in lower numbers. Carfentanil continues to maintain a presence, accounting for 8.3% of reported blood cases involving NSOs. Novel non-fentanyl related opioids isotonitazene, buprenorphine, and metonitazene have accounted for 0.5, 2.0, and 3.8% reported blood NSO cases. Accounting for over 82% of reported NSO findings, the frequency of para-fluorofentanyl detections and reporting has greatly increased in 2021. In most cases, fentanyl was detected in conjunction with para-fluorofentanyl, which raises the questions of sourcing, adulteration, and trafficking.

Other atypical opioid agonists include tianeptine and mitragynine; tianeptine has been reported in 12 blood cases and mitragynine has been reported over 1,060 times in the first seven months of 2021.

NPS reports in 2021 included over 40 compounds representing the various subclasses. Some of these compounds, including etizolam and mitragynine, have been reported for almost a decade, which begs the question of when to transition a compound from “emergent” and “NPS” to part of the routine or traditional drug testing scopes. Conversely, some NSOs are emerging and disappearing quickly, within lifespans of less than a year. Para-fluorofentanyl has emerged and proliferated so rapidly that its positivity characteristics are more aligned with supply chain for illicit narcotics rather than NPS. Assessment of the 2021 NPS landscape remains challenging. Understanding that positivity is underestimated due to lags in testing implementation and lack of inclusion in testing scopes is vital.

Novel Psychoactive Substances, Novel Synthetic Opioids, Designer Benzodiazepines

K44 Multimodality Surveillance of Adverse Events of Designer Stimulants From 2013 to 2020

Jeri Ropero-Miller, PhD, RTI International, Research Triangle Park, NC; Amanda Mohr, MS, CFSRE, Willow Grove, PA; Barry Logan, PhD, NMS Labs, Horsham, PA; Marilyn Huestis, PhD, Huestis & Smith Toxicology, LLC, Severna Park, MD*

Learning Overview: After attending this presentation, attendees will understand and be able to describe the adverse events and toxicological signs and symptoms associated with designer stimulant use.

Impact Statement: This presentation will impact the forensic science community by increasing awareness of adverse events associated with designer stimulant use to better characterize international emerging drug threats.

Introduction: An important role of modern forensic and clinical toxicologists is to monitor the adverse events of Novel Psychoactive Substances (NPS). This presentation describes adverse events from case reports and reference data on NPS designer stimulants during an eight-year period from 2013–2020. The primary objective of this study is to assist in the assessment and interpretation of these cases as well as provide references for confirmation methods. Chemistry, pharmacology, adverse events, and user profiles (e.g., polypharmacy) for novel stimulants are provided including case history, clinical symptoms, autopsy findings, and analytical results.

Methods: Literature reviews were performed in PubMed® and Google® Scholar for publications dated between January 2017 and December 2020.^{1,4} Search terms included NPS-specific names, general terms (e.g., “designer drugs,” “novel psychoactive substances”) and drug class (e.g., “designer stimulants”), as well as outcome-based terms (e.g., “overdose,” “death”). Government and website drug surveillance databases were also reviewed (e.g., National Forensic Laboratory Information System [NFLIS], European Monitoring Centre for Drugs and Drug Addiction [EMCDDA], NPS Discovery). Abstracts published by the Society of Forensic Toxicologists (SOFT) and American Academy of Forensic Sciences (AAFS) were also investigated. Toxicological data and detailed case information were extracted, tabulated, analyzed, and organized by drug category. Similar methods were used in the initial study from 2013–2016.³

Results: From 2017 to 2020, This study found 64 case reports of designer stimulants reported in the literature and in drug surveillance systems for fatalities (41 cases), clinical treatment and hospitalization (21 cases), and Driving Under the Influence of Drugs (DUID) (2 cases). This is nearly a 400% increase in designer stimulants case reports compared to those reported in the previous four years.³ Confirmed adverse events with associated toxidromes of ten designer stimulants were reported: 4F-MPH, 4-MEAP, 4F- α PVP, Dibutylone, EPH, MPHP, NEH, NEP, α -EAP, and α -PHP5. The toxicity profile of the designer stimulants included agitation, psychosis, delusions, aggression, irritability, paranoia, delirium, hallucinations, sedation, coma, abnormal behavior, altered fluctuating consciousness, tachycardia, hypertension, palpitations, increased respiration rate, hypothermia, mydriasis, rhabdomyolysis, compartment syndrome, and sweating. Common autopsy findings included organ edema and congestion. Almost 70% of the cases had multiple drugs confirmed. The observations and analytical methods associated with these postmortem, clinical, and DUID cases will be discussed.

Conclusion: This study provides insight and context of case findings for postmortem, clinical, and DUID reports for novel stimulants described in the literature and in digital government surveillance databases and websites during the past eight years.

Novel Psychoactive Substances, Designer Stimulants, Adverse Events

K45 An Evaluation of Enzyme-Linked Immuno-Sorbent Assay (ELISA) for the Detection of Novel Psychoactive Benzodiazepines

Christie Mitchell-Mata, MFS, Cuyahoga County Regional Forensic Science Laboratory, Cleveland, OH; Szabolcs Sofalvi, MSc, Cuyahoga County Regional Forensic Science Laboratory, Cleveland, OH; Shelby Travaglianti, University of Toledo, Toledo, OH; Luigino Apollonio, PhD, Cuyahoga County Regional Forensic Science Laboratory, Cleveland, OH*

Learning Overview: This presentation will provide attendees with an understanding of the capability of ELISA to detect novel psychoactive benzodiazepines and select metabolites in toxicology casework.

Impact Statement: This presentation will impact the forensic science community by providing valuable insight into the use of ELISA technology to detect novel psychoactive benzodiazepines and metabolites in blood, thereby assisting in the interpretation of screening results to direct further testing.

With the continued emergence of novel psychoactive substances (NPS), the detection and confirmation of NPS has become of increasing interest to the forensic toxicology community. Several benzodiazepines are among the emerging group of NPS and, in response, an in-house Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) method was developed to detect 40 benzodiazepines. Among these are 17 NPS benzodiazepines that are not currently listed as having been investigated for cross-reactivity with the Immunalysis™ Benzodiazepine Direct ELISA kit.^{1,2} The 17 benzodiazepines and/or metabolites are as follows: alpha-hydroxymidazolam, alpha-hydroxytriazolam, bromazolam, N-desmethyloclobazam, 3-hydroxyflunitrazepam, phenazepam, deschloroetizolam, clonazolam, delorazepam, diclazepam, flualprazolam, flunitrazolam, 4-hydroxyalprazolam, meclonazepam, methylclonazepam, nitrazolam, and pyrazolam.

In the study presented, the 17 compounds listed above were spiked individually into drug-negative blood (synthetic) at the corresponding Lower Limit of Quantitation (LLOQ) detailed in the LC/MS/MS method.¹ Each sample was then analyzed using the Tecan Freedom EVO 100/4 (with Tecan Sunrise Reader) to determine the cross-reactivity with the Benzodiazepine Direct ELISA kit. A specimen absorbance less than or equal to the cutoff calibrator absorbance indicates a positive finding, whereas a specimen absorbance that is higher than the cutoff calibrator but within 30% is considered elevated and an absorbance greater than the cutoff calibrator absorbance indicates negative.

The following compounds were positive at the LLOQ concentration: alpha-hydroxymidazolam (10ng/mL), alpha-hydroxytriazolam (10ng/mL), bromazolam (10ng/mL), N-desmethyloclobazam (10ng/mL), phenazepam (10ng/mL), delorazepam (5ng/mL), diclazepam (5ng/mL), flualprazolam (5ng/mL), flunitrazolam (5ng/mL), 4-hydroxyalprazolam (5ng/mL), methylclonazepam (5ng/mL), nitrazolam (5ng/mL), and pyrazolam (5ng/mL). Those compounds that did not flag as positive at the LOQ were then ran at higher concentrations until a positive result was obtained. The following four compounds were positive at higher concentrations: 3-hydroxyflunitrazepam (20ng/mL), deschloroetizolam (4ng/mL), clonazolam (10ng/mL), and meclonazepam (25ng/mL). The concentrations triggering a positive response is a particularly valuable demonstration considering a 100% ELISA positive corresponds to 100ng/mL of the target compound, oxazepam.

This study helps in understanding the cross-reactivity of the 17 benzodiazepines and/or metabolites studied and can help navigate testing protocol for specimens when novel psychoactive benzodiazepines are suspected.

ELISA, Benzodiazepines, Novel

K46 An Analysis of Methylphenidate, Ethylphenidate, Lisdexamfetamine, and Amphetamine in Oral Fluid by Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS)

Christina Smith, BS, Sam Houston State University, Huntsville, TX; Madeleine Swortwood, PhD, Sam Houston State University, Huntsville, TX*

Learning Overview: After attending this presentation, attendees will understand how to effectively isolate and quantify various stimulants from Oral Fluid (OF).

Impact Statement: This presentation will impact the forensic community by providing a Solid Phase Extraction (SPE) method for cognitive-stimulants from OF. Additionally, a novel approach to quantify these stimulants using LC/MS/MS will be presented.

Attention-Deficit/Hyperactivity Disorder (ADHD) is a disorder in the brain that is more commonly studied in children and adolescents. In more recent years, there has been an increase in cognitive stimulant abuse at the collegiate level. Students illicitly use these medications to speed up brain activity to perform better in their studies. There are various medications that are commonly prescribed to treat ADHD such as Methylphenidate (MPH), Lisdexamfetamine (LDX), and Amphetamine (AMP). There are limited methods that analyze multiple compounds in a single assay using Solid Phase Extraction (SPE) and LC/MS. For this reason, the goal was to develop a broad method to isolate multiple cognitive stimulant drugs from OF. OF is an alternative matrix that is non-invasive and allows for quick collection. The objective of this study was to develop and validate a method to isolate MPH and its metabolite, Ethylphenidate (EPH), LDX and AMP and quantify them in OF utilizing LC/MS/MS.

MPH, EPH, LDX, and AMP were extracted using SPE. OF samples (250µL OF: 750µL Quantisal® extraction buffer) were fortified with calibrator (25µL) or control (10µL) and internal standard (25µL) solutions. Drugs were isolated using a pre-conditioned, mixed mode polymeric SPE column and eluted with 5% ammonium hydroxide in dichloromethane:isopropyl alcohol (80:20). Analysis was performed on an Agilent® 1290 Infinity liquid chromatograph coupled to an Agilent® 6470 Triple Quadrupole mass spectrometer with a gradient elution starting at 90:10 mobile phase A:B at 0.4mL/min. Mobile phase A was 5mM ammonium formate and 0.05% formic acid (FA) in diH₂O. Mobile phase B was 0.1% FA in acetonitrile. A multiple reaction monitoring (MRM) method with one transition for qualification and one transition for quantification was used for analyte detection. This method was validated according to American National Standards Institute/Academy Standards Board (ANSI/ASB) Standard 036. For proof of applicability, authentic OF samples (n=4) were collected via Quantisal® OF collection device in an Institutional Review Board (IRB) -approved study and analyzed as above.

MPH, EPH, and AMP had a linear range of 0.5–500ng/mL and —500ng/mL for LDX ($R^2 > 0.99$). Limit of Detection (LOD) and Limit Of Quantitation (LOQ) for MPH, EPH, and AMP was 0.25 and 0.5ng/mL, respectively. LOD and LOQ for LDX were both 5ng/mL. Extraction recovery was >90% for all analytes. Matrix effects displayed suppression for all analytes except LDX, which displayed enhancement. Bias ranged from -1—6.1% with maximum within-run precision of 15.7% for all analytes at three concentrations. Processed sample stability in the autosampler (4°C, 24h) was evaluated and all compounds were considered stable ($\pm 17\%$ bias). Dilution integrity was sustained at a factor of 1/10 ($< 7.3\%$ bias). No carryover or interferences (exogenous, endogenous, or stable-isotope) were observed. Authentic OF samples were collected within six hours of prescribed dose and were positive for LDX (n=1) and AMP (n=4). LDX was detected at 5.8ng/mL, while mean (range) AMP concentrations were 34.4 (6.0–78.8) ng/mL. These results are consistent with the prescribed medications reported.

The developed technique provides a fully validated quantification method for select cognitive stimulants in OF by LC/MS/MS. Additionally, this method was used to successfully analyze authentic OF samples containing LDX and AMP. The present research is relevant for advancement of routine forensic practices with the evolving trend of abuse of these drugs.

Stimulants, Oral Fluid, LC/MS/MS

K47 An Assessment of Biological Matrices for the Detection of *In Utero* Cannabis Exposure

Marta Concheiro, PhD, John Jay College of Criminal Justice, New York, NY; Frank Martin Gutierrez, BS, John Jay College of Criminal Justice, New York, NY; Alejandro Ocampo, BS, John Jay College of Criminal Justice, New York, NY; Elena Lendoiro, PhD, Universidade de Santiago de Compostela, Santiago de Compostela, A Coruña, Spain; Eva González-Colmenero, MD, PhD, Complejo Hospitalario Universitario de Vigo, Vigo, Pontevedra, Spain; Ana Concheiro-Guisán MD, PhD, Complejo Hospitalario Universitario de Vigo, Vigo, Pontevedra, Spain; Manuel López-Rivadulla, PhD, Universidade de Santiago de Compostela, Santiago de Compostela, A Coruña, Spain; Ana de-Castro-Ríos, PhD, Universidade de Santiago de Compostela, Santiago de Compostela, A Coruña, Spain*

Learning Overview: After attending this presentation, attendees will have a better understanding of the best biological matrices and biomarkers for detecting cannabis use during pregnancy and child exposure.

Impact Statement: This presentation will impact the forensic science community by presenting evidence of the best analytical tools to detect child cannabis exposure during pregnancy.

Cannabis consumption has been increasing worldwide among pregnant women. According to the 2017 National Survey on Drug Use and Health, 7% of pregnant women used cannabis in the past month, a 1.3% increase from the 2014 survey. As a result of the increase in legalization and decriminalization of marijuana at the state level across the United States, this upward trend is expected to continue rising. Due to the negative effects of prenatal cannabis exposure, it is necessary to develop an objective, sensitive, and specific method to determine cannabinoids use during pregnancy and child exposure.

This study compared four different biological samples—maternal hair, meconium, umbilical cord, and placenta—for the detection of *in utero* cannabis exposure. The biological samples were collected from 627 mother–newborn dyads. All hair and meconium samples were analyzed, and umbilical cord and placenta if hair and/or meconium were positive for cannabinoids. Maternal hair samples were divided into three segments corresponding to the three trimesters of pregnancy, when possible. All analysis were performed by liquid chromatography/tandem mass spectrometry-validated procedures.

Among the 627 cases, 32 cases (5.1%) tested positive for cannabinoids in maternal hair and/or meconium. Meconium and hair showed to complement each other, with an agreement between hair and meconium results of 96.7%, but only 34.3% if just positive results were considered. Umbilical cord and placenta results showed a better agreement with meconium (91.3% and 92.6%, respectively) than with hair (39.1% and 34.6%, respectively). Tetrahydrocannabinol (THC) hair concentrations ranged from 51.3 to 1,002.8pg/mg. The predominant metabolites in meconium were 11-nor-carboxy-THC (THCCOOH) and 8,11-dihydroxy-THC (diOHTHC), and in umbilical cord and placenta was THCCOOH-glucuronide. Cannabidiol (CBD) and Cannabinol (CBN) were detected in meconium but not in any umbilical cord or placenta. Cannabinoids' concentrations in meconium were higher (up to 887.4ng/g) than in placenta and umbilical cord (up to 28ng/g).

For the first time, prenatal marijuana exposure was analyzed and compared in paired hair, meconium, umbilical cord, and placental samples. Hair and meconium positivity rate was similar, but a more sensitive and specific analytical method for the hair may resolve discrepancies between the matrices. Umbilical cord and placenta may be considered suitable alternative matrices to meconium through the determination of THCCOOH-glucuronide as a biomarker of cannabis exposure.

Cannabis, Hair, Meconium

K48 An Evaluation of Three Extraction Techniques for the Analysis of 11 Drugs and Metabolites in Authentic Hair Reference Material

Brianna Spear, MS, Florida International University, Miami, FL; Anthony DeCaprio, PhD, Florida International University, Miami, FL*

Learning Overview: After attending this presentation, attendees will understand which of three commonly used techniques is optimal for extraction of each of a variety of abused drugs and metabolites from hair.

Impact Statement: This presentation will impact the forensic science community by presenting the most effective extraction techniques for analysis of oxycodone, diazepam, nordiazepam, methamphetamine, cocaine, cocaethylene, norcocaine, p-hydroxycocaine, morphine, 6-acetylmorphine, and fentanyl in hair and by providing data toward creating standardized procedures for hair testing.

Hypothesis: The hypothesis of this work is that different drugs will be extracted most effectively from hair using different extraction techniques, based on the physicochemical properties of the drugs of interest.

There are many differing opinions regarding the optimal methods for forensic hair analysis, especially concerning pretreatment and extraction parameters. Extraction methods include enzymatic, acid/base, and solvent techniques, each with their own advantages and disadvantages. The Society of Hair Testing (SoHT) suggests that any extraction technique can be utilized with the use of adequate control samples. This lack of consensus regarding best practice extraction methods contributes to possible bias in hair testing across multiple laboratories. Previous research in this laboratory has focused on pretreatment parameters, such as hair particle size, extraction solvent to sample size ratio, and extraction time. However, published work has not assessed the best extraction techniques for different drugs and metabolites of interest.

Authentic Hair Reference Material (HRM) containing the drugs of interest was obtained from a commercial source. Samples of 20mg each were weighed into steel milling jars. The hair samples were pulverized into a powder using a Retsch MM200 ball mill with chrome-steel milling beads at 3,800rpm for 30s. The samples were extracted using one of three techniques: a 2-h incubation in 12.5 µL/mg hair of methanol:acetonitrile:2mM ammonium formate (25:25:50, v/v/v) at 37°C (solvent swelling technique), a 2-h incubation in 12.5µL/mg hair of 1M NaOH at 37°C (base technique), or a 2-h incubation in 12.5µL/mg hair of aqueous 12mg/mL dithiothreitol and 2mg/mL proteinase K at 37°C (enzymatic degradation technique). The samples were then transferred into Eppendorf tubes and centrifuged for 30min. Post-centrifugation, the eluent was subjected to solid phase extraction using an Agilent® Bond Elut LRC mixed mode C8 and Strong Cation-Exchange (SCX) cartridge. An Agilent® 1290/6460 Liquid Chromatography/Triple Quadrupole/Mass Spectrometry (LC/QqQ/MS) was used for analysis.

Recovery of each drug by each extraction technique was evaluated to determine which methods were most effective. Those with the highest extraction recovery included solvent swelling (for diazepam, nordiazepam, cocaine, p-hydroxycocaine, oxycodone, and 6-acetylmorphine), base (for fentanyl), and enzymatic degradation (for methamphetamine, cocaethylene, norcocaine, and morphine). In conclusion, the most effective extraction technique for removing drugs/metabolites from authentic HRM varies based on the physicochemical properties of the drugs of interest.

Forensic Hair Analysis, Extraction Techniques, Authentic Hair Reference Material

K49 Fantastic Cases and Where to Find Them

Katherine Dozier, PhD, Armed Forces Medical Examiner System, Dover, DE; Bryan Platt, MD, Armed Forces Medical Examiner System, Dover, DE; Eric Berg, MD, Armed Forces Medical Examiner System, Dover, DE and Dept of Pathology Blanchfield Army Community Hospital, Ft Campbell, KY*

Learning Overview: After attending this presentation, attendees will be familiar with the problem-solving approach required for difficult, non-standard forensic toxicology cases. Attendees will also understand the importance of fully utilizing all testing options available to report the forensically correct, scientifically accurate results.

Impact Statement: This presentation impacts the forensic science community by demonstrating the thought process required for difficult, non-standard forensic toxicology cases, and provides insights that can be applied to all forensic casework.

The Division of Forensic Toxicology at the Armed Forces Medical Examiner System (AFMES) is the only military forensic toxicology laboratory that can test postmortem, investigative, drug-facilitated sexual assault, Driving Under the Influence/Driving While Intoxicated (DUI/DWI), and other case types. Due to the unique mission of AFMES, submissions are received from military personnel stationed around the globe. Primary matrices are blood and urine, but there is the capability to test and report from tissue, vitreous, and more.

Case 1: A drunk-on-duty investigation provides multiple blood specimens, along with a urine specimen. However, upon testing, the one sodium fluoride blood tube confirms for ethanol, but there is no ethanol present in the urine. After a different blood tube is tested and confirmed positive for ethanol, the laboratory explores the possibility of the oxidative agents in the urine. The urine specimen is sent for validity testing and found to be valid, with no oxidative agents present.

Case 2: The laboratory's synthetic cannabinoid confirmation method is validated for blood and urine. However, an exsanguination case that screened presumptively positive for synthetic cannabinoids leaves the laboratory with no blood or urine specimens for confirmation. An examination of the available specimens yields a bloody tissue sample that holds the answers the laboratory seeks.

Case 3: A decedent is found unresponsive and later dies in the hospital after prolonged treatment. None of the specimens give any clues to cause or manner of death. However, a shirt covered in gastric contents was also found at the scene, and later provides the information that the laboratory needs in order to help the forensic pathologist determine cause and manner.

This presentation will examine each of these cases and the problem-solving necessary to effectively report the forensic toxicology results. As new cases are submitted to AFMES from around the world, the laboratory is poised to continue problem-solving.

Postmortem, Ethanol, Synthetic Cannabinoid

K50 Quantifying the Relationship Between 1-Propanol and Postmortem-Formed Ethanol

Robert Kronstrand, PhD, National Board of Forensic Medicine, Linköping, SE, Sweden; Shimpei Watanabe, PhD, RIKEN Spring-8 Center, Nyoogo, JP, Japan; Markus Roman, BSc, National Board of Forensic Medicine, Linköping, SE, Sweden*

Learning Overview: After attending this session, attendees will better understand the risk of postmortem ethanol formation, how to identify it, and how to interpret postmortem ethanol concentrations.

Impact Statement: This presentation will impact the forensic science community by providing attendees with means to identify and quantify postmortem formation of ethanol using two independent markers of postmortem ethanol formation, 1-propanol and ethylsulphate.

Analysis of ethanol and other alcohols is routinely performed as part of the postmortem investigation. However, the detection of ethanol does not necessarily reflect ingestion since it can be formed during the decomposition process when fungi and bacteria start to ferment the available substrates to produce energy. During this process, in addition to ethanol, acetaldehyde, butanol, and propanol can also be produced. A common approach to diagnose postmortem ethanol is to analyze two matrices, preferably femoral blood and vitreous. The ethanol concentration in vitreous usually is slightly higher than the one in blood as a result of the matrix water content. Another approach is to analyze for propanol and butanol as markers for postmortem formation. A third means is to analyze the direct ethanol metabolite, Ethyl Sulphate (EtS), that is only formed *in vivo*. A negative result for EtS excludes ingestion of ethanol.

The objectives of this study were to develop and validate a method for the quantitation of methanol, ethanol, acetone, isopropanol, propanol, and butanol and to investigate the relationship between propanol concentration and ethanol concentration in EtS negative cases.

Alcohols were analyzed by head space Gas Chromatography/Flame Ionization Detector (GC/FID). Samples were prepared by dispensing 0.1mL blood, 0.5mL water containing internal standard *t*-butanol, and 0.5mL saturated potassium carbonate solution in head space vials. Calibration ranged from 0.01mg/mL to 2.5mg/mL for methanol, ethanol, acetone, and isopropanol and from 0.001mg/mL to 0.25mg/mL for propanol and butanol.

EtS was analyzed qualitatively by Supercritical Fluid Chromatography (SFC) and mass spectrometry. After the addition of deuterated internal standard, 0.5g of blood was prepared by protein precipitation with 1mL ice-cold methanol. Threshold for EtS was 0.025µg/g. Mobile phase A was carbon dioxide and phase B was 0.1 % ammonia in 90/10 methanol/water with a flow rate of 2.5mL/min. Sixty-four cases with suspected postmortem ethanol formation were included. Of the cases, 41 were negative for EtS but contained ethanol up to 1.35mg/mL, with 11 cases above 0.50mg/mL. All cases but two cases were positive for propanol (0.002–0.105mg/mL). The coefficient of determination between propanol and ethanol in all cases was 0.12 but 0.39 when only EtS negative cases were included.

This study concludes that propanol explains around 40% of the variation of ethanol in cases where all ethanol was formed postmortem. It also concludes that at least 1.35mg/mL of ethanol can be produced postmortem.

Postmortem Ethanol Formation, 1-Propanol, Ethylsulphate

K51 Branching Out: A Report of a Fatal Intoxication Case Involving 2-Methyl-2-Butanol

Michael Lamb, MS, NMS Labs, Horsham, PA; Carolina Noble, PhD, NMS Labs, Horsham, PA; Mark Annand, BS, NMS Labs, Horsham, PA; Frederick Strathmann, PhD, NMS Labs, Horsham, PA*

Learning Overview: After attending this presentation, attendees will have a better understanding of the abuse of 2-methyl-2-butanol, a substance abused as an alternative for ethanol or benzodiazepines. Additionally, this presentation will describe an effective analytical method developed and validated in the laboratory to identify and quantify 2-methyl-2-butanol.

Impact Statement: The forensic science community will benefit from the reporting of an uncommon finding and be alerted about its potential for abuse.

Tert-Amyl Alcohol (TAA) or 2-methyl-2-butanol is a tertiary alcohol commercially used as an intermediate in organic synthesis and as a solvent for a wide variety of industrial products such as paint removers, among others. TAA is also a metabolic product of the O-demethylation of Tert-Amyl-Methyl Ether (TAME), both used as a gasoline oxygenate additives, and with psychoactive effects.^{1,2}

2-methyl-2-butanol has originally been used as an anesthetic and recently reported in forensic case investigations as a recreational substance due to its benzodiazepine and ethanol-like effects. Additionally, this alcohol is easy to obtain, affordable, and usually not detectable via routine screening analysis. A case report of a 28-year-old male that attempted suicide using TAA quantified 83µg/mL of TAA in the blood, deep coma, respiratory failure, and tachycardia as the main observed symptoms.³

Pharmacological data is scarce in the scientific literature for TAA. However, *in vitro* experiments estimated a potency of TAA at the GABAA receptors around 10–20 times higher than that of ethanol.²

The aim of this study is to report the second case received in the laboratory where TAA was detected, and the analysis used in the laboratory to quantify this substance in the blood sample.

Quantitative determination of TAA in blood was approached as a custom assay development with supporting validation data. Blank patient samples (no standard added) were prepared diluted and neat in tandem with three fortified levels of standard addition at 0.5, 1.0, and 5.0µg/mL. Fifty µL of 0.00625% v/v 1,4-Dioxane was added as the internal standard. Analysis of the sample was performed by headspace Gas Chromatography/Mass Spectrometry (GC/MS) method using Single Ion Monitoring (SIM) mode: quantifier ion 73 and qualifier ions 59,71.

In the presented case received in May 2021 from New Jersey, a 37-year-old male with a history of substance abuse (heroin and alcohol) was found deceased without an obvious cause of death. The toxicological findings based on the originally requested testing showed only the presence of 13mg/dL acetone in the blood; further analysis of beta-hydroxybutyric acid was none detected, indicating that alcohol/diabetic ketoacidosis was not likely contributory to the death. Additional police investigations revealed the presence of liquid bottles labeled as “2-methyl-2-butanol” 97.5% purity, which was subsequently confirmed in the blood sample of the decedent. No anatomical findings were reported from the autopsy. The cause of death was attributed to fatal intoxication of TAA with a concentration measured in femoral blood of 1,000µg/mL.

Conclusions: This study describes an authentic TAA-related intoxication and the development and validation of an analytical method to quantify this substance of abuse.

Tert-Amyl Alcohol, 2-Methyl-2-Butanol, Intoxication

K52 Fatal Intoxication Involving 2-Methyl AP-237: A Case Report

Michael Truver, PhD, University of Florida, Gainesville, FL; Alex Gillette, MS, University of Florida, Gainesville, FL; Sara Brogan, BS, University of Florida, Gainesville, FL; Jennifer Hoyer, MS, University of Florida, Gainesville, FL; Chris Chronister, PhD, University of Florida, Gainesville, FL; Bruce Goldberger, PhD, University of Florida, Gainesville, FL*

Learning Overview: The goal of this presentation is to disseminate information on the Novel Synthetic Opioid (NSO) 2-methyl AP-237.

Impact Statement: This presentation will impact the forensic science community by increasing the awareness of 2-methyl AP-237 in fatal drug overdoses.

Introduction: In the United States, the opioid epidemic continues with NSO leading as the driving force. NSO are categorized as either fentanyl analogs or non-fentanyl analogs. Previously, fentanyl analogs were the most prevalent NSO, but subsequent to the scheduling of fentanyl-related substances in 2018, there has been a notable increase in non-fentanyl analog NSO. Recently, cases have emerged involving 2-methyl AP-237. This NSO is an analog of bucinnazine, also known as AP-237, which is an opioid that has similar potency to morphine. Presented here is a fatal intoxication case involving 2-methyl AP-237.

Case History: A 54-year-old White male was found deceased due to a possible drug overdose. The decedent, who was a transient, was found lying supine under a tree. Paramedics arrived and pronounced the decedent. The decedent was cool to the touch and had signs of rigor mortis in his extremities. There was a plastic container labeled “2MAP” and a cut straw found in the decedent’s backpack. There was a white powder found in the plastic container and straw that later tested positive for fentanyl by field testing. The decedent had a history of depression, shoulder pain, and early signs of dementia. Medical history revealed the decedent was treated for a drug overdose in October 2018. The case was pended for toxicological analysis.

Results: The case was submitted by the medical examiner for drug analysis. The Gas Chromatographic drug screen utilizing Nitrogen Phosphorous Detection (GC/NPD) revealed an unknown substance in the blood and urine. Further analysis by Gas Chromatography/Mass Spectrometry (GC/MS) and Liquid Chromatography/quadrupole Time-Of-Flight/Mass Spectrometry (LC/qTOF/MS) confirmed the presence of 2-methyl AP-237. Quantitation by GC/NPD was performed. The concentrations of 2-methyl AP-237 in the blood and urine were 480ng/mL and 4,200ng/mL, respectively. Additionally, alprazolam was detected in the blood at 55ng/mL.

Conclusion: The identification and quantitation of the NSO 2-methyl AP-237 was determined. There is minimal literature available regarding fatal intoxications involving 2-methyl AP-237. This case is illustrative of a lethal concentration of 2-methyl AP-237, considering the only other drug detected was alprazolam.

2-Methyl AP-237, Synthetic Opioids, Postmortem

K53 Drug Taxonomy in Forensic Science Data for Integration Into Medicolegal Death Investigation Systems

Alex Krotulski, PhD, CFSRE, Willow Grove, PA; Donna Iula, PhD, Cayman Chemical, Ann Arbor, MI; Agnes Winokur, MS, DEA, Miami, FL; Jeri Roper-Miller, PhD, RTI International, Research Triangle Park, NC; Bruce Goldberger, PhD, University of Florida, Gainesville, FL*

Learning Overview: After attending this presentation, attendees will be able to explain the challenges associated with drug taxonomy and its incorporation into medicolegal death investigation systems.

Impact Statement: This presentation will impact the forensic science community by laying the framework for how drugs are named and communicated in the United States and, ultimately, how the information effects forensic sciences data exchange and stakeholder processes.

Introduction: The National Institute of Justice (NIJ), in partnership with its Forensic Technology Center of Excellence (FTCoE, 2016-MU-DX-K110) at RTI International, and the Center for Disease Control and Prevention (CDC), convened a virtual Medicolegal Death Investigation Data Exchange Working Group (MDI-Data-WG) over a 12-month period beginning in September 2020. The MDI-Data-WG was formed to advance forensic science and ensure communication between Medical Examiners and Coroners (ME/C), death investigators, forensic scientists, and other stakeholders.

Objective: A subcommittee of the MDI-Data-WG focused on methods of capturing and disseminating information on the types of drugs involved in deaths, including drug taxonomy and other categorizations, and classification needs concerning drug naming, drug terms, drug mappings, and drug classification. The goal is to disseminate information to all relevant stakeholders to facilitate information exchange of data related to drug overdose mortality.

Methods: The MDI-Data-WG consisted of more than 40 stakeholders (e.g., data producers like ME/C, data consumers like federal agencies) who participated in further formed Subcommittees (SC) that focused on a specific purposes and goals (e.g., drug taxonomy). The MDI-Data-WG met across five two-day meetings and intermittent SC monthly meetings. Approaches to collecting information included user case scenarios and feedback stakeholder types; presentations from invited guests with Q&A sessions; group experiential sharing; and forums with data programmers and technology developers. The work of the MDI-Data-WG resulted in a final report published by NIJ's FTCoE and CDC to include guidance to move toward consistency, data standards, and best practice for improving the process. The efforts of this working group will result in various user case profiles, presentations, implementation forums, further research, and process mapping and evaluations of the various processes.

Results: This presentation will focus on the work of the drug taxonomy SC directed on nomenclature of toxicological substances that may be identified by a laboratory to streamline the reporting of those substances by forensic pathologists, chemists, toxicologists, and others. The MDI-Data-WG produced guidance on naming conventions for newly emergence synthetic drugs and developed a flow chart to assist with the understanding of complex drug taxonomy. The working group reviewed and discussed online information management systems that would benefit forensic scientists as they relate to drug nomenclature and tracking, and outlined what information should be collected, consolidated, and archived. Through interactions among the SC and with others in the forensic science community, the working group provided recommendations for drug taxonomy and ideas for how to maintain an online database in real-time.

Conclusion: Drug taxonomy remains a vital component for communication and information sharing within the medicolegal death investigation systems. Forensic data are often queried and reported based on findings listed on death certificates, toxicology reports, and other data streams. To facilitate proper data exchange and communication, the forensic community needs standardized data and a common drug language, especially one that is adaptable and updated in real-time as emerging drug threats appears. The work of the MDI-Data-WG will be documented in a final report to be available on the FTCoE website (www.forensicCOE.org).

Medicolegal Death Investigation, Taxonomy, Nomenclature

K54 Postmortem Polysubstance Use Trends in Tramadol-Positive Cases From 2015–2020 in Pennsylvania

Stephanie Marco, PhD, NMS Labs, Horsham, PA*

Learning Overview: After attending this presentation, attendees will understand how trends in tramadol-positive postmortem toxicology have changed in Pennsylvania since 2015.

Impact Statement: This presentation will impact the forensic science community by providing new information on polysubstance use trends in tramadol-positive postmortem toxicology cases.

Introduction: Tramadol is a central nervous system analgesic commonly prescribed for the treatment of moderate to severe pain. Recently, reports of tramadol overdoses have increased, with the primary cause of intoxication being suicide followed by abuse and unintentional intoxication. Additionally, tramadol has been detected in seized street drug mixtures containing heroin, fentanyl, methamphetamine, synthetic cannabinoids, and cocaine. Polysubstance use involving tramadol and other common drugs of abuse can increase the risk of adverse effects and fatal complications. This study identifies trends in drug positivity and polysubstance use in tramadol-positive postmortem blood.

Methods: Postmortem blood specimens submitted for analysis by Pennsylvania-based death investigators between January 2015 and December 2020 were studied. Drugs of abuse including barbiturates, benzodiazepines, cannabinoids, ethanol, hallucinogens, hypnotics/sedatives, inhalants, opioids, and stimulants were identified in cases positive for tramadol and/or its metabolite O-desmethyltramadol. Specimens were screened by Enzyme-Linked Immuno-Sorbent Assay (ELISA), Liquid Chromatography/Time of Flight/Mass Spectrometry (LC/TOF/MS), and/or headspace Gas Chromatography (GC). Confirmation testing was performed using High-Performance Liquid Chromatography/Tandem Mass Spectrometry (HPLC/MS/MS) and/or Gas Chromatography/Mass Spectrometry (GC/MS).

Results: Between 2015 and 2020, 771 cases met the study criteria. The number of tramadol-positive cases ranged from 89 to 157 per year. From 2015 to 2020, stimulants (+23%) and benzodiazepines (-10%) had the highest total percent change in positivity rates. The most pronounced yearly increase for analyte positivity was observed for opioids (+38%) between 2019 and 2020, whereas the highest decrease in analyte positivity occurred for opioids (-33%) between 2018 and 2019. Except for 2019, opioids were the most frequently identified analytes in tramadol-positive postmortem cases, with 2015 having the highest percent positivity at 77%. Fentanyl was consistently the most positively identified opioid from 2016 to 2020, whereas oxycodone had the highest percent positivity in the opioid class in 2015. In 2019, benzodiazepines were more frequently detected than opioids (42% vs. 36%), with alprazolam having the highest positivity rate in the benzodiazepine class. Barbiturates, hypnotics/sedatives, and inhalants were the least frequently identified drug classes in tramadol-positive cases during the study period (all $\leq 1\%$).

Conclusions: Over the past five years, there has been a modest increase in polysubstance use associated with tramadol-positive postmortem cases in Pennsylvania. The popularity of opioids and benzodiazepines in these cases has been the most consistent throughout this period, although the positivity rates varied, especially for opioids. The rise in stimulant positivity in tramadol-positive cases during the study period could be due to increased drug experimentation among tramadol users or the increased presence of tramadol as an adulterant in street drugs. Further studies may help elucidate the cause(s) of these findings.

Tramadol, Trends, Postmortem

K55 A 3D Origami Paper-Based Microfluidics Device for Creatine Analysis in Urine: A Disposable Tool for Identifying Urine Sample Adulteration by Dilution

Giacomo Musile, PhD*, University of Verona, Verona, Italy; Yvane Agard, MS, University of Verona, Verona, Italy; Sara Pesavento, University of Verona, Verona, Italy; Matilde Murari, MS, University of Verona, Verona, Italy; Elio De Palo, PhD, University of Verona, Verona, Italy; Franco Tagliaro, PhD, University of Verona, Verona, Italy and Sechenov University, Moscow, Russian Federation

Learning Overview: Attendees will receive detailed information on the use of a novel technique to control the integrity of urine samples using paper-based microfluidics technology. In the present case, this technique was applied to the analysis of creatinine, the most common analyte to control urine adulteration by dilution.

Impact Statement: Because of the low cost and portability of the developed devices, this method has a potential application outside the use of specialized laboratories and may be used to control urine integrity immediately at the site of collection in doctor's offices, in small laboratories, and/or in occupational medicine centers.

The relevance of the problem of sample tampering is well-known in forensic toxicology, and sample dilution is the most used method to cheat toxicological controls. The prevalence of this phenomenon, with a long history in analytical toxicology, is reported also in recent papers.¹⁻³ Among the criteria to assess urine integrity by excluding dilution, the quantification of creatinine probably represents the most popular method.

Although the majority of analytical methods offer adequate sensitivity and specificity, at present, creatinine analysis requires laboratory instrumentation, which hinders the possibility of direct test of urine at the collection site. This hinders the immediate interaction with the urine donor, which could be important to prevent claims of post-collection counterfeiting.

Since the first introduction by Whitesides et al., the use of Paper-based microfluidic Devices (μ PADs) for the development of chemical sensors has been extensively reported.^{4,5} Among several approaches for producing μ PADs, the use of commercial wax printers proved to be inexpensive and straightforward in the fabrication of the device. The procedure is based on two steps: (1) patterning chromatography paper into hydrophilic channels by fabricating hydrophobic barriers, and (2) addition of the reagent to the hydrophilic portion of the paper support. The sample is driven through the reagent zone as a result of the wicking capacity of the paper without external assistance. This approach does not require highly qualified personnel nor expensive instrumentation. Also, it can be performed on-site, enabling a prompt analytical response also in less-equipped environments. The advantages of μ PADs have provided forensic science with reliable tools to face different forensic issues.

On grounds of the above considerations, the goal of the present work was to develop a low-cost device able to provide a rapid and sensitive colorimetric detection of creatinine in urine samples. This presentation will provide details of the developed procedure, which was conceived as a first-line screening potentially to be confirmed with laboratory instrumentation.

The proposed microfluidic devices were designed as a 3D origami pattern. The test was based on three specific reactions for the detection of creatinine using picric acid, 3,5-dinitrobenzoic acid, and Nessler's reagent. The urine sample was transferred without any treatment directly onto the hydrophilic portion of the paper and colorimetric reactions are developed in few minutes. The color change was measured in terms of "RGB distance" by using a simple and free software for smart phone cameras. The device was also validated for quantitative determinations in terms of accuracy and precision. The optimized method was tested on real urine samples ($n=53$) using as reference a clinical chemistry method performed on immunoassay instrument.

In conclusion, the perspective usefulness of paper-based microfluidics as a low-cost and easy to use technique in forensic toxicology will be presented with a specific focus on its possibilities of on-site analysis to prevent urine adulteration.

K56 The Evaluation and Laboratory Testing of Synthetic Urines and Urine Adulterants Available in the United States

Svante Vikingsson, PhD, RTI International, Research Triangle Park, NC; Shannon Krauss, PhD, RTI International, Research Triangle Park, NC; Dale Hart, BS, RTI International, Research Triangle Park, NC; Eugene Hayes, PhD, MBA, Substance Abuse and Mental Health Services Administration, Rockville, MD; Ron Flegel, BSMT, MS, Substance Abuse and Mental Health Services Administration, Rockville, MD; Ruth Winecker, PhD, RTI International, Research Triangle Park, NC

Learning Overview: Attendees of this presentation are expected to learn about the current state of synthetic urines and urine adulterants and how they impact workplace drug testing.

Impact Statement: This presentation will impact the forensic community by informing laboratory directors and other decision makers about the current state of synthetic urines and urine adulterants, allowing them to better interpret data from urinary testing and to evaluate their methodology.

Urine drug testing has been the standard in both military, federally mandated, and non-regulated workplace drug testing for more than 30 years. However, as the impacts of a positive drug test often are severe for the donor, there has always been an incentive to “beat the test.” In the past decade, a number of commercial manufacturers have specialized in products designed to subvert urine drug testing, including synthetic urines that replace the sample, adulterants that interfere with testing methods, and various contraptions to hide the former from the collector. To identify the use of these products, the collector measures the temperature of urine specimens at the time of collection and the laboratories employ various Specimen Validity Tests (SVT), as discussed below.

An online market survey conducted in December 2020 identified 32 synthetic urine products and 3 urine adulteration products. Based on the survey, 16 synthetic urine products and all 3 urine adulterants were purchased and analyzed in-house and by five Health and Human Services (HHS) -certified reference laboratories. Adulterants were added to negative urine and urine containing amphetamine, methamphetamine, benzoylecgonine, codeine, morphine, PCP, THC-COOH, and synthetic opioids at concentrations approximately two times the federally mandated cutoff levels. In-house analyses included visual inspection and SVT using dip sticks. Laboratory testing was conducted on ten synthetic urine products, all three adulterants and control urine samples. Included were sample validity testing (pH, oxidants, creatinine, and specific gravity), immunoassay screening, and confirmation of spiked drug concentrations.

Visual inspection revealed that most products were professionally packaged, indicating the size and maturity of the industry. Also, both the synthetic urines and the adulterated urine samples would be difficult to distinguish from authentic urine specimens based on their appearance. Except for one sample with low specific gravity, all synthetic urine samples passed mandated laboratory SVT tests for creatinine, specific gravity, oxidants, and pH. However, specific gravity is normally not tested on specimens with normal creatinine levels.

The first adulterant was clearly identified by general oxidant tests, in line with manufacturer warnings that it was detectable. It also interfered with the internal standard of one confirmation assay. The second adulterant was undetected by SVT testing, but did not affect any drug test results. The last adulterant produced two negative screening results in one laboratory and lowered the quantitative value of some drug analytes. However, the adulterated sample was identified as invalid by immunoassay suppression, loss of internal standards in confirmatory testing, and the iodate SVT test.

In summary, most synthetic urines would have been difficult to identify at the laboratory using current testing protocols, but several laboratories are working on novel methods to identify urinary biomarkers. It is harder to subvert a urine drug test with an adulterant as the only adulterant that was not identified by SVT testing did not affect the drug test results.

Synthetic Urine, Adulterant, Workplace Drug Testing

K57 Respiratory Depressant Effects and Pharmacokinetics of Oral Mitragynine (Kratom) and Oxycodone in Rats

Marilyn Huestis, PhD, Huestis & Smith Toxicology, LLC, Severna Park, MD; Aaron Magnusson, PhD, Care Research LLC, Colorado Springs, CO; Dan Wang, BS, PinneyAssociates, Bethesda, MD; Wanzhu Zhao, MA, iC42, University of Colorado, Aurora, CO; Uwe Christians, MD, PhD, iC42, University of Colorado, Aurora, CO; Jack Henningfield, PhD, PinneyAssociates, Bethesda, MD*

Learning Overview: Attendees will be able to better compare the respiratory depressant effects and relative toxicity of oral mitragynine and oxycodone.

Impact Statement: Lack of respiratory depression following high-dose mitragynine in rats questions the appropriateness of designating kratom as cause of death in postmortem cases.

Mitragynine, the primary active alkaloid in kratom and partial μ -opioid receptor agonist, has substantially different pharmacology from the full μ -opioid receptor agonists morphine and oxycodone. Mitragynine does not recruit β -arrestin for G-protein signaling, has activity at adrenergic receptors, and a lower risk of respiratory depression, acute poisoning, death, and abuse-related effects. The kratom alkaloid, 7-Hydroxy-Mitragynine (7-OH-MG), constitutes <1.5% of the total alkaloid content, is more potent at the opioid receptor than mitragynine, and a mitragynine metabolite. Mitragynine is not scheduled in the Controlled Substance Act; however, the Food and Drug Administration (FDA) recommended scheduling of mitragynine in 2016, in part out of safety concerns, though the request was rescinded by the Assistant Secretary of Health in 2018. Mitragynine is taken by millions of people in Southeast Asia and the United States as a mild stimulant and analgesic and to treat opioid dependence and withdrawal.

In 2020, the FDA recently recommended a rat model for evaluating drug respiratory depressant effects, utilizing oxycodone as a positive control. This study employed this model to compare respiratory depression following 20, 40, 80, 240, and 400 mg/kg oral mitragynine and 6.75, 60, and 150mg/kg oral oxycodone in rats. Oxycodone, mitragynine, and 7-OH-mitragynine were quantified by Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) pre-dose, 1, 2, 4, 6, 8, and 12h after administration. Blood gases were determined at the same time points with the VetScan i-STAT Alinity V Handheld Analyzer. Clinical observations of opioid associated effects and toxicity were performed throughout.

A significant decrease in oxygen saturation compared to baseline sO₂ following the 60 and 150mg/kg oxycodone doses was observed, with no significant differences in sO₂ following 20, 40, 80, 240, and 400mg/kg mitragynine over 12h. Partial CO₂ pressure change from baseline was significantly increased after 60 and 150mg/kg oxycodone hydrochloride, but not following any mitragynine dose. Two animals receiving oxycodone, one at 60 and one at 150mg/kg, died after dosing, and 66.7% and 100% of animals receiving these doses had abnormal clinical observations. One animal following 240mg/kg and multiple animals following 400mg/kg mitragynine had abnormal clinical observations. Median blood oxycodone C_{max} were 33.5, 39.9, and 131ng/mL following 6.75, 60, and 150mg/kg oxycodone, respectively, with T_{max} at 1h. Median mitragynine C_{max} were 723, 1,665, 2,140, 6,278, and 6,341ng/mL after 20, 40, 80, 240, and 400mg/kg mitragynine, respectively, with T_{max} generally at 1h. 7-OH-mitragynine C_{max} were 11.0, 17.4, 18.9, 32.0, and 62.5ng/mL after 20, 40, 80, 240, and 400mg/kg mitragynine, respectively, with T_{max} at 1h. 7-OH-mitragynine concentrations were approximately 100-fold lower than mitragynine concentrations in the same sample.

Mitragynine doses as high as 400mg/kg did not produce any clinically relevant or significantly measurable effects on respiration based on blood gas measurement, whereas 60 and 150mg/kg oxycodone resulted in moderate to severe respiratory depression in rats. Similarly, there were no abnormal clinical observations after 20, 40, and 80mg/kg, one after 240mg/kg and multiple after 400mg/kg oral mitragynine, while 60 and 150mg/kg oxycodone produced many abnormal observations and two deaths.

Conclusion: Oral mitragynine had little respiratory depression in rats following up to 400mg/kg doses, much higher doses than generally taken by humans, suggesting caution in attributing cause of death to mitragynine respiratory depression in postmortem deaths.

Mitragynine, Respiratory Depression, Pharmacokinetics

K58 The Application of All Ions Data Acquisition and SureMass Quantitative Data Analysis for Comprehensive Drug Screening Detection in Whole Blood

Jessica Ayala, MS, Sam Houston State University, Huntsville, TX; Sarah Kerrigan, PhD, Sam Houston State University, Huntsville, TX; Vadim Kalmeyer, PhD, Agilent Technologies, Inc., Santa Clara, CA; Bjorn Ogren, MS, Agilent Technologies, Inc., Santa Clara, CA; Peter Stone, PhD, Agilent Technologies, Inc., Santa Clara, CA; Karen Yannell, PhD, Agilent Technologies, Inc., Santa Clara, CA*

Learning Overview: After attending this presentation, attendees will understand the advantages of utilizing an All Ions Liquid Chromatography/quadrupole Time-Of-Flight (LC/qTOF) data acquisition approach for comprehensive toxicology drug screening analysis.

Impact Statement: This presentation will impact the forensic science community by presenting toxicological data analysis challenges.

Forensic toxicology serves the community through civil, criminal, and medicolegal investigations. The analytical burden associated with the detection of drugs of abuse, prescription medications, over-the-counter drugs, and new psychoactive substances in complex biological matrices (i.e., whole blood) is significant. The scope and sensitivity of toxicological screening is a challenge for many laboratories, and sample preparation is key in the performance of targeted or non-targeted assays.

Common sample preparation methods include protein precipitation, lipid removal, dilution, filtration and centrifugation, Liquid-Liquid Extraction (LLE), Supported Liquid Extraction (SLE), and Solid Phase Extraction (SPE) -based technologies, including dispersive SPE and Quick, Easy, Cheap, Effective, Rugged, and Safe (QuEChERS). However, no single technique can produce high extraction efficiencies for hundreds of drugs with a wide range of physicochemical properties and removing all matrix interferences. Likewise, although chromatographic separation of all components is desired, this may not be achievable. Therefore, a practical compromise is often struck between assay performance and overall efficiency. This study reports how data analysis tools were used to mitigate some of these issues using All Ions data acquisition.

High-resolution mass spectrometry was used to identify >200 compounds in whole blood using SLE and LC/qTOF using All Ions acquisition. The comprehensive screening assay targeted drugs of interest in impaired driving and medicolegal death investigation at the recommended cutoffs.^{1,2} The method was successfully validated in accordance with published guidelines.³

Later, a series of adjudicated case samples that had been stored for an extended period (i.e., years) were re-evaluated using the methodology herein described. These specimens displayed increased matrix interferences and background noise for selected compounds, including 11-nor- Δ^9 -Carboxy-Tetrahydrocannabinol (THCA), a Tier I drug of importance. As a result, false negatives were obtained for samples that previously confirmed positive. New data analysis techniques were explored using Agilent® MassHunter Quantitative software with SureMass capability. The combination of All Ions acquisition and optimized data analysis was able to overcome the assay limitations due to the degraded matrix. Data collection at various collision energies and the elimination of abundance thresholds and projected ion transitions mitigated the false negative results.

This research shows the utility of the All Ions acquisition technique for analyzing complex biological matrices (i.e., whole blood) and for alleviating matrix effects from co-eluting interferences with innovative data analysis techniques.

K59 Field Impairment Testing: Establishing the Statistical Variability and Uncertainty of Measurement in the General Population

Lucy Victoria Watson, MSc, Queen Mary University of London, London, England, United Kingdom; Atholl Johnston, PhD, Queen Mary University of London, London, England, United Kingdom; Nikolas Petros Lemos, PhD, Queen Mary University of London, London, England, United Kingdom*

Learning Overview: Attendees can expect to learn about the differences in the United States and United Kingdom Field Impairment Testing systems, and the performance ability of the general public when considering individual factors such as sex, age, weight, and height. The attendees will further learn that even in complete sobriety, increased age and Body Mass Index (BMI) resulted in increased failed impairment tests. Finally, attendees will also learn that even though these tests have been previously validated, most participants negatively commented on the difficulty of the administered tests.

Impact Statement: This presentation will impact the forensic science community by highlighting the problems associated with Field Impairment Tests, including the issues with validation linked with degree of impairment, the effects of independent characteristics, and difficulty associated with the tests success rate.

Field Impairment Testing within the policing system as a method for determination of the intoxication of an individual was examined in the United Kingdom and compared to the original United States Standardized Field Sobriety Tests.

In the United Kingdom, although police officers are trained to perform such tests on members of the public and to identify indications of impairment throughout each individual test, there is no standardized indication or clue number, unlike the United States' system. Thus, officers must subjectively decide on the impairment of the individual based on performance, leaving room for potential personal bias within the decision process. Despite police officers always seeking to obtain details of medical conditions as a reason for inability to perform, there is no current consideration on whether other factors such as sex, age, weight, or height will alter the outcome of these tests.

This raises questions regarding the ability of the individual being assessed, specifically if they would be classified as impaired when sober. This study carried out research to determine whether individual factors could influence the test outcome. Fifty-four volunteer participants completed all five Field Impairment Tests, and the results were collated dependent on sex, age, weight, and height.

The results suggest that impairment indication scores tend to increase with increasing BMI. The research also found significant variation in test results of participants aged 30+ in comparison to younger age groups. Additionally, correlation of elderly adults with increased likelihood of medical conditions was linked to failed impairment tests. Medical conditions resulted in increased likelihood of failed impairment tests over all age, sex, weight, and height groups. Difficulty of the tests were also highlighted, thus suggesting the tests are not fit for purpose and should be revised for use under Section 6 of the Road Traffic Act 1988 in the United Kingdom, in addition to suggestion for revision of the original scoring system used in the United States.

Driving While Impaired, Field Impairment Testing, Statistical Variability and Uncertainty of Measurement

K60 Carfentanil and Xylazine: Veterinary Drugs Detected in Drug Abuse-Related Forensic Casework

Andrea Carolina Noble, PhD*, NMS Labs, Horsham, PA; Donna Papsun, MS, NMS Labs, Horsham, PA; Barry Logan PhD, NMS Labs, Horsham, PA

Learning Overview: After attending this presentation, attendees will have a better understanding of the increase in the use of two potent tranquilizers approved to be used in veterinary medicine, but extensively misused as a drug of abuse and/or as a toxic adulterant.

Impact Statement: This presentation will impact the forensic science community by presenting trends in the use of two veterinary drugs, xylazine and carfentanil, detected in routine forensic casework.

Xylazine and carfentanil are drugs commercially available to use in the veterinary field to tranquilize large animals, mainly used as horse anesthetics. These two drugs belong to different chemical classes; xylazine is a non-opioid sedative drug from the phenothiazine analog group that acts at the alpha-2-adrenergic receptors, while carfentanil is a fentanyl analog and a μ -opioid receptor agonist.^{1,2} Forensic investigations have reported these drugs have been extensively detected in illicit drug formulations, especially since 2017.^{3,4}

Blood samples from forensic casework investigations were considered for this study. Two different routine Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) methods were used to determine xylazine and carfentanil, with a limit of quantification of 5ng/mL and 0.05ng/mL, respectively. For this study, only those samples received in the laboratory from 2020 and Q1 and Q2 of 2021 were considered to analyze the recent trends in the illicit use of carfentanil and xylazine.

Xylazine was confirmed in a total of 2,776 blood samples during the considered period. An average of 119 samples/month were confirmed for xylazine during 2020; while in 2021, the average was 192 xylazine-positive samples/month during January–June 2021. Twenty-five percent of the positive samples were received from Pennsylvania and 10% from Michigan in 2020. However, in 2021, 21% were from Pennsylvania, 13% from Connecticut, followed by New Jersey and New York at 6–7%. Peripheral blood mean concentration, median, and range were as follows: 29.9ng/mL, 16ng/mL, and 5–610ng/mL ($n=1800$). The most prevalent co-occurring drug in those cases positive for xylazine was fentanyl (96%), delta-9 THC (27%), heroin, and methamphetamine (both 23%).

A total of 370 blood samples were positive for carfentanil from January 2020–June 2021, 220 in 2020 versus 150 in 2021 (Q1 and Q2), with an average of positivity of 8 (2020) versus 14 (2021) samples/month. Mean carfentanil peripheral blood concentration was 0.57ng/mL, median 0.23ng/mL, and range 0.051–5.9ng/mL ($n=153$). For carfentanil, however, fentanyl was present in 45% of positive cases, delta-9 THC in 24%, methamphetamine in 30%, cocaine in 26%, and heroin in 22%. An increasing amount of methamphetamine positivity was observed in carfentanil-involved cases, a trend that has increased over the past four years, which is likely due to the growing use of methamphetamine by drug users.⁵

The increase in the illicit use of carfentanil and especially of xylazine has been alarming in 2020. These data show that intoxication cases where xylazine or carfentanil are involved are still growing in 2021. However, both drugs seem to have different roles: xylazine as an adulterant of the illicit use of fentanyl (so-called “tranq dope” mix); while fentanyl was not detected in 55% of the analyzed carfentanil positive blood samples and, within these cases, cocaine, heroin, and methamphetamine were the most prevalent drugs of abuse.

LW1 A Forensic Analysis of the 1960 Rome Olympics' 100-Meter Dash Final

John D. Bullock, MD, Ophthalmic History Research Institute, Winchester, MA*

WITHDRAWN

LW2 Who Am I? What is My Name?

Colleen M. Fitzpatrick, PhD, Identifinders International LLC, Fountain Valley, CA*

Learning Overview: After attending this presentation, attendees will have a better understanding of how modern research methods can illuminate the historical context of the Holocaust.

Impact Statement: This presentation will impact the forensic science community by describing the role played by multidisciplinary analysis in identifying Holocaust survivors and reuniting them with their families.

Of the 1,600,000 Jewish children who lived in Europe before World War II, only 100,000 survived the Holocaust. Most child survivors were hidden children, shuttered away in attics, cellars, convents, or farms. Unfortunately, in the chaos that reigned after Europe was liberated, restoring children to their birth families was especially difficult—many parents perished in the camps, and children were often too young to know their own names. Today, there are still hundreds of child survivors who have been unable to recover their birth identities.

This presentation is about efforts to restore the identity of just one of those children—Pnina Gutman, a 74-year-old great grandmother now living in Israel. Pnina was smuggled from the Warsaw Ghetto in 1942 when she was an infant. She has lived her life with no knowledge of who she is.

Pnina's life was saved by Charlotte Rebhun, a Christian woman from Berlin whose Jewish husband had just been arrested in Warsaw and sent to Treblinka. What little we know of Pnina's rescue from the Ghetto comes from the eyewitness accounts Charlotte's children Adele and Wolfgang gave to the Yad Vashem when they were reunited with Pnina in 1997:

It all started with a conversation between Mrs. Gertrude Spyra, wife of a Jew from Berlin, and our mother, Charlotte Rebhun born Schössow. The conversation involved the adoption of a small child of a Jewish family from the Warsaw ghetto—the safekeeping and the survival of the child until its retrieval after surviving threats to life and limb. The birth parents were organized resistance fighters in the Warsaw ghetto.

The handover of Baschke by the birth mother took place in our former apartment in Warsaw Krochmalna No. 33, and included a baby stroller with baby clothing. The intention was presented to my mother, that after taking care of their responsibilities in the Ghetto, the parents would return for the child after not too long a period of time.

After that, in the fall of 1942—the exact time, unfortunately, does not come to mind—there was no sign of the parents. Barbara's parents were Polish Jews.

In daily life, Barbara was our child and our sister, with the name Barbara Rebhun.

The story continues from there with only one other small, yet highly significant, clue. According to the Rebhuns, upon her departure from their apartment that day in 1942, Pnina's mother counselled Charlotte, "If we don't come back for our daughter, send her to our relatives in America." That was only weeks before the Warsaw Ghetto uprising in April 1943.

Research into Pnina's identity has been both difficult and rewarding. The search has been global; Holocaust records, like Holocaust survivors, are scattered throughout the world. So many questions have been answered, yet there are so many more. Thanks to direct-to-consumer DNA testing, those relatives in America described by Pnina's still anonymous mother have been discovered. One of Cousin Helen's aunts was Pnina's grandmother. Yet which aunt, and who did she marry? This presentation discusses how even Helen's collection of family photos, some with names on the back, has brought the solution to the mystery of Pnina's identity so much closer, and yet her identity still remains frustratingly just beyond reach.

Holocaust, Survivor, DNA

LW3 Who You Gonna Call? Forensic Scientists as Responsive and Responsible Practitioners

Matteo Borrini, PhD, Liverpool John Moores University, Liverpool, England, United Kingdom; Marco Morocutti, Cicap, Padova, Italy*

Learning Overview: After attending this presentation, attendees will be informed regarding how being responsive not only means reacting quickly and being ready to face the challenges proposed by the modern crime scene, it also means being responsible and reliable in way that the experts select and using the appropriate tools during forensic investigations.

Impact Statement: This presentation will impact the forensic science community by providing examples regarding the importance of understanding which equipment is the most appropriate for specific needs by knowing the potential of each tool, as well their limitations.

The word “modern” associated with “science” brings to mind the idea of limitless equipment with super-powerful equipment that can help scientists in their daily challenges. However, scientists have an obligation to be responsive and reliable, and these characteristics can only be achieved by a wise and responsible use of the available tools. The selection and application of the appropriate equipment can only be achieved if the users know the potential of the available methods and, more importantly, their limitations and weaknesses.

To better explain this concept, this presentation will discuss the paradox offered by alleged scientific disciplines that often try to equalize themselves to the forensic world: ghost hunting. Ghost hunters, often self-defined as paranormal detectives, try to increase the credibility of their alleged discipline, portraying themselves as investigators focused on the search for evidence of spirits and disembodied entities.

Even if there are cases where the malevolent influence of spirits has been (unsuccessfully) proposed to explain the death of some individual or the aberrant actions of heinous homicides, this presentation aims to analyze the daily (and nightly) routine of ghost hunters and their approach to scientific equipment. In addition to carrying shinning badges and paramilitary uniforms, modern ghostbusters attempt to appear professional by using sophisticated equipment that people would expect to be employed by forensic investigators in very complex crime scenes. However, the reality is rather different.

One of the most iconic tools for ghost hunters is the electromagnetic field detector. The device is designed to detect, but not measure, electromagnetic fields. Consequently, the detector is a non-diagnostic analytical tool despite the misuse in ghost hunting expeditions. In these contexts, people are more interested in the emotions of “seeing something” rather than measuring and analyzing an event.

Thermographic cameras represent another example of misusing a tool. This kind of apparatus has been designed to make visible what usually is not detectable by the naked eye: temperature variations. In this case, ghostbusters are victims of a scientific oversimplification, assuming that if the camera can make noticeable what usually is not, it should achieve the same with what is supposedly impossible to be seen: spirits. In addition, thermographic cameras do not have high resolution, which helps create evocative stimuli in the users and, consequently, pareidolic effects.

The thermal imager offers food for thought also regarding the lack of habit with a non-common tool, stressing how it is essential to know all the equipment’s characteristics, potential, and weaknesses before bringing it into the field. A similar problem is encountered even with traditional photo cameras, where backscatters from unfocused motes of dust are classified as paranormal phenomena under the name of “orbs.” Forensic scientists are not misled by these artifacts. Nevertheless, as cameras are ubiquitous on the crime scene, it is still common to see some practitioners equipped with expensive and sophisticated digital reflex cameras using them in fully automatic mode—a clear example of a lack of knowledge of the limits and potential of the tool.

Pseudoscience, Ghost Hunting, Debunking

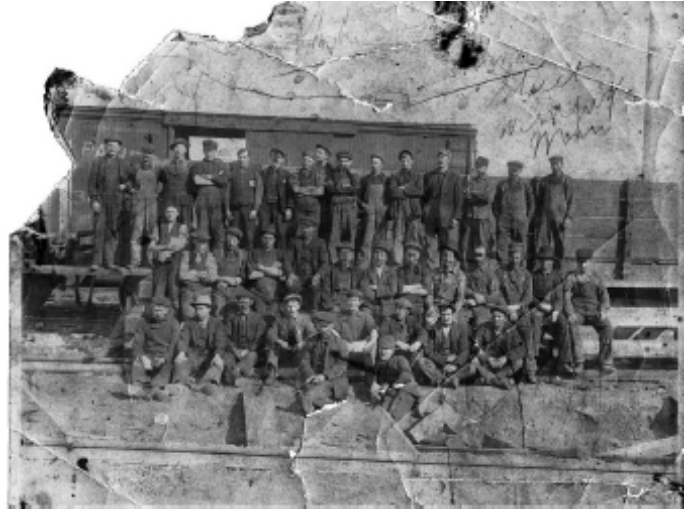

LW4 A Forensic Photo Mystery: The Railroad Picture

Colleen M. Fitzpatrick, PhD, Identifinders International LLC, Fountain Valley, CA*

Learning Overview: After attending this presentation, attendees will have learned how attention to detail is an important element in forensic photo analysis.

Impact Statement: This presentation will impact the forensic community by illustrating the value of a multidisciplinary approach for extracting information that can be used to answer the questions who, what, when, and why.

There was not much information supplied by the owner of this picture of a group of railroad workers from the early 20th century—only that it was taken in Canada, and that his Uncle Patrick Swords was one of the workers. Yet through careful observation, it has been possible to construct the narrative for Uncle Patrick after he arrived in Canada, and to derive much information about other workers in the picture along with the circumstances under which the photo was taken. The most obvious clue to the photo is the writing that appears across the top that can be deciphered as “Sherburn Street, Winnipeg, Man.” The writing on the boxcar in the left background is also informative. An investigation of the history of Winnipeg shows that by the late 1880s, the city had become a major hub for the Canadian Pacific Railroad. The word on the boxcar is “Pacific.” Another look at a map of Winnipeg shows that Sherburn Street dead ends close to the main depot of the Canadian Pacific Railroad. Winnipeg city directories from 1910–1914 quickly lead to a Michael Swords residing at 951 Sherburn Street, who worked as a laborer for the railroad. The 1915 city directory gives the listing at that address as “Kate, wid. Michael.” But is it possible to do more? Is it possible to identify any of the other men in the picture, if not by name, at least by occupation? Is it possible to deduce the time and approximate location the picture was taken and the reason? Through careful attention to detail, the answer is yes. Through observations of the clothing, the accessories, and the postures of the workers, it is possible to discover what positions they filled on the railroad crew. Other less-obvious details lead to an approximate time and date and the place the photo was taken, along with a good guess for the reason. Even the weather is a factor in developing a backstory for the photograph and to solve the mystery of its who, what, when, where, and why.

Forensic, Photograph, Analysis

LW5 A Life for the Dead: In Memory of Bill Haglund (1943–2021)

Constantine Eliopoulos, PhD, Liverpool John Moores University, Liverpool, England, United Kingdom*

Learning Overview: After attending this presentation, attendees will have been informed about the life and contributions of Bill Haglund to the field of forensics and, in particular, the investigation of war crimes and human rights abuses.

Impact Statement: This presentation will impact the forensic science community by showcasing human rights investigations led by a leading figure in the application of forensic anthropology in the scientific excavation of mass graves.

Bill Haglund's life is a shining example of resilience and perseverance. Having an extremely difficult childhood and moving around a lot, he faced many challenges that all made him stronger and gave him a sense of empathy. When he was a teenager, his mother was stabbed to death in a Minnesota bar, a tragedy that led him down the forensic path later in his life. After graduating from high school, he worked at a funeral home and attended the California College of Mortuary Science. This was followed by a bachelor's degree in biology from U.C. Irvine. In the late 1970s, he started to work as a death investigator with the King County Medical Examiner's Office in Seattle, WA, and while at his post, he earned a PhD in physical anthropology from the University of Washington under the mentorship of Daris Swindler. It was around this time that he started working in the field of human rights as a consultant for investigations in the Balkans, Latin America, and Africa. He later took on roles such as senior forensic advisor to the United Nations' International Criminal Tribunals and served as Director of the international forensic program of the organization Physicians for Human Rights. His work took him to several countries, many of which were active war zones.

In the academic sphere, Bill Haglund published several articles on death investigation, but his main contribution is considered by many to be the volumes on forensic taphonomy that he edited with Marcella Sorg.

Bill was also an active member of several forensic associations and a Fellow of the American Academy of Forensic Sciences. He received the T. Dale Stewart award in 2013 recognizing his lifetime contribution to the field of forensic anthropology.

Forensic Anthropology, Human Rights, Mass Grave

Y1 DNA Integrity and Fungal Contamination as a Function of Time in Freshwater Drowning Deaths

Maeve Godshalk, BS, Duquesne University, Pittsburgh, PA*

Learning Overview: This presentation aims to better evaluate the current knowledge of the DNA and fungal relationship in a forensic setting, or lack thereof. Specifically, this research examines if human DNA is degraded due to fungi and the environment.

Impact Statement: This presentation aims to give forensic laboratories a better understanding of tissue contamination as it relates to fungus and improve decision-making in regard to processing such samples.

Drowning and drowning deaths are categorized as a public health issue. Fatal and potentially criminal drowning often results in the inability to process DNA evidence. Drowning deaths have a unique pathology, including wrinkling of the skin, skin slippage, putrefaction, and adipocere formation. The combination of these pathological changes with the freshwater environment allow for microbial and fungal degradation of the victim's tissue to occur at a hastened rate and make it difficult to process tissue samples. Forensic mycology, the study of fungi, is an emerging field and has been proven to be crucial in different cases.

In drowning deaths, forensic mycology can be used to evaluate the level of degradation to the victim and other evidence, as well as give insight into the health of the individual while they were alive. Fungal contamination can create issues during DNA processing and negatively affect the integrity of the sample. *Candida albicans* is an opportunistic, pathogenic fungus found in the human body. It lives on the skin and inside of the body, typically without any harm to the host. In immunocompromised individuals, *C. albicans* will exhibit a pathogenic response and cause harm in the form of vaginal yeast infections, oral thrush, candidiasis, and sepsis, to name a few. In freshwater drowning environments, *C. albicans* can also take advantage of the host, causing fungal contamination to the tissue. This contamination can affect the integrity of the tissue samples that are collected. Materials for biological testing are expensive and it is not cost effective to process potentially contaminated samples. Crime labs may choose not to process such samples due to assumed DNA degradation.

By inoculating tissue samples with a clinical wild-type strain (SC5314) of *C. albicans* in river water, Optical Density (OD) readings can be taken to evaluate the level of *C. albicans* growing in the presence of the tissue. DNA processing of the tissue will allow the integrity of the tissue to be evaluated. Tissue extraction via QIAamp® DNA Mini Kit will isolate the human DNA within the tissue sample. Quantitation by Quantifiler® HP DNA Quantitation Kit and QuantStudio™ 5 Real-Time PCR System will measure the amount of DNA extracted. Amplification by GlobalFiler® PCR Amplification Kit will make copies of the DNA sequence. Genotyping via SeqStudio™ Genetic Analyzer will allow the genetic differences between samples to be evaluated. Analysis by GeneMarker® HID of the data from the genetic analyzer will be able to compare genotypes between the samples. This overall process will allow for a better understanding of the integrity of the experimental tissue sample. The level of contamination may also help evaluate if it is positively or negatively correlated with the growth rate of the fungus. The results are expected to support the hypothesis that there is positive correlation between the two, that is that the more *C. albicans* that is present, the lesser the integrity of the DNA.

This work aims to give forensic laboratories a better understanding of tissue contamination as it relates to fungus and improve decision-making in regard to processing such samples.

Drowning, *Candida albicans*, Contamination

Y2 The Production of Recombinant Semenogelin Protein Fragments for the Improved Antibody-Based Detection of Body Fluids

Thomas Washington, BS*, Duquesne University, Pittsburgh, PA; William Gibbs, Duquesne University, Pittsburgh, PA; Clancy McIntyre, Duquesne University, Pittsburgh, PA; Pamela Marshall, PhD, Duquesne University, Pittsburgh, PA; Michael Jensen-Seaman, PhD, Duquesne University, Pittsburgh, PA

Learning Overview: After attending this presentation, attendees will have learned about recombinant protein expression and how to implement allelic variation considerations into forensic serology.

Impact Statement: This presentation will demonstrate one approach to providing an improved semen identification test less prone to false positives and negatives.

The identification of body fluids on evidence items is an important component of forensic science. Sometimes, simply identifying a body fluid is enough to impact a case.¹ Forensic serology is also critical because determining if a body fluid is present, then identifying it, allows for downstream laboratory testing, including DNA analysis.¹ A body fluid commonly discovered at crime scenes is semen. Targets of current forensic semen identification tests include the seminal enzymes Prostate-Specific Antigen (PSA) and Acid Phosphatase (AP), as well as spermatozoa and semenogelins. Proteins known as Semenogelin I (Sg I) and Semenogelin II (Sg II) are the main structural components of the gelatinous mass formed by human semen after ejaculation.^{2,3} These proteins make up 20% to 40% of all seminal plasma protein.^{2,3} The coagulum liquefies 5 to 20 minutes after ejaculation.² PSA plays a large role in this process, known as liquefaction, by cleaving semenogelin proteins through protease activity.^{2,3} Current forensic semen identification tests have flaws, including false positives and false negatives. Therefore, this study sought to develop an improved semen identification test.

In order to accomplish this, this study produced and purified fragments of Sg I protein located between PSA cleavage sites.⁴ Using databases of human genetic variation, this study found one such fragment of Sg I (later named the THW fragment) containing no common non-synonymous Single Nucleotide Polymorphisms (SNPs). This study Polymerase Chain Reaction (PCR) -amplified the THW fragment and used an *E. coli* expression system to produce THW protein. Affinity chromatography was used to purify THW protein. A different fragment of Sg I (the Seminal Plasma Motility Inhibitor [SPMI] fragment) targeted by a previously developed semenogelin-targeted test, and an allelic variant of the SPMI fragment containing a common non-synonymous SNP, were produced and purified using the same system used for THW.⁵ This study evaluated the ability to detect these recombinant semenogelin protein fragments with a commercially available semenogelin-targeted semen identification kit.

Overall, the study seeks to improve serological testing aimed at semen identification by providing a test less prone to false positives and negatives, through targeting semenogelin and consideration of common allelic variants. By providing an improved test, the potential to solve more sexual assault cases is increased.

Semen Identification, Semenogelin, Recombinant Proteins

Y3 A New Algorithm for Source Identification of Look-Alike Footwear Impressions Based on Automatic Alignment

Hana Lee*, Iowa State University and Center for Statistics and Applications in Forensic Evidence, Ames, IA; Alicia Carriquiry, PhD, Iowa State University and Center for Statistics and Applications in Forensic Evidence, Ames, IA

Learning Overview: After attending this presentation, attendees will have learned about automatically aligning two look-alike images of footwear impressions to the extent that human examiners would do prior to comparison. Moreover, this study demonstrates how well the proposed algorithm based on the features resulting from the alignment can identify whether the two images were taken from the same shoe or not. The images used were obtained from Everspy Outsole Scanner collected by the Center for Statistics and Applications in Forensic Evidence (CSAFE).

Impact Statement: Digital images of footwear impressions taken at a crime scene are often useful to connect a suspect to the crime scene. Comparing an image from a crime scene with one from a suspect's shoe has usually been conducted by manual alignment with Photoshop® and examiners' experience for comparison, which is time consuming and labor intensive. The proposed algorithm enables objective comparison of alike images of footwear impressions with high accuracy, in less than a minute per comparison. Therefore, this algorithm can be a useful tool for examiners. The automatic alignment process that is proposed produces images that are ready to be overlaid, and thus are convenient for further analysis.

Suppose that there are two images denoted by R , and M where R indicates a reference image, and M indicates a moving image that will be aligned to R . First, a thousand Speeded Up Robust Features (SURFs) are extracted from each of R and M . SURF is an interest point descriptor invariant to scale and rotation.¹ The strongest 500 SURFs of M are aligned to those of R by the Iterative Closest Point (ICP) algorithm, that minimizes the difference between two sets of points, by providing the optimized rotation angle and translation of the SURFs of M . Next, the similarity (or dissimilarity) features are computed using the aligned 500 SURFs of M and 1,000 SURFs of R . These include the closest distance, the number of R 's SURFs around the aligned SURFs of M , and the number of aligned SURFs of M that have no neighboring SURFs on R . Additionally, the maximum of the phase correlation between the transformed M and R is also used as a similarity feature. Phase correlation estimates the translative offset at which the inverse Fourier transform of the normalized cross spectrum between two images is maximized.² Note, therefore, that the alignment by SURF and ICP and the adjusted translation by maximum phase correlation can align images better because it considers the offset due to the transition from SURF points to pixels. Lastly, the similarity features are combined using a random forest to estimate the probability that M and R came from the same shoe.

The proposed algorithm's performance in terms of a Receiver Operating Characteristic (ROC) curve was almost comparable with 0.96 of Area Under the Curve (AUC) to Park et al. based on maximum cliques that produced AUC greater than 0.99 where two images from the same shoe are just replicated scans of the shoe, and those from different shoes have the same class characteristics.³ On the other hand, when using two images from the same shoe taken several months apart so that they possess different wear and tear, the proposed algorithm with 0.94 of AUC outperformed Park et al. with 0.85 of AUC, which demonstrates its distinguishing ability in a more practical and challenging scenario.

Y4 An Ensemble of Score-Based Likelihood Ratio (SLR) Systems for Forensic Evidence

Federico Veneri, MS, Iowa State University, Ames, IA; Danica Ommen, PhD, Iowa State University, Ames, IA*

Learning Overview: The objective of this presentation is to provide attendees with an introduction to the proposed approach to ensemble SLR systems. Using the elemental composition of glass, this presentation illustrates how sampling can be used to create sets of independent observations to estimate random forest-based similarity metrics and density estimations and ensemble their result into a final SLR.

Impact Statement: Despite their obvious drawbacks, SLRs continue to be the preferred method of quantification for complex impression and pattern evidence. This presentation aims to provide an improved methodology for producing SLRs for use by forensic practitioners.

SLRs have been used as an alternative to feature-based likelihood ratios when the construction of a probabilistic model becomes challenging or infeasible.¹ Although SLRs have been shown to provide an alternative way to present a numeric assessment of evidential strength, there are still concerns regarding their use in a forensic setting.²

The SLR approach requires two key components. First, developing a (dis)similarity score, and second, estimating the distribution of the scores under both prosecutor and defense propositions. This process relies on the construction of pairwise comparisons in both stages. Previous work addresses the dependency on the sets used for producing SLR, how introducing perturbation to the sets can lead the forensic examiner to different conclusions, particularly the sensitivity during the second stage.³

A second less-explored dependence structure is produced because forensic glass evidence can be thought to be generated by a hierarchical model.⁴ When a pairwise comparison is made, the same source enters the comparison multiple times, undermining the independence assumption often required by the methods used for developing a (dis)similarity score and estimating their distribution.

This work introduces an ensemble method for creating an SLR system that aims to reduce sensitivity to perturbation in the samples and remove the dependence structure. This study creates independent subsets by sampling only one comparison from each source to create base SLR systems, and then ensemble them in a final system that can be used in a later stage.

Score Likelihood Ratios, Learning Algorithms, Glass Evidence

Y5 A Forensic Assessment of Morphed Audios Using Conventional and Modern Techniques of Speaker Identification

Palak Aneja Pursuing, PhD, Rashtriya Raksha University, Gandhinagar, Gujarat, India; Sumit Choudhary, PhD, Rashtriya Raksha University, Gandhinagar, Gujarat, India; Surbhi Mathur, PhD, National Forensic Science University, Gandhinagar, Gujarat, India*

Learning Overview: This presentation will help identify if audio is edited using software. It can also help in identifying the challenges present in the current speaker identification techniques used in forensic science.

Impact Statement: This presentation will impact the forensic science community by helping identify if audio is edited using software and by identifying the challenges present in the current speaker identification techniques used in forensic science.

Perpetration of crime using digital media has witnessed unprecedented escalation and modification apropos to the technological advances across the globe. The multimedia forensics, and the audio forensics in particular, has also harnessed the innovative counter-technological potential to pinpoint the identifiable elements in any crime for the overall aid of the criminal justice system. While speaker recognition and tests of authenticity constitute the bulk of the work in the audio forensics domain, the possibilities of exact identification is being constantly complicated by the scope of digitally altering the voices or converting them into completely unrecognizable voices, popularly referred to as morphing. Morphing of digital voices or converted voices is generated by the software freely available in the cloud system. Criminals may like to use this disguising morphing technology for ulterior motives with the instinct of camouflaging their identity. The software used in creating these audios have pre-set algorithms that modify the voice into that of alien, monster, or cartoon, or they can change the gender of the speaker in the final audio output in addition to providing several other options and kinds of morphed conversions. These softwares are freely available and most of them are compatible to Microsoft® Windows or Android® operating systems.

Crime laboratories across the world have graduated to using automated technologies for processing the various issues related to audio examination, but unfortunately not yet for tackling the issue of morphing. There are no validated techniques that have been able to produce a favorable statistic and conclusively identify the speaker. A survey of published literature would also highlight the absence of much scientific work on tackling morphing. The present research is thus an attempt to get some breakthrough in this largely untraversed scientific challenge. To conduct this research, 100 speakers (50 male and 50 female) who can speak Hindi and English were randomly selected. The speakers were given the transcript (of approximately two minutes duration) 30 minutes before their audio sample collection. All speakers were asked to repeat the script five times with the a ten-minute gap in each recording. Every fourth recording of the speaker was used to create the morphed audio using one software each from Android®- and Microsoft® Windows-based operating systems. For the samples, analysis using auditory, spectrographic, and automatic techniques were used.

The results of this study clearly indicated that no single method is 100% capable for identification of morphed audios in the present time. But it was felt that the combination of these techniques can be useful when one is performing linguistic and prosodic feature analysis; for the type of phoneme, the formant frequency value (out of all of the four formants calculated) can be used for the identification. Also, while doing the analysis using automatic technique, the log10 value was very low, and in most of the comparison, the concluding hypothesis indicated was “control and questioned audio do not have same source.” Certainly, with limitations, some specific formant frequencies indicative of the morphing can be combined with auditory parameters, especially the degradation of background noise for a suspected case of morphing, then comparing it with a possible list of suspects for speaker identification based on spectrographic analysis, which can help in recognizing the perpetrators of crime. Later, the audios were also compared on the basis of the American Board of Recorded Evidence, and the result for maximum speakers was in the inconclusive category.

Morphing, Speaker Identification, Digital Audio

Y6 Toward a Score-Based Likelihood Ratio (SLR) for Footwear Analysis

Valerie Han, BS, Iowa State University, Ames, IA; Alicia Carriquiry, PhD, Iowa State University, Ames, IA*

Learning Overview: By attending this presentation, attendees will gain a better understanding of how to formulate an SLR on multivariate features and the impact of non-independence of observations.

Impact Statement: A shoeprint is found at a crime scene and investigators want to determine whether the shoeprint matches the shoeprint made by the shoe of a person of interest. This presentation will impact the forensic science community by explaining how SLRs can be computed to quantify the strength of the evidence in this scenario. This presentation will also explore how the dependence of the observations affect the estimation of the SLR.

SLRs are a statistical method used to quantify the weight of evidence and have been used in many areas of forensics, including footwear analysis. Park and Carriquiry proposed a method based on the idea of a maximal clique to find the best alignment for a pair of shoeprint images.¹ Once two images are aligned, variables can be measured that may help quantify the closeness between the aligned images. Three variables are considered: maximal clique size, percent of overlapping features in the two images, and median Euclidean distance between overlapping features. The scores on their own are difficult to interpret, so they must then be compared with two different reference sets of scores: matching and non-matching. Matching scores are computed from features of a pair of shoeprints known to come from the same shoe. Non-matching scores are computed from two shoeprints known to come from two different shoes.

Computing the SLR requires estimating the distribution of the three variables. Since the distribution is not a recognizable parametric distribution, Kernel Density Estimation (KDE) is used. However, since the three variables are computed from pairs of shoes, the observations are dependent. This present research explores how dependent observations affect the kernel density estimation and thus the SLR, and three different ways to modify the KDE are proposed and evaluated by measuring the accuracy and discriminating power of the estimated SLRs while also measuring the calibration, generalization, coherence, and robustness.²

Footwear Evidence, Score-Based Likelihood Ratios, Weight of Evidence

Y7 The Development of a Rapid Drug Detection Method for Insects Using Paper Spray Ionization Mass Spectrometry (PSI-MS)

Alexandria Plyler, BS, Duquesne University, Pittsburgh, PA*

Learning Overview: Attendees can expect to learn about a toxicological method that, per research, contains a novel combination of methods and instrumentation. Forensic entomotoxicology is still a relatively underdeveloped field, making its study in an academic setting important should it ever be implemented in the field.

Impact Statement: PSI-MS as an analytical technique offers great advantages to not only forensic toxicology, but to forensic chemistry and trace evidence professions as well. Its ability to detect analytes with minimal sample preparation yet without sacrificing sensitivity or specificity can make it a valuable tool by which crime labs can combat the evidence backlog.

Insects have the ability to reflect the chemical environment in which they have developed. Thus, necrogenous insects can reflect the chemical environments of the cadavers they have fed on. In cases where cadavers are skeletonized, burned, or otherwise too badly damaged for tissues to be collected, forensic scientists can potentially utilize insect larvae as an alternate toxicological matrix to detect drugs in cadavers. Traditional techniques for drug detection by Gas Chromatography/Mass Spectrometry (GC/MS) and/or Liquid Chromatography/Mass Spectrometry (LC/MS) often involve lengthy sample preparation, use expensive reagents, and are destructive to important evidence. This poses a problem for crime labs that do not possess the time, funding, or resources to perform such techniques.

Analysis of insects using PSI-MS, an analytical method requiring little to no sample preparation, could provide a rapid, cost-effective, and non-destructive alternative form of toxicological analysis. PSI-MS has the distinct advantage of being an ambient ionization technique, allowing for the running of insect samples with virtually no sample preparation at STP without sacrificing sensitivity and specificity. In addition, the use of disposable paper triangles during PSI-MS analysis greatly reduces sample carryover between runs.

To validate a PSI-MS method for insects, several different extraction techniques for drug detection in the model insect *T. molitor* were explored. *T. molitor* larvae first fed on substrate spiked with Phenethylamine (PEA), a surrogate for illicit monoamine drugs such as methamphetamine and MDMA. Various extraction techniques were then explored, including ethanol extraction, methanol extraction, and Quick, Easy, Cheap, Effective, Rugged, and Safe (QuEChERS) extraction. In addition, a novel “bug-spray” technique which bypassed insect sample preparation entirely was investigated. By employing each extraction method and analyzing the insect samples using PSI-MS with Collision-Induced Dissociation (CID), the most time-efficient, cost-effective, and reliable detection method was developed. The successful implementation of PSI-MS in a forensic setting can pose a useful tool for combating the evidence backlog due to its rapid nature. The ability to study the chemical content of an insect’s environment could have significant potential not only in forensic science, but in conservation studies and the environmental sciences as well.

Entomotoxicology, Paper Spray Ionization, Mass Spectrometry

Y8 A Characterization of Metal-Peroxide Explosive Complexes Using Paper Spray Ionization-Tandem Mass Spectrometry (PSI-MS/MS)

Kayla Massari, Duquesne University, Pittsburgh, PA*

Learning Overview: After attending this presentation, attendees will better understand how the analysis of metal-peroxide complexes using PSI-MS/MS allows the presence of these complexes to be reliably detected in pre- and post-blast explosive residue.

Impact Statement: Organic peroxides have become a common agent in Improvised Explosive Devices (IEDs) because they are accessible for purchase and are susceptible to extremely exothermic reactions due to the instability of the peroxide bond.¹ IEDs have been used in acts of terrorism such as the Oklahoma City bombing and the Olympic Park bombing, and the detection of the explosive component is necessary in terms of eventually identifying the perpetrator who had the means and materials to make the IED.² Thus, a reliable and rapid detection method for organic peroxides commonly used in IEDs is of interest for the analysis of pre- and post-blast residue in forensic investigations.

The goal of this project is to develop PSI-MS/MS with Collision-Induced Dissociation (CID) for the detection and identification of peroxide-based explosives. Benzoyl peroxide and dicumyl peroxide were used as model compounds. To complement experimental studies, Density Functional Theory (DFT) was used to determine probable ion structures. Benzoyl peroxide and dicumyl peroxide samples were spiked with lithium, sodium, and potassium alkali metal cations. The peroxides were also pipetted onto silver-impregnated filter paper. These samples were ionized utilizing the THERMO FISHER™ LTQ-XL, and the fragmentation patterns of the peroxide-metal complexes were investigated using CID at the MS² stage. DFT calculations of ion structures were performed at the B3LYP/6-311+G(d) and B3LYP/MWB28/6-311+G(d) level of theory.

Initial experiments showed that both dicumyl and benzoyl peroxide form abundant complexes with Li⁺, Na⁺, K⁺ and Ag⁺ by PSI. In general, PSI produced 1:1 complexes between the peroxides and Li⁺, Na⁺, and K⁺. Studies completed with silver cations and both model peroxides showed that PSI will generate Ag⁺ complexes with 1 or 2 peroxide ligands. Because the silver-impregnated filter paper allowed for the Ag-peroxide complexes to form, it was determined that a swipe sampling method should be tested with the other metal-peroxide complexes. If this method is successful, it would allow a sample to be swiped from a surface using filter paper and analyzed using PSI with minimal sample preparation.

Mass Spectrometry, IED, Peroxide-Based Explosives

Y9 The Extraction and Identification of Illicit Compounds From Baked Goods Using Paper Spray Ionization-Tandem Mass Spectrometry

Isabella Haberstock, Duquesne University, Pittsburgh, PA*

Learning Overview: After attending this presentation, attendees will better understand how the Quick, Easy, Cheap, Effective, Rugged, and Safe (QuEChERS) solid phase extraction method can be used to extract an illicit compound from a complex matrix containing proteins, carbohydrates, and lipids. Attendees will also learn about the versatility of paper spray ionization-mass spectrometry in the rapid analysis of the QuEChERS supernatant for the presence of the illicit compound.

Impact Statement: Complex matrices like cookies and other baked goods have become common methods of consumption for illicit substances, and a rapid and accurate method for the extraction and detection of these substances is necessary for ongoing forensic investigations. Forensic toxicological analysis in drug-related cases often involves the detection of substances like MDMA, amphetamine, and methamphetamine, so an efficient solid phase extraction method would benefit time-sensitive investigations.¹ The paper spray ionization method can also be optimized and has the potential to advance the field of drug detection because of its versatility and rapidity.²

The goal of this project is to couple the QuEChERS extraction method with paper spray ionization-mass spectrometry to create an optimized extraction and detection method for illicit substances in baked goods. The QuEChERS method, although not typically used for baked goods, isolates the illicit compound from a complex matrix of carbohydrates, lipids, and proteins, allowing for accurate detection of the compound.³ Paper spray ionization is a versatile method that produces accurate quantitative and qualitative data for drug detection studies.⁴ Dough for individual sugar cookies was made using a basic recipe, and the cookies were spiked with 0µL, 1µL, 3µL, 5µL, and 10µL of phenethylamine. Each cookie was extracted in acetonitrile, magnesium sulfate, sodium chloride, and a lipid sorbent for the QuEChERS method.³ The supernatant was analyzed using the THERMO FISHER™ LTQ-XL for the presence of the phenethylamine peak, which was confirmed through the use of tandem mass spectrometry and Collision-Induced Dissociation (CID). Using paper spray ionization-mass spectrometry, the phenethylamine peak was seen in the 1µL, 3µL, 5µL, and 10µL phenethylamine cookies. CID on the phenethylamine peak confirmed these results for each cookie. The cookie with 0µL phenethylamine did not display the phenethylamine peak, which confirmed that the cookies were not cross contaminated. Because phenethylamine was successfully extracted and detected using QuEChERS and paper spray ionization, future experiments include the quantification of the illicit substance, the use of MDMA in place of phenethylamine, and the use of the Liquid Chromatography/Triple Quadrupole/Mass Spectrometry (LC/QqQ/MS) to further perform targeted analysis on the extracted illicit substance.

Paper Spray Ionization-Mass Spectrometry, QuEChERS Extraction, Baked Edibles

Y10 Estimating Decomposition Time Via Bacteria From Rat Models

Kayce Boggess, BS, Duquesne University, Pittsburgh, PA; Jan Janecka, PhD, Duquesne University, Pittsburgh, PA; Lisa Ludvico, PhD, Duquesne University, Pittsburgh, PA; Evan Penrod, MS, Duquesne University, Pittsburgh, PA; Lyndsie Ferrara, PhD, Duquesne University, Pittsburgh, PA*

Learning Overview: By attending this presentation, attendees will learn more about potential bacterial patterns and abundance when looking at necro-microbiomes that could be implemented in Postmortem Interval (PMI) estimations.

Impact Statement: PMI can be an invaluable asset to crime scene investigators when investigating a crime involving a dead body. It can help to establish a time frame of death to prove or disprove certain causes of death. It could even change a guilty verdict. However, PMI can be hard to estimate due to several factors such as insect activity, temperature, and where the body is located at death. These elements can affect the rate of decomposition, making it nearly impossible to find out the time frame of death. In these situations, the only decomposition methods would be only the body itself, which includes its enzymes and microbiome. Thus, by incorporating bacterial analysis into PMI calculations, a better time frame of death could be found in these rarer instances. A bacterial pattern of abundance could spell out how long the person has been deceased and could help bring truth to a case.

This study strives to learn whether a microbiome can be used in closed-environment cases to estimate decomposition time. Microbiomes are communities of microbes that live on and in human bodies. Through their unique make-up per individual, identifying characteristics can be discovered by analyzing the organisms present. Current research looks at an open-air environment that considers the amount of decomposition to determine a time of death. In closed-air cases, however, a victim may decompose differently, limiting the ability to estimate time of death. This can lead decomposition to look completely different in closed environments when only the microbiome and other bacterial species are present to perform decomposition. Thus, with these closed-air cases, it is difficult to use traditional means to determine the PMI.

The purpose of this study is to use the microbiome's abundance and pattern to potentially determine a time of death based on decomposition time to be used in closed-air cases. This study utilizes a week-long trial of having 40 rats decomposing, with half in an open-air setup and the other half in a closed-air setup. The rats were swabbed every other day. By using Dneasy® PowerSoil Pro Kit DNA extraction on the bacterial species and MiSeq® Illumina® Next-Generation Sequencing or Massively Parallel Sequencing (MPS) on the swabs, this study aims to find a common pattern of decomposition between different rat models to better estimate time of death. This data will be processed downstream utilizing QIIME2™ and Weka to create a taxonomic bar graph and a decision tree, respectfully. These tools can be utilized to estimate not only the breakdown of the bacterial organisms from QIIME2™, but are also a way for a computer to estimate time of death from the patterns inputted from Weka. By using this research's data and a literature review of previous studies exploring necro-microbiomes, a more accurate PMI can be established. The literature review so far has shown that the percentage difference between the main four phyla, Proteobacteria, Firmicutes, Actinobacteria, and Bacteroidetes, could allude to some pattern. Further review of the literature and this study's trial will be compared to come to a true conclusion due to more data being available to be placed into QIIME2™ and Weka.

This study concludes if there were a pattern and/or order of bacterium in microbiomes that relate to decomposition time and if there is a major difference in this information between closed and open-air environments. Per research, there is not another study that examines closed-environment decomposition in relation to bacterial activity. Thus, this study will be the first to discover a way to use microbiomes to estimate the time of death in closed-environment cases, thus providing a more accurate time of death that can potentially be utilized in these certain forensic cases, allowing a narrowing time window for alibis or to search for evidence. The knowledge gains from this research about microbiome examination could also be applied to forensic cases that may not normally have a time of death or even for cases that may have been too broad in their original PMI category. This impact to the forensic community will increase the accuracy of PMI in both open-air and closed-air cases.

Microbiome, Decomposition Time, Postmortem Interval (PMI)

Y11 The Identification of Counterfeit Alcohols in Cocktails by Paper Spray Ionization-Mass Spectrometry (PSI-MS)

Derek Heacox, BS, Duquesne University, Pittsburgh, PA; Michael Van Stipdonk, PhD, Duquesne University, Pittsburgh, PA*

Learning Overview: After attending this presentation, attendees will understand the origin of methanol in alcoholic beverages, how PSI-MS can be utilized in detecting laced alcohol, and what can be done if an alcoholic beverage is suspected to be tainted.

Impact Statement: This presentation will provide a greater understanding of the methods of detecting methanol in a suspected tainted alcohol case.

In May of 2020, as a result of the SARS-CoV-2 virus, distilleries in Chiconautla, Mexico, were labeled non-essential, resulting in an influx of counterfeit liquors by criminal organizations. Twenty people in Chiconautla died as a result of consuming the counterfeit liquor. As of April 2021, 326 people have been treated with methanol poisoning and 127 people in the Dominican Republic have died as a result of consuming methanol-laced alcoholic beverages. The consumption of counterfeit alcohol is a worldwide problem and developing a method to the legitimacy of alcohol consumed could save thousands of lives yearly. Thirty milliliters of methanol was determined to be the amount of methanol, when consumed, to cause severe illness, such as blindness or death. The purpose of this study is to determine if a counterfeit alcohol can be found in a cocktail-like solution using PSI-MS. A triangular piece of filter paper was infused with silver nitrate, and a series of deuterated ethanol and methanol standards were created to determine if methanol could be found using the PSI-MS methods. A vodka soda sample was then made containing a lethal amount of methanol, Pinnacle® vodka, and Sprite®. In the pure Pinnacle® vodka sample, only trace amounts of methanol were found. During the distillation process, 100% of the methanol cannot be removed, but trace amounts of methanol can be passed through the body without harm. During a home distillation, methanol is cut in to the final product to increase the overall yield; this was a main contributor to methanol poisoning. Standard experiments have been conducted to determine the limit of detection of the PSI-MS. Methanol-d4 had been utilized to determine the detection limit of the instrument.

Further experiments will be conducted to determine if quantification of ethanol and methanol can be determined using the PSI-MS method. This will be used to aid in the determination of whether a person had enough methanol in their system to cause dizziness, illness, or death. Methanol is a volatile liquid; a time trial will be conducted in order to ascertain a time limitation at which the methanol would be detected. Methanol that had been present on a filter paper minutes or hours after preparation are to be expected to be detected. This would lead to further studies to create a litmus test for methanol-laced beverages. A consumer could dip their drink on a testing paper and a color change would indicate trace or potentially lethal amounts of methanol in their beverage.

Forensic Science, Paper Spray Ionization, Counterfeit Alcohol

Y12 The Analysis of Commercially Available Kratom Products in Richmond, Virginia, Using Direct Analysis in Real Time-Mass Spectrometry (DART®-MS) and Inductively Coupled Plasma/Optical Emission Spectroscopy (ICP/OES)

James Fleming, BS, Virginia Commonwealth University, Richmond, VA; Emanuele Alves, PhD, Virginia Commonwealth University, Richmond, VA

Learning Overview: After attending this presentation, participants will have learned about the inorganic and organic chemical profile of kratom products and the methods used for the detection of adulterants and/or heavy metals. In addition, participants will learn the fundamentals of Direct Analysis in Real Time (DART®) and Inductively Coupled Plasma-Optical Emission Spectroscopy (ICP-OES) and how it can be used in forensic casework.

Impact Statement: This presentation will impact the forensic science community by informing participants about the variability of active compounds and heavy metals present in kratom products that show toxicological and public health concerns. This work highlights the need to “surpass the challenges of a modern forensic science world”, especially as kratom usage is evolving.

Kratom, also known as “Ketum” or “Biak-biak”, is a novel psychoactive substance that has gained popularity in the United States within the past ten years. Kratom originates from the leaves of the *Mitragyna speciosa* tree that is native to Southeast Asia, where it is known for its historical, medical, and recreational uses. Today, a variety of kratom products are commercially available in the United States, including powder, tea, capsules, extracts, and even carbonated beverages. These products are sold on the Internet, in tobacco shops, and in convenience stores. Mitragynine is the main psychoactive substance in kratom, followed by its derivative 7-hydroxymitragynine, which both play a key role in kratom central nervous system effects¹. As a natural product, kratom is a complex mixture of more than 40 alkaloids with different properties. In excessive amounts, kratom leaves can cause stupor, sweating, dizziness, nausea, and dysphoria – effects that are usually expressed in opioid overdose.

Kratom products are not regulated and products often include a statement of “not for human consumption” on the labels. “Krypton” and “4x100” are kratom cocktails previously associated to fatal cases. “Krypton” combines kratom leaves with O-desmethylnaloxone, while “4x100” combines kratom leaves with Coca-Cola and codeine containing cough syrup². Due to the lack of regulation of commercial products, lethal cocktails like these demonstrate the need for a quick and easy method to detect unlisted components in commercially available kratom products. The Food and Drug Administration (FDA) has found toxic levels of lead and nickel in various kratom products. Furthermore, several studies have described higher concentration of mitragynine and other alkaloids in different commercial products obtained from kratom.

For the chemical profile study, 29 kratom samples were obtained from tobacco and vape shops in the Richmond, Virginia area. Samples included powders, teas, capsules, extracts, and a carbonated beverage. Active compounds were analyzed using Direct Analysis in Real Time-Time of Flight-Mass Spectrometry (DART-MS) and elements were analyzed using Inductively Coupled Plasma-Optical Emission Spectroscopy (ICP-OES). The DART analysis was performed for the untargeted screening of the exact masses of kratom alkaloids. For this analysis, a capillary tube was dipped in a methanolic solution obtained from kratom samples and introduced into the helium stream of the DART-MS. Elements included Al, As, Cu, Fe, K, Mg, Mn, Na, Ni, and Pb. For ICP-OES analysis, powder samples underwent an acid digestion.

Kratom use has become more popular with each passing year, and while methods for kratom active compounds already exist, there is no information about the total chemical profile of samples currently in the market. As a herbal product, no quality control is expected from manufacturers, which brings a public health concern due to the association of high concentrations of active substances and toxic metal levels in commercial kratom samples.

Program Committee Financial Disclosure—2022

As a sponsor of continuing education, the American Academy of Forensic Sciences (AAFS) must ensure balance, independence, objectivity, and scientific rigor in all its educational activities. All faculty participating in a sponsoring activity are expected to disclose any significant financial interest or other relationship: (1) with the manufacturer(s) of any commercial product(s) and/or provider(s) of commercial services discussed in an educational presentation; and (2) with any commercial supporters of the activity. (Significant financial interest or other relationships can include such things as grants or research support, employee, consultant, major stockholder, member of speaker's bureaus, etc.) AAFS has an established policy regarding conflicts of interest that includes decisions the Program Committee members may make in selecting content for the Annual Scientific Meeting Program. By serving on the committee, regardless of the role, each member has agreed to comply with Section 1.4.7. of the AAFS Policy and Procedure Manual.

To serve on the 2021–22 Program Committees, it is required that relevant AAFS staff members, program committee members, and/or reviewers complete a Financial Disclosure Form before being provided access to review submissions for the program. For continuing education accreditation purposes, the disclosed relationships are published below so learners are aware of the nature of any relationships that may impact the selection of presentations for the program. If a committee member failed to provide complete disclosure of a relevant financial interest or relationship, the committee member or reviewer was not allowed to serve. The executed Faculty Disclosure Forms are on file in the AAFS Office.

The following 2021–22 Program Committee members have disclosed financial relationships with commercial entities.

Bierly, Jolene-Reviewer NMS Labs (Salary)	Mozayani, Ashraf-Reviewer CRC (Royalty), International Forensic Science Consultants (Consulting Fees), Springers (Royalty), Texas Southern University (Salary)

As an accredited provider of Continuing Medical Education, the American Academy of Forensic Sciences requires speakers to disclose any real or apparent conflict of interest they may have related to the content of their presentation(s). The existence of commercial or financial interest of authors related to the subject matter of their presentation(s) should not be construed as implying bias or decreasing the value of their presentation(s). However, disclosure should help participants form their own judgments. AAFS and the Program Committee review the submissions to ensure that the content is educational and not a commercial presentation for companies and their products. Participants may notify AAFS by email (abstracts@aafs.org) should any presentation be considered solely a commercial endorsement presentation. Notification should include presentation number/ID (e.g., BS10, E100, W30) and speaker name.

If an author failed to provide complete disclosure of the discussion of commercial products, a relationship with the manufacturer including employee/employer relationship, sources of support for the research project, and/or the discussion of unlabeled or unapproved uses of pharmaceuticals/medical devices, the presentation was not accepted. Authors are required to disclose at the beginning of each presentation any information disclosed and listed below. Copies of the executed disclosure forms are kept on file in the AAFS office.

The following presenting authors have disclosed financial relationships with commercial entities.

A

Adedayo, Oluwasola Mary-C27
 The University of Winnipeg (Stipend)
 Adeoye, Alexandra-B131
 National Institute of Justice (Grant Support)
 Aggazzotti, Cristina-D14

The presenting author index can provide a quick reference to find when and in what section presenting authors are scheduled to present at the 2022 Annual Scientific Conference. The reference table below assists you in finding the section in which the presentation will be given. Letters correspond to the scientific discipline/section in which the presentation is being made while the number corresponds to the numerical sequence of the presentation within the section.

A Anthropology
 B Criminalistics
 C Digital & Multimedia Sciences
 D Engineering & Applied Sciences
 E General
 F Jurisprudence
 G Odontology
 H Pathology/Biology

I Psychiatry & Behavioral Science
 J Questioned Documents
 K Toxicology
