

THE AMERICAN ACADEMY OF FORENSIC SCIENCES

PROCEEDINGS

A RESPONSIVE ACADEMY

MEETING AND SURPASSING THE CHALLENGES OF A
MODERN FORENSIC SCIENCE WORLD

AAFS
2022

FEBRUARY 21 - 25
SEATTLE, WASHINGTON

410 North 21st Street
Colorado Springs, CO 80904
Phone: (719) 636-1100
Fax: (719) 636-1993
Email: info@aaafs.org
Website: www.aaafs.org

PROCEEDINGS

of the American Academy of Forensic Sciences 74th Annual Scientific Conference

The *Proceedings* of the American Academy of Forensic Sciences is an official publication of the American Academy of Forensic Sciences (AAFS). It is devoted to the publication of the abstracts of technical oral papers and posters presented at the AAFS Annual Scientific Conference. These include various branches of the forensic sciences such as anthropology, criminalistics, digital evidence, engineering, jurisprudence, odontology, pathology, psychiatry, questioned documents, and toxicology. Similar submissions dealing with forensic-oriented aspects of the social sciences are also included.

Please note that some of the abstracts included in the *Proceedings* deal with topics, results, and/or conclusions that are controversial. The publication of abstracts does not imply that the AAFS, its sections, or the individual section program chairs/committee members have verified or agree with the studies, results, and/or conclusions of each abstract. During the process of planning a scientific program, it is impossible to “peer-review” each abstract and presentation to the degree that is accomplished during manuscript review. Abstracts and presentations are accepted, in part, so they can be critiqued and reviewed by other scientists. Thus, a forum is created to discuss controversial issues.

The views expressed in this publication are not those of the AAFS. The data and opinions appearing in the published material were prepared by and are the responsibility of the contributor(s), not of the AAFS nor its respective employees, employers, officers, and agents. The AAFS does not supply copies of meeting papers. Please write directly to individual authors to obtain copies of specific papers. Presentation of some abstracts may have been scheduled or canceled after the publication of this document.

English is the official language of the AAFS and its meetings; neither oral nor written translations will be provided.

Copyright 2022 by the AAFS. Unless stated otherwise, non-commercial *photocopying* of editorial material published in this periodical is permitted by the AAFS. Permission to reprint, publish, or otherwise reproduce such material in any form other than photocopying must be obtained from the AAFS.

S1 Interdisciplinary Symposium: Problems of Today and Solutions for Tomorrow

Christopher M. Milroy, MD, LLB, University of Ottawa, Ottawa Hospital, Ottawa, Ontario, Canada; Paul Messner, JD*, Dry Ridge, KY; James L. Caruso, MD*, Office of the Chief Medical Examiner/Coroner, Denver, CO; Lucy Davis, BHS, LDH Consultants, LLC, Pikeville, KY; Heidi Eldridge, PhD*, RTI International, Research Triangle Park, NC; Roderick T. Kennedy, JD, Los Ranchos, NM; Barry Logan, PhD, NMS Labs, Horsham, PA*

Learning Overview: After attending this presentation, attendees will have a greater understanding of current challenges in multiple forensic science disciplines, death investigations, and in the courts.

Impact Statement: This presentation will impact the forensic sciences community by offering various perspectives regarding current issues and possible future solutions.

This session will present various perspectives as they relate to forensic science, medicine, and the courts including: workload and workforce issues in forensic pathology and their impact on death investigations; the analytical challenges presented by the rapid development of illicit novel psychoactive substances; why standards created by the Academy Standards Board (ASB) are crucial to forensic science; and how pattern recognition discipline validity challenges are being addressed. The symposium will also discuss why courts are both reluctant to recognize challenges to previously accepted forensic science techniques and resistant to admitting evolved techniques.

Forensic Science Disciplines, Death Investigation, Court

S2 Young Forensic Scientist Forum (YFSF) Special Session: Meeting and Overcoming Challenges Faced by Young Forensic Scientists

Zain Bhaloo, MSc, Canada Border Services Agency, Ottawa, Ontario, Canada; Hannah Simmons, BS*, Dirk Vastrick Presents, Spokane Valley, WA; Timothy Campbell, BSc*, Canada Border Services Agency, Ottawa, Ontario, Canada; Kelly Freeman, MS*, Houston Forensic Science Center, Houston, TX; Cheryl Hunter*, American Academy of Forensic Sciences, Colorado Springs, CO; Brian Janysek, MFS*, Oakton, VA; Modhuparna Manna, BTech*, Louisiana State University, Baton Rouge, LA; Robert Lynch, BArch*, Haymarket, VA; Carl R. McClary, MS*, ATF, Atlanta, GA; Aja Moss, MS*, Houston Forensic Science Center, Houston, TX; Jessica Powers, MS*, Houston Forensic Science Center, Houston, TX; Joe Trevino, MS*, Forensic Investigations, Sunnyside, NY; Dirk Vastrick, BA*, Dirk Vastrick Presents, Spokane Valley, WA; Molly Van Buren, MSc*, Houston Forensic Science Center, Houston, TX; Matthew R. Wood, PhD*, Ocean County Sheriff's Department, Forensic Science Laboratory, Toms River, NJ*

Learning Overview: The YFSF will aim to bring to light some of these challenges and more importantly, highlight how the members and attendees of our very own American Academy of Forensic Science met these challenges head on, rose to the occasion and circumvented these challenges in order to get to their current positions.

Impact Statement: The impact of this Special Session will focus mostly on, but not exclusively on, the younger forensic scientists who are still in the process of trying to get to their "dream job". We say not exclusively because the age of the person will never dictate their entrance into a new career in forensics, therefore anyone and everyone can and will benefit from the information provided in this Special Session.

This session is designed from the ground up and tailored to the Young Forensic Scientists Forum attendees as well as any members of the AAFS who are or were experiencing difficulties in the transition from Student to Professional. So many hurdles are present in this journey, many of which young scientists are completely unprepared for: building and updating resumes, job interviewing skills and techniques, proper and efficient networking, and all the mistakes, difficulties and challenges in between.

YFSF, Forensics, Special Session

S3 Tale of the Tape—The Media’s Impact on Forensic Science Cases

J.C.U. Downs, MD, forensX, LLC, Charleston, SC; Tanisha Henson, JD*, Maricopa County District Attorney’s Office, Phoenix, AZ; Barry Fisher, MBA, MS*, NIJ, Indio, CA; John Fudenberg, MBA*, IACME, Las Vegas, NV; Judy Melink, MD*, PathologyExpert, Inc., San Francisco, CA; Bobbi Jo O’Neal, RN*, Charleston County, North Charleston, SC; Greg Ramey, MPA*, Lafayette, GA; Edwin P. Stevens, APS Films LLC, Glendale, CA*

Learning Overview: Attendees can expect to learn about the impact that media can and does have on forensic casework at multiple levels and how to successfully engage with journalists while maintaining objectivity in casework.

Impact Statement: This presentation will impact the forensic science community by showing documented pitfalls and successes in various media and forensic science professionals in handling casework and suggest strategies for future improvement in the flow of information while protecting necessary information.

Forensics professionals are keenly aware of the impact their services have on cases. Part and parcel of this is intense public interest in and scrutiny of casework. One need only do a brief internet search to find over 1.5 million hits for “case of the century,” including references to the accompanying media frenzies associated therewith. In many settings, the players—forensics experts and the media—are placed at seeming odds with each other, in a real or perceived effort to control information flow. Comfort comes in knowing that the crucible of second-guessing burns hot—but only until the next such case comes along. As this cycle of investigation-analysis-court-critique-resolution repeats, lessons are available for those willing to learn from their forebearers. As Voltaire asked, “Is there anyone so wise as to learn by the experience of others?”

All cases begin at the scene, where experience teaches many cases are won or lost based upon how a scene is processed and how an initial investigation commences. Los Angeles County, CA, is an enormous jurisdiction and no stranger to high-profile cases, including O.J. Simpson, Phil Spector, The Night Stalker, and too many others to count. A discussion of lessons learned from decades of leading the forensic laboratory analysis of such high profile cases provides valuable insights into the “dos” and “don’ts” of casework.

High-interest cases, far from being limited to major jurisdictions, can literally occur anywhere and at any time. Case in point, 20 years ago a sleepy northwest Georgia community of just over 60,000 people became home to a macabre nightmare of a case—an originally unknown number of human remains (later tallied at 339) was found literally dumped in and around the grounds of a family compound surrounding an operating crematory. Nothing similar on such a scale had been encountered before or since. The primary investigators had to deal with not only the casework to be done in order to identify the deceased and to prove criminal charges, but had to simultaneously inform the public while preventing the media from interfering with investigators’ duties. Issues encountered along the way proved challenging but a (partial, at least) successful case resolution followed, thanks to good public relations anchoring good detective work.

Many jurisdictions conduct exhaustive preparatory exercises in order to be ready to face possible future mass disaster scenarios. Large or small, one can never be ready for all scenarios. The task of primary medicolegal death investigation falls in many jurisdictions on the coroner, who must be prepared for any death(s) falling under their jurisdiction. One of the worst-case situations involves mass shooting fatalities. These happen suddenly and without warning. The Las Vegas shooting is an example of such a potentially overwhelming investigation. Lessons learned from the experience provide insights in readiness if such awful acts occur again. Although fortunately involving fewer fatalities, smaller-scale investigations can be no less troubling and warrant similar media scrutiny. The racially motivated slaying of nine parishioners with clergy at a Bible study group shocked a city, a nation, and the world. How could this happen here? In a city not unfamiliar with shocking cases (nine firefighters dead in the line of duty, a suspect shot in the back while fleeing, and the like), these are another day at the office for a medicolegal death investigator.

When the deceased come in, the task of examination of the remains and telling their story falls upon the forensic pathologist. As with other forensics professionals, the stories are waiting to be told, awaiting only an attentive ear and an eloquent voice. Personal recollections of the medical examiner can make for best-selling non-fiction. But, are there lessons to be learned about and in the telling?

Eventually, the press interest in cases comes to center on the courtroom where evidence—good or bad—is presented to a presumably objective arbiter of fact. With intense pre-trial and in-trial scrutiny, including live televised trials, attorneys have had to adapt and perfect new strategies to best present their cases. Lessons learned from a career trial criminal defense attorney (ongoing) –turned-TV journalist offer a unique perspective on the good, the bad, and the ugly of courtroom as entertainment and the media as fact source.

Often downplayed in the entire media hoopla surrounding a case is the victim, without whom there would be no story. Every victim has a story, but not everyone has someone to tell it. In a unique circumstance, the surviving family can tell the decedent’s tale in such a way as to capture not only public but also professional interest. The session closes with the brother of a homicide victim, who shared his sister’s story in an award-winning documentary. The session will close with a special screening of her story: *Alice is still dead*.

In the “sweet science” of pugilism, participants are assessed according to their literal physical dimensions—the “tale of the tape.” In the modern era of ubiquitous video, the forensic sciences have been and continue to be judged based on a different, but no less real physical comparison: the taped record of events. Properly anticipated and thoughtfully pursued, information flow can be successfully managed and utilized, leaving both sides, the pursuit of truth and the quest for justice, as winners.

Media, Scrutiny, Journalism

BS1 The Path Forward Continues: What's Happening in Forensic Standards

Teresa Ambrosius, BA, American Academy of Forensic Sciences, Colorado Springs, CO; Allison Getz, MS*, National Institute of Standards and Technology, Gaithersburg, MD; Karen Reczek, MS*, National Institute of Standards and Technology, Gaithersburg, MD*

Learning Objective: Participants will learn about updates in standards development in the United States and internationally from United States Standards Developing Organizations (SDOs). Participants will also get an update from the Organization of Scientific Area Committees (OSAC) for Forensic Science regarding how they are working with the SDOs and encouraging forensic science service providers to implement standards.

Participants will gain a better understanding of the progress of consensus standards development, including submission, drafting, public and committee commenting and resolutions, and finalization. Participants will also realize the importance of public input into the standards process and will learn how to participate, even if they are not part of an SDO consensus body or committee.

Impact Statement: The 2009 National Research Council (NRC) stressed the lack of standardization in forensics. The advent of OSAC, administered by the National Institute of Standards and Technology (NIST), and the AAFS Standards Board (ASB) has resulted in several years of concerted efforts to identify gaps in needed standards and begin their development using the voluntary consensus standards development process. All forensic professionals need to be aware of new and emerging standards in the various forensic disciplines, their importance, and how they can be implemented.

In 2009, the NRC published the Report, *Strengthening Forensic Science in the United States: A Path Forward*, which summarized the challenges facing the forensics community and the lack of mandatory standardization, certification, and accreditation. From this report, the Department of Justice (DOJ) and the NIST signed a Memorandum of Understanding that led to the establishment of the National Commission on Forensic Science (NCFS) and the NIST-administered OSAC for Forensic Science.

Presenters will provide an overview of the standards currently in development, those soon to be published, and the new standards published by various SDOs. New standards include those related to interdisciplinary topics, such as evidence collection and labeling, interpretation and reporting, and discipline-specific standards in the areas of criminalistics, toxicology, digital evidence, anthropology, facial recognition, photography, biology, pattern evidence, and crime and fire scene investigation, with a focus on terminology, measurement uncertainty, measurement traceability, quality assurance, and calibration.

Presenters will describe the process that a document goes through from inception through drafting, commenting, voting, and publication. This overview will give participants the education they need to participate in the standards development process.

OSAC has been working closely with various SDOs to bring the community together to define requirements for disciplines to submit standards through the development process. OSAC's role in the standards development process and promotion of implementation of these standards will also be covered.

Standards, Consensus, Forensic Science

BS2 Autopsy of a Crime Lab: The Evolving Approaches Toward Forensic Evidence in Court

Brandon Garrett, JD, Duke University School of Law, Durham, NC*

Learning Overview: This presentation will survey the current state of litigation and judicial review of admissibility of forensic evidence, as well as providing an overview of a recent book, *Autopsy of a Crime Lab*, that surveys the sources of error in forensic work and approaches designed to improve the process and safeguard reliability.

Impact Statement: This presentation will provide an overview of the book, but particularly focus on legal research and developments in the courts as judges have evolved in their approach toward forensic evidence. Studies examining how lay jurors evaluate forensic testimony in court will be summarized.

“That’s not my fingerprint, your honor,” said the defendant after Federal Bureau of Investigation (FBI) experts reported a “100-percent identification.” They were each wrong, and Brandon Mayfield was later cleared. How does error, even in high-profile cases, occur? Is it the quality of the latent fingerprint, the role of databases, individual examiner error, cognitive bias, or uncertainty inherent in a method that can lead to error? How should lawmakers, labs, and courts approach each of these challenges? The recently published book, *Autopsy of a Crime Lab*, is the first to catalog the sources of error behind a range of well-known forensic evidence, from fingerprints and firearms to forensic algorithms. At the crime scene, the book explores the need for scientific standards regarding evidence collection. Moving to the lab, the book explores quality controls, human factors, and the need for further studies to validate basic premises of widely accepted techniques. Turning to individual experts, the book asks how proficiency tests could be used to better assess individual performance, and the need for standards governing report writing and testimony. Reaching the courtroom, the book examines how concepts of judicial gatekeeping have slowly evolved, regarding discovery, testimony, and expert admissibility.

Taking us into the lives of the wrongfully convicted or nearly convicted, into crime labs rocked by scandal, and onto the front lines of promising reform efforts driven by professionals and researchers alike, *Autopsy of a Crime Lab* describes the forensic landscape and recent efforts to place evidence, from the crime scene to the laboratory to the courtroom, on a sound scientific footing.

Gatekeeping, Testimony, *Daubert*

BS3 Procedures for Breaking the Zodiac Killer's Code

Jeanne Anderson, Federal Bureau of Investigation Laboratory, Quantico, VA; David Oranchak*, Roanoke, VA*

Learning Overview: Attendees will learn about the forensic cryptanalysis of the Zodiac Killer's 50-year old unsolved cipher, how this code was broken, and the procedures used by the Federal Bureau of Investigation (FBI) Laboratory in cases such as this.

Impact Statement: This presentation impacts the forensic science community by bringing awareness of forensic codebreaking capabilities.

The field of forensic cryptanalysis, or codebreaking, is a little-known but well-established forensic discipline that, when applied, can produce reliable and informative results. Cryptanalysis can be applied to records of illicit businesses, such as drug distribution or manufacturing, human smuggling, and commercial sex, as well as coded messages.

The FBI Laboratory houses the Cryptanalysis and Racketeering Records Unit (CRRU) and is staffed with forensic cryptanalyst examiners trained to decipher coded messages and cryptic illicit business records. This forensic analysis relies on standard operating procedures based on steps developed in the early 1900s by a United States Army cryptologist and that remain accepted by forensic and academic cryptologic communities today. These procedures provide a framework for the analysis of codes and records that apply regardless of crime, context, or record type. Despite this framework's historical basis, it remains largely unknown by the forensic community; this presentation will inform attendees about this forensic capability. Further, this presentation will introduce one such codebreaking case, that of the never-caught Zodiac serial Killer. This case involved a coded message that remained unsolved for 50 years before it was broken this past December. This development provided the law enforcement community with new material on an unsolved serial killer case and the cryptologic community with a new encipherment technique that confounded professional and amateur cryptanalysts for 50 years.

One of the three-person team who broke this message will provide background on techniques employed for over a decade of work on the Zodiac Killer's code, including those techniques that eventually helped decrypt this coded message as well as how these techniques may apply to remaining unsolved coded messages. An FBI Cryptanalyst Forensic Examiner will present on law enforcement's approach to coded messages, specifically the standard operating procedures used for analysis of records and codes such as this. Several remaining unsolved coded messages will be introduced for those interested in applying any of the presented cryptanalytic techniques to actual unsolved codes.

Cryptanalysis, FBI Codebreaking, Zodiac Killer

BS4 Pursuing Truth Through Forensic Evidence—But Does the Family Believe?

T.L. Williams, MFS, United States Army Criminal Investigation Command, Quantico, VA; Phillip Curran, MFS*, United States Army Criminal Investigation Command, Quantico, VA; Tanya Marlow, MFS*, United States Army Criminal Investigation Command, Quantico, VA*

WITHDRAWN

BS5 Helping the Marines Correct the Historical Record: Identifying the Iwo Jima Flag Raisers Using Photographic Comparison and Facial Recognition

Richard Vorder Bruegge, PhD, Federal Bureau of Investigation, Quantico, VA*

Learning Overview: Attendees will learn how Digital and Multimedia Sciences techniques, including photographic comparison, facial recognition, and 3D face modeling, were used to help the United States Marine Corps correct the historical record in regard to the individuals depicted in the iconic “Iwo Jima Flag Raising” photograph by Joe Rosenthal. This case provides an example of how new techniques may be tested against unusual types of evidence in a matter of historical significance.

Impact Statement: The forensic science community will see an example of how established and innovative forensic science techniques can be “stress tested” in unusual circumstances to help further define the limits of these techniques.

On February 23, 1945, United States Marines raised an American flag on Mount Suribachi, Iwo Jima. A photograph depicting that event taken by Associated Press photographer Joseph Rosenthal immediately became iconic in Marine Corps and United States lore, with the image serving as the basis for the United States Marine Corps War Memorial in Washington, DC, and the National Museum of the Marine Corps in Quantico, VA. While most Marines will tell you that the individual names of those in the photograph do not matter, historians, and many in the public, want to be able to put names to the faces.

Previous Marine Corps reviews led to updates of the record in 1947 and 2016, but after the 2016 Huly Board findings were released, historians Dustin Spence, Stephen Foley, and Brent Westemeyer brought forth additional evidence indicating that further changes were needed. As a result, a third Board was convened in 2018. This “Bowers Board” requested the assistance of the Federal Bureau of Investigation (FBI) Digital Evidence Laboratory (DEL) in analyzing photographs and film footage from that day to help establish, once and for all, which Marines are depicted and in which positions around the flag.

The flag raised in the Rosenthal photograph was the second raised on the summit that day, replacing a smaller one. Several photographers, including one with a 16-mm movie camera, were also present and captured multiple photographs and film recordings of events on the summit that day, culminating in a series of celebratory photos known as the “Gung Ho!” photos. The combination of these photographs and film recordings make it possible to track the movements of various individuals during this sequence and establish their presence through image analysis (photographic comparison), primarily based on their faces and details of their helmets, clothing, and gear.

Through this examination process, the identities of four of the six individuals around the flagpole in the Rosenthal photo can be established with either “Strong Support” or “Extremely Strong Support,” while there is “Some Support” or “Limited Support” for the other two. Facial recognition technology and 3D-facial modeling software were also utilized in support of these analyses. When combined with further information from historical records, these findings offered a compelling case for the Bowers Board to declare in 2019 that the record is now complete.¹

Requests like this—which do not involve criminal or civil litigation—allow multimedia evidence labs to not only stress test their existing standard procedures on different materials and content, but also allow them to experiment with new techniques and procedures under more “realistic” conditions than may otherwise be available. In this case, facial recognition technology and 3D-modeling software were utilized in support of traditional image analysis techniques for photographic comparison. Through this process, potential limitations of these technologies were identified. This presentation will provide attendees with a better understanding of the process involved in this image analysis examination, as well as how the facial recognition and 3D-modeling software were leveraged in this case, along with the potential limitations.

Contributing editor: Breanne Robertson, PhD., Marine Corps History Division, Quantico, Virginia, 2019, LCCN 2019035917 | ISBN 9781732003071 (Also Available at: https://www.usmcu.edu/Portals/218/Investigating%20Iwo_WEB2.pdf)

Facial Recognition, Image Analysis, Photographic Comparison

BS6 Electrical Torture, Electrocuting, and Homicide—The Istanbul Protocol

Helmut Brosz, BASc, Forensic Sciences International Group, Markham, Ontario Canada; Renee Knight, BSFS*, Forensic Sciences International Group, Markham, Ontario, Canada*

Learning Overview: This presentation will provide an overview in identifying electrical torture injuries through a foundational background in body resistance to electricity and electrocution scenarios. After attending this presentation attendees will: (1) have an understanding of what is Electrical Shock Torture as defined by the Istanbul Protocol; (2) Mechanisms of Electrocution; and, (3) the variables to be applied in the identification of electrical torture, injury, and homicide.

Impact Statement: This presentation will impact the forensic science community by improving the ability of Authorities Having Jurisdiction (AHJ), including investigators, medical examiners, lawyers, prosecutors, and engineers, to identify when an electrical torture or other electrical incident has taken place. Attendee knowledge of electrical shock injuries, torture, and homicide will be increased.

AHJ attending to a suspected electrical torture scene or homicide scene involving electrocution sometimes have difficulty discerning between natural death and death due to electricity. On average in North America, between 500 and 1,100 electrocutions occur annually, including suicide, auto-erotic, accidental, homicide, etc. The statistics for electrical torture are hard to come by; however, this form of torture “Parilla” appears to be practiced in certain South American and far Eastern Countries. There are also approximately ten times as many arc flash burn injuries and more than ten times as many non-fatal electric shocks. Some minor shock situations result in fall reactions that can lead to death and injury. These low-voltage shocks/electrocutions frequently leave no visible marks on the person. High-voltage electrocutions mostly leave distinctive marks and catastrophic injuries.

In scenarios involving electrical torture, readily identifiable marks may not always be available. Scenarios involving an individual being shocked in the presence of water may sometimes obscure contact entry and exit marks. Scene photos, hospital admission notes and sketches, autopsy photos, and reports are important data to be created, then assembled, studied, and analyzed as set out in the Istanbul Protocol.

The review and study of applicable standards and codes can assist the AHJ or investigator. For example, the Istanbul Protocol provides a definition on what is deemed as electrical shock torture, the device mechanisms utilized, and the various pathological outcomes of the torture relating to independent and dependent variables. For electrocution situations, the National Electrical Safety Code (NESC), Occupational Safety and Health Administration (OSHA) 26CFR1910, 26CFR1926, National Fire Protection Association (NFPA) 70E, and California General Order 95 may apply.

Variables in identifying electrical shock include voltage, body resistance, time, and the paths the current takes through the body. Through these factors, reconstruction and forensic analysis can be conducted in identifying and interpreting the method and potential motive for electrical torture through case presentations, examples, and artifacts.

Torture, Electrocuting, Istanbul Protocol

BS7 Forensic Nursing Science: A New Section for a New Scientific Era

Nancy Cabelus, NDP*, University of New Haven, New Haven, CT; Virginia Lynch, MSN*, Forensic Nurse Consultants, International, Divide, CO; Joyce Williams, DNP*, Stevenson University, Owings Mills, MD; Amy Carney, PhD*, California State University, San Marcos, CA

Learning Overview: After attending this presentation, attendees will have a better understanding of the history of this dynamic discipline, the inception of forensic nursing worldwide, and how forensic nurses contribute to clinical practice, research, and policy.

Impact Statement: This presentation will impact the forensic science community by presenting exemplars of the application of care of victims, survivors, and perpetrators of violence of trauma.

In 1991, the American Academy Forensic Sciences (AAFS) distinguished forensic nursing as a scientific discipline.¹ This pronouncement launched a movement now recognized worldwide. The following year, the International Association of Forensic Nurses (IAFN) was founded.² In 1995, the American Nurses Association (ANA) Congress of Nursing Practice bestowed the official status of a nursing specialty upon the science of forensic nursing.³ The forensic aspects of nursing have long existed. Nurses have historically cared for victims of violence—both the living and the dead. In the 17th century, nursing had not yet become a science and midwives filled this role.⁴ Two centuries later, Florence Nightingale established the first aspects forensic nursing when caring for the war wounded and dead.

Forensic nursing is a dynamic discipline that recognizes human violence and trauma through a contemporary domain of scientific knowledge, health care, human rights, social justice, public health, and evidence-based practice. Broadly defined, forensic nursing science is nursing applied to the law, following the long-established exemplar of forensic medical science. Forensic nurses are health care providers qualified in the examination and evaluation of patients presenting with forensic biomarkers of crime-related trauma and the clinical investigation of questioned deaths. Global violence and problematic social and cultural situations reinforce the need to define the dynamics, processes, and guidelines for forensic nursing practice as it evolves and endures change.

Educational requirements to practice in forensic nursing vary. The nurse must have, at a minimum, an Associate's degree in nursing but a Bachelor's degree is preferred. After completing the degree, the nurse must successfully pass the board exam in the state in which they intend to practice. After practicing clinical nursing for a year or more, s/he may desire to specialize in forensic nursing as a Forensic Nurse Examiner (FNE) generalist or select a subspecialty of this discipline. Opportunities for role development include the Sexual Assault Forensic Examiner (SANE) course or pursuing the forensic aspects of training as a legal nurse consultant, accident investigator, mental health nurse practitioner, or nurse death investigator. Educational opportunities may be offered in risk management agencies, law firms, correctional settings, or domestic violence shelters. Regardless of the specialized role, forensic nurses work with victims of all ages who have suffered abuse, neglect, sexual assault, trauma, or any other crime-related injuries. Forensic nurses may practice in hospitals and community settings, typically interfacing with the legal system and treating victims, suspects, or perpetrators of crime.

Policy development in forensic nursing has evolved as the professional role grows and changes. Across the United States, individual Boards of Nursing have evaluated the forensic nursing response and the gaps that are filled when forensic nurses work with law enforcement, attorneys, and fellow medical professionals. As individual states evaluate their Nurse Practice Acts and the impact they have on forensic applications, forensic nurses are examining the effect that state, national, and federal rules and policies have on their interactions with both individuals and institutions. Forensic nurses also shape policy, bringing change through advocacy and research.

Graduate forensic nursing programs are available, often online, and require a number of clinical hours (typically 500) in addition to the didactic requirement of 30–40 credits. Forensic nurses with a graduate degree may opt to teach, conduct research, or in a clinical practice. Advanced practice forensic nurses may pursue a doctorate degree in forensic nursing research (PhD) or a doctorate with a clinical forensic focus, the Doctor of Nursing Practice (DNP).

W2 The National Institute of Standards and Technology (NIST) Forensic DNA Activities: Foundations, Research, and Standards

John Butler PhD, National Institute of Standards and Technology, Gaithersburg, MD; John Paul Jones, MBA*, National Institute of Standards and Technology, Gaithersburg, MD; Peter Vallone, PhD*, National Institute of Standards and Technology, Gaithersburg, MD; Sarah Riman, PhD*, National Institute of Standards and Technology, Gaithersburg, MD; Melissa Taylor, BA*, National Institute of Standards and Technology, Gaithersburg, MD; Katherine Gettings, PhD*, National Institute of Standards and Technology, Gaithersburg, MD*; Carolyn R. "Becky" Steffen, MS*, National Institute of Standards and Technology, Gaithersburg, MD*

Learning Overview: This presentation will review activities at NIST involving forensic DNA foundational studies, research, and standards.

Impact Statement: Presentations in this workshop will impact the forensic science community by contributing to an understanding of NIST activities in advancing knowledge and practice of forensic DNA through foundation studies, focused research, and development of documentary standards.

NIST has been Congressionally-funded to: (1) perform forensic science research, (2) administer the Organization of Scientific Area Committees for Forensic Science (OSAC) to promulgate scientifically sound standards, and (3) conduct scientific foundation reviews of forensic methods and practices. The NIST Applied Genetics Group has conducted cutting-edge research in DNA sequencing and other areas of forensic DNA for the past three decades.¹ The OSAC Human Forensic Biology Subcommittee has completed ten standards working with the AAFS Standards Board DNA Consensus Body.² Another two dozen documentary standards and best practice recommendations are in development. A DNA mixture interpretation foundation review was completed in 2021 that identifies and documents what is empirically supported and describes where future efforts are needed.³ Valuable research on Probabilistic Genotyping Software (PGS) systems has also been conducted in the past year. In conjunction with the National Institute of Justice (NIJ) Forensic Technology Center of Excellence, NIST began work in 2020 with a DNA Interpretation Human Factors Working Group. Process maps describing decisions made during forensic DNA measurement and interpretation have been prepared by OSAC and reviewed by the Scientific Working Group on DNA Analysis Methods (SWGDM). This workshop examines these various efforts and shows how they are interconnected and will benefit the forensic DNA community and its stakeholders in the criminal justice system.

Effective training and continuing education are crucial to keep up with evolving forensic DNA technologies and applications. Forensic laboratories invest in the continuing education of their staff. Universities with forensic science programs seek to prepare their students to be future contributing caseworkers. Stakeholders in the criminal justice system (e.g., law enforcement personnel, lawyers, and judges) using DNA results also benefit from regular training and continuing education to understand capabilities and limitations of methods and practices. Forensic scientists, students, and stakeholders can profit from drawing from a common informative knowledge base.

NIST forensic science efforts identify, consolidate, and share core principles, advance the state-of-the-science, and provide supporting publications and documentary standards to encourage deeper learning and understanding of forensic DNA. Based in part from the foundation review on DNA mixture interpretation and through discussions with experienced forensic DNA scientists, an initial list of 500 informative publications across 26 topic categories in forensic DNA was presented as an AAFS workshop in 2021.⁴ An update on this list of most valuable publications will be provided as well as initiatives to provide additional training for practitioners and stakeholders.

DNA Mixture Interpretation, DNA Research, DNA Standards

W3 Determining Sufficiency for the Identification of Gasoline

Brenda Christy, MS, Virginia Department of Forensic Science, Norfolk, VA; Reta Newman, MA*, Pinellas County Forensic Laboratory, Largo, FL; Kelsey Winters, MSFS*, Virginia Department of Forensic Science, Norfolk, VA; Larry Tang, PhD, University of Central Florida, Orlando, FL*

Learning Overview: Attendees can expect an overview of the current gasoline identification limitations as well as an introduction to key diagnostic features of gasoline used in a statistical framework to enhance interpretation and identification.

Impact Statement: This workshop will detail chromatographic peak ratios with varied support for the identification of gasoline as well as a method to graphically demonstrate the overall statistical support for gasoline in the sample.

Currently, the consensus standard for identification and classification of ignitable liquids and ignitable liquid residues is ASTM E1618-19 Standard Method for Ignitable Liquid Residues in Extracts from Fire Debris Samples by Gas Chromatography-Mass Spectrometry. The guidance in this standard is limited to generalities about “the matching of the sample chromatogram with a reference ignitable liquid chromatogram obtained under similar conditions, noting points of correlation or similarities.” The document goes further to describe “Criteria for the Identification of Gasoline” that include brief pattern illustrations and hydrocarbon class characteristics. ASTM E1618 lacks definitive guidance for interpreting data when complex matrices are present that may alter or mimic patterns typified in gasoline. The standard does not have a mechanism to evaluate the strength of a possible agreement between the unknown sample and a reference ignitable liquid. The result is subjectivity potentially causing two analysts to reach different conclusions regarding the presence or absence of gasoline in a sample. The information to be presented fills those gaps with a method that is intuitive to explain and is relevant to fire debris analysts as an extension of what they are doing in the lab. By applying a statistical method based upon peak pair ratios, the level of subjectivity is greatly reduced and the strength of a potential association between the unknown sample and a reference ignitable liquid can be easily assessed.

The information to be presented provides instructions to build a sufficiency graph with decision lines to demonstrate the sufficiency of the data for the identification of gasoline to further strengthen the data interpretation process and provide transparent documentation. The objective of this information is to make the fire debris analysis process more standard, objective, and transparent by establishing a validated method with quantitative measures that include the implementation of documentation methodology and verification.

The identification of gasoline in a fire debris sample is dependent on the subjective interpretation of chromatographic peak patterns. As the complexity of the matrix contributions increases, the subjectivity of the identification also generally increases. Unfortunately, limited information has been published to assist in the formation of conclusions in the presence of complex matrix. These subjective interpretations can lead to interpretation inconsistencies among examiners and no objective method for the trier of fact to determine the basis for these conclusions.

In an effort to strengthen data interpretation, an objective, statistically based method for interpreting a sample to support a gasoline identification will be introduced.¹ This methodology directly translates to the visual pattern recognition techniques currently employed in the field and can be completed by a trained examiner in a short period of time. The developed method mirrors the theoretical sufficiency graph developed for use in friction ridge analysis, but augments this method by creating plot values that represent the Total Ion Chromatogram (TIC) and Extracted Ion Profile (EIP) features based upon peak ratios of key diagnostic features. Displayed on a sufficiency graph, these plot values visually demonstrate support for identification or non-identification of gasoline by placement on the graph with decision lines.

This intermediate workshop is designed for fire debris examiners and will use presentations and hands-on activities to: describe the current state and limitations of gasoline identification; present the project design and experimental results; direct the attendees in application of the process; demonstrate software (Excel®) techniques for calculating peak pair ratios and charting results; provide practical exercises for completing an analysis of a complex sample; and provide discussions on the validation and implementation of the technique in a laboratory setting. A special emphasis will be included on the chromatographic features showing high statistical support for gasoline.

By the completion of the workshop, the attendee should have the framework to evaluate the sufficiency of gasoline identification using a statistical method that enhances current visual pattern recognition techniques used in most forensic laboratories.

In order to get the most from the practical exercises of this workshop, each attendee (or group of 2–4 attendees) should have a laptop computer with Microsoft® Excel® and Agilent® ChemStation® or another Gas Chromatography/Mass Spectrometry (GC/MS) data processing software. Attendees may, but are not required to, bring hard copies and electronic data files from known gasoline samples acquired using existing laboratory methodologies.

Gasoline, Fire Debris, Interpretation

W4 The Application of Evaluative Reporting for Forensic Handwriting Examinations

Tobin Tanaka, BSc, Canada Border Services Agency, Ottawa, Ontario, Canada; Miriam Angel, MS*, Los Angeles Police Department, Los Angeles, CA*

Learning Overview: Attendees will learn how to apply Evaluative Reporting for evidence interpretation and conclusions. Handwriting comparisons will be used as examples. There will be a short lecture, followed by a demonstration using a mock case. The majority of the class will be hands-on group practice and feedback.

Impact Statement: This presentation will impact the forensic science community by describing modifications to the current interpretation method and reporting conventions that can help elucidate the evaluation process and advance forensic document examination as a science.

This workshop will focus on the application of the “Evaluative Approach” to evidence interpretation and reporting conclusions for handwriting examinations. Using this approach requires no change in the examination and comparison of handwriting but does involve adjustment in the evaluation if logical reasoning is to be followed. The fundamental principles of this method of forensic interpretation require that evidence be interpreted: (1) within a framework of relevant case circumstances, (2) by considering at least two competing propositions, and (3) by reporting the probability of the evidence given the propositions rather than the probability of the propositions themselves. Following these principles will allow the examiner to provide logically coherent and balanced evaluations.

Attendees will receive mock cases to examine, but not evaluate, prior to commencement of the workshop. The workshop will begin with a brief introduction of the key principles of the approach and general theory, followed by a demonstration of the method using one of the mock cases distributed earlier. For the remaining cases, attendees will break into groups and evaluate evidence using the approach. After each group breakout session, class will reconvene for discussion with the instructors.

The target audience of this workshop is forensic document examiners who are receptive to further awareness of the logic behind the evaluation process. A prior understanding or exposure to the approach is recommended but not necessary.

Evaluative Reporting, Evidence Interpretation, Conclusions

W5 Unseen Threats

Agnes Winokur, MS, DEA, Miami, FL; Michelle Peace, PhD*, Virginia Commonwealth University, Richmond, VA; Shannon Krauss, PhD*, RTI International, Research Triangle Park, NC; Victor Weedn, MD, JD*, Maryland Office of the Chief Medical Examiner, Baltimore, MD; Elizabeth Zaney, BSc*, Miami-Dade Medical Examiner Department, Miami, FL; Kim Aldy, DO, MS, MBA*, Toxicology Investigators Consortium, Dallas, TX; Katie Heidere, MSW*, King County Public Health, Seattle, WA; Jason Bory, MS*, CBP, Newark, NJ; Alex Krotulski, PhD*, CRSFE, Willow Grove, PA; Richard Laing, MSc*, Health Canada, Burnaby, British Columbia, Canada*

Learning Overview: Attendees will gain a better understanding of public threats in respect to emerging drugs that are not often discussed (e.g., electronic cigarettes and their role in drug use, the effect of polydrug overdoses in toxicology and emergency rooms, online resources and how they can be used to predict future emerging drugs, fentanyl supervised consumption sites, and drug concealment techniques). Attendees will also gain awareness of innovative techniques used to address challenges in these areas (e.g., Direct Analysis in Real Time-Mass Spectrometry [DART®-MS] for the rapid screening of the chemicals in electronic cigarettes, and real time fatal overdose surveillance).

Impact Statement: Attendees will become aware that drug-related deaths continue to significantly impact communities. There are topics that influence the illicit drug landscape in these communities that are not frequently discussed.

The dynamic landscape of illicit drugs and its role in overdoses continue to be at the forefront of community efforts in maintaining public safety. However, there are topics that need more discussion to obtain better clarity on their influence on drug-related deaths. This workshop is geared to raise awareness of these emerging drug threats that deserve more attention and focus (e.g., electronic cigarettes and their use with drugs, the role of polydrug in overdoses and the challenges they present in emergency rooms, drug concealment techniques, online sites, fentanyl supervised consumption sites).

This workshop will discuss how electronic cigarettes are being adopted by recreational drug consumers for their culture acceptability and concealability. E-liquids contain chemicals considered safe for oral consumption, creating an aura of safety for consumers. While the E-cigarette, or Vaping, product use Associated Lung Injury (EVALI) epidemic exposed the toxic nature of vaping, the e-cig industry has facilitated the public consumption of recreational drugs. While traditional analytical techniques have been used to characterize the chemical composition of e-liquid formulations and their resulting aerosols, a more rapid screening technique is highly desired. This workshop will discuss the use of the DART®-MS system and method for coupling directly with commercial electronic cigarettes without sample preparation.

In addition, the complications of polydrug in toxicology testing and the challenges they present in death determination will be discussed. Interesting postmortem case studies, involving polydrug overdoses and instances where an unexpected analyte was detected after the initial information told a different story will be presented. This workshop will also explore the treatment of emergency department patients (with illicit drug overdose symptoms) and the possible unknown co-exposures that create challenges in treatment.

While mortality data, based on death certificates, are the traditional means of tracking the opioid/drug overdose crisis for law enforcement and public health, other innovative ways to obtain and evaluate data are being explored. This workshop will show how real time fatal overdose surveillance uses investigation, in-house drug and paraphernalia testing, rapid toxicology, and family interviews to detect emerging threats and more quickly certify overdose deaths. Another example is the use of online resources to provide insights into next-generation threats, especially those related to drug use and emerging synthetic drugs. Online web market sites detail in real time the newest drugs being sold, most of which are produced to evade national and international regulations. As drugs appear on these sites, discussions on drug use forums (e.g., Reddit) often follow and may be accompanied by anecdotal information about drug activity and adverse effects. Discussion will include how monitoring these data streams has proven useful for predicting the next wave of drug threats and better preparing forensic laboratories.

Another area often overlooked is the complex concealment techniques used by drug traffickers to circumvent law enforcement. With constantly changing drug trends, varying supply routes, and a wide variety of concealment methods, intercepting narcotics coming into the country is never a straightforward endeavor. An overview of some of the more unique concealment methods utilized by drug traffickers will be presented, as well as some of the sampling and extraction methods used to prepare these submissions for analyses.

In conclusion, the material presented in this workshop will be geared to bring more clarity to some of the unseen threats affecting drug-related deaths.

Vaping, Polydrug Overdoses, Predicting Drug Threats

W6 Impairment: A Look at Causes, Data, and Policies

Karen S. Scott PhD, Arcadia University, Glenside, PA; Sabra Botch-Jones*, MS, Boston University, Boston, MA; Joseph Jones, MS*, North Louisiana Criminalistics Laboratory, Shreveport, LA; Jana Price, PhD*, National Transportation Safety Board, Washington, DC; Amanda D'Orazio, MSFS*, NMS Labs, Horsham, PA; Marilyn Huestis, PhD*, Heustis & Smith Toxicology, LLC, Severna Park, MD; Michael Whitekus, PhD*, Robson Forensic, Inc., Lancaster, PA; Amanda L.A. Mohr, MS*, CFSRE, Willow Grove, PA; Curt Harper, PhD, Alabama Department of Forensic Sciences, Hoover, AL; Marc LeBeau, PhD*, FBI Laboratory, Quantico, VA*

Learning Overview: Attendees of this workshop will gain: (1) expertise in the role of Drug Recognition Experts (DREs) and their role in impairment investigations; (2) detailed knowledge of the role of fatigue in transportation accidents and an understanding of the factors impacting fatigue; (3) in-depth knowledge of the most recent recommendations for the toxicological investigation of drug-impaired driving and motor vehicle fatalities; (4) an appreciation of the roles of alcohol and cannabinoids in driving impairment and various strategies to control their use within the population; (5) an awareness of the tools available, roadside screening of oral fluid samples, and the policies regarding these samples; and (6) a detailed overview of the Academy Standards Board (ASB) Standards and the role they play in impairment investigations from testing in the laboratory all the way through to courtroom testimony.

Impact Statement: This workshop will impact the forensic science community by providing a detailed overview of recent policy changes and current developments within impairment testing.

From the time a subject is stopped by the police and assessed by a DRE until testimony at court, various policies, data, and circumstances come into play. This cross disciplinary workshop is equally relevant for forensic toxicologists, policy makers, pathologists, lawyers, and anyone who has a general interest in impairment.

One of the frequent requests of the forensic toxicologist is to assist the court with impairment determinations. A DRE is an individual who has successfully completed all phases of the Drug Evaluation and Classification Program's (DECP) training requirements for certification. A DRE is skilled in detecting and identifying persons under the influence of drugs and in identifying the category or categories of drugs causing the impairment.

Fatigue-related impairment can result from sleep loss, time of day, time on task, medical issues, drug use, or a combination of those factors. It can affect cognitive performance in many ways, most notably in a loss of sustained vigilance, which can lead to errors and—in some cases—major safety events.

The Driving Under the Influence of Drugs (DUID) recommendations were based on a survey sent to laboratories throughout the United States and Canada about testing practices, scope of testing and cutoffs, matrices tested, and compliance with the 2017 recommendations. Tier I and Tier II scope and cutoffs for screening and confirmation were re-evaluated and updated based on analysis of the survey results, ongoing research, current levels of testing, and concentrations in DUID cases.

There is a lack of linear cannabis dose concentration effect and therefore it can present challenges for impairment interpretation. The pharmacokinetics of Δ^9 -Tetrahydrocannabinol (THC) after smoked, vaporized, and oral cannabis will be presented, including the lack of a linear concentration-effect curve and future drug policies that may lessen the impact of cannabis medicalization and legalization.

Alcohol and cannabis are two of the most frequently detected drugs in serious/fatal injured drivers. Studies of the relative risk of a serious injury or death from impairment for these two substances range from slightly to extremely increased risk. Studies by the National Highway Traffic Safety Administration indicate that about 4–6 percent of road users were positive for both alcohol and cannabis in 2020. The combined effect of alcohol and THC on driving impairment has been studied and found to be greater than either drug effect alone.

Oral fluid has continued to gain popularity as an acceptable matrix for drug detection in impaired driving cases and is an approved specimen in 22 states. There are now available tools designed for screening oral fluid samples at the roadside, considerations for laboratory testing and the implementation of oral fluid screening in DRE certifications must be put into place.

Polydrug use in DUID cases at different blood alcohol concentrations is often not included in toxicology casework as the focus is placed on alcohol testing. Other drug trends and a comparison between blood and oral fluid drug concentrations in DUID cases can be important demographic data to obtain. The impact of stop testing limit programs will be evaluated by comparing the advantages and disadvantages of different DUID testing schemes and workflows.

Forensic toxicology standards published by the Academy Standards Board (ASB) through the American National Standards Institute (ANSI) have led the way to promoting consistency in common practices within the field. ANSI/ASB Standard 120—*Standard for the Analytical Scope and Sensitivity of Forensic Toxicological Testing of Blood in Impaired Driving Investigation* and ANSI/ASB Standard Best Practices Recommendation 037—*Guidelines for Opinions and Testimony in Forensic Toxicology* are critical for improving the testing performed in DUID investigations and how analytical results and expert opinions are presented through courtroom testimony.

Impairment, Standards, Policy

W7 Histology for Non-Pathologists

Katherine Maloney, MD, Erie County Medical Examiner Office, Buffalo, NY; Milad Webb, MD, PhD*, Hillsborough County Medical Examiner Office, Tampa, FL; Ashley Perkins, DO*, Hillsborough County Medical Examiner Office, Tampa, FL; Omar Rayes, MD*, Wayne County Medical Examiner Office, Detroit, MI; Teresa Nguyen, MD*, Wayne County Medical Examiner Office, Detroit, MI; Kelly Devers, MD*, Hillsborough County Medical Examiner Office, Tampa, FL*

Learning Overview: Attendees of this workshop will learn the basics of histology as well as receive an introduction to the histologic interpretation of infection and trauma, including trauma to the brain and spinal cord.

Impact Statement: This presentation will impact the forensic science community by providing non-pathologists with an understanding of the process of histology interpretation and, in particular, its relevance to their forensic specialty.

During their anatomic pathology training, forensic pathologists learn the art of histopathology, which involves looking at small sections of tissues under the microscope for identification and interpretation. The results of this examination can be used to determine the cause and manner of death, extent and type of disease process, and nature of identified abnormalities. Although extensive training is provided to pathologists on this topic, little to none is given to other forensic practitioners, even those whose work can be affected by the results of these examinations. It is not uncommon for histology findings to be referenced in a court of law in both criminal and civil proceedings. Additionally, while the interpretation of certain findings is nearly universally agreed upon by well-trained pathologists, others can be fraught with controversy. The goal of this training is to provide non-pathologists with an introduction to histopathology such that they have an understanding of some of the basic concepts, terminology, and findings.

Histopathology, Infection, Trauma

W8 Subaerial Weathering of Bone

James Pokines, PhD, Boston University School of Medicine, Boston, MA*

Learning Overview: Attendees of this workshop will learn about the taphonomic processes causing subaerial weathering of bone and how to score weathering stages following the standard 0-5 scale from Behrensmeyer.¹ Participants also will learn about estimation of the Postmortem Interval (PMI) from the weathering stage and the other types of taphonomic alterations that commonly co-occur with surface exposure and how to tell the effects of subaerial weathering (cracking, delamination, and bleaching) from other causes that may produce similar effects.

Impact Statement: This workshop will impact forensic practice by teaching standard scoring procedures for subaerially weathered bone and the procedures for estimating PMI based on those scores. This workshop will encourage participants to gather additional taphonomic data to improve greater understanding of subaerial weathering and its regional variation.

Taphonomy is the study of an organism's changes from its death until the recovery of its remains. Multiple environmental processes act upon biological remains, including directly upon the bone itself. These processes vary by depositional environment and may alter bones in ways that are unique to remains from that environment. Investigators often recover remains from exposed terrestrial environments, and the bones often present a suite of distinctive characteristics, including carnivore gnawing, rodent wet- or dry-bone gnawing, algae formation, soil staining, and subaerial weathering. Recording of these taphonomic alterations is aided by standardization of methods. One of the earliest standardized analytical scales still in use in forensic anthropology and related disciplines is Behrensmeyer's stage 0 (unweathered) through 5 (severely weathered/falling apart) scale for bone weathering.¹ Bones undergoing subaerial weathering typically sun-bleach, dry, crack, and flake due to exposure to solar radiation, temperature fluctuations, freeze-thaw, wetting-drying, and mineral recrystallization. The end result is a fragmented bone that has become part of the lithosphere, completing its taphonomic cycle.

Significantly, subaerial weathering stages can be used to help estimate the PMI in the "middle" range between the time when decomposition and entomological studies leave off (typically less than one year) and the time at which radiocarbon dating becomes appropriate. Forensic anthropologists have few viable options within this interval and often must rely upon artifactual evidence or development of annual rings in tree roots found in direct association with remains. Subaerial weathering analysis also has the potential for misuse when temporal standards developed in different environments and species are applied uncritically to human remains to estimate the PMI, and these methodological difficulties are examined in this workshop.

Taphonomic alteration due to subaerial weathering should be distinguished from other sources, including other environments that bleach and/or crack bone, in order to understand the bone's recovery context. This patterning includes taphonomic alterations that may link a bone to a certain depositional setting, such as weathered remains from a surface deposit, even when the bone later gets moved to a new environment. Similarly, the movement of a bone from its original orientation while remaining in the same general location is often discernible from its subaerial weathering pattern. Since taphonomic changes vary by environment, regional differences are expected among these types of environments/sources of bone, and workshop participants are encouraged to gather and disseminate taphonomic data from their own areas so that regional standards can be developed in the future.

Forensic Taphonomy, Subaerial Weathering, Postmortem Interval (PMI)

W9 Forensic Science Standards Development and Implementation . . . You Want Me to Do What?

Linton Mohammed, PhD, Forensic Science Consultants, Inc., Poway, CA; ary McKiel, JD*, American Academy of Forensic Sciences, Colorado Springs, CO; Teresa Ambrosius, BA*, American Academy of Forensic Sciences, Colorado Springs, CO; Linda Wilson, MS, American Academy of Forensic Sciences, Colorado Springs, CO; Kris Cano, MA*, Scottsdale Police Department, Scottsdale, AZ; Mark Goff, BA*, MSP Lansing Laboratory, Lansing, MI; Jennifer Floyd, BS*, Arkansas State Crime Laboratory, Little Rock, AR; Pamela King, JD*, Minnesota Judicial Branch, Rochester, MN*

Learning Overview: The goal of this workshop is to discuss the development process of forensic science standards, how these standards are implemented in crime laboratories, and how they are viewed by the legal profession.

Impact Statement: This presentation will impact the forensic science community by enabling attendees to understand: (1) the process through which standards are developed and published; (2) issues with implementation of standards in crime laboratories; and (3) how the legal profession views and assesses the role of standards in court proceedings.

In 2015, the Academy Standards Board (ASB) was formed by the American Academy of Forensic Sciences (AAFS) to address concerns about lack of standardization in the forensic sciences. Erroneous convictions cast doubt on the scientific merit of some disciplines. It was thought that standardization would ameliorate these concerns by providing practitioners, attorneys, and the courts with documents procedures and best practices.

ASB is an American National Standards Institute (ANSI) -accredited Standards Development Organization (SDO), and it must meet ANSI's requirements before any document can be published. These requirements can be time-consuming, and many practitioners have become frustrated by the length of time that standard development takes. There have also been concerns about the lack of depth and content in some of the published standards. This workshop will explain the process through which an ASB document is published, and the reasons why the process cannot be rushed. Information on commenting on draft documents will be provided so that interested parties can give their input while the standard is in the development process. This is a very important part of the process that can take time, but is vital in publishing a sound document that meets the consensus of the stakeholders.

Once the ASB documents are published, crime laboratories may wish to adopt them for their manuals and reference documents. Federal, state, and local laboratories may each have different issues with implementation of the standards. Presentations will be given by practitioners and a laboratory director on their experiences in implementing standards in their laboratories. Forensic science does not exist in a vacuum, and the use of standards in other professions and how forensic science can learn from them will be discussed.

Finally, the value of the standards will, in part, be determined by the legal system. Standards may support the bases for opinions, and the courts will determine the weight of this evidence. Courts may pay close attention to varying conclusions given by experts who use the same standards, and experts who used different standards, or none.

Standards, Forensic, Implementation

W10 Inference From Evidence in Forensic Science and Pathology: Turning Something That Has Been Wrong Into Something Right

Thomas Young, MD, Heartland Forensic Pathology, LLC, Kansas City, MO; Ljubisa Dragovic, MD*, Oakland County Medical Examiner's Office, Pontiac, MI*

Learning Overview: After attending this workshop, attendees will have learned which forms of inference—the reasoning involved in drawing conclusions from evidence—are highly reliable for truth and which forms are highly unreliable. Attendees will also learn how to apply proper inference to their forensic casework.

Impact Statement: This workshop will impact the forensic science community by revealing how demonstrably incorrect ways of inferring from evidence have led to numerous injustices from false accusations and incarcerations. This workshop will also disclose a reliable way to infer that is both scientifically and logically valid.

For several decades, many have criticized the forensic sciences, even to the point where one may wonder if what is purported as courtroom science is really “scientific.” Ever since DNA testing has repeatedly falsified the sworn statements and opinions of forensic doctors and scientists, the Innocence Project has leveled criticism at them, citing 52% of wrongful convictions to be from “misapplied forensic science” on their website, only second to the 63% they cite from “eyewitness misidentification.” In recent months and years, the criticism of forensic pathologists has also ramped up due not only to highly publicized cases but also to research purporting to demonstrate substantial cognitive bias in the ways forensic pathologists draw conclusions. Even seasoned forensic pathologists recognize the subjectivity of their conclusions. Is there a way for forensic scientists and pathologists truthfully to offer opinions from the witness stand made “to a reasonable degree of medical/scientific certainty”? Is there a way to put the “science” back into forensic science and pathology? Is there a way for forensic pathologists and scientists to offer opinions that are reliably truthful and helpful to triers of fact in a courtroom?

There is. The Inferential Test (IT) is a theorem or tautology of deductive logic applied to the forensic arena that is demonstrably always true, all the time, under all circumstances. The IT—“One can be reasonably certain if witness accounts of the past are consistent or not consistent with physical evidence in the present, but one cannot reliably surmise past events from physical evidence unless there is only one plausible explanation for that evidence”—points out what works and what doesn’t work for drawing conclusions from evidence. This workshop will demonstrate the basis for the IT in both deductive (what can be guaranteed as truthful) and inductive (what can be asserted as probable) logic. It will also instruct attendees how to apply the IT properly in forensic casework, using examples from the media and from the case files of both instructors.

Inference, Evidence, Forensic Science and Pathology

W11 Successful Strategies for the Accreditation of Crime Scene Units

Mark Mogle, BS*, U.S. Department of Justice, Washington, DC; Abraham Aysa, JD*, Pacific Architects and Engineers, LLC, Panama City, Panama; Domingo Villarreal*, Houston Forensic Science Center (Retired), Houston, TX; Alejandro Madrigal, BS*, Pacific Architects and Engineers, LLC, Weslaco, TX

Learning Overview: After attending this workshop, attendees will have learned about the planning process for the accreditation of crime scene processes.

Impact Statement: In 2009, the National Academies of Sciences (NAS) issues their landmark Report, *Strengthening Forensic Science in the United States: A Path Forward*.¹ The Report recommended the accreditation of forensic laboratories and rightfully identified crime scene investigation as part of the forensic science community. However, since the publication of the Report, the accreditation of crime scene units globally has not kept pace with other disciplines. This presentation aims to reduce the perceived barriers that may stop an agency from pursuing accreditation of crime scene investigation processes, resulting in an increasing number of accreditations in this area, and thus improving the quality of forensic science at a systemic level.

It has been over a decade since the NAS issued their landmark Report on how to strengthen forensic science in the United States which, among other recommendations, advocated for the international accreditation of forensic services. Since the issuance of the report, the number of domestic and international forensic laboratories accredited under the applicable standards issued by the International Organization for Standardization (ISO) has increased dramatically. However, while most people agree that quality begins at the crime scene, the accreditation of crime scene activities has significantly lagged behind other forensic disciplines.

This workshop aims to address the misconceptions that may be stopping agencies from pursuing accreditation in crime scene processing. This workshop will share experiences in successfully supporting the accreditation of crime scene units both in the United States and internationally. A useful framework will be offered to manage the accreditation process and guidance on building a quality management system. Specific suggestions will be offered of how to address the ISO accreditation standards commonly viewed as barriers to accreditation of crime scene units such as measurement of uncertainty, proficiency testing, and validation. The workshop content will not be specific to any one accrediting body but will cover the general requirements under the ISO standards as well as the supplemental guidelines issued by the International Laboratory Accreditation Cooperative (ILAC) G19:2014—Modules in a Forensic Science Process.

Last, the workshop will cover the role of management in an effective quality system to include communication with stakeholders, management reviews, and dealing with non-conformities as they arise. Effective management is essential to extracting value out of accreditation. Accreditation requires not only an investment in time and money, but the desire for change, including modifications in work processes and organizational culture. The workshop will address resistance to change that may also inhibit the accreditation process by providing examples of how resistance has presented itself in past situations and suggestions on how it can be mitigated.

Accreditation, Quality, Crime Scene

W12 Forensic Postmortem Radiology: Crossing the Border Between Radiology and Pathology

Michael Thali, MD, Institute of Forensic Medicine, University of Zurich, Zurich, Switzerland; Jeroen Kroll, MSc*, Department of Radiology, Forensic Radiology Maastricht University Medical Center, Maastricht, AZ, Netherlands; Natalie Adolpho, PhD*, Office of Medical Investigator University of New Mexico, Albuquerque, NM; Christopher O'Donnell, MBBS*, Victoria Institute of Forensic Medicine, Brandon Park, Victoria, Australia; Edward Mazuchowski, MD, PhD*, Autopsy and Forensic Pathology, Health Network Laboratories, Allentown, PA; Rick van Rijn, MD, PhD*, Department of Forensic Medicine, Netherlands Forensic Institute, Amsterdam, AZ, Netherlands; Lars Oesterhelweg, MD*, Institute of Forensic Medicine, Charite Universitätsmedizin Berlin, Berlin, Germany; Fabrice Dedouit, MD, PhD*, Forensic Department University Hospital of Toulouse, Toulouse, France; Summer Decker, PhD*, USF Health Morsani College of Medicine, Tampa, FL; Hideki Hyodoh, MD, PhD*, Department of Forensic Medicine Hokkaido University, Sapporo, Japan; Lars Ebert, PhD*, Insitute of Forensic Medicine University of Zurich, Zurich, Switzerland; Jonathan Ford, PhD*, USF Health Morsani College of Medicine, Tampa, FL*

Learning Overview: After attending this workshop, attendees will: (1) have learned the basics of how to get started in the field of forensic radiology; (2) understand the current state of the art and levels of evidence in forensic radiology; (3) have learned about applications to assist forensic pathologists and practitioners in medical death investigation; and (4) will be aware of potential resources available to interested practitioners.

Impact Statement: This presentation will impact the forensic science community by providing attendees with expertise from around the world on the use of best practices and the evidence base of forensic postmortem radiology.

It has been nearly 12 years since the publication of the National Academy of Sciences Report calling for the strengthening of the forensic sciences. In this seminal report, they stated the critical role that imaging plays in the documentation of findings sufficient for courts, for providing the opportunity for review by outside experts, as well as for allowing for reevaluation of evidence as medical knowledge advances. Since then, forensic radiology and imaging has grown significantly as a field around the world.

The “Virtual Autopsy” or “Virtopsy” utilizes Multi-Slice Computed Tomography (MSCT) or Postmortem Computed Tomography (PMCT) and Magnetic Resonance Imaging (MRI) combined with 3D imaging technology to create vivid images of the interior of the human body. CT scanning and MRI has been shown to present a better visual picture of some injuries, reduce the number of autopsies conducted to rule out occult injury, and document the extent of injury in accidents in greater detail. The advantages of the Virtopsy are that it is not invasive or destructive to tissues and can provide clear pictures of skeletal and soft tissue injury. It also provides some information when there is a religious objection to autopsy. Additionally, Virtopsy has the potential to detect internal bleeding, bullet paths, bone and bullet fragmentation, fracture patterns, brain contusion, and gas embolism, as well as occult fractures that are technically difficult to demonstrate during the traditional autopsy.

In the United States, only a few medical examiners/coroner’s offices (approximately 20) have access to this advanced medical imaging at this time and very few have the budget to purchase the expensive equipment or to build a suitable facility with staff to maintain it. The current public health crisis of opioid deaths is stretching an already strained medical examiner’s system with regard to autopsy caps set by the National Association of Medical Examiners (NAME) standards. Postmortem medical imaging can play a critical role in easing these demands for full autopsy on offices through triage screening from PMCT.

Within the past years, the National Institute of Justice (NIJ) has fully supported forensic imaging as a supplement to the traditional autopsy and as a triage and long-term evidence documentation tool. NIJ efforts have attempted to bring field standards from around the world and establish major research areas of need in order to help facilitate the field’s growth in the United States since it lags behind other countries in the field. Additionally, the post AAFS 2018 attendee survey indicated in several places the desire of members for more information on assisting forensic pathology workloads with the use of CT scans/documentation of trauma via imaging, even going as far as suggesting modifying of National Association of Medical Examiners guidelines to accomplish this. With the field well established in practice outside the United States, lessons learned from experts will help those interested in incorporating these technologies into their facility’s everyday practice. Exposure to emerging technologies in the field will also help practitioners be exposed to potential applications that will alleviate their workflow in an already overtaxed death investigation system.

This workshop will show how to start a program, give an overview of the current state of forensic imaging in the world and how future technologies may impact the field of forensics. A similar workshop was previously presented at an American Academy of Forensic Sciences (AAFS) conference by the same team and it was highly attended by members from different sections.

Radiology, Medical Imaging, Postmortem

W13 Forensic Techniques Applied in Military Investigations

Steven Geniuk, MS, U.S. Army CID, Fort Leonard Wood, MO; Donald Hayden, MFS*, U.S. Army CID, Fort Leonard Wood, MO; Edward Mazuchowski, MD, PhD*, Forensic Pathology Associates, Health Network Laboratories, Allentown, PA; Michelle Miller, PsyD*, U.S. Army CID, Quantico, VA; Arthur Chancellor, MCJA*, U.S. Army CID, Fort Bragg, NC; Vanessa Neff, MS, MA*, U.S. Army CID, Fort Hood, TX; Nicole Daniels, MFS*, U.S. Army CID, Joint Base Fort Myer-Henderson Hall, VA; Adam Armstrong, MS*, U.S. Army CID, Kaiserslautern, Rheinland-Pfalz, Germany; Andrew Mansell, MS*, U.S. Army CID, Fort Bragg, NC; Armando Dela Rosa, MFS*, U.S. Army CID, Fort Irwin, CA; Matthew James, MFS, MS*, U.S. Army CID, Joint Base Fort Myer-Henderson Hall, VA; Michael Easter, MFS* U.S. Army CID, Fort Hood, TX*

WITHDRAWN

W14 Interdisciplinary Approaches to Age Estimation

Sarah Ellingham, PhD, ICRC, Geneva, CH, Switzerland; Sara Zapico, PhD*, New Jersey Institute of Technology, Newark, NJ, Joe Adserias Garriga, PhD*, Mercyhurst University, Erie, PA; Douglas Ubelaker, PhD*, Smithsonian Institute, Washington, DC; Sara Getz, PhD*, University of Wisconsin-Plattenville, Plattenville, WI; Sakher AlQathani, PhD*, King Saud University, Riyadh, SA, Saudi Arabia; Christian Crowder, PhD*, Dallas County Medical Examiner's Office, Dallas, TX; Victoria Dominguez, PhD*, City University of New York, New York, NY*

Learning Overview: After attending this workshop, attendees will have a heightened understanding of: (1) age-at-death assessments as well as age assessment of the living from the anthropological and odontological point-of-view; (2) application of alternative techniques, based on the biochemical fundamentals of aging, to improving age estimates; and (3) age assessment implications in humanitarian contexts.

Impact Statement: This workshop will impact the forensic science community through the presentation of interdisciplinary approaches toward improving age assessments, encouraging collaboration and innovation among different forensic specialties. This workshop will further highlight the importance of age estimation in various contexts, including humanitarian applications.

Age-at-death estimation represents one of the key components for the creation of a biological profile to facilitate the identification of human remains. At the same time, it is one of the most challenging tasks, particularly in adult individuals where estimated age intervals tend to be very wide and point estimates are often biased. Additionally, in mass fatality events and other forensic contexts such as armed conflict, the presence of fragmentary remains can complicate the correct age assessment, and as a result, the identification of the individual.

This workshop will give an overview of the importance of age estimation in forensic science as well as other scenarios such as the context of migration; different age assessment methodologies from the point-of-view of forensic anthropology and forensic odontology in both juvenile and adult remains—living and dead—will be discussed; current state-of-the-art techniques based on the biochemical basics of aging will be introduced; finally the significance of age assessments in humanitarian contexts will be pointed out, drawing reference to implications of children not being issued a birth certificate, the 1989 United Nations Convention on the Rights of the Child and modern Asylum Law. The last session of the workshop will be devoted to practical examples of these aforementioned methodologies.

This workshop will demonstrate how the awareness of the problems faced with regard to age assessment, out-of-the-box thinking, the application of new and interdisciplinary techniques, and promoting collaborations among different forensic specialties such as anthropology, odontology, criminalistics are essential to improve age estimates, and as a result, the identification of the victim. Thus, this workshop will provide a step toward finding solutions to these challenges by improving the knowledge on the most state-of-the-art techniques available to forensic scientists.

Age Estimation, Forensic Anthropology, Forensic Odontology

W15 Unlocking the Truth: The Impact of DNA Testing and Legal Strategies in Post-Conviction Cases

Lisa Mertz, MS, Office of Chief Medical Examiner, New York, NY; Krista Currie, MS*, Laurentian University, Sudbury, Ontario, Canada; Andrew Schweighardt, PhD*, Office of Chief Medical Examiner, New York, NY; David McCallum, South Mineola, NY; Ken Klonsky, MA*, Innocence International, Vancouver, British Columbia, Canada; Ray Klonsky*, Brooklyn, NY; Oscar Michelen, JD*, New York, NY; Janis Puracal, JD*, Forensic Justice Project, Portland, OR; Jeff Reisig, JD*, Yolo County, Woodland, CA; Hillary Blout, JD*, For The People, Oakland, CA*

Learning Overview: Over the past 30 years, advancements in the field of forensic science have greatly impacted the criminal justice system. Advances in DNA testing and the development of new technology have led to an increase in exonerations of those wrongfully convicted.

Impact Statement: Attendees, armed with the knowledge of how best to efficiently and cost effectively process post-conviction cases, will be able to watch clips from a documentary to further inspire them to perform post-conviction DNA testing in their laboratories and form integrity units in their district attorney offices. This workshop will motivate those attending to realize that we can all participate in the quest for justice and, in the words of Dr. Rubin Carter, “. . . to live in a world where truth matters and justice, however late, really happens, that world would be heaven for us all.”

In this workshop, the case of David McCallum will be examined. David McCallum was convicted of murder when he was only 16 years old and served almost 30 years in prison for a crime he did not commit. His story was showcased by filmmaker Ray Klonsky in the documentary *Fight for Justice: David and Me*, released in 2014. This documentary explores the bond the two formed as they desperately tried to free David from jail. Attendees of this workshop will be presented with clips of the documentary and will hear both David and Ray detail their experiences.

This workshop will also highlight the legal struggles that David faced in his journey for freedom, which will be presented by his lawyer, Oscar Michelen, as well as others in the legal field who will talk about the legal hurdles involved in post-conviction cases. Also discussed will be the formation of conviction integrity units within the prosecutorial office. These units are instrumental to prevent and identify false convictions. In addition, attendees will hear from the father of Ray Klonsky, Ken Klonsky, who is the director of Innocence International, an organization founded by the late Dr. Rubin “Hurricane” Carter, a famed boxer who was also wrongfully convicted. Dr. Carter started Innocence International because of his own struggle. He had been wrongfully accused, convicted, and imprisoned for almost 20 years.

In discussing the DNA testing involved in David McCallum’s case, this workshop will present the challenges faced processing DNA evidence in post-conviction cases. Attendees will hear suggestions about how best to handle issues faced with vetting and processing older cases. This workshop will demonstrate how to use the efforts of multi-agency investigations and new technologies to efficiently and cost effectively perform DNA testing and aid in the exoneration of those wrongfully convicted. Also discussed will be recent advancements in forensic science that have enabled us to revisit old, degraded, or compromised samples to determine if current DNA testing methods can now achieve a DNA profile. Today, techniques are so sensitive that one may obtain a DNA profile from just a few cells worth of DNA. With greater sensitivity, a whole new realm of possible evidence left behind at a crime scene can now be considered for DNA testing and help those who are wrongfully convicted.

DNA, Post-Conviction, Justice

W16 The Neurobiology and Toxicology of Aggression

Alan R. Felthous, MD, Saint Louis School of Medicine, St. Louis, MO; Marilyn A. Huestis, PhD*, Huestis & Smith Toxicology, LLC, Severna Park, MD; Scott Akridge, MD*, Saint Louis School of Medicine, St. Louis, MO; Joe Bou Nassif, MD*, Saint Louis University School of Medicine, St. Louis, MO; Felice F. Carabellese, MD*, University of Bari, Bari, Italy; Dean M. DeCrisce, MD*, Coast to Coast Forensic Associates, Division of Behavioral Health Sciences, Elizabeth, NJ; Alexandre Demais, MD*, Institut Universitaire en Santé Mentale de Montréal, Montreal, Quebec, Canada; Marissa Hirsch, MD*, Saint Louis School of Medicine, St. Louis, MO; Rebecca J. Houston, PhD*, Department of Psychology, Rochester, NY; Daniel S. Isenschmid, PhD*, NMS Labs, Horsham, PA; Graham R. Jones, PhD*, Edmonton, Alberta, Canada; Dayong Lee, PhD*, Houston Forensic Science Center, Houston, TX; Barry K. Logan, PhD*, NMS Labs, Horsham, PA; Katherine McArthur, MD*, Saint Louis School of Medicine, St. Louis, MO; Michael L. Smith, PhD*, Huestis & Smith Toxicology, LLC, Severna Park, MD*

Learning Overview: This workshop examines the nature and origin of aggression and the modulating effect of various drugs.

Impact Statement: This presentation will demonstrate how impulsive and premeditated aggression in humans is understood from neurocircuitry and neuroimaging studies, Central Nervous System (CNS) neurotransmitter involvement, and electrophysiology, including the P3, an Event-Related Potential (ERP) component elicited in the process of decision making that varies from person to person.

Aggression is described, categorized, and explained beginning with the neurocircuitry of defensive and predatory aggression in animal models. Drugs, recreational as well as therapeutic, can promote or reduce aggression. The chemistry, toxicology, and neurophysiology of cocaine, phencyclidine, cannabinoids, methamphetamine and alcohol, anti-impulsive aggression therapeutics and pharmacotherapies with paradoxical aggression will be discussed as potential modulators of aggressive behavior. The role of cocaine in violent deaths is examined, including a discussion of analytical results in violent deaths compared to other cocaine-related fatalities and other factors such as use of tasers and restraints. One well-documented PCP effect is aggression with post-surgical psychosis listed as a reason for its discontinuation as a marketed anesthetic.

A significant association was observed between Cannabis Use Disorder (CUD), difficulty managing anger, aggressive impulses/urges, and problems controlling violence in the past 30 days in a large sample of Iraq/Afghanistan-era veterans with Post-Traumatic Stress Disorder (PTSD), even accounting for demographic variables, comorbid symptoms of depression and PTSD, and co-morbid alcohol and substance use disorders. In addition, emerging research describes the long-term effects of cannabis on aggression in individuals with schizophrenia. Methamphetamine is a sympathomimetic stimulant whose use is associated with excited behavior, including agitation, suspicion, paranoia, impulsivity, and at higher doses and in patterns of more intense use, dissociation and delusions, sometimes leading to homicides and suicides. Novel synthetic psychotomimetics, including cathinones and synthetic cannabinoids, can induce aggressive behavior together with other mental symptoms, including delirium and psychosis. The unpredictable nature of alcohol-mediated aggression will be highlighted by the case of a young man who murdered a man he didn't know, in a local park, in front of witnesses, and later professed to have no recollection of events and suffered a total alcoholic blackout. Five Food and Drug Administration (FDA) -approved therapeutic agents for the treatment of other medical and mental disorders reduced the intensity and frequency of episodes of impulsive aggression or intermittent explosive disorder; however, on rare occasions, intake of these drugs lead to unusual aggressive responses. Mechanisms of action are unclear and the literature is limited; however, case studies showed anti-anxiety drugs that usually reduce aggressive behavior, such as benzodiazepines and selective serotonin reuptake inhibitors, may cause paradoxical aggressive reactions. Additionally, aggression may be an unintended side-effect of antiepileptics, anti-smoking medication, and anabolic-androgenic steroids.

Neurobiology, Toxicology of Aggression, Drugs

W17 Forensic Examination and Evaluation of the Fine and Subtle Elements of Signatures and Handwriting

Linton Mohammed, PhD*, Forensic Science Consultants, Inc, Poway, CA; Lloyd Cunningham*, Alamo, CA; Brett Bishop, BS*, Washington State Police Crime Laboratory, Spokane, WA; Karen Nobles, MSFS*, Forensic Document Services, LLC, Pensacola, FL

Learning Overview: This workshop will increase Forensic Document Examiners' (FDEs') knowledge regarding the fine and subtle elements of signatures.

Impact Statement: This workshop will impact forensic document examiners by increasing the accuracy and reliability of their opinions in signature and handwriting examinations.

The examination of signatures to determine whether they are genuine or simulated is a common task for FDEs who have demonstrated proficiency in this type of examination. In 2001, a study reported that FDEs had a Type I (calling a simulation genuine) error rate of 0.49% and a Type II (calling a genuine signature a simulation) error rate of 7.05%.¹ Another study found that FDEs had an error rate of 3.4% in their opinions regarding whether signatures were genuine or simulated.² Similar results were found for examinations conducted with photocopies and online documents.^{3,4}

An auto-simulation (intentional distortion) is a strategy in which the writer attempts to disguise his/her signature with the intent to claim later that it was simulated. Auto-simulations often share similar characteristics with simulations. Studies cautioned that FDEs will find making a determination as to whether a signature is auto-simulated or simulated to be challenging.⁵⁻⁸

A five-year study was conducted in which 29, 811 opinions were expressed by FDEs on trials comprised of randomized questioned signatures that were categorized as genuine, auto-simulated (disguised), and simulated. The researchers found that, as a group, FDEs were significantly more confident at identifying writers' genuine signatures than identifying writers' disguised signatures or eliminating specimen writers from having authored simulated signatures. In this study, a 37.5% misleading score for disguised signatures as opposed to 4.8% for simulated signatures were reported.⁹

A recent study on Bias and Reliability of expert FDEs reported that the examiners were not biased by the agency of the submitter, or the instructions given, but were unreliable in the blind examination to determine whether the questioned signature was genuine, an auto-simulation, or a simulation. This study cautions that due to limitations of the study no definitive conclusions can be drawn regarding the applicability of the study's results to actual casework.¹⁰ Nevertheless, the lack of reliability of many FDEs to differentiate between auto-simulated signatures and simulated signatures warrants concern, and insight is required as to the root cause of the problem.

A consideration of this workshop is that the observation and correct interpretation of the fine and subtle (inconspicuous) elements of signatures are required for the FDEs to come to reliable conclusions. The elements are caused by the unconscious writing habit of an individual who may not even be aware of these features.

This workshop will begin with a lecture session reviewing the research data regarding genuine, disguised (auto-simulated), and simulated signatures. Attendees will then be given practical problems to the hands-on session. They will be asked to present their results (in groups) and give reasons for their opinions. The workshop will then go into the fine and subtle details of the signatures in the problems to illustrate and explain how these details can be observed and evaluated.

Signature Examination, Handwriting Examination, Evaluation

W18 An Advanced Bloodstain Pattern Analysis Hands-On Workshop With an Accompanying Principles of Bloodstain Patterns Lecture

Lawrence Renner, MA, Santa Fe Police Department (Retired), Santa Fe, NM*

Learning Overview: After attending this workshop, attendees will have an increased understanding of bloodstain patterns, their relevance to crime scene reconstruction, the determination of events that occurred, and potential charges that could be issued.

Impact Statement: This workshop and the accompanying lecture will expand the understanding of lab and scene personnel who have not had previous bloodstain pattern analysis classes.

This workshop is a hands-on opportunity for attendees to become involved in re-enactments of multiple, fresh, bloody crime scenes without the worry of contaminating themselves or their clothing. Attendees will experience the “real thing,” be required to collect data, evaluate the scenes and statements of witnesses, determine the action resulting in the blood-letting events, determine potential classification of events, and conclude how these findings relate to subsequent criminal charges. This opportunity is closely followed by the bloodstain pattern analysis lecture, which, by its conclusion, will reveal the actions and events studied in the session workshop. The “scene” session is ideally limited to a maximum of 35 to 40 participants.

An opportunity to re-visit the scenes for re-evaluation purposes will occur at the close of the lecture session. The lecture session will be of immense value in the evaluation of the previously visited “scenes.” Such factors as position and movement of the victim, including removal and storage after the event, as well as bleeding prior to removal, can be determined. Estimation of volume loss and identification of tissue present can be utilized to determine the incident’s effect on the victim and, thus, his capacity for mobility under his own momentum. Actual analysis of blood is still a laboratory function; but the actions at the scene causing the blood loss are often of much greater value in reconstruction of the events of the incident that transpired than learning whose DNA is present. The physical relationship between individuals at the time of the incident can often be determined by bloodstain pattern analysis. Bloodstain patterns are classified by the type of action that produced them. Stain patterns reveal action that produced them and the amount of force required. Stain patterns reveal characteristics that can be utilized to determine directionality, number of impacts, and that actual position of the source at the time of the incident. Proper documentation of the scene, by either actual collection of items or by scene photography, allow the bloodstain pattern analysis to be completed at any distance and time. This analysis can be of value in determining events that have occurred and charges potentially brought against those individuals present during the event(s).

Hands-On, Bloodstain Patterns, Scene Significance

W19 Silent Disasters: Establishing and Operationalizing New Technologies for Missing Persons Programs

Frederick R. Bieber, PhD, Harvard Medical School, Boston, MA; Charla Marshall, PhD*, AFMES - AFDIL, Dover, DE; Chelsey Juarez, PhD*, Fresno State University, Fresno, CA; Colleen Fitzpatrick, PhD*, Identifinders International, Fountain Valley, CA; Bruce Budowle, PhD*, University of Texas Health Science Center, Fort Worth, TX; Swathi A. Kumar, PhD*, Verogen, San Diego, CA; Mayra Eduardoff, PhD*, International Commission on Missing Persons, The Hague, Netherlands*

Learning Overview: After attending this presentation, attendees will be more familiar with the established and emerging science, law, and ethics surrounding the use of emergent DNA technologies to bring justice and closure in the wake of genocide, armed conflict, and other humanitarian crises. This includes, but is not limited to, mitochondrial DNA, autosomal Single Nucleotide Polymorphisms (SNPs), and other non-traditional markers.

Impact Statement: This workshop will showcase innovative strategies and governance considerations for implementing missing persons programs and inform laboratories and organizations to scale these programs effectively.

Every year, 4,400 unidentified bodies are recovered in the United States, according to the National Missing and Unidentified Persons System (NamUs). National databases such as the Combined DNA Index System (CODIS) can provide a powerful framework for tracking repeat crime and confirming identity, yet they are utilized to identify approximately one percent of unidentified recovered remains. On an international level, statistics are lower, as most countries still do not have a national DNA index that can be leveraged to catalog and identify missing persons. The sheer number of remains that go unidentified from armed conflicts, acts of terrorism, and force majeure has collectively become a phenomenon known as the “silent mass disaster.”

This workshop will review how the community can use a multidisciplinary approach to successfully address this silent mass disaster. Experts from academia, policy specialists, forensic practitioners, social and forensic anthropologists, and genetic genealogy data analysts will review established and emerging methods to reconnect victims to families and to provide attendees with a blueprint for how they can operationalize an end-to-end small, large-scale or national program for the identification of unidentified human remains.

Missing Persons, Kinship Studies, DNA Sequencing

W20 Novel Synthetic Opioids (NSO) in a Post-Fentanyl Analog Environment

Donna Papsun, MS, NMS Labs, Horsham, PA; Reta Newman, MA*, Pinellas County Forensic Lab, Largo, FL; Donna Iula, PhD*, Cayman Chemical, Ann Arbor, MI; Michael Baumann, PhD*, NIDA, Baltimore, MD; Robyn Parks, MD*, County of Los Angeles Department of Medical Examiner-Coroner, Los Angeles, CA; Barry Logan, PhD*, NMS Labs, Horsham, PA; Lynda Biedrzyski, MD*, Waukesha County Medical Examiner Office, Waukesha, WI; Alex Krotulski, PhD*, CFSRE, Willow Grove, PA; M.J. Menendez, JD*, NMS Labs, Horsham, PA*

Learning Overview: After attending this workshop, attendees will have a better understanding of how core-structure scheduling for fentanyl analogs and related drug policy actions have shifted the NSO landscape, what the new drugs on the markets are, and what challenges they pose to the scientific community.

Impact Statement: The presentations in this workshop will impact the forensic science community by providing an update covering the latest generation of NSO, providing comprehensive pharmacological and analytical characterization, drug chemistry and toxicology workflows, and case histories.

A new generation of NSO emerged after domestic class-wide scheduling of fentanyl-related substances in February of 2018 by the United States Drug Enforcement Administration followed by Chinese legislation that controlled two popular fentanyl precursor chemicals, NPP and 4-ANPP. These actions saw fentanyl analog positivity decreased for the most part; however, there was a subsequent shift to new varieties of opioid receptor agonists. These include 2-benzylbenzimidazoles (e.g., isotonitazene, metonitazene), benzimidazolones (e.g., brorphine), and cinnamoylpiperazines (e.g., 2-methyl AP-237, AP-238). The NPS monitoring community was able to use workflows honed over the past decade in response to these rapid market shifts to quickly identify these novel opioids, characterize them, and detect them in authentic toxicological specimens obtained during the course of medicolegal investigations, thus tying these new substances to impairment and harms.

This workshop will begin with a timeline of events, NSO trends, and an introduction of the tools and workflows that have proven effective in the quick identification of these new substances. Further, these novel opioids will be characterized, including discussions about development of standardized nomenclature and naming conventions, in vitro and in vivo studies, and postmortem cases that showcase the impacts posed by these substances. Later presentations will cover examples of how investigators and laboratories have mobilized to respond to the investigation of NPS toxicity outbreaks, and how the analytical data are used to support public health and safety measures. Two medical examiner perspectives from different parts of the country will be provided to share differing experiences and challenges with the novel synthetic opioids. The last part of the program will look at the impacts of open access information and timely dissemination. There will be discussion of strategies for early identification and monitoring proliferation of emerging substances and how this information lays the scientific support for scheduling actions. Finally, core-structure scheduling for fentanyl analogs will be reviewed from the perspective of how the NPS market responded, and if class-wide bans are considered a more effect drug policy strategy compared to specific drug scheduling actions.

Due to coordination, collaboration, and increased information sharing by the NPS monitoring community, the lifespans of newer novel synthetic opioids seem to be decreasing compared to previous substances, such as U-47700 and 2-furanylfentanyl. Although core-structure scheduling may have prompted new varieties of opioids, there appears to be decreased prevalence and a quicker response to those that ultimately emerge and proliferate. NSO will continue to impact the United States and its forensic science community. Collaborative efforts to combat these drugs are required and this workshop will be an example of that.

Novel Synthetic Opioids, Novel Psychoactive Substances, Core-Structure Scheduling

W21 The Forgotten Ones: Post-Traumatic Stress Disorder (PTSD) in First Responders

Jessica Morel, DO*, Fayetteville, NC; Giuseppe Troccoli, MD*, Mental Health Services, Bari, Italy; Vivian Shnaidman, MD*, Jersey Forensic Consulting, LLC, Princeton, NJ; Kathryn Seigfried-Spellar, PhD*, Purdue University, West Lafayette, IN; Kyle Krebs, MA*, Gilbert, AZ; Megan Stacy, BS*, Gretna, LA; Allison Gaines, MS*, Cobb County Medical Examiner's Office, Marietta, GA

Learning Overview: The goal of this presentation is to discuss various experiences of first responders from Emergency Medical Services (EMS), police, crime scene investigators, physicians, and others, in addition to different agency and regional responses to PTSD and processing of PTSD and grief. Symptoms experienced in these groups and how chronic exposure to trauma and vicarious trauma affect responders' mental health will be identified. This workshop will include small group discussions and larger collaborations of ways to prevent and recognize PTSD in one's home agency.

Impact Statement: This presentation will impact the forensic sciences community by addressing a serious aspect of mental health and responder well-being by discussing vicarious trauma, ways to recognize symptoms, and resources available for treatment.

This presentation will discuss how PTSD can affect first responders in federal, state, and local agencies such as local fire departments, law enforcement, emergency medical services, and public health officials. In this presentation, current research studies and data will be presented to help identify how PTSD is affecting first responders who are continuously exposed to traumatic and stressful incidents over the course of one's career.

PTSD and Acute Stress reactions are not reserved for crime victims and war veterans. The American Psychiatric Association defined PTSD during the 1980s in the Diagnostic and Statistical Manual of Mental Disorders, Third Edition.¹ Researchers have extensively researched the effects of PTSD on military veterans returning from conflict whereby mental health professionals were then able to use standard criteria to properly diagnose patients who have PTSD. Since the 1980s, researchers have been branching out from focusing on military veterans who have PTSD to researching the effects of PTSD on first responders.

The nation's first responders experience a wide variety of mental health symptoms that often go unrecognized. Recent research suggests that first responders such as firefighters, emergency medical technicians, paramedics, police officers, crime scene investigators, and allied health professionals are just as vulnerable to the effects PTSD. This presentation's focus will address the history of PTSD, recently published research, and new research areas to be studied in the future. For example, according to Stanley, the research data uncovered some shocking results of 1,027 retired and current firefighters, finding that 46.8% had suicidal ideations.² First responders have been overlooked over the years without the opportunity to ask for help. This can be attributed to the culture and stigmatism of being considered weak if one asked for mental health help to overcome the traumatic stress encountered on the job. Many first responders have suffered in silence, and the only way first responders will be able to get help is through further research into how PTSD affects first responders and public acknowledgment that PTSD is a real problem destroying first responder's lives.

This presentation is designed to help the forensic sciences community understand the serious implications of the current mental health crisis affecting first responders. Understanding how PTSD is affecting first responders may also help address the need to research the forensic science community's potential risk. The forensic science community is not immune to the effects of PTSD and should also investigate how PTSD could be affecting the members of the forensic science community.

PTSD, Vicarious Trauma, PTSD-C

A1 Pedagogical Access and Ethical Considerations in Forensic Anthropology and Bioarchaeology

Micayla Spiros, MSc, Michigan State University, East Lansing, MI; Amber Piemons, MA, Michigan State University, East Lansing, MI; Jack Biggs, BA, Michigan State University, East Lansing, MI*

Learning Overview: After attending this presentation, attendees will have a pathway toward creating a digital pedagogy in forensic anthropology along with ethical considerations that must be made when developing online resources of skeletal materials. Attendees will also gain an understanding of the importance of equitable access to learning opportunities.

Impact Statement: This presentation will impact the forensic science community by demonstrating the importance of developing a digital pedagogy to improve diversity and inclusion of our field through equitable resources.

Concepts such as evolution, environmental conditions, biological plasticity, and genetic theory are interdependent, deeply influenced by culture, and are the foundation of human variation. Human variation, being the pinnacle of osteological methodology, is critical for training osteologists. Thus, instruction must extend beyond “typical” models of human bones and generic osteological education. Using three online resources as case studies, this presentation will focus on the discussion of pedagogy, access, and ethics surrounding digital osteology. These three digital projects, 3D-MMS, MapMorph, and J-Skel, can be used to teach students topics ranging from human variation methods and theory to juvenile age estimation.

Digital pedagogy is the study of how to teach using digital resources. Technology can be used for in-classroom, hybrid, or fully online educational contexts. We can anticipate an increased expectation of digital technologies used for education and training following COVID-19. Traditional education in biological anthropology relies solely on hands-on and highly visual experiences. Therefore, forensic anthropologists are encouraged to collaborate in creating widespread digital pedagogy suitable for our discipline. This presentation discusses considerations and suggests pathways toward a forensic anthropology digital pedagogy, such as: accommodating for varying levels of digital fluency, equity in accessibility, ethical strategies, prioritization levels of content that need to be made publicly available, appropriate platforms and forms media for disseminating different types of content, and the necessity of multiple modalities.

While dialogue surrounding equity in higher education has gained momentum, discovering how to pursue awareness and then take action to rectify systemic issues of access still needs to be expanded.¹ Open-access to learning resources is one way to attract and retain students from a variety of backgrounds historically underrepresented in forensic anthropology. Skeletal and methodological casts are essential for learning but inaccessible in certain programs or remote learning. For research, skeletal collections have long been utilized to create, validate, and expand previous methods and protocols in higher education programs, yet research is dependent on the student’s location, opportunities for funding, and/or time constraints. Widespread academic access to donated skeletal materials also aims to eliminate the mistreatment and sharing of human remains that were unethically retained.

A clear avenue to accessibility is open-access paired with digital dissemination of pedagogical resources. Scholarship surrounding humans in any context should be equally tied to the education of ethical principles regarding the treatment of human remains. Legislation regarding how humans should be treated after death is slow moving and lacks the ability to stay current with constantly evolving pedagogical approaches; hence, the need for moral and ethical education. Key principles of ethics surrounding digital distribution of human remains include permission, respect, justification, and education.² When it comes to sharing human remains online, permission from the individual before death or from family members posthumously is the optimal standard. Likewise, the de-identification of donated remains and transparency from where and how the remains were obtained are essential. In bioarchaeological contexts, respect for the cultural beliefs and justification for education are necessary.

Forensic Anthropology, Digital Pedagogy, Ethics

A2 A Virtual Anthropological Approach to Assessing the Similarity of Joint Surfaces With Applications for Sorting Commingled Human Remains

Helen Brandt-Litavec, MS, Binghamton University, Binghamton, NY

Learning Overview: The learning objectives of this presentation are for attendees to develop a better understanding of the intra-/inter-individual variation at the sacroiliac joint and to recognize the utility in incorporating Virtual Anthropology (VA) methods when taking a quantitative approach to traditionally qualitative research.

Impact Statement: This presentation will impact the forensic community by providing an alternative method to sorting Commingled Human Remains (CHRs) using joint articulation analysis at the sacroiliac joint. This novel method will help improve current techniques for sorting CHRs.

CHRs complicate the identification process and can result in a significant loss of information regarding the individuals present. One common technique used to sort CHRs is joint articulation analysis. However, many current methods involve either physically fitting the bones together to determine goodness of fit or linear measurements. These techniques can be subjective and open to observer error or, in the case of linear measurements, limited in their ability to describe the entirety of the joint surfaces. In recent years, forensic researchers have demonstrated the ability to improve traditionally subjective techniques by incorporating VA methods. Therefore, this research aims to test the hypothesis that commingled individuals can be sorted through the comparison of their joint surfaces, specifically at the sacroiliac joint, by using VA methods.

Data were collected from individuals in the Binghamton University Skeletal Collection. The virtual models were created from 12 left os coxae and their articulating sacra using a NextEngine® 3D laser scanner. The shape of the auricular surfaces was analyzed using Landmark Editor and MorphoJ. Fifteen curves were placed around the exterior of the auricular surface and each curve was composed of three landmarks and eight semi-landmarks, resulting in a total of 135 landmarks.

Each individual's ilium and sacrum files were opened together in MorphoJ and a Procrustes analysis of fit analyzed the congruency of the two intra-individual auricular surfaces. The Procrustes sum of squares value produced by this test was recorded for each individual as a value of similarity. This value ranges from 0 to 1, with values closer to 0 indicating fewer differences in shape while values closer to 1 indicate extreme differences in shape. Subsequently, an artificially commingled sample of 104 of the possible combinations of commingled sacroiliac joints from the scanned virtual models was assembled to test the applicability of this method in separating CHRs. The same process was performed in MorphoJ, except with a random assortment of sacra and ilia files from separate individuals, and the Procrustes sum of squares values were also recorded for each commingled pair.

This work showed promising results. The Procrustes sum of squares values from sacroiliac joints of commingled individuals (mean=0.02108; range=0.00322 to 0.07038) are approximately twice as large as those of the non-commingled individuals (mean=0.01185; range=0.00198 to 0.02666). Additionally, the range and mean of the non-commingled group is closer to 0 than the artificially commingled group. Therefore, it appears that there is a noticeable difference between groups, in that the non-commingled individuals have more similarly shaped auricular surfaces than the commingled individuals. To understand if the perceived differences in the mean Procrustes sum of squares values between commingled and non-commingled groups are significantly different, an Independent Samples T-Test was conducted in IBM® SPSS Statistics 22. At the $p < 0.05$ level, this test showed a significant difference between the commingled and non-commingled groups ($p=0.026$).

In sum, these results illustrate the benefit of using VA methods to help sort CHRs at the sacroiliac joint. This novel and objective technique improves upon previously subjective strategies in sorting CHRs and in the future will be applied to additional joint surfaces.

Commingling, Virtual Anthropology, Sacroiliac Joint

A3 The Segregation of Individuals From Large Commingled Assemblages Via Stable Isotope Ratio Analysis of Bone Collagen

Mary Megyesi, PhD, Defense POW/MIA Accounting Agency, Joint Base Pearl Harbor-Hickam, HI; Gregory Berg, PhD, Defense POW/MIA Accounting Agency, Joint Base Pearl Harbor-Hickam, HI; Lesley Chesson, MS, Defense POW/MIA Accounting Agency, Joint Base Pearl Harbor-Hickam, HI*

Learning Overview: After attending this presentation, attendees will understand the application of intra-person isotopic variation limits for human bone collagen to segregate individuals from commingled assemblages.

Impact Statement: This presentation will impact the forensic science community by illustrating a process to resolve commingling using isotopic data that can be used when osteometric data are unavailable and DNA testing has limited success.

Stable isotope ratio analysis has been used by anthropologists since the 1970s to investigate diet. Human tissues, such as bone collagen, reflect the isotopic composition of food consumed. When diets vary due to food availability, distinct populations emerge isotopically; measuring the isotope “delta” values of carbon ($\delta^{13}\text{C}$) and nitrogen ($\delta^{15}\text{N}$) in collagen from an unknown individual and comparing to previously characterized populations can thus be used to predict origin.¹

Isotopic data could be useful for associating skeletal elements, as postulated by Berg et al. and McCormick et al.^{2,3} Berg et al. published forensic interpretative values for: (1) determining if two bones “are probably” different (0.75‰ for $\delta^{13}\text{C}$ values and 1.05‰ for $\delta^{15}\text{N}$ values), and (2) determining if two bones “are” different (0.95‰ for $\delta^{13}\text{C}$ values and 1.30‰ for $\delta^{15}\text{N}$ values).² A model built by McCormick et al. with simulated isotopic and osteometric data confirmed the potential utility of stable isotope ratio analysis for resolving commingling.³

This study uses isotopic data gathered during casework at a skeletal identification laboratory to segregate individuals in commingled assemblages. Remains came from two Common Graves (CGs), exhumed from the Cabanatuan Prisoner of War Camp, Republic of the Philippines. A CG was used to bury all individuals who died within a 24-hour period. Historically, the CGs were associated with six (CG 1) and nine (CG 2) individuals. Remains were identified after World War II, leaving three unknowns from CG 1 and four unknowns from CG 2.

Collagen was extracted from 80 long bone samples and analyzed via elemental analyzer-isotope ratio mass spectrometry to measure $\delta^{13}\text{C}$ and $\delta^{15}\text{N}$ values. Additional samples were collected for mitochondrial DNA (mtDNA) analysis. Chemical preservation hampered mtDNA results, with only 50% in CG 1 and 87% in CG 2 producing a sequence (typical $\geq 95\%$ success). Physical condition limited the use of osteometric methods, as most diaphyseal ends were eroded/missing.

Using the intra-person isotopic variation limits of Berg et al., four skeletal elements from CG 1 were segregated as originating from one individual.² All other samples overlapped in isotopic data distributions (i.e., formed one cluster). Between the remains of the three unknowns from CG 1, four mtDNA sequences were present; only one sequence was present in the elements segregated isotopically.

For CG 2, five isotopic data clusters were observed. Two isotopically distinct clusters represented single individuals, one consisting of 11 elements and the other of 3 elements. These isotopic segregations were supported by mtDNA data, as each contained a single sequence. Two additional clusters each contained a single mtDNA sequence but narrowly failed to meet the criteria for “are probably different.”² The largest isotopic data cluster ($n=22$ elements) was associated with three mtDNA sequences. Overall, the data suggested the remains from CG 2 represented at least seven individuals, of which two could be segregated isotopically.

This study demonstrated that isotopic data can be used to segregate some individuals from commingled assemblages, even when population members were expected to have similar diets. Isotope testing alone is unlikely to resolve all commingling; however, once an assemblage is partially sorted, DNA analysis can be used strategically for deconvolution. Isotope testing is a useful tool in the forensic anthropologist’s toolbox that can be deployed in combination with other analytical techniques.

Stable Isotope Ratio Analysis, Bone Collagen, Commingling

A4 Forensic Anthropology Casework at the Cook County, Illinois, Medical Examiner's Office, 2012–2020

Erin Waxenbaum, PhD, Northwestern University, Evanston, IL; Anne Grauer, PhD, Loyola University, Chicago, IL*

Learning Overview: After attending this presentation, attendees will have an appreciation for forensic anthropology consultations at the Cook County Illinois Medical Examiner's Office between 2012 and 2020.

Impact Statement: Attendees will appreciate forensic anthropology casework in the third- largest city in the country and be able to amass comparable data upon which decisions at the local, regional, and even national level can be informed.

As a relatively “young” area of forensic science, anthropology’s popularity in recent years has been fueled by media representations of the field, as well as greater numbers of medical examiners and coroner’s having first-hand interaction with forensic anthropology practitioners. However, few practicing forensic anthropologists publish on the composition of their casework, resulting in a minimal understanding by academics, forensic professionals, and lay individuals of the operationalization of the field. Many variables influence the number, type, and timeline of forensic anthropology casework in the United States, including local climate, jurisdiction caseload, and the familiarity of medical examiner/coroner’s offices with the field of forensic anthropology. Evaluation of the composition of anthropology casework from varied jurisdictions will provide essential data upon which planning, needs assessment, and resource determinations can be appraised. Continued discussion and publication of casework detail and composition not only serves future practitioners within anthropology but the broader audience of forensic scientists who engage with or request their expertise.

At the Cook County Illinois Medical Examiner’s Office, two anthropologists, working in concert, consult on a part time, case-by-case/as needed basis. The anthropologists are notified of a forensic pathologist’s consult after remains have been brought to the medical examiner’s office and, upon anthropologists’ requests, the remains are macerated, if necessary, by medical examiner’s staff.

With the objective of evaluating the composition of forensic anthropology casework at the Cook County Medical Examiner’s Office between 2012 and 2020, the following variables were recorded: month of discovery, decedent depositional environment, condition of remains upon initial discovery, type of anthropology consult requested, time from discovery to consultation request, time from consultation request to analysis, and time from analysis to report submission.

A total of 111 cases distributed over nine years produce an average of 12.33 cases per year, with the greatest number of cases occurring in 2015 ($n=18$) and the fewest in 2020 ($n=8$). A majority of cases were discovered in September ($n=19$), with the fewest cases discovered in January ($n=5$). Most cases were outdoor, surface recoveries ($n=45$). Upon initial discovery, a majority of cases were fully skeletonized ($n=48$), many were in a state of severe decomposition with partial skeletonization ($n=30$), and few were fully fleshed ($n=12$) or thermally altered ($n=7$). While consult requests may include multiple components, 86 requests were for biological profile estimation, 51 requested trauma analysis, 15 requested human/non-human assessment, and 5 required the determination of the minimum number of individuals. On average, 90.7 days elapsed from discovery to anthropology consult, 51.0 days from consultation request to anthropology visit of the case, and 14.3 days from anthropology analysis in person to report submission.

Disclosure and discussion of the range of services, support, and expertise forensic anthropologists provide medical examiner and coroner’s offices broadens the understanding of the field, allows for the formulation of best practices, and serves as data upon which decisions regarding protocol, funding, resources, and need can be based. With additional practitioners collecting and sharing their data, a clearer window into the scope and utility of the field will be appreciated by both colleagues and the greater forensic scientific community.

Forensic Anthropology, Casework, Consultation

A5 Myriad Maps and Applied Anthropology: Needs and Limitations

Molly Miranker, MA*; Texas State University, San Marcos, TX

Learning Overview: The goal this presentation is to examine both the utility and limitations of different digital mapping techniques used in searches, rescues, recoveries, and tracking of missing person cases in a fatal migration context.

Impact Statement: The juxtaposition of different maps that depict searches for and the tracking of missing migrants specifically will impact the forensic science community by demonstrating how maps both facilitate inter-entity communication and can affect search or identification outcomes for human remains.

As the United States-Mexico border has become increasingly challenging to cross (ca. 1986), the number of migrant fatalities has proliferated in remote areas away from traditional ports of entry.¹ In the wake of these deaths, multiple federal, state, academic, and non-profit institutions, as well as affected families, have come together to search and rescue or recover and identify these decedents. Along with these efforts, maps and Global Positioning System (GPS) sharing have become common practice to launch search and recovery or maintain case tracking.² Currently, most maps that depict the numbers of deaths, dangers of terrain, or geospatial evidence for identification are based on Arizona data.¹⁻³ While the use and need for mapping is recognized in Texas, the data are, for now, insufficient for accomplishing similar spatial statistical analyses on a statewide scale.^{3,4}

This contribution presents a contemporary sample of Google® Map imagery ($n=2$), mapping apps traditionally used for hunting ($n=2$), and Geographic Information Systems (GIS) -generated maps ($n=2$) collected by this study over a field expedition during June–July 2021 in South Texas. This research was conducted under Institutional Review Board (IRB) approval and the maps were shared with interviewees' verbal consent. Specifically, the maps shared in this presentation were produced by law enforcement, firefighter/Emergency Medical Services (EMS), and non-profit organizations.

These exemplar maps reflect the ingenuity of those faced with a death crisis in Texas, as well as the barriers to maintaining sufficient information about missing migrant cases, specifically, inaccurate locational data and systemically decentralized forensically relevant information.⁵ In combination, these long-standing obstacles prevent the establishment of an Open Geographic Information System (OGIS) in Texas that is similar to the Arizona OGIS. Without standardized data collection and maintenance in Texas, the risk of losing information and the inability to utilize spatial analyses for predictive capabilities and identification hypotheses will persist.⁴

Applied Anthropology, GIScience, Humanitarian GIS

A6 Documenting Outdoor Simulated Scenes With Photogrammetry: Methods for Improving Dappled Lighting Conditions

Caroline Jasiak, MA, University of Central Florida, Department of Anthropology, Orlando, FL; John Schultz, PhD, University of Central Florida, Department of Anthropology, Orlando, FL and the National Center for Forensic Science, University of Central Florida, Orlando, FL; Morgan Ferrell, MA, University of Central Florida, Department of Anthropology, Orlando, FL*

Learning Overview: After attending this presentation, attendees will understand how to combat adverse lighting conditions when employing Close-Range Photogrammetry (CRP) to record outdoor forensic scenes. In particular, this presentation will focus on using CRP methods to record two simulated scenarios representing variable outdoor lighting conditions.

Impact Statement: This presentation will advance forensic sciences by providing a preliminary investigation for mitigating adverse lighting conditions when recording scenes in outdoor environments. This research will improve previous photogrammetry research by exploring data collection techniques to improve imagery affected by adverse lighting conditions.

Although CRP is used to document archaeological sites and create 3D models, this method is not commonly employed to document forensic scenes and lacks a sufficient procedural basis to guide data recording when encountering problematic environmental conditions. The purpose of this study is to test how an overhead sheet and artificial lights can improve CRP imagery for scenes with adverse lighting conditions.

The scenes were located in the natural lands of the University of Central Florida and included mixed ground surfaces. Two scenes were created, one with trees partially blocking overhead sunlight and a second in an open location without tree cover. Scenes were constructed using a partial composite human teaching skeleton and clothing items to represent a slight scatter (approximately 4m x 3m). Calibrated photogrammetric scale bars from Cultural Heritage Imaging were placed around each scene, and they were photographed multiple times using various combinations of light correction tools: (1) no artificial lighting tools; (2) a white sheet over the scene; (3) artificial lights around the scene; and (4) a combination of lights and sheet. Approximately 240 photographs were taken for each model using a Nikon® D7200 camera, at five different view angles. Additional parallel overhead photographs and close-up photographs were also taken. The 3D models were processed multiple times using Agisoft® Metashape® Professional to improve the visual quality.

The 3D models of the two scenes were evaluated quantitatively and qualitatively. It is suggested that accurate models should have a Root Mean Square (RMS) reprojection error value of less than 0.3 pixels. Qualitative accuracy was assessed using orthomosaics and close-up model screengrabs of the cranium. The orthomosaic is an overhead view of the scene that is extracted from the 3D model. Assessing visual accuracy of the imagery involved subject-subject interface distortion, scale bar distortion, ground surface-subject distortion, and skeletal geometry distortion.

When comparing both scenes, the RMS reprojection error was highly accurate, as the error for all models was less than 0.3 pixels. While both scenes exhibited few qualitative distortions in the orthomosaics, the close-ups of the cranial screengrabs displayed increased skeletal geometry distortions. The dappled scene, without light correction tools, exhibited severe distortion due to bright sunlight patches. When the overhead sheet was utilized, these light patches were eliminated. However, scale bar distortion occurred where the overhead sheet provided minimal coverage. The open scene exhibited ground surface-subject interface distortion in all the orthomosaics. However, there was improved skeletal geometry accuracy of the close-up cranial screengrabs when the overhead sheet was applied. In both scenes, the use of the artificial lights did not appear to improve the quality of the 3D imagery.

It is recommended to use an overhead sheet, or light-colored tarp, when encountering dappled or overhead lighting issues when photographing forensic scenes for CRP applications. Proper cleaning of the scene prior to data collection is essential to improve model accuracy by removing all ground foliage around the skeletal elements and scale bars to reduce ground surface-subject matter distortions. Further research should involve larger scenes to develop protocols for implementing this recordation method.

Photogrammetry, Forensic Archeology, Scene Documentation

A7 Tracing Academic Relatedness Via The Forensic Anthropology Phylogeny (FAP)

Katharine Kolpan, PhD, University of Idaho, Moscow, ID

Learning Overview: After attending this presentation, attendees will have a better understanding of how the Forensic Anthropology Phylogeny (FAP) works and how it can provide information about academic relatedness across time and space.

Impact Statement: This presentation will impact the forensic science community by demonstrating how the FAP allows forensic anthropology practitioners to trace trends in academic relatedness over time and across institutions.

The purpose of this research is to introduce forensic practitioners to the FAP. The current iteration of the FAP was compiled via an ongoing volunteer survey. As such, it is meant to serve as a living document that is housed in cyberspace and periodically updated so that academic phylogenetic relationships can be tracked over time. The survey itself asks respondents to provide information concerning: their masters and doctoral institutions; their academic advisors; the years they matriculated and graduated; the type of degree earned (MA, MS, MSc, PhD); whether they specialized in any other subfield, such as bioarcheology, paleopathology, or molecular anthropology, while matriculating; any specific outside mentors who they felt aided their academic careers; their current employment; and any professional certifications they may hold. The survey also includes demographic information. The comprehensive nature of the survey questions is meant to provide information that can be reconstructed visually as a phylogenetic tree and to assess patterns of relationships between academic institutions via methods such as network analysis.

The FAP functions in a manner similar to that of the Academic Phylogeny of Biological Anthropology (APBA), but with a narrower focus and modifications meant to examine academic relationships that are specific to forensic anthropology. For example, the APBA phylogeny only allows for the participation of people who have completed their PhD. However, forensic anthropology has a significant applied component and attracts practitioners who make important contributions to the field without obtaining a doctorate. The FAP survey asks separate questions related to the completion of the master's degree and the PhD and maintains two phylogenetic trees, one for master's students and practitioners and one for PhDs. This creates a space in which to trace the academic trajectories of master's-level forensic anthropologists rather than erasing them. Moreover, as a highly specialized field with a limited number of doctoral institutions, many students of forensic anthropology who matriculate to the doctoral-level attend separate master's and PhD institutions. In this case, 52% of survey respondents attended disparate master's and PhD institutions, while 26% attended a combined MA/MS and PhD program at the same institution, and 22% attended a terminal master's program. Additionally, when students receive their master's and PhDs at different institutions, compiling data in two separate phylogenies allows for the analysis of relationships between master's and PhD institutions over time and space. For instance, of the seven respondents who attend the PhD program at Texas State, four completed their masters at New York University (NYU), while the other three respondents matriculated from different institutions.

Furthermore, because the phylogeny tracks a respondent's year of matriculation and graduation, the data capture trends related to which programs accept students from which institutions over time and permit researchers to examine patterns. The data from the phylogeny also capture the ebb and flow of programs, as well as when new programs begin to graduate students, where those students matriculate when and if they continue on with their education, and their current professional position. For instance, the four students attending Texas State with master's degrees from NYU all matriculated after 2008, which makes sense since NYU did not institute its Master of Science in Human Skeletal Biology until the mid-2000s and Texas State's PhD in Applied Anthropology program is quite new.

Phylogenetics, Academia, Network Analysis

A8 Exploring Forensic Research Interests of a United States-Based Anthropology Faculty

Rhian Dunn, MS, Michigan State University, East Lansing, MI; Christopher Rainwater, MS, Office of Chief Medical Examiner, New York, NY and New York University, New York; Nicholas Passalacqua, PhD, Western Carolina University, Cullowhee, NC*

Learning Overview: After attending this presentation, attendees will have a better understanding of how forensic anthropological research interests are presented by forensic and biological anthropologists.

Impact Statement: This presentation will impact the forensic science community by examining the inclusion of forensic anthropology as a research interest by individuals in the broader field of biological anthropology.

Forensic anthropology is commonly considered a subdiscipline of biological anthropology. While the discipline of forensic anthropology currently requires specific training and certification, many faculty members in the broader discipline of biological anthropology continue to list forensic anthropology, or “forensics,” as a research interest, specialty, or focus (herein referred to as research interest) in addition to their primary research foci. This project aims to investigate whether those who list forensic anthropology as a research interest are invested in the discipline of forensic anthropology.

As of 2021, the Integrated Postsecondary Education Data System lists 459 schools that offer undergraduate anthropology degrees in the United States. Of these, 215 schools were found to have public departmental websites where faculty reported research interests. Pertinent data (e.g., research interests) were webscraped, culminating in 2,831 total faculty profiles. Of these, 78 individuals (2.8% of all faculty) listed some variation of “forensic” as a research interest. For the purposes of this study, individuals were categorized into forensic and non-forensic groups. Individuals were placed into the forensic group if one of two criteria were met: (1) certification through the American Board of Forensic Anthropology; and/or (2) active membership in the American Academy of Forensic Sciences (AAFS) conference.

Of the 78 individuals, 42 (53.8%) were designated to the forensic group and 36 (46.2%) were designated to the non-forensic group. In regard to active research in the discipline, 88.1% of the forensic faculty, have presented at least once at an annual meeting of the AAFS and 73.8% of forensic faculty have published at least one paper in the *Journal of Forensic Sciences* (JFS). On the other hand, only 2.8% of the non-forensic faculty have presented at the AAFS, and only 16.7% of the non-forensic faculty have published in the JFS.

Research interests were also examined to reveal whether forensic faculty were more likely to list specialties within forensic anthropology (e.g., age estimation, trauma); 52.4% of forensic faculty and 13.9% of non-forensic faculty listed specific forensic anthropological specialties. This was further explored via the use of word frequencies and predictors (via term frequency-inverse document frequency [tf-idf] scores) in R using the “tidytext” package. Words more predictive of forensic faculty include “bone,” “methods,” “death,” “growth,” and “quantitative,” while words more predictive of non-forensic faculty include “studies,” “southwest,” “southeast,” “paleoanthropology,” and “identity.” These word predictors indicate a methodological focus among the forensic faculty and more regional and/or theoretical foci among the non-forensic faculty. However, when clustered by natural topics in R using the “topicmodels” package, individuals could not be reliably classified into the forensic and non-forensic groups.

Finally, Network Analysis procedures in R using the “textnet” and “igraph” packages assessed latent social structures among and between the two groups. These analyses highlight trends seen in the word frequencies and predictors, but better showcase the relationship between research word and forensic status, as well as latent relationships among all faculty. While several words are common in both groups (e.g., anthropology, forensic, bioarcheology), words such as “legal,” “identification,” “histology,” and “biomechanics” are more likely to be used by forensic faculty and words such as “cultural,” “theory,” “mortuary,” and “paleoanthropology” are more likely to be used by non-forensic faculty. This network highlights areas of overlap and divergence in research between forensic anthropology and the greater biological anthropology.

Forensic Anthropology, Text Analysis, Network Analysis

A9 Advances in Sorting Commingled Human Remains: A Preliminary Study Using the Subtalar Joint

Ioanna Anastopoulou, PhD, National and Kapodistrian University of Athens, Athens, Goudi, Greece; Nikoletta Manta, MSc, National and Kapodistrian University of Athens, Athens, Goudi, Greece; Konstantinos Katsos, MD, PhD, National and Kapodistrian University of Athens, Athens, Goudi, Greece; Emmanouil Sakellidis, MD, MSc, PhD, National and Kapodistrian University of Athens, Athens, Goudi, Greece; Moraitis, MSc, PhD, National and Kapodistrian University of Athens, Athens, Goudi, Greece*

Learning Overview: After attending this presentation, attendees will have a better understanding of the issue of commingled human remains and how geometric morphometrics target to solve it.

Impact Statement: This presentation will impact the forensic science community by presenting a new semi-automated approach in re-associating commingled human remains.

The term commingling is used for characterizing the osteological contexts in which skeletal remains of different origins are intermixed.¹ Its presence is common in both forensic and bioarcheological contexts and, until recently, the sorting methods were mainly based on optical similarities or metric re-association.² Given that multiple skeletal elements may present optical similarities due to the impact of the same taphonomic factors, as well as multiple skeletal elements may be of similar size, the evaluation of shape may be more individualized.

For the evaluation of shape, the tali and calcanei of 25 individuals were scanned with a structured light 3D scanner. The individuals originate from a skeletal collection that is housed at the Forensic Anthropology Unit, Department of Forensic Medicine and Toxicology, School of Medicine, National and Kapodistrian University of Athens. A number of six landmarks were placed on the rim of the talus' posterior articular surface for the calcaneus and the adjoining calcaneus' posterior articular surface for the talus. The landmarks' raw coordinates were transformed into Procrustes coordinates for removing the factor of size. The two skeletal elements that presented the smallest Procrustes distance were the ones that mostly resembled in overall shape and it was recorded whether they actually belonged to the same individual.

The results showed that in 22/25 (88.00%) of the cases, the correct talus-calcaneus match was found between the skeletal elements that presented the two smallest Procrustes distances compared with all the other elements. It is advised that this method should be utilized in rejecting an approximate 90% of the possible matches based on shape differences.

Future research could further evaluate the applicability of landmark and/or semi-landmark-based methods in re-associating two bones with adjoining articular surfaces.³ The aforementioned approach could retrieve shape information for each skeletal element of the articulation and become a valuable addition to the existing sorting methods.

Forensic Anthropology, Commingling, Sorting

A10 Calculating the Minimum Number of Individuals (MNI) and Most Likely Number of Individuals (MLNI) for a Commingled Fetal and Infant Remains Sample

Ariana V. Agyemang, BS, SUNY Binghamton University, Vestal, NY; Helen Brandt-Litavec, MS, SUNY Binghamton University, Vestal, NY; Elizabeth A. DiGangi, PhD, SUNY Binghamton University, Vestal, NY

Learning Overview: After attending this presentation, attendees will be informed about how to calculate both the MNI and the MLNI of commingled fetal and infant remains.

Impact Statement: This presentation will provide information about how to investigate commingling in fetal and infant remains, as there is scant literature that discusses resolution for this group of individuals.

Various taphonomic forces can cause disarticulation of human remains; as a result, forensic anthropologists are often tasked with separating remains for individualization purposes. Literature on the commingling of infant bones has not been as developed when compared to that regarding the commingling of adult bones. Therefore, this research project focuses on estimating MNI and MLNI in infant and fetal remains.

Fetal and infant remains comprising part of the Antioquia Modern Skeletal Reference Collection were examined. This assemblage is a commingled one from a modern ossuary and therefore represents a real-world case study of commingling in fetal and infant remains. Every region of the body is represented with an absolute number of 271 bones present in the assemblage. The side, estimated age based on development and metrics, and other notable characteristics, such as taphonomic alterations, were recorded for each bone. Schaefer et al. was used for measurement definitions as well as to estimate age.¹ Linear measurements were taken in millimeters (mm) using a digital sliding caliper. Age was estimated when possible for each element based on the metrics, and this study used this age division when calculating MNI and MLNI. The MNI was calculated based on the formula: $N = \text{Max}(L, R)$.² This is done by sorting the assemblage into bone type, then left and right sides; the bone and side with the most elements are recorded as the MNI. The MLNI was calculated to ensure that the number of individuals were accurately estimated. The literature suggests this metric is a better estimate of the number of individuals because pair matching is taken into account, especially for well-preserved samples.³ Here, the long bones (humeri, radii, ulnae, femora, tibiae, and fibulae) were used to estimate MLNI because they have a stronger pair-wise association than other bones.³ The Chapman formula, $N = ((R+1)(L+1) / (P+1)) - 1$, was used to calculate MLNI.⁴ Visual pair matching (color, staining, morphology, etc.) coupled with age estimation from metrics was used to match antimeres of long bones.

The estimated ages fell into nine separate cohorts from 22 prenatal weeks to 40+ weeks. Taking these ages into account, the calculated MLNI of the long bones ranged from 2–20, while the MNI of the same bones ranged from 2–7. The range for MLNI is greater than that for MNI; this may be due to the relatively small number of pairs (16) of long bones found in the assemblage. Bones falling into the 40 prenatal weeks and 40+ weeks age cohorts have the largest MNI and are the most represented in the sample.

Resolving commingling in fetal and infant remains can be more complex than for adult remains due to the strong effect that small differences in age (i.e., on the order of single months) will have on size. Their fragility as compared to adult remains can also hamper recovery and measurement efforts. As a result, this research aims to provide practical procedures involving the commingling of infant bones and reporting MNI vs. MLNI. In the case of infant and fetal remains, this study recommends the use of MLNI over MNI as a stronger metric for resolving commingling.

A11 We Take Care of Our Own: Utilizing the LGBT+ Accountability for Missing and Murdered Persons (LAMMP) Database

Anthony Redgrave, MS, Redgrave Research Forensic Services, Athol, MA; Amy Michael, PhD, University of New Hampshire, Durham, NH; Jessica Veltstra, MS, Redgrave Research Forensic Services, Athol, MA; Samantha Blatt, PhD, Idaho State University, Pocatello, ID; Mariyam Isa, PhD, Texas Tech University, Lubbock, TX, USA*

Learning Overview: Attendees will understand the need for a queer-informed database for missing and murdered LGBTQ2S+ (Lesbian, Gay, Bisexual, Transgender, Queer, Two Spirit) community members and will learn how to use and contribute to this database. Attendees will also understand the limitations of traditional databases in the context of increasing fatal violence directed at LGBTQ2S+ people.

Impact Statement: A variety of resources are needed to document LGBTQ2S+ decedents who may not be accurately reported in traditional databases. This presentation offers suggestions for the use of a new database to expediently track cases, identify decedent patterns, and share essential information leading to identification.

Rising fatal violence and hate crimes against LGBTQ2S+ individuals necessitates a more strategic response outside of existing databases. The most recent Federal Bureau of Investigation (FBI) data on hate crimes (2019) indicated that 20.3% of incidents were committed due to sexual orientation or gender identity.¹ Government databases and clearinghouses such as the National Missing and Unidentified Persons System (NamUs) and National Center for Missing and Exploited Children (NCMEC), along with public entities like Charley Project (CP) and Doe Network (DN), are powerful tools for use in information sharing about missing and murdered individuals. Yet, these and other databases and state clearinghouses present challenges when researching or entering cases of LGBTQ2S+ individuals.

For example, missing and unidentified persons databases lack clear guidelines for entry of inconclusive or uncertain sex, exclude selections outside binary sex, and lack input options for evidence of gender identity. This can both lead to biases and gaps in functionality within databases, thus making it more difficult to recognize such biases. Further, deadnames (the individual's name given at birth that is no longer used) are often entered and pre-transition photos are often used in media and databases, while their current names and photos may be excluded. Misgendering, deadnaming, and focusing on the individual's assigned sex potentially exposes the individual to further harm and hinders case resolution.²

In response to inadequate databases, the LGBT+ Accountability for Missing and Murdered Persons (LAMMP) database was created to gather data with queer-informed and harm-reduction perspectives.³ LAMMP acts as a citizen-powered resource to serve the LGBTQ2S+ community by: (1) matching unidentified, possibly LGBTQ2S+ Does with missing persons reports; (2) identifying cases of possibly LGBTQ2S+ individuals based on available information; and (3) providing a comprehensive, searchable database for family members (chosen family and/or family of origin), law enforcement, and others to provide essential information leading toward identification.

LAMMP offers several features to ensure the privacy and safety of the missing and those reporting them. Case reports and information can be submitted to administrators anonymously and without creating an account. The missing persons component of LAMMP is private and searchable only to those with approved credentials. The database is intended for use by professional investigators and researchers (e.g., anthropologists, medical examiners, law enforcement), as well as forensic genetic genealogists, and includes fields for GEDMatch numbers of family members and related family trees.

This presentation will present LAMMP case examples to demonstrate how the database differs from NamUs, NCMEC, DN, CP, and other clearinghouses in the following ways: (1) incorporation of data from non-traditional sources (e.g., Facebook® posts, Reddit® threads, activist organizing); (2) removal of the gatekeeping aspect of governmental databases as information does not have to be submitted by law enforcement, forensic professionals, or reported by family of origin; and (3) recognition of, and response to, the problems caused by binary sorting of individuals in databases, allowing for comparison across sex and gender categories.

Identification, LGBTQ+, Database

A12 Applying a Biocultural Signature of Embodied Stress to Identify Latin American Migrants from a Cold Case Sample in South Florida

Enrique Plasencia, BA, University of West Florida, Pensacola, FL; Allysha Winburn, PhD, University of West Florida, Pensacola, FL*

Learning Overview: After attending this presentation, attendees will understand how skeletal and dental indicators of stress may be used to recognize the skeletal remains of Latin American migrants in the South Florida region.

Impact Statement: This presentation will impact the forensic science community by presenting evidence supporting the inclusion of skeletal and dental indicators of non-specific stress in the biocultural profile of Latin American migrants in South Florida.

Immigration policy in the United States remains a polarizing topic of discussion throughout the political spectrum. Current policy amendments making immigration to the United States illegal or more difficult contribute to the ever-rising number of undocumented migrants who have died while attempting to enter the United States through rural and dangerous regions—such as southern Arizona’s remote and inhospitable Sonoran Desert and mountains.

Compared with migrants crossing the United States-Mexico border, less forensic anthropological attention has been paid to migrants entering South Florida.¹ The difficulties associated with aquatic deposition of remains make the recovery of migrants’ remains from the South Florida coastline challenging. The diverse cultural and geographic origins and multifaceted biological histories of Latin American populations in the South Florida region—especially Cuban Americans—also make discriminant function analyses based on traditional craniometrics inadequate for estimation of population affinity or region of origin.²⁻⁴

A forensic anthropologist’s ability to differentiate between the remains of Latin American migrants and those of United States-born citizens is essential to forensic investigations. This study expands on previous research conducted by forensic anthropologists on the southwestern United States border and tests its relevance to the unique context of the South Florida “border.”⁴ A skeletal sample of 102 cold-case decedents in the Miami-Dade County Medical Examiner Department was analyzed for the presence of skeletal and dental indicators of non-specific stress, particularly porotic cranial lesions and enamel hypoplasias, in an attempt to flag decedents as possible migrants and potentially guide the investigation of their cases.

Of the 102 decedents, 28 were identified or had believed-to-be associations; these 28 served as the control group of known origin (i.e., United States-vs. Latin American-born.). Of the control sample, 46% ($n=13$) of decedents had enamel hypoplasias, which were over three times more likely in Latin American migrants ($n=10$) than United States-born citizens ($n=3$). Of the control sample, 18% ($n=5$) had porotic cranial lesions, which were four times more likely in Latin American migrants ($n=4$) than in United States-born citizens ($n=1$).

These data suggest that the stress indicators that have proved effective in differentiating United States from non-United States decedents in the southwest may also be applicable to the context of South Florida casework. Thus, the indicators of stress were examined in the sample’s 74 unidentified decedents. Of these, 24% ($n=18$) had enamel hypoplasias, and 23% ($n=17$) had porotic cranial lesions. Based on the presence of these stress indicators, 28 sets of unidentified skeletal remains were flagged as possible migrants. It is hoped that these tentative associations inform future case investigation and expedite identifications for these individuals.

The above findings are consistent with documented inequities between many Latin American countries and the United States in access to health care and a nutritive diet at the time of growth and development. The presence of non-specific indicators of stress, in combination with context and other aspects of the biocultural profile, should indicate to forensic anthropologists and other medicolegal personnel that the remains in question may belong to Latin American migrants—not only in the southwest, but also in the region of South Florida.⁵

Forensic Anthropology, Unidentified Migrants, Non-Specific Stress Indicators

A13 OsteoID: A Freely Available Tool for Skeletal Species Identification

Heather Garvin, PhD, Des Moines University, Des Moines, IA; Rachel Dunn, PhD, Des Moines University, Des Moines, IA; Sabrina Sholts, PhD, National Museum of Natural History, Smithsonian Institution, Washington, DC; M. Schuyler Litten, MA, National Museum of Natural History, Smithsonian Institution, Washington, DC; Merna Mohamed, MSc, Des Moines University, Des Moines, IA; Nathan Kuttickat, BSc, Des Moines University, Des Moines, IA; Noah Skantz, BS, BA, Des Moines University, Des Moines, IA*

Learning Overview: After attending this presentation, attendees will be familiar with a new online resource that facilitates species identification from skeletal remains.

Impact Statement: This presentation will impact the forensic science community by introducing a freely available online tool that can be utilized by medicolegal agencies to evaluate forensic significance of skeletal remains.

Without specific training in comparative osteology, determining whether an isolated skeletal element is human or faunal in origin can be challenging. Many medicolegal agencies will rely on forensic anthropologists to make such assessments, and although forensic anthropologists are experts on the human skeleton, they may rely on other resources to determine the specific species of isolated faunal elements. Not all forensic anthropologists or medicolegal agencies have access to large comparative skeletal collections and may rely on textbooks or broad internet searches. The goal of this project was to create a freely available online tool to facilitate species identification from skeletal remains.

Photographs and metric data were collected from the long bones, scapulae, sacra, and ossa coxae of 28 common North American species, including humans, 20 additional mammals, three birds, and two turtles. In total, more than 16,000 measurements were collected from 436 human and 984 non-human specimens. The photographs were edited to create a single figure with multiple views for each element (six views for all long bones), along with a metric scale, penny for scale, and documented range of maximum bone length. At times, unique identifying features are also indicated on the figures. Descriptive statistics were run on the metric data, which consisted of maximum bone lengths, midshaft diameters, and proximal and distal breadths and depths. These resources were then incorporated into an online tool: OsteoID.¹

OsteoID asks users to first identify what type of element (i.e., bone) they have, providing exemplar images of the various forms of each bone; if unknown, users can search all elements. Users can then input the maximum length, proximal width, or distal width of the bone (one at a time in a nested format), which will return images for only those species within that size range. The search tool was limited to these three measurements because they could be collected from almost all element types and preliminary research indicated they were the easiest for less-experienced users to collect. Size ranges input into the tool were based either on the full measurement range from the data or two-standard deviations from the mean, whichever was broader to better encompass size variations. Clicking on the figures enlarges them for visual comparison and species identification. Additional resources are also provided at the website, including a link to a Morphosource project page where 3D scans of many of the elements have been uploaded as part of this study, a link to access images of other non-measured elements (e.g., crania, carpals and tarsals), and a list of other texts or webpages that may be of use to practitioners.² OsteoID is now publicly available, providing an additional and free resource to forensic anthropologists, medicolegal agencies, and archaeologists, among others. Research is ongoing to assess the possibility of including a more robust statistical framework for species identification, although all final identifications should be confirmed via visual assessments.

Forensic Anthropology, Forensic Significance, Non-Human

A14 Assessing Opioid Exposure and Opioid Overdose Deaths in Skeletal Casework Through Collaboration With Organ Procurement Organizations

Janna Andronowski, PhD, Memorial University of Newfoundland, St. John's, Newfoundland, Canada; Randi Depp, MS, The University of Akron, Akron, OH*

Learning Overview: Attendees of this presentation will be introduced to critical information relating to the effects of prolonged opioid use on skeletal biology through modern decedent data collected in collaboration with an American Organ Procurement Organization (OPO). Specific goals include: (1) outlining the lack of detailed decedent medical and social histories in existing skeletal collections commonly used in forensic anthropology, and (2) demonstrating the effectiveness of targeted skeletal specimen procurement through medical-based organizations.

Impact Statement: This presentation will impact the forensic science community by providing new insights and potential avenues for modern skeletal sample procurement for forensic anthropological research. Accessing well-documented modern specimen collections will allow us to adapt morphological and histologic methods within the field of forensic anthropology for application to chronic opioid users.

The opioid epidemic is a public health crisis that resulted in almost 50,000 Opioid Overdose Deaths (OODs) in 2019 alone.¹ Exacerbated by the COVID-19 pandemic, OODs jumped to more than 69,000 in 2020.² Commonly encountered in forensic casework, chronic opioid use and OODs pose a serious problem for forensic anthropological analyses due to induced osteoporotic effects demonstrated in clinical research.³ As such, it is vital that future research seeks to understand the impact of substance abuse on forensic anthropological methodologies. Existing human skeletal collections, however, are not wholly representative of modern populations and drug users, and detailed drug use histories are especially lacking.

To fill this gap, it is proposed that researchers utilize OPOs to target modern populations, especially marginalized and underrepresented groups, including OODs. Demographics of 100 recent decedents from Northeast Ohio were obtained through an American OPO and compared to the demographics of existing skeletal collections (William M. Bass Donated Skeletal Collection, Hamann-Todd Human Osteological Collection, and Robert J. Terry Anatomical Collection). The Bass and Terry collections have similar sex distributions as the Northeast Ohio samples with approximately 60% males and 40% females. The Hamann-Todd collection contains predominantly males (83%). The Northeast Ohio samples were more balanced for age distribution, with nearly equal distribution for age cohorts 20-29 (22%), 30-39 (23%), 40-49 (27%), and 50-59 (25%). All three skeletal collections had left-skewed age distributions with middle-aged and older cohorts represented more frequently. Ancestral affinity was not representative of larger populations for either Northeast Ohio samples or skeletal collections, but this may be more reflective of historical mistrust in the medical community by minority groups.⁴ Still, decedents from Northeast Ohio included 80% European ancestry and 10% each of African American and Latinx ancestries.

The detailed medical and social histories of our Northeast Ohio decedents illustrated that demographic risk factors often interacted (e.g., prior incarceration, chronic health conditions, mental health disorders) and many OODs have multiple marginalized identities and/or contributing health cofactors. Of the 100 decedents, 17 were OODs and accounted for 41% of those previously incarcerated and all LGBTQIA+ individuals. Of the OODs, 53% involved polysubstance use, 41% had chronic health conditions (e.g., high blood pressure, diabetes, chronic pain, HCV, HBV, HIV), and 47% had a known mental health disorder(s).

Medically based sources (e.g., OPOs) are ideal for skeletal research since their extensive medical histories reveal many comorbidities and lifestyle factors that are typically unknown when studying traditional skeletal collections and human remains curated via body donation programs. Overall, the Northeast Ohio data demonstrate the effectiveness of OPOs to provide skeletal samples that are more representative of targeted modern groups under study, particularly when a balanced age distribution is desired.

Opioids, Forensic Anthropology, Skeletal Collections

A15 Evaluating the Effect of Cocaine Use on Dorsum Sellae (DS) Demineralization

Tanin Zadeh, MS, Western University of Health Sciences, Pomona, CA; Ellen Fricano, PhD, Western University of Health Sciences, Pomona, CA; Vicki Wedel, PhD, Western University of Health Sciences, Pomona, CA*

Learning Overview: After attending this presentation, attendees will have developed a better understanding of the relationship between cocaine use and dorsum sellae demineralization.

Impact Statement: This presentation will impact the forensic community by demonstrating the value of identifying the correlates of cranial bone resorption amongst multiple variables.

Introduction: Bone metabolism is normally under control due to a balance between osteoblastic and osteoclastic activity, but when one process exceeds the other, bone growth or destruction result. The Sella Turcica (ST) is a depression in the sphenoid in the base of the skull that borders many important anatomical structures including the pituitary gland in the hypophyseal fossa, internal carotid and anterior cerebral arteries, cavernous sinus, and cranial nerves. The Dorsum Sella (DS) makes up the posterior wall of the ST and is bounded by the posterior clinoid processes laterally. Of the cranial bones frequently eroded, the DS is at great risk due to its thin nature, with an average thickness of 2-7mm. This study aimed to explore whether a correlational relationship exists between cocaine use and DS Demineralization (DSD), with other potential correlates, such as age, alcohol use, hypertension, and diabetes, being tested as well.

Hypotheses: H₁: There is significantly more DSD in cocaine users than in non-users. H₂: Additional variables that could result in DSD are age, sex, hypertension, diabetes, and alcohol use.

Materials and Methods: Computed Tomography (CT) scans of 201 individuals ($n=109$ females, $n=92$ males) were compiled from the New Mexico Decedent Image Database (NMDID). Medical records indicate 108 had history of cocaine abuse and 93 did not. Scans were analyzed using Dragonfly in which a contour mesh of bone was created to visualize a 3D model (slice thickness=1mm with 0.5mm overlap). The DS was assessed to locate any perforations indicating DSD. Statistical analysis was performed using chi squared analysis and binomial logistic regression.

Results: Of those who reportedly used cocaine, 20 had perforations and 87 did not. Out of the non-users, 30 had perforations while 61 did not. It was found that a reported history of cocaine use was not correlated with DSD in this sample and the frequency of DSD was higher in the non-user group. Using a multivariate binomial logistic regression, it was found that the relationship between DSD and age, sex, hypertension, diabetes, and alcohol use was found to be significant ($p<0.001$). This model explains 13% of the variation in DSD found. However, only age ($p<0.001$) and sex ($p=0.05$) were found to be driving this significant relationship with DSD. DSD is more frequently present in older and female individuals.

Discussion: Per research, this study was the first to utilize CT imaging to assess the frequency of DSD while accounting for environmental and health factors. It was demonstrated that DSD may be more common in the broader population than previously thought. The hypothesis that suggested a correlation between DSD and cocaine use was not supported; however, there are a number of potentially confounding factors that may be obscuring the relationship. Most importantly, there were no records of duration or volume of cocaine use, method of ingestion, or purity of the cocaine.

The only risk factors for DSD that were significantly correlated were both natural, physiologic processes. On average, the non-user group included older individuals, which may be a critical factor considering the effect of natural bone loss with age. In addition, females have overall thinner bone structure than males and lose bone density with age and menopause as well.

Significance: Assessing the frequency of DSD in cocaine users and the general population is valuable to the forensic community due to the wide range of physiologic and pathologic processes that result in bone demineralization. This study can be used as a foundation for utilizing radiography to ID unidentified remains by matching physical findings to changes expected from medical and social histories.

Sella Turcica, Bone Resorption, Computed Tomography (CT)

A16 The Effects of Prolonged Opioid Exposure on Bone Fracture Strength of Rabbit Middle Ribs

Reed Davis, MSc*, The University of Akron, Akron, OH; Mary Cole, PhD, The Ohio State University, Columbus, OH; Henry Astley, PhD, The University of Akron, Akron, OH; Janna Andronowski PhD, Memorial University of Newfoundland, St. John's, NL, Canada

Learning Overview: After attending this presentation, attendees will better understand the effects of prolonged opioid use on bone mechanical qualities.

Impact Statement: This presentation impacts the forensic science community by demonstrating the differences in force required to fracture the middle ribs of a model organism. These data may serve as a foundation for examining the effects of opioids on human bone fracture in a forensic context.

Previous work on the effects of opioids on bone maintenance and healing have focused on weight-bearing bones, such as the spine, pelvis, and femur.^{1,2} Studies examining non-weight-bearing bones have focused on medical record analyses to predict future fracture risk, but none explicitly examine the effects of opioid use on bone mechanical properties and fracture risk.³ Examining changes in yield strength of rib segments collected from rabbits exposed to opioid analgesics demonstrates how prolonged opioid use changes bone mechanical properties. Ribs were selected as they are under relatively constant stress from respiration and do not bear body weight, thus limiting external effects from lifestyle. The middle ribs are a common site used for histologic aging in forensic anthropology.^{4,5} Murine models (mice and rats) require cortical bone remodeling to be induced. As such, rabbits were chosen as a model organism since they are the smallest, commonly used laboratory animal with spontaneous cortical bone remodeling similar to humans. This experiment sought to determine if: (1) opioid use causes changes in bone geometry of non-weight-bearing bones; and (2) biomechanical properties (e.g., peak stress, elastic modulus) of opioid groups are lower compared to controls examined via compression testing.

Rabbits were divided into three groups (fentanyl, morphine, and control). Differences in drug administration required the controls to be split into two groups. Following eight weeks of morphine/saline injections or transdermal delivery of fentanyl/sham patch, animals were euthanized. Right fifth ribs were excised from each animal and cleaned of soft tissue and the ventral portions were sectioned into thirds for testing. Each sample was tested until failure using an Instron® 5567 universal test frame housed at Akron Polymer Training Services using a 1kN load cell and a compression rate of 0.05mm/min. Data were normalized by cortical area and sample length of the rib section, respectively, to produce stress-strain curves and analyzed using MATLAB® (R2021a, Mathworks). Gross rib measurements were collected before sectioning and compared using the BoneJ plugin in FIJI.^{6,7} Statistical analyses were completed using a one-way Analysis of Variance (ANOVA) using drug treatment as a fixed factor in SPSS (v.26, IBM®).

Preliminary results indicated that drug group animals were not significantly different from controls in either the gross geometric or biomechanical properties tested. Due to differing drug administration routes and splitting of the control group to accommodate this, the sample size was uneven, which may have contributed to a lack of statistical power. Additional statistical analyses are planned to account for individual differences between animals. Certain animals in this study further adapted their behavior to compensate for physiological changes caused by opioid administration (e.g., lethargy), which may have limited observed differences between groups.

Per research, this work demonstrates the first experimental method of assessing fracture risk from opioid use in non-weight-bearing bones. Future work may apply this method to forensic samples to determine what role, if any, opioids played in fracture risk.

Certain work included here is supported by the National Institute of Justice (Award 2018-DU-BX-0188). The opinions, findings, and conclusions expressed are those of the authors and do not necessarily reflect those of the Department of Justice.

Skeletal Biology, Biomechanics, Opioid Use

A17 Understanding Skeletal and Body Donation in Forensic Anthropology: Developments and Procedures

Kerianne Armelli, MS, Kent State University, Kent, OH; Rhian Dunn, MS, Michigan State University, East Lansing, MI; Carolyn Isaac, PhD, Michigan State University, East Lansing, MI

Learning Overview: The results of this presentation will reflect and compare the current practices of skeletal and body donation within forensic anthropology for attendees, both in the United States and worldwide.

Impact Statement: This presentation will impact the forensic science community by initiating discussions about the practice of body donation in forensic anthropology and guidelines the discipline wants to establish for developing and maintaining skeletal collections for teaching and research.

Donation programs have been an indispensable component of medical education, where human anatomy has benefited from dissection and laboratory coursework.¹ In recent years, donation programs have also become an integral component within anthropology programs, where skeletal donations are an important tool for study and research.^{2,3} Yet the manner in which skeletal materials are obtained and maintained varies between programs. Currently no protocols have been established regarding the management and curation of a donor skeletal collection within forensic anthropology.

The purpose of this research is to document and compare current practices and opinions regarding the development and maintenance of body donation programs and skeletal collections in forensic anthropology. Two anonymous surveys were electronically distributed to the forensic anthropology community. The first survey focused on practitioner's opinions of body donation within forensic anthropology and the second survey explored current practices in body donation.

There were 111 participants, including individuals from Asia (1.2%), Europe (4.9%), and Africa (1.2%), although the majority were from North America (92.7%) with most employed within a university setting (79.3%). It was found that skeletal collections are most commonly used to teach undergraduates (59.3%), followed by masters and doctoral students (48.1% and 43.2%, respectively). Respondents indicated that skeletal casts (63%) and purchased human skeletal materials (50.6%) were most commonly used.

Almost all of the survey respondents (95.1%) agreed with the use of donated materials for teaching and research, but agreement was less for the use of historic (48.8%), unclaimed (38.3%), or unidentified (32.9%) individuals, and only 26.8% thought that unprovenanced archaeological remains should be used. The majority of respondents (89%) were also in favor of accepting donations by next-of-kin, but fewer respondents agreed with the acceptance of donations from private citizens (59.8%), medical examiners/coroners (46.9%), or skeletal material found on private property (24.7%). Utilizing donors in trauma or taphonomic research was acceptable to 70.4% and 90.2% of participants, respectively, and the vast majority (89% for trauma and 82.7% for taphonomy) thought explicit approval should be sought for such research.

While investigating current body donation practices in forensic anthropology, it was found that only 37% accepted donations from medical examiner/coroners and only 17.9% accepted unclaimed individuals. Responses regarding donation restrictions cite health status as the most common reason for donation rejection. Respondents indicate that donors are used in taphonomy (40%), trauma (32%), other transformative (36%) research, and to create or expand fragmentary skeletal collections (12%).

A18 Modeling Grave Depressions Using Open-Source Light Detection And Ranging (LiDAR) Data at the Forensic Anthropology Research Facility

Mariah Moe, MA, Texas State University, San Marcos, TX; Shelby Garza, MA, Texas State University, San Marcos, TX; Nicholas Herrmann, PhD, Texas State University, San Marcos, TX*

Learning Overview: After attending this presentation, attendees will have a better understanding of the utility of open-source Light Detection And Ranging (LiDAR) data for the detection of ground surface depressions consistent with single or mass graves and how hydrologic modeling techniques can be used in conjunction with mapping software to model these depressions.

Impact Statement: This presentation will impact the forensic science community by presenting an alternative method for grave detection that can be accomplished using free, open-source data.

The Forensic Anthropology Research Facility (FARF), located in Hays County, TX, is used for a variety of research projects through the Forensic Anthropology Center at Texas State's (FACTS) willied body donation program. This includes the burial of remains in single and mass graves, which provide the opportunity to investigate whether the ground surface depressions associated with these inhumations can be adequately and consistently detected using free, aerial-based LiDAR remote sensing data offered through the Texas Natural Resources Information System (TNRIS). No systematic evaluation of grave detection using aerial-based LiDAR at FARF has been conducted, yet recent studies have demonstrated moderate success in the detection of single and mass graves using terrestrial-based equipment.¹

This study analyzed TNRIS LiDAR point cloud data at a 50cm resolution from 2017 to examine whether elevation changes consistent with known burials at FARF could be effectively detected using ground points parsed from the large datasets.² Geographic Information Systems software (ArcGIS Pro) and the LASTools package were used to generate topographic and slope maps. Additionally, digital elevation models were created to identify burial depressions.

An adaptation of hydrologic modeling techniques was employed in which digital elevation models typically used for watershed analysis and floodplain management were investigated for the presence of "sinks" (areas of low elevation for which all surrounding data cells represent higher elevation values). These areas of low elevation were noted to be consistent with the location of several known burials, including multiple single and one mass grave located at the facility.

The final model readily identified ground surface anomalies associated with large depressions resulting from long-term burials. This included depressions that contained human remains and ones in which the remains had previously been excavated, but the surface depression persisted. This study demonstrates the potential for open source LiDAR data to provide enough resolution to identify both single and mass graves. Additionally, these data have the potential to help direct on-the-ground investigative efforts in the search for clandestine burials. As more remote sensing data are collected and disseminated, future studies can evaluate the temporal and topographical changes associated with these additional datasets and whether smaller and/or more shallow inhumations can consistently be detected.

A20 A Robust Methodology for Stable Isotope Analysis of Human Tooth Enamel

Francesca Spencer, BS, BA, University of Utah, Salt Lake City, UT; Kirsten Verostick, PhD, University of Utah, Salt Lake City, UT; Alejandro Serna, PhD, University of Utah, Salt Lake City, UT; Lesley Chesson, MS, DPAA Laboratory, Joint Base Pearl Harbor-Hickam, HI; Gregory Berg, PhD, DPAA Laboratory, Joint Base Pearl Harbor-Hickam, HI; Gabriel Bowen PhD, University of Utah, Salt Lake City, UT

Learning Overview: After attending this presentation, attendees will have an improved understanding of how standardized sample preparation protocols can improve the comparability of stable isotope data produced in different laboratories and support more robust interpretations of stable isotopic data in human provenance investigations.

Impact Statement: This presentation will identify the most critical considerations for developing a robust, standardized methodology for the Stable Isotope Analysis (SIA) of human tooth enamel, which, if adopted, will support generations of data that can be replicated and is comparative across laboratories.

Traditional forensic analyses such as DNA and fingerprinting are often limited in the identification of human remains due to sample loss, contamination over time, and ability to locate reference samples. In the past three decades, SIA has become increasingly important in determining region of origin and life histories from unidentified remains. Forensic scientists and anthropologists have been guided by SIA in various cases, resulting in positive identifications.

Tooth enamel is a useful tissue when analyzing stable isotopes because its oxygen isotope ratios are resistant to change after the enamel has developed. It has been established that there is a relationship between the oxygen isotopes of enamel and those of water from the enamel's region of origin, providing a basis for inferring an individual's region of origin based on tooth enamel oxygen isotopes.¹ However, laboratories conducting isotope analyses for forensic purposes have not established a uniform methodology, leading to large interpretable differences and potential biases that limit comparison of results and interpretations between laboratories.²

This study builds on a history of methodological research on archeological samples and presents a series of experiments designed to test and quantify the effects of different sample preparation and analysis methodologies on the measured isotopic composition of modern human tooth enamel.³ The experiments included treatments comparing different tooth enamel sample particle sizes, storage conditions during pretreatment and prior to Isotope Ratio Mass Spectroscopy (IRMS) analysis, organic contaminant removal treatments, and mass spectrometric analysis conditions. These experiments used relatively large sample sets and replicate analyses to support quantification of effect sizes.

Preliminary results from these experiments showed that the reproducibility of oxygen isotope measurements improved from 0.17‰ to 0.09‰ (1 standard deviation) if samples were ground to a fine and uniform particle size (125µm), likely due to improved homogenization of the samples. They also demonstrated a small (0.18‰) but significant offset ($p < 0.1$) between the measured oxygen isotopic composition of fine- and coarse-grained samples. In the same experiment, the Carbon Dioxide (CO₂) yield from the fine-grained samples was 28% higher than that for the coarse-grained samples. This is attributed to the observed isotopic effect to particle-size-dependent differences in reaction efficiency during mass spectrometric analysis. In contrast, the data show no detectible impact of variations in sample storage conditions (exposed to the ambient environment or stored in a desiccator). This suggests that oxygen exchange between atmospheric water vapor and enamel does not affect the isotopic values, even for finely ground samples.

The results of these experiments suggest “best practices” that can easily be adopted in SIA tooth enamel protocols to improve data comparability in inter- and intra-laboratory settings. In addition, they highlight methodological variables that have little impact on SIA results and need not be standardized. These methodological guidelines should help establish a firm methodological basis for building high-quality tooth enamel SIA reference databases and thus increase the applicability of SIA in forensic science for use in human identification efforts.

A21 Repatriation and Responsibility: Consideration Beyond Traditional Constructs

Rose Leach, MA, Kent State University, Kent, OH; Kerianne Armelli, MS, Kent State University, Kent, Ohio, USA*

Learning Overview: Attendees can expect a comprehensive overview of repatriation practices, emphasizing the need to critically reexamine current collections housed at museums and universities beyond just the demands of the Native American Graves Protection and Repatriation Act (NAGPRA). Attendees will also learn about the multiple ethically sourced osteological collections they can utilize for current and future research, with particular consideration for digital databases.

Impact Statement: This presentation strives to bring continued awareness to the issues in repatriation by highlighting not only problems within the context of NAGPRA, but also providing additional insight into ethical considerations of skeletal remains and collections. This discussion will also provide resources on modern, ethically built collections that can be utilized for current and future research.

While forensic anthropology has recently begun to recognize a need for a culturally sensitive approach to training and research, many institutions actively make use of unrepatriated remains of Native Americans and individuals whose use within education and research today is ethically questionable (e.g., compared to individuals and groups whose skeletal donation was given explicit self- or next-of-kin consent). While there is a known responsibility to notify and return Native American remains through NAGPRA, these collections often continue to be used in educational settings. Due to the complex nature of relationships between faculty and trainees, along with the political and legal issues that accompany careers in the Academy, enacting change that leads to repatriation can be extraordinarily difficult.

The continued use of Native Americans and individuals whose acquisition was ethically questionable, or whose tribal affiliation warrants further investigation within collections in anthropology, has been argued as a necessity, citing limited resources for research and teaching as reason.¹ While the use of these collections can continue with explicit permission and communication with the ancestral communities of the descendants, the problem arises in the refusal to begin the process of seeking permission. Additionally, non-Native remains that may have been collected through unethical means, by current standards, are often overlooked, with many failing to question the ethics behind their acquisition. The use of historic and prehistoric samples in the development of forensic methods has been proven to be counterproductive, as current needs within the field require these methods to be modified for modern populations.²

This presentation seeks to bring awareness to the field regarding the active oversight of forensic anthropologists in the repatriation of Native American and other non-ethically sourced individuals/groups. With the advent of digital collections as well as physical ones comprised of modern individuals, it is clear that there are viable alternatives for research that can be utilized. Collections such as the William M. Bass, the New Mexico Decedent Image Database, and The Skeletal Series at Western Michigan University have developed collections consisting of consenting individual donors or next-of-kin donations, showing this can be done.

It is in the benefit of practicing forensic anthropologists to hold each other and their institutions accountable in the use of these collections and work toward more ethically sourced donations. This presentation will highlight the issues within modern anthropological skeletal collections and the resources and path forward to decolonizing collections.

Repatriation, Decolonization, Skeletal Collection Management

A22 Morphometric Comparison of Eight Small Non-Human Species of Long Bones to Juvenile Human Long Bones for the Purpose of Identification in a Forensic Context

Kaitlyn Schoonover, BS, Mercyhurst University, Erie, PA; Luis Cabo MS, Mercyhurst University, Erie, PA*

Learning Overview: Attendees to this presentation will gain a better understanding of the importance of non-human osteology in forensic contexts, as an essential tool to assess the forensic significance of skeletal remains based on human versus non-human determinations, particularly in scenarios involving potential adolescent remains.

Impact Statement: Human versus non-human determinations represent a significant portion of a forensic anthropologist's workload. Quick assessments of forensic significance based on this factor prevent significant waste of time and resources. Determinations based on positive species identification are much more robust and reliable, and less susceptible to error than those based simply on excluding human origin. In the training of forensic anthropologists, stress is often placed mainly on the identification of large species of mammals, in the body size range of human adults. However, the remains of small mammals can also be confused with those of subadults; with the added complication of small-sized species being more abundant and diverse in non-human communities.

While the identification of elements from immature vertebrates requires more thorough examinations and a stronger osteology background, the remains of adult small vertebrates are also often mistaken for potential human bones as a result of the common misconception among the public that bones of infants and juveniles are just smaller versions of fully developed adult bones. Any system that could be used to streamline those identifications at the initial stages of the investigation would significantly reduce the waste of investigative time and resources.

However, there are few studies using morphometrics specifically to compare human and non-human bones, let alone any studies using juvenile human bones in comparison to various small mammal species. A 2016 study tried to determine whether bone morphometry analyses on long bones would be robust enough for this purpose, obtaining promising results.¹ Nonetheless, those authors utilized ratio transformations in their analyses, a strategy that has been proven to be ineffective and highly problematic in morphometry.²

A pilot study is presented here illustrating two alternative strategies to streamline the identification of small vertebrate elements that are frequently mistaken as potential infant human remains. One strategy utilizes morphometric analysis, with the second being the classic dichotomous key structure.

Although mammals, along with other vertebrates, have homologous skeletal structures, their function and biomechanics varies across taxonomic groups, leading to easily interpreted morphological differences between taxa; for example, the differences in the use of arms/forelimbs in bipedal (grasping or flying) versus quadrupedal animals (walking and/or running). This difference in biomechanical function leads to differing structure morphologies that can often be observed as easily recognizable discriminant traits.³ Dichotomous keys based on the visual assessment of these traits are widely utilized in zoology to identify species based on these traits.

However, morphology also changes with age, with skeletal elements of immature individuals being more similar across species than their adult counterparts. The morphometric approach has the advantage of detecting and encapsulating not only size and raw shape differences, but also allometry. This allows us to extend the results to a wider range of ages and body sizes and ages, by factoring in allometric patterns in addition to anatomical differences related to function and biomechanics. The biometric model is intended to take advantage of this factor, also presenting some advantages for easier automation through software applications.

The study sample was obtained from the Mercyhurst University zooarchaeological comparative collection. A set of small vertebrate species was selected based on their high frequency in North American environments, as well as on their potential to be mistaken for human infants or fetuses based on their body size. Skeletal elements were 3D scanned with an Artec Space Spider. Scans were also utilized to create dichotomous keys. All statistical analyses were carried out using GraphPad Prism 9.2.0. It was determined that lower limb elements are better than the upper limb when measuring morphometric differences between non-human and fetal human bones, with the femur showing the most robust results. Although this is only a preliminary study, the statistical data show that there are significant differences between non-human and juvenile human bones, depending on the bone and features analyzed.

Forensic Anthropology, Zooarchaeology, Morphometrics

A23 A Spatiotemporal Analysis of the National Missing and Unidentified Persons System (NamUs) Unidentified Person Cases along the United States-Mexico Border

Justin Z. Goldstein, MA*, Texas State University, San Marcos, TX; Courtney Siegert, MA, Texas State University, San Marcos, TX; Nicholas Herrmann, PhD, Texas State University, San Marcos, TX

Learning Overview: After attending this presentation, attendees will have a greater understanding of the spatial distribution of National Missing and Unidentified Persons System (NamUs) Unidentified Person (UP) cases along the United States-Mexico Border and how these cases relate to deaths reported by the Border Patrol.

Impact Statement: This presentation will impact the forensic science community by providing important context for understanding changes in reported deaths across the United States-Mexico Border over time.

Unidentified human remains present a significant challenge for forensic practitioners in the United States, particularly given its decentralized medicolegal framework.¹ Identification efforts on the United States national scale must navigate the various protocols, financial resources, and organizational barriers that are unique to each state and/or county. NamUs acts as a powerful tool for connecting forensic professionals and investigating agencies across the United States, although engagement across the nation remains inconsistent.^{2,3} However, along the United States-Mexico border, where thousands of migrants are apprehended or found deceased, NamUs has played a crucial role in identification efforts.^{4,5} Thus, understanding the relationships between NamUs UP cases and Border Patrol statistics may provide important insights into the factors that have contributed to death along the border over time. This study sought to explore these relationships, asking: (1) can NamUs UP cases, apprehensions at the border, and Border Patrol staffing be used to accurately predict reported deaths across Border Patrol sectors, and (2) do the relationships between these variables change over time?

NamUs UP cases from Arizona, California, Nevada, New Mexico, Oklahoma, and Texas ($n=6,857$) were exported from NamUs 2.0 and geocoded in ArcGIS® Pro 2.8 to county shapefiles obtained from the United States Census Bureau.^{6,7} Border Patrol sector reports on staffing, apprehensions, and deaths were obtained from United States Customs and Border Protections.⁸ In ArcGIS®, Border Patrol sector statistics and NamUs UP cases were joined to Border Patrol sector shapefiles, which were generated using publicly available jurisdictional data.⁹ In each sector, UP Cases and Border Patrol statistics were summarized for three approximately equal time periods: 1998-2006, 2007-2013, and 2014-2019. Ordinary Least Squares (OLS) regressions were performed in ArcGIS® Pro for each time period, with reported deaths as the dependent variable. In addition, Border Patrol apprehensions per sector by migrant region of origin were summarized by year to contextualize regression results over time.

OLS regression models indicate no consistent predictors for reported deaths over time. The lack of significance between NamUs UP cases and reported deaths is likely due not only to the inconsistent application of NamUs across Border Patrol sectors, but also to the unknown number of previously identified cases that are no longer listed in NamUs 2.0. Moreover, Global Positioning System (GPS) location data for NamUs cases is inconsistently collected, impacting the precision of spatial analyses. Removing NamUs UP cases from OLS regression models shows a more consistent relationship between border apprehensions and reported deaths ($p < 0.01$). Additionally, adjusted R-squared values decreased from 0.82 to 0.57 between the 2007-2013 and 2014-2019 models. Considering that Texas surpassed Arizona in migrant deaths in 2012, lower model performance may reflect changing migration trajectories and demographics, the decentralized medicolegal system, and the difficulties recovery contexts encountered in Texas.⁵

Although NamUs UPs are not strong predictors of reported deaths along the United States-Mexico border, data here likely represents an incomplete account. Including higher-resolution NamUs data, particularly GPS location and data from previously resolved cases, may improve model precision.

A24 Developing a Tissue-Specific Multi-Isoscape ($\delta^{18}\text{O}$ and $^{87}\text{Sr}/^{86}\text{Sr}$) to Estimate Region of Origin

Julianne Sarancha, MS*, Arizona State University, Tempe, AZ; Alexis Baide, MA, University of Utah, Salt Lake City, UT; Clare Dittmore, BA, Montana State University, Bozeman, MT; Thomas Delgado, BA, California State University-Chico, Chico, CA; Gabriel Bowen, PhD, University of Utah, Salt Lake City, UT

Learning Overview: After attending this presentation, attendees will understand the utility of creating multi-isotope tissue-specific isoscapes to estimate region of origin via Stable Isotope Analysis (SIA).

Impact Statement: This presentation will impact the community by describing a novel method of combining isotope systems in the creation of tissue-specific isoscapes for region of origin estimation to increase the accuracy of stable isotope analytical methods.

Forensic applications of SIA have shown this method's utility to aid in the identification of unknown remains. As its use becomes more widespread, methods to improve the ability of isotopic analysis to provide geographic history of unidentified human remains are essential. Currently, many forensic applications of SIA rely on the comparison of isotopic values from human tissues (i.e., bone, teeth, or hair) to predicted environmental isotopic values derived by modeling precipitation, tap water, and/or bedrock maps for particular regions, commonly referred to as isoscapes.¹⁻³ While this has shown to be a useful comparison, it cannot be assumed that environmental isotopic values are equivalent to the isotopic signatures preserved in the human body because this method fails to account for tissue-specific metabolic processes which may cause isotopic fractionation. To remedy this assumption, it is recommended that environmental isoscapes are calibrated with human tissues using known matrix-matched samples.

To assess the efficacy of a human tissue-specific isoscapes, this study developed a multi-isotope model of $d^{18}\text{O}$ and $^{87}\text{Sr}/^{86}\text{Sr}$ from hair as a function of tap water to infer the region of origin for individuals. For $^{87}\text{Sr}/^{86}\text{Sr}$, a linear regression was generated using data from Ammer et al. that consists of hair and associated tap water samples collected in Mexico.⁴ The linear regression was used to calibrate an environmental $^{87}\text{Sr}/^{86}\text{Sr}$ isoscape of the United States. A $d^{18}\text{O}$ isoscape was constructed using hair data from Ehrlinger et al. and existing tap water isoscapes for the United States.⁵ The $d^{18}\text{O}$ and $^{87}\text{Sr}/^{86}\text{Sr}$ isoscapes were then stacked to provide a multi-isotope model. All modeling, mapping, and statistical analyses were conducted in R version 3.6.2 using the ASSIGNR package.⁶

To test the accuracy of the multi-isotope model, $d^{18}\text{O}$ and $^{87}\text{Sr}/^{86}\text{Sr}$ of hair samples with known region of origin (obtained from Tipple et al.) were evaluated.⁷ The model provided estimates that included the correct region of origin for 91% of the known samples tested.

The high accuracy of the multi-isoscape model highlights the utility of multi-isotope tissue-specific models in forensic applications. Despite this high accuracy, considerations to ensure consistent data reference scales and the ways in which local $^{87}\text{Sr}/^{86}\text{Sr}$ values may contaminate a sample in question must be taken into account. This study serves as an initial multi-isotope model for human hair and may serve as an example for the development of additional models.

Stable Isotope Analysis, Multi-Isotope Model, Hair Isoscape

A25 Last Seen Location: Using Missing Persons Data for Identification in Forensic Anthropology.

Liam Johnson, MA, University of Nevada-Las Vegas, Las Vegas, NV; Teresa Wilson, PhD, Louisiana State University, Baton Rouge, LA*

Learning Overview: After attending this presentation, attendees will understand how the spatial precision of a missing person's last-seen location relates to their case's closure and how the value of spatial data relate to the identification of unidentified individuals.

Impact Statement: This presentation will impact the forensic science community by expanding the scope of the types of data that forensic anthropologists use as it relates to current forensic casework.

The study and practice of forensic anthropology is centered on unidentified individuals and, as practitioners, improving the field's ability to successfully assist in identification efforts. Traditional methodological practice relies on "the big four"—age, ancestry, sex, and stature—to create a biological profile. In recent years, there has been an increasing call by forensic anthropologists to expand beyond skeletal material in their analysis and interpretation of unidentified remains to include sociocultural data.¹

With the augmentation from the sociocultural data, the biocultural profile provides a more holistic understanding of an unidentified individual and may provide a more effective means to establish possible identifications. Furthermore, the inclusion of an unidentified individual's geographic recovery location has been shown to be an effective biocultural identifier in establishing a putative identification by cross-referencing missing persons cases.² However, the spatial relationship of establishing a putative identification involving recovery location is dependent on the missing person's case report and potentially the degree of knowledge of an individual's last-seen location.

To explore the relationship between an individual's last-seen location and case outcomes, this study analyzed a total of 419 open and closed missing persons reports from the Louisiana Repository for Unidentified and Missing Persons Information Program of individuals last seen in the past 64 years from 1956–2020.³ Missing persons reports were categorized by the level of spatial precision available (e.g., exact address, street, city, parish/county, or unknown). The data indicate that there is no significant relationship between the level of spatial precision and overall case closure rate. However, temporal data, when available, suggests a correlation between the level of spatial precision and average time from when the individual was last seen to their case's closure; missing person cases with spatial precision at the parish level remain open for an average of 7,650 more days than cases with an exact last-seen location. This present research shows the utility of spatial data in forensic investigative efforts and highlights the varied relationship spatial information has to unidentified persons cases in forensic anthropology.

A26 Understanding the Spatial Relationships Between NamUs Unidentified and Missing Persons Cases in Texas

Shelby L. Garza, MA, Forensic Anthropology Center, Texas State University, San Marcos, TX; Justin Z. Goldstein, MA, Forensic Anthropology Center, Texas State University, San Marcos, TX*

Learning Overview: After attending this presentation, attendees will have a better understanding of the spatial relationship between National Missing and Unidentified Persons System (NamUs) Unidentified Persons (UP) and Missing Persons (MP) cases in Texas.

Impact on the Forensic Science Community: This presentation will impact the forensic science community by contextualizing spatial trends in NamUs cases in relation to the demographic variation in Texas.

Existing literature has contextualized unidentified human remains and MP as vulnerable populations, subject to larger systems of structural violence in the United States.¹ According to NamUs, as of August 2021, there are 1,651 MP and 1,737 UP in the state of Texas.² However, given that the medicolegal systems in Texas are decentralized across 254 counties, it is likely that MP and UP cases have differential access to investigative resources.

The purpose of this study is to explore the similarities and differences between NamUs UP, NamUs MP, and county demographics to answer the following questions: (1) is there non-random spatial distribution in the NamUs UP and MP cases in Texas, and (2) if the spatial relationships are non-random, are there similar spatial patterns in county demographics?

Data were collected on population, self-reported race, self-reported ethnicity, average income, and poverty rate for each county in Texas from the United States Census 2019 ACS 5-Year Survey.³ MP and UP data were collected from NamUs on August 28, 2021. Maps were generated to visually represent the UP, MP, and county demographic data in ArcGIS® Pro using the symbology feature. Global Moran's I spatial autocorrelations were run to test for non-random spatial distributions of MP cases, UP cases, and county demographics.

The results of the Global Moran's I spatial autocorrelation test showed that significant clustering is occurring with the distribution of MP by population ($p < 0.01$; $z = 7.66$), UP by population ($p < 0.01$; $z = 7.50$), Hispanic individuals by population ($p < 0.01$; $z = 23.61$), and Black individuals by population ($p < 0.01$; $z = 19.37$). Furthermore, the clustering pattern reveals that the areas with the higher number of UP and MP cases are also the areas with the highest number of Hispanic and Black individuals by population.

These results show that, when standardized by population size, there is a statistically significant correlation between the distribution of Black and Hispanic individuals in Texas and the distribution of unidentified and missing persons in Texas. Collectively, these results may speak to the impacts of structural violence on socially marginalized communities, defined here as avoidable limitations placed on groups of people by society that prevents them from achieving an otherwise attainable quality of life.⁴ This project serves as an important step in understanding how structural violence can impact individuals both during life and death.

Forensic Anthropology, Spatial Analyses, Structural Violence

A27 Initial Review of the Long-Term Unidentified Cases Managed by the Forensic Anthropology Center at Texas State University

Emilie L. Wiedenmeyer, MA*, Texas State University, San Marcos, TX; Justin Z. Goldstein, MA, Texas State University, San Marcos, TX; Petra Banks, MA, Texas State University, San Marcos, TX; Mariah Moe, MA, Texas State University, San Marcos, TX; Sophia Mavroudas, MA, Texas State University, San Marcos, TX; Michelle D. Hamilton, PhD, Texas State University, San Marcos, TX

Learning Overview: After attending this presentation, attendees will have a greater understanding of the contextual and demographic information currently available for long-term unidentified cases at the Forensic Anthropology Center at Texas State University (FACTS).

Impact Statement: This presentation will impact the forensic science community by presenting data on a representative group of forensic cases managed by FACTS to highlight common discrepancies in long-term unidentified casework at academic institutions.

When medicolegal agencies and jurisdictional authorities request forensic anthropological consultation on unidentified human remains, forensic anthropologists in academic institutional settings are often responsible for the continued curation of unidentified human remains after analysis is complete.¹ Unidentified human remains represent a marginalized group of individuals in the global humanitarian crisis of the missing and unidentified, and academic institutions face challenges in balancing both consultation and stewardship when managing such vulnerable individuals.² For cases that remain unidentified after traditional forensic methods are applied and reported, the challenges become multifold as long-term storage inherently requires casework reassessment, further procedural standardization, and additional detailed recordkeeping over time.

The Identification & Repatriation Initiative (IRI) was created at the FACTS in 2021 to standardize the inventory of and re-engage identification efforts for all unidentified individuals retained in long-term storage at FACTS, particularly for cases analyzed prior to the formation of FACTS in 2008. Dates of discovery for these individuals span from the 1960s to the present. This presentation summarizes the IRI's initial findings, focusing on the availability of associated contextual data and the completeness of forensic analyses already conducted. The IRI also surveyed the demographic breakdown of long-term unidentified cases in order to better understand the communities represented by these individuals.

The IRI reviewed all existing cases and associated documents and found that 95% of the total cases required additional analysis or reanalysis. Of these, 80% were deemed to be modern and therefore medicolegally significant. Cases that demonstrated evidence of identification attempts beyond submission of the biological profile included: (1) bone samples apparently removed for DNA submission (24%); (2) documentation of submission of bone samples for DNA profiling by the University of North Texas Center for Human Identification (16%); and (3) entry into the National Missing and Unidentified Persons System (NamUs) (11%). Perhaps most notable, only 32% of all forensically relevant cases had an associated and completed forensic anthropological report. Of those with estimated age, sex, and population affinity information recorded, the majority were estimated as male (62%), between the ages of 15–50 (82%), and of Hispanic (33%), American White (30%), or American Black (4%) affinity, with the rest being of unknown or undetermined affinity. These initial estimations, paired with the associated reports of discovery from counties along the United States-Mexico border, suggest many of these individuals may have suffered from broader vectors of structural inequality and vulnerability during life.³ Moreover, as they remain unidentified throughout the years, those lived experiences are reflected in their marginalization in death.⁴

Although the problems that the IRI encountered when reassessing the institutional holdings of the unidentified dead were significant, the IRI is working toward new directions in identification for these individuals. The IRI is hopeful that reporting this general information on the unsolved forensic cases currently housed at FACTS will promote conversation between academic institutions regarding the stewardship, management, and solvability of long-term unidentified cases. By highlighting these discrepancies and contextualizing these decedents as embedded in larger systems of structural violence and vulnerability, this presentation encourages a collective discussion of potential solutions for identification barriers and institutional challenges.

A28 Stature Estimation From Facial Parameters—A Computed Tomography (CT) Scan-Based Observational Study in a South Indian Adult Population

Siddhartha Das, MD, Forensic Medicine & Toxicology, Jawaharlal Institute of Postgraduate Medical Education and Research, Puducherry INDIA*

Learning Overview: After attending this presentation, attendees will be able to appreciate the role of CT measurements of facial parameters for estimating the stature in a south Indian population.

Impact Statement: This presentation will impact the forensic science community by shedding light on the importance of CT measurements of facial parameters for estimating the stature in a south Indian population.

Background: Establishing the identity of a deceased individual is vital in forensic casework. Stature estimation helps in partial identification of the individual and is determined by anatomical or mathematical methods. The anatomical method is applied when the entire skeleton is available for examination; however, in many cases, mutilated or dismembered bodies are found and only the mathematical method can be applied. In some cases, only the cranium may be available for forensic evaluation. Researchers who have evaluated stature from the cranium have used mostly living individuals or the dry bone.¹⁻³ In recent years, CT measurements of the cranium have been used for estimating stature. The objective of this study was to estimate stature from CT scan measurements of facial parameters in a south Indian adult population.

Methods: A total of 330 males and 181 females, ranging in age from 21-60 years, scheduled for elective CT of the head and neck were recruited for the study. The patient's height was measured before obtaining the CT scan. Bizygomatic Breadth (BZB), Minimum Frontal Breadth (MnFB), Nasal Breadth (NB), Nasal Height (NH), Orbital Breadth (OB), Biorbital Breadth (BB), Interorbital Breadth (IOB), Orbital Height (OH), and Upper Facial Height (UFH) parameters were measured from reconstructed CT images. Univariate and multivariate linear regression was performed to establish a predictive stature estimation model using these parameters for a south Indian population.

Results: The mean stature for males was 167±6.03cm and 157.40±6.33cm for females. All the studied parameters showed statistically significant positive correlation with stature. Multiple linear regression analysis using backward elimination containing all the independent predictors revealed a statistically significant model, with a r^2 value of 0.17. There was no violation in model assumptions, such as linearity, constant variance, or residual distribution. Multicollinearity was ruled out using the variance inflation factor. When correlation was studied individually in the female and male sample, only NH ($p=0.02$), OBL ($p=0.003$), OHR ($p=0.03$) in the female sample and BZB ($p<0.001$) NH ($p<0.001$) and UFH (<0.001) in the male sample demonstrated a statistically significant positive correlation with stature. The multivariate linear regression predictive model using backward elimination of all independent variables yielded a statistically significant model with an r^2 value of 0.104 with predictors BZB, NH, and LOH for males and an r^2 value of 0.06 with predictors NH and LOB for females.

Conclusion: This CT-based observational study demonstrated that anterior facial parameters are positively correlated with stature, but the predictive accuracy for estimating stature in a south Indian adult population is low.

Stature Estimation, Facial Parameters, South Indian Population

A29 OsteoFlo: A FIJI/ImageJ Toolkit for Semi-Automated Identification and Characterization of Fluorescently Labeled Secondary Osteons

Mary Cole, PhD*, Skeletal Biology Research Lab, Injury Biomechanics Research Center, The Ohio State University, Columbus, OH; Joshua Taylor, BSc, Memorial University of Newfoundland, St. John's, Newfoundland, Canada; Medhat Hassan, Memorial University of Newfoundland, St. John's, Newfoundland, Canada; Janna Andronowski PhD, Faculty of Medicine, Memorial University of Newfoundland, St. John's, Newfoundland, Canada

Learning Overview: The goal of this presentation is to introduce an open source FIJI/ImageJ (NIH) toolkit for morphometric analysis of vascular pores and secondary osteons on histological images of cortical bone tissue.

Impact Statement: This presentation will impact the forensic science community by introducing novel software that significantly expedites histomorphometric analysis using automation. Vascular pores and secondary osteons are typically manually identified on microscopic images, with forensic application of their morphometry to assess histological age-at-death, remodeling activity, and bone tissue quality.

The developmental dataset was femora of New Zealand White rabbits, who were subcutaneously injected with a bone-labeling fluorochrome, calcein, at three timepoints over eight weeks. This toolkit identifies vascular pores on Differential Interference Contrast (DIC) microscopic images, stemming from previous work on brightfield images.¹ Secondary osteons formed during this period are calcein-labeled, as visualized with fluorescent microscopic images. Toolkit macros are fully automated unless denoted with an (M).

Toolkit Macros for Pore Analysis on DIC Images:

Pre-Processing: The DIC image is evenly illuminated through application of a high pass filter, contrast enhancement, and background subtraction.

Pore Extractor: Probable pore Regions Of Interest (ROIs) are extracted from the DIC image using an Intermodes auto-threshold, particle size and circularity thresholding, and binary closing.

Pore Modifier (M): Pore ROIs are manually edited using custom keyboard shortcuts, including auto-saving.

Pore Analyzer: Pore ROIs are classified as cortical or trabecularized based on proximity to the marrow cavity versus minimum diameter.² Pores are also regionally subdivided between anatomical quadrants (long bones) or cutaneous and pleural halves (ribs), calculated using the centroid and major axis.³ Summary pore morphometry is calculated for each pore type within each region, including percent porosity, pore density, and mean pore size and shape descriptors.

Toolkit Macros for Osteon Analysis on Fluorescent Images:

Osteon Extraction: Probable osteon border ROIs are extracted using local contrast enhancement, histogram equalization, an Intermodes auto-threshold, and binary opening. Fluorescent rings within osteons representing calcein labels are extracted as a binary image using background subtraction and an auto local Phansalkar threshold.

Osteon Border Correction (M): Osteon border ROIs are manually edited using custom keyboard shortcuts, including osteon splitting and expansion.

Osteon Type: Osteon border ROIs are regionally assigned as in Pore Analyzer. An ellipse is fitted over each ROI, and its major axis is superimposed on the binary image of its calcein labels. An intensity profile along this major axis displays peaks that correspond to the number and spacing of calcein label intersection. This intensity profile is used to guess Osteon type (forming, single, double, or triple labeled), Mineral Apposition Rate (On.Mar), which is the distance between two consecutive calcein labels, and osteon Wall Thickness (W.Th), which is the distance from the pore centroid to the osteon border.⁴

Osteon Type Correction (M): Osteon border ROIs are colored by guessed osteon type, and coordinates for guessed On.Mar spacing and W.Th pore centroids are superimposed as overlays. Custom keyboard shortcuts quickly change osteon type and re-locate coordinates for On.Mar and W.Th. Summary morphometry is automatically calculated for each region, including osteon type counts, corrected On.Mar and W.Th, and mean size and shape descriptors.

Mineralizing Surface Per Bone Surface: The ratio of labeled to unlabeled bone on the periosteal (Ps.MS/BS) and endosteal (Es.MS/BS) surfaces is calculated as the number of white pixels intersected by the bone surface perimeter.⁴

Resorption Cavities (M): Probable unlabeled resorption cavities are identified as pore ROIs that do not intersect with osteon borders and fall above the lowest histogram bin value for pore size. Users can manually change this classification.

Image processing automation improves user consistency while significantly reducing time investment for histomorphometric analysis.

A30 A Multi-Isotopic Analysis of Ajnala Skeletal Remains for Provenance of Their Local or Non-Local Origin, Geographic Affinity, and Mobility Patterns

Jagmahender Singh Sehrawat*, Panjab University, Chandigarh, Chandigarh, India

Learning Overview: After attending this presentation, attendees will get sensitized about the importance of stable isotope analyses in provenance of unknown human remains recovered from forensic anthropological contexts.

Impact Statement: This presentation will impact the forensic science community by informing attendees that the chemical markers of identity imprinted in human teeth and bones as stable isotopes can help in identification of origin, geographical affinity, and movement history (if any) of the badly damaged and commingled human osseous remains

The technique of stable isotope analysis is still underutilized in modern forensic casework, probably due to its novelty, ongoing research, additional expenses involved, the unavailability of databases for different geographic regions of the world, and, lastly, the expertise of the investigator. In the present study, the dentine collagen and enamel samples collected from randomly selected third mandibular molars were subjected to detailed multi-isotopic analysis ($\delta^{13}\text{C}$, $\delta^{14}\text{N}$, $\delta^{18}\text{O}$ and $^{87}\text{Sr}/^{86}\text{Sr}$) using Isotope Ratio Mass Spectrometer (IRMS) with the objective of narrowing down the potential region of origin (local or non-local to site), geographic affiliation, and mobility history of unknown human remains exhumed non-scientifically from an abandoned well at Ajnala, India. The mandibular third molars were considered for analysis to avoid duplication of individuals as the remains were commingled and badly fragmented. It was hypothesized that Ajnala individuals belonged to a specific regiment, having recruited soldiers from a particular geographic region who were non-local to the site. The standard protocols were followed for the pre-treatment of the tooth dentin and enamel samples for isotope analyses. The collagen from the vial dentine samples was extracted using Merck's Amicon® Ultra 1.5 micro-filter columns before their encapsulation was done for sending them for $\delta^{13}\text{C}$ and $\delta^{14}\text{N}$ analyses.

The $\delta^{13}\text{C}$ and $\delta^{14}\text{N}$ values ($N=21$) ranged from -18.7‰ to -22.9‰ (avg. $-20.5 \pm 1.2\text{‰}$) and $+7.6\text{‰}$ to $+11.7\text{‰}$ (avg. $+9.3 \pm 1.1\text{‰}$), respectively having C/N ratio varying from 2.8-3.6 (avg. 3.4 ± 0.2). The carbon, oxygen, and nitrogen isotope values of bones and teeth often represent the dietary as well as provincial signatures of the individuals.¹ Using Schoeninger et al., isotopic model of dietary reconstruction from $\delta^{13}\text{C}$ and $\delta^{14}\text{N}$ concentrations of collagen samples, it was found that Ajnala victims consumed mixed diets derived from both C3 and C4 resources.² Thus, the majority of the Ajnala individuals were consuming a varied diet of foods like wheat, rice, pulses, millet, maize, etc., and possibly animals foddered/grazed on C4 plants. These observations are in full agreement with the hypothesis that the human remains excavated from the site belonged to the reported regiment of a colonial army whose sepoys were killed and buried at the site following their mutiny during the 1857 rebellion.³ A particular division of the military would be expected to draw from different members of the public and would not be expected to be a uniform group of individuals.

The projected source water $\delta^{18}\text{O}$ v. VSMOW values for the majority of samples ($n=32$) varied from -5.89‰ to -9.00‰ (avg. $-7.64 \pm 0.03\text{‰}$), and these results were consistent with Orissa, West Bengal, Bihar, parts of Meghalaya, and parts of Manipur as potential regions of geographic origin.^{4,5} The higher $\delta^{18}\text{O}$ v. VSMOW values ranging between -9.31‰ and -11.40‰ (avg. $-10.29 \pm 0.13\text{‰}$) were consistent with Jharkhand as the potential region of geographic affinity of Ajnala skeletal remains, though it cannot be ruled out that these individuals came from a region or regions where riparian water fed by snow melt was the predominant source of potable water, thus suggesting the northern region of Assam along the Brahmaputra as their possible geographic affinity. The two samples having $\delta^{18}\text{O}$ v. VSMOW values as $-4.78 \pm 0.06\text{‰}$ and $5.33 \pm 0.03\text{‰}$ reflected Tripura, southern Assam, and parts of Meghalaya or Manipur as their possible place of origin.

The $^{87}\text{Sr}/^{86}\text{Sr}$ values of enamel samples ($n=47$) varied from 0.727949 to 0.715938 (with an average of 0.722463 ± 0.00030), which revealed that the less radiogenic ($^{87}\text{Sr}/^{86}\text{Sr} \sim 0.716$) values probably came from the individuals inhabiting the Ganga river basin, whereas the individuals with relatively higher $^{87}\text{Sr}/^{86}\text{Sr}$ ($^{87}\text{Sr}/^{86}\text{Sr} \sim 0.7200$) values probably resided in the Bihar and West Bengal states.^{6,7} The 87/86Sr dataset revealed that the individuals analyzed were dependent on vastly different base geologies during their adulthood (since only mandibular third molars were analyzed). These observations are also fully congruent with the isotopic characterization one can expect for an infantry division comprising of a diverse set of people from different parts of the former British India. Each data point was compared with 87/86Sr data of the reported base geologies to ascertain the range of states/provinces to which the slain sepoys of the ill-fated battalion belonged. The $^{87}\text{Sr}/^{86}\text{Sr}$ didn't support the local origin theory of Ajnala skeletal remains and attributed their affiliations to the Indian states of Uttar Pradesh, Bihar, and West Bengal.

This multi-isotopic dataset is the richest one for human skeletal remains excavated from a specific site in India and provided a scientific basis to the written accounts that Ajnala skeletal remains belonged to victims of the provinces of Awadh (northeastern Uttar Pradesh), Bengal, Bihar, and some northeastern Indian states. Thus, the results demonstrate the success of applying multidisciplinary approaches for forensic anthropological identification of unknown human remains. The detailed results will be presented in the textual, graphical, tabular, and diagrammatic forms in this presentation.

Ajnala Skeletal Remains, Multi-Isotope Analysis, Provenance

A31 The Impact of British Biometry and Race Studies on the Origins of Forensic Anthropology in the United States

Nicholas Passalacqua, PhD, Western Carolina University, Cullowhee, NC; Iris Clever, PhD, University of Chicago, Chicago, IL*

Learning Overview: After attending this presentation, attendees will have a greater understanding of the origins of modern forensic anthropology as stemming from early biometric race scientists in Britain.

Impact Statement: This presentation will impact the forensic science community by providing new insights into the early development of forensic anthropology in the United States by connecting it to novel anthropological-biometric developments in early 20th-century Britain, associated with early biometric studies of race. Specifically, it will show how T. Wingate Todd and Wilton M. Krogman adapted methods from statistician Karl Pearson and anthropologists Sir Arthur Keith and Miriam L. Tildesley, putting them to new use in the United States and laying the foundations of modern American forensic anthropology.

Traditional histories of the emergence of forensic anthropology focused on the United States are typically separated by early forensic anthropology case consultation and early forensic anthropological scholarship in the late 19th century. Early casework examples include the murders of George Parkman in 1849 and Louisa Luetgert in 1897, in which both subsequent trials involved expert testimony on skeletal remains. Early scholarly contributions began with the 1878 work of Thomas Dwight, earning him the moniker of “father of forensic anthropology” by T. Dale Stewart.

It was not until Krogman’s 1939 publication, *A Guide to the Identification of Human Skeletal Material in the Federal Bureau of Investigation (FBI) Bulletin* that the discipline of forensic anthropology began to be formalized. Interestingly, little has been written about the impetus for Krogman’s FBI Bulletin paper. This project delves into the forensic anthropology-adjacent work being performed both in the United Kingdom and the United States in the 1920s and 1930s, leading up to, and directly shaping, Krogman’s landmark 1939 publication. This interdisciplinary presentation combines historical-archival research with citation mining and demonstrates key connections between American and British actors through historical correspondence, scholarly citations, and associated discussions.

The results demonstrate that anthropologist Miriam L. Tildesley, her former professor statistician, Karl Pearson, and her then-supervisor, renowned anthropologist Sir Arthur Keith engaged in efforts to “authenticate” (i.e., identify) historic crania in the 1920s and 1930s in the United Kingdom using new anthropological-biometric methods developed by Pearson. The work of Tildesley in particular served as inspiration for similar work in the United States by T. Wingate Todd. Contemporaneously, Krogman received a fellowship under Todd at Western Reserve University from 1928–29; and Todd introduced Krogman to Pearson and Keith. Krogman then traveled to the United Kingdom to work with Keith and Pearson from 1930–1931, before returning to Western Reserve University to work with Todd in his Anatomical Laboratory, until Todd’s passing in 1938. Additionally, while Todd’s casework is not well recorded, there is documentation of his examination of the remains of multiple individuals associated with the Cleveland Torso Murders that occurred from 1935–1938, at least one of which Krogman assisted with.

Based on these findings, while Krogman is credited for an early popularization of forensic anthropology, this would not have been possible without his mentorship by Todd and their interactions with Tildesley, Pearson, and Keith. First, this study argues that Todd treated Krogman as a protégé and to some degree supervised the production of Krogman’s 1939 publication *A Guide to the Identification of Human Skeletal Material in the FBI Bulletin*. Second, it is argued that both Todd and Krogman benefited from scholarly and personal discussions with Tildesley, Pearson, and Keith regarding what would now be considered forensic anthropological pursuits, and that these racial-biometric British methods shaped Krogman’s 1939 publication.

History, Biometry, Wilton M. Krogman

A32 Fifty Years in the American Academy of Forensic Sciences (AAFS)

John Williams PhD, Western Carolina University, Cullowhee, NC; Katherine Kolpan, PhD, University of Idaho, Moscow, ID*

Learning Overview: After attending this presentation, attendees will have a better understanding of how the membership of the Anthropology Section of the AAFS has grown and changed over time.

Impact Statement: This presentation will impact the forensic science community by providing attendees with information regarding trends in Anthropology Section membership over time, information that underscores how the section has grown and diversified since its inception in 1972.

In 1972, 14 anthropologists attended the AAFS annual meeting as members of the newly created Physical Anthropology Section. In the 50 years that followed the inception of the Anthropology Section, membership has grown to over 600.

The AAFS has maintained section membership data for every year since 1972. These data, albeit limited in scope, serve as the basis for a demographic and membership study of how the Anthropology Section has progressed over its five decades. For the purposes of this study, members were designated only using standard cis-orientation. This assignment was based on first names and personal knowledge. Names that could not be given a standard cis-assignment were not included. Also tracked for each of the years was regular membership (Associate, Full, Fellow, Retired), Trainee Affiliate, and Student.

The 1970s, not surprisingly, were a period of slow steady growth for the section. Membership more than doubled. Although the number of women in the section more than doubled, the ratio of males to females was 4.4 to 1 at the end of the decade.

The 1980s was a decade of change for the section. The first Trainee Affiliates and the first Students were elected, and, by the end of the decade, these members would account for 24% of the section. At the beginning of the decade, the male:female ratio was 3.6:1, but by the end of the decade, the overall ratio would drop to 1.6:1, although among regular members, the proportion of females increased more slowly with an ending sex ratio of 3.2:1. The high proportion of women among Students and Trainee Affiliates was an indicator of the section's future.

Driven by a continued increase in Student membership throughout the 1990s, membership in the section almost doubled. By 1999, Students comprised nearly 1 in 3 section members. This changed the demographics of the Anthropology Section and by 1998, women outnumbered men. However, women had not yet reached equity in regular membership.

Membership steadily increased in the 2000s, but not as rapidly. Student membership dipped in the early part of the decade but rebounded to 35.7% of all members by 2009. Female members increased substantially. Student members accounted for over half (56.6%) of the total number of female section members. At the end of the decade, female regular members exceeded males for the first time.

As the section finished the most recent of its five decades, membership nearly doubled from 384 in 2010 to 604 in 2021. The biggest gains were among women, who now comprise 72.6% of all members in the Anthropology Section. During this time, the number of men in all membership categories remained relatively unchanged. Student membership fluctuated wildly, dropping in 2018 to only 128 from a high of 224 five years earlier.

There is also a relationship between Trainee and Student Affiliate designations. Prior to student membership, Trainee Affiliates were greater in numbers. In 1984, they made up 31.7% of the section's members, but decreased once Student membership became available. In 1995, the section had only three Trainee Affiliates. However, the past few years have shown a resurgence in Trainee Affiliate membership with 32 members in 2021.

Anthropology, History, Members

A33 Pioneers of Color: Diversifying the Pantheon of Forensic Anthropology Luminaries

Matthew C. Go, PhD, SNA International, Supporting the Defense POW/MIA Accounting Agency, Joint Base Pearl Harbor-Hickam, HI; Elaine Y. Chu, MA, University of Nevada-Reno, Reno, NV; Nandar Yukyi MA, University of Nevada-Reno, Reno, NV; An-Di Yim, PhD, Truman State University, Kirksville, MO; Isis Dwyer, MA, University of Florida, Gainesville, FL; Alba E. Craig, BA, University of Indianapolis, Indianapolis, IN; Jesse R. Goliath, PhD, Mississippi State University, Mississippi State, MS; Chaunese M.J. Clemmons, MA, University of Texas-San Antonio, San Antonio, TX; Tanya Ramos, BA, University of Indianapolis, Indianapolis, IN; Allison Nesbitt, PhD, University of Missouri, Columbia, MO; Evonne Turner-Byfield, MSc, Ohio State University, Columbus, OH; Kamar Afra, MA, University of Tennessee, Knoxville, TN; Jessica K. Juarez, PhD, SNA International, Supporting the Defense POW/MIA Accounting Agency, Joint Base Pearl Harbor-Hickam, HI; Sydney S. Garcia, MA, SNA International, Supporting the Defense POW/MIA Accounting Agency, Joint Base Pearl Harbor-Hickam, HI; Aaron J. Young, MA, University of Arizona, Tucson, AZ; Isabel S. Melhado, BS, University of Indianapolis, Indianapolis, IN; Fatimah Bouderdaben, BS, Texas State University, San Marcos, TX; Tisa N. Loewen, MA, Arizona State University, Tempe, AZ; Ivanna Robledo, MA, Texas State University, San Marcos, TX*

Learning Overview: After attending this presentation, attendees will appreciate the lack of diversity among the most widely taught historical figures in forensic anthropology's foundations and learn of people of color who were also foundational to the discipline.

Impact Statement: The goal of this presentation is to impact the forensic science community by colorizing the pantheon of forensic anthropology's predominantly White forbearers in order to provide a more inclusive and diverse discipline.

The history of forensic anthropology in the United States centers specifically around the work of several key figures, particularly in how their research on human skeletal variation and collaboration with law enforcement have shaped the way the field is defined and practiced today. These key figures also happen to be predominantly White. To give grounds for this claim, this study drew from journal articles, textbooks, and book chapters specifically dealing with the history of forensic anthropology to identify the most often cited forbearers of the field. The most encountered names include Dwight, Hrdlička, Hooton, Stewart, Terry, Angel, Krogman, Todd, Kerley, and Snow, among other prominent figures, many of whom lend their names to special awards given out by the Anthropology Section or Kerley Foundation. This study contends that these individuals comprise the traditional pantheon of forensic anthropology's luminaries, yet do not represent the diversity of our field, past or present. To ameliorate this gap, this study highlights people of color in forensic anthropology's foundational history that are often overlooked in texts on the subject. This study adds early pioneers such as W. Montague Cobb, Charles Warren, Caroline Bond Day, Tadao Furue, Kazuro Hanihara, Mahmoud El-Najjar, and others to the existing, well-recognized, and widely taught pantheon of forensic anthropology's founders. Their biographies, legacies, and contributions to the field are followed by a critique of why such an endeavor was required in the first place and of the challenges in compiling a robust list of names to include. Moreover, this study on this project includes a diverse set of early career scholars of color, which is intended to symbolize the current generation lifting up those from prior generations who may have been historically excluded. Such a colorization of our history coincides well with this year's annual conference theme of responding to and surpassing the needs of a modern forensic world and is intended to celebrate 50 years of anthropology at the AAFS in a more diverse and inclusive way. This presentation complements another symposium during these meetings called "Pioneers of Color: A Diverse Narrative of Forensic Anthropology," which colleagues are encouraged to attend.

History of Forensic Anthropology, Diversity and Inclusion, Decentering Whiteness

A34 Contributions of Master's Degree Programs to Forensic Anthropology Education, Training, and Professionalization

Ashley Kendell, PhD, California State University-Chico, Chico, CA; Krista Latham, PhD, University of Indianapolis, IN; Sara M. Getz, PhD, University of Wisconsin-Platteville, Platteville, WI; Eric Bartelink, PhD, California State University-Chico-Chico, CA; Shannon Clinkinbeard, MA, California State University-Chico, Chico, CA; Dennis C. Dirkmaat, PhD, Mercyhurst University, Erie, PA; Colleen Milligan, PhD, California State University-Chico, Chico, CA; Stephen P. Nawrocki, PhD, University of Indianapolis, Indianapolis, IN*

Learning Overview: After attending this presentation, attendees will better understand the roles of master's-level programs, and their associated forensic anthropology laboratories, in education, training, and professionalization of forensic anthropology graduate students.

Impact Statement: This presentation will impact the forensic science community by discussing: (1) the advantages and challenges of the increased availability of specialized forensic anthropology education and training at the master's level, and (2) how master's-level programs contribute to the training and professional development of students.

For most of the 20th century, the dominant model of education and training within forensic anthropology has been a broad, four-field undergraduate education, followed by specialization in biological anthropology or bioarchaeology at the graduate level, and subsequent mentorship and hands-on training in forensic techniques and methodological approaches.

Increased recognition and utilization of forensic anthropologists, alongside the development of specialized theory, methods, and techniques for forensic contexts, has driven the need for focused education and hands-on training. In response, beginning in the 1970s, an increasing number of post-baccalaureate and graduate degree programs have filled this niche. This presentation highlights the contributions of such programs in forensic anthropology.

Three long-standing programs—California State University, Chico (Chico State), The University of Indianapolis (UIndy), and Mercyhurst University—that began accepting graduate students in 1975, 1996, and 2004, respectively, are used to emphasize broader trends in education at the master's level. Collectively, these three programs have produced over 250 graduates with master's degrees in Anthropology, Human Biology, and Forensic & Biological Anthropology, respectively. Of these graduates, more than 112 have completed or are currently enrolled in PhD or advanced professional degree (e.g., JD, MD) programs. Eighteen have been certified as Diplomates of the American Board of Forensic Anthropology (D-ABFS) with others in the process of obtaining this certification. Graduates have found employment within the forensic community in medical examiner and coroner offices, crime laboratories, agencies such as the Federal Bureau of Investigation (FBI), the Defense POW/MIA Accounting Agency (DPAA), and the International Commission on Missing Persons (ICMP), and as university faculty, while others have found related careers in anatomy, medicine, archaeology, and law.

The success of these programs is grounded in their ability to provide practical, hands-on training through specialized, laboratory-based classroom courses, student-focused research, and participation in forensic cases alongside their faculty mentors. Importantly, each institution began accepting forensic casework prior to graduate program formation (Chico: 1972; UIndy and Mercyhurst: 1991), which laid the foundation for graduate student training. These programs also offer continuing education courses to law enforcement and medicolegal professionals, which in turn promotes the use of forensic anthropology and a significant expansion in casework.

With the field's increasing popularity and visibility, external pressures to expand class sizes have become increasingly prevalent. In response, existing programs have taken steps to combat the negative consequences of producing a large number of graduates in a small, competitive field by promoting small class sizes, increasing professionalization opportunities, and promoting applicable skills within fields, such as biology, forensic science, and bioarchaeology. With an emphasis placed on training students in a diverse range of scientific methodologies, these programs facilitate job placements in other areas of forensic science or related professions.

The goal of master's-level degree programs should continue to be the integration of hands-on teaching, research, and casework, which provides young professionals with real-world forensic experience and prepares them for entering the workforce or pursuing higher education. For some graduate students, master's-level training is the only opportunity they will have to develop their skills participating in forensic casework opportunities. Therefore, development of a masters-level certification will provide an additional avenue for developing professionals to demonstrate competency and commitment to professional involvement in the field.

Forensic Anthropology, Master's Programs, Professionalization

A35 Daubert: Lip Service or a Substantive Change in Forensic Anthropology?

Kate Lesciotto, PhD*, Sam Houston State University, Conroe, TX

Learning Overview: After attending this presentation, attendees will have a better understanding of how the United States Supreme Court decision *Daubert v. Merrell Dow* has impacted forensic anthropological research.¹

Impact Statement: This presentation will impact the forensic science community by presenting data on the subject matter, methods, and relevant legal standards discussed in forensic anthropology articles published in the *Journal of Forensic Sciences*.

This project examines trends in forensic anthropology articles, with specific emphasis on whether the 1993 United States Supreme Court *Daubert v. Merrell Dow* decision on the standard for admissibility of expert witness evidence has changed the landscape of forensic anthropology research. In the wake of *Daubert*, many forensic anthropologists anticipated significant impacts on the admissibility of forensic anthropological expert witness testimony, with numerous articles citing *Daubert* as motivation to create more objective and statistically backed methods.

This bibliometric study evaluated 1,142 peer-reviewed forensic anthropology articles published between 1972 and 2020 in the *Journal of Forensic Sciences* (JFS). Data collected included the topic, article type, data type, inclusion of accuracy and error testing, and discussion of relevant legal standards, in order to address the following research questions: (1) re there general trends in the topics of published JFS anthropology articles?; (2) Has there been a change in how frequently publications discuss or cite legal standards, including *Daubert*?; (3) Did the field of forensic anthropology respond to *Daubert* by advancing toward more objective methods?; and (4) Has the field's overall discussion and awareness of *Daubert* initiated a shift in how forensic anthropology research is conducted?

Forensic anthropology articles published in JFS have risen from 1 article in 1972 to a high of 70 in 2015, with a decrease to 34 in 2020. The biological profile was the most common topic (36%), followed by taphonomy and/or postmortem interval (12%), and trauma (11%). Legal standards were discussed in 123 articles, with 85 specifically citing the *Daubert* decision. Articles as early as 1982 referenced relevant legal standards, with the first specific reference to *Daubert* occurring in 2005. Chi-squared trend tests showed a significant increase in the proportion of articles that referenced legal standards (including *Daubert*) over time ($\chi^2=19.538$; $p<0.001$), indicating a growing awareness of the potential implications for forensic anthropology.

Using the biological profile articles as a case study, a chi-square trend test revealed no significant decrease over time in the proportion of studies using subjective data ($\chi^2=2.509$; $p=0.1132$), suggesting that *Daubert* has not significantly driven forensic anthropology research toward more objective methods. However, there was a significant increase in the proportion of studies that performed intra- and inter-observer error studies ($\chi^2=12.264$; $p<0.001$).

Qualitative analyses were also performed to further evaluate the articles that did reference legal standards ($n=123$). Thematic analysis revealed that articles commonly referenced legal standards while providing a general background of a legal framework (e.g., listing the *Daubert* guidelines) (50%) or as justification for conducting the study (19%). Forty-three of the articles (35%) specifically contextualized the results of the study within the relevant legal framework, such as explaining how the study met one or more of the *Daubert* guidelines.

While no articles disputed the influence of *Daubert* and other relevant legal standards on forensic anthropology research, the data demonstrate that authors are commonly using *Daubert* to point out deficiencies in previous research and justify a new study or publication. However, the field of forensic anthropology still needs to take further steps toward advancing more objective, quantifiable, and statistically backed methods and research to bring the field more into compliance with the *Daubert* guidelines.

Forensic Anthropology, Daubert, Legal Standards

A36 50 Years of Taphonomic Research: From Death's Acre to a Global Footprint

Sophia Mavroudas, MA, Texas State University, San Marcos, TX; Dawnie Steadman, PhD, University of Tennessee, Knoxville, TX; Katie Zedjlik, PhD, Western Carolina University, Cullowhee, NC; Daniel Wescott, PhD, Texas State University, San Marcos, TX; Timothy Gocha, PhD, Texas State University, San Marcos, TX; Sheree Hughes, PhD, Sam Houston State University, Huntsville, TX; Gretchen Dabbs, PhD, Southern Illinois University, Carbondale, IL; Melissa Connor, PhD, Colorado Mesa University, Grand Junction, CO; Jodie Ward, PhD, University of Technology, Sydney, New South Wales, Australia; Erin Kimmerle, PhD, University of South Florida, Tampa, FL; Jane Harris, PhD, Northern Michigan University, Marquette, MI; Shari Forbes, PhD, Université du Québec à Trois-Rivières, Trois-Rivières, Québec, Canada; Anthony Falsetti, PhD, George Mason University, Fairfax, VA*

Learning Overview: This presentation will inform attendees as to the history of outdoor decomposition facilities and the evolution of taphonomic research over the past 50 years.

Impact Statement: This presentation will impact the forensic science community through the presentation of history pertinent to the field of forensic science, particularly forensic taphonomic research.

The first outdoor human decomposition research facility was established by Dr. William Bass in 1981 at the University of Tennessee in Knoxville, TN. The Anthropology Research Facility, originally one acre in size, is located on a bluff top overlooking the Tennessee River. With the establishment of this facility, Dr. Bass initiated the important connection between time-since-death estimation and questions pertinent to the field of forensic anthropology. Many early research questions focused on single environmental variables (e.g., decomposition rates in sun or shade, clothed and unclothed, etc.). More recently, however, forensic anthropology has grown as a discipline such that taphonomic research is more holistic and multidisciplinary. This has led to research at outdoor decomposition facilities that investigates much more complex relationships between the decomposing body and its environment in diverse landscapes across the United States in North Carolina, Texas, Illinois, Colorado, Florida, Michigan, and Virginia.

To date, there are nine working facilities within the Consortium for Anthropological Research in Taphonomy (CART) within the United States in addition to one each in Australia, Canada, and the Netherlands. Most of these facilities are run by female anthropologists; however, several are now led by specialists in other disciplines, including geonomics, chemistry, and archaeology. The focus on hypothesis-driven scientific research and pedagogy has grown exponentially since 1981, and these facilities now play an important role in the field of forensic science providing real-world laboratory environments, research material, opportunities for student research at all levels, and documented modern skeletal collections.

This presentation will cover the history and current research of decomposition facilities across the world from the original facility in Tennessee through to the most recent facility in Quebec, Canada. This presentation will focus on the unique specialties of each facility, cross-disciplinary research that has grown out of these facilities, and where the consortium sees the future of forensic taphonomy research headed. Special emphasis will be placed on the evolution of taphonomic research design and scope across the five decades.

Taphonomy, Outdoor Decomposition Facilities, Forensic Science History

A37 Beatings, Broken Bones, Bullet Holes, and 3D Prints: The Evolution of Bone Trauma From the Morgue to the Virtual World/Space

Ericka N. L'Abbe, PhD, University of Pretoria, Pretoria, Fauteng, South Africa; Alison F. Ridel, PhD, University of Pretoria, Pretoria, Fauteng, South Africa; Charlotte Theye, MSc, University of Pretoria, Pretoria, Fauteng, South Africa; Rudolph G. Venter, MMed, Stellenbosch University, Stellenbosch, Western Province, South Africa; Alieske Hagg, MSc, University of Pretoria, Pretoria, Fauteng, South Africa; Pearl Bothma, BSc, University of Pretoria, Pretoria, Fauteng, South Africa; Angelique Carmichael, BSc, University of Pretoria, Pretoria, Fauteng, South Africa; Clarisa van der Merwe, MSc, University of Pretoria, Pretoria, Fauteng, South Africa; Steven A. Symes, PhD, Office of the State Medical Examiner of Mississippi, Pearl, MS*

Learning Overview: After attending this presentation, attendees will have a better understanding of the use of 3D surface scanning, micro- Computed X-Ray Tomography (micro-XCT) scanning, 3D mesh creation and 3D printing of bone trauma.

Impact Statement: This presentation will impact the forensic science community by presenting a history of bone trauma in the United States and how 3D technology can improve the application of bone trauma in laboratory, classroom, and courtroom.

Worldwide, a high burden of trauma exists in both clinical and medicolegal disciplines. While not all bone fractures cause death, a fracture can be related to the cause of death, which is important in any medicolegal investigation. The interpretation of traumatic injury to bone is a critical component of a forensic anthropological case report and in clinical applications.

The interpretation of bone trauma as part of a forensic anthropologists toolkit began in the 1990s out of the Office of the State Medical Examiner in Memphis, TN. During postmortem investigations, forensic anthropologists resected broken bones, cleaned, reconstructed, and used them, in association with soft tissue and prior knowledge, to assist a forensic pathologist in interpretations of cause and manner of death.¹ In the majority of cases, the resected bone was retained as evidence and used either in the courtroom or the postgraduate classroom. Bone trauma analysis expanded an anthropologist's contribution to forensic investigations, but education in bone trauma has faltered nationally and internationally, with varied ethics and legislation around the retainment of human bone. Forensic anthropology postgraduate students and practitioners struggle with practical experience in bone trauma analysis as few illustrative examples exist and, due to the nature of biological materials and ethics, access to these specimens are limited to certain facilities.

As part of the Bakeng se Afrika ("for Africa") project, a total of 67 bone trauma specimens were micro-XCT scanned from 2019 to 2020 at the Nuclear Energy Corporation South Africa (NECSA), and include both crania (n=48) and postcrania (n=17) of adults and two juveniles (n=1 cranium and n=1 rib cage). The specimens are comprised of anonymized and donated resected bone and/or complete skulls from closed cases in both the United States and South Africa. The distribution of trauma types includes blunt force trauma (n=26), ballistic/projectile trauma (n=25), sharp force trauma (n=4), healed injuries (n=9), and thermal alterations (n=3). Two femora have projectile trauma with known weapons, along with two cases of substantiated child abuse. All digital volumes of these specimens were processed into 3D meshes, providing a way in which to generate high-quality 3D prints of traumatic injury.

Digital imaging technology provides an opportunity to improve education in bone trauma analysis, as a 3D mesh or print of a bone is not a biological material and can be ethically used in both undergraduate/postgraduate education and workshops. While micro-XCT and professional expertise associated with them are not readily available in many laboratories, the use of 3D surface scanners can effectively capture the shape and size of the morphology of a traumatic injury in a non-invasive way, thereby easing documentation, data sharing, collaborative analysis, and 3D printing. 3D imaging and printing provide practitioners, students, and the public an opportunity to handle broken bones in both undergraduate and postgraduate classrooms, workshops, and the courtroom.

Bone Trauma, 3D Prints, Forensic Science Education

A38 Situating Activism In Forensic Anthropology: Historical Understandings of Advocacy in the Discipline

Raphaella Meloro, MA*, University of Florida, Department of Anthropology, Gainesville, FL; Isis Dwyer, MA, University of Florida, Department of Anthropology, Gainesville, FL; Thomas Delgado, BA, California State University-Chico, Department of Anthropology, Chico, CA

Learning Overview: After attending this presentation, attendees will understand how the role of activism in the field of forensic anthropology has developed and shifted over time.

Impact Statement: This presentation will impact the forensic science community by providing insight into current and future understandings of the role of activism within forensic anthropology and science at large.

In the wake of an escalating civil rights movement with severe government responses, many disciplines have had to consider the way in which racism and discrimination against minority groups exists in their histories and understand the roles that activism and advocacy currently play in the field. This is of particular relevance for the field of forensic anthropology in the wake of public backlash against the use of unprovenanced human remains in skeletal collections used for teaching and research. Public perception of forensic anthropology would suggest a decline in activism and advocacy over time, as demonstrated by the responses of key leaders in the American Academy of Forensic Sciences (AAFS) and American Board of Forensic Anthropology (ABFA) to the Black Lives Matter movement and backlash regarding the storage of human remains from the 1985 MOVE bombing in public news.^{6,9} Yet, forensic anthropologists are not, and have not been, shy about promoting justice via activism over the formative years of our practice. Indeed, the direct involvement of anthropologists in international humanitarian crises over the years serves as a stark reminder of our role. Human rights work by forensic anthropologists has continued on in the present with the field's engagement in modern international humanitarian crises and in the re-examination of historic cases, such as the 1921 Tulsa Race Massacre and the identification of Native American remains from historic boarding schools.^{1-5,11} Nonetheless, there have been views expressed from within the field that are opposed to the role of anthropologist as advocate.

This presentation aims to situate this issue in the historical context of the discipline and examine the role of activism in forensic anthropology over the past 50 years. By examining contributions of notable forensic anthropologists to historic and modern rights movements, such as the investigations of human rights violations in Nazi Germany and South America, this presentation demonstrates the shifting nature of activism in the field over time.^{1,2,4,5,7,9} Results of this retrospective review suggest that the definition of activism has changed in the field over time, and this presentation captures this change by differentiating between humanitarian efforts, activism, and reactionary efforts to current events. A paradigm shift initiated by diversification and growth in the field requires a reexamination of the role of activism in forensic anthropology.⁸⁻¹¹

A39 Standards Development Activities in Forensic Anthropology

Gregory E. Berg, PhD, Defense POW/MIA Accounting Agency, Honolulu, HI*

Learning Overview: After attending this presentation, attendees will have a better understanding of the status of discipline-specific standards pertinent to the field of forensic anthropology.

Impact Statement: This presentation will impact the forensic science community by creating greater awareness of standards development activities pertinent to forensic anthropology. It will also increase awareness regarding training, tools, and resources that support implementation, compliance monitoring, and broader understanding.

Even during this trying time of a global pandemic, the forensic anthropology community continues to strive forward and make progress in the Standards world. Specifically, the Organization of Scientific Area Committees (OSAC) for Forensic Science was created to strengthen the nation's use of forensic science by promoting the use of discipline-specific forensic science standards. To this end, the OSAC drafts standards that are forwarded to Standards Developing Organizations (SDOs) that further develop and publish them, often as an American National Standard or an American Society for Testing and Materials Standard, among others. The OSAC also reviews standards and recognizes them on the OSAC Registry, which serves as a central repository of high-quality, consensus-based, technically sound standards. This presentation will cover the latest advances made by the OSAC and the other SDOs in regard to forensic anthropology.

During this presentation, updates related to standards development in forensic anthropology will be presented. These include: (1) recent standards that have been added to the OSAC Registry (none yet, but three are under consideration); (2) OSAC-proposed standards (nine documents in process at OSAC and the Academy Standards Board [ASB]); (3) published standards from the ASB that have yet to go through the Registry approval process (as noted earlier, these are under consideration for OSAC Registry inclusion and deal with the topics of Stature Estimation, Facial Approximation, and Sex Estimation); (4) priorities for new documents or work products (six documents entering the queue for development on items such as Qualifications, Documentation, Proficiency Testing, Isotope Analysis, etc.), as well as other highlights. Opportunities for supplemental training related to discipline-specific standards will be presented, as well as additional resources and tools designed to facilitate gap analysis, compliance monitoring, and outreach efforts.

Forensic Anthropology, Standards, OSAC

A40 Fatal Environments: Survey Results and Best Practices for Human Donor Programs and Body Farms Around the World

Kelsee Hentschel-Fey, MA, University of South Florida, Tampa, FL; Gennifer Goad, MA, University of South Florida, Tampa, FL; Erin Kimmerle, PhD, University of South Florida, Tampa, FL*

Learning Overview: After attending this presentation, attendees will better understand the ways in which outdoor decomposition facilities are managed around the world, the diversity of research and innovation taking place in these facilities, and the changing practices within living human donor programs.

Impact Statement: This presentation will impact the forensic science community by bringing attention to the multidisciplinary nature of outdoor decomposition facilities, the problems associated with the application of experimental research, and the unique familial and kinship research opportunities afforded by skeletal collections.

Human donation programs and outdoor research facilities (“body farms”) enable critical research necessary for method testing and development in areas of identifying unknown persons, locating burials, and trauma interpretation, all of which can be critical to solving cases and prosecuting offenders. These human donations are kept in perpetuity and accessioned into donated skeletal collections, which provide a wealth of opportunity for students and scholars in need of ethically sourced research collections with known demographic and life history information.

To date, there are 12 programs utilizing a human donation program for forensic research at an outdoor decomposition facility. Each of the 12 directors participated in a jointly written survey to share information about their donation policies, available research collections, and current trends in research. Survey results from the 12 facilities include 9 that are domestic and 3 international: (1) Forensic Anthropology Research Facility (FARF), Texas State University; (2) Southeast Texas Applied Forensic Science (STAFS) Facility, Sam Houston State University; (3) Complex for Forensic Anthropology Research (CFAR), Southern Illinois University; (4) Facility for Outdoor Research and Training (FORT), University of South Florida; (5) Forensic Research Outdoor Station (FROST), Northern Michigan University; (6) Forensic Osteology Research Station (FOREST), Western Carolina University; (7) Forensic Investigation Research Station (FIRS), Colorado Mesa University; (8) Anthropology Research Facility (ARF), University of Tennessee; (9) Forensic Science Research and Training Laboratory, George Mason University; (10) Australian Facility for Taphonomic Experimental Research (AFTER), University of Technology, Australia; (11) Amsterdam Research Initiative for Sub-surface Taphonomy and Anthropology (ARISTA), Amsterdam University Medical Centers, The Netherlands; and (12) Research on Experimental and Social Thanatology (REST[ES]), University of Quebec, Canada.

Results of this survey found that research conducted at these facilities is multidisciplinary, combining anthropology, archaeology, legal medicine, geology, chemistry, biochemistry, geochemistry, remote sensing, botany, genetics, engineering, and art. A wide range of studies have been and are continuing to take place, including remote sensing techniques for locating burials, evaluation of chemical changes in soils, DNA degradation, mineral variation in tumor growth, facial recognition, and generalized postmortem decomposition research. This survey also found interesting and unique trends common to multiple facilities that differ from forensic casework, illustrating some of the inherent challenges in applying experimental research to real-world scenarios.

The Facility for Outdoor Research and Training at the University of South Florida (USF-FORT) will be used as an in-depth case study to illustrate some of the trends found in this survey. Created in 2014, the program has over 100 donors and 250 registered pre-donors to date. Reasons for donation vary and frequently include individual perceptions of environmental sustainability, support for the forensic community or education, and/or low-cost/affordability. Further, a surprising trend in donation practices includes family registrations: at least 30 families have registered with the program, including spousal/life partnerships, parents/children, grandparents/grandchildren, siblings, and second-degree relatives. This suggests forensic facilities are used by families as alternatives to traditional final disposition sites like cemeteries or mausoleums. As forensic facilities continue to be established internationally, these perceptions are relevant to facility directors and donation coordinators who are involved with end-of-life care and planning. Further, permanent donation programs comprised of households and multi-generational family lineages may offer unique research avenues regarding kinship, including heritability of skeletal traits, isotopic analyses, and genetic analyses.

Forensic Anthropology, Decomposition, Collaboration

A41 F-Track: A Model for Forensic Professionalization

Joanne Devlin, PhD, University of Tennessee, Knoxville, TN; Giovanna Vidoli, PhD, University of Tennessee, Knoxville, TN; Lee Jantz, PhD, University of Tennessee, Knoxville, TN; Mary Davis, MSc, University of Tennessee, Knoxville, TN; Dawnie Steadman, PhD, University of Tennessee, Knoxville, TN*

Learning Overview: After attending this presentation, attendees will have a model program and a successful blueprint for professional development in forensic anthropology graduate programs. This roadmap follows educational accreditation standards without the potential accreditation roadblocks.

Impact Statement: Recent discussions have focused on accreditation of forensic anthropology programs in higher education.¹ The Department of Anthropology at The University of Tennessee, Knoxville has an established undergraduate concentration in forensics for anthropology majors; however, no such program formally exists at the graduate level. Unfortunately, an accredited forensic program via the Forensic Science Education Programs Accreditation Commission (FEPAC) or other accreditation body is improbable given other university and department priorities. However, it is still a departmental responsibility to establish programmatic standards and to provide graduate students pathways to professional success. This approach must extend beyond basic classroom instruction, opportunistic experiences, and thesis or dissertation-related research. Further, in light of the upcoming American Board of Forensic Anthropology (ABFA) forensic anthropology certification available to Masters-level students, systems that provide students the opportunities to learn, and practice, how to be solid forensic practitioners and professionals are critical. The absence of a waiting period before seeking Diplomate-ABFA (D-ABFA) certification after earning a degree further underscores the importance of incorporating a system like the one outlined in this presentation into established anthropology graduate programs.

Well-rounded educational programs aim to blend classroom-based sessions where methods, techniques, and best practices are conveyed, with practical professional development through participation in applied opportunities, training courses, apprenticeships, and internships. However, this format—classroom with practical opportunities—may not be sufficient to develop knowledgeable and well-rounded forensic professionals. Graduate students deserve a structured program that provides a pathway to blend academic requirements with professional and practical milestones. As a result, in the fall of 2017, the Forensic Anthropology Center (FAC) at The University of Tennessee implemented Forensic track (F-track), a voluntary program designed to fulfill suggested competencies. Two years later at the American Academy of Forensic Sciences (AAFS) annual meeting, Langley and Tersigni-Tarrant shared seven core competencies and associated Entrustable Professional Activities for forensic anthropologists to sustain lifelong learning, professional growth, and personal growth.¹ University of Tennessee Anthropology's F-track program provides a model to accomplish these competencies.

F-track currently has two major branches. One is aimed at providing the pathway for access to, and success in, forensic case work, starting with competency tests, required coursework, and then transitioning to primary analyst level. The other branch is geared toward professionalization by nurturing confidence and capabilities in science communication, presentations, and inter-professional instruction. This branch is equally important and provides opportunities to work on communication skills, professionalism, and inter-professional collaborations. Each branch is comprised of several modules. Successful completion of a module indicates a participant has acquired and demonstrated knowledge of practices relevant to case work and professional development. Several modules require understanding of Standard Operating Procedures (SOPs) used at the FAC. F-track provides the milestones necessary for motivated students to secure forensic training and experience while developing and nurturing their professional capabilities. Importantly, each participating student will have a documented and detailed training log that they can include in their application for certification upon graduation. The F-track model can be adopted by all who seek a formal, structured system of professional graduate training without external programmatic accreditation that may be unobtainable for most anthropology departments.

Graduate Student Training, Professionalization, Accreditation

A42 The Readability of Forensic Anthropological Abstracts

Donovan Adams, PhD, University of Central Florida, Orlando, FL; Clairia Ralston, MS*, University of Nevada, Las Vegas, NV; Kelly McGehee, BA, University of Central Florida, Orlando, FL

Learning Overview: After attending this presentation, attendees will gain a better understanding of the factors contributing to the readability of forensic anthropological abstracts and how these factors impact the ability of both anthropologists and the general public in understanding academic research.

Impact Statement: This presentation will impact the forensic science community by providing information regarding the complexity of abstracts and providing potential avenues for science communication improvement.

The intent of abstracts is to provide a concise, yet thorough, summary of an article. Oftentimes these are the only sources of information, whether through lack of subscription access or through conference proceedings. Additionally, these serve as the entry to a publication as both researchers and non-researchers search for relevant information. Effective science involves effective communication; otherwise accurate interpretation, replication, and knowledge-building is hampered. The present research examines the readability, defined here as the processing and understanding of a text, of anthropological abstracts.¹

Abstracts from 2010-2021 were gathered from PubMed® using the pubmedR2 package and the American Academy of Forensic Sciences website. These included Anthropology papers in the Journal of Forensic Sciences (JFS; n=574), Forensic Anthropology (FA; n=85), and the AAFS Conference Proceedings (AAFS; n=1,578). As a comparative sample to broader biological anthropology, abstracts were collected from the American Journal of Physical Anthropology (AJPA; n=2,034). The program Tool for the Automatic Analysis of Lexical Sophistication (TAALES) and packages koRpus and quanteda.textstats were used to calculate various readability and lexical indices.³⁻⁶ The following questions were addressed: (1) are abstracts becoming more complex over time?; (2) are forensic anthropological abstracts more complex compared to the average bioanthropological abstract?; (3) do certain aspects of writing contribute to more complex abstracts?; and (4) how do the answers to these questions inform better science communication?

Preliminary results suggest abstracts in AAFS are the most complex and JFS are the least complex in readability measures. Of the journal abstracts, FA appears to be more difficult in readability. AAFS appears to be decreasing in readability while AJPA remains the most relatively consistent. Abstracts in JFS exhibit variability in text familiarity, imageability, and concreteness across years, though this may be related to smaller sample size. On average, however, JFS had the highest and FA had the lowest text familiarity, imageability, and concreteness, respectively (JFS had terms that were more familiar and less abstract). Comparisons between journals for these measures were significant, but effect size was small. Measures of word range and frequency and bigram proportions in academic, news, fiction, and magazine corpora indicate most abstracts are written more similar to other academic texts compared to non-academic sources. Although AAFS shows a higher similarity to non-academic corpora, this may, in part, be due to the longer length of AAFS abstracts, which allows for greater possibility of similarity. These results agree with traditional measures like Flesch's Reading Ease and Flesch-Kincaid Readability Score that abstracts are generally written for at least a college graduate level.

These preliminary results suggest anthropological abstracts, especially those of conference proceedings, are inaccessible, particularly to those with minimal to no training in (forensic) anthropology. Notably, AAFS consistently had values in each of the indices that are reflective of lower readability. While practitioners may argue these results fit their audience, we must consider that we should write abstracts (any scientific writing) for the broader public. Research is spread across the internet, in sometimes nefarious ways, so it is important that anthropologists ensure that, at minimum, abstracts are written for everyone. This presentation will discuss avenues for improved science communication regarding jargon, writing, text length, and sentence construction.

Abstract Readability, Science Communication, Forensic Anthropology

A43 Estimating the Postmortem Interval (PMI) in High Desert Climates

Mackenzie Sullivan, BA, University of Nevada-Reno, Reno, NV; Marin Pilloud, PhD, University of Nevada-Reno, Reno, NV; Mary Megyesi, PhD, Defense POW/MIA Accounting Agency, Joint Base Pearl Harbor-Hickam, HI; Laura Knight MD, Washoe County Regional Medical Examiner's Office, Reno, NV*

Learning Overview: After attending this presentation, attendees will better understand how regionally specific methods to estimate PMI can be created and how well they perform.

Impact Statement: This study will impact the forensic community by comparing different methods of scoring decomposition to estimate PMI.

Estimating PMI is challenging due to the variety of factors that affect decomposition rates (e.g., temperature, sun exposure, humidity, animal scavenging). One commonly used method is that of Megyesi et al.¹ This method utilizes a decomposition scoring system of visual indicators, which when totaled, provide the Total Body Score (TBS). This score is then correlated with Accumulated Degree Days (ADD) to estimate the PMI. An alternative method of scoring TBS by Connor et al. incorporates desiccation rates as regionally appropriate for western Colorado.² Connor and colleagues conclude that incorporating the Total Body Desiccation Score (TBDS) may help refine PMI estimates in areas where remains desiccate. This project recreates the research of Megyesi et al. and Connor et al. on a sample of cases from northern Nevada to identify if a regionally specific equation and/or one that incorporates desiccation rates can better predict PMI.

Cases of identified decedents were obtained from the Washoe County Regional Medical Examiner's Office (WCRMEO) in Reno, NV. The PMI was determined by the difference of days between when the decedent was last seen and the day the decedent was recovered. Only cases including full-color, high-quality photographs of each region of the body were accepted, and all cases had macroscopic signs of decay at the scene and/or in the autopsy. The TBS and TBDS were scored for each set of remains ($n=99$) with observer error checked. Of the total sample, the majority were found indoors ($n=93$) and between March 1 and August 31 ($n=67$). The ADD was obtained by averaging the high and low daily temperature collected from the nearest weather station to the decedent's location and totaling each daily average for all days in the PMI. The PMI in this sample ranged from 1 to 75 days and the ADD ranged from 0 (all daily temperature averages below 32° Fahrenheit) and 3,741. The TBS ranged from 3 to 23; the TBDS ranged from 0 to 40.

A linear regression model was created specific to northern Nevada to estimate PMI based on the two different decomposition scores as well as the ADD for each case. The models were created using a training set ($n=80$); a testing set was used to test the models ($n=19$). For the test set, this study tested its Adapted Megyesi score (based on TBS and ADD specific to the cases of the WCRMEO), a model based on the TBDS, and the original formula created by Megyesi et al. to estimate PMI. All analyses were conducted in the R statistical computing environment.³

Between the two new models, the Adapted Megyesi Model provides more accurate predictions of PMI (correct in 57.9% of test cases), whereas the model based on TBDS was accurate in 47.4% of cases. The Original Megyesi model was most accurate at 84%. However, the Original Megyesi model also had the largest standard error, over six times that of the new models created here, which allowed it to be more accurate but much less precise.

Based on this research, the Original Megyesi Model held the most predictive value for estimating PMI. However, the two models built using a regionally specific sample offered a narrower error range and were more precise in PMI estimates. Therefore, an accurate and more narrowly precise PMI estimation for local medicolegal death investigations (i.e., a regionally specific equation) could be constructed with a larger sample size and further investigation into mitigating variables. This research and continued efforts to study PMI will aid in creating more refined and regionally appropriate methods.

Decomposition, Desiccation, Taphonomy

A44 Toward a Better Understanding of the Effects of Leaching and Diagenesis on $^{87}\text{Sr}/^{86}\text{Sr}$ of Human Hair Keratin

Saskia Ammer, PhD, Vrije Universiteit Amsterdam, Amsterdam, NH, Netherlands; Lisette Kootker, PhD, Vrije Universiteit Amsterdam, Amsterdam, NH, Netherlands; Gareth Davies, PhD, Vrije Universiteit Amsterdam, Amsterdam, NH, Netherlands*

Learning Overview: Attendees will learn how diagenesis/postmortem burial contexts and leaching protocols can alter the $^{87}\text{Sr}/^{86}\text{Sr}$ ratios recovered from human hair keratin.

Impact Statement: This presentation will inform the forensic science community how hair keratin cleaning methods commonly employed by forensic scientists influence the Sr isotope composition. This presentation will give guidance as to which cleaning methods are preferred.

The application of isotope analysis to aid human identification processes in forensic cases is becoming more common. In contrast to dental enamel, hair and nail keratin can potentially provide valuable insights into recent diet and health status (e.g., C-N-S), and geolocation (e.g., Sr-Pb). Recent studies, however, have shown that it is difficult to separate diet-related endogenous Sr-Pb signatures from environment-specific exogenous signatures in human hair keratin. Inevitably, the effectiveness of hair keratin as a means of evidence for reconstructing recent mobility patterns depends greatly on its susceptibility to diagenetic alterations (e.g., burial context).

To gain a better understanding of the optimal pre-treatment of hair keratin samples and the applicability of hair keratin samples in various forensic contexts, an experimental leaching project was combined with actualistic experiments at the Amsterdam Research Initiative for Sub-surface Taphonomy and Anthropology (ARISTA) facility in the Netherlands and human hair samples recovered from Undocumented Border Crossers (UBCs) provided by the Pima County Office of the Medical Examiner in Arizona. The samples from ARISTA consist of pre-burial and post-clandestine-burial samples, which were then compared to investigate if the exogenous signature can be successfully removed, and the endogenous (pre-burial) signature recovered. The UBC samples consist of hair samples recovered from individuals found above ground. Here, the leachates of every cleaning step and a subsample of hair were collected to examine during which cleaning steps (exogenous) Sr is released.

The data show a close connection between hair color (i.e., the amount of melanine present in the sample) and the effectiveness of the leaching protocol on retrieving the antemortem Sr isotope composition of hair keratin. More importantly, following previously reported data from FARF (Forensic Anthropology Research Facility) in Texas, the data from the actualistic experiments at ARISTA and the data from the UBCs accentuate the extreme difficulty or even impossibility of recovering the hair's biogenic Sr isotope compositions after 306 days of burial, despite the application of the most effective pre-treatment protocol (2:1 MC-MQ-0.1M HCL-MQ).¹ The UBC leaching experiment demonstrates the differences in effectiveness of cleaning steps and during which steps Sr was released from the human hair.

Strontium, Diagenesis, Human Hair

A45 Diagenesis of Human Bone, Dental Elements, and Scalp Hair in Taphonomic Experiments: Implications for Isotope Analysis for Human Identification

Lisette M. Kootker, PhD, Vrije Universiteit Amsterdam, Amsterdam, NH, Netherlands; Saskia T.M. Ammer, MSc, Vrije Universiteit Amsterdam, Amsterdam, NH, Netherlands; Daniel J. Wescott, PhD, Forensic Anthropology Center, San Marcos, TX; Gareth R. Davies, PhD, Vrije Universiteit Amsterdam, Amsterdam, NH, Netherlands; Hayley L. Mickleburgh, PhD, Forensic Anthropology Center, San Marcos, TX*

Learning Overview: After attending this presentation, attendees will have learned how taphonomic processes, diagenesis, and cleaning protocols can influence the strontium and lead isotope ratios recovered from human bone, dental elements, and scalp hair and the subsequent implications for forensic investigations using isotope analysis. Further, this presentation will provide recommendations on which human tissues to target for forensic isotope analyses for provenancing purposes.

Impact Statement: This research aims to contribute to the forensic science community by examining how taphonomic processes and diagenesis affect the recoverability of pre-burial isotope ratios in different human tissues. This presentation highlights the need for research into the effects of these processes on human samples frequently consulted in forensic investigations. This presentation will also caution the scientific community to further examine the effects of cleaning procedures on isotope signatures recovered from human tissues.

This presentation presents the results of a small-scale study on the effects of taphonomic processes and diagenesis on the strontium and lead isotope signatures of human scalp hair, human bone (iliac and tibia), and tooth enamel and dentin. The pre-placement and post-recovery Strontium-Lead (Sr-Pb) isotope data of five whole body donations studied at the Forensic Anthropology Research Facility (FARF) were compared. Two donations were buried in shallow graves, two were placed in shallow open pits, and one was first allowed to naturally mummify through solar and aeolian desiccation and was then buried. In addition to pre- and post-burial human tissue samples, soil samples of each grave and one control sample from an unused part of FARF were collected.

The Sr-Pb analysis of the hair samples from four of the donors demonstrated that it is difficult to recover pre-placement isotopic Sr signatures from human hair.¹ The results showed significant shifts in Sr-Pb isotope compositions between pre- and post-placement samples. The hair keratin Pb isotope composition shifted toward the Pb signature of FARF soil samples. The Sr isotope compositions of the hair keratin samples, however, were affected by the burial environment, but possibly also by the applied cleaning method. The experiment showed that hair keratin is highly susceptible to diagenetic alteration, but also highlights the possible effects of pre-treatment on the isotopic authenticity of hair keratin.

The iliac samples (i.e., spongy or trabecular bone) show inconsistencies in the recoverability of the pre-burial Sr-Pb isotope signatures. While the post-burial signatures of the buried donations are only slightly elevated over the pre-burial signatures, the post-placement signatures of open pit donations are significantly elevated. This could potentially be related to the exposure of these body donations to periodic heavy precipitation and temporary submerging during the experiment. Contrarily, burial in the clay-rich soil at FARF appears to have prevented this from happening in donations buried in shallow graves.

In contrast, the tibia and tooth enamel and dentin samples showed the most consistency out of all human samples used in this study, demonstrating less susceptibility to diagenesis compared to the hair and iliac samples. These more densely mineralized elements show good recoverability of the pre-placement isotope signatures in both burial and open pit contexts, and are thus deemed useful for usage in forensic investigations at least until three years after burial in similar environmental and climatological conditions.

In conclusion, this presentation highlights the need for continuous research into the effects of taphonomic processes, diagenesis, and cleaning protocols on Sr-Pb isotope compositions in human samples frequently consulted in forensic investigations. Based on this and previous studies, it is not recommended that human hair and/or spongy bone samples be used for Sr-Pb isotope analysis for provenancing purposes in cases involving buried individuals.

Isotope Analysis, Diagenesis, Human Tissue Samples

A46 The Reliability of Bone Features Commonly Used to Predict Saw Class Characteristics

Alexandra Klaes, PhD, Washburn University, Topeka, KS; Ashley Maxwell, PhD, Washburn University, Topeka, KS; Heather Garvin, PhD, Washburn University, Topeka, KS; Erin Chapman, PhD, Erie County Medical Examiner, Buffalo, NY; Lauren Butaric, PhD, Des Moines University, Des Moines, IA*

Learning Overview: After attending this presentation, attendees will understand the reliability of bone features that are used to predict inflicting tool type and saw class characteristics in sharp force trauma cases.

Impact Statement: This presentation will impact the forensic science community by testing whether or not commonly scored saw cut features found in bone can be reliably scored.

Determining saw class characteristics is dependent upon the macro- and microscopic analysis of features in cut bone. The entire suite of features present in a case is then used to predict class characteristics of the saw blade and teeth, such as power source, tooth set/size/shape, blade progress and direction, and/or inflicting tool type. While several studies have described these features, albeit often inconsistently, very few have tested the reliability of scoring these traits in cut bone.

To examine reliability, nine manual ($n=4$) and mechanically ($n=5$) powered reciprocating saws with variable class characteristics were used to create experimental complete ($n=27$) and incomplete ($n=18$) cuts in the long bones of a fleshed cadaveric sample ($n=5$ individuals), thereby mimicking actual saw trauma cases. Following cutting and processing, each cut surface was given a unique randomized identification number to facilitate blind analysis. Two observers, with varying experience levels and not involved in the saw selection, cutting, or labeling/identifying, blindly scored each cut using a digital microscope with 3D capabilities. Each observer scored 13 features: breakaway notch, breakaway spur, exit chipping, entrance shaving, kerf flare, kerf shape (letter/number in incomplete cut sample only), false starts/incomplete cuts (scored incomplete cut sample only), harmonics, striation uniformity, polishing, pullout striations, tooth hop, and tooth imprint. Percent agreement was used to compare agreement between the observers.

Overall, reliability varied considerably by feature. Agreement was high ($>85\%$) for presence of false starts/incomplete cuts (92.3%), breakaway spurs (88.9%), and exit chipping (85.3%). Scoring agreement was lower ($<85\%$) for kerf flare (82.6%), pullout striations (72.7%), polishing (71.1%), breakaway notches (70.4%), harmonics (70.3%), tooth imprints (68.8%), tooth hop (66.7%), entrance shaving (65.9%), striation uniformity (60.5%), and kerf shape (46.7%). When disagreement occurred for entrance shaving, the more experienced observer scored more as present, while the less experienced observer scored more as absent. The opposite was true for disagreements on presence/absence of polishing. Nearly all of the disagreement on harmonics presence/absence occurred in incomplete cuts (90.9%). For tooth hop and tooth imprints, higher agreement was obtained in the incomplete cuts than the complete cuts primarily from agreeing upon absence of the features. Over half of the disagreements on kerf shape occurred between shape A versus shape B.

The results of this study suggest that some features used in the analysis of saw trauma can be reliably scored and, therefore, can be used to predict class characteristics of the inflicting tool; however, the vast majority of the features ($n=10$) examined here had low levels ($<85\%$) of observer agreement. Scoring inconsistencies means these features should be used with caution at present when applied to differentiating power source, tooth set, tooth shape, and/or tool type of the inflicting weapon. More research with a larger sample size is needed to confirm their reliability and utility in analyzing saw trauma to bone.

Trauma Analysis, Sharp Force Trauma, Saw

A47 A Retrospective Analysis of Scavenging in Southern Nevada Forensic Anthropology Cases (2000–2021)

Katharine Woollen, MS, University of Nevada-Las Vegas, Las Vegas, NV; Jennifer Byrnes, PhD, University of Nevada-Las Vegas, Las Vegas, NV*

Learning Overview: After attending this presentation, attendees will better understand vertebrate scavenging patterns of human remains from southern Nevada.

Impact Statement: This presentation will impact the forensic science community by providing an understanding of vertebrate scavenging, including prevalence, scavenger-type, and commonly impacted skeletal elements of human remains recovered across southern Nevada.

The Mojave Desert spans southeastern California and southern Nevada, with smaller portions within Utah and Arizona. This desert is considered the smallest and driest in the United States, exposing human remains to unique taphonomic processes in this harsh environment. One such taphonomic process is vertebrate scavenging. To date, no other forensic analysis has been conducted to explore the taphonomic patterns of vertebrate scavenging in southern Nevada. Coyotes, kit foxes, gray foxes, domestic dogs, bobcats, mountain lions, and domestic cats are among the most common carnivore scavengers in southern Nevada. There are several species of rodents as potential scavengers in this region as well, including the deer mouse, mice, rats, squirrels, and chipmunks. Carrion avian species in southern Nevada include various species of owls, falcons, and hawks, as well as turkey vultures, golden eagles, and bald eagles.

This presentation will offer an analysis of forensic anthropology case files from 2000–2021, which were reviewed for documentation of scavenging from the Clark County Office of the Coroner and Medical Examiner's Office (CCOCME) database. Of the 107 forensic anthropology cases reviewed, 30 cases (28%) had documented evidence of vertebrate scavenging. This included tooth pits, punctures, scores, and furrows attributed to carnivore dentition, as well as shallow scoring from vultures, and furrows created by rodents. The most commonly scavenged skeletal elements included the lower extremities (e.g., femora, fibulae, and tibiae), radii, ribs, and skull. These body regions, such as the thorax and long bones, are easy to grasp and provide access to high fat content, which is consistent with carnivore scavenging patterns. The least common body region with skeletal traces of scavenging were the hands, feet, sternum, and vertebrae. However, these least-scavenged skeletal elements are also the body regions most often missing from recovered cases. It is unknown if these body regions were consumed and/or carried off through scavenging activity, or if the skeletal elements were not recovered due to other taphonomic processes (e.g., weathering) since they are primarily small and/or high trabeculae bones. Comparative research conducted in the Sonoran Desert found that the small bones of the hands and feet are the least likely skeletal elements to preserve. Vulture scavenging data at the Forensic Anthropology Center at Texas State (FACTS) resulted in the skull and mandible being the first skeletal elements to be disarticulated. While these comparative data offer valuable insight into possible vertebrate scavenging patterns for southern Nevada, it is apparent that scavenging patterns in similar geographic areas, as well as at controlled facilities, are highly variable.

Scavenging, Southern Nevada, Forensic Taphonomy

A48 Testing Blade Set Width Prediction From Minimum Kerf Width Using Fleshed Human Samples

Alexis VanBaarle, BA, Des Moines University, Des Moines, IA; Ibrahim Mustaly, MS, Des Moines University, Des Moines, IA; Lauren Butaric, PhD, Des Moines University, Des Moines, IA; Heather Garvin, PhD, Des Moines University, Des Moines, IA*

Learning Overview: After attending this presentation, attendees will have a better understanding of the accuracy and challenges in predicting saw blade set width from minimum kerf widths.

Impact Statement: This presentation will impact the forensic science community by presenting error rates for published blade width prediction equations.

In cases of dismemberment, saws often leave characteristic markings in bone that can provide evidence about the utilized tool, thereby facilitating investigations and impacting legal proceedings. One such characteristic, minimum kerf width, has been suggested to be a direct indicator of saw blade width. However, variables such as tissue presence, sawing methodology, and saw characteristics potentially impact minimum kerf width and consequently predicted blade width. This study aimed to test four previously published equations/rules for estimating saw blade width from minimum kerf width using a human cadaveric sample with intact soft tissue and a free sawing methodology that likely mimics actual forensic scenarios. Cadaveric samples were obtained through the Des Moines University Body Donor Program and the research was conducted with university approval following established Body Donor Program protocols.

Three hand saws and five mechanically powered reciprocating saws were used to create 48 measurable incomplete cuts in 20 limb segments (i.e., arm, forearm, thigh, leg) from five donors, taking care to vary the saws by limb segments and position along the diaphyses. Minimum kerf width was measured and collected using sliding calipers for each incomplete cut and compared to two equations presented by Norman et al. to predict blade set width, as well as blade width general rules presented by Symes and Cunningham and Holtrop.¹⁻³

Supporting the Symes Rule, all blade set widths were within 0.02in (0.508mm) of the minimum kerf width. All minimum kerf widths were also less than 1.5x the blade set width, as suggested by Cunningham and Holtrop. Both of the Norman equations underestimated blade set width across the sample with an average absolute difference between the predicted and true blade set width of 0.40mm (both equations). Given the systematic underestimation, the predicted values were then compared to blade spine width measurements, which resulted in more balanced and accurate predictions (0.14mm average absolute difference). Through personal communications, however, Norman confirmed that blade width was measured at the cutting edge, and thus the higher accuracy with blade spine width is just a byproduct of spine width being less than blade set width. Despite small absolute differences, the percent error rates are high (27% average for blade set and 16% for blade spine) due to the relatively small size of kerfs. There was no pattern in accuracy for either equation across saw power type or teeth-per-inch. This study highlights the possible effects of soft-tissue presence and restraint conditions on minimum kerf width and the need for further testing in these conditions. Additionally, with such small measurements, even minimal rounding errors or measurement variability related to specimen modality, measurement tool, or measurement location can produce significant impacts on estimations—the effects of which need to be better understood when interpreting tool mark characteristics/measurements.

Dismemberment, Sharp Force Trauma, Saw

A49 The Evaluation of the Transition Analysis 3 (TA3) (Beta Ver. 0.8.0) Age-Estimation Program Using Two International Samples

Sara Getz, PhD, University of Wisconsin-Platteville, Platteville, WI; Jacqueline Galimany, MA, Santiago, RM, Chile*

Learning Overview: After attending this presentation, attendees will understand the current capabilities and limitations of the TA3 program.¹

Impact Statement: This presentation impacts the forensic science community by presenting the first systematic validation study of TA3 and contributing to ongoing method development using the TA3 traits.

In 2014, National Institute of Justice (NIJ) grant #2014-DN-BX-K007 was awarded for the development of an age-at-death estimation method using a suite of traits combined in a new analytical framework. In 2018, a reference dataset containing TA3 trait data for more than 1,700 documented individuals from four continents was completed. Although method and software development are ongoing, a version of the TA3 program has been released for public testing.¹

The current program uses machine learning—a different approach for estimating age than the TA2 (ADBOU) software. For each case, a Random Generalized Linear Model (RGLM) predictor is trained using a portion of individuals in the TA3 reference sample and applied to generate an age estimate. The performance of the model in the training sample is visualized in a scatter plot and the sample size, correlation coefficient, and standard error are provided, along with the predicted point age estimate and 95% interval for the case analyzed.

In this study, 511 individuals from the University of Athens Human Skeletal Reference Collection ($n=202$) and Santiago Subadult Osteology Collection (SSOC) ($n=309$) were evaluated using the TA3 Trait Manual.² For estimating age, the TA3 program (beta Ver. 0.8.0) software interface and the source code were tested and explored by: (1) directly entering data into the software; and (2) executing the ta3.R analysis file modified into a loop to allow for batch analysis and extraction of associated analytical data.

Overall sample accuracy (documented age within the 95% interval) was 84.5%; however, critical differences exist for individuals under 40 years (57.0%, 73/128) versus those 40 years and older (93.7%, 359/383). Substantial age-estimation bias was present in the predicted point estimates with essentially all individuals (125/128) under 40 years overestimated by an average of 12.2 years. Between 40 and 80 years of age, a mix of over- and under-estimation occurred, with a slight trend of increased underestimation with advancing age. Precision (95% interval width) for individuals under the age of 40 was poor (average 27.4 years), while precision for individuals 40 years and older was similar to other age-estimation methods (average 36.9 years).

These patterns are distinct from those found combining TA3 traits using a transition analysis framework, which indicates issues with the analytical approach used, and not the TA3 trait reference data.³ Most importantly, RGLM requires that individuals with missing data be removed from the reference sample to generate a training set that contains only individuals with all traits entered for the unknown case. This results in an inverse relationship between number of traits scored and size of the sample used to train the age-estimation model. Moreover, the demographic details of the training sample, which contains only a subset of the TA3 reference sample, are not available. Additional problems with the interface and source code were also identified; however, none were found to have significant effects on these results.

Based on these results, the current TA3 program is inappropriate for forensic or archaeological contexts and should be modified before stable release. As the TA3 traits have demonstrated potential to improve age estimation, additional analytical approaches that utilize the full TA3 reference dataset should be evaluated.

Data collection was partially funded by National Science Foundation Doctoral Dissertation Research Improvement Grant (NSF DDRIG) Award #1455810 and an Forensic Sciences Foundation, Inc. (FSF) Field and Lucas Research Grant.

TA3, Age-at-Death Estimation, Skeletal Biological Profile

A50 A Test of Anthropological Accumulated Degree Day (ADD) Methods of Postmortem Interval Estimation on an Iowan Autopsy Sample

Natasha Andersen, University of Iowa, Iowa City, IA and Iowa Office of the State Medical Examiner, Ankeny, IA; Emily Archibald, Iowa Office of the State Medical Examiner, Ankeny, IA, and Valparaiso University, Valparaiso, IN; Taylor Brown, Iowa State University, Ames, IA and Iowa Office of the State Medical Examiner, Ankeny, IA; Hannah Spencer-Greathouse, BA, Iowa Office of the State Medical Examiner, Ankeny, IA and Simpson College, Indianola, IN; Jonathan Thompson MD, Iowa Office of the State Medical Examiner, Ankeny, IA; Heather Garvin, PhD, Des Moines University, Des Moines, IA*

Learning Overview: After attending this presentation, attendees will have a better understanding of how two published anthropological methods of estimating postmortem interval from ADD perform on United States forensic cases in the state of Iowa.

Impact Statement: This presentation will impact the forensic science community by presenting accuracy rates for published methods, which can be used to assess method applicability in areas with similar climates and environments.

Megyesi et al. and Moffatt et al. are two of the most commonly utilized published methods for estimating postmortem interval in forensic anthropological cases.^{1,2} The methods involve scoring the level of decomposition of three body regions (head and neck, trunk, and limbs) to develop an ADD estimate, then working backward from the date found to total up the average daily temperatures until the ADD estimate is reached, which is considered to be the point estimate for the date of death. Both methods also present 95% prediction intervals for estimates. Previous studies report variable results when applying these methods to cases or samples at decompositional facilities, with many expressing the need for region-specific formulae, given variability in climates and environments. This study aimed to test the accuracy of these two methods when applied to an Iowa forensic sample.

Seventy-one cases from the Iowa Office of the State Medical Examiner were identified for inclusion in the study. Only those cases in which decedents were found indoors (with recorded thermostat data) or outdoors on terrestrial surfaces were included. Signs of decomposition had to be evident and investigative documentation had to support the date of last contact as the likely date of death. The Megyesi and Moffatt methods were employed, scoring decomposition from scene and autopsy photographs, and using local national weather service temperature data to calculate ADDs. Accuracy of the methods was assessed based on percentage of cases that fell within the 95% prediction intervals and deviations between the method point estimates and presumed date of death.

Sample decomposition total body scores range from 4–30 (Megyesi) and documented postmortem intervals ranged from 0 to 255 days, although the sample is biased toward lower total body scores (Megyesi average=13, median=4) and shorter postmortem intervals (average=12 days, median=11 days). The Megyesi method is more accurate with 94.4% of the cases falling within the prediction interval as compared to 71.8% with the Moffatt method. The point estimates for the Moffatt method, however, are closer on average to the presumed date of death, with 10 cases with perfect point estimates and an average absolute difference of 13 days, as compared to 7 perfect point estimates and an average of 16 days for Megyesi. The Megyesi prediction intervals are significantly broader than the Moffatt intervals, thereby limiting utility, but the need for accuracy in forensic cases outweighs the desire for precision. Additional analyses are being performed to assess whether type/amount of clothing, sun exposure, environment, body size, or season of deposition can explain some of the variance observed.

Forensic Anthropology, Time Since Death, Decomposition

A51 Assessing Patterns of Moisture Content in Decomposing, Desiccated, and Mummified Tissue in the Southeastern United States: Trial 1 Data

Christine Bailey, MA, Cleveland Museum of Natural History, Cleveland, OH; Autumn Lennartz, MA, Argument-Driven Inquiry, Austin, TX; Maggie Klemm, Western Carolina University, Cullowhee, NC; Cameron Privette, Western Carolina University, Cullowhee, NC; Carter Unger, Western Carolina University, Cullowhee, NC; Rebecca George, PhD, Western Carolina University, Cullowhee, NC*

Learning Overview: After attending this presentation, attendees will understand patterns of desiccation observed in Western North Carolina between March 2021 and August 2021 and how these preliminary data compare to the findings of previous research.¹

Impact Statement: This presentation will impact the scientific community by providing regional data of desiccation and mummification observed in an area that is classified through Köppen-Geiger as a warm-temperate, fully humid, warm summer (Cfb) region.² Additionally, this study provides a direct comparison to the study conducted by Lennartz and colleagues in central Texas in 2020.¹

Medicolegal death investigators and forensic anthropologists are often asked to estimate the Postmortem Interval (PMI) of unknown remains. Accurately estimating PMI is a difficult task, particularly when remains are desiccated or mummified. Desiccation refers to the general moisture loss in tissue, while mummification is the point at which decomposition and decay are suspended.³ Understanding the patterns of desiccation and mummification in different regions can inform PMI estimates and improve methods used to generate them. The goal of this study is to observe natural mummification, with particular attention paid to the sequence and rate at which it occurs in the southeastern region of the United States as compared to those in central Texas.¹ The research presented here originates from the first trial of the mummification study.

This project is occurring at Western Carolina University's (WCU) Forensic Osteology Research Station (FOREST). Three donors from WCU's Body Donation Program were enrolled in the first trial of this study (March 2021–August 2021). It was not possible to enroll additional donors as the research model stipulates donors be placed at a similar time due to weather and seasonality and there were no additional donors within this period to the Body Donation Program. Prior to placement, enrolled donors underwent an "intake" procedure where baseline moisture measurements, using the Delmhorst® RDM-3TM moisture meter with 22-E electrodes, and initial photos of the head, torso, and extremities were recorded. Twenty data points were collected for each donor daily, excluding weekends and inclement weather days, until all points were assessed as "inaccessible" due to skeletonization. A HOBO® remote weather station recorded hourly rain, temperature, solar radiation, and relative humidity. The data collected were graphically represented in a scatterplot that utilized Accumulated Degree Days (ADD) as a standardized time scale. In order to more accurately capture the curve of moisture loss, a Locally Weighted Scatterplot Smoothing (LOWESS) curve was added.

The relative moisture contents of the first trial individuals had conditional and marginal R² values ranging from 0.508–0.555, suggesting that 51–56% of the variation in moisture content was attributed to fixed (environmental) effects. Multi-level modeling of these fixed effects on each body region demonstrated that temperature has the greatest influence over moisture content with a fixed effects coefficient of -6.052, humidity and precipitation having less significant influence on moisture content with fixed effects coefficients of 0.635 and 0.275, respectively. Finally, solar radiation was not found to have a significant effect on moisture content, with a coefficient of 0.011.

The results of this trial correspond with those of Lennartz and colleagues in central Texas where the data demonstrated that environmental effects contributed to 50–55% of the variation in moisture content.¹ However, the data from this trial do not display an asymptotic relationship, which was observed in central Texas, and none of the donors in this study reached true mummification. The continuation of this study will examine if these trends persist or if seasonality impacts desiccation and mummification differently in the southeastern region of the United States. This preliminary data, however, do demonstrate that, despite regional differences in patterns of desiccation, there may be similarities in how environmental effects contribute to processes of mummification.

Postmortem Interval (PMI), Decomposition, Mummification

A52 The Perimortem Trauma Pattern in Human Rights Violations: Comparative Case Studies From Spain, Cambodia, and Argentina

Raffaella Minella, MSc, Liverpool John Moores University, Liverpool, England, United Kingdom; Constantine Eliopoulos, PhD, Liverpool John Moores University, Liverpool, England, United Kingdom; Matteo Borrini, PhD, Liverpool John Moores University, Liverpool, England, United Kingdom

Learning Overview: After attending this presentation, attendees will be informed about the potential of an anthropological approach to investigating mass graves from totalitarian regimes: Franco's Spain, Khmer Rouge, and Argentina's Guerra Sucia.

Impact Statement: This presentation will impact the forensic science community by reviewing how the scientific excavation of mass graves may serve different purposes in the collective rebuilding processes in the aftermath of violent conflicts and the critical role that forensic disciplines play.

On a global basis, violence has been directed against the victims for various reasons and in different manners and degrees, mainly depending upon socio-cultural practices and political ideology.¹ The late half of the 20th century has been characterized by an increase of incidents of genocide taking place around the world. Only in 1948 did the United Nations Genocide Convention first defined genocide as “the intent to destroy, in whole or in part, a national, ethnical, racial or religious group, as such.”

Genocidal practices are often associated with mass graves to conceal the crime and prevent individual identification, and forensic anthropology, along with other disciplines, has played a key role in investigating the systematic violation of human rights during armed conflicts and genocide.² The excavation of mass graves can help in the aftermath of genocides by providing closure for surviving families and successfully prosecuting those responsible for the crime.

This work presents a comparative study of three cases from totalitarian regimes responsible for committing gross human rights violations: Franco's Spain (1936–39), Khmer Rouge (1975–79), and Argentina's Guerra Sucia (1976–83). The purpose was to consider whether a pattern could be discerned in relation to the traumatic mechanism recorded by the skeletons and the demographics data of the victims.

The sample consists of 2,875 individuals: 1,762 of the Spanish Civil War, 643 of the Khmer Rouge Regime, and 470 for Argentina. The majority of victims appear to be male, aged between 20–35 years old. Although only a few studies mention the type of trauma inflicted, thus creating a bias for the overview, the most frequent cause of death was due to projectile trauma. The comparison between the three cases illustrates how dissimilar political beliefs can all be accomplices in unimaginable violence and crimes against humanity, despite the different contexts and manners in which they occurred. In addition, this research addresses some of the issues with finding scientific information and published literature on the matter.

The present research underlines the crucial contribution of forensic anthropology in analyzing cases of violation of human rights and mass grave investigations. The value of the discipline is represented by the exhumations and identifications that achieve reconciliation for the relatives of the victims, consequently accomplishing the search for truth and justice. The contribution has been quite evident in the cases presented, whereas great awareness has been raised about the rights of victims and their families.³

Forensic Anthropology, Human Rights Violation, Trauma Analysis

A53 The Differences in Fracture Healing Based on Fracture Classification in Young Children (Less Than 6 Years of Age)

Diana Messer PhD, Western Carolina University, Cullowhee, NC; Andrielle Finch, Western Carolina University, Cullowhee, NC*

Learning Overview: After attending this presentation, attendees will recognize differences in fracture healing between humeral fracture types in young children.

Impact Statement: This presentation will impact the forensic science community by presenting evidence of the effect of fracture type on healing in young children and discussing implications for time since injury estimation in cases of suspected abuse.

Young children are most vulnerable to death resulting from physical abuse.¹ Certain fracture types and locations, such as humerus fractures without a known mechanism of injury and that are not immediately treated, are concerning for abuse.² Identification of such abuse may rely on accurate time since injury estimation of the healing fracture. Despite the influence of multiple factors on the healing process, including fracture type and fracture location, timelines of fracture healing are often applied universally.³ The objective of this preliminary study was to examine the effect of fracture type on fracture healing in a sample of young children.

This retrospective review examined children five years old or younger radiographically evaluated for an unintentional humeral fracture at a pediatric level I trauma center between 2000–2016. Exclusion criteria included: (1) obscured casted radiographic exams, (2) unknown injury date, (3) individuals with bone disorders, and/or (4) fractures requiring instrumentation. Features of fracture healing (Subperiosteal New Bone Formation [SPNBF] and callus formation) were evaluated from initial and follow-up radiographic exams. Determination of fracture type was made by a medical professional and reported as written in the medical record. Analysis of fracture type was limited to the three most common within the dataset: transverse, spiral, and oblique.

Seventy-two humeral fractures were analyzed from 72 children (males: 35, females: 37). Of these, 41.6% (30) were infants one year or younger. A total of 232 radiographic exams were analyzed, with an average of 3 post-injury exams per child, and an exam range of 0 to 92 days (mean: 19 days); 93.1% (67) of fractures were complete and 55.6% (40) were diaphyseal. More than half the fractures were classified as transverse (58.3%, 42).

Across all fracture types, SPNBF and callus was present by three weeks post-injury. Analyses of Covariance (ANCOVAs) were performed to determine the effect of fracture type on fracture healing, controlling for child age. Post hoc analyses were performed with a Bonferroni adjustment. After adjustment for child age, there was no significant difference in first observation of SPNBF ($p=0.955$). However, there was a statistically significant difference in first callus observation ($p=0.052$), with oblique fractures observed earlier than transverse or spiral fractures (mean difference: 5 days). When all recorded observations were evaluated, there was no statistical difference based on callus type (soft $p=0.914$, intermediate $p=0.132$, hard $p=0.841$). For intermediate and hard callus, there was a mean difference of between 5–6 days.

These results suggest that callus may form earlier in some fracture types than others. A five-day difference in appearance may have repercussions for identification of abuse in a forensic context or child protection in a clinical case. Increased sample sizes would improve statistical robusticity.

The results of this preliminary study may impact analysis and interpretation of healing fractures in cases of suspected abuse. Understanding the basic factors that influence fracture healing will ultimately lead to improved methods to estimate fracture age.

Fracture Healing, Child Abuse, Time Since Injury

A54 Histological Differentiation of Burnt Cortical Bone in Northeast Ohio Mammals

Evin Hessel BSc, The University of Akron, Akron, OH; Mary Cole PhD, Skeletal Biology Research Laboratory, Injury Biomechanics Research Center, The Ohio State University, Columbus, OH; Anna Andronowski, PhD, Memorial University of Newfoundland, St. John's, Newfoundland and Labrador, Canada*

Learning Overview: Following this presentation, attendees will have a basic understanding of how burning affects the microscopic structures of mammalian cortical bone and whether species differentiation can be made using qualitative and quantitative methods.

Impact Statement: This presentation will impact the forensic science community by illustrating how varying temperatures impact the visibility of cortical bone microstructure in burned mammalian bone. Microstructural products of remodeling, such as secondary osteon size and shape, are essential for distinguishing human from non-human bone in fragmentary remains.

A first step in the analysis of skeletal remains of unknown origin includes determining whether the remains are human or non-human. Attempts to destroy a body or circumstances surrounding death involving fire often result in small fragments of bone, making it difficult to apply gross morphological techniques to identify species origin. Previous studies, including Dominguez and Crowder, have shown that histologic techniques can be used to identify whether a bone is human or non-human.¹ Dominguez and Crowder previously demonstrated that mean osteon area and mean osteon circularity can distinguish unburned human ribs, humeri, and femora from the same elements of deer and dogs with high accuracy. This study expands this methodology to burned skeletal remains to determine whether histomorphometry remains useful for distinguishing human and non-human remains at varying burn temperatures. This study hypothesized that: (1) aspects of osteon morphometry can be qualitatively identified in burnt skeletal remains exposed to varying temperatures, and (2) histomorphometric parameters such as osteon area and circularity can be used to quantitatively determine species origin of burnt skeletal remains from a selection of Northeast Ohio mammals.

The study sample consisted of right femora, ulnae, and sixth ribs from a variety of Northeast Ohio mammals (e.g., canine, deer, pig, cow) commonly encountered in forensic casework, and one human cadaveric femur. One-cm sections were procured from the diaphyses to be used as controls while the remainder were burnt in ceramic crucibles at 600°C, 800°C, and 1,000°C for 20 minutes using a muffle-furnace. All sections were subsequently embedded in methyl methacrylate using a protocol developed by the Andronowski Lab and ~150µm-thin sections were procured using a Well® Diamond Wire saw and mounted with Eukitt® mounting medium. Sections were visualized under brightfield at 100x using an Olympus® BX51 microscope, and overlapping images were acquired with cellSens® Entry software (v.1.16). Adjacent images were photomerged into a single image of the entire cross-section using Microsoft® Image Composite Editor (v.2.0.3.0) and Adobe® Photoshop® 2020. Morphometric analyses were performed in ImageJ (v.1.53k).

Preliminary qualitative results indicated that typical cortical histomorphometry is maintained at 600°C, including primary and secondary osteons, cement lines, osteocyte lacunae, vascular pores (Haversian canals), and cross-sectional geometry. The 600°C specimens revealed darker and more defined cement lines compared to controls. Collagen fiber orientation is also visible in 600°C specimens in primary and secondary bone under linearly polarized light, although not to the degree typical of unburned bone. This tissue histomorphometry is obliterated at 1,000°C, however, leaving only the spaces that characterize vascular pores and cross-sectional geometry as viable variables. This suggests a threshold of burn temperature for applying the Dominguez and Crowder method for distinguishing human and non-human remains, which requires distinguishable secondary osteons.

Results of this work potentially provide a new method of species determination in burnt bone, leading to the identification of fragmented burnt bone in a forensic context.

Histology, Forensic, Cortical Bone

A55 Testing the Use of Bone Weathering to Estimate the Postmortem Interval (PMI) on Forensically Relevant Bone in an Arid Environment

Joyce Chu*, Colorado Mesa University, Grand Junction, CO; Alexander Smith, BA, Colorado Mesa University, Grand Junction, CO; Melissa Connor, PhD, Colorado Mesa University, Grand Junction, CO

Learning Overview: After attending this presentation, attendees will be able to understand the limitations of using bone weathering to estimate PMI on human skeletal remains as well as understanding how complex environmental variables impact the temporal trajectory of bone weathering patterns.

Impact Statement: This presentation will impact the forensic science community by demonstrating that regional and microenvironments impact bone weathering patterns, making their use in the estimation of the PMI challenging.

Bone weathering is the process in which both the organic and inorganic elements of a bone separate and are destroyed by physical and chemical external factors *in situ*. Behrensmeyer's seminal work developed a Likert scale for weathering patterns seen on bones, associating each stage with a PMI estimate.¹ This scale continues to be cited in recent research and textbooks as a measure for PMI in forensic cases.²⁻⁴ However, observations at Colorado Mesa University's Forensic Investigation Research Station (FIRS) in Whitewater, CO, suggested that, in that environment, bone weathering rates may not follow the published literature.

The FIRS is a human decomposition taphonomic facility located in western Colorado, on the eastern portion of the Colorado Plateau. The facility is situated at an altitude of 1,457m Above Mean Sea Level (AMSL) in a semiarid steppe environment with relatively high solar radiation. The area generally receives less than 24cm of rain, and approximately 19cm of snow per annum. Remains generally desiccate and tissue may remain for years.⁵

To examine the relationship between bone weathering and PMI, a stratified convenience sample of 24 skeletons was selected based on PMI from the donated human skeletal collection at the FIRS. The PMI of the selected individuals ranged from 270 days to 1,768 days. Each skeletal element was scored using Behrensmeyer's stages and descriptions.¹ Smaller bones in the hands and feet were excluded as per Behrensmeyer.¹ Impacts to the bone from pathology and trauma were characterized and those skeletal elements excluded from data. A score for each skeleton was determined using the criteria of most advanced stage covering more than 1cm².¹ It was hypothesized that solar radiation may impact bone weathering as others have noted sun bleaching and solar radiation as causes of accelerated bone weathering.³⁻⁴ Hourly solar radiation levels measured from an on-site weather station were used to calculate Accumulated Solar Radiation Days (ASRD). Both PMI and ASRD were compared with the maximum weathering scores. The sample exhibited stages 0-4 of Behrensmeyer's stages. Stage 5 was not present in the sample. The results were analyzed with a linear regression model and chi square test of independence.

In this sample, both PMI and ASRD have only a weak correlation with the maximum weathering scores. The data suggest that there is no significant association between PMI or ASRD and bone weathering, indicating that the amount of bone weathering is not related to either variable in this environment. Behrensmeyer's stages of bone weathering, although excellent in the descriptions of bone weathering stages, should not be used for estimation of PMI in forensic cases as environment and other factors impact the trajectory of bone weathering.

Taphonomy, Bone Weathering, Postmortem Interval (PMI)

A56 Serrated Versus Non-Serrated Blade Class Interpretation: An Interactive Survey

Miriam Soto Martinez, PhD, Harris County Institute of Forensic Sciences, Houston, TX; Julie Fleischman, PhD, Harris County Institute of Forensic Sciences, Houston, TX; Jason Wiersema, PhD, Harris County Institute of Forensic Sciences, Houston, TX; Deborrah Pinto, PhD, Harris County Institute of Forensic Sciences, Houston, TX*

Learning Overview: The goal of this presentation is to assess forensic practitioners' familiarity with blade class interpretation resulting from Sharp Force Trauma (SFT), and to collect survey data to establish baseline factors that may influence the accuracy of these analyses.

Impact Statement: This presentation will impact the forensic science community by highlighting the challenges associated with blade class interpretation and demonstrating how blade characteristics influence the appearance of striation patterns on cartilage.

SFT analysis and interpretation have been extensively studied, particularly saw marks and blade kerf characteristics, and are recognized as a valuable tool in the forensic anthropology toolkit. However, the current knowledge base for adequately and accurately conducting such analyses remains insufficient. The variation in striation patterns imparted by non-serrated blades is largely unknown, potentially resulting in a misidentified or indeterminate blade class interpretation. This gap in knowledge is primarily based on the medium used for research. Most SFT studies use bone as a testing medium, limiting the appreciation of the range of variation in striation pattern produced by blades. Cartilage, in contrast, is a firm but compliant tissue with the potential to record a level of blade detail that bone cannot. Non-serrated blades may be coarsely milled and/or have defects along the cutting edge that are observable on cartilage but not bone.

Few studies have examined blade kerf characteristics using cartilage as a testing medium. A case study by Rao and Hart described the identification of a suspected blade by comparing the victim's costal cartilage kerf striation patterns to casts of the blade and test kerfs made in porcine costal cartilage.¹ Pounder et al. evaluated differences in kerf striation patterns in non-human costal cartilage imparted by serrated and non-serrated blades, but primarily focused on patterns imparted by serrated blades.² Finer striations associated with blade edge imperfections were occasionally observed, but these differences were not presented photographically.²

The aforementioned studies suggest that striae imparted by serrated blades can be readily differentiated from striae imparted by non-serrated blades. Kerf walls with a pattern of coarse striae or a mixture of coarse and fine striae that appear regularly spaced are generally interpreted as consistent with serrated blades (i.e., the serrated teeth leave coarse striations), and kerf walls with fine striae as consistent with non-serrated blades.^{3,4} However, the observed striation pattern may not definitively indicate either blade class resulting in an indeterminate blade class interpretation. Furthermore, studies examining the reliability of blade class estimation from kerf characteristics suggest there is considerable potential for misidentifying blade class based on kerf characteristics.^{4,5} Additionally, in this study's SFT case analyses (20–30 cases per year), distinguishing between serrated and non-serrated blades was found to be complicated by an array of factors, including blade quality and manufacturing variation.

This interactive presentation will assess the accuracy of blade class interpretation to generate baseline data regarding SFT analysis. Attendees of this presentation—primarily targeting forensic anthropologists and pathologists—will be encouraged to participate in an anonymous survey, accessible via Quick Release (QR) code, to evaluate their familiarity with blade class interpretation. Microscopic images of striation patterns on cartilaginous kerf walls and their associated casts (AccuTrans® casting medium) from six SFT cases analyzed at the Harris County Institute of Forensic Sciences will be provided to attendees to elicit interpretations. Blade class (i.e., serrated or non-serrated) for these cases were determined via review of scene/law enforcement photographs. Survey participants will choose from the following interpretations for each case: serrated blade/blade portion, non-serrated blade/blade portion, or indeterminate. A free text box will be associated with each response should the participant wish to provide an explanation. The following non-identifiable data will also be collected: (1) participant's forensic discipline/field; (2) education level; and (3) total number of cases in which the participant has evaluated blade class characteristics. These data will be used to ascertain what additional research and/or training is needed by forensic anthropologists, and possibly pathologists, to improve the accuracy and reliability of blade class interpretation.

A57 The Usefulness of Transmission Electron Microscopy (TEM) for the Estimation of the Postmortem Interval (PMI): An Analysis of Ultrastructural Autolytic Changes in the Osteocyte of Human Remains

Chiara Rossetti, MD, Department of Medicine and Surgery, University of Insubria, Varese, Italy; Cesare Garberi, Department of Biotechnology and Life Science, University of Insubria, Varese, Italy; Mario Picozzi, Department of Biotechnology and Life Science, University of Insubria, Varese, Italy; Jutta Maria Birkhoff, MD, PhD, Department of Biotechnology and Life Science, University of Insubria, Varese, Italy; Marcella Reguzzoni, Department of Medicine and Surgery, University of Insubria, Varese, Italy*

Learning Overview: After attending this presentation, attendees will know an innovative use of TEM for the estimation of PMI.

Impact Statement: The ultrastructural study of the postmortem modifications of the osteocyte, by TEM use, could provide useful results for the estimation of the PMI in the first three months from death.

The estimation of the PMI of human skeletal remains is one of the most important issues in forensic sciences. Although further analyses have been performed on human remains, the PMI evaluation can be very changeable and difficult, especially in decomposed or skeletonized remains. Therefore, it should be very important to investigate the progress of bone diagenesis. This could be possible through the ultrastructural study of the autolytic modifications of the osteocyte by techniques not widely used in forensic pathology, such as TEM.

In this work, fragments of I rib were taken from eight subjects, males, aged between 25 and 50 years, without metabolic pathologies, subjected to autopsy. Each fragment was placed in an empty box, then placed in a laboratory with steady temperature and humidity. From each sample, at certain time intervals (PMI: 24h, PMI: 1 month, PMI: 2 months; PMI: 3 months; PMI: 4 months; PMI: 6 months; PMI: 10 months; PMI: 20 months), small fragments of cortical bone were taken. After specific preparation, inclusion in epoxy resin and microtome cutting with a diamond blade (90-120nm) were performed. The samples were observed at TEM, focusing on the ultrastructure of the osteocyte, detecting the progressive degeneration of nuclear and cytoplasmic components.

At PMI 0 it was possible to observe well-preserved osteocytes, with walls well attached to the osteocyte lacuna, the presence of a nucleus with normal chromatin, the evidence of preserved mitochondria and extensions containing cytoplasm; however, the first signs of cellular autolysis were evident: the dilation of the perinuclear cistern, the fragmentation of the endoplasmic reticulum, the presence of ribosomes clusters, the precipitation of the glycocalyx, the swelling of the mitochondria; at PMI 1, the core begins to detach itself from the gap; in some osteocytes the chromatin was thickened, typical of a pycnotic nucleus; in other osteocytes, cariorexes and caryolysis had already occurred; residues of endoplasmic reticulum and ribosomes were evident; at PMI 2, some osteocyte lacunae show large masses of cytoplasmic debris; from PMI 3 to PMI 20, the lacunae appear almost empty with peripheral cytoplasmic residues in the canaliculi.

The ultrastructural study of the postmortem modifications of the osteocyte, by TEM use, seems to provide useful results for the estimation of the PMI. In particular, appreciable differences were noted between PMI 0, PMI 1, and PMI 2, while from the third month after death, lacunae appear almost empty. This result makes it possible to use the bone matrix also for the estimation of PMI very close to the time of death, a case of great forensic interest.

TEM, PIM, Ultrastructure

A58 The Effects of Thermal Alteration on Sharp Force Trauma in Human and Non-Human Skeletal Remains

Hailey Collord-Stalder, MA, Shasta County Coroner's Office, Redding, CA; Nicholas Herrmann, PhD, Texas State University, San Marcos, TX, USA*

Learning Overview: After attending this presentation, attendees will better understand the morphological changes that occur from various Sharp Force Trauma (SFT) toolmarks in burned human and *Sus scrofa* skeletal remains.

Impact Statement: This topic will impact the forensic science community by addressing the ability to recognize peri- and postmortem SFT in thermally altered human and *Sus scrofa* remains and approximate the type of tool from the trauma.

Thermal alterations to human and Non-Human (NH) research analogs have been extensively documented in the literature, but fewer studies have addressed how tool class is identified from trauma in morphologically altered burned remains.¹ Additionally, though forensic investigators deal with human remains in their casework, experimental research has been relatively limited to use of NH proxies, which show substantial differences in bone morphology and composition. Questions addressed by this research are whether tool class can still be assessed from SFT in burned human and NH skeletal remains using digital microscopy and whether pigs are an acceptable NH proxy in toolmark research.

Data were collected on the long bone and axial elements of a human donor ($n=19$) and one pig ($n=41$). A total of 216 controlled toolmarks using a flat-edge knife blade, a serrated-edge knife blade, a reciprocating saw, and a handsaw were produced on each of the human and NH skeletal elements; thereafter, half were subjected to controlled thermal alterations. Kerf width, depth, length, angle, and the presence of striae were analyzed using a digital stereomicroscope for a total of 175 toolmarks. Profiles of each kerf mark were turned into 3D, manipulatable models.

Kruskal-Wallis tests indicated that there are significant differences with the flat-edge maximum width measurements among the four groups ($H=8.737$, $df=3$, $p=.033$) and with reciprocating saw maximum width measurements among the four groups ($H=10.868$, $df=3$, $p=.012$). Mann-Whitney U-tests further indicated where the significant differences arose.

A chi-square test of independence with a post-hoc Cramer's V test indicated that there is no statistical significance between the control and burned samples in presence of striae for the reciprocating saw, and that there is a weak correlation among the variables ($\chi^2=0.865$, $p=0.352$, Cramer's $V=0.136$). The results for the handsaw additionally exhibit that there is no statistical significance between the control and burned samples regarding presence of striae, and that there is a weak correlation among the variables ($\chi^2=0.481$, $p=0.488$, Cramer's $V=0.107$). The Goodness of Fit test results for the striae with the reciprocating saw depict statistical significance ($\chi^2=26.064$, $p<.001$). The results for striae with the handsaw also depict statistical significance ($\chi^2=18.667$, $p<.001$).

A goal of this research was to estimate tool class from trauma in burned remains and to assess the appropriateness of using pigs as NH analogs in experimental thermal alteration and trauma research. The results indicated that tool class was still identifiable in the burned remains and there were no significant differences between the representations and morphological changes in the human and pig remains. Future research is needed to diversify the sample and shore up the limitations of the trauma-infliction method, loss of data due to destructive analyses and preparation of samples, and the loss of natural biomechanical differences during trauma infliction.

Forensic Anthropology, Thermal Alteration, Sharp Force Trauma

A59 Wounded to Death: A Paleo-Forensic Analysis of a Case of Multiple Sharp-Force Lesions From the Medieval Cemetery of San Biagio in Cittiglio in Northern Italy

*Chiara Tesi**, Centre of Research in Osteoarchaeology and Paleopathology, Department of Biotechnology and Life Sciences, University of Insubria, Varese, Lombardy, Italy; *Stefano Ricci*, Research Unit in Prehistory and Anthropology, Department of Physical Sciences, Earth and Environment, University of Siena, Siena, Tuscany, Italy; *Jacopo Crezzini*, Research Unit in Prehistory and Anthropology, Department of Physical Sciences, Earth and Environment, University of Siena, Siena, Tuscany, Italy; *Roberta Fusco*, Centre of Research in Osteoarchaeology and Paleopathology, Department of Biotechnology and Life Sciences, University of Insubria, Varese, Lombardy, Italy; *Chiara Rossetti*, Department of Medicine and Surgery, University of Insubria, Varese, Lombardy, Italy

Learning Overview: Through this presentation, attendees will have a practical example of how legal medicine and physical anthropology can interface in the paleo-forensic resolution of past violent events.

Impact Statement: This presentation will impact the forensic science community by presenting evidence of ancient violence and showing how new interpretative and accurate data can be obtained through the analysis of skeletal remains.

The experimentation and development of innovative approaches, aimed at reconstructing the dynamics of ancient violent episodes, could have a historic-archaeological and forensic relevance. Without prejudice to the ethical standards of treatment of human remains, thanks to the “non-urgency” of the resolution of the case, it is possible to dedicate an in-depth and accurate study, approaching with different innovative tools that, once tested, may even be useful in the more crucial field of legal medicine.

Paleoforensic and paleotraumatology investigations constitute a significant scientific channel able to trace the history and the spread of violence in the past. Human remains from archaeological contexts occasionally provide traces of traumatic injuries, shedding light on the degree of interpersonal violence of a population, on the weaponry and technologies available at that time, and on the occurrence of certain historic events. Today, thanks to the advancement of scientific technologies, we can fully understand the extent of a lesion in order to shed light on the occurrence of the trauma.

As the most vulnerable and targeted area of the body, the skull often retains clear signs of the wounding weapon. Among all the types of injury, sharp-force lesions are frequently found on the skeleton of victims of violence and are bearers of significant information on the causative implement and modalities of wound formation.

This study describes a case of traumatic injuries recorded in a skeleton recovered during archaeological excavations at the medieval cemetery of San Biagio in Cittiglio (Varese, northern Italy). Evidence of multiple sharp-force trauma was observed on the skull, representing a unique case of raw violence in the past of this rural population.

The analysis of multiple lesions displayed on the skull required a systematic multi-analytical approach, combining classic macroscopic examination, computer tomography, photographic 3D modeling, and 3D digital microscopy in order to study the morphological and morphometric features of the lesions, verify the nature of the injuries, the direction of infliction to the bone, and the kind of weapon used. In particular, digital microscopic observation was performed in order to build magnified 3D images of the surfaces, examine the micro-morphological features, and conduct thorough qualitative and quantitative analyses.

Through the systematic study of the lesions, from the macroscopic to the microscopic level, this study was able to understand the dynamics of each lesion and hypothesize the reconstructive sequence of the violent event that led to the death of the victim.

In this study, the application of digital microscopy proved to be a necessary and non-replaceable technical tool for the analysis of microscopic marks on bones since it enables the analysis of bone surface changes by reconstructing a virtual model of their microstructure, whose features can be quantified and compared, enhancing the interpretation of the osteoarchaeological evidence.

Osteoarchaeology, Perimortem Trauma, Medieval Violence

A60 Decomposition in the Desert: Testing the Validity of Using Accumulated Degree Days (ADD) and Total Body Scores (TBS) for Postmortem Interval Estimation in the Sonoran Desert

Kaitlyn Fulp, MA*, School of Mathematical and Natural Sciences, Arizona State University, Glendale, AZ; Jacob Harris, PhD, School of Mathematical and Natural Sciences, Arizona State University, Glendale, AZ; Katelyn Bolhofner, PhD, School of Mathematical and Natural Sciences, Arizona State University, Glendale, AZ

Learning Overview: After attending this presentation, attendees will understand the discrepancies in the application and utility of the ADD and TBS methods to postmortem interval estimation in a desert environment.

Impact Statement: This presentation will demonstrate that further geographically nuanced research in decomposition is critical to the development of a method for accurate, reliable estimates of postmortem interval.

The Sonoran Desert, which extends through southwestern North America and northern Mexico, presents unique environmental challenges both to sustaining life and to interpreting circumstances of death, particularly to assessing stages of decomposition and estimating the postmortem interval. Within a single month during the summer, temperatures have been documented to range between 58° and 124°F, with relative humidity as low as 7%.¹ In Arizona, this extreme climate is met with two growing populations who present a higher risk of heat-related deaths.² Maricopa County is part of the Tucson Sector of the United States-Mexico border, where more than 200 sets of remains belonging to known undocumented border crossers have been recovered since 1980.³ The city of Phoenix also has a homelessness crisis, with 25,832 reported homeless individuals in 2015.⁴ The vulnerability of these groups is further compounded by an increased likelihood for a longer interval between death and the recovery of the remains. An accurate postmortem interval estimate is critically important to the identification of deceased individuals in this region, thus the need to improve understanding of the progression and timing of decomposition in this environment is crucial.

The ADD method has been proposed as a means to estimate postmortem interval in forensic cases.⁵ This method incorporates scoring the visual stages of decomposition through TBS with daily weather data to produce a postmortem interval range. Since its publication, the method continues to be applied and validated, and attempts have been made to revise the method to make it more accurate and precise.

In this study, ADD was estimated using two adult porcine models (*Sus scrofa domesticus*). The models were placed in an area of natural desert near Phoenix, AZ, and allowed to decompose through the month of June. One model was placed in direct sunlight and the other in the shade of a tree. Photographs were taken at 30-minute intervals, and temperature and humidity readings were taken at 10-minute intervals throughout the study. TBS was scored using photographs each day for both specimens. On day 8, the TBS for the shade specimen was 21, and on day 7 the TBS for the sun specimen was 17. The TBS did not change for either specimen after this point in the study. Using the formula provided in the original ADD method, these scores represent 95% prediction intervals for a postmortem interval of 1-38 days and 1-30 days for the shade and sun specimens, respectively. These ranges are too broad to be applicable to a forensic case and are concerning with regard to the same postmortem interval estimation being presented at one week versus after 25 days. The ranges are also counter to expectations based on visual observations of decomposition, as the shade specimen progressed through the visual stages of decomposition more rapidly, but presented a higher TBS and postmortem interval range. For this study, the ADD method was not precise enough to provide a reliable postmortem interval range and did not accurately reflect the nuances of decomposition in this region, even in a period of intense macroscopic changes. Further studies are needed in this environment to better ascertain the relationship between the numerous variables that influence decomposition, the process of decomposition, and postmortem interval estimation.

Accumulated Degree Days, Postmortem Interval (PMI), Decomposition

A61 The Evaluation of Postmortem Interval (PMI) Using Collagenous to Non-Collagenous Ratios in Skeletal Remains: A Validation Study

Theresa De Cree, BA, Mercyhurst University, Erie, PA; Luis Cabo, MS, Mercyhurst University, Erie, PA

Learning Overview: After attending this presentation, attendees will better understand the applicability of collagen content measurements in determining the PMI.

Impact Statement: This presentation will impact the forensic science community by furthering research on determining time since death in forensic investigations.

Forensic anthropologists are called to assist in death investigations when remains are fully skeletonized or in an advanced stage of decomposition. Soft tissue changes are well documented and help to establish the short PMI, within a range of hours to a few days.¹ However, PMI becomes more difficult to establish as soft tissue becomes degraded or even absent. PMI estimation methods can utilize both intrinsic and extrinsic markers. For example, several estimation methods rely on external taphonomic agents and processes, such as insect colonization, while others rely on the intrinsic natural degradation process of bodily tissues. Bone collagen may be the most important of those tissue components at advanced PMIs, when bone is the only tissue remaining.

In this study, 17 male individuals ranging from 40–94 years of age and known PMI were utilized to investigate if collagen degraded at a predictable rate, through the measurement of Collagen to Non-Collagenous ratios (Co/NCo) in histological preparations of bone. The documented intervals ranged from 2 to 13 years at the time of staining. Success with this method was reported in Jellinghaus et al. on a sample of both modern and historical remains, the latter comprising PMIs outside the accepted timeline for forensic significance.² This study assessed the method on a larger, forensic sample.

Femoral samples were taken from each individual, thin sectioned, and stained with the Sirius Red fast Green Staining system from Chondrex.³ This is an easily accessible method that can be applied with and without microscopy. In this study, microscopy was utilized. Microscope images of the stained bone samples were analyzed for red- and green-stained relative area ratios in MATLAB®.⁴ Results revealed an apparent slight downward trend in the correlation between collagen ratios and PMI, but the relationship is not significant ($P=0.653$). A paired *t*-test was performed to compare the results of this study with those expected from the equations reported in Jellinghaus et al., finding significant differences ($P<0.001$).² The majority of the sample for this study was part of the donated body program at Mercyhurst University. In that program, individuals are macerated and bones are stored in the collection. During the maceration process, the tissue endures temperatures up to 400°F. Thus, the results could be explained by the denaturation of collagen at these temperatures during processing.⁵ This indicates that the method could not be applicable after standard bone processing. However, since no samples were stained completely green, if denaturation did occur, it was not total. Further research is required in this avenue.

The results showed a non-isometric relationship between the two parts of the utilized ratio, which would render the ratio transformation inappropriate for regression models such as the ones utilized by Jellinghaus et al. to develop their predictive equations.² Further studies utilizing unprocessed bone samples are necessary to confirm or reject this possibility.

PMI, Collagen, Bone Diagenesis

A62 Differences in Fracture Types, Locations, and Severity in Pre-, Peri-, and Post-Menopausal Women.

Danielle Delelio, BS, University of Nevada- Reno, Reno, NV; Kyra Stull, PhD, University of Nevada- Reno, Reno, NV; Laura Knight, MD, University of Nevada-Reno, Reno, NV and Washoe County Regional Medical Examiners Office, Reno, NV*

Learning Overview: After attending this presentation, attendees will have a better understanding of how the expression and location of blunt trauma varies throughout adulthood in females and its potential relationship to hormonal changes.

Impact Statement: This presentation will impact the forensic science community by creating a foundation for understanding how traumatic injuries vary through the female lifespan, which can inform practitioners by facilitating the interpretation of traumatic injuries.

Trauma analysis and interpretation is a key component for forensic anthropologists and pathologists during any analysis of remains. A recent study has suggested that frequency of fracture increases with age, and middle-aged and older females presented with the highest frequencies per age and sex group.¹ However, there is still a lack of empirical data on how intrinsic factors, including age and its associated hormonal changes, influence the appearance and severity of fractures. Hormones, such as estrogen, are present in substantial amounts during the pre-menopausal period but substantially diminish once a woman enters menopause. Estrogens work in conjunction with osteoblasts, hence a decrease in one will initiate a decrease in the other. Thinning of trabecular bone occurs as a result of decreased osteoblastic activity, and this is reflected in a low Bone Mineral Density (BMD). With a decrease in BMD related to age, we expect to see the number of fractures increase, but also the severity of fractures increase, and the location of fractures to change compared to pre-menopausal women.

The sample was collected from the Reno Orthopedic Center and the Washoe County Regional Medical Examiner's Office and included women older than 20 years of age with blunt trauma. Each of the 212 fractures were evaluated by type of fracture (comminuted, transverse, spiral, butterfly, oblique, buckle, avulsion, segmental, and longitudinal), location of fracture per bone (tibia, fibula, femur, radius, ulna, and humerus), severity of fracture (measured as displacement in centimeters), and completeness of fracture (25%, 50%, 75%, 100% complete). The sample was separated into three age groups relating to their presumed menopause status; individuals ages 20 to 49 years were classified as pre-menopausal ($n=67$), individuals aged 50 to 55 years were classified as peri-menopausal ($n=22$), and individuals aged 56 to 80 years were classified as post-menopausal ($n=123$).

A chi-squared test of independence was conducted to reveal if different patterns existed between the age groups and specified covariates. Statistically significant results were found in all comparisons, except when bone had exhibited a fracture. The analyses revealed post-menopausal women suffered not only more frequent displacements, but also a greater severity in displacement ($p=0.024$). Interestingly, most post-menopausal women had significantly different ($p<0.05$) fracture locations compared to younger women; specifically, post-menopausal women had a greater number of fractures located distally rather than proximal. The type of fracture was also statistically different across the lifespan ($p=0.005$), with post-menopausal women sustaining more than double the amount of comminuted, oblique, and transverse fractures compared to spiral, avulsion, butterfly, longitudinal, and segmental fractures.

By using a large cross-sectional sample of women, we can reveal how the expression of traumatic injuries change throughout the female lifespan beyond the expectation of a higher likelihood of sustaining fractures. Documentation of trauma patterns elucidates normal and abnormal patterns in fracture type, location, and severity across the female lifespan and facilitates trauma interpretation for the forensic scientists. Continuation of this research, including a larger sample of peri-menopausal women, will provide a deeper understanding of the complex relationship between the skeleton, biomechanical forces, and the expression of injuries, allowing scientists to substantiate trauma interpretations and move beyond descriptive interpretations.

Menopause, Trauma Analysis, Blunt Trauma

A63 Fractur3D: A Computed Tomography Reference Atlas of Skeletal Trauma

Terrie Simmons-Ehrhardt, MA, Richmond, VA; Sara Sochor, MS, University of Virginia, Charlottesville, VA; Anthony Falsetti, PhD, George Mason University, Fairfax, VA*

Learning Overview: After attending this presentation, attendees will have learned what types of data can be extracted from computed Tomography (CT) scans containing skeletal trauma and embedded in an interactive web-based reference atlas to support forensic anthropological casework. Attendees will interact with examples and have the opportunity to provide feedback on features.

Impact Statement: This presentation will impact the forensic science community by demonstrating the advantages of interdisciplinary collaborations and the applicability of data sources generated outside forensic science to developing innovative and interactive reference databases utilizing modern web technology.

CT databases and the increased application of postmortem CT have expanded the scope of forensic anthropology methods to include virtual examination of skeletal features. Postmortem CT allows for the virtual examination of diagnostic skeletal features as well as skeletal trauma before removal of soft tissue for traditional forensic anthropological analyses. Virtual skeletal data from CT volumes can be viewed as 2D image sequences along any plane, as 3D volume renderings of soft and/or bone tissue, as 3D surface models, or any superimposed combination of the above, allowing for a comprehensive visualization and examination of skeletal injuries, including fracture lines, internal and external surfaces of affected elements, displacement and relative position of fragments, and trajectory/direction of injuries. This digital data can be used to build more comprehensive reference atlases of skeletal trauma to support forensic anthropology casework. In individuals with documented antemortem and/or perimortem skeletal injuries, postmortem or even post-autopsy CT scans can contribute to accessible and interactive references for forensic anthropologists to compare to injuries encountered in casework. Since not all practitioners should be expected to learn CT modeling and visualization methods, virtual skeletal reference data must be presented in accessible formats to prove useful.

The University of Virginia Center for Applied Biomechanics (UVA CAB) is recognized as one of the world's leading research groups in the field, specializing in impact biomechanics for injury prevention by using state-of-the-art equipment to analyze the intricacies of how the human body responds to injury. The Center's mission is to improve the quality of life through the mitigation and prevention of injury made possible by better understanding the mechanical response of the human body utilizing cadaveric donors. For many donors, pre- and post-experimental CT scans were collected, providing an opportunity to visualize superimposed skeletal elements before and after injury. Although UVA CAB does not perform weapon or ballistic experiments, several donors were identified with perimortem injuries such as gunshot wounds that were captured in CT scans, providing for additional trauma examples relevant to forensic anthropology.

A preliminary dataset of CT scans from UVA CAB were selected to populate a web-based 3D skeletal trauma reference database, Fractur3D, to be hosted at George Mason University. CT scans were collected with 0.625mm image spacing and converted to de-identified volumes with 3D Slicer. The primary advantage of using CT data for a skeletal trauma atlas is the ability to visualize internal surfaces and structures to better visualize the full extent and pathways of injuries. To make this data accessible to forensic practitioners, a web format using open-source javascript libraries that support 3D interaction with biomedical imaging data, such as transparency, clipping, and measurements, was implemented. This presentation will demonstrate the types of interactive data that can be extracted from CT scans and embedded in web pages so that other researchers may implement similar atlases. Web pages embedded with volumetric or 3D CT data provide a more modern, accessible approach to skeletal atlases beyond traditional photographic atlases.

Skeletal Trauma, Computed Tomography (CT), Fractur3D

A64 The Effects of Soft Tissue on the Crystallographic Changes to Bone Mineral Upon Heating

Hannah Cross, MS, Keele University, Newcastle-under-Lyme, Staffordshire, United Kingdom; Charlene Greenwood, PhD, Keele University, Newcastle-under-Lyme, Staffordshire, United Kingdom*

Learning Overview: After attending this presentation, attendees will better understand the effects that heating bone in conjugation with soft tissue has on bone specimens.

Impact Statement: Nearly all heated bone studies have utilized dry, defleshed bone. However, the results of this study have highlighted differences between fleshed and defleshed bone upon heating, which must be taken into consideration when applying such techniques to forensic casework.

Upon the recovery of burnt remains in a forensic or archaeological context, bone is often fragmented and comingled, making differentiation between human and non-human samples extremely challenging and subjective. Due to thermal degradation of the organic component, biological techniques, such as DNA analysis, are often rendered futile, so attention is drawn to the final surviving component of bone, the mineral hydroxyapatite. Exploring the physicochemical modifications that occurs to hydroxyapatite upon heating has shown promise in differentiating between species based on characteristic changes within its crystal lattice structure and the presence of extraneous mineral phases.¹ However, the effects soft tissue has on the heat-induced changes are not fully understood, yet are of paramount importance as most bodies are intact, not skeletonized, during a burning event. This study aims to explore the effect heating has on fleshed bone, specifically investigating modifications to the nanocrystalline structure of bone mineral, and whether this has a significant impact on species differentiation.

Femoral cortical bone was taken from bovine specimens. Varying weights (5g, 7g, and 10g) of muscle and fat, and one layer of skin (10g) were tested separately to understand their individual affect. A combination of the three tissue types was also considered. The samples were heated for two hours at various temperatures (200°C, 400°C, 600°C, and 900°C). Powder X-Ray Diffraction (pXRD) analysis was utilized to calculate coherence length and lattice parameter values and the weight percentages of extraneous mineral phases formed during the thermal degradation of hydroxyapatite. Coherence length, which gives an indication on crystallite size and strain, was calculated using the Scherrer equation and the Full Width Half Maximum (FWHM) peak values. Fourier Transform Infrared (FTIR) spectroscopy was utilized to collaborate XRD data and to further our understanding of the relationship between the degradation of the organic matrix and the crystallographic changes. The color changes to bone were also measured using a Colorimeter.

It has been demonstrated that overall, soft tissue has a shielding effect on bone, reducing the expected thermally induced modifications. This is most prominently observed in samples heated with a combination of muscle, fat, and skin, which is likely due to the larger quantities of tissue protecting the sample from the thermal energy required to induce physicochemical modifications. Significant differences ($p < 0.05$) were observed between defleshed samples and those heated with a combination of tissue types with at least one tested parameter when heated at 400°C, 600°C, and 900°C. Furthermore, the crystallographic parameters of defleshed samples were found to be significantly different ($p < 0.05$) to all other fleshed sample types when heated at 900°C. Therefore, the effects of soft tissue must be considered when applying findings to forensic and archaeological heated bone cases whereby samples have been heated at these higher temperatures. Further research must now be conducted that incorporates different species of bone, heated in conjugation with soft tissue, to determine whether species differentiation can still be achieved using such parameters.

A65 Identifying Taphonomic Factors Affecting the Dispersal Patterns of Surface-Scattered Human Remains: A Study of a Forensic Sample From Actual Casework

Kristine Kortonic, BS, Mercyhurst University, Erie, PA; Luis Cabo-Perez, MS, Mercyhurst University, Erie, PA*

Learning Objectives: Attendees of this presentation will gain a better understanding of the significance of specific taphonomic factors on the deposition patterns of surface-scattered human remains.

Impact Statement: This presentation will impact the forensic science community by presenting findings from a retrospective taphonomic study of a forensic anthropological sample with a wide range of postmortem intervals (PMI) and environmental conditions not previously studied.

An understanding of a wide variety of taphonomic factors, agents, and processes, and their effect on the final deposition of human remains at the outdoor scene is crucial to forensic taphonomic interpretation and crime scene reconstruction.¹ Although distribution patterns are commonly utilized in forensic taphonomic analysis to reconstruct the death event, there has been little applicable research into the subject.¹ At death scenes, investigators are tasked with answering questions regarding the PMI, scattering of skeletal elements, damage to remains, and absence of skeletal elements. These questions are addressed through thorough analysis of taphonomic data collected from the scene and the human remains. Analysis of the distribution patterns of the remains and associated evidence in relation to environmental features is used to understand the processes that lead to the final disposition of the remains and ultimately reconstruct the death event.

Research into the common dispersion patterns of surface-scattered human remains within the context of the scene can be used to identify the specific taphonomic variables and their effect on the final distribution patterns of human remains and associated evidence. In addition, quantifying the common distribution of surface-scattered remains would assist in structuring scene recoveries and training protocols. Many of the current studies on distribution patterns of surface-scattered remains have utilized small-sampled, non-human studies with short PMI. These studies are useful for identifying possible effects of different taphonomic factors, but the lack of actualistic studies on human models with extended PMI limits the applicability of the findings to forensic cases.

One retrospective study conducted spatial analysis on a sample 36 cases of surface-deposited human remains in Louisiana to investigate patterns in body dump location and dispersal overtime.² A significant correlation was found between PMI and the shortest dispersion distance, but no relationship was found between PMI and the greatest or average distance of dispersion. These findings contradicted the conclusions of a previous retrospective study with a maximum PMI of 4 years.³ The latter study found that the recovery of skeletal elements decreased with increased PMI; indicating that remains became more dispersed over time.³ Although studies have suggested that particular taphonomic variables such as clothing, scene topography, and vegetation density have specific effects on the distribution of surface-scattered human remains, the effect of these factors has not been directly studied.¹

The goal of this study was to analyze the preservation and distribution patterns of human remains in a forensic anthropological sample in relation to specific taphonomic variables including PMI, topography, and animal scavenging. This study utilized a forensic sample of 41 forensic anthropological cases with a known PMI range of approximately 2.5 months to 22 years. Each case was recovered through forensic archaeological methods and had full forensic osteological and taphonomic analyses. Spatial data was collected for each case by assigning cartesian coordinates to each individual skeletal element from scene maps using image processing software. The spatial distribution of each case was analyzed in relation to the known PMI, topographic data collected from the scene, the skeletal inventory, and osteological evidence of animal scavenging. The relationship between the dispersion and recovery of skeletal elements, and taphonomic variables, including PMI, scene topography, and animal scavenging, has been investigated using statistical analysis.

Forensic Taphonomy, Postmortem Interval (PMI)SA, Forensic Archaeology

A66 Taphonomic Change in the Sonoran Desert: Monitoring Morphology in the Period of Mummification/Advanced Skeletonization

Kassandra Parrish, BS; Arizona State University, Glendale, AZ; Professor Katelyn Bolhofner, PhD, Arizona State University, Glendale, AZ*

Learning Overview: The major goal of this presentation is to utilize subaerial taphonomic data to better understand the morphological changes that occur in the process of natural mummification and advanced skeletonization in a desert environment.

Impact Statement: This presentation will impact the forensic science community by establishing expectations for the degree of morphological change that may be observed during late stages of decomposition in a hot and arid desert climate, with the ultimate goal of improving estimates of postmortem interval in this region.

The Sonoran Desert covers vast regions of Mexico, California, and Arizona. As with other desert environments, extreme temperature fluctuations are characteristic of the region. From May through September, average daily temperatures may range from 69°F to 120°F at the end of August. In contrast to other desert climates, though, a significant period of rainfall occurs during both the winter and summer seasons, resulting in a diverse range of vegetation and wildlife and producing a very unique climate overall. In Arizona, the summer “Monsoon Season” of June through September, coupled with the extreme heat at this time of year, produces a drastic wet/dry cycle, resulting in unique patterns of variability in the decomposition rates and stages of human remains and directly impacting estimates of postmortem interval.¹

This unique climate and its impact on estimates of postmortem interval become a critical issue for medicolegal death investigators confronted with the challenge of addressing the deaths of undocumented border crossers in this region. Despite the extreme temperatures and intense storms during the summer in Arizona, crossings at the United States-Mexico border at this time of year can reach peak numbers with fatal results for many. In 2020, 227 migrants’ remains were found. In June of 2021 alone, 43 migrants’ remains were found along the border.² Often, remains are recovered in advanced stages of mummification and skeletonization, states in which postmortem intervals are particularly difficult to ascertain, further complicating identifications and death investigations.

To begin to address these issues, the goal of this study is to monitor visual changes associated with the late decomposition stages of mummification and advanced skeletonization. Here, this study presents the initial results of an ongoing, long-term study intended to track the timeline of changes through these stages. Two porcine models with minimal tissue adhering were placed in observation cages in a natural desert environment in Carefree, AZ, on May 22, 2021. One cage was placed in direct sunlight and the other was placed in the shade of a Palo Verde tree to assess whether sun exposure had a significant impact on the rate or stages of mummification or advanced skeletonization. Visual observations and digital images were recorded once a week for the first month and every other week to the present date.

The results of the initial phase of this project (to date: 4 months; 92 days) demonstrated rapid mummification within the first two weeks of initial placement and minimal skeletonization, followed by very little measurable change to date. Currently, both models appear mummified and little-to-no skeletal elements are exposed, leading to almost no observable change since initial placement. There has been minimal rodent activity and minimal insect activity observed.

Observations are ongoing, with the ultimate goal of developing a nuanced system of expected taphonomic change in this period of decomposition in a hot and arid environment, both to update existing systems and to provide data that may contribute to improved estimates of postmortem interval when remains are found in this condition.³

Taphonomy, Advanced Decomposition, Sonoran Desert

A67 Identification of Differential Burning Among Highly Fragmented Cremated Human Remains

Lisa Monetti, MSc, University College London Institute of Archaeology, London, United Kingdom and Drew University, Madison, NJ*

Learning Overview: Attendees, after attending this presentation, can expect to better understand the potential for the use of image analysis software toward the identification of differential burning patterns among highly fragmented burned human remains. Attendees will learn that such analysis can contribute toward the reconstruction of burning scenarios for remains that would otherwise not reveal such information.

Impact Statement: This research will impact the forensic science community by presenting a free and accessible method for the interpretation of highly fragmented burned human remains. The method allows for feasibility toward the reconstruction of the burning scenario through the identification of subtle but significant differential burning, which was previously out of reach given fire's ability to obscure a great deal of information on burned bone. Instead of working against the heat-induced changes, this method approaches analysis by interpreting such changes.

The analysis of burned human skeletal remains requires specialized experience and expertise. In cases where remains are highly fragmented, such analysis is further complicated and far more time-consuming. Bones transform dramatically during heating, but many of the factors contributing to these heat-induced changes have been realized through experimentation and observation of forensic cases.^{1,2} As a result, the identification of differential burning and unexpected burn patterns can aid the anthropologist in estimating and reconstructing burning scenarios. A particularly useful example is extreme changes in color representing areas that were differentially covered with flesh or other materials during burning, reducing the bone's exposure to heat in some areas, while allowing others to char.² The areas that were covered maintain a white color, while the exposed areas appear black from charring. This type of macroscopic observation of differential burning can indicate the direction of the fire's movement or the location of the body in relation to the heat source.

Differential burning on a macroscopic level is a reliable and valuable observation for the forensic anthropologist when reconstructing the burn scenario. Completely calcined remains, however, do not allow the forensic anthropologist to observe macroscopic differential burning, as the remains can appear uniform and are often highly fragmented. While calcined remains with high levels of fragmentation can also obscure elements of the biological profile, this presentation reveals an alternative avenue of analysis: the interpretation and estimation of the burning scenario through identification of differential burning on highly fragmented remains. This presentation explores the applicability of image analysis software toward the identification of differential burning across the human skeleton in cases where macroscopic observation is otherwise impossible.

Image analysis software allows the anthropologist to observe changes in the bone's morphology through shape descriptors that examine the overall shape and size, the shape of the object's corners, and the texture of the edge of the fragment. These represent large-, medium-, and small-scale analyses, respectively, which are not attainable through standard methods of observation. The morphology of the remains is directly linked to the burning process, as fragmentation is caused by heat-induced fractures.

This project examined 6,712 fragments of burned human remains using image analysis to calculate values representative of bone morphology, and heat-induced fractures were also quantified for each fragment. These data were analyzed using Non-metric Multidimensional Scaling (NMDS) to identify patterns of differential burning, and the results were compared with standard methods for identifying differential burning on the same fragments. The results of the NMDS and post hoc Permutational Multivariate Analysis Of Variance (PERMANOVA) indicate that differential burning can be observed using image analysis software to a significantly ($p < 0.05$) greater degree than can be completed through standard anthropological analysis.

The future implications of this research are significant. Not only does it create new possibilities for the interpretation of a burning scenario, it also utilizes free image analysis software (ImageJ), making the analysis of burned human remains more accessible to smaller or underfunded labs or less-experienced practitioners. Further, more preliminary results of an ongoing follow-up study indicate that image analysis combined with Random Forest machine learning allows for rapid classification of remains into skeletal region and bone type based on the shape descriptors alone. This presentation explores the possibility of utilizing image analysis toward identifying differential burning patterns in highly fragmented burned remains and also identifies the value and future potential for this accessible method. Analysis of burned human remains is often a struggle against the heat-induced changes caused by fire, but this method allows those changes to instead contribute to their interpretation.

Differential Burning, Cremation, Image Analysis

A68 Tuning Microbial Succession-Based Postmortem Interval (PMI) Estimation Models: The Effect of Environmental Parameters on Model Prediction

Allison Mason, BS*, University of Tennessee-Knoxville, Knoxville, TN; Hayden McKee, MSc, University of Tennessee-Knoxville, Knoxville, TN; Katharina Hoeland, MS, University of Tennessee-Knoxville, Knoxville, TN; Sarah Schwing, MA, University of Tennessee-Knoxville, Knoxville, TN; Erin Patrick, MSc, University of Tennessee-Knoxville, Knoxville, TN; Shawn Campagna, PhD, University of Tennessee-Knoxville, Knoxville, TN; Dawnie Steadman, PhD, University of Tennessee-Knoxville, Knoxville, TN; Jennifer DeBruyn, PhD, University of Tennessee-Knoxville, Knoxville, TN

Learning Overview: After attending this presentation, attendees will better understand the application of random forest models to predict PMI from soil microbial succession during human decomposition. Specifically, this presentation will increase attendees' knowledge of how inclusion of environmental parameters (e.g., pH, conductivity) impact model accuracy.

Impact Statement: This presentation will impact the forensic science community by considering additional data in microbial-based models for the purpose of improving PMI estimation in a human system.

Establishing PMI, or time since death, is often pertinent to death investigations, providing information to establish a timeline of events.¹ Multiple methods for PMI estimation exist, including estimation via insect ecology and morphology changes over time.^{2,3} Recently, microbes have been suggested as potential predictors of PMI, as microbes are ubiquitous and change during decomposition⁴⁻⁶. A few models have attempted to assess the predictability of microbiome succession on the skin and in decomposition soils and estimate PMI.^{4,7} These models generally include application of machine learning techniques to taxonomic marker genes (e.g., 16S rRNA, 18S rRNA) datasets and produce error ranges from 2.5 to 7 days.⁷ While promising, these models are based solely on sequencing data and do not consider environmental factors. Therefore, the goal of this work was to evaluate how inclusion of environmental data in microbial-based models impacts PMI estimation from soil samples collected during human decomposition.

Research data were obtained from a 19-individual ("donors") decomposition study completed at the University of Tennessee Anthropology Research Facility (ARF) in Knoxville, TN. Soil samples (0-5cm) were collected from the decomposition-impacted area surrounding donors at predetermined Accumulated Degree Hours (ADH) intervals until the end of active decomposition. Soil samples were homogenized and either flash frozen for DNA extraction or used to measure soil pH, electrical conductivity, and extracellular enzyme activities; bacterial community composition was assessed using 16S rRNA gene amplicon sequencing.^{8,9}

Random Forest regressors were applied to taxa abundance or taxa abundance plus soil data, respectively, to create PMI estimation models. Only samples ≤5,000 ADH were used to keep timepoints consistent between donors. Models were created using Operational Taxonomic Units (OTUs) and at three taxonomic levels (order, class, and phylum) in order to assess the effect of taxonomic level on model predictions. All models were generated in R using the Ranger package.¹⁰ Model accuracy was measured by calculating the Mean Square Error (MSE) and Mean Absolute Error (MAE), then compared between models.

Across all models, MAE ranged from 804.3 ADH up to 884.5 ADH. Of the models without environmental data, the order level was most accurate (MAE 814.2), while all others performed similarly. Effect of environmental parameters on model accuracy differed based on taxonomic level. At the phylum and class levels, addition of environmental parameters improved MAE by 48.6 and 65.1, respectively. In contrast, models with and without environmental data performed similarly at the order level, while models at the OTU level were negatively affected by the inclusion of soil data. Overall, the phylum and class level models with environmental data resulted in the lowest MAE (805.0 and 804.3, respectively).

Within this dataset, the inclusion of environmental data generally improves model predictability, but this result is dependent on taxonomic level and sampling timeframe. Additionally, only a few environmental variables were considered, and others (e.g., nitrate, dissolved carbon, etc.) may improve models further and should be investigated. These preliminary results differ from those previously reported, suggesting the impact of different sampling conditions and size and data processing methods on model accuracy, and highlighting the need for large-scale validation of microbial-based PMI estimation models.⁷

Microbial Succession, Postmortem Interval (PMI), Random Forest Model

A69 The Importance of Recognizing the Indicators of Vulture Scavenging for Forensic Archaeological Recoveries and Taphonomic Interpretations

Kristine Kortonick, MS, Mercyhurst University, Department of Applied Forensic Sciences, Erie, PA; Anthony Lanfranchi, MS, Mercyhurst University, Department of Applied Forensic Sciences, Erie, PA; Luis Cabo-Perez, MS, Mercyhurst University, Department of Applied Forensic Sciences, Erie, PA*

Learning Overview: After attending this presentation, attendees will have an understanding of the importance of the utilization of forensic archaeological methods to support accurate forensic taphonomic analyses and outdoor crime scene reconstruction.

Impact Statement: This presentation will impact the forensic science community by demonstrating the importance of forensic archaeological methods for a proper forensic taphonomic analysis utilizing a novelty forensic anthropological case of vulture scavenging of human remains.

Animal scavenging activity has the potential to alter significantly the final deposition of human remains and the surrounding environment. Thus, understanding the behavior of different scavenger species becomes crucial to detect and interpret their effects as taphonomic agents in forensic settings. Indeed, scavenging activity has been reported to affect Postmortem Interval (PMI) markers, the spatial patterning of surface-scattered remains, and postmortem bone preservation and alteration, thus, affecting PMI inferences, trauma interpretation, and scene reconstruction.^{1,2} Vultures in particular are known to alter human remains and the site of deposition due to rapid consumption of soft tissue, dispersion and damage to the remains, and alteration of the contextual environment.¹ Therefore, recognizing the indications of animal scavenging associated with different types of scavengers can improve the interpretation of the scene.

Published data on the effects of animal scavenging in Pennsylvania are extremely scarce and limited to sporadic observations on a reduced set of scavenging species. Regional differences in scavenger behavior have been reported for an even more limited number of species. There are some episodic reports of migratory patterns of vultures in Pennsylvania, but a lack of published literature about their presence and behavior in Central and Western Pennsylvania.

The first comprehensively documented example of vulture scavenging activity on human remains in Central Pennsylvania, was the human remains representing one individual located in the woods in a state of advanced decomposition. The individual was almost completely skeletonized and was significantly scattered. Most of the lower limb was not recovered. The main concentration of material included clothing, a partial vertebral column, and multiple ribs. No clear decomposition stain could be identified. Twenty feathers consistent with those of a turkey vulture (*Cathartes aura*) were collected from the scene. Superficial scratches were visible on the materials covering the surface of some skeletal elements, but they washed away as the remains were cleaned for osteological examination. Additionally, extensive damage was present in the orbital areas, in particular on the lacrimals and ethmoid. The scene was comprehensively documented following forensic archaeology protocols. Despite the nearly skeletonized state of the remains, the individual had only been missing for less than four months. It has been suggested that approximately two years are required for the removal of all soft tissue by natural processes in Pennsylvania.² Thus, if the evidence of vulture scavenging had not been considered, the PMI would have been likely overestimated by around two years. The evidence of scavenger activity present at the scene provided the necessary information to detect and correct the bias introduced by vulture activity, resulting in a more accurate, scientifically backed taphonomic interpretation.

Aside from providing the first documented information on forensically-significant vulture scavenging in Central Pennsylvania, this example of animal scavenging illustrates the importance of proper recognition and collection of taphonomic evidence, and presents basic scene processing protocols and strategies to detect and interpret this type of information.

Scavenging, Forensic Archaeology, Taphonomy

A70 The Bone Weathering Simulator: An Investigation of Bone Change Informing Forensic Anthropology Recovery Best Practices Using Crowd Sourcing

Matthew Rolland, MS, Florida Gulf Coast University, Fort Myers, FL; Heather Walsh-Haney, PhD, Florida Gulf Coast University, Fort Myers, FL*

Learning Overview: After attending this presentation, attendees will have a better understanding of how to introduce Science, Technology, Engineering, and Math (STEM) students to the effect that geological, environmental, and human-induced movement has on bone preservation in addition to the utility of crowdsourcing data collection through virtual platforms for scientific investigation.

Impact Statement: This presentation will impact the forensic science community by presenting evidence of taphonomic change to skeletal material “recovered” through forensic anthropological best practices.¹ Additionally, a novel research design and data collection methodology will be presented that may be extended for further scientific investigations.

As part of the Florida Gulf Coast University (FGCU) 2021 Whitaker Center’s Summer Research Opportunities (SRO), students evaluated changes to chicken (*Gallus gallus domesticus*) and Burmese python (*Python bivittatus*) bones in weathering simulators. In essence, the students simulated the passage of time and the effect that weather, substrate, and water (all postmortem or after-death changes) have on bone preservation by sifting the chicken and python bones through ½" and ¼" inch screening. The students evaluated how mechanical hand sifting contributes to the destruction of bones and how effectively the ½" and ¼" screening catches forensic evidence.

Each student received one bone weathering simulator (i.e., one 23 x 16 x 6 Sterilite container with lid, one soil sieve with ¼" screening, one soil sieve with ½" screening, five sterile chicken bones, and five sterile python bones) and one type of substrate (gardening soil, sand, pebbles, and rocks). Some students additionally received distilled water.

All the participants were split into groups of five or six and each group was defined by the substrate inside their bone weathering simulator. Each student placed a bone of each type in each sieve with the substrate. The students shook the substrate through the sieve until all of the substrate had worked its way out of the sift. Taphonomic changes to the bones at each level were recorded and photographed.² Due to COVID-19 contact restrictions, the students were led through their data collection operations at their own homes via Microsoft® Teams. This study argues that rather than a hinderance to the data collection procedure, this virtual crowdsourcing of data collection allowed larger volumes of reliable data to be gathered over a shorter time frame than traditional data collection methodologies. As such, crowdsourcing data collection has far-reaching implications for forensic research and is gaining traction in areas of scientific research other than forensic anthropology.³

This study additionally presents data that statistically significant taphonomic differences were observed between skeletal material sifted through the varying substrates and water conditions as investigated by R Studio General Linear Models ($t(5)=.71, p=.018$).

Forensic Anthropology, Taphonomy, Crowd Sourcing

A71 World Trade Center—A Historical Overview

Amy Mundorff, PhD, University of Tennessee, Knoxville, TN; Eric Bartelink, PhD, California State University-Chico, Chico, CA; Jason Wiersema, PhD, Harris County Institute of Forensic Sciences, Houston, TX; Gaille Mackinnon, MSc, Aleto Forensic Services, Watchfield, Oxfordshire, United Kingdom*

Learning Overview: This presentation will provide an overview of the World Trade Center (WTC) attack and identification efforts. The goal of this presentation is to present a historical perspective of events in New York City on September 11, 2001, and how anthropological contributions developed following the large-scale loss of life. After attending this presentation, attendees will better understand the initial role of anthropology in the management of the WTC victim identification effort, in particular, the different mortuary approaches adapted to address extensive fragmentation and commingling, and how this effort paved the way for identification protocols in subsequent mass fatality incidents.

Impact Statement: This presentation will impact the forensic science community by discussing the challenges of an open-population mass fatality with an ongoing search operation and a complicated recovery site at a time when most disaster preparedness exercises were geared toward events no larger than a plane crash. This presentation will discuss the continuous evaluation and changing approach to mortuary work due to extreme commingling, calcined remains from hot spots burning for longer than three months, and the challenges of rapidly developing new DNA technology.

Ground Zero encompassed 16 acres and reached 140 feet in depth. Buried within the 1.7 tons of debris were fires exceeding 1,500°F and the remains of 2,749 deceased individuals. The site comprised multiple events as the North Tower collapse pushed through the debris of the collapsed South Tower. Within hours, the Office of Chief Medical Examiner (OCME) began implementing plans to identify the victims, issue death certificates, and facilitate returning remains to next of kin.

It became clear that lower Manhattan was not conducive to this scale of work, so plans were made to utilize the closed Fresh Kills Landfill on Staten Island, including the water barge system for direct transport of the debris. At the landfill site, building material was sorted from dirt, which was sent to massive sifting screens and on to conveyor belts for remains recovery. This facility was in operation 24/7 through to August 2002, three months after the closure of Ground Zero. More than 4,200 fragments of human remains were recovered from this operation.

Recovery operations at Ground Zero were complicated by prolonged search efforts for survivors and the need for large machinery to assist in deconstructing such a dangerous site. As decomposition set in, already fragmentary remains were further disrupted and commingled by grapples and excavators. Human remains were collected by the Fire Department of the city of New York (FDNY) and transported to the OCME multiple times a day. However, due to lack of training in identifying and recovering compromised remains, additional incidents of commingling occurred during recovery. Further complicating identifications, the forces from the building collapses rendered remains so fragmentary that fingerprints and dental matching were limited to the few hundred that had teeth or fingers present. DNA would become increasingly important to identify the nearly 22,000 fragments recovered, of which more than 5,000 were no larger than an inch.

The unprecedented commingling was not initially evident; for example, tissue from one individual fused to bone of another, and bone fragments from multiple individuals were found embedded in others. As it became clear that instances of commingling may have been missed, two programs were implemented to add quality control measures to the identification efforts. The Anthropological Verification Project focused efforts on re-examining over 18,000 cases to look for potentially missed commingling. The Final Anthropological Review entailed examining identified remains as part of the reconciliation process, to ensure a final check of each identified fragment prior to approving its release. These two programs illuminated unforeseen issues, contributed to additional identifications, and ensured that initial protocols were continually assessed to respond to the unprecedented scale of this incident.

Commingling, Mass Disaster, WTC

A72 The Role of Forensic Anthropology in the Aftermath of the 9/11 Attack on the Pentagon

Robert Mann, PhD, John A. Burns School of Medicine, Honolulu, HI; Thomas Holland, JD PhD, Defense POW/MIA Accounting Agency, Honolulu, HI; John Byrd, PhD, Defense POW/MIA Accounting Agency, Honolulu, HI; Andrew Tyrrell, MD, PhD, Vancouver Island Health Authority, British Columbia, Canada*

Learning Overview: This presentation will provide an overview of the methods, roles, and types of information that forensic anthropologists can contribute to the identification of victims of mass disasters.

Impact Statement: The 9/11 attack on the Pentagon was a tragic historical event that we in the forensic community should remember and learn from.

Events on the morning of September 11, 2001, would forever change the world. Terrorists had hijacked four commercial airplanes and flown them into the Twin Towers in New York City, the Pentagon in Virginia, and an open field in Shanksville, PA. American Airlines Flight 77 departed Dulles Airport near Washington, DC, at 8:20 a.m. en route to Los Angeles, CA. Five hijackers took control of the plane and crashed it into the Pentagon at 9:37 a.m., killing all 64 passengers and crew and 125 military personnel and civilians on the ground. The fragmented, commingled, and sometimes burned condition of some bodies would make identifying them extremely difficult.

A team of four forensic anthropologists and two forensic odontologists from the United States military's Central Identification Laboratory (CIL) in Hawaii was deployed to assist with sorting and identifying the dead at Dover Air Force Base in Delaware. But just getting to Dover from Hawaii would prove to be a challenge. The Main Gate at Hickam Air Force Base where the team worked had become a parking lot as security personnel inspected vehicles and pedestrians to ensure there were no threats, either by personnel or objects coming onto the base. The sprawling military base was, in military terminology, at Force Protection Delta, its highest level of security. After arriving on base and selecting the identification team, the next hurdle was getting this team of specialists to Delaware at a time when all aircraft in United States airspace were grounded—there were no available flights from Hawaii to Delaware for four days.

Once cleared for travel, the team flew into Newark, NJ, and spent the next week at the military mortuary in Dover moving from one table to the next, as they employed their unique osteological skills in sorting and identifying body parts and burned fragments of bone, sometimes covered with rubble from the Pentagon. Establishing the personal identity of a human body can pose many difficulties, but the level of difficulty greatly increases if the body or remains are fragmented, commingled, burned, and covered with concrete rubble, jet fuel, and aircraft wreckage. This presentation will cover the role of the CIL forensic anthropologists at Dover, and the information forensic anthropologists are able to glean from examination of human remains, whether fleshed or dry bone, complete and intact, or partial and fragmented.

9/11, Pentagon Attack, Forensic Anthropology

A73 A Historical Review of the Recovery and Disaster Victim Identification Protocols Employed in the September 11, 2001, Crash of United Flight 93 in Shanksville, PA, and Lessons Learned

Dennis C. Dirkmaat, PhD, Mercyhurst University, Erie, PA; Marilyn R. London, MA, University of Maryland, College Park, MD*

Learning Overview: After attending this presentation, attendees will have a clear understanding of the roles played by anthropologists in the recovery, analysis, and identification of victims in the September 11 Flight 93 crash in Shanksville, PA.

Impact Statement: This presentation will impact the forensic science community by demonstrating the use of anthropologists in the response to multiple fatality incidents, both in the field and in the morgue, and especially those with forensic aspects.

On September 11, 2001, a hijacked plane with 44 individuals aboard crashed in southcentral Pennsylvania, instantly killing all aboard. United Flight 93 had left Newark International Airport earlier that morning and was headed to San Francisco International.

Wallace Miller, the coroner in Somerset County, PA, was the first official on the crash scene outside Shanksville, PA. The scene contained fragmented, commingled, and scattered human remains, personal effects, and aircraft wreckage strewn over the mixed forest and open field landscape of approximately 80 acres. One of Miller's earliest decisions was to call a forensic anthropologist, as well as a coroner in the neighboring county, for help. Officials from the Pennsylvania State Police, the National Transportation Safety Board (NTSB), and the Federal Bureau of Investigation (FBI) arrived shortly thereafter.

Given the number of victims and condition of the remains, the best course of action for identification of the victims was to request assistance from the Disaster Mortuary Operational Response Team (DMORT), part of the United States Department of Health and Human Services. DMORT arrived on September 13 and set up a temporary morgue at a National Guard Armory building a few miles away from the crash site.

In terms of recovery and documentation of the victims from the scene, protocols for efficient large-scale outdoor forensic scene recoveries were developed in 2000 that became known as the Weldon Spring Protocols. The original plan at the scene in Somerset County was to put these protocols into action with a combination of local, state, and federal personnel and resources. However, it was decided that since this was a criminal case of national significance, a different course of action for processing the scene should be implemented. After two weeks, recovery operations were completed, and the scene was returned to Coroner Miller. The first visit to the scene, immediately following release of the scene to the coroner's office, however, led to the discovery of more human remains on scene.

A renewed search of the crash site was planned and conducted by volunteers over the course of two consecutive weekends, in the spring of 2002. Significant amounts of human tissue and aircraft wreckage were found. Periodically, throughout the ensuing ten years, additional searches were conducted.

Members of DMORT Region III, from the mid-Atlantic area, were deployed to the scene in Somerset County. DMORT brings its own logistics personnel, pathologists, forensic anthropologists, medical records technicians and transcribers, fingerprint specialists, forensic odontologists, dental assistants, X-ray technicians, and other personnel. DMORT usually provides a fully stocked mobile morgue. However, in 2001 the DMORT system had only one mobile morgue, which was sent to the World Trade Center. Local resources and private companies were utilized to supplement the government's supplies. The DMORT III Team Leader and Morgue Director organized the personnel at each station and wrote up detailed operations protocols in what became the DMORT Morgue Protocols.

The morgue operation, consisting of ten individual stations (both documentation and identification stations), continued smoothly and was completed in 12 days (on the afternoon following the completion of the field operations). More than 1,600 fragments of human remains were analyzed for DNA and matched to 40 crew members and passengers. Four sets of remains were not identified and were turned over to the FBI as presumed remains of the terrorists.

Coroner Miller's lasting contribution to the effort and future efforts was the positive interface with the families of the victims. He utilized his experience as a funeral director to fully embrace their concerns. He met with them individually and as a group, becoming not an adversary but an ally and advocate for family rights.

Disaster Scene Recovery Protocols, Disaster Morgue Operations, History of September 11, 2001

A74 Lessons Learned From the September 11, 2001, Terrorist Attacks and Other Recent Mass Fatality Incidents

Frank DePaolo, PA-C, New York City Office of Chief Medical Examiner, New York, NY; Emily Carroll, MSPH, New York City Office of Chief Medical Examiner, New York, NY; Helen Alesbury, MA, New York City Office of Chief Medical Examiner, New York, NY*

Learning Overview: The goal of this presentation is to provide attendees with data and characteristics from recent mass fatality incidents for use in future planning and preparedness efforts. After attending this presentation, attendees will have an appreciation for the complexities of responding to a mass fatality incident and better understand the objectives to successfully manage such an incident.

Impact Statement: This presentation will impact the forensic science community by providing data and characteristics on mass fatality incidents that will guide planning and preparedness efforts within their jurisdictions.

This presentation, utilizing data from a study of recent mass fatality incidents, will identify characteristics, trends, and lessons learned that may inform planning and preparedness efforts for the medicolegal community. The study includes several large-scale incidents that, as outliers, have influenced fatality management operations and preparedness efforts on a national level.

It is imperative that medicolegal jurisdictions prepare for the occurrence of a mass fatality incident. The failure to appropriately plan for a mass fatality incident will cause additional delays, potential lost data, jurisdictional confusion, and negatively impact the families and loved ones of victims. Despite the trend to plan for catastrophic and complicated incidents, this analysis of recent mass fatality events seeks to better inform authorities regarding the scale and types of incidents that could potentially impact their jurisdiction. The guidance provided by this study serves as a tool to guide the development of plans, acquisition of appropriate resources, and training of staff.

To perform this analysis, data were collected from mass fatality incidents occurring in the United States from January 1, 2000, to July 31, 2021, that resulted in ten or more fatalities. Specific data points were collected for each incident, including the date, location, number of fatalities, incident type (man-made or natural), incident subtype, and description (mass shooting, hurricane, aviation, etc.). A total of 180 incidents fit the criteria for inclusion in the analysis, resulting in a total of 626,548 fatalities. The average number of incidents was eight per year during the study period. The analysis demonstrates that most mass fatality incidents (86.1%) result in between 10 and 50 fatalities and are variable based on incident type and geographic location. The average number of deaths caused by a single incident was 3,480; however, removing the large-scale outliers (September 11, 2001, attacks, Hurricane Katrina, Hurricane Maria, and COVID-19) lowers this average to 27 deaths per incident. In addition, the data indicates that a majority of incidents involve open populations (83%) with none or partial victim manifests. The top incidents based on the average number of fatalities per incident include Biological (COVID-19), Terrorism (as dictated by the September 11, 2001, attacks), hurricanes, tornados, and aviation incidents. However, the incidents occurring at the highest frequency include tornados, aviation incidents, mass shootings, and hurricanes.

The September 11, 2001, terrorist attacks resulted in 2,753 fatalities associated with the World Trade Center, 184 fatalities associated with the Pentagon, and 40 associated with Flight 93 in Shanksville, PA. The subsequent remains recovery and identification operations, especially associated with the World Trade Center, have served to inform the New York City Office of Chief Medical Examiner (NYC OCME) of the capabilities required to manage a complex, protracted victim identification process involving extensive body fragmentation and commingling. While the World Trade Center Attack, as well as the Pentagon attack and crash of Flight 93, has been shown to be outside the normal trends of mass fatality incidents, it has none the less offered the medicolegal community several invaluable lessons.

Notwithstanding the scale of the incident, the events of September 11 occurred across jurisdictions, resulted in fatalities of numerous nationalities, and required protracted operations lasting for years. The unique nature of these incidents has provided the medicolegal community with valuable knowledge and lessons that can be implemented in future planning and training efforts. The complexities associated with the September 11 terrorist attacks, with special attention to the NYC OCME recovery and identification efforts associated with the World Trade Center, will be compared and contrasted with other more “typical” mass fatality events that have occurred over the past 20 years in the United States.

Mass Fatality Incidents, Lessons Learned, 9/11

A75 The Role of the Medical Examiner in Two Mass Fatality Events: The World Trade Center Disaster and the COVID-19 Pandemic

Jason K. Graham, MD, New York City Office of Chief Medical Examiner, New York, NY; Barbara Sampson, MD, PhD, New York City Office of Chief Medical Examiner, New York, NY*

Learning Overview: Attendees will be informed about the role of the medical examiner in mass fatality events, using the events of 9/11 and COVID-19 in NYC as examples.

Impact Statement: Forensic science has and will continue to learn from the experience of the New York City medical examiner office with respect to mass fatality events of several different kinds in the areas of pathology, anthropology, fatality management, and identification.

The role of the medical examiner is critical in mass fatality events. It includes documenting, recording, investigating, recovering, and processing decedents in a dignified and respectful manner, accurately determining the cause and manner of death, performing the accurate and efficient identification of victims, and supporting the judicial, public health, and investigative objectives and requirements. Depending on the nature of the event, different roles may be predominant. This presentation will offer suggestions for effectively handling a mass fatality event based on lessons learned from previous events.

New York City has experienced the largest homicide rate in United States history, as well as the largest number of fatalities resulting from a natural disease pandemic in United States history. After providing an overview of the Office of Chief Medical Examiner (OCME) of the City of New York, the response to each disaster will be outlined and the experiences compared and contrasted with emphasis on the lessons learned. Details of the World Trade Center (WTC) and COVID-19 responses will include changes to operations in case intake and investigations, case recovery and transport, establishment of disaster portable morgues, and identification of decedents with outreach to their next of kin. The coronavirus response also required significant assistance to overwhelmed hospitals. Discussion of lessons learned will include the importance of technology for improving the response, flexibility with the plan and with deployment of staff, planning for the respectful storage of remains beyond the immediate event, clear messaging and managing expectations with families, media and staff, and early implementation of health and safety measures.

Finally, the importance of wellness and resiliency for staff will be described. Over the past few years, OCME has recognized that the repetitive exposure to traumatic subject matter, compassion fatigue, and cultural pressure have created a unique stress on staff. The agency has prioritized the wellness of agency personnel. The OCME Wellness and Resiliency Program works to develop materials, provide resources, host trainings, and empower staff to build resiliency holistically—focusing not just on mental health, but also considering the emotional, physical, and spiritual health of staff. Staff are encouraged to participate in ongoing activities and trainings throughout the year and take advantage of resources in an effort to build a strong baseline resiliency, both personally and as a work community.

Fatality Management, 9/11 Attacks, Medical Examiner

A76 The Changing Role of Forensic Anthropology in Investigations of Mass Fatality Incidents

Douglas H. Ubelaker, PhD, Smithsonian Institution, Washington, DC*

Learning Overview: After attending this presentation, attendees will be more familiar with the variation of the role of the forensic anthropologist in the investigation of mass fatality incidents

Impact Statement: This presentation will impact attendees by making them more aware of the nature of anthropological contributions to the investigation of mass fatality incidents.

Working in their home laboratories and institutions, forensic anthropologists become accustomed to their usual roles and procedures in casework. When anthropologists participate in the investigation of mass fatality incidents, those roles and procedures likely will differ from those they are accustomed to. The magnitude of the mass fatality problem being investigated, and the nature and structure of the team assembled, shape the participation of forensic anthropologists. In such investigations, anthropologists may be assigned specific roles as designated by team leadership, such as assisting in recovery, sorting commingled remains, or assessing age at death. While these roles utilize the unique skills and training of the forensic anthropologist, they may be focused on particular aspects of the investigation. When participating in such investigations, the forensic anthropologist must rapidly become familiar with the defined structure and responsibilities and adapt usual protocols to meet the needs of the investigation. Participation may present significant challenges, especially regarding equipment access, logistics, culture/ language issues, and team dynamics. Although the participation role may be narrower and more focused than the forensic anthropologist is accustomed to, the participant must identify and address any associated ethical issues and apply appropriate methods to the problems assigned. Anthropologists should not perform work that they consider unethical (such as offering opinions beyond their expertise).

This presentation reviews the different contributions made by forensic anthropologists in the investigation of mass fatality events. Perspective from personal experience in contributing to the investigation of the 9/11 Pentagon investigation, as well as other mass fatality events, will be provided. The role of the forensic anthropologist varied considerably in the investigation of fatalities associated with 9/11, the Branch Davidian compound in Waco, TX (1993), Operation Desert Storm (1991), the 1995 bombing of the Alfred P. Murrah Federal Building in Oklahoma City, and the military dictatorship period (1973-1990) in Chile. All of these investigations involved a team approach, but each presented unique challenges and professional demands for the forensic anthropologist. Although the institutions and teams involved were highly variable, specialists worked well together. Involvement in such complex endeavors offers an opportunity to contribute to issues of great importance. Such involvement also provides an educational experience to all involved.

Forensic Anthropology, Mass Fatality, 9/11 Pentagon

A77 20 Years of DNA Developments for World Trade Center Victim Identification

Mark Desire, MS, JD, New York City Office of Chief Medical Examiner, New York, NY; Carl Gajewski, MS, New York City Office of Chief Medical Examiner, New York, NY; Andrew Schweighardt, PhD, New York City Office of Chief Medical Examiner, New York, NY*

Learning Overview: After attending this presentation, attendees will be more familiar with developing DNA techniques to make identifications from a mass fatality.

Impact Statement: This presentation will demonstrate the commitment to not giving up and how we can learn from failure to reach our goals.

The New York City Office of Chief Medical Examiner (OCME) continues to fulfill their promise to the families of the victims of the 2001 World Trade Center attack—a promise to use every means necessary to identify their loved ones. From day one, the families looked to the OCME for hope. They continue to put their trust in the OCME today and this has not been forgotten. Through the challenges of working on the country's largest forensic investigation on some of the most degraded of human remains, this study set out to explore the 20 years of pushing forward and evolving DNA methods from lessons learned.

Two thousand, seven hundred fifty-three individuals were killed that morning, shattering the victims into 21,905 pieces scattered over many square blocks. The OCME had the immense job of identifying these victims.

DNA testing on each bone fragment has been attempted multiple times over the past 20 years. From the first step of pulverizing the bone into a fine powder, to decalcifying the cells and extracting what little DNA is left, each step has been modified and advanced.

The first phase yielded a 38% success rate, meaning that DNA profiles were generated with enough alleles to reach the statistical threshold to identify. Not all remains were linked to a reference sample, but at the very least, they could be identified should one be received in the future. The second phase of DNA testing saw a change in the Short Tandem Repeat (STR) kit and a more robust bone grinding process. As a result, the success rate increased to 45%. The third phase began with the use of mini-STRs and a new bone optimization DNA extraction protocol. The success rate increased to 54%. These samples were the most degraded and had been attempted during the previous two phases, which means the increased success rate was achieved on samples that previously yielded no results. The fourth phase began in 2006 with 6,317 bones remaining negative from prior attempts. With new grinding protocol, demineralization, and amplification technique, a 59% success rate has been observed. In addition, Y-chromosomal Short Tandem Repeat (Y-STR), mitochondrial DNA, and Single Nucleotide Polymorphism (SNP) testing have all played a role during the four phases. As advancements in testing protocols have been made, the results continue to improve, even when only the most challenging samples are left.

Some 2,400 fragments still provide little to no information. These are the remains that have been the most severely degraded by fire, water, heat, mold, bacteria, insects, jet fuel, diesel fuel, and sunlight; all factors present at Ground Zero, making this not only the largest investigation, but also the most difficult.

The necessity to improve protocols led to something else—using the experience gained to aid in the daily body identification cases, and to share this knowledge with laboratories all over the world. DNA testing is the most conclusive mode of identification of fragmented and degraded human remains. Through the efforts of the OCME to identify the unidentified, while equipped with experience garnered from 20 years of effort, this staff of scientists is well prepared to optimize and disseminate this knowledge to relevant communities.

Further expansion on these techniques is possible, giving the ability to identify victims of mass fatalities that are impossible using traditional methods. New technologies in the DNA field are rapidly evolving. Next-generation DNA sequencing is one such technology that can be applied to accelerate victim identification by enabling the comprehensive analysis of DNA to become inexpensive and routine. These capabilities are the next step for World Trade Center identification 20 years later.

DNA, 9/11, Bone

A78 World Trade Center Data Analysis Project: 20 Years of Ongoing Identification Efforts

Bradley Adams, PhD, New York City Office of Chief Medical Examiner, New York, NY; Julia Sommer, PhD, SNA International, Alexandria, VA; Jennifer Odien, PhD, New York City Office of Chief Medical Examiner, New York, NY; Angela Soler, PhD, New York City Office of Chief Medical Examiner, New York, NY; Christopher Rainwater MS, New York City Office of Chief Medical Examiner, New York, NY, Franklin Damann, PhD, DPAA, Offutt Air Force Base, NE*

Learning Overview: For the past 20 years the New York City Office of Chief Medical Examiner (OCME) has been continuously working to identify the World Trade Center (WTC) victims who died on September 11, 2001. The work continues to this day. This presentation provides the results of a data analysis project focusing on the identification trends from 9/11/2001 to 9/11/2021. The presented data were analyzed in collaboration with scientists at the Defense POW/MIA Accounting Agency.

Impact Statement: For 20 years, the OCME has been analyzing victims' remains from the 9/11 WTC attack in order to identify as many individuals as possible. This presentation presents the findings from an analysis of these data spanning 20 years, specifically pertaining to victim identification status and body fragmentation, among other parameters. The results will be useful for managing expectations with other large-scale mass fatalities.

On September 11, 2001, two planes struck the WTC towers, leading to their eventual collapse. The terrorist attack resulted in the death of 2,753 known victims and the eventual recovery of 21,905 remains. Based on data pertaining to last known location, there are 1,510 victims associated with Tower 1; 736 victims associated with Tower 2; 87 victims associated with American Airlines Flight 11 (AA11) that impacted Tower 1; and 60 victims associated with United Airlines Flight 175 (UA175) that impacted Tower 2. An additional 360 people died at different locations surrounding the WTC site, in hospitals, or their location at the site is unknown. The reported values only reflect victims of 9/11 and do not include terrorists.

As of September 2021, the OCME's efforts have resulted in the identification of 14,750 remains. Currently, there are still 1,106 known victims (40%) who have never had any remains identified to them. Results show that 42% of the victims associated with Tower 1, 40% from Tower 2, 24% from AA11, and 53% from UA175 remain unidentified.

Results show there is an association between last known location in the towers and identification status. Fewer individuals have been identified from the floors impacted by the airplanes, specifically Floor 97 in Tower 1, which has a 34% identification rate, and Floors 82 and 83 in Tower 2, which have 23% and 30% identification rates, respectively. The largest number of victims from a single employer worked at Cantor Fitzgerald, located in Tower 1 on Floors 101–105, just above the impact site. To date, 285 of the 658 victims from Cantor Fitzgerald (43%) have never been identified. Aon, located in Tower 2 just above the impact site on Floors 92, 93, and 98–105, has 51% of employees unidentified (88 unidentified; 87 identified). While the exact location of all individuals cannot be known at the time the planes struck or the towers collapsed, data indicate a lower identification rate associated with the areas of impact and above.

Among the WTC victims, there is a wide range of body fragmentation and variability in body completeness. While most identified victims have had less than 10 remains associated to them, some individuals have had over 100 linked fragments. Data indicate that bodies associated with lower floors are more complete than from upper floors. The high degree of body fragmentation has led to a heavy reliance on DNA testing. Approximately 93% of the identified remains (13,725) have involved DNA analysis. As DNA testing becomes more sensitive, remains are periodically retested if they did not previously produce a viable profile. Currently, there are 3,404 remains undergoing additional DNA testing. Only unidentified remains with associated bone were selected for ongoing testing.

DNA testing provides three possible outcomes: (1) a new identification (first time remains identified to a victim); (2) linked remains (additional remains linked to a previously identified victim); or (3) insufficient DNA (profile not generated). Trends show that the number of new identifications was highest from 2001 to 2003 and by 2005 had plateaued, with most DNA results linking to previously identified victims. Between January 2006 and September 2021, there have been 3,798 links to previously identified individuals and 49 new identifications. Using an Identification Accumulation Curve (*c.f.* species accumulation curve) and the Good-Toulmin Estimator, an additional 76 +/- 55 (95% confidence interval) new identifications are estimated from the 3,404 samples, and the remainder would be links to previously identified victims. These results will be useful for managing expectations as the identification work continues.

9/11, Victim Identification, World Trade Center

A79 Victim Identification and the Notification Process: A 9/11 Family Member Perspective

Mary Fetchet, LCSW, Voices Center for Resilience, New Canaan, CT*

Learning Overview: Through this presentation, attendees will learn the complicated issues that victims' families experience following acts of mass tragedies and recommendations for improving the process and helping them navigate.

Impact Statement: Victims' families require access to detailed information, support, and guidance during their initial and ongoing processes related to the identification and notification process of their loved ones' remains. They often require emotional and bereavement services subsequent to the notification from an organization outside of the medical examiner's office and other authorities involved with other aspects of the crime.

On September 11, 2001, 2,977 innocent individuals were murdered when 19 terrorists used four passenger planes as weapons to attack the United States. Two thousand, seven hundred fifty-three died at the World Trade Center (WTC) site, 184 at the Pentagon, and 40 on United Airlines Flight 93 in Shanksville, PA. The victims' families were geographically dispersed around the United States and in 90 countries abroad. This presentation will focus on the victims' family members whose loved ones died at the WTC site.

In the days following the attacks, family members were uncertain if their loved one was dead or alive. Accessing information was challenging, and providing DNA samples was complicated. The recovery effort at the WTC site continued for nine months at multiple locations, lengthening the collection of body parts, which impacted the identification and notification process. Despite these challenges, the New York City Office of Chief Medical Examiner (OCME), led by Dr. Charles Hirsch, made a promise to the families that they would continue the identification and notification process indefinitely.

In the immediate aftermath, a group of 9/11 family members met regularly with the OCME for updates on the collection of human remains and advocated for a streamlined notification process. This process empowered family members to determine if, when, and how they received notifications. Some families chose to be notified only once and some families chose to be notified every time there was a new identification. Some families decided to have their loved ones remains in the repository located within the 9/11 Memorial.

Beyond the complexities of the notification process, victims' families had to navigate complex systems and issues at a time when they were grieving. Funerals, religious rituals, and burials were delayed. Memorial services were held without bodies to bury. Because families were geographically dispersed, local authorities often conducted the collection of DNA samples and made notifications about new identifications. Often these local officials were untrained and support services were not provided to help guide the family. Multiple notifications have led to complicated decisions related to the burial process. In some circumstances, severed relationships between family members, especially spouses and parents of the deceased, have led to questions about the transfer of rights from the next-of-kin to claim remains.

Twenty years following the attacks, over 1,100 of the 2,753 victims at the WTC site have not yet been identified. Dr. Barbara Sampson, Dr. Hirsch's predecessor, and her dedicated team at the OCME have maintained the promise that the identification process will continue. With the passage of time, special consideration has to be given when making new notifications to the next generation of families. In retrospect, the OCME staff has demonstrated caring and compassion in their interactions with 9/11 families. Through the OCME's collaboration with Voices Center for Resilience (VOICES), the families have been supported throughout the notification process to help mitigate complicated mental health issues that many families experience due to the horrific deaths of their loved ones.

In the aftermath of 9/11 and other acts of mass violence, victims' families are grieving, yet they are often required to navigate complicated issues related to the processes in identifying, recovering, and interring the remains of their loved ones. This presentation will cover the first-hand experience of a 9/11 family member, and the perspectives she's gained through her work in providing long-term support for thousands of 9/11 families. This presentation will also draw upon her expertise in supporting communities impacted by other tragedies and parallels to the experience of those who recently lost a loved one following the COVID-19 pandemic.

9/11 Victims' Families, Human Remains Notification, Bereavement

A80 Geophysical Imaging of Buried Human Remains in a Mass Grave Experimental Setup

Kennedy Doro, PhD, The University of Toledo, Toledo, OH; Amar Kolapkar, The University of Toledo, Toledo, OH; Carl-Georg Bank, PhD, University of Toronto, Toronto, Ontario, Canada; Daniel Wescott, PhD, Forensic Anthropology Center, Texas State University, San Marcos, TX; Hayley Mickleburgh, PhD, Department of Cultural Sciences, Linnaeus University, Kalmar, Smaland, Sweden*

Learning Overview: After attending this presentation, attendees will have learned how measured geophysical anomalies associated with a mass grave experiment vary with time after burial. A comparison of temporal changes in geophysical signals with soil and climatic variables will also be presented. Ultimately, this presentation will highlight and compare the use of different non-invasive geophysical techniques, including electrical resistivity tomography, electromagnetic, self-potential and ground penetrating radar for locating mass graves and monitoring the spatio-temporal changes around them.

Impact Statement: Robust and reliable non-destructive (i.e., without excavating) methods of locating mass graves are important as logistical restrictions and security issues can mean that destructive techniques are not always feasible or desirable options. This project will contribute to existing knowledge on the detection of mass graves by monitoring landscape/soil changes throughout the experiments using geophysical techniques and by evaluating the validity and reliability of these methods to detect the presence of a mass grave with human bodies throughout different stages of decomposition.

Geophysical methods provide non-destructive approaches for detecting anomalies that provide investigative leads to clandestine individual and mass graves.^{1,2} Studies on investigating the use of geophysical techniques for locating graves and monitoring human decay have mostly relied on proxies such as pigs, while case applications, though with promising results, are not without uncertainties.^{3,4} The success rates have been dependent on seasonal variations, with their effects yet to be rigorously tested. These create uncertainties with open questions such as: How do geophysical anomalies resulting from buried human remains vary with time as the body decays? How do changes in soil properties around decaying bodies correlate with measured geophysical signals? What effects do climate variables have on measured geophysical signatures? What methods are more suitable at the different decay stages? To investigate these research questions, this study hypothesized that the burial and decay of human remains with time cause changes in the soil physical and biochemical properties, including electrical conductivity, temperature, pH, and redox potential around them. These changes in contrast to their surrounding soils create measurable anomalies in the soil bulk geophysical responses, including electrical conductivity and dielectric permittivity.

To investigate the above hypothesis, this study was conducted as part of a novel, interdisciplinary mass grave experiment established in May 2021 consisting of a mass grave with six willied/donated human remains, an empty control mass grave, three individual graves with a human remain in each, and an empty control individual grave. Prior to establishing the graves, this study conducted background measurements of Electrical Resistivity Tomography (ERT), Electromagnetic (EM) and Ground-Penetrating Radar (GPR) while soil profiles were analyzed *in situ* after excavating the graves. All the graves are also instrumented with soil sensors for monitoring temporal changes in soil moisture, temperature, and electrical conductivity *in situ*. Geophysical measurements of ERT, EM, and GPR were repeated two days, as well as one and two months, after burial while further measurements are planned on a bi-monthly basis for the next 15 months.

Results obtained to date show over a 20 percent decrease in electrical conductivity measured from EM imaging and an increase in resistivity measured from electrical resistivity imaging immediately after burial with the resistivity decreasing over time within the graves with human remains. GPR profiles also consistently show distorted reflectors and hyperbolas indicative of ground disturbances and the presence of human remains.

This presentation will highlight the experimental design, field implementation, and results of this study and discuss their implications for using geophysical methods as non-destructive techniques to guide the detection of clandestine graves.

Ford, MSc, Bournemouth University, Bournemouth, United Kingdom; Sarah Gino, MD, Università del Piemonte Orientale, Novara, Italy; Timothy P. Gocha, PhD, Forensic Anthropology Center, Texas State University, San Marcos, TX; Lisette M. Kootker, PhD, Vrije Universiteit Amsterdam, Amsterdam, Netherlands and Co van Ledden Hulsebosch Centre (CLCH), Amsterdam, Netherlands; Noemi Procopio, PhD, E Northumbria University, Newcastle, United Kingdom; Eugene Robinson, Forensic Anthropology Center, Texas State University, San Marcos, TX; Daniel J. Wescott, PhD, Forensic Anthropology Center, Texas State University, San Marcos, TX*

Learning Overview: After attending this presentation, attendees will have learned how actualistic experiments can contribute to the refining and testing of methods and techniques used during the investigation of mass graves, as well as training in mass grave excavation and documentation. This presentation highlights how expertise from forensic archaeology, forensic anthropology, forensic isotopes, forensic chemistry, forensic proteomics, metabarcoding, geophysics, human remains detection canine research, and remote sensing are combined to support humanitarian forensic science.

Impact Statement: The presentation aims to contribute to the development, testing, and validation of scientific methods for mass grave investigation by increasing current knowledge and understanding of mass grave taphonomy. Specific objectives include developing and refining detection and documentation techniques, investigating the potential of proteomic and microbial biomarkers for more precise and accurate Postmortem Interval (PMI) and age-at-death estimation, and evaluating diagenesis and alteration of isotopic signatures of different human tissues. Each of the subprojects will generate recommendations for documentation, sampling, and analysis protocols. These, as well as the 3D documentation of the donors and graves during the experiment, form the basis for a 3D virtual training tool that will function as a teaching aid to demonstrate the complex taphonomy of mass graves and provide guidance on choices made during excavation.

This presentation introduces an actualistic study replicating a small-sized mass grave with donated human remains at the Forensic Anthropology Center, Texas State University (FACTS) and presents the results of the first phase of development of a 3D virtual training tool for mass grave excavation and documentation. The “Mass Grave Project” aims to advance methods of detection, documentation, and analysis of mass graves and the human remains within them. The experiment is designed to enable comparison of mass grave and individual grave contexts and increase understanding of the effects of the environment and taphonomic variables, such as weather and soil properties. It examines the effects of burial and decomposition of multiple bodies in close proximity on the preservation and recovery of human tissue biomarkers and potential transference between individuals within mass graves. This project includes four core research areas (subprojects): (1) detection and location, (2) documentation, (3) methods supporting human identification, and (4) training—development of a virtual 3D training tool.

In May 2021, a mass grave (six donors), a control mass grave (no donors), three individual graves, and one individual control grave were placed at the Forensic Anthropology Research Facility, San Marcos, TX. The graves are being monitored *in situ* over a period of 18 months, after which they will be excavated. Human tissue and environmental (soil, vegetation) samples were collected prior to burial. Soil samples, Volatile Organic Compounds (VOCs), and remote and geophysical data are being collected from the graves at intervals throughout the experiment. Temperature, moisture, and electrical conductivity are monitored by soil sensors. Prior to and during burial, the donors, graves, and environment were documented in 3D using Computed Tomography (CT) scanning and photogrammetry. The results of the first three subprojects, combined with the 3D data generated in the experiment, provide research-based educational materials that are used to develop a 3D virtual training tool for documentation and excavation of mass graves.

The 3D virtual training tool will be made available to international humanitarian organizations involved in mass grave investigation. The first phase of development of the training tool consists of a 3D virtual environment combining data from different 3D documentation methods (CT scanning, [aerial] photogrammetry, 360-degree environment capture, laser scanning) collected prior to and during burial. The 3D environment and interactive modules are developed using 3D modeling, animation, and videogame engine software. This presentation demonstrates the virtual environment and shows how initial results from the subprojects are incorporated into the training tool.

Mass Grave, Experimental Taphonomy, Method Development and Training

A82 Open Source Geographic Information Systems (GIS) Models for Clandestine Mass Grave Prediction in Developing vs. Industrialized Countries

Perla Santillán, MSFS, Office of the Chief Medical Examiner, Richmond, VA; Tal Simmons, PhD, Virginia Commonwealth University, Richmond, VA*

Learning Overview: After attending this presentation, attendees will have a better understanding of how open source tools can assist in the location of mass graves in both developing and more industrialized countries.

Impact Statement: This presentation will impact the forensic science community by comparing the application of GIS to the location of clandestine graves in two countries, developing and industrialized, that have undergone conflict.

The location of clandestine graves, whether individual or mass, is often critical to prosecution of perpetrators, community recovery, and familial closure. Traditional methods of post-conflict grave location include, among others, witness testimony, extensive ground searches with probes and/or ground penetrating radar, and expensive purchases of satellite imagery, if available. While the use of GIS for grave mapping has been attempted in the post-conflict context, these previous efforts have primarily relied on commercially purchased and licensed GIS programs, which may be beyond the economic means of most Non-Governmental Organizations (NGOs) and families searching for missing persons.¹

Using open source data, systems, and tools, such as the open source QGIS and open source maps, proved to be user friendly for both countries used in this comparison.² Organizations or groups wanting to explore the use of these tools may not feel intimidated by the complexity or programs requiring purchase and licensing. Additionally, using QGIS allowed manipulation and visualization of data to gain further insights.

In Guatemala the civil conflict and killings originated in the 1960s and lasted until the 1980s, revolving around both ethnic and socioeconomic factors; conflict predominantly occurred in less-developed rural areas. In this country, the intersection of roads, waterways, and points of interest (e.g., churches, plazas, etc. within possible towns, found by use of transformations in QGIS) were the best predictors of clandestine grave locations.³ These three features eliminated ca. 90% of the geographic area of the country. Thus, this model alone decreased the area needing to be searched and defined its boundaries, providing both searchers on the ground and those using satellite imagery considerably less territory to cover.

In Bosnia, as expected, the model generated from the Guatemalan data did not perform well due to several factors, including the greater infrastructure in the areas of the country where killings (1991–1995) took place. The intersection of roads, waterways, and points of interest in Bosnia eliminated almost none of the country's area. Another difference affecting the model was the number of victims per grave, which ranged from 40 to 1,751, whereas in Guatemala, the model included graves containing 5 to 150 victims.⁴ The Bosnian data also links victims found in clandestine graves to known execution sites, primary graves, and secondary graves, enabling the exploration of distances from origin to disposal. These differences highlight that background information (e.g., resources available to the perpetrators) and the geographic nature of the conflict is crucial to model development and more studies of this type need to be conducted on existing data in order to refine and enhance the utility of predictive models.

Open Source, GIS, Mass Grave

A83 The Detection of Clandestine Graves in an Arid Environment Using Unmanned Aerial Vehicle (UAV) Remote Sensing

Abdullah Alawadhi, MSc, Liverpool John Moores University, Liverpool, Merseyside, United Kingdom; Constantine Eliopoulos, PhD, Liverpool John Moores University, Liverpool, Merseyside, United Kingdom*

Learning Overview: After attending this presentation, attendees will have a better understanding of the effectiveness of using different imaging techniques assisted by UAVs in narrowing the search area of possible recent and old gravesites in arid environments.

Impact Statement: This presentation will impact the forensic science community by improving the current grave detection methods in arid environments, which will be an excellent addition for all the agencies involved in the detection of burial sites.

Several countries in the Middle East have suffered from armed conflicts that resulted in many clandestine mass graves.¹ Covering a large land area and thoroughly searching it for a possible burial site places a significant demand on both human and financial resources.

This research was carried out in Kuwait, a country known for its arid environment, using different imaging sensors mounted on UAVs to help improve the current grave detection methods in an arid climate. Multiple single graves and a mass grave with sheep carcasses were simulated in a fenced Kuwaiti desert area. Pigs have always been the first analog choice to simulate human bodies when it comes to conducting forensic experiment; however, since pigs are not available in Kuwait, sheep would be the closest equivalent available to use.² It is not the first time other mammals have been used when conducting such experiments.³ The results obtained from the analysis of the acquired data confirm the effectiveness of such technology in detecting burial sites. They support and favor the proposed aims and objectives of the research. Differences in elevation between the graves and their surroundings were identified. Also, the analysis of the images captured with the multispectral sensor revealed a slightly noticeable variation in the Normalized Difference Vegetation (NDVI) index. Furthermore, both the Red/Green/Blue (RGB) and multispectral sensors were used successfully to detect surface anomalies on and around the graves.

The results from analyzing the data captured using thermal imaging also support the view that temperature variation between the graves and their surroundings exists. Subsequently, the calculation of Temperature Vegetation Dryness Index (TVDI) confirmed the effect of buried cadavers that produced a difference in soil moisture in the grave area.

The goal of this research is to develop a cost- and time-effective burial detection method that can be used in an arid climate.

This research affects many countries in the Middle East region, which in the past decades have suffered from war conflicts and human rights violations resulting in many clandestine graves. It is hoped that the present research will help locate these graves and identify the missing individuals, bringing closure to their families.

A84 Continuing to Shift the Forensic Anthropology Paradigm: Let's Be Realistic!

Dennis Dirkmaat, PhD, Mercyhurst University, Erie, PA; Luis L. Cabo, MS, Mercyhurst University, Erie, PA; Joe Adserias-Garriga, PhD, Mercyhurst University, Erie, PA, USA*

Learning Overview: After attending this presentation, attendees will have a better understanding of the recent paradigm shift in goals and roles of forensic anthropology within the medicolegal community.

Impact Statement: This presentation will impact the forensic science community by presenting a detailed review of the state of the field of forensic anthropology in 2022.

A few years ago, American Forensic Anthropology stepped back to reconsider its components as a scientific discipline. One of the most visible results of this reevaluation was the change of the name of the corresponding AAFS section, from Physical Anthropology to just Anthropology. Most immediately, this change was intended to acknowledge the growing importance of forensic archaeology and forensic taphonomy as two of the essential components of the field. The adoption of these two components in the past three decades increased the range and depth of data collection in the field and the hypotheses that this discipline was able to construct and confront. At a deeper level, the change implicitly acknowledged a paradigm shift in forensic anthropology, from an applied, lab-based discipline aimed exclusively at victim identification to a much broader fully scientific one concerned also with the reconstruction of past events.

These changes have generated healthy and fruitful discussions on the most academic aspects of this field, from desired research lines or course curricula to changes in the professional certification requirements. However, it is also necessary to again take a step back to consider how these changes should translate into the practical role in the investigative process and within the forensic community. This is especially true with respect to the needs and expectations of those stakeholders whom we are supposed to assist in that process. Why do law enforcement and coroners invite us into the forensic investigation? What do they think forensic anthropologists can add to the investigative process, and what in our specific skillset can meet those needs and expand those expectations to better fit what modern forensic anthropology can actually offer?

The answer to these questions reveals that it may be useful to divide the skillset of forensic anthropology into two different but interrelated sets of capabilities, useful both to guide the development of this field and to communicate more efficiently what forensic anthropologists can do for coroners, medical examiner offices, and law enforcement agencies.

The first subdiscipline or set of capabilities is the classic one, focused on aiding in victim identification through osteological analyses. It is likely what comes to the mind of law enforcement and other medicolegal professionals when thinking of forensic anthropology. Constructing a biological profile, noting unique features to help narrow the missing person list; and maybe analyzing bone trauma at the lab. This subdiscipline can be called Biological Profile Assessment.

The other set of skills and subdiscipline is concerned with reconstructing the history of, primarily, the outdoor scene. This is termed Outdoor Crime Scene Reconstruction, which refers to the reconstruction of the chain of events surrounding death and emplacement of the decedent, focusing primarily on the role that humans may have played in those events and during the forensic taphonomic interval. This component requires the classic osteology skills for evaluating forensic significance, and subsequent laboratory analysis of biological profile and trauma analysis. But it also requires forensic archaeology for locating and documenting spatial distribution of the evidence, scene and event context, and hypotheses of association. Finally, it requires forensic taphonomy to tie the room together and provide the background, data, and scope (from disciplines apart from forensic anthropology) to scientifically assess the potential human role in the death, deposition, and post-depositional disturbance events.

Forensic Anthropology, Forensic Taphonomy, Outdoor Crime Scene Reconstruction

A85 Pair-Matching Commingled Femora: Applying Geometric Morphometrics to Detect Shape Similarities in Human Femora

Christina Recheis, Cranfield Forensic Institute, Cranfield University, Shrivenham, Oxfordshire, United Kingdom; Roland Wessling, MSc, Cranfield Forensic Institute, Cranfield University, Shrivenham, Oxfordshire, United Kingdom*

Learning Overview: After attending this presentation, attendees will gain an understanding of how geometric morphometrics can be applied to digitally collected landmark datasets and how it can be utilized to pair-match human femora and aid in the resolution of commingled cases.

Impact Statement: This presentation will impact the forensic science community by presenting the new approach of resolving commingled remains based on shape similarities of paired elements by using 3D models from scan data. It provides a basis for increasing the accuracy of pair-matching and extending it to other skeletal elements. By using 3D models generated from Computed Tomography (CT) scans or scans from structured light scanner systems, a simultaneous digital collection can be created that can be accessed anywhere and shared more easily among investigators.

Commingled remains are found in a multitude of contexts, such as mass graves, mass disasters or ossuaries. Large-scale commingled cases especially can pose major challenges and their resolution is dependent on the examining experts and available resources. With the progressing digitization of science, virtual anthropology offers an application possibility for analytical methods like geometric morphometrics that can help face challenges like the resolution of commingled remains. Applying shape analysis to the investigation of bilateral (a)symmetry has already been shown to be effective in certain commingled cases for some skeletal elements when used with 2D images and manual landmark selection.¹

Geometric morphometrics is a landmark-based approach to analyze the shape of a structure. Based on 2D or 3D landmark data in the form of Cartesian coordinates, shape is preserved and compared between two samples to evaluate their distance, called the Procrustes distance to each other.²

The aim of this research is to show that geometric morphometrics can be used to identify the femora of one individual among commingled remains. It aims to show how landmark data can be collected digitally and semi-automatically from 3D femur models as input for the geometric morphometrics method. Semi-automatic detection of landmarks using an algorithm limits the inter- and intra-observer error as opposed to a completely manual selection. This presentation demonstrates how this can be used as a criterion for pair-matching femora and reducing the inter-observer error inherent with approaches like visual pair-matching.

This study analyzing 18 landmarks and 8 shapes across the femoral surface show a statistically significant ($p < 0.001$, single-factor Analysis of Variance [ANOVA]) shape difference between correctly matched and incorrectly matched pairs. This already reduces the number of potential matches down to a few possible pairs that the anthropologist must investigate and rule out based on other approaches.

Thus, geometric morphometric offers a valuable addition to conventional methods and is a promising tool in the investigation of commingled remains.

Geometric Morphometrics, Pair-Matching, Semi-Automatic Landmark Detection

A86 Digital Pair-Matching Based on a Mesh-to-Mesh Comparison of 3D Images

Yangseung Jeong, PhD*, Middle Tennessee State University, Murfreesboro, TN; Eun Jin Woo, PhD, Sejong University, Seoul, Korea; Charlene Sullivan, BS, Middle Tennessee State University, Murfreesboro, TN; Omar Ali, BS, Middle Tennessee State University, Murfreesboro, TN; Marcus Luciano, Middle Tennessee State University, Murfreesboro, TN; Yuryang Jang, PhD, Ministry of National Defense Agency for KIA Recovery & Identification, Seoul, Korea

Learning Overview: After attending this presentation, attendees will have learned how to perform a pair-matching of bilateral bones via mesh-to-mesh comparisons using 3D image data. Additionally, attendees will understand that this new method will be useful for quantifying the degree of asymmetry of paired bones as well as segregating commingled skeletal remains recovered in a forensic context.

Impact Statement: This presentation will impact the forensic science community by suggesting a new objective pair-matching method that will not only enhance the accuracy of segregation of commingled remains but also overcome the drawbacks associated with traditional pair-matching methods.

Forensic anthropologists often encounter a challenge where multiple human skeletal remains are recovered in a commingled state. Without accurate segregation of commingled remains into individuals, the accuracy of subsequent forensic analyses will be compromised. Pair-matching is one of the popular segregation methods based on the similarity/dissimilarity of the shape and size of bilateral bones. The idea behind the method is that the within-individual discrepancies of the bones should be smaller than the between-individual discrepancies. Traditional pair-matching methods have their own limitations. For example, visual pair-matching is not free from an issue of subjectivity and its accuracy likely depends on the researchers' personal training and experience level significantly.¹ Osteometric pair-matching also has multiple statistics-related drawbacks.² The purpose of this research is to generate a new objective pair-matching method based on the mesh-to-mesh comparisons of bilateral bones using their 3D images

Computed Tomography (CT) images of the upper and lower limb bones from 106 Korean individuals (55 females, 51 males) were obtained from the Digital Korean Project (<http://dk.kisti.re.kr/>). The mean ages are 50.9 years (SD=9.8 years) and 53.9 years (SD=8.1 years) for males and females, respectively. After mirroring all left bones using Meshmixer®, each of the mirrored bones were overlapped/aligned with the corresponding right bones from the same individuals using CloudCompare®. In addition, 94-150 pairs from different individuals were randomly selected and compared in the same way. Then, the mean and standard deviation of the distances (D_{mean} and D_{sd} , respectively) between corresponding faces of the overlapped bones were calculated. To calculate the probability of a pair of bones belonging to a single individual or different individuals, the logistic regression analysis was carried out where the D_{mean} and/or D_{sd} were used as variables.

The results show that both the D_{mean} and D_{sd} are lower in the within-individual pairs (0.55mm-0.85mm and 0.48mm-0.78mm for D_{mean} and D_{sd} , respectively) than in the between-individual pairs (1.14mm-3.12mm and 0.89mm-2.09mm for D_{mean} and D_{sd} , respectively) for all bones. Overall, the D_{mean} and D_{sd} are lower in females than males, which indicates that female bones tend to be more symmetric. Within an individual, the lower limbs tend to be more asymmetric than the upper limbs. Logistic regression models yield the Correct Classification Ratios (CCR) ranging between 89.8% (variable: D_{sd} of radius) and 100% (variable: both D_{mean} and D_{sd} of humerus) for males and between 74.6% (variable: D_{sd} of humerus) and 96.0% (variable: D_{mean} and D_{sd} of tibia) for females.

This study suggests a new method to quantify the asymmetry/symmetry of bilateral bones using 3D images of the Korean population. The result of this study will particularly contribute to an accurate segregation of commingled skeletal remains in an objective way.

Digital Pair-Matching, Commingled Skeletal Remains, Korean

A87 Expanding Lines of Evidence: Contextualizing Open Forensic Cases to Enhance Identification Efforts in Texas

Molly Kaplan, MA, Texas State University, San Marcos, TX; Shelby Garza, MA, Texas State University, San Marcos, TX; Jennifer Barron, MLitt, Texas State University, San Marcos, TX; Michelle Hamilton, PhD, Texas State University, San Marcos, TX*

Learning Overview: After attending this presentation, attendees will better understand of the importance of pursuing contextual identifications for long-term unidentified decedents.

Impact Statement: This presentation will impact the forensic science community by exemplifying how unresolved forensic anthropological cases in Texas can be further characterized using geospatial, archival, and biocultural data to further identification efforts.

Marginalization and structural inequities that affect people in life can also impact their postmortem treatment in the investigative sphere. Disparities in resource allocation, case prioritization, and conscious and unconscious biases within forensic science, law enforcement, and medicolegal agencies influence the degree of sustained focus a case may receive. Particularly for the long-term dead, a lack of traceable antemortem information, absence of comparative DNA samples, and limited postmortem data often make positive identification extremely difficult, if not impossible. The current presentation argues, however, that investigating these cases should remain a priority and should be carried out by incorporating additional lines of evidence that go beyond the traditional biological profile.

This presentation explores the potential use of non-traditional contextual information via open forensic cases currently housed at the Forensic Anthropology Center at Texas State University (FACTS). The study examines a selection of open cases, ranging from 1967 to 2014, representing at least 81 unidentified individuals who have been transferred to FACTS custody from various medicolegal agencies and legal jurisdictions. cursory analyses suggest that 18 of these cases (22.2%) are likely archaeological in origin and should be repatriated accordingly, while one case is non-human and has been de-accessioned. The remaining 62 cases are of medicolegal significance, and, of these, only 25 (40.3%) have recorded dates of recovery, while 45 (72.6%) have provenience data in the form of county jurisdictions. Fifty-two cases (83.9%) also have associated case numbers from law enforcement or other agencies, while six cases (9.7%) have associated law enforcement reports, and four (6.5%) have available scene photographs. Eight cases (12.9%) have evidence of DNA submission, but only two cases (3.2%) have traceable National Missing and Unidentified Persons System (NamUs) case numbers. These inconsistencies in case documentation highlight systemic roadblocks to identification that often characterize the long-term unidentified, especially in academic institutions where personnel turnover is steady and there is an overreliance on institutional memory.

This research seeks to utilize geospatial, demographic, and records data in order to generate a more holistic characterization of this unidentified population to inform potential new investigative directions. By cross-referencing state and county missing and unidentified persons data in Texas with geographic information on socioeconomic status, mental health, Uniform Crime Reporting statistics, and migration and migrant death rates, the present study examines various biocultural profiles that could potentially supplement unknown persons cases with additional pathways to identification.

The goal of this presentation is to demonstrate the potential application of contextual data to unresolved casework. The integration of disparate types of biocultural, geospatial, and archival information may serve to further characterize unknown individuals when no positive identification is forthcoming, even after the biological profile has been estimated, the remains have been entered into NamUs, and DNA samples submitted. The prioritization of long-term open cases is a way to pursue expanded humanitarian definitions of identity and justice, while broadening the role of forensic anthropologists as scientific investigators and identification specialists.

Forensic Anthropology, Contextual Identification, Open Case Investigation

A88 Addressing Informational Gaps in Family Reference Sample Practices for Transnational Missing Persons' Cases

Diana Madden MA, Lurie Children's Hospital, Chicago, IL; Zecilly Guzman, BS, Lurie Children's Hospital, Chicago, IL; Courtney C. Siegert, MS, Texas State University, San Marcos, TX; M. Katherine Spradley, PhD, Texas State University, San Marcos, TX; Sara H. Katsanis, MS, Lurie Children's Hospital and Northwestern University, Chicago, IL; Annika Larson, Smith Child Health Outcomes, Research, and Evaluation Center and Lurie Children's Hospital, Chicago, IL and Northwestern University, Evanston, IL*

Learning Overview: After attending this presentation, attendees will understand how a novel social science research strategy was used to document challenges, leading to the development of informational resources.

Impact Statement: This presentation will exhibit an educational resource to address informational gaps in family reference sample collection practices for transnational DNA identification.

When people go missing in United States border states, families and professional stakeholders may not know how best to report a missing person or how to provide family reference samples for DNA identification of deceased migrants. Navigating a lengthy, open-ended missing person search, both families and stakeholders would benefit from improved understanding of family reference sample management practices and increased awareness of the options for families seeking their relatives.

To better understand the challenges faced in cross-border DNA identifications, the study team developed an empirical research strategy to collect qualitative and quantitative data to assess stakeholders' challenges, varying priorities, and points of agreement on solutions, as well as gaps in data necessary to inform policies and practices. In 2020, 26 professional stakeholders were convened for a semi-structured "stakeholder forum." This strategy combined a focus group approach to gather perspectives from stakeholders with similar interests with a community forum approach to collect themes. A pre-forum questionnaire, the forum discussions, and audience response questions were collected and coded for challenges and proposed solutions, yielding 79 challenges and 36 solutions. The challenges and solutions were formulated into 44 challenge statements under six categories and 24 solution statements under four categories for post-forum testing in a modified-Delphi analysis. Stakeholders attending the forums were invited to rank the priority of challenge statements and viability of solution statements via Likert scales, providing comments on their reasoning. Rankings from the 15 respondents were evaluated for consensus across stakeholder types, and comments were assessed for commonalities and differences. Ten of the challenges were grouped for ranking under "Education and Communication," the top two with consensus being "long turn-around time for matches" and "inadequate communication with families while investigations are ongoing."

Partly motivated by the need for improved communication on these practices, the academic BorderDNA working group formed to develop unbiased educational resources on three related applications of DNA at the United States border, including for transnational missing persons. Guided by a master menu of target audiences, product types, and dissemination outlets, the group created an animated video short for families on how to provide family reference samples for transnational DNA identifications. The video aims to educate viewers on: (1) the overall process for use of family reference samples to identify deceased persons; (2) the options available to families to provide family reference samples to the Combined DNA Index System (CODIS) or a private database; (3) the privacy and security protections afforded DNA data; and (4) who should provide family reference samples.

An effective resource should not only address educational gaps; it should also be calibrated to reach audiences enmeshed in a multi-stakeholder context. This entails an unbiased presentation of facts and contexts that remains compassionate and trauma informed. The working group innovated an iterative process to develop and test the content of its resources. First, drafts are shared within the neutral academic working group, which brings unbiased, diverse content expertise. Then, final drafts are shared with potentially biased but contrasting representative expert stakeholders for feedback and further refinement by the working group.

This research exemplifies how an empirical research strategy can directly inform the development of unbiased resources. This is an evolving model for identifying challenges and bridging knowledge gaps in a complex multi-stakeholder context.

Family Reference Samples, Missing Persons, Social Science

A89 Practitioner Attitudes Toward the Management of Unidentified Human Remains in the United States

Jennifer E. Spence, PhD, Tulane University, New Orleans, LA; Courtney Siegert, MA, Texas State University, San Marcos, TX; Petra Banks, MA, Texas State University, San Marcos, TX; Devora Gleiber, MA, Texas State University, San Marcos, TX; Justin Z. Goldstein, MA, Texas State University, San Marcos, TX; Sophia Mavroudas, MA, Texas State University, San Marcos, TX; Mariah Moe, MA, Texas State University, San Marcos, TX; Emilie Wiedenmeyer, MA, Texas State University, San Marcos, TX; Kate Spradley, PhD, Texas State University, San Marcos, TN*

Learning Overview: This research contributes to the investigation of policy and practice regarding Unidentified Human Remains (UHR) in the United States by examining factors that facilitate the management and identification of UHR cases.

Impact Statement: This presentation educates attendees about medicolegal practitioners' attitudes toward management of UHR—including awareness of laws, assessment of whether these laws are adequate, and degree of satisfaction with how agencies handle UHR cases—and what factors influence these perspectives.

Although identifying human remains is essential for legal, ethical, and humanitarian reasons, UHR cases pose a major ongoing challenge in the United States. In 2007, the National Institute of Justice declared the number of missing persons and unidentified dead a “silent mass disaster over time,” with the magnitude of the problem overwhelming local and state capacity to respond effectively.¹ Unlike mass disasters typically associated with sudden events, the missing and unidentified crisis in the United States spans decades. Between 1980 and 2004, for instance, the remains of approximately 10,300 UHR were reported to the United States National Death Index.² Currently, the remains of around 4,400 unidentified individuals are recovered annually in the United States, with roughly a quarter of those still unidentified after one year.³

State laws typically govern how UHR cases are handled. In the absence of such laws, institutional policy provides guidance. Because medicolegal practitioners are charged with upholding these laws and policies, they provide critical insight into understanding the challenges and issues related to the management and identification of UHR. Therefore, to assess the attitudes of practitioners toward the management of UHR cases, an online anonymous survey was disseminated to members of the American Academy of Forensic Sciences (AAFS) (Anthropology, General, and Pathology/Biology Sections); members of the American Board of Medicolegal Death Investigators (ABMDI); and Medical Examiners (MEs), coroners, and law-enforcement officials with publicly available contact details. In addition to professional demographic information, recipients were asked to comment on the adequacy of existing state laws and office policies regarding UHR and their awareness of and degree of satisfaction with these laws.

One hundred eighty-six individuals responded to the survey (AAFS $n=85$, ABMDI $n=7$, Other $n=94$). Most responses (51.6%) were from coroners, followed by MEs (32.8%), sheriffs (4.8%), educational institutions and law-enforcement agencies (3.2% each), and other agencies (4.3%). Respondents whose offices provided training related to state policy for dealing with UHR were equally divided between yes and no (48.3% each), with 3.3% unsure. Almost twenty-five percent (24.7%) of respondents had worked for their current office or jurisdiction for 0–5 years, 20.4% for 6–10 years, and more than half (54.8%) for >10 years.

A two-way table with chi-square test indicated that training was significantly associated with awareness of laws regarding UHR ($P=0.000$), assessments of adequacy of these laws ($P=0.032$), and satisfaction with the ways in which offices handled UHR cases ($P=0.020$). Respondents with training were more likely than expected to be aware of laws, find laws adequate, and be satisfied with laws, while respondents without training were more likely than expected to report themselves unaware of laws, find laws inadequate or be unsure about adequacy, and be occasionally unsatisfied or unsatisfied with handling of UHR cases. In addition, office type was a significant predictor ($P=0.024$) of whether the respondent regarded laws regarding UHR as adequate. Respondents from coroners' offices were more likely to consider laws adequate, while respondents from MEs' offices were more likely to find laws inadequate.

These findings highlight the importance of training for medicolegal practitioners working with UHR across the United States and hint at fundamental organizational or professional differences underlying practitioners' perspectives. Results will be discussed in the broader context of policies regarding UHR.

Unidentified Human Remains, Jurisdictional Authority, Medicolegal Practitioner

A90 State Policy Regarding the Treatment of Unidentified Human Remains and the Need for Scientific Advocacy

Courtney C. Siegert, MA*, Texas State University, San Marcos, TX; Jennifer Spence, PhD, Tulane University, New Orleans, LA; Petra Banks, MA, Texas State University, San Marcos, TX; Mariah Moe, MA, Texas State University, San Marcos, TX; Devora S. Gleiber, MA, Texas State University, San Marcos, TX; Emilie Wiedenmeyer, MA, Texas State University, San Marcos, TX; Justin Z. Goldstein, MA, Texas State University, San Marcos, TX; Sophia Mavroudas, MA, Texas State University, San Marcos, TX; Kate Spradley PhD, Texas State University, San Marcos, TX

Learning Overview: Through this presentation, attendees will gain a better understanding of the complexities of state policies regarding the treatment of Unidentified Human Remains (UHR) in the United States.

Impact Statement: This presentation will impact the forensic science community by presenting data collected from all 50 states and Washington, D.C. regarding the treatment of UHR and highlighting the variability and inconsistencies in these state laws.

Investigating the identity of UHR who enter the medicolegal system is crucial for several reasons beyond criminal justice. These efforts enable families of the missing and disappeared to pursue restorative justice and seek closure through answers, and the reclamation of dignity and respect for the dead has been invoked globally in support of the imperative to identify the deceased.¹⁻⁵ Additionally, it is argued that universal, inherent rights apply not only to the living but also to the dead, and the failure to fulfill these obligations, the first of which is to establish identity, constitutes a human rights violation.^{4,5} Despite these compelling factors, UHR cases continue to pose a major challenge for forensic practitioners, government officials, law enforcement, and local communities on a national and international scale.⁶ To address the political, social, and structural barriers contributing to and resulting from this “silent mass disaster,” a community of practice that facilitates case resolution is desperately needed.⁶

This research examined policies from all 50 states and Washington, D.C. to better understand how UHR cases are being handled at the state level and to assess the impact of these laws on UHR casework. A series of questions ($n=23$) regarding the investigative process, record keeping, and final disposition were evaluated using the most recent versions of state statutes publicly available through state legislative websites. The location of relevant laws relied on keyword searches including unidentified human remains, unknown decedent(s), missing person(s), autopsy, medical examiner, coroner, inquest, and DNA.

While 48 (94%) locales have active statutes relating to the treatment of UHR, only 32 (63%) explicitly state that investigation into the decedent's identity is required. Furthermore, only 29 (56%) specify postmortem data collection that could aid in the identification process and even fewer ($n=19$; 37%) require genetic sampling when alternative means of identification are not productive. The paucity of comprehensive clearly stated, and organized policy regarding the treatment of UHR illustrates a potential cause for the continuation of the “silent mass disaster” defined by the National Institute of Justice in 2007.⁶ However, even sound policy is inconsequential when not consistently applied in practice.⁷ Future work will investigate the impact of United States Census Bureau state statistics (e.g., population size, GDP, poverty level, etc.) and UHR historic case statistics from the National Crime Information Center (NCIC) on policy regarding the treatment of UHR cases.

The unique perspective provided to anthropologists through specialized training within social and “hard” sciences enables forensic practitioners to take a more active role in the identification process beyond report generation and to serve their communities through scientific advocacy and working toward policy change. For instance, although many state policies discuss the treatment of UHR and the handling of missing persons cases, few states recognize that UHR and missing persons cases are often one and the same. This disconnect seems to be exacerbated within vulnerable populations, including people of color and transnational migrants. This study does not suggest that a “one-size-fits-all” approach is the most effective path forward in mitigating the overwhelming effects of UHR casework. However, by evaluating and understanding state policies, forensic practitioners may work toward crafting proactive, collaborative, and interdisciplinary solutions that will facilitate the herculean task of identification.

Unidentified Human Remains, State Policy, Scientific Advocacy

A91 A Model for Multidisciplinary Identification Investigations in Medical Examiner and Coroner Offices: The New York City Office of Chief Medical Examiner (NYC OCME) Identification Review Committee

Allison Sharplin, MA, New York City Office of the Chief Medical Examiner, New York, NY*

Learning Overview: After attending this presentation, attendees will be familiar with the thorough decedent documentation protocols and investigative actions taken for decedents that are tentatively identified, unidentified, or that have complex alias issues leading up to presentation at the NYC OCME Identification Review Committee (IRC) meeting. The IRC applies a multidisciplinary quality assurance system for the confirmation of identity in the more challenging and complex cases, including decedents who are unknown without context, visually unrecognizable, and/or present with multiple identification aliases. These investigative methods and actions can be applied on a smaller or larger scale, depending on the need of the medical examiner or coroner office.

Impact Statement: This presentation will impact the forensic science community through the presentation of a multidisciplinary approach of forensic specialties to human identification in medical examiner and coroner offices. This model recommends thorough documentation of unidentified decedents as well as investigation into their identity and search for next of kin prior to temporary disposition.

The IRC format has its roots in Disaster Victim Identification (DVI) procedures in mass fatality management operations. Humanitarian law dictates that in natural disasters or armed conflict, the management of the dead is a priority during the response and survivors have a right to know the whereabouts and fate of their deceased loved ones. Common law also supports the right of next of kin and families to sepulcher (to choose and control the burial, cremation, or other final disposition of a deceased person). In day-to-day operations, medical examiners and coroners are tasked with confirming the identity of deceased persons in their care as part of the death investigation. A confirmed identification is necessary to notify the legal next of kin, resolve estate issues and criminal and/or civil litigation, and to issue death certificates.

At NYC OCME, decedents are brought into the office as unidentified or tentatively identified. Identifications are confirmed through modalities including visual, fingerprints, radiology, odontology, DNA analysis, or contextual methods. NYC OCME serves a large, diverse population that includes persons without close family, in a transient state, and otherwise without context. The steps leading up to case presentation at IRC ensure a thorough documentation of decedents, identification investigation, and next of kin search. Documentation of decedents begins on the day of autopsy or external examination. Identification Investigators work to confirm identifications. Family investigators search for next of kin.

As time passes from the date of death, decedents that remain unidentified or without resolution to complex aliases are presented to the IRC. The process of the IRC ensures an effective system to ensure a diligent search of available avenues for confirmation of identification, integration of several lines of evidence into a recommended identification outcome, as well as the search for next of kin for each decedent. The monthly IRC meeting consists of experts from each relevant OCME discipline who evaluate evidence presented and provide input for additional avenues of investigation: Identification Unit, Anthropology, DNA (Forensic Biology), Medicolegal Investigations, Medical Examiners, NYPD Missing Persons Unit, and Family Outreach. Each case discussed at IRC results in a recommendation to approve a confirmed identification through a selected modality, or additional investigative direction, recommendation for DNA analysis, or burial with an unverified identification status. After a recommendation of unidentified or unverified identification status from the IRC, temporary traceable burial in the city cemetery ensures that future methods can be utilized to confirm identification and allows future family members to determine final disposition.

Decedent Identification, Unidentified Decedent, Alias

A92 An Introduction to the International Committee of the Red Cross (ICRC) Resolve Platform, a Web-Based Application for the Management of Information of Missing Persons and Human Remains

Maria Mikellide, MA, International Committee of the Red Cross, Geneva, Switzerland; Mirjana Kobasica, MSc, International Committee of the Red Cross, Geneva, Switzerland; Kristy Winter, MA, International Committee of the Red Cross, Geneva, Switzerland; Matthew Vennemeyer, MA, International Committee of the Red Cross, Geneva, Switzerland*

Learning Overview: After attending this presentation, attendees will have gained insights on the challenges, opportunities, and constraints of building an electronic tool for the management of information on missing persons and human remains.

Impact Statement: This presentation will impact the forensic science community by introducing a new tool for the management of forensic data while also sharing experiences on the challenges and limitations encountered during its construction.

Through the ICRC's experience in multiple contexts, the ICRC has observed significant variation in methods and standards for the management of forensic data. Sudden surges in cases caused by disasters, armed conflicts, violence, and disease outbreaks further impede efforts to properly manage forensic data. As a result, traceability of unidentified and unclaimed remains may be lost, records may be unavailable or poor in quality, and, in some instances, remains may fail to maintain their identity in overwhelmed mortuaries, giving rise to administrative disappearances. Meanwhile, when systems and mechanisms are not in place for the proper management of information, family requests may be lost and families may not receive timely updates about the status of their cases.

To respond to modern challenges and assist both local missing persons agencies and mortuaries improve the management of information, the ICRC began building the Resolve Platform in 2017.¹ The overarching objective is to replace the existing tool developed in the 2000s (called AMPM Database) with a comprehensive solution that addresses the original needs, as well new challenges, such as managing large data sources, demand for remote collaboration, and integrating multiple sources of data of different quality.² The aim is to offer the application as an empty shell to requesting agencies to help improve management of information on missing and dead. The application can be utilized for the management of routine cases or cases resulting from emergencies by forensic specialists and non-specialists such as mortuary technicians and administrative staff as well as first responders.³

While there is growing need worldwide for such systems, there are also challenges when developing a technical platform that is flexible enough to be adapted to different operational environments, legal frameworks, languages, and workflows. Variations in local infrastructure and availability of human resources further compound efforts for the development of a solution. Similarly, there are added layers of complexity, such as building internal security requirements, storage availability, data protection standards, and the ability for software maintenance.

In late 2019, the ICRC completed the first module, which focuses on missing persons (antemortem data), events linked to disappearances, and potential burial sites. In late 2021, the second module was completed, which includes functionality for the data on recovery operations of sites and both field and lab documentation of human remains, as other cases (artifacts, samples).

This presentation will offer an opportunity to view key functions of the application with an emphasis on postmortem data while also sharing insights into the build process of the software.

Humanitarian Forensic Action, Human Identification, Forensic Data Management

A93 An Overview of Recent Migrant Drowning Deaths in the Balkans

Sherry Fox, PhD, International Committee of the Red Cross, Pristina, Kosovo*

Learning Overview: Migrants are drowning around the world, with families often suffering from the ambiguous loss of their loved ones. Although migrant drowning deaths in the Mediterranean Sea are generally known, attendees can expect to gain an appreciation for migrant drowning deaths on the European mainland in the Balkans, as migrants drown in rivers in their attempts to reach northern Europe. Secondly, unfortunately, some of these individuals are not identified nor will their identification be possible in the future.

Impact Statement: This presentation draws attention to migrant drowning deaths in the Balkans, particularly in rivers, as migrants attempt to reach northern Europe. Demographic information regarding sex and age data, when known, are presented, among other factors, including, for example, the times of year when migrant drowning deaths are occurring in the Balkans. Additionally, a shift in migratory patterns may be emerging, regarding the country of origin of migrants. Unfortunately, some dead migrants may never be identified, and as such, promotion of their dignified management is presented. It is hoped that by bringing attention to this situation, perhaps fewer migrant drowning deaths will occur in the future in the Balkans.

Migrant deaths along European maritime routes are well reported and are once again on the rise, with the Mediterranean leading the world among the deaths of migrants.¹ Many migrants passing through Greece and/or Turkey *en route* to northern Europe will traverse the Balkans. According to the International Organization for Migration (IOM) in 2021, through the month of July, the majority of migrants dying in Europe are dying in the Balkans by a factor of three times the combined deaths elsewhere on the continent.² The purpose of this study is to raise awareness of migrant drowning deaths in the Balkans. Utilizing data from the Regional Information Center (RIC) of the International Committee of the Red Cross (ICRC) collected for the purposes of helping family members locate their loved ones who have gone missing during migration, insight has been gained into recent migrant deaths in the region, including drowning deaths. It should be noted that along with the ICRC, the RIC data is gathered by many people among the various Red Cross societies as part of the Red Cross/Red Crescent Movement in the Balkans from published accounts where identity could not be established at the scene. Between February 24, 2015, and June 21, 2021, 95 incidents have been recorded in the RIC database documenting 166 deaths, including 59 drowning deaths or approximately one-third of migrant deaths in the Balkans. It should be noted that this figure is an underrepresentation of actual migrant drowning deaths in the region. Additionally, if bodies were not recovered from an incident, or if the cause of death of bodies recovered from bodies of water was unknown, these individuals were not recorded.

Information will be presented on migrant drowning deaths in the Balkans based on publicly available data, including: the number of deaths by drowning per incident, biological sex, age at death, month of drowning, where the drownings are occurring, country of origin, if these individuals are identified, and if the burial location is known. Results indicate that most migrant drowning deaths represent adult males, which is representative of the migrant population in the region. Most migrant drowning deaths in the Balkans are in rivers, including rivers demarcating political boundaries, such as the Danube. The largest number of migrants drowning per incident is nine, with two such incidents reported. The identities of these individuals often remain unknown, are from unknown countries of origin, and are with unknown burial locations. June and November are the deadliest months for drowning among migrants in the Balkans with no record of drowning deaths among migrants in the region during the winter months of January and February, and no record of drowning deaths among migrants in the summer months of July and August. The latter may be due in part to lower water levels in the smaller rivers during mid-to-late summer. There may also be a shift in recent years in the countries of origin among migrants with more migrants traveling from countries in Asia, such as Syria and Iraq, rather than from countries in Africa, as was common in the past. Additionally, burial locations of unidentified migrants need to be marked and recorded such that human remains can be exhumed if identified and ultimately returned to their loved ones.

The forensic sciences can contribute to helping solve humanitarian problems: by ensuring that the dignity of the deceased and the dignity of the bereaved are preserved; by restoring identities to the unidentified; by providing families of migrants with information on their loved ones; and by returning those identified to their families. It is hoped that by raising greater awareness of migrant drowning deaths in the Balkans, fewer migrants will die by drowning in the future.

Migrant, Drowning, Balkans

A94 Forensic Crisis in Mexico: Lessons Learned From International Cooperation

Aurora Marcela Pérez-Flórez, MSc, GIZ, Mexico City, Mexico; Maximilian Murck, MSc, Jr., GIZ, Mexico City, Mexico; María Fernanda Lazcano Campos, BSc, GIZ, Mexico City, Mexico*

Learning Overview: After attending this presentation, attendees will have a better understanding of the challenges of the forensic crisis in Mexico that has left more than 50,000 unidentified individuals in forensic institutes and public graves. Lessons learned from the perspective of international cooperation, especially between Mexico and Germany, will be presented.

Impact Statement: This presentation will impact and contribute to a technical and scientific discussion on how the international forensic science community can support international efforts to overcome this forensic crisis.

In Mexico, disappearances have been a common denominator since the late 1960s. Starting with the so-called “Dirty War” and even more so in the war against drug trafficking declared by former President Felipe Calderón, an important growth of this criminal phenomenon was identified. Today, Mexico has more than 90,840 missing persons according to the National Registry of Missing and Unidentified Persons (RNPDO) and around 52,000 Unidentified Deceased Persons (UDP).^{1,2} Given the lack of action by the Mexican state, in 2009 groups of families of disappeared persons began to form throughout the national territory. These groups, together with the recent National Search Commission (CNB), have managed to locate hundreds of clandestine or official graves in all the states of the Republic. However, the identification processes do not advance at the same pace as problems associated with the lack of institutional capacities for identification, including the sparse use of fingerprints or DNA for identification purposes, deficient use of databases, lack of transparency, homologation of approved criteria, among others, shows that Mexico is currently experiencing a forensic crisis regarding human identification.²

This presentation collects the problems evidenced by international cooperation, especially the case of the German Development Cooperation (GIZ), a German government-owned development agency, with the project *Strengthening the Rule of Law* (www.identificacionhumana.mx) in Mexico, and the learning and areas of opportunity that have been developed with a view to preventing this type of scenario in the future. The case of the State of Tamaulipas is presented, where a multidisciplinary forensic identification team with the support of the Forensic Anthropology Foundation of Guatemala (FAFG) and GIZ was created in the state attorney’s office. The implementation of process flows for the standardization of fingerprints will also be discussed. Likewise, the results of the generalized search processes (file searching) in mass graves of municipal cemeteries in Veracruz will be presented.

Human Identification, International Cooperation, GIZ

A95 Forensic Anthropology in the United Kingdom: The Evolving Landscape and Professional Certification of the Discipline

Julie Roberts PhD, Liverpool John Moores University, Liverpool, United Kingdom; Sarah Ellingham, PhD, International Committee of the Red Cross, Geneva, Switzerland; Rachael Carew, PhD, Coventry University, Coventry, United Kingdom; Linda Ainscough, MSc, Cellmark Forensic Services, Chorley, United Kingdom*

Learning Overview: This presentation will outline the development of forensic anthropology and associated professional bodies in the United Kingdom. It will further discuss the positioning of forensic anthropology within the United Kingdom Criminal Justice System (UK CJS), the development of forensic anthropology degree programs, professional certification system and typical areas of employment, and types of cases commonly encountered in the United Kingdom.

Impact Statement: This presentation will impact the forensic science community by showcasing how the United Kingdom—as one of the forerunners in Europe—has professionalized the discipline of forensic anthropology, including the creation of a certification system and granting of chartered status to senior practitioners. This framework can function as a blueprint for countries who are yet to embark on professionalization of forensic anthropology.

Forensic anthropology first gained visibility in the United Kingdom in the 1990s through the involvement of United Kingdom Forensic anthropologists with the criminal tribunals for the former Yugoslavia and Rwanda, after which their assistance with domestic criminal cases was increasingly requested. Since the early 2000s, a number of United Kingdom universities have offered both undergraduate and postgraduate degrees in Forensic Anthropology, either alone or often paired with other fields. The establishment of a United Kingdom Forensic Science Regulator (FSR) in 2008 catalyzed the development of professional bodies in forensic anthropology, with the formation of the British Association for Forensic Anthropology (BAFA) and the Forensic Anthropology Committee of the Royal Anthropological Institute (RAI) in 2011. A collaboration between these two organizations sought to address the need for a national standardized framework for forensic anthropology practitioners in the United Kingdom. Further aims were to provide a career pathway for forensic anthropologists and a means of demonstrating professional competence.

In 2013, a three-tiered professional certification scheme was introduced by the RAI to provide a transparent framework for the practice of forensic anthropology casework in the United Kingdom, as well as transparency regarding competence for police, judiciary, and other clients. The framework further demonstrated a career development pathway through a system of mentorship and attaining competencies at each level of expertise. This United Kingdom certification scheme continues to evolve with the recent granting of Chartered status to those practitioners certified at the most senior level.

The forensic anthropology framework was developed in conjunction with the Forensic Science Regulator and was designed to meet the evolving quality standards required in the United Kingdom CJS. Importantly, all United Kingdom forensic science practitioners are now required to adhere to the FSR Code of Practice and Conduct, and forensic anthropologists are required to practice in compliance with the RAI Code of Practice for Forensic Anthropology published in 2018. Further, the Forensic Science Regulator was granted statutory powers in May 2021, meaning that quality standards can now be legally enforced.

This presentation highlights developments in forensic anthropology that have been made in the United Kingdom over the past 30 years in education, policy, and practice. Future challenges and goals around continuing to evolve with the modern forensic science world will also be discussed, including the extension of the certification scheme to internationally based forensic anthropologists, the impact of the FSR gaining statutory powers, and concerns regarding the limited accessibility to casework to gain practical experience in the United Kingdom.

The goal of this presentation is to highlight this successful example of how forensic anthropology in the United Kingdom has been transformed from an almost unknown discipline to a fully recognized profession in its own right. The framework presented can serve as a blueprint for countries who are yet to embark on their journey of professionalization of the discipline and facilitate the continued evolution of professional forensic anthropology practices globally.

Forensic Anthropology, Professionalization, United Kingdom

A98 Education and the Biological Profile: Survey Data on the Construction of the Biological Profile

Ashley Smith MSc, University of Toronto, Toronto, Ontario, Canada; Alexis Dzubak, MS, The Ohio State University, Columbus, OH; Alexandra Saly, MSc, University of Toronto, Toronto, Ontario, Canada; Evonne Turner-Byfield, MS, The Ohio State University, Columbus, OH; Justin Maiers, MS, University of South Florida, Tampa, FL*

Learning Overview: After attending this presentation, attendees will have learned about the congruences and the variability that exist in the process of learning to construct a biological profile, as well as the perceived efficacy of the practice of constructing the biological profile in practice.

Impact Statement: This presentation will impact the forensic science community by highlighting the pedagogical practices taught across different universities and subdisciplines of anthropology and how they affect the construction of the biological profile.

The four primary biological profile categories are used to develop a potential identity of a set of skeletal remains and are based on metric and morphometric data. Recently, the efficacy of the biological profile has been questioned. The potential for different results highlights the necessity for education and practice, yet this type of training is not standardized from institution to institution. With the variety of interconnected external variables that influence ancestry assessments, small differences in the education and experience of the observers may result in dramatically different outcomes in final reports. Furthermore, the range of human variation found in any population is perpetually in flux, which makes reflection on the techniques used in ancestry assessment critically important. Likewise, sex estimation brings along its own social and cultural variations, particularly with regard to transgender, non-binary, and gender non-conforming individuals. This means that an individual in a given case may have identified with a different gender than what may be recorded using current anthropological practices and procedures.

Beyond the social aspects of the biological profile, other aspects of the profile also demonstrate questions as to “usefulness,” namely that of age and stature estimations. Adult age estimation methods as currently used and taught tend to have wide ranges, with some demonstrating statistically valid ranges (95% Confidence Interval [CI]) of ± 15 –20 years or more. Further complicating matters is the fact that morphological traits, both macroscopic and microscopic, can be affected by factors such as genetics, pathology, and even trauma. One of the greatest problems for stature estimation is errors in how measurements are taken, resulting in actual measurement error. Further, the resulting stature ranges emanating from the calculations tend to be wide themselves, ranging around ± 5 ", which could potentially cover more than a plurality of the population's average stated stature.

With these in mind, a study was conducted on the educational practices, utility, and efficacy of the biological profile, both in graduate and undergraduate institutions, as well as with practicing professionals. An anonymized study was conducted and sent out to 80 academic institutions, as well as selected professional organizations and listservs. The survey was hierarchical in nature with similar questions posed to both students and educators/professionals, while others were geared toward one group or another. There was a mix of quantitative and qualitative questions with categories including educational background/career focus, training in the construction of the biological profile, importance of the profile in anthropological casework, and reflections on individuals' practice in the field. Analysis was limited to basic descriptive statistics regarding the quantitative data and thematic analysis for the qualitative data.

While data collection is on-going, preliminary data was collected from a number of students and suggests they view forensic anthropology as primarily consisting of the biological profile while also reporting a lack of hands-on experience requiring looking outside their home institutions for mentorship and training. Further, students noted an interest in more training in taphonomy and trauma to augment the biological profile and that course textbooks are not sufficient in providing a comprehensive understanding of the field. In addition to the survey, anecdotal results demonstrated there is a variance in the training and understanding of the biological profile, in both practice and theory.

Given the results, this study has compiled a series of recommendations to the field including, but not limited to: the creation of a better textbook for undergraduate and graduate training; the incorporation of tangent fields, such as statistics and theory, as a part of required coursework; the creation and use of diversified skeletal teaching collections' and, for graduate education, training in an applied setting.

Biological Profile, Pedagogy, Praxis

A99 Theoretical and Methodological Considerations of the Estimation of Osteological Sex Utilizing Fuzzy Rule-Based Inference Systems

Katherine Lane, MA*, University of Central Florida, Orlando, FL; Donovan Adams, PhD, University of Central Florida, Orlando, FL

Learning Overview: The goal of this presentation is to inform attendees of the variation in biological sex, which is not discrete and binary as traditionally conceived and constructed within forensic anthropology, and how this information may be incorporated into quantitative models.

Impact Statement: This research will impact the forensic science community by rethinking how sex is framed and estimated in forensic anthropology by examining how individuals cluster and are classified using fuzzy logic.

Forensic anthropologists traditionally estimate sex in a binary, discrete model that does not reflect biological sex variation. Forensic anthropologists differentiate between gender and biological sex, with biological sex being assigned at birth primarily on the basis of external organs and impacted by a combination of chromosomal, hormonal, and anatomical characteristics. The biological variation for each of these factors exists on a spectrum of their own, and there can be a discordance between these aspects of sex.¹ From this, the estimation of sex in forensic anthropology is not as clear-cut as traditionally considered, and focusing on only a two-sex model reinforces biological normalcy.^{2,3}

This study investigates the variation in biological or, more specifically, osteological sex using craniometric data of females ($n=961$) and males ($n=1,634$) from the Forensic Data Bank to address: (1) do the categories of female and male accurately reflect biological variation? and (2) how do fuzzy principles affect classification in our current binary system?⁴

Descriptive statistics and exploratory tests were conducted for both sexes. Fuzzy C-Means (FCM) was conducted on nine dimensions derived from principal component analysis on a reduced (to limit the amount of estimated data) and k-nearest neighbor ($k=5$) imputed data set to examine patterns within the data and estimate the optimal number of clusters.⁵⁻⁷

The FCM analysis resulted in two optimal clusters being defined with a fuzzifier of 1.3. While the FCM produced a two-cluster model, the degree of membership to each cluster and the cluster of maximum membership varied for both males and females, though female clustering results exhibited a narrower range of variation than males.

Two fuzzy classification methods were tested on the data to approximate traditional forensic methods.⁸ These included Chi's (FRBCS.CHI) and rule-weighted (FRBCS.W) fuzzy rule-based classification systems. Additionally, Adaptive-Network-based Fuzzy Inference System (ANFIS) was tested as a regression model.⁸ The FRBCS.W and FRBCS.CHI with 12 Gaussian membership functions developed on the training model was found to have the highest "accuracy" rate into traditional sex categories (FRBCS.W—76.62%; male: 86.98%, female: 57.98%; FRBCS.CHI—76.43%, male: 82.54%, female: 65.43%). These methods were also tested on three clusters derived from the FCM analysis to assess the impact of expanding from the traditional two-sex model on estimating osteological sex. For the three cluster models, the FRBCS.W (76.81%) and FRBCS.CHI (76.24%) with ten Gaussian membership functions were found to have the highest "accuracy" rate. ANFIS models generally showed a grouping of individuals into one category or cluster; however, additional research will investigate the impact of type and number of membership functions in the utility of these models.

These preliminary results indicate substantial overlap between traditional categories of male and female and that these binary categories fail to capture the variation observed in biological sex. There is potential to continue exploring the utility of fuzzy techniques to address issues of bionormalcy in the discipline. By using unsupervised clustering and allowing for multiple memberships, it is possible to observe natural, rather than constructed, patterns in the data that may be used to better inform practice/research.

Fuzzy Rule-Based Inference Systems, Osteological Sex, Sex Estimation

A100 The Precision of Morphoscopic Traits for Sex and Ancestry Estimation From 3D Surface Scans of the Crania

Sarah Schwing, MA, University of Tennessee-Knoxville, Knoxville, TN

Learning Overview: After attending this presentation, attendees will have a better understanding of the utility of virtual human skeletal elements as proxies to physical bone in the construction of the biological profile. This presentation will focus on the precision and reliability of morphoscopic data for sex and ancestry estimation obtained from 3D surface scans of crania.

Impact Statement: This presentation will impact the forensic science community by discussing a novel application of two widely used morphoscopic methods, Walker's cranial traits for sex estimation and Hefner and Ousley's traits for the Optimized Summed Scored Attributes (OSSA) method for ancestry estimation, to virtual human skeletal remains.^{1,2}

Virtual anthropological investigations of morphoscopic traits have increased over the past two decades, as virtual approaches have gained traction within forensic anthropology.³ The majority of published studies focusing on morphoscopic traits, however, pertain to the Suchey-Brooks age estimation method using the pubic symphysis.⁴ Few additional skeletal elements or biological parameters (e.g., sex or ancestry) have been considered in such morphoscopic investigations and, to date, it appears no virtual anthropological investigation has focused on the Walker or OSSA morphoscopic methods for sex and ancestry estimation.

Further, most virtual anthropological investigations have employed Computed Tomography (CT) technologies. As such, research regarding the precision of morphoscopic data obtained from 3D surface scans is scant and error rates for these virtual methods are unknown, making said techniques inadmissible in courts of law under the *Daubert* criteria.⁵

This investigation sought to understand the applicability of methods developed for use on dry bone to virtual models, specifically 3D surface scans, by analyzing the agreement between morphoscopic data obtained from paired dry and virtual skeletal elements. Using a sample of 42 crania sourced from the William M. Bass Donated Skeletal Collection, housed at the University of Tennessee, Knoxville, Walker's cranial traits for sex estimation and OSSA cranial traits for ancestry estimation were evaluated for agreement across dry and virtual human crania, serving to inform the precision of virtual evaluation of these traits. The impact of experience on inter-format score agreement (e.g., dry scores vs. virtual scores) was also investigated through the inclusion of six additional scorers of divergent experience levels. These results also offer a more informed understanding of the precision and ease of implementation of these methods virtually.

Weighted Kappa tests revealed slightly higher agreement between dry and virtual formats among Walker traits than OSSA traits, with inter-format comparisons of the former demonstrating fair to almost perfect agreement (Kappa values=0.277–0.834), and the latter demonstrating slight to substantial agreement (Kappa values=0.159–0.720). Results also suggest that graduate versus professional experience does not have a statistically significant impact on score agreement between dry and virtual formats.

This study demonstrates the potential for 3D surface scans, and virtual human skeletal elements in general, to serve as proxies for physical bone in research and casework when the latter are unavailable or inaccessible. This research also helps lay the foundation for modifying traditional morphoscopic methods to best suit virtual evaluation of human skeletal remains.

3D Surface Scans, Morphoscopic Traits, Virtual Anthropology

A101 An Evaluation of the Influence of Socio-Cultural Identity on the Morphology of the Mid-Face Among Black South African Groups for Forensic Implications Using 3D Surface Scanning Modality

Alison Ridel, PhD, University of Pretoria, Pretoria, Gauteng, South Africa; Anna Oettl, PhD, Sefako Makgatho Health Sciences University, Pretoria, Gauteng, South Africa; Ericka L'Abbé, PhD, University of Pretoria, Pretoria, Gauteng, South Africa*

Learning Overview: After attending this presentation, attendees will better understand the influence of Black South African socio-cultural identity on variation in the shape of the skeletal mid-face.

Impact Statement: This presentation will impact the forensic science community by providing data on mid-facial shape configurations and on sub-specific discriminate shape matrices for South African socio-cultural identity estimation.

Due to the high number of unidentified bodies in Gauteng province each year, researchers have developed South African standards for establishing a biological profile to identify unknown persons.¹ However, as significant differences in population affinity-related morphological variations exist, the probable identification of an unknown individual is based on the presence of quantifiable phenotypic variations and the relationship of these variations to the individual's socio-cultural identity (e.g., Khoisan, Pedi, Sotho, Swazi, Tsonga, Tswana, Venda, and Zulu).¹ This study aims to evaluate the influence of socio-cultural identity on the morphology of the mid-face among a Black South African sample, with a particular emphasis on developing standards for predicting mid-facial variation within this population.

The sample consisted of 120 adult South Africans representing eight Black South African socio-cultural groups, namely Khoisan, Pedi, Sotho, Swazi, Tsonga, Tswana, Venda, and Zulu, who were obtained from the Pretoria Bone Collection in the Department of Anatomy, at the University of Pretoria.² 3D modeling of the relevant anatomical area was performed using a NextEngine® 3D surface scanner Ultra HD. The 3D anatomical extraction was performed by placing standard craniometric landmarks and sliding landmarks (interpolation factor=1mm) on 3D models using the Avizo® 9.4 software. Forty-one craniometric and 378 sliding landmarks were recorded on 3D models. A reproducibility testing of the landmarks and sliding landmarks on these 3D models were assessed and calculated using the dispersion analysis. A socio-cultural groups analysis on all shape matrices acquired was visualized and quantified through applying Geometric Morphometric Methods (GMM). All shape configurations (e.g., Mid-Face Landmarks (MFL) (18), Mid-Face Sliding Landmarks (MFLS) (378), as well as sub-specific discriminate shape matrices (e.g., Nasal Aperture Sliding Landmarks [NASL]) (50); Nasal Bones Sliding Landmarks (NASL) (16); right and left Zygomatic Sliding Landmarks (ZSL) (curve 1=21; curve 2=22; and curve 3=24); and right and left Maxillae Sliding Landmarks (MSL) (curve 1=29; curve 2=25; and curve 3=30), were analyzed.

Both anatomical and sliding landmarks were reproducible (<2mm). The analysis of variance showed that variation in midfacial shape were statistically significant ($p < 0.001$) for all eight socio-cultural groups for all configurations, including sub-specific discriminate shape matrices, separately. Additionally, cross-validated linear discriminant function analysis yielded an accuracy between 79.59% and 100% for all shape configurations, as well as sub-specific discriminate shape matrices (MFL=93.10%; MFLS=97.96%; NASL=85.71%; NBSL=95.92%; right ZSL=83.67% (curve1), 100% (curve2), 85.71% (curve3); left ZSL=94.90% (curve1), 79.59% (curve2), 90.82% (curve3); right maxilla=83.67% (curve1), 97.96% (curve2), 93.88% (curve3); left maxilla=83.67% (curve1), 92.86% (curve2), 96.94% (curve3) reflecting the discriminative power of socio-cultural groups in the Black South African population.

In contrast to classical non-metric and metric approaches based on morphological traits, linear distances, and angles, the utilization of geometric morphometric for socio-cultural estimation using the midface retain the objects' geometry and analyses subtle differences among structures. In forensic analysis, the use of the geometric morphometric overcomes the non-utilization of fragmented bones by creating sub-specific discriminate shape matrices to analyze specific patterns not readily observable with traditional approaches. In a real-life application, reliable, accessible, and more efficient methods using 3D imaging approaches may allow forensic anthropologists to estimate the socio-cultural identity of Black South Africans in a more precise and repeatable way.

Skeletal Mid-Face, Sub-Specific Discriminate Shape Matrices, Geometric Morphometrics

A102 Assessing the Validity of Palate Shape as an Indicator of Population Affinity Through the use of Elliptical Fourier Analysis (EFA)

Christopher Goden, MA, The Ohio State University, Columbus, OH; Alice Gooding, PhD, Kennesaw State University, Kennesaw, GA*

Learning Overview: The learning objectives for this presentation will allow attendees to: (1) better understand the analysis of macroscopic traits through a contour-fitting geometric morphometric approach, EFA; and (2) enable a better understanding of the limitations associated with the use of EFA in relation to palate shape.

Impact Statement: This presentation will impact the forensic science community by quantifying palate shape using a geometric-morphometric approach. Additionally, this presentation will provide new information on human skeletal variation of palate shape while also assessing its validity in relation to the estimation of population affinity.

The estimation of population affinity from skeletal remains has become a highly debated topic within the forensic science community, largely attributed to the macroscopic methodologies employed by forensic anthropologists when assessing the craniofacial complex. While quantitative methodologies exist for the estimation of population affinity, forensic anthropologists employ macroscopic trait observation of the craniofacial region argued to be experienced-based and lack statistical backing.¹ As a result, it is feared by some that improper use of observation methods may hinder identification efforts of skeletal remains.¹ Conversely, others argue that the macroscopic trait analysis is reliable and replicable with proper training.³ Prior research has demonstrated the utility of EFA to accurately quantify complex closed-contour shapes and uses resulting in data to delineate population affinity of skeletal remains.² However, at present, many traits commonly assessed via macroscopic observation (e.g., palate shape) have not been evaluated with EFA.

In response to the call to action for empirical assessment of macroscopic trait observation,¹ this pilot study quantifies the shape of the palate using EFA to explore the variation present among three modern population groups. Further, this study evaluates classification rates of population affinity with resulting EFA data.

3D craniofacial volume renderings were constructed from postmortem Computed Tomography (CT) scans of 150 individuals of equally represented Black, Hispanic, and White population groups obtained from the New Mexico Decedent Imaging Database (75 males, 75 females). Once visualized in a standardized orientation, 2D images of the palate were obtained, outlined in Adobe® Photoshop®, and subjected to EFA using SHAPE 1.3 software. Following obtainment of EFA coefficient and Principal Component (PC) data, Analysis of Variance (ANOVAs) were performed to assess for variation among the three population groups and between sexes. Linear Discriminant Function Analyses (DFAs) and Bootstrap Random Forest Modeling (RFM) were utilized to evaluate correct classification rates of population groups. It was hypothesized that correct classifications would meet or exceed 85% correct classifications.

Principal Component Analysis (PCA) of reconstructed contours exemplifies similar amounts of variation within and among all three population groups regardless of sex. ANOVA results indicate insignificant amounts of variation between sexes and among the three groups ($p > 0.05$). DFAs performed demonstrate correct classification rates varying from low classifications (23% for all groups) to moderately successful (73% for Black and White groups independent of sex). Moreover, RFM exhibits 87% correct classifications for all groups.

Results demonstrate that EFA is useful in understanding variation of palate shape within and among groups. Nonetheless, forensic anthropologists should use caution when utilizing statistical methodologies in conjunction with EFA as discrepancies exist when comparing different statistical classification analyses. Specifically, in this study, DFA performed with lower correct classifications when compared to RFM. Results of DFA indicate that the palate does not confidently delineate population affinity. Additionally, results of DFA may mask some individualizing expression exhibited between individuals. Conversely, results of bootstrap RFM indicate highly successful classifications, suggesting that machine learning techniques, such as RFM, may be of better use with EFA data.

Forensic Anthropology, Population Affinity, Palate Shape

A103 A Survey of Ancestry Estimation Method Preferences and Utilization in Forensic Anthropology

Marion Davidson, MSc, University College London, Bloomsbury, London, United Kingdom; Ruth Morgan, DPhil, University College London, Bloomsbury, London, United Kingdom*

Learning Overview: After attending this presentation, attendees will have a better understanding of which ancestry estimation techniques and methods are most preferred and most frequently utilized by practicing forensic anthropologists.

Impact Statement: This presentation will impact the forensic science community by presenting the findings from a survey that sought to identify the most preferred and the most frequently utilized ancestry estimation techniques and methods in forensic anthropology.

The published literature contains conflicting statements regarding which ancestry estimation methods are the most preferred and employed by practicing forensic anthropologists. However, to date, there is no published research that examines the preferences and employment of ancestry estimation methods by forensic anthropology practitioners. To assure that further research into ancestry estimation is applicable to practicing forensic anthropologists, it is important to know which methods are preferred and utilized most frequently.

In this study, an anonymous online survey was developed to determine the most preferred and most frequently utilized ancestry estimation methods and techniques among forensic anthropologists and other disciplines that similarly examine human skeletal remains. Of the 109 respondents, 67% had completed or were in the process of completing a doctoral degree, with a mean year of degree completion of 2013. Approximately 40% of respondents were trained in the United States, 40% in the United Kingdom, and the remainder were trained elsewhere, predominantly in Europe. Of all respondents, 56% reported that they had forensic casework experience.

While the words “technique” and “method” are often used interchangeably, within this study the two words have different, non-interchangeable meanings. “Technique” refers to a *general* process or procedure of estimating the ancestry of skeletal remains. In this study, three different techniques were considered: the type of assessment (e.g., metric, non-metric); the skeletal element examined (e.g., the cranium); and the type of analysis (e.g., trait list, computer software program). “Method” refers to a *specific* process or procedure of estimating the ancestry of skeletal remains (e.g., the Rhine (1990) method, FORDISC®).

Preliminary analysis of the results revealed that among all respondents, the most preferred techniques to estimate ancestry were a combination metric and non-metric assessment, a cranial examination, and a trait list analysis. Additionally, the results revealed that among all respondents, the most preferred method to estimate ancestry was FORDISC®. These findings align with the results of the most utilized techniques and method by practicing forensic anthropologists.

Of the 56% of respondents who reported forensic casework experience, the most utilized assessment technique was a combination of metric and non-metric. The most examined skeletal element was the cranium, and the most utilized analysis technique was a trait list. Additionally, of respondents with casework experience, the most utilized method to estimate ancestry was FORDISC®. When respondents were asked why they utilize these techniques and this method in forensic casework, the most selected reason was that the techniques and method are perceived as accurate.

These insights into the most preferred and most utilized techniques and methods can help to ensure that further research into ancestry estimation is applicable to the practicing forensic anthropologist. The results of this study can be used to further inform future research into the most utilized ancestry estimation techniques, can assist in the development of comparative studies focusing on several of the most utilized methods, or can explore new approaches that can complement the currently utilized methods.

Ancestry Estimation, Forensic Anthropology, Forensic Science

A104 A Pilot Study to Improve the Identification of Unknown American Indians and Hispanic/Latinx Americans

Heather Edgar, PhD, University of New Mexico, Albuquerque, NM; Nicollette Appel, MS, University of New Mexico, Albuquerque, NM; Kate Spradley, PhD, Texas State University, San Marcos, TX; Hannah Cantrell, University of New Mexico, Albuquerque, NM; Nichole Benally, University of New Mexico, Albuquerque, NM*

Learning Overview: Attendees of this presentation can expect to learn about the limitations currently facing forensic anthropology in contributing to dismantling the epidemic of missing American Indians (AI). Further, attendees will learn about ongoing research to improve identification of AI and Hispanic/LatinX Americans (HLA).

Impact Statement: This project will impact the forensic science community by making important improvements to the Forensic Databank and FORDISC®, a common tool for forensic anthropologists estimating population affinity, by increasing sample sizes for underrepresented groups

AI are disproportionately affected by the crisis of unidentified decedents; there are more than 4.5 times more missing AI reported than human remains that have been found and estimated to be AI.¹⁻³ One reason for the large number of missing AI may be the misclassification of their remains as some group other than AI. Misclassification greatly reduces the likelihood that a missing person can be matched with human remains that have been recovered. The pilot study described here demonstrates the use of up-to-date methods coupled with a new research resource, the New Mexico Decedent Image Database, to improve the accuracy of population affinity estimation for AI and HLA.⁴

Pilot data include 3D craniometric coordinate data (52 points) from 53 AI and 10 New Mexican HLA from a Computed Tomography (CT) dataset. These data were compared with the same data points collected from crania of migrants to the United States from Mexico, Guatemalan Mayans, and Yucatecan Mayans ($n=181$). Both Mahalanobis and Procrustes distances between group centroids were significant for all pairwise comparisons. This preliminary research indicates that: (1) it should be possible to accurately estimate population affinity for AI with the sample proposed here; and (2) there is a great deal of variation within the sample this study intends to collect. This second observation provides hope that, even though this sample is limited to AI from New Mexico and eastern Arizona, it may be useful across a wider geographic area. Also, although the sample is small, New Mexican HLA are generally different from the AI sample and at the extreme of the Latin American samples. While it seems very likely that it will be possible to discern AI from HLA with the data this study intends to collect, more data are needed to determine whether it will be possible to reliably estimate whether an unknown individual was a United States citizen or a migrant, for example, New Mexican or Mexican.

Population Affiliation Estimation, Computed Tomography (CT), Craniometrics

A105 Postmortem Radiological Computed Tomography (CT) Identification Based on Cranial Sutures

Michal Peer, MSc*, National Center of Forensic Medicine, Tel Aviv, Israel; Chen Kugel, MD, National Center of Forensic Medicine, Tel Aviv, Israel; Haim Cohen, PhD, National Center of Forensic Medicine, Tel Aviv, Israel and Adelson School of Medicine, Ariel University, Ariel, Israel

Learning Overview: After attending this presentation, attendees will better understand the application of Sekharan's method for human identification using X-rays of cranial sutures on Computed Tomography (CT) scans. This is a preliminary study.

Impact Statement: Attendees will be informed of an improved and advanced identification method using head CT scans for positive human identification based on cranial suture morphology. With the increased usage of CT scans, both in postmortem examination in forensic facilities and in medical treatment, their usage for identification will become increasingly relevant.

Background: One of the methods for determining positive personal identification is the comparison of postmortem radiological images of decedents and antemortem radiological images of their presumed identity. Cranial suture morphology is permanent throughout life from the age of seven and usually remains visible into the seventh decade.^{1,2} Although cranial suture morphology is considered unique, research on its use for identification is scarce.³ In 1985 and 1989, Sekharan studied 320 skulls and 8,000 skull radiographs and determined that suture patterns constitute positive means of identifying the person, providing that there are antemortem records available for comparison.^{3,4} In 2004, Rogers and Allard reviewed Sekharan's methodology in the framework of expert testimony and the *Daubert* ruling.¹ They argue that the method as it is originally described encounters problems such as lack of pattern description and recognition and the necessity for the antemortem and postmortem radiographs to be obtained from the same angle. Due to an increase in antemortem CT scans, performing postmortem CT scans at forensic institutions may become of paramount importance in cases of confirming identification as they can reveal significant details of cranial anatomy that can be used for identification.⁵

Goals: (1) To examine the applicability of Sekharan's radiograph method of using cranial suture morphology for postmortem CT scans, and (2) to develop an improved and suitable method for using cranial suture morphology for personal identification.

Materials and Method: Three hundred postmortem head CT scans (150 males, 150 females; age range 10–92) from the National Center of Forensic Medicine, Israel, were used for this study. According to Sekharan's method, eight areas on the sutures were examined, two on the sagittal and three on each side of the lambdoid. The effect of age and sex on the identification of suture patterns was also examined. Subsequently, 30 antemortem and postmortem paired scans from the same individuals were also examined in order to confirm that the same pattern could be identified in both.

Results: Sekharan's method for identifying suture morphology on radiographs was found to be not applicable to CT scans. In this study, Sekharan's ten patterns were reduced to four different morphological patterns of the suture: (1) Single Direction; (2) Wavy; (3) Closed; and (4) Complicated. These morphological patterns were common and easily identified in both sexes on 41% ($n=123$) of the CT scans that were examined. In the other 59% of the scans, no clear pattern could be identified. These four suture patterns were most identifiable adjacent to the meeting point of the sagittal and lambdoid sutures (lambda). The Wavy pattern was found to be the most common pattern, hence the least indicative pattern for identification. The Closed pattern was found to be the least common pattern, hence the most indicative pattern for identification. The same variations of patterns could be identified in both antemortem and postmortem paired scans.

Conclusion: Based on this preliminary study, suture morphology can be used for personal identification using CT scans.

Cranial Sutures, Identification, Computed Tomography (CT)

A106 A Multifaceted Short Tandem Repeat (STR) and Next Generation Sequencing (NGS) Assessment of Burned Human Remains Using Comparative DNA Extraction and In-Solution Hybridization Capture

Matthew Emery, PhD, Arizona State University, Tempe, AZ; Katelyn Bolhofner, PhD, Arizona State University, Glendale, AZ; Suhail Ghafoor, Arizona State University, Tempe, AZ; Amanda Wissler, MA, University of South Carolina, Columbia, SC; Erin Rawls, Arizona State University, Tempe, AZ; Stevie Winingear, MA, Arizona State University, Tempe, AZ; Robert Oldt, BS, Arizona State University, Glendale, AZ; Sreetharan Kanthaswamy, PhD, Arizona State University, Glendale, AZ; Jane Buikstra, PhD, Arizona State University, Tempe, AZ; Laura Fulginiti, PhD, Maricopa County Office of the Medical Examiner, Phoenix, AZ; Anne Stone, PhD, Arizona State University, Tempe, AZ*

Learning Overview: Attendees will leave this presentation with a better understanding of how fire impacts the preservation of DNA in human bones and teeth.

Impact Statement: This research impacts the forensic community by presenting DNA evidence obtained from victims of fire-related incidents from Maricopa County, AZ.

DNA analysis is an important tool in the identification of human remains recovered from forensic contexts. Under ideal conditions, DNA is sufficiently preserved for rudimentary Polymerase Chain Reaction (PCR) -based analysis, including STR profiling. However, exogenous factors such as depositional environment, microbial activity, and time since death often limit the amount of recoverable DNA from skeletal material. In circumstances where skeletal tissues are exposed to more severe insults, such as fire, obtaining adequate quantities of DNA for downstream analysis has proven even more challenging. Recent studies have shown that DNA yields are inversely proportional to the degree of thermal alteration of skeletal tissues. The amount of DNA obtained from bones and teeth are primarily impacted by the temperature and duration of fire exposure. To better understand how fire impacts DNA preservation, this study employed a suite of traditional and NGS analyses to assess a range of burned human remains. More specifically, this study compares quantitative PCR, STR, whole-mitochondrial genome, and genome-wide Single Nucleotide Polymorphism (SNP) results obtained from real-time fire victims from Maricopa County, AZ, using comparative ancient and forensic DNA extraction methods coupled with in-solution targeted enrichment techniques.

A total of 27 bone and tooth samples were transferred from the Maricopa County Office of the Medical Examiner (MCOME) for DNA analyses at the Molecular Anthropology Laboratory at Arizona State University. Bone and tooth samples were further subsampled into five burn categories. This study extracted DNA from these burned victims using two different DNA extraction methods: one devised by Loreille and colleagues (forensic DNA) and a second using a modified Dabney and colleagues (ancient DNA) extraction protocol. DNA concentrations were measured using the Quantifiler™ Trio DNA Quantification Kit. STR profiles were generated using the Promega® PowerPlex® ESX 17 Fast System, a kit that co-amplifies 16 STR loci, as well as the sex-typing amelogenin marker. In addition, this study re-extracted and built double-stranded DNA libraries from the burned remains, then enriched those libraries for whole mitochondrial genomes and genome-wide SNPs (5k panel) using synthetic biotinylated baits. Libraries were pooled and sequenced Illumina® MiSeq® and NextSeq® 550 platforms and the resulting reads were processed using an in-house custom computational pipeline. The analysis suggests that both extraction methods are suitable for obtaining DNA yields for STR and NGS analyses at lower temperatures. In the case of STR analysis, the ancient DNA extracted samples produced higher quantities for STR calling at temperatures >350°C. These results also suggest a critical point of DNA degradation at temperatures >350°C, wherein a significant drop in STR alleles, mitochondrial DNA (mtDNA) read counts and depth of coverage, and SNP calls are observed. The integration and adoption of optimized ancient DNA protocols, such as Dabney and colleague's DNA extraction protocol, in addition to in-solution targeted capture methods offers an alternative means to study DNA preservation in skeletal tissues subjected to a high degree of thermal alteration and pyrolytic degradation.

Forensic Genomics, Ancient DNA, Burned Human Remains

A107 Centering Gender-Inclusive Strategies in Forensic Anthropology

Mariyam Isa PhD*, Texas Tech University, Lubbock, TX; Amy Michael, PhD, University of New Hampshire, Durham, NH; Samantha Blatt, PhD, Idaho State University, Pocatello, ID; Taylor Flaherty, MSc, University of Nevada-Las Vegas, Las Vegas, NV

Learning Overview: After attending this presentation, attendees will understand the importance of gender-inclusive strategies in forensic anthropology and will learn how to center these in casework and research.

Impact Statement: Gender inclusive strategies are needed to improve case resolution for Transgender and Gender Variant (TGV) decedents, prevent further postmortem marginalization of vulnerable individuals, and promote diversity and inclusion in the forensic sciences. This presentation impacts the forensic science community by offering suggestions for incorporating gender-inclusive strategies in casework and scholarship.

Fatal violence against TGV individuals in the United States has been characterized as an epidemic.¹ At this time, 2021 is on track to be the deadliest year on record for TGV individuals.² Cultural attitudes toward the TGV population can hinder identification efforts and further marginalize TGV decedents through underreporting and non-standard documentation of missing and murdered persons, inequitable distribution of investigative resources, inaccurate and inconsistent reporting of gender, (dead)names, and sex, and unfamiliarity with context clues related to gender identity.³

The following are suggestions for how anthropologists can contribute to the development of gender-inclusive strategies in education, research, and casework that recognize and address the social factors impeding identification of TGV Does.

Prioritize the needs and concerns of the TGV community. Researchers should account for the safety and privacy of research participants, engage with community members as collaborators, and pursue research questions informed by the wants and needs of community members. Adams et al. provide guidelines for transgender health research focused on collaboration, language, accountability, informed consent, protection, allyship, and censorship; these can also guide forensic anthropology research and casework.⁴

Engage with social theory and incorporate it into casework and research. Queer theory critiques essentialist views of sex and gender, therefore exhibiting how Westernized perceptions of sex and gender are assigned to the skeleton. Additionally, intersectionality and structural vulnerability frameworks illustrate why Black and Latinx transwomen and Two Spirit Indigenous people are at the highest risk for lethal violence.

Commit to education and continued conversation. Educating oneself on issues of gender diversity, violence against TGV individuals, and current literature in and out of forensic anthropology is the first step to supporting this at-risk population. Tallman and colleagues found that only 42.4% of forensic anthropologists surveyed view sex as non-binary, and 75% were unfamiliar with gender-affirming surgeries, indicating that intra-field conversations about sex and gender are necessary.⁵ Anthropologists should incorporate issues of gender diversity into student curricula and actively engage in discussions about sex, gender, and the limitations of skeletal methods with law enforcement and medicolegal professionals. It is also crucial that TGV individuals be included in these conversations.

Embrace an advocacy role. While some forensic scientists are personally uncomfortable with direct engagement in advocacy, embracing an advocacy role does not invalidate one's scientific objectivity. In fact, some cases may *require* advocacy to achieve resolution. Advocacy can include willingness to conduct case reviews with a gender-informed approach, revive attention on the case, seek resources outside of academia or the medicolegal system, and educate investigators about issues of sex and gender.

Engage in and facilitate interdisciplinary collaboration. The scope of fatal violence against TGV people is not yet understood, so the response to the epidemic must be multidimensional. Listening to, acknowledging, and uplifting the essential perspectives and expertise of non-academic experts, activists, and students (especially those who are TGV) aids in information exchange and leads to better research and casework strategies. The responsibility of meaningful allyship should fall on those in positions of power and privilege in the forensic sciences, including professors and conference organizers, to provide accessible opportunities and spaces for TGV researchers.

A108 Disciplinary and Community Ethics Surrounding Gender- and Sex-Diverse Individuals in Forensic Casework

Laura Cirillo MA, University of Nevada-Reno, Reno, NV; Marin Pilloud, PhD, University of Nevada-Reno, Reno, NV; Jaxson Haug, MA, Southern Methodist University, Dallas, TX*

Learning Overview: After attending this presentation, attendees will understand the roles of competency, responsibility, and non-maleficence in an ethical forensic anthropological practice with a particular focus on how to improve engagement with the Gender- and Sex-Diverse (GSD) community.

Impact Statement: This presentation will impact the forensic community by highlighting paths toward a more ethical practice within forensic anthropology that aims to improve outcomes for communities while also doing no harm.

The reconstruction of the biological profile as an extension of personhood and identity necessitates that forensic anthropology practitioners work within an ethical framework. The discipline of forensic anthropology lacks comprehensive ethical policies, largely due to the failure of relevant professional organizations to create, maintain, and enforce robust ethical codes.¹ Drawing on ethical principles outlined by neighboring fields (namely bioethics and the American Psychological Association), this presentation proposes key components of ethical practice in forensic anthropology, specifically in the context of research and casework involving GSD individuals. These components center on competency, responsibility, and non-maleficence as integral aspects of ethical practice.

Competencies are the various sets of skills needed to perform disciplinary tasks. There are several defined types of competencies, including those intended to meet changing social demands and minimize harmful downstream effects. For example, cultural, linguistic, and structural competencies are incorporated into medical curricula to understand and mitigate the complex interaction of social variables that affect medical care.² Forensic anthropology is uniquely positioned to provide a multidisciplinary perspective bolstered by the social sciences in defining and creating sets of competencies for forensic science. In the case of working with the GSD community, one such structural competency would involve engagement with social and structural factors that result in disproportionate violence against GSD individuals and a recognition of historical vulnerabilities within GSD populations. This engaged competency would promote ethical practice in a field tasked with identification of these victims.

As forensic anthropologists maintain an influential position within the medicolegal system, they have a responsibility to beneficent practice. Currently, methods to estimate biological sex do not acknowledge that sex is on a spectrum, nor do they provide space for a consideration of gender. While biological sex and gender are two separate concepts, they can be intertwined in an individual's identity and gender expression, which can affect the ability to identify a set of remains of an unknown decedent. While we work to establish protocols and better methods to incorporate the broader range of human variation and the human experience, we should ensure that our reports and scientific writing do not reinforce the concept of binary sex and gender roles.

Non-maleficence is related to beneficence but is more focused on preventing harm. There is currently a high level of interest but relative paucity in foundational research in both skeletal growth and development and forensic identification of GSD individuals. Increased considerations apply to the ethical use of GSD individuals as a source of data in research as they could represent a vulnerable population to the Institutional Review Board (IRB). Stakeholder participation in research design has been suggested as means of minimizing harm beyond the subjective risk assessment of the IRB and builds trust in a marginalized community that has historically been exploited in research.^{3,4}

Ethics, Anthropology, Gender/Sex Diverse

A109 Necropolitics and Trans Identities: Language Use as Structural Violence

Thomas Delgado, BA, California State University-Chico, Chico, CA; Kinsey Stewart, MA, University of Tennessee-Knoxville, Knoxville, TN*

Learning Overview: After attending this presentation, attendees will better understand why inclusive language is an essential standard in the creation of representative and ethical systems of death investigation and deathcare.

Impact Statement: This presentation will impact those involved in death investigation by highlighting how lack of inclusive linguistics standards in case reports, death certificates, forensic methodology, human identification databases, and final disposition documents harms Transgender and Gender Non-Conforming (TGNC) individuals even after their death.

Despite the increasing visibility of TGNC people in United States society, current practices within medicolegal death investigation, forensic anthropology, and deathcare as a whole are not TGNC inclusive. This lack of consideration for TGNC decedents can cause unnecessary delays in the identification and disposition of their remains; moreover, it may ultimately lead to the non-consensual, forced postmortem detransition from their chosen identities.¹

This presentation uses DeLeón's concept of necroviolence—"violence performed and produced through the specific treatment of corpses that is perceived to be offensive, sacrilegious, or inhuman by the perpetrator, the victim (and [their] cultural group), or both"—as a framework to illustrate how the (mis)use of language within death investigation and deathcare reflects and reinforces structural violence against TGNC people.² First, this presentation highlights the systemic failure to acknowledge differences between sex and gender. Examples from publicly available cases are then used to show how language and language-enforced bureaucratic structures can harm TGNC decedents, their surviving friends and chosen family, the broader TGNC community, and the process of medicolegal death resolution itself.

This presentation concludes by suggesting steps anthropologists, pathologists, death investigators, and their affiliated partners can take to reduce the systemic necropolitical violence faced by the TGNC community. While acknowledging that TGNC-inclusive methods will take time to develop and implement, it is essential that core standards appropriately serve these individuals. The core language used in death investigation will therefore need to disengage from binary and essentialist standards of "male/female" that fail to represent complex social and biological realities within human populations.

Necroviolence, Necropolitics, Deathcare

A110 Identifying Transgender and Gender-Variant Individuals in Public Records: Reconciling Differences Between Law Enforcement Data and Non-Government Organizations (NGOs)

Raphaella Meloro, MA, University of Florida, Department of Anthropology, Gainesville, FL; Fatimah Bouderdaben, BS, Texas State University, Department of Anthropology, San Marcos, TX*

Learning Overview: After attending this presentation, attendees will understand where discrepancies may arise in calculations of Transgender and Gender Non-conforming (TGN) violence and homicide rates NGOs and Government Organizations (GOs).

Impact Statement: This presentation will impact the forensic science community by providing recommendations for determining TGN identity in database records and tracking rates of violent hate crimes and homicide involving TGN individuals.

Published reports on TGN violent hate crimes and homicide by GOs indicate that TGN groups experience comparable rates of violent hate crimes and homicide to non-TGN groups. However, published reports by LGBT+ NGOs indicate that TGN homicide is at epidemic proportions. This study builds on previous work examining these discrepancies to determine where these differences in calculations may arise and the impact of such differences.^{2,5} An in-depth analysis of the Trans Doe Task Force's (TDTF) LGBT+ Accountability for Missing and Murdered Persons (LAMMP) database aids in this study of discrepancies by comparing self/personal reports with information gathered by the TDTF from the National Missing and Unidentified Persons System (NamUS).⁶

Counts of transgender homicides from 2013 through 2021 were collected from the published reports by the Federal Bureau of Investigation (FBI) Hate Crime Statistics Program, the Human Rights Campaign (HRC), and the National Coalition of Anti-Violence Program (NCAVP).^{1,3,7} Slight differences were found between counts reported by the two NGOs and large differences were found between counts reported by the FBI and those reported by the NGOs. Of the three sources, HRC publications generally reported the largest number of homicides with steadily climbing numbers over time while FBI publications reported the lowest numbers with little-to-no change from year to year.

Differences in homicide counts arose from variation in the number and reporting methods of data sources. NGOs reported all TGN homicides documented by sources, including LGBTQ+ organizations and news reports. FBI data was sourced from participating law enforcement districts and restricted reported homicides only to those classified as a hate crime. The limited number of districts participating meant that FBI data did not span as much of the United States as NGO data did. Furthermore, it is unlikely that all participating districts recognized and documented TGN identities in reports or that all homicides involving TGN individuals were reported.⁴

Further analysis of the LAMMP database also highlighted discrepancies that NGOs deal with when working with GO data. Based on the LAMMP database of missing transgender persons reported, 77.6% of transgender individuals missing were trans women and 22.4% were trans men. However, when compared to NamUS data, cases that were flagged as possible transgender cases were overwhelmingly trans women, 91.4%, compared to trans men, 8.6%. This is a major discrepancy identified by directly comparing NGO data to GO data.

The results of this study demonstrate that NGOs and GOs calculate significantly different rates of crime against TGN individuals, even when using similar data sources due to their different methods of interpretation. Solutions to this discrepancy may come from incorporation of inclusivity practices, including the use of diverse gender categories on reporting forms, sensitivity training, and allying with TGN community liaisons to build better relationships with this at-risk population.

Transgender, Necroviolence, Anthropology

A111 Identifying Trans Individuals From Skeletal Remains: Indicators of Gender-Affirming Interventions

Angelica Bourgeault, MSc, University College London, London, Great Britain, United Kingdom*

Learning Overview: After attending this presentation, attendees will have a better understanding of the current state of research regarding the impact of Gender-Affirming Interventions (GAI) on the skeletal composition of transgender individuals and its implications for the forensic anthropologist.

Impact Statement: This presentation will impact the forensic science community by addressing the dearth in forensic literature on gender diversity, presenting evidence of the malleability of sexually dimorphic features that may be achieved through endocrinal and surgical GAI. Findings will guide experts through the identification process of skeletal remains and highlight the importance and potential of interdisciplinary collaboration.

A challenge is posed to the identification process when a person's skeletal features lead to conflicting or "indeterminate" sex estimations. Trans-identifying individuals may subject their bodies to an extreme degree of change by undergoing hormonal interventions and gender-confirmation surgeries to treat gender dysphoria and transition their physical appearance to align with their gender identity. Yet, despite disproportionate homicide rates of trans-identifying individuals, there are no forensic anthropology standards for determining whether an individual has undergone GAI from skeletal evaluation.¹

This research aims to bridge the gap by proposing skeletal and medical indicators for the identification of trans individuals through a critical review of the current literature. The purpose of this project was four-fold to identify: (1) skeletal indicators for identifying trans individuals, (2) associated surgical devices, (3) differentiations between trans and cisgender (cis) surgeries, and lastly, (4) a proposed method for conducting the "sex estimation" of trans skeletal remains.

In terms of the skeletal impacts of endocrinal GAI, changes in cortical and trabecular areal and volumetric Bone Mineral Density (BMD) absolute values and z-scores/t-scores, bone mass, area, thickness, and turnover, as well as endosteal and periosteal circumference were analyzed. In addition, the effect of pubertal suppressors on epiphyseal fusion and final achieved height were explored, along with the effects of surgical implants on bone composition. Pubertal suppression and feminizing/masculinizing hormonal therapy, prior to and following gonadectomy, led to significant differences in bone density, morphology, and morphometry between trans individuals, specifically trans women, and their age-matched cis genotypic peers.

On the other hand, surgical indicators of GAI were determined by analyzing the effects of facial feminization/masculinization surgery and urological/gynecological gender-confirmation surgeries. The most reliable surgical indicators in trans women consist of combined evidence for bone shaving, various osteotomies, and breast implants. Conversely, the most durable postmortem surgical devices likely to lead to the positive identification of a trans man are the combined presence of facial implants and/or bone grafts, and penoscrotal prostheses.

Forensic anthropologists should be cautious not to confound evidence of surgical interventions with those used to treat traumatic, pathologic, or simple cosmetic procedures in the cisgender population. From a forensic anthropology point of view, GAI are most discernible and positively identifiable in individuals who have undergone the full extent of the transition and its hormonal and surgical effects on the skeleton. Nonetheless, findings may inform skeletal involvement in gender non-conforming, non-binary, or genderqueer populations undergoing lesser GAI, if any. In conclusion, the more the presence of extensive bilateral gender-affirming indicators, the higher the likelihood of ascribing the correct "sex" to an unidentified trans individual.

This research highlights the importance for forensics to remain up-to-date with innovative medical interventions of increasing popularity. The intricate relationship between sex and gender in trans individuals offers a unique opportunity to modernize the way forensic anthropologists interpret "indeterminate" scores. Future interdisciplinary collaboration and community involvement is key to better understanding the true extent of GAI impacts on the skeleton.

Forensic Anthropology, Sex Estimation, Transgender

A112 Supporting the Positive Identification of Trans Men in Forensic Anthropological Contexts

Jenna Schall, MSc, University of Toronto-Mississauga, Mississauga, Ontario, Canada; Tracy Rogers, PhD, University of Toronto-Mississauga, Mississauga, Ontario, Canada; Jordan Deschamps-Braly, MD, Deschamps-Braly Clinic of Plastic & Craniofacial Surgery, San Francisco, CA*

Learning Overview: After attending this presentation, attendees will have a better understanding of the rise in anti-trans violence and the role forensic anthropologists play in supporting the correct identification of trans individuals, particularly trans men.

Impact Statement: This presentation will impact the forensic science community by providing knowledge and additional tools to support and recognize trans men in forensic contexts.

The identification of unidentified human remains begins with the construction of the biological profile, which consists of an individual's sex, ancestry, age, and stature. This profile is then compared to descriptions of missing persons in order to narrow the scope of a forensic investigation. In cases of transgender and gender-diverse individuals whose sex assigned at birth has little correlation with their social identity, positive identification can be delayed or hindered.¹⁻⁵ There are many gender confirmation options for trans individuals who physically transition in order to alleviate gender dysphoria, such as hormone therapy, and genital and/or facial gender-confirmation surgeries.^{5,6}

While not all trans people undergo these treatments for various reasons, undergoing gender-confirmation surgery should not hinder or complicate positive identification. Instead, forensic anthropologists need to be able to recognize evidence of gender-confirmation surgery in order to create a holistic and accurate biological profile, ultimately supporting correct positive identification. This growing body of knowledge is becoming increasingly more relevant and necessary as gender-affirming surgeries become more accessible for both trans women and men.⁵⁻⁹

Unfortunately, the number of trans and gender non-conforming individuals subjected to violence has also increased, due in part to the rise in anti-LGBTQ legislature being passed across the United States.^{10,11} In 2020, the Human Rights Campaign (HRC) tracked a record number of violent fatal incidents against transgender and gender non-conforming people.¹¹ Forty-four fatalities were recorded by HRC, making 2020 the most violent year on record since HRC began documenting these crimes in 2013.¹¹ Also steadily increasing is the number of trans men and boys being reported as victims of these hate crimes.^{11,12} While there is some preliminary research to support the identification of trans women in forensic anthropology, there is none on trans men.^{3-5, 13}

The goal of this research is to illuminate the increase in reporting of trans men as victims of violence and review current gender-confirmation procedures to evaluate their potential in supporting the identification of trans men in forensic contexts.

Forensic Anthropology, Transgender Identification, Trans Men

A113 When a Reanalysis Changes Everything: A Cold Case Study of a Possible Gender-Variant Individual

Alexis Goots, MA, Michigan State University, East Lansing, MI; Carolyn Isaac, PhD, Michigan State University, East Lansing, MI; Todd Fenton, PhD, Michigan State University, East Lansing, MI*

Learning Overview: After attending this presentation, attendees will understand how cognitive bias can influence sex estimation in forensic anthropology.

Impact Statement: This presentation will impact the forensic science community by providing practitioners with an example of how to respectfully and scientifically address potentially gender-variant individuals in a cold case context.

The identification of an unknown decedent in forensic anthropology relies on the accurate estimation of the biological profile, including age, sex, stature, and ancestry. Although the methods for estimating the biological profile are well-established, many factors can impact whether these four components are estimated accurately. Intrinsic factors, such as ambiguous skeletal morphology, or extrinsic factors, such as personal effects, can lead to cognitive bias and increase the possibility of an inaccurately estimated biological profile. In these scenarios, the potential for a positive identification is limited.

When reanalyzing a cold case, therefore, an important first step is to determine whether the original analysis is accurate. Often, new methodology can improve accuracy in estimating the biological profile. Importantly, these re-analyses may reveal past mistakes, albeit made in earnest, that can help explain why a case has remained unresolved for a significant length of time. It is not only valuable to ameliorate these issues from a case resolution standpoint, but also to understand the circumstances that contribute to these inaccuracies, which may provide insight into broader issues in the field.

One such circumstance is the biasing effect of gendered clothing on sex estimation in forensic casework. A study of cognitive bias in sex estimation found that gender-stereotypical clothing associated with unambiguous skeletal remains had substantial biasing power, leading to inaccurate sex estimation despite the remains clearly expressing characteristics of a particular sex.¹ As gendered clothing can lead to inaccurate sex estimates and impact the ability to make identifications, its biasing effect should be considered when analyzing new cases and reevaluating cold cases in a forensic laboratory.

During a reanalysis of cold cases in the Michigan State University Forensic Anthropology Laboratory (MSUFAL), this study identified a case in which the reported sex was female, but the remains themselves appeared more ambiguous with respect to sex. The originally reported biological profile for this case was that of a Black female between the ages of 28 and 40 with a stature of approximately 65 inches. Notably, the decedent was found with personal effects, including a wavy, collar-length wig, blue jeans, a violet-colored long-sleeved blouse, a beige-colored long-sleeved blouse, a reddish-brown nylon neck scarf, panty hose, a bra, and black high-heeled shoes.

In the reanalysis, substantial disagreement between several anthropological methods resulted in an overall “indeterminate” estimation of sex. Ultimately, nuclear Short Tandem Repeat (STR) DNA analysis was used to identify the sex of this individual; the presence of X and Y chromosomes in the decedent’s DNA are consistent with a sex estimation of male. However, the stereotypically “feminine” personal effects in this case suggest that the decedent’s gender expression may have differed from their sex assigned at birth.

Given this information, the MSUFAL produced a follow-up report, noting the sex estimated using DNA analysis, as well as the potential for this individual to have been gender non-conforming in life. Although an identification has not yet been made in this case, the likelihood of eventually identifying this individual has been substantially improved based on the anthropological reanalysis. This case provides an example of the biasing power of extraneous information on skeletal analysis and the importance of thinking outside the gender binary in forensic casework.

Cognitive Bias, Sex Estimation, Gender Variance

A114 A Diverse Past, Present, and Future: Resituating the Anthro in Forensic Anthropology

Chaunesey M.J. Clemmons, MA, University of Texas-San Antonio, San Antonio, TX; Matt C. Go, PhD SNA International, Joint Base Pearl Harbor-Hickam, HI; Alba E. Craig, BA, University of Indianapolis, Indianapolis, IN; Isis Dwyer, MA, University of Florida, Gainesville, FL; Aaron J. Young, MA, University of Arizona, Tucson, AZ; Kamar Afra, MA, University of Tennessee, Knoxville, TN*

Learning Overview: After attending this presentation, attendees will be introduced to the symposium “Pioneers of Color: A Diverse Narrative of Forensic Anthropology,” whereby the impetus, goals, and significance of the symposium will be outlined.

Impact Statement: This presentation will impact the forensic science community by supplying a richer understanding of forensic anthropology’s history than what is currently understood and provide space for discourses that disrupt the status quo.

For the first time at the American Academy of Forensic Sciences annual conference, a symposium is introduced that is entirely dedicated to the celebration of anti-traditional perspectives in forensic anthropology with a panel entirely composed of early-career scholars of color with diverse backgrounds. In providing spaces to disrupt the status quo, the contributors center the stories of early luminaries of color; the incorporation of feminist, critical race, and postcolonial theories in approaching medicolegal problems; and the dismantling of epistemological boundaries between science/activism and objectivity/subjectivity, among other pressing issues. In addition to introducing the symposium and presenters, the authors discuss why they are doing this, why it is essential, the difficulties they encountered in curating this content, and how these relate to the larger issues of representation and diversity within our field.

The content and presenters of this symposium align well with this year’s theme of a responsive academy, meeting and surpassing the challenges of a modern forensic science world. *Responding* to a modern forensic world begins by reclaiming forensic anthropology’s diverse historical foundations and acknowledging those routinely left out of the narrative. *Surpassing* the needs of a modern forensic world requires a counter-narrative to dominant renderings of forensic anthropology’s theories and praxis. This presentation and symposium also celebrates the Anthropology Section’s 50th Anniversary by bridging a biased past with a turbulent present and envisioning a more inclusive future for forensic anthropology and the forensic sciences.

Forensic Anthropology, Diversity and Inclusion, Biased Objectivity

Go, PhD, SNA International, Supporting the Defense POW/MIA Accounting Agency, Joint Base Pearl Harbor-Hickam, HI; Allison Nesbitt, PhD, University of Missouri, Columbia, MO; Aaron J. Young, MA, University of Arizona, Tucson, AZ; Sydney S. Garcia, MA, SNA International, Supporting the Defense POW/MIA Accounting Agency, Joint Base Pearl Harbor-Hickam, HI*

Learning Overview: After attending this presentation, attendees will better understand the important contributions of early non-White forensic anthropologists and related scientists and their contributions to the field.

Impact Statement: The goal of this presentation is to impact the forensic science community by highlighting the lack of diversity when teaching the history of forensic anthropology, its implications, and providing a solution to this gap.

The prevailing narrative of who has participated in forensic anthropology is arguably exclusive of non-White scholars and practitioners. Introductory textbooks in forensic anthropology and award names of the American Academy of Forensic Sciences Anthropology Section are examples of the types of people the field has traditionally regarded as worthy of exaltation. Our discipline retains a gaping hole in the historical record of important contributions led by those left out of the established pantheon. Unvaried participation in forensic anthropology creates a stagnant discipline that stifles innovation, impedes talent acquisition and retention by demoralizing the participation of non-White professionals, and obstructs the possibility to adapt to the needs of a just and equitable discipline. Through this presentation, there is hope to shed light on the lack of diversity among those widely cited as American forensic anthropology's forebearers and to provide other luminaries to consider when teaching our history and considering names for section awards and accolades.

The format of this presentation adopts the widely used periodic system of forensic anthropology's historical foundations, whereby its development is split between a Formative Period (Early 1800s–1938), Consolidation Period (1939–1971), and Modern Period (1972–Present). Within each period, this presentation introduces early pioneers such as W. Montague Cobb, Charles Warren, Caroline Bond Day, Tadao Furue, Kazuro Hanihara, Mahmoud El-Najjar, and others by highlighting their contributions to the discipline. Importantly, this presentation critiques the need to engage in this endeavor and why it has taken this long to do so and also reflects on the difficulties in curating this list and how it speaks to larger systemic issues of inclusion and recognition vis-à-vis race within the discipline of forensic anthropology.

History of Forensic Anthropology, Diversity, BIPOC

A116 Back to Black: The Legacy and Contributions of Black Pioneers of the 20th Century

Isis Dwyer, MA, Department of Anthropology, University of Florida, Gainesville, FL; Tisa N. Loewen, MA, School of Human Evolution and Social Change, Arizona State University, Tempe, AZ; Chaunese M.J. Clemmons, MA, Department of Anthropology, University of Texas-San Antonio, San Antonio, TX and Department of Anthropology, Texas State University, San Marcos, TX; Evonne Turner-Byfield, MSc, Department of Anthropology, Ohio State University, Columbus, OH; Jesse Goliath, PhD, Department of Anthropology and Middle Eastern Cultures, Mississippi State University, Mississippi State, MS; Allison Nesbitt, PhD, Department of Pathology and Anatomical Sciences, School of Medicine, University of Missouri, Columbia, MO; Carter Clinton, PhD, Department of Anthropology, Department of Biology, Pennsylvania State University, State College, PA; Kendra Isable, MA, Department of Anthropology, University of Nevada, Reno, NV*

Learning Overview: Following this presentation, attendees will know the impactful contributions of 20th-century Black anthropologists who pioneered our field and will have a tangible resource of media that can be used as tools for education and citation.

Impact Statement: This presentation will impact the forensic community by highlighting the research of Black scholars and practitioners to the field of forensic anthropology and illuminating their continuous contributions.

Black biological anthropologists have made significant contributions to forensic anthropology and continue to contribute to the scientific field. Yet these theoretical, educational, scholarship, and technical contributions have been overlooked in undergraduate and graduate degree courses, forensic anthropology textbooks, and the forensic literature. The research of Black pioneers in forensic anthropology is not broadly shared, and inclusion of the work, ideas, and hypotheses of these anthropologists would greatly enhance the state of the discipline.

Forensic anthropology draws upon multiple medicolegal and social disciplines and is most effective at applying methods when consideration of the socio-cultural consequences are taken. Like their contemporaries, early Black anthropologists whose work impacted forensic anthropology were educators and researchers with diverse research interests and careers. They were biological anthropologists, cultural anthropologists, and applied anthropologists who worked with the military, anatomists, and forensic psychologists.

William Montague Cobb, the first African American to complete a doctorate in biological anthropology, employed multidisciplinary methods across physical anthropology, anatomy, and human biology to refute the perceived differences between Black and White Americans, counter the scientific justifications for racism, and explore health disparities. Cobb's work exemplifies a pioneering instance of applied anthropology and social responsibility that provides vital context to current constructions of population variation utilized in forensic ancestry estimation today.

Charles Warren was a contemporary of Furue and Kerley and worked occasionally for 25 years as a civilian forensic anthropologist for the United States Army and identified human remains from World War II, the Korean War, and Vietnam War. As a professor and educator, he consulted on forensic cases in Illinois and Indiana. His most high-profile case was identifying human remains from the house of John Wayne Gacy in 1975. As a researcher, he dispelled the belief that because of their skin color, the Black Asian population in the Philippines were a homogenous group.

Key figures in forensic psychology, Drs. Mamie and Kenneth Clarks' "doll test" and research were instrumental in demonstrating the harmful effects of segregation in *Brown v. Board of Education of Topeka* (1954). Likewise, Caroline Bond Day, a student of Earnest Hooton at Harvard, used genealogies, interviews, and anthropometrics in her expansive 1932 Master's thesis to show that laws prohibiting miscegenation predicated on biological inferiority were baseless.

When exploring the contributions of Black pioneers of the 20th-century, it is difficult to quantify their impact in parallel to their non-Black peers. Many early Black scholars in the forensic disciplines faced considerable obstacles to traditional markers of academic success, such as publications and tenured promotion, while others were pushed out of the discipline altogether. Despite these obstacles, the legacies of Black pioneers in forensic anthropology live on not only through distinguished labs and collections, but also their influence on the theory and praxis of current Black scholars and practitioners. While current events have revealed our discipline's intent to maintain "objectivity," Black pioneering scholars maintained passionate rigor in activist scholarship while emphasizing the importance our discipline has on the everyday world. A clearer understanding of the scholarship of Black anthropologists is alive and offers critical perspectives and diversity necessary to enhance our discipline.

History, Diversity, Forensic Anthropology

A117 Drawing Parallels: Black, Indigenous, and People Of Color (BIPOC) Representation in Other Medicolegal Fields

An-Di Yim, PhD, Truman State University, Kirksville, MO; Jessica Juarez, PhD, SNA International, Supporting the Defense POW/MIA Accounting Agency, Joint Base Pearl Harbor-Hickam, HI; Jesse Goliath, PhD, Mississippi State University, Mississippi State, MS; Isabel Melhado, University of Indianapolis, Indianapolis, IN*

Learning Overview: After attending this presentation, attendees will have a better understanding of the scopes of BIPOC representation in different medicolegal fields, as well as the strategies or initiatives to increase BIPOC representation proposed by different medicolegal fields.

Impact Statement: This presentation will impact the forensic community by providing data on diversity, inclusion, and representation from different medicolegal fields and by identifying the strategies used or proposed to achieve goals in supporting diversity, equity, and inclusion.

The benefits of a diverse and inclusive working environment have been well-documented. This is especially needed in forensic sciences, where new scientific advances can greatly benefit society. Underrepresentation may lead to a bias that ideas and topics that are culturally and/or biologically significant to certain groups are less important to the community as a whole. Additionally, there is a general mistrust and negative connotations associated with law enforcement and the medicolegal system among people of color.

This study surveyed the literature and data reported from professional organizations in an attempt to find information about diversity within different subdisciplines of medicolegal fields. Results showed that for anthropology, 7% of members in the American Association of Biological Anthropology (AABA) identified as being an underrepresented minority, while about 32% of members of the Anthropology Section of the American Academy of Forensic Sciences (AAFS) self-identified as being a member of an underrepresented group. However, the Anthropology Section represents less than 4% of the total membership of the Academy. There is no direct data on BIPOC representation in other medicolegal fields. However, insights can be gleaned from statistics of the greater scientific communities. In pathology, about 15% of the trainees (pathology residents) in 2016 reported to be members of an underrepresented minority. Significant differences were also found in terms of underrepresented minority pathology fellows and residents compared to the United States population. The Society of Toxicology (SOT) also openly acknowledged there is racial, ethnic, and gender inequality in participation and leadership within the society, but did not report actual statistics regarding their membership or leadership compositions. This study acknowledges that its results may not represent accurate BIPOC representation in medicolegal fields, but they all signify an overall problem of a lack of diversity. Acknowledgment and recognition is not enough to mitigate the trend of underrepresentation. It is imperative that we implement, in earnest, strategies to diversify the scientific community as a whole. While not exhaustive, some of these strategies may include: acknowledgement of differing experiences for BIPOC individuals; early education outreach; encouragement and access to opportunities throughout educational and career trajectories; and correcting compensation inequalities.

Finally, this study recognizes that while different statistics from different organizations or research projects may not be directly comparable (as the definition of “underrepresented group” may differ), professional organizations are encouraged to be open about the diversity (or lack thereof) in their membership. This openness is beneficial in identifying strategies to improve BIPOC representation within their fields. Without this transparency, we, as a scientific community, run the risk of a narrowly focused approach to solutions and services that affect the scientific community as a whole.

Diversity, Representation, Medicolegal

A118 Objectivity in the Historical Narrative of Forensic Anthropology

Kamar Afra, MA, University of Tennessee, Knoxville, TN; Elaine Y. Chu, MA, University of Nevada, Reno, Reno, NV; Sydney S. Garcia, MA, SNA International, Joint Base Pearl Harbor-Hickam, HI*

Overview: After attending this presentation, attendees will have gained a more in-depth understanding of the historical factors that led to enhanced racial categorization in science and anthropology and how this translated to the othering and exclusion of Black, Indigenous, and People Of Color (BIPOC) professionals.

Impact Statement: The goal of this presentation is to understand some of the tools that impacted the perspective of historical and current anthropologists and impede the contribution of BIPOC experts.

The objectivity of forensic science has been tangled in quantitative analysis due to expectations outlined in legal proceedings. Numerous fields rely on statistical tests to uphold the authenticity and admissibility of a result.¹ Statistical analyses and classification accuracy rely on that—the assumption that groups are distinct (based in scientific truth). When applied to humans, these groupings are grounded in oppressive socio-political hierarchies that are embedded in subjective thought.

In the late 19th and early 20th century, the predisposed ideas of human typology and xenophobia popularized anthropology. The eugenics movement reiterated the concept of “culture as biology” by linking genetic determinism, savagery, and racial classification.² This movement fueled the research of early anthropologists and other scientists who were working in a forensic sphere.

Historically, only those in power who created and benefited from the hierarchy were heard. Thus, objectivity of experts was defined by this subjective bias. Expert bias has been the seed for several fields, such as anthropological studies, that linked cranial capacity to intellect and levels of humanity to cranial morphology. These contributions to the field promoted and validated the othering of prominent people of color professionally and socially, such as W.E.B. Du Bois, Caroline Bond Day, and Anténor Firmin.³ This presentation provides a snapshot of the interdependence of conscious “objectivity” with an active effort to dismantle the theory of racial inferiority driven by eugenics ideas that contributed to the masking of BIPOC experts’ contributions for more than a century. Human variation does not equal racial or ethnic categorization, and understanding the history that led to these assumptions is necessary to decrease unconscious expert bias and defer scientific racism. Forensic anthropology should be anthropology first.

Forensic Anthropology, Expert Bias, Objectivity

A119 Forensic Anthropology's Role in Activism and Advocacy

Fatimah Bouderdaben, BS, Texas State University, San Marcos, TX; Ivanna Robledo, MA, Texas State University, San Marcos, TX; Alba Craig, BA, University of Indianapolis, Indianapolis, IN; Sydney Garcia, MA, SNA International, Joint Base Pearl Harbor-Hickam, HI; Tanya Ramos, BA, University of Indianapolis, Indianapolis, IN; Evonne Turner-Byfield, MSc, Ohio State University, Columbus, OH*

Learning Overview: After attending this presentation, attendees will understand the need for activism to be ever-present in the work of forensic anthropologists. Hearing from minorities in the field will ensure that attendees will be presented with a variety of points of view that are often unknown or have gone unnoticed.

Impact Statement: This presentation will bring about a discussion that is much needed in today's current climate regarding activism, human rights, and the role/effect of racism in forensic anthropology. This presentation was created and is presented by early-career persons of color in the field to shed light on the points of view of these individuals and communicate them to the community at large.

There is no space for objectivity in forensic anthropology because impartiality favors the side of the oppressor. This places an obligation on the forensic anthropologist to become an activist with their work and daily lives. Anything from non-profit work to inclusive teaching practices are considered acts of advocacy forensic anthropologists can pursue to fulfill that obligation. For Black, Indigenous, and People of Color (BIPOC) in this field, the act of existing in White academia and professional spaces is activism.¹

Historically, activism has changed the field and evolved the practices of forensic anthropology into becoming more humane. It is undeniable that the work of activists has changed the field for the better. This has relied heavily on BIPOC activists like W.E.B. Du Bois and St. Clare Drake and their work.²

Forensic anthropologists are often hired to assist with the exhumation and identification of individuals who have died tragically from genocide and other violations of human rights. Forensic anthropologists aiding in this type of investigation are able to use their authority to advocate and bring awareness to the injustices that caused the demise of innocent people. Oftentimes being a part of this type of work also means working with *living* communities who are continually affected by the same injustices in their day-to-day lives. Forensic anthropologists can then advocate helping alleviate turmoil and support affected communities.

The belief that advocacy and activism do not have a place in forensic science comes from a place of privilege that BIPOC scientists do not have. These should not be mutually exclusive, especially when the public relies on the advocacy of scientists to improve the system by recognizing its flaws and limitations. There should be an incorporation of activist research.³ This is further supported by organizations and individuals such as Carlina de la Cova, Michael Blakey, the Argentine Forensic Anthropology Team (EAAF), The Peruvian Team of Forensic Anthropology (EPAF), and the Forensic Anthropology Foundation of Guatemala (FAFG) that have and continue to use advocacy and activism as a tool to better support underserved communities.⁴

Anthropology, Activism, Human Rights

A120 The (Colonial) Impacts of (Western) Forensic Anthropology in the International Sphere

Nandar Yukyi, MA, Department of Anthropology, University of Nevada-Reno, Reno, NV; An-Di Yim, PhD, Department of Health and Exercise Sciences, Truman State University, Department of Biology, Kirksville, MO; Matthew C. Go, PhD, SNA International, Supporting the Defense POW/MIA Accounting Agency, Joint Base Pearl Harbor-Hickam, HI; Ivanna Robledo, MA, Department of Anthropology, Texas State University, San Marcos, TX*

Learning Overview: After attending this presentation, attendees will understand and be able to recognize past and current practices of Western forensic anthropology that are deemed normal but are colonial in nature.

Impact Statement: The goal of this presentation is to impact the forensic science community by identifying issues with parachute forensic anthropology and suggesting a set of working guidelines to decolonize current practices in international collaborations in forensic anthropology.

Recent work has shown that Western nations, especially the United States, lead research in forensic anthropology significantly more than non-Western counterparts by absolute count of publications and citation impact.¹ This finding supports sentiments that the research and practice of forensic anthropology within Western contexts dictates the discipline's formation and exports their ideas to other parts of the world. This presentation seeks to highlight the inverse, where Western practice can stand to learn from non-Western contexts in their approaches. International collaboration in forensic anthropology takes place in both academic and professional contexts. Current practices in international forensic anthropological fieldwork typically involve the Western anthropologist traveling to a given host country to collect data at institutions or participate in excavations and promptly departing once the job is completed, a *modus operandi* known as parachute science or helicopter research.^{2,3}

One example can be found in forensic humanitarian work, a well-established subfield of forensic anthropology that has been discussed extensively in the literature. Such work, often taking place in countries that are not part of the global West, is seldom spearheaded by local specialists. However, forensic humanitarian efforts often require context-specific approaches to be successful. Past experience also highlights the value of capacity-building and training in the sustainability of humanitarian projects.

To date, literature on ethics and professionalism in forensic anthropology does not provide explicit guidelines for working in foreign nations. Further, differences in how institutions across the globe operate call for the Western anthropologist to adapt to appropriate sensitivities when working in an international sphere. As such, protocols for how international collaborations should be conducted in forensic anthropology are relatively loose. Given a racist and colonial past in the history of Western anthropology, especially when dealing with international research, this study contends that guidelines for conducting international research should be specified.

This presentation aims to provide actionable steps by: (1) proposing working guidelines for international collaboration; (2) encouraging foreign experts to involve the local community in projects on equitable footing; and (3) ensuring data sharing and accessibility to additional materials. Through these steps, this presentation aims to provide a space for the local communities in various host countries to advocate for themselves and promote the decolonization of current practices within forensic anthropology.

A121 Homework for Modern Forensic Anthropologists

Elaine Y. Chu MA, University of Nevada-Reno, Reno, NV; Nandar Yukyi, MA, University of Nevada-Reno, Reno, NV; Matthew C. Go, PhD, SNA International, Supporting the Defense POW/MIA Accounting Agency, Joint Base Pearl Harbor-Hickam, HI, USA*

Learning Overview: After attending this presentation, attendees will understand the barriers currently preventing retention of diversity in forensic science and how each attendee may work toward a more diverse and inclusive discipline.

Impact Statement: The goal of this presentation is to impact the forensic science community by providing actionable items to bring to their own institutions to foster a more inclusive work environment and accommodate the diversity of a modern forensic world.

The Anthropology Section at the American Academy of Forensic Sciences (AAFS) has seen a sharp increase in diversity of attendance and membership since the inclusion of undergraduate students as Student Members and the creation of the Diversity and Inclusion Committee. Fifteen years ago, a symposium featuring only early-career researchers who identify under the umbrella-term of Black, Indigenous, and People of Color would not have been possible, if not due to fear of reprisal, then simply due to a lack of numbers. While this symposium has highlighted the strides in ethnic diversity seen by AAFS membership and the advancements in thoughts and perspectives that come along with it, it is important to highlight the intersectionality of identity and acknowledge the other improvements to diversity that the section has achieved.

Research shows that increasing diversity is only the first step in creating a more collegial scientific environment—the “leaky pipeline” persists as a barrier to true diversity at the highest levels of academia and industry.¹ Diversity has often been used by institutions as a commodity, simply a numbers game in which a certain goal is determined by the dominant group and once achieved, is checked off as complete.² The general justification for increasing diversity is that diversity improves science by bringing new perspectives to foster innovation.^{2,3} Such expectations then unduly rely on underrepresented groups to perform at levels higher than that expected of their majority peers.³ Yet novel concepts from underrepresented groups are less likely to be recognized and/or adopted by their disciplines.⁴ Therefore, it is important to intentionally dedicate space and time toward recognizing and celebrating all forms of diverse perspectives—especially in forensic science.

Drawing from diversity and inclusion research, this presentation evaluates the current state of diversity and inclusion efforts in the Anthropology Section of AAFS. Further, recommendations are provided for increasing *inclusion* in the discipline for higher *retention* of diversity.

Diversity, Inclusion, Retention

A122 Quantification of the Mincer et al. (1993) Age Estimation Method Using Radiographs

Bailey Oettel MA, University of Nebraska-Lincoln, Lincoln, NE; Brittany Walter, PhD, Department of Defense POW/MIA Accounting Agency, Offutt Air Force Base, Omaha, NE; William Belcher, PhD, University of Nebraska-Lincoln, Lincoln, NE*

Learning Overview: At this presentation, attendees will be introduced to a method developed with the goal of quantifying the subjective, stage-based Mincer et al. age estimation method.¹ Specifically, attendees will become familiar with the advantages and limitations of using sectioning points derived from odontometric measurements from radiographs to assign developmental stages of the third molar.

Impact Statement: This presentation will impact the forensic science community by demonstrating the high reliability, but variable accuracy, of assigning developmental stages of the third molar based on odontometric measurements from radiographs. Furthermore, this study will attempt to validate the Mincer method on a sample of, mostly young, adult males that includes individuals with impacted molars.

Experience plays an important role in the age estimation of human remains, particularly for methods that are based on scoring subjective stages. This can leave inexperienced observers at a disadvantage. Given that research has shown metric measurements are typically reliable even when measured by observers with varying experience levels, stages assigned based on metric measurements may yield estimates of age that are more accurate and reliable, especially by less-experienced observers.² This study developed an age estimation method assigning developmental stages of the third molar based on sectioning points derived from metric measurements, and subsequently assessed the reliability and accuracy of the method. Additionally, the validity of the original Mincer method was also evaluated on a sample of adult males who were mostly young adults.

This study used radiographs of third molars from 49 casualties of the World War II USS *Oklahoma* incident housed by the Defense POW/MIA Accounting Agency Laboratory, which was comprised of 17–52-year-old males. For each individual, five measurements were taken from a radiograph of at least one mandibular third molar and measurement ratios were calculated. Measurement ratios that significantly correlated to each Mincer stage of development were used to establish sectioning points that differentiated the developmental stages. To estimate the reliability of the stages assigned based on sectioning points, a separate sample of 12 third molars were re-measured and re-scored after one week. To assess the accuracy of the stages assigned based on sectioning points for each of the measurement ratios, stages from the 12 third molars were compared to stages previously assigned by experienced forensic anthropologists using the original method. Finally, to validate the original Mincer method on this sample of young adult males, the estimated age using the original Mincer method was compared to the known age of the individuals.

The results indicate excellent intra-observer reliability for obtaining the stages from the sectioning points, with Intra-Class Correlation Coefficient (ICC) values of at least 0.972. However, the accuracy of assigning stages was variable, with correct classification ranging from 25% to 75% for the different measurement ratios; the apical width ratios were the most accurate. Finally, application of the Mincer method on this sample provided age estimates that, on average, were younger than the actual age for all of the stages. However, the sample included individuals with impacted molars, which recent research has shown can result in underestimation of age.³

According to this study, sectioning points derived from metric measurement ratios of the third molar using radiographs are reliable (i.e., successfully replicated); however, the use of these sectioning points to accurately assign Mincer stages of development for age estimation is not supported due to low accuracy, with the exception of the apical width measurement ratios. Additionally, the findings support previous research that the use of third molar development for age estimation generally provides underestimates of age, which may in part be due to the inclusion of impacted teeth.

Age Estimation, Third Molar, Sectioning Points

A123 Does Structural Violence Impact Forensic Anthropological Age Estimation? Investigating Skeletal Indicators of Biological “Weathering” in Modern United States Individuals

Taylor Walkup, BA, University of West Florida, Pensacola, FL; Allysha Winburn PhD, University of West Florida, Pensacola, FL*

Learning Overview: After attending this presentation, attendees will be familiar with the weathering hypothesis—the concept that Black Americans’ health begins to cumulatively decline in early adulthood, with embodiment as its mechanism—and its potential skeletal impacts.

Impact Statement: This presentation will impact the forensic science community by showcasing how the lived experiences of social inequity and structural violence can become embodied, affecting individuals on the skeletal level and in turn affecting the accuracy of forensic anthropological age estimations.

Accuracy in estimating the biological profile is imperative to the medicolegal personal identification process. Yet, most forensic anthropological methods have not been generated or tested on the remains of people of color—the very populations global forensic anthropological casework most frequently serves. The donated skeletal collections on which many biological profile methods are based do not reflect global population demographics, containing disproportionately high numbers of individuals who identified as “White.”¹ Methods developed on the remains of relatively privileged United States White individuals may not be appropriate in many domestic medicolegal and international human rights contexts.

The disconnect between method production and the reality of medicolegal casework is highlighted by decades of public health research, such as the weathering hypothesis.² The weathering hypothesis states that the overall health of Black Americans declines cumulatively, beginning in early adulthood, compared to White Americans, due to living with the chronic stress of social inequity. Members of different cultural, religious, socioeconomic, and racial groups experience and embody different stressors over the life course, with the social becoming biological in a process that may be discernible skeletally.³ Embodiment and weathering have direct relevance to the biological profile—specifically, age estimation—as the remains of prematurely weathered individuals may “look older” than their chronological age and thus result in an inaccurate age estimate. However, the potential for skeletal weathering has yet to be investigated.

In order to test whether premature aging (i.e., weathering) is discernible in human skeletal remains, 183 skeletal individuals from the W.M. Bass Collection were analyzed for several age indicators, “blind” to their demographic data. Each individual was scored on: Antemortem Tooth Loss (AMTL) via the Eichner index; the Suchey-Brooks pubic symphysis aging method; and the San-Millán-Rissech acetabulum aging method.⁴⁻⁶ The sample included White ($n=127$) and non-White ($n=56$) self- or kin-donated individuals. The White sample included lower-Socioeconomic Status (SES) males and females ($n=63$) and higher-SES males and females ($n=64$), and the non-White sample included Black ($n=31$), Hispanic ($n=9$), and “Biracial” ($n=16$) individuals regardless of SES. It was hypothesized that the non-White individuals would “score older” on all age indicators compared with both White sub-populations, and that lower-SES White individuals would “score older” on all age indicators compared with the higher-SES White sample.

The hypothesis that non-White individuals would “score older” was supported in one acetabular rim variable (V3; Kruskal-Wallis run in R ; $p<0.05$). When only high-SES White individuals were included, however, non-White scores were also significantly higher for Suchey-Brooks phase and the acetabular fossa variables V6 and V7 (Kruskal-Wallis; $p<0.05$). The hypothesis that lower-SES White individuals would “score older” than high-SES was supported for AMTL (Kruskal-Wallis; $p<0.001$) and one acetabular fossa variable (V6; Kruskal-Wallis; $p<0.05$).

These preliminary results highlight that skeletal aging is neither monolithic nor simply biologically determined. It is, to some degree, influenced by individuals’ lived, embodied experiences—potentially including both race- and class-based inequities. This evidence encourages the development of aging methods on large and diverse samples and highlights the role of biocultural processes in patterning human skeletal variation.

Age Estimation, Weathering, Embodiment

A124 The Combined Use of Craniometrics and Odontometrics to Estimate Parameters of the Biological Profile

SaMoura L. Horsley, University of Nevada-Reno, Reno, NV; Cassie Skipper, MA, University of Nevada-Reno, Reno, NV; Marin Pilloud, PhD, University of Nevada-Reno, Reno, NV*

Learning Overview: After attending this presentation, attendees will better understand how measurements of the cranium, mandible, and the dentition are correlated and how they may be used together to estimate parameters of the biological profile.

Impact Statement: This study will impact the forensic community by identifying how multiple data sets can be used together to arrive at improved estimates of the biological profile.

In methods to estimate parameters of the biological profile, practitioners often employ only a single variable type. For example, metrics and non-metric traits are not typically combined, nor are different types of metric variables (e.g., cranial metrics are analyzed separately from postcranial metrics). There are some exceptions to this finding, however. For example, Berg and Kenyhercz employ metric and non-metric variables to estimate population affinity and sex on mandibles, and there has been work to explore the relationship of cranial macromorphoscopies and dental morphology to understand population variation.^{1,2} However, there has not been work exploring the relationship of cranial metrics and dental metrics and how the incorporation of both data sets may improve estimates of the biological profile. The goals of this project are to identify how measurements of the cranium and mandible are correlated with those of the dentition and to use this information to combine datasets in a biologically meaningful way to test if this dataset can improve estimates of the biological profile.

Data were collected from the Texas State University Donated Skeletal Collection. This study collected data on cranial and mandibular metrics, then dental metric data on the same individuals ($n=57$) were collected. Correlations among the variables were noted to identify correlated patterns of growth and development of the craniofacial complex. A network analysis was conducted to identify modules of interrelated variables. The largest module was then used in a Discriminant Function Analysis (DFA) to explore the ability of the variables in the module to estimate biological sex and population affinity as identified via self-reported social race and sex categories. The results of this DFA were compared to a stepwise DFA to identify which model performed better. All statistical analyses were done in the R statistical computing environment and SPSS 26.^{3,4}

Pearson Correlation coefficients show that the vast majority of variables were positively correlated. Many of the measurements of the face were highly correlated with measurements of the teeth, predominantly measurements of the lower third molar. These results identify correlating patterns of growth and development between the face and the dentition. The stepwise DFA for population affinity estimates identified four metric variables of the teeth and was accurate in 55.2% of cross-validated cases. The network analysis identified a module of 12 craniometric and 15 odontometric variables that contained the highest percentage of variables within the network. These variables (with the exception of the third molar measurements) were then used in another discriminant analysis. This revised model was able to correctly classify individuals in 86.2% of cross-validated cases, significantly improving on the original step-wise model. The same process was undertaken to estimate biological sex. The stepwise DFA identified four craniometric and five dental metric variables and was correct in 93% of cross-validated cases. In this case, the DFA using the variables from the network analysis module was less accurate (68.4% accuracy in cross-validated cases).

This work highlights the complexity of skeletal variation and how it may or may not correlate to a binary of biological sex and self-reported social race categories. However, generally incorporating measurements of the cranium, mandible, and dentition served to provide a more robust picture of human variation. It is important when studying modern human variation to carefully consider the phenotypic traits employed in analyses and to understand their evolutionary background. Future research would further investigate the impact of variable choice on statistical estimates and explore the potential negative impact of reinforcing biological categories of sex and population affinity within forensic anthropological research and casework.

Dental Metrics, Mandible, Cranium

A125 Validating the Use of Osteoarthritis as an Indicator of Age in Human Skeletal Remains

Ariana Strasheim, BA*, University of West Florida, Pensacola, FL; Allysha Winburn, PhD, Metro State University of Denver, Denver, CO; Michala Stock, PhD, Metro State University of Denver, Denver, CO

Learning Overview: After attending this presentation, attendees will have a better understanding of the Utility of Osteoarthritis (OA) in estimating the age of human skeletal remains.

Impact Statement: This presentation will impact the forensic science community by illustrating how OA—previously proposed as an age indicator for United States individuals who identified as White—was independently validated and its application expanded to include a more diverse sample.

Age at death is a critical aspect of the biological profile that forensic anthropologists generate from a set of human skeletal remains. However, current methods of age estimation rely on select bones, such as the innominates or fourth ribs, and if these bones are missing or damaged due to dismemberment, animal scavenging, or other taphonomic processes, then their utility for age estimation is limited. One way to remedy this methodological shortcoming is to investigate regions of the body that could be age-informative even in fragmentary contexts. Age estimation using OA is an example of one such approach.

In 2019, Winburn and Stock demonstrated that despite the multifactorial nature of OA, age was the only variable proven to predict the presence or absence of OA within a joint.¹ The presence or absence of OA in a given joint surface is therefore able to provide an estimation of age. The current study independently validated the results of Winburn and Stock on a sample of United States individuals.¹

Using a binary scoring system, every appendicular joint surface (and the Temporomandibular Joint [TMJ]) from 275 self- or kin-donated skeletal donors from the William M. Bass collection was evaluated for presence or absence of OA ($n=12$ American Indian or White/American Indian, $n=4$ Asian, $n=31$ Black, $n=9$ Hispanic, $n=223$ White). Using a binomial Generalized Linear Model (GLM) probit link function analysis, transition analysis enabled the prediction of the age at which an individual would transition from “no OA present” to “OA present” in a given joint surface.²⁻⁴

All statistical analyses were performed in *R Studio* (version: 1.4.1717; *R* Core Team, 2021). Alpha levels were set at $p=0.05$ for all analyses. The “VGAM” package in *R Studio* enabled the probit link function of binomial GLMs to use log-scaled age to generate the modal age-at-transition, standard deviation, and estimates of the ages at which 90 and 95 percent of the population will have transitioned, for males and females.⁵ In males, estimates of the age at transition (of “no OA present” to “OA present”) for 90% of the population ranged from 32.9 (knee) to 50.8 years (foot), and for 95% of the population from 37.5 (hip) to 87.4 years (TMJ). The age at transition to “OA present” estimate for 90% of the female population ranged from 28.0 (elbow and hip) to 48.7 years (foot) and for 95% of the population from 29.9 (elbow and hip) to 61.3 years (TMJ). When the two sexes were pooled, the age at transition estimate to “OA present” for 90% of the population ranged from 31.2 (knee) to 49.7 (foot) and from 35.4 (hip) to 73.5 (TMJ) for 95% of the population. In general, ages at transition were consistent with the findings of Winburn and Stock. Further, this study confirmed the lack of correlation initially reported by Winburn and Stock between OA and age in the female ankle joint, in addition to identifying that the male elbow is a problematic joint for OA-based age estimation. These joints should not be used to estimate age in these groups.

Since OA has been demonstrated to have a significant and reliable relationship with age, it has the potential to serve as a valuable tool for forensic anthropologists in their efforts to age human skeletons—particularly in fragmentary contexts.

Forensic Anthropology, Osteoarthritis, Age Estimation

A126 An Evaluation of Palate Shape Scoring Systems

Christopher Maier, PhD*, Eckerd College, St. Petersburg, FL

Learning Overview: After attending this presentation, attendees will understand differences in application and performance of existing systems for evaluating palate shape as a macromorphoscopic cranial trait for assessing population affinity.

Impact Statement: This presentation will impact the forensic science community by directly comparing and evaluating several existing systems for recording palate shape. This will allow practitioners who estimate population affinity to be informed regarding the replicability and efficacy of the available methods.

Palate shape has a long history as a cranial macromorphoscopic trait, appearing even in some early attempts to describe population-based human variation.¹ Consequently, over the decades, many different systems for recording palate shape have been developed.¹⁻⁶ However, with so many methods available, choosing the most appropriate method can be difficult, especially when direct comparison is unavailable. This presentation examines a selection of methods and evaluates their replicability and the strength of their association with population affinity to establish the pros and cons of each.

A sample of 670 individuals was evaluated from digital photographs taken of the cranium from an inferior view. Each palate was given a score according to the guidelines set forth by each of the palate scoring methods under consideration.¹⁻⁶ Method replicability was measured by the rate of observer error as measured by Cohen's weighted Kappa statistic.⁷ Association with population affinity was measured with a variety of association statistics, including chi-squared tests, Cramér's V, Sakoda's corrected contingency coefficient, and correspondence analysis.⁸ Finally, to assess overall performance, each method was ranked based on the statistics generated by the previous analyses. The sum of the ranks for each method represents an overall score relative to the other methods examined.

With respect to replicability, all the methods were recorded with substantial agreement or better ($K > 0.72$) following the guidelines of Landis and Koch, though one part of the component system (anterior curvature) was less consistent with only moderate agreement ($K = 0.578$).⁹ Although all the systems are robust to observer error, methods with fewer options, like the three-shape system of Gill, are more replicable ($K = 0.83$) than other systems.

As concerns association with population affinity, every system exhibits statistically significant differences, which is consistent with a relationship between palate shape and affinity. However, specific measures of association between scores and population affinity reveal a more complicated relationship. The effect size of the differences detected by the chi-squared tests, as measured by Cramér's V, is weak overall ($0.11 < V < 0.17$).¹⁰ Although the association is weak, the strongest association observed is that of the Gill method; however, one component of the component system, angle of the sides, did have a stronger association.^{2,4} In contrast, a different pattern emerges if association between method scores and population affinity is measured with a contingency coefficient. Using C as measure of association, the scores in the component system and the 5-shape system proposed by Maier are the most strongly associated.^{4,5} Finally, when considering both replicability and association together, the Gill and Maier shape systems appear to be the best systems.^{2,5} Noteworthy is that the angle component alone performed as well as the Gill system.^{2,4}

In conclusion, simpler systems produce results that are easiest to replicate, while systems with more levels and the component system bear a stronger association with population affinity.^{2,4,5} The strong performance of the component system, and one of its components alone, suggest that a component approach may be viable going forward. Each of the methods examined offers advantages and disadvantages depending on if the practitioner more strongly weights replicability, association with population affinity, or a balance of the two.

A127 A Pilot Study Re-Examining the Hartnett Adult Age-at-Death Estimation Methods as Component Systems

Amelia Konda, BA, Texas State University, San Marcos, TX; Sara Getz, PhD, University of Wisconsin-Platteville, Platteville, WI; Nicholas Passalacqua, PhD, Western Carolina University, Cullowhee, NC*

Learning Overview: After attending this presentation, attendees will have a greater understanding of the contributions of individual features within the Hartnett methods for estimating the age of individuals over the age of 45 years and the potential benefits of reconfiguring these phase-based methods into a component system.

Impact Statement: This presentation will impact the forensic science community by demonstrating the potential for a revision of the Hartnett age-at-death estimation methods from phases into components.

The Hartnett phase-based methods for the pubic bone and fourth rib were published in 2010.¹ They were derived largely from features described in historically popular methods, but provided updated trait descriptions, included several new features potentially indicative of advanced age, and provided age intervals based on large, contemporary reference samples. For these reasons, these updated methods have largely replaced earlier approaches for those regions of the skeleton in forensic practice.

The Hartnett Methods, like all phase-based methods use a series of ordinal categories, each containing descriptions of multiple characteristics that typify an anatomical region, which are associated with an age interval calculated from a reference sample. Because such methods include multiple features within each phase description and it is not uncommon for an individual to possess features of multiple phases, a description of an individual's morphology cannot be inferred solely from a phase designation (e.g., Phase 5). This prevents the evaluation of the contributions of individual features to age estimates.

Therefore, this pilot project reconsidered the Hartnett methods as component systems. A component scoring system was developed by identifying individual features present in multiple Hartnett phase descriptions and generating character states based on changes in each feature between phases. Collectively, 5 traits were identified for the fourth rib, and 11 traits were identified for the pubic bone, with between 3 and 7 character states for each.

All traits were scored from 77 individuals (males: $n=41$, females, $n=36$) with documented age-at-death from the John A. Williams human skeletal collection at Western Carolina University. This collection primarily represents older White females and males from North Carolina and the surrounding states with most individuals (72/77) being over 45 years of age (average age: 64.9 years). All traits were scored on both the right and left sides for each individual. Because of these sample limitations (e.g., size, age distribution), this pilot project focused on evaluating the traits individually to assess their contributions to age estimates for older individuals, which could lead to the development of improved methods.

For all pubic symphysis components, essentially all individuals over the age of 45, were scored as the oldest two or three character states, depending on the trait. Weak age-related patterns were found for porosity and bone quality variables. Similar patterns were found for rib components, with weak age-related patterns identified for bone quality and the development of bony projections. The substantial overlap among the age distribution of individuals scored within each category indicates that the majority of these variables contribute little-to-no information to age estimates beyond the age of 45 years.

These data indicate that conversion of the Hartnett phases into component systems is unlikely to dramatically improve age estimates for older individuals. However, the use of a component system would improve documentation of the features used to estimate age, as well as providing the type of data necessary for research investigating variation in the aging process. As the pubic symphysis and sternal ribs are commonly used areas of the skeleton for adult age estimation around the world, the development of a component-based method using a large, modern sample and incorporating features of advanced age is recommended.

Age Estimation, Fourth Rib, Pubic Bone

A128 Application of the forAGE Program to Pubic Symphyseal Surface in a Korean Population

Hyun Jin Park, MSc*, Yonsei University College of Dentistry, Seoul, Korea; Eun Jin Woo, PhD, Sejong University, Seoul, Korea; Kyung-Seok Hu, DDS, PhD, Yonsei University College of Dentistry, Seoul, Korea

Learning Overview: After attending this presentation, attendees will understand what points need to be considered when applying the *forAGE* program to a population other than European American, through the results of applying the *forAGE* program, an age estimation program that utilizes the 3D difference of the pubic symphysis surface, to the Korean population.

Impact Statement: This presentation will impact the forensic science community by presenting new results of estimating the age of Asian populations using the *forAGE* program and the limitations of age estimation programs designed with specific populations.

ForAGE is a program that estimates the age-at-death of human pubic symphysis based on 3D scans. This program was devised by Dennis E. Slice and Bridget F.B. Algee-Hewitt and based on the three different scores: Slice and Algee-Hewitt (SAH) score, Bending Energie (BE), and Ventral Curvature (VC).^{1,2} However, these scores and age estimation regression equations were obtained through European American pubic symphysis.

Changes to the pubic symphysis surface by aging were evaluated as one of the most reliable indicators for estimating age. However, there has been no study conducted regarding the relationship between changes in the pubic symphysis and actual age and applying the age estimation method for a specific population among a Korean population. The purpose of this study is to compare the difference between the actual age and the estimated age in a Korean population to see if the *forAGE* program is applicable to other populations of different ancestral origin.

One hundred seven Korean pubic symphysis surfaces, donated from Yonsei University College of Medicine, (40 males and 21 females, age range 47–96 years, mean age 75.9 years) were used in this study. Specifically, the number of pubic symphysis surfaces was 4 people in their 40s, 6 people in their 50s, people in their 60s, 39 people in their 70s, 35 people in their 80s, and 4 people in their 90s. The pubic symphysis surfaces were scanned using Arctic Space Spider scanner (Artec3D). The difference between the actual age and the estimated age was compared via the *forAGE* program.

First, the prediction equations using the SAH score in a Korean population showed the following results.¹ According to all pubic symphysis samples over 60 years of age, the estimated age was lower than the actual age. Interestingly, for those under 60 years, the estimated age was higher than the actual age. The Root Mean Square Error (RMSE) of the 60s, 70s, 80s, and 90s Korean age groups were 7.02, 18.32, 27.24, and 37.38, respectively. With aging, the difference between the actual age and estimated age became larger.

Second, similar patterns were found in the analysis of the new regression lines using VC, SAH score, and BE. The estimated age of all pubic symphysis sample, was lower than that of the actual age. Among the five new regression lines, the regression line with VC had the lowest RMSE. The RMSE increased in order of the regression line with VC&SAH, SAH, VC&BE, and BE. Below 60 years, the RMSE of new regression line with VC was 15.46, but 18.85 in 60 years, 33.54 in 70 years, 36.42 in 80 years, and 50.81 in 90 years. Surprisingly, the difference between the actual age and estimated age was greater in those aged over 70.

This investigation confirmed whether the age estimation method through a 3D scan of pubic symphysis can be applied to the Korean population. The *forAGE* was a study based on young and middle-aged people that showed large differences among the Korean population. The prediction equations using SAH score and new regression lines using VA are more accurate for the 50-year and 60-year groups. In the 50–60 age groups, *forAGE* age estimation can complement and improve the accuracy of other age estimation methods. However, this research for middle- and old-aged Koreans shows there is yet a need for further research to apply the equation to a wider variety of age groups.

Pubic Symphysis, Age Estimation, Korean

A129 Age Estimation From Sternebral Fusion in an Indian Population: A Computed Tomographic Evaluation

Rutwik Shedge, MSc, All India Institute of Medical Sciences, Jodhpur, Rajasthan, India; Tanuj Kanchan, MD, All India Institute of Medical Sciences, Jodhpur, Rajasthan, India; Pawan Garg, MD, All India Institute of Medical Sciences, Jodhpur, Rajasthan, India; Shilpi Dixit, MD, All India Institute of Medical Sciences, Jodhpur, Rajasthan, India; Varsha Warriar, MSc, All India Institute of Medical Sciences, Jodhpur, Rajasthan, India; Kewal Krishan, PhD*, Panjab University, Chandigarh, Punjab, India*

Learning Overview: After attending this presentation, attendees will have a better understanding of the use of sternebral fusion in human age estimation.

Impact Statement: This presentation will inform attendees and the forensic science community of the utility of sternebral fusion in ascertaining whether an individual has attained the medicolegally significant ages of 16 and 18 years.

Forensic age estimation is a crucial aspect of the human identification process. It is routinely done in dead as well as living individuals and in civil as well as criminal cases. The most common methods of forensic age estimation include the study of epiphyseal fusion of the bones and development of the teeth. The human sternebrae are an example of skeletal indicators of age that can be used in human identification practices. Limited literature exists on their utility in estimating the age of individuals nearing the legal age of maturity.

The present study was conducted with the aim of assessing the utility of each of the sternebral fusion in age estimation and to ascertain if these fusion stages can help in identifying whether an individual has attained the medicolegally significant ages of 16 and 18 years. The present study investigated the extent of fusion of sternebrae 1–2, sternebrae 2–3, and sternebrae 3–4 in 148 study participants (74 females, 74 males) aged 10.06 years to 23.47 years by analyzing their thoracic Computed Tomography (CT) images. The age of male and female participants was evenly distributed—there were 10 males and 10 females in the age group of 10 to 12 years, there were 10 males and 10 females in the age group of 12 to 14 years, there were 11 males and 10 females in the age group of 14 to 16 years, there were 10 males and 10 females in the age group of 16 to 18 years, there were 11 males and 11 females in the age group of 18 to 20 years, there were 12 males and 11 females in the age group of 20 to 22 years, and there were 10 males and 12 females in the age group of 22 to 24 years. The fusion scores for these were found to be statistically significant ($P < 0.001$) with sternebrae 1–2 fusion showing the highest coefficient of correlation at $R=0.900$. Simple and multiple linear regression models were generated using each of the sternebral fusions separately and together for estimation of age. The standard error of estimate for the regression models ranged from 1.51 to 2.86 years. Box and Whisker plots were constructed to see the fusion score wise age distribution of the study population, and it was observed that sternebral fusion has the ability to indicate whether an individual has attained the age of 16 and 18 years.

The present study concludes that sternebral fusion can act as an accurate method of forensic age estimation of juveniles and young adults and can be used by itself or as an adjunct to other established methods of age estimation in juveniles.

Forensic Anthropology, Age Estimation, Sternebral Fusion

A130 Age Estimation Via Dry Bone Measurements: Evidence From Samples of Soldiers Exiled in Two Concentration Camps in Bari

Mirko Leonardelli, PhD*, University of Bari, Bari, Italy; Valeria Santoro, PhD, University of Bari, Bari, Italy; Antonio De Donno, MD, University of Bari, Bari, Italy; Federica Mele, MD, University of Bari, Bari, Italy; Mariagrazia Calvano, MD, University of Bari, Bari, Italy; Enrica Macorano, MD, University of Bari, Bari, Italy; Stefano Duma, MD, University of Bari, Bari, Italy; Carmelinda Angrisani, MD, University of Bari, Bari, Italy; Sara Sablone, MD, University of Bari, Bari, Italy; Francesco Introna, MD, University of Bari, Bari, Italy

Learning Overview: After attending this presentation, attendees will have a greater understanding of the contributions of mandibular dimensions measured on dry bone in estimating age at death from skeletal remains.

Impact Statement: This study will impact the forensic science community by offering an improved method of estimating age at death from mandibular measurements.

In cases where the identification of human remains is necessary as a result of accidents or in cases of criminal investigations or ethnic studies, the determination of age and sex is one of the first objectives sought by the medical examiner.

Recently, studies have highlighted that the anatomy and shape of the mandible change in proportion to age and sex.¹ In regard to age, a modification in the structure of the masticatory muscles was observed, which is manifested by a reduction in contractile strength.² Furthermore, sex differences in the morphology of the mandible are a result of different genetic patterns, with exponential growth during puberty observed for males, but not females.

This study analyzed three mandibular dimensions (gonial angle, bigonial width, and ramus height) as determinants of age for a group of soldiers of the Royal Yugoslavian-Chetnik Army in exile in Bari in 1941. The literature shows how these mandibular dimensions have been studied through radiological investigations (panoramic radiographs, computed tomography, cephalograms).³ The goal of this research is to collect the three mandibular measurements (gonial angle, bigonial width, and ramus height) directly from the skull to further examine mandibular age-related dimensional variations.

The sample consisted of 93 mandibles of Yugoslav origin from the skeletal collection of the Institute of Legal Medicine at the University of Bari. The remains represent soldiers of the Royal Yugoslavian-Chetnik Army who lived at two concentration camps of the Bari area during the World War II. A single observer collected the three mandibular measurements. To assess reliability and reproducibility, a second observer recorded the measurements at a later date.

The analyses were performed using an Excel® database and a statistical analysis was performed using Statal 13MP software. Bivariate analysis was used to compare the study parameters with age. All independent variables with a p-value ≤ 0.25 have been considered suitable for the multivariate analysis. Multivariate logistic and linear regression models were used to correlate independent variables with age. The results of the multivariate analysis were expressed in 95% Confidence Intervals (CIs), with a statistically significant level of p-value 0.05.

Statistically significant differences in the bigonial width and gonial angle were noted in this study according to the age of the individuals, while the ramus height was not statistically correlated with age.

In conclusion, this research confirms that the mandible is important for age determination and these findings showed statistically significant differences in bigonial width and gonial angle measurements according to the age of a sample of soldiers who lived inside the two concentration camps of the Bari area during the World War II. The ramus height dimension was not statistically significant with age. The greatest strength of this study, however, is the absence of geometric distortions of radiography present in other studies, due to direct measurements performed on the mandibles. Thus, knowledge of these different patterns is essential in determining the age of human skeletal remains, and the morphometric analysis of mandibular dimensions can be a helpful tool in forensic science.

A131 Developing Subadult Sex Estimation Standards Using Adult Morphological Sex Traits and an Ontogenetic Approach

Stephanie Cole, MS, University of Nevada-Reno, Reno, NV*

Learning Overview: After attending this presentation, attendees will understand how subadult sex estimation can be achieved using traditional adult morphological sex traits within an ontogenetic framework.

Impact Statement: This presentation will impact the forensic science community by providing a unique approach to subadult sex estimation that is as accurate as methods used for adults.

Morphological traits of the skull and pelvis are the most relied upon for estimating sex from the human skeleton. Currently, these traits are typically only applied in individuals estimated to be 18 years of age and older. However, these traits are associated with puberty and, therefore, should be applicable in individuals prior to adulthood. Recent research has shown that dimorphism in the morphological traits of the skull and pelvis is expressed as early as 13 years of age.^{1,2} Further, ossification of the iliac crest is associated with menarche in females and, therefore, can serve as a skeletal indicator of puberty, thus providing insight into the status of skeletal maturity without needing to rely on an age-at-death estimate.³⁻⁵

A new method for estimating subadult sex is currently being developed using an ontogenetic framework. The method utilizes the most frequently relied upon adult morphological sex traits of the skull and pelvis, but with reworked trait definitions and ordinal scoring procedures that are more appropriate for use with immature remains. The skull traits include: mastoid process, glabella, supraorbital margin, nuchal crest, and mental eminence. The pelvic traits include: ventral arc, pubis morphology, subpubic contour, medial aspect of the ischiopubic ramus, obturator foramen, greater sciatic notch, and preauricular sulcus. Additionally, the method incorporates skeletal indicators of puberty, such as the iliac crest, to assist practitioners in deciding whether an individual is mature enough for sex estimation to be attempted.

The modified traits were scored using a sample of 292 American individuals (m=165, f=127) aged 8 to 21 years from the Subadult Virtual Anthropology Database. Random forest was used to develop predictive models to estimate sex. A subset of individuals was then assessed for stage of iliac crest development and only individuals exhibiting ossification and/or fusion were retained (n=154, m=72, f=82, age=10-21yrs). A second round of random forest models was then employed to determine if accuracy improved.

When all individuals were included in the analysis regardless of iliac crest development stage, the combined sex accuracy was 92.8% with a large sex bias in favor of male classification (m=96.9%, f=87.4%). Out of 21 misclassified cases, 18 had an unossified iliac crest, and two of the three additional misclassifications were individuals younger than 13 years of age. When only individuals with an ossified and/or fused iliac crest were considered, the combined sex accuracy was 97.4% with a small sex bias in favor of male classification (m=100%, f=95.1%). Three out of four misclassified cases were individuals aged 11 years, with one case exhibiting minimal ossification.

The high classification rates demonstrate that adult morphological sex traits can be accurately applied to individuals that have yet to reach skeletal maturity when using an ontogenetic approach. The balanced, and higher, classification accuracy obtained when stage of iliac crest development was considered suggests that skeletal indicators of puberty provide a valid way to capture skeletal maturity without the need to rely on an age-at-death estimate.

Additional skeletal indicators of puberty are being incorporated and additional data will be collected from the United States and abroad. The finalized method is anticipated for 2022 and will be available as a graphical user interface, which will be freely accessible across multiple platforms, including MorphoPASSE and KidStats.

This research was funded by the Forensic Sciences Foundation (Lucas Grant) and the National Institute of Justice (2015-DN-BX-K409, 2020-R2-CX-0024).

A132 Investigating Reproducibility of a Skeletal Age Estimation Method on Two Samples With Remarkably Different Demographic Profiles

Elena Sierra-Serrano, MSc, Simon Fraser University, Burnaby, British Columbia, Canada; John Albanese, PhD, University of Windsor, Windsor, Ontario, Canada; Hugo FV Cardoso, PhD, Simon Fraser University, Burnaby, British Columbia, Canada*

Learning Overview: After attending this presentation, attendees will have a more nuanced understanding of how composition of the reference sample as a methodological issue can constrain age estimation of human skeletal remains.

Impact Statement: In situations in which age estimation is used as evidence in a court of law, methods used should be reliable according to *Daubert*'s admissibility standards. Careful examination of their reproducibility will produce more robust evidence overall.

While age estimation methods are routinely applied in biological anthropology, investigating their reliability has never been straightforward. Typically, a method is considered reproducible if agreement is over 80% or Cohen's Kappa is "substantial" ($\kappa > 0.6$).¹ Yet, investigating the validity of these boundaries has not been carried out in detail. Among other issues, these parameters do not consider key aspects, such as the demographic profile of the study sample.²

The present research attempts to investigate how reproducibility of the same method is influenced by tests in different samples. To this end, two intra-observer repeatability trials were compared. This involved scoring of 25 morphoscopic traits on the pubic symphysis of 29 adult human remains from the Carlos Germann Collection curated at Simon Fraser University and 30 individuals from the Terry Collection at the Smithsonian Institution.

In the former sample, age-at-death ranged from 52 to 92 years, with an average of 75.4 years. Results indicate that agreement was 84% on average and Cohen's kappa was substantial ($\kappa = 0.63$). On the contrary, the sample from the Terry Collection consisted of individuals aged 23 to 97 years with a lower mean value at 57.6 years. Results of this trial showed virtually the same degree of reproducibility, with 85% and substantial Cohen's kappa agreement ($\kappa = 0.67$). Both tests were performed by the same observer, separated by a period of two years.

However, the demographic profile of both samples was fundamentally different. The trial using the Terry Collection was performed on a strategically selected sample, which ensures maximum representativeness of all age-related variation.³ This implies a broader range of scores is to be expected in each feature. On the other hand, the sample from Simon Fraser University was not carefully selected. Instead, all available bone fragments in the collection were examined, which is not an uncommon practice in bioanthropology. Being this is a limited range of ages-at-death, there is potentially less variation in each feature. This would undoubtedly make the observer more likely to agree on given scores. Despite this fundamental difference, intra-observer agreement results are virtually equivalent and meet all standards.

Overall, details about demographic composition of the test sample are essential for assessing reproducibility of a method. However, this information is often not disclosed in bioanthropological literature. In light of this issue, more error tests are needed to assess the impact of observer bias in age estimation of human skeletal remains.

A133 A Revised Method for Adult Age-at-Death Estimation From the Auricular Surface of the Ilium

Krista Bennett, MA, Louisiana State University, Baton Rouge, LA; Sophia Reck, MA, Louisiana State University, Baton Rouge, LA; Teresa Wilson, PhD, Louisiana State University, Baton Rouge, LA*

Learning Overview: After attending this presentation, attendees will have a better understanding of age-related features on the auricular surface of the ilium that may assist with providing more accurate age estimations for individuals of advancing age.

Impact Statement: This presentation will impact the forensic community by providing preliminary results from the application of a revised Buckberry and Chamberlain (BC) adult age-at-death estimation method using the auricular surface of the ilium.¹

The original BC method used assessments of five traits on the auricular surface of the ilium surface. The lead investigator scored each of the 104 ox coxae from the William Bass Donated Collection using the original five traits from the BC method as well as retroauricular activity and bone quality. The combined seven traits were used to produce a new set of composite scores with nine corresponding age phases. The resulting age phases were then evaluated for an association with known age-at-death and compared to the original BC method. Spearman's rho denotes a high correlation between age and phase ($r=0.821$; $p<0.01$) for the revised method, as compared to the moderate correlation between age and phase for the original BC method ($r=0.692$; $p<0.01$).

To address inter-observer error, three investigators independently scored 29 auricular surfaces from the Louisiana State University Forensic Anthropology and Computer Enhancement Services (LSU FACES) Donated Skeletal Collection in the blind using the revised method. Cohen's Kappa was used to measure agreement between the three investigators ($r=0.095-0.223$). While the inter-observer agreement was low, the accuracy of the age intervals associated with the nine age phases was high. For age-at-death estimations, 79%–93% of the specimens age-at-death fell within the three investigators assigned phase age intervals.

The goal of this project was to determine if including two additional age-related features of the auricular surface of the ilium could increase the ability to provide accurate age-at-death estimation. The preliminary results are promising, suggesting that integrating assessments of retroauricular activity and bone quality produce a stronger correlation between age and phase for the features of the auricular surface than previously observed. The low inter-observer agreement, however, implies further clarification is needed for all scorable features to allow for greater repeatability of the revised method.

Forensic Anthropology, Age Estimation, Auricular Surface

A134 The Application of Computed Tomography (CT) -Rendered Images for the Evaluation of Traits Associated With Ancestry Estimation in Children

Marianna Cervantes, MSc, Simon Fraser University, Burnaby, British Columbia, Canada; Hugo Cardoso, PhD, Simon Fraser University, Burnaby, British Columbia, Canada*

Learning Overview: After attending this presentation, attendees will have an improved understanding of the reliability of using a digital approach to the examination of juvenile remains.

Impact Statement: This presentation provides the forensic science community with data on the reliability of visualizing morphological traits often used in ancestry estimation on CT scans of a juvenile sample.

Very few studies have been able to show good accuracy rates for ancestry estimation in adults. No research has been able to assess the accuracy of ancestry estimation in children, even though a few studies have suggested that features associated with ancestry are stable across the prenatal and postnatal periods.¹ While we are of the opinion that ancestry estimation is plagued with unsurmountable methodological and theoretical problems and may, in fact, be ineffective and futile, in practice the reliability of different visualizing techniques for the purpose of ancestry estimation is important to assess when engaging in a critical investigation of ancestry.² This is particularly true given the increasing availability of CT scans and 3D rendering methods for research purposes, which are considered reasonable proxies for visualizing and measuring dry bone for a variety of goals.^{3,4} This study questions whether 3D rendering of CT scans can be used to accurately visualize the six traits used in the Optimized Summed Scored Attributes (OSSA) method. The OSSA method has been studied and used for adults of Black and White ancestry.^{5,6}

For this study, 30 CT scans of individuals from 0 to 19 years of age were selected from the New Mexico CT collection. The sample is equally split between males and females. Only individuals listed as “Black” or “White” were chosen for this study. Cause of death was considered to avoid selecting individuals with trauma to the head or face area, which could obscure the visibility of the traits.

Scans had a 1mm slice interval and were rendered using RadiAnt 2021.1 DICOM viewer software. While the scans were preselected based on the above criteria, scoring was done blind, without knowing case demographics.

The sample was divided into five age groups (0-2.9, 3-6.9, 7-9.9, 10-14.9 and 15-19.9 years) with six individuals per group. Results indicate a 70% accuracy overall, comparable to studies using adults and dry bone.⁶ While the results seemed increasingly consistent with the recorded ancestry with increased age, the 3-6.9 age group showed a 16% accuracy rate. In the oldest age group, the results were 100% consistent with the recorded ancestry. While this may suggest improved accuracy closest to adult age, this sample includes a majority of “White” individuals, resulting in low (73% in “Whites”) to very low (50% in “Blacks”) ancestry-specific accuracy rates.

Some features presented difficulty. An OSSA score of 0 defines features considered more common among “American Blacks” and 1 among “American Whites.” Nasal bone sutures were almost universally challenging to discern. This introduces some uncertainty into scoring the Nasal Bone Structure (NBS) feature. If the difference between an oval or low/round NBS (OSSA score 0) is indiscernible from NBS exhibiting a plateau or triangular morphology (OSSA score 1), the overall score will be impacted. The Inferior Nasal Aperture (INA) is another potential source of error in younger individuals since the nasal sill feature may be smaller than the slice interval. The presence of a sill differentiates an OSSA score of 1 from 0. Both of these may result in a different outcome.

This research suggests that 3D-rendered CT scans of juveniles can be reliably used to visualize traits included in the OSSA method. However, this visualization confirms the generally poor to very poor accuracy of the method and highlights the difficulty in scoring the traits, particularly in smaller individuals whose features are smaller than the slice interval. A critical investigation of ancestry estimation can reliably use CT scan technology as long as it has proper consideration for the limitations of the technology.

A135 Geometric Morphometrics for Sex Estimation of the Scapula

Savannah Holcombe, BSc, Mercyhurst University, Erie, PA and Michigan State University, East Lansing, MI*

Learning Overview: After attending this presentation, attendees will have a better understanding of the use of scapular Linear Measurements (LM) and Geometric Morphometrics (GM) for sex estimation.

Impact Statement: This presentation will impact the forensic science community by describing the accuracy in sex estimation obtained from LM versus GM assessment. This is significant as estimating the biological profile of the individual is one of the main tasks of the forensic anthropologists' casework.

When forensic anthropologists are called to consult on casework, there is an identification hierarchy that includes estimating four parameters of the biological profile (age, sex, stature, and ancestry). Sex estimation can significantly increase chances for positive identification of deceased individuals, reducing the missing persons pool by approximately 50%. Skeletal elements may be easier to classify if they have a sexually dimorphic appearance, meaning there is a distinct and consistent difference in size or shape between the females and males of a particular species. If the deceased individual is left in a context that makes them vulnerable to various environmental factors, it is likely that the skeleton may be incomplete during recovery. Current forensic anthropological literature focuses primarily on the skull for sex estimation when the pelvis is not available, excluding the use of postcranial elements for these methods.

To address this gap, this project explores scapular morphology through both traditional LM and GM. Traditional LMs are more influenced by size variation, while GM, a quantitative method that captures geometry rather than just the isolated linear distances, is expected to be more efficient at capturing and detecting shape differences. The formal hypothesis for this project was that, since the pelvic girdle morphology relates to both shape and size variations within females and males, the same could be expected from the shoulder girdle. Therefore, this study expected the GM to be more efficient at discriminating sex from the scapula than the LM method, as the former captures shape (geometry) more efficiently. Data for this project were obtained from the Bass Collection ($n=106$) to assess the GM method, and from the Forensic Databank ($n=1,252$) to assess the LM method.

Linear Discriminant Analyses (LDA) were conducted on two LMs (scapular height and scapular breadth), as well as on the Principal Component Analysis (PCA) obtained from the GM analysis. Overall, the Correct Classification Rate (CCR) for sex estimation using LR was 93.1%. The CCR for the GM analysis was only 69.9%. Sex estimation from the linear measurements was therefore more accurate, contradicting the formal hypothesis. This indicates that, unlike in the pelvic area, the most significant scapular variation between females and males, as measured in this study, appears primarily related to Sexual Size Dimorphism (SSD). However, due to the limited array of landmarks selected for this study, the resulting rough, overall scapular shape would fail to detect subtle or localized sexual shape differences, and thus classification through GM would likely produce better results when a larger number of scapular landmarks are defined and considered in the analysis.

Sex Estimation, Geometric Morphometrics, Biological Profile

A136 The Impact of Sex and Population Affinity on the Dental Development of Subadult Individuals

Carolynn Sauter, BS*, Michigan State University, East Lansing, MI; Kelly Kamnikar, MA, Michigan State University, East Lansing, MI; Joseph Hefner, PhD, Michigan State University, East Lansing, MI; Nicholas Herrmann, PhD, Texas State University, San Marcos, TX; Jennifer Spence, PhD, Tulane University, New Orleans, LA

Learning Overview: After attending this presentation, attendees will understand the impact of sex and population affinity on subadult age estimation using dental development within a framework of Transition Analysis (TA).

Impact Statement: This presentation will impact the forensic science community by quantifying the impact of sex and population affinity on age estimation following the Moorrees and colleagues method of dental development within the statistical framework of TA.¹ This framework attempts to estimate age based on a multitude of skeletal features, which allow for age estimates that are unique to each individual. Estimates from TA include a maximum likelihood estimate, which is expressed as a point age, and confidence intervals at varying levels, which are an age range. By combining developmental traits into one age estimate, several issues can be addressed and resolved, including the ability to use multi-feature phases with fixed age intervals, solving the reliance on open-ended age categories, and reference sample mimicry.^{2,3} When estimating age, dental development is preferred as the timing and growth of human dentition is heavily regulated by genetics, with less influence from environmental factors.^{3,4} As such, age estimated from tooth root and crown development is generally accepted as more accurate than those based on skeletal features.

Radiographs from 189 individuals (males=94; females=95) from the University of New Mexico Orthodontics case file system (UNM; <https://searchorthodontics.health.unm.edu>) were examined for this project. Individuals ranged in age from 6 to 18 years old, and comprised five ancestral groups: American Black (*n*=26), American Indian (*n*=32), American White (*n*=65), Asian (*n*=15), and Hispanic (*n*=51). Age cohorts were divided into one-year groups. At a minimum, two individuals were used per age cohort. Each mandibular tooth was assigned a score ranging from 1-14 for permanent dentition and 1-17 for deciduous dentition to account for resorption following Moorrees and colleagues original method.¹ From these observations, age estimations were generated using the TA code modified by Kamnikar and colleagues.⁵ Maximum likelihood point age estimates and age ranges at the 90% confidence interval were generated for each individual.

Results show that males and females follow a consistent developmental trajectory between estimated dental age and chronological age. Average female inaccuracy was, on average, 12 months, and average male inaccuracy was 10 months. All populational affinities analyzed following along a consistent trajectory between estimated age and chronological age. For age six cohort, populational affinity differences varied from 36.6 months for American White individuals and a low of 11.5 months for American Black individuals. However, these results could be due to multiple radiographs for one individual and a small sample size (*n*=1) for another. In the age seven cohort, the highest variance between estimated and chronological age was 61.4 months for American Whites. The lowest variance was 2.8 months in Hispanic individuals. Ages 8 to 18 had variances less than one year among all population affinities, and some were so small (.96 months) as to be considered negligible. Because small sample sizes were utilized in this study, the results describing variation in estimated and chronological age among population affinities requires further investigation with a larger sample size by age cohort.

Prior research has determined that females mature before males, both skeletally and dentally. This research comparing estimated and chronological age using dental development in a framework of TA showed that females and males showed minimal variation between ages. This was also true for population affinity; however, reassessment with a larger sample size per age cohort is strongly recommended.

Forensic Anthropology, Age Estimation, Sex

A137 The Correlation Between Spheno-Occipital Synchondrosis (SOS) Fusion and Pubertal Stage From Postmortem Computed Tomography (CT) Scans

Francesca Dunn, MSc*, University of South Florida, Tampa, FL; Jordan Wright, MA, University of South Florida, Tampa, FL; Zia Coblenz, BS, University of South Florida, Tampa, FL; Jonathan Bethard, PhD, University of South Florida, Tampa, FL

Learning Overview: After attending this presentation, attendees will have reviewed the correlation between the development of the SOS and pubertal stage after Shapland and Lewis.^{1,2}

Impact Statement: This presentation will impact the forensic science community by presenting novel analysis of the correlation between the fusion of the SOS and pubertal stage.

Puberty is a significant life history event associated with developing fecundity.³ The age of onset of puberty and how this is related to skeletal development is of particular interest to those that are tasked with age estimation, whether of the living or the dead, because it may shed light on patterns of variability that are widely documented and yet remain poorly understood.^{4,5}

This study analyzed staged SOS and assessed pubertal scores from 322 postmortem CT scans to examine the possible correlation between the SOS and pubertal stage. The CT scans were obtained from the New Mexico Decedent Image Database, and are of individuals aged between 8 and 20 years (53% male).^{6,7} Pubertal scores were assessed after Shapland and Lewis; the seven stages were prepuberty, initiation of puberty, acceleration, Peak Height Velocity (PHV), deceleration, maturation, and postpuberty.^{1,2} SOS scores were adapted from Franklin and Flavel, these stages were unfused, fusing endocranially, fusing ectocranially, and fused.^{8,9} Pearsons correlation test was performed using R version 4.1.0.¹⁰

Pearson's r was .798 ($p<.000$) for females and .851 ($p<.000$) for males. For the pubertal scores, the mean ages by stage (in years) for males were prepuberty=9.0 (standard deviation [sd]=1.20), initiation= 9.85 (1.07), acceleration=12.89 (0.99), PHV=14.24 (1.13), deceleration=16.33 (1.13), maturation=18.00 (1.29), postpuberty=19.02 (1.05), and in females were prepuberty=8.33 (sd=0.58), initiation= 9.14 (0.69), acceleration=12.07 (2.28), PHV=13.77 (1.96), deceleration=16.10 (1.81), maturation=18.03 (1.18), postpuberty=19.22 (1.28). For SOS scores, the mean ages by stage were unfused=11.24 (2.43), fused endocranially=13.86 (1.90), fused ectocranially=15.69 (1.49), fused=17.80 (1.93) for males and unfused=10.00 (1.75), fused endocranially=12.86 (2.73), fused ectocranially=13.67 (2.52), fused=17.65 (2.19) for females.

A statistically significant correlation between the SOS and pubertal stage is presented here. The slightly lower correlation between SOS stage and pubertal stage in males could indicate that the development of SOS is less sensitive to the effects of environmental factors that affect puberty. A larger study with environmental factors (such as socio-economic and nutritional status) included could yield support for this hypothesis.

Forensic Anthropology, Age Estimation, Pubertal Age

A138 A Comparison of Frontal Sinus Morphology Using Scout Radiographs and 3D Skull Images: Implications for Forensic Identification Methods

Patricia Avent, BA, Des Moines University, Des Moines, IA; Jessica Campbell, PhD, Des Moines University, Des Moines, IA; Heather Garvin, PhD, Des Moines University, Des Moines, IA; Lauren Butaric, PhD, Des Moines University, Des Moines, IA*

Learning Overview: After attending this presentation, attendees will better understand the effect of image modality on basic frontal sinus features.

Impact Statement: This presentation will impact the forensic community by illustrating that practitioners can combine modalities (radiographs and images derived from Computed Tomography [CT] scans) when visually assessing frontal sinus features for identification purposes.

Currently there is a general acceptance that frontal sinus morphology can be used as an identification method when comparing antemortem and postmortem images. Frontal sinus comparisons are commonly completed via visual assessment, although several quantitative methods have been developed in consideration of the *Daubert* standards. All methods, however, are influenced by certain basic frontal sinus features, such as number of arcades. While most frontal sinus identification studies utilize antemortem and postmortem samples of the same imaging modality, in practice, an antemortem CT image may need to be compared to a postmortem radiograph. The goal of this preliminary study is to assess whether basic frontal sinus features can be observed consistently across image modalities.

This study incorporates scout radiographic images and CT scans from 30 individuals from the New Mexico Decedent Image Database.¹ Translucent models from the CT scans were created to view the frontal sinus, oriented to match their scout images, and saved as 2D images. A different observer then assessed frontal sinus morphology for both the scout radiographs and CT-model images. First, sinus Presence/Absence (P/A) was established, with presence being above the supraorbital line. If present, the following variables were recorded: intersinus septum (P/A), right sinus (P/A), left sinus (P/A), number of arcades for right and left sinuses separately, and number of total arcades. Due to difficulties in counting arcade number, a range was recorded with minimum and maximum counts.

Statistical analyses were run in SPSSv25 with significance set at 0.05. Non-parametric McNemar's tests were used to investigate differences in binary (P/A) traits between paired scout and CT-model images, while Wilcoxon Matched Pairs Signed Ranks tests were employed for continuous traits (arcade number). Results of the McNemar's test showed that P/A of the intersinus septum ($p=0.250$) and right/left sinus ($p=1.000$) were consistent across the two modalities. The Wilcoxon tests also revealed no significance differences in scoring between image modalities. Z-scores indicated that the minimum and maximum total arcade counts were scored with higher consistency, though the overall estimated error was slightly lower when scoring the left and right sides independently (e.g., the estimated percent error for total arcade = 6.79%, left arcade = 5.07%, right arcade = 4.06%).

Although some variables were more consistent than others, the overall results of this study indicate that utilizing different image modalities should not alter assessments of basic frontal sinus morphology—as long as the images are orientated similarly. This provides preliminary support for mixed-modality frontal sinus comparisons. Future research should be conducted on larger sample sizes to test how reliability and accuracy rates vary for additional variables (e.g., intra-sinus septa) and ways to address scoring issues in low-quality images (as encountered when identifying intersinus septa and arcade numbers). Deviations in scoring, either due to image quality or modality that affect features such as arcade number, could negatively impact identifications, particularly when quantitative coding methods are employed.

Forensic Anthropology, Image Modality, Positive Identification

A139 The Relationship Between Environmental Factors and Skeletal Metrics in Contemporary New Mexicans

Chelsea Cataldo-Ramirez, MS*, University of California-Davis, Davis, CA; Kerianne Armelli, MS, Kent State University, Kent, OH; Jessica Yopak, MS, SNA International, Omaha, NE

Learning Overview: After attending this presentation, attendees will better understand the differential effects of environmental factors on postcranial skeletal metrics across sex and sociocultural groups.

Impact Statement: This presentation will present an assessment of whether socioeconomic and environmental variables have differential effects on skeletal metrics across sex and sociocultural groups that may affect the accuracy of the use of postcranial skeletal metrics when constructing a biological profile.

The biological profile is a fundamental portion of a forensic anthropology report, aiding law enforcement in the identification of skeletal remains. Stature and sex estimations can be performed with a high degree of accuracy from postcranial skeletal metrics, and this accuracy increases when ancestry is taken into consideration.¹⁻⁶

Negative effects from tobacco and substance use on skeletal health have been widely documented by the medical community, including the reduction of bone mineral density in tobacco and alcohol users.⁷⁻⁹ Additionally, health outcomes are often correlated with the socioeconomic status and perceived race of individuals in the United States.¹⁰ Within the law enforcement community, race is often utilized interchangeably with population affinity or ancestry. However, race is a cultural construct and is variably associated with the actual genetic similarity of individuals within a population. Because social categories impact the life experiences of individuals, incorporating these categories into sex and stature estimation equations may improve predictions because of the sociocultural environmental effects that potentially significantly differ among groups. These factors are often not considered in the interpretation of skeletal metrics within forensic anthropology. Therefore, the intersection between environmental factors and perceived race within the United States must be thoroughly investigated to assess if the performance of commonly used stature equations and sex estimation methods derived from postcranial metrics may be significantly affected. This pilot study tested the assumption that socioeconomic and environmental variables have differential effects on skeletal metrics across sex and socioculturally-defined groups.

The sample consisted of 147 whole body Computed Tomography (CT) scans from the New Mexico Decedent Image Database (NMDID) of individuals between 20–55 years of age, listed as “White” ($n=42$ female, 43 male) and “Hispanic” ($n=33$ female, 29 male), with recorded demographic information.¹¹ Environmental factors included in this study were tobacco use, alcohol use, childhood socioeconomic status, and history of strenuous lifting. Maximum diaphyseal measurements were taken from five long bones as well as bi-iliac breadth using RadiANT DICOM™ viewer.¹² Additionally, living height was obtained from the NMDID records. The data were analyzed using basic functions of the R statistical language.^{13,14}

Two multivariate linear regression models relating living height and skeletal metrics to demographic and environmental covariates were fitted. The null model only included the additive effects of sex, sociocultural group, year of birth, and environmental factors, while the full model incorporated the interactions of sex and sociocultural group with each of the environmental factors. An Analysis of Variance (ANOVA) was conducted to test if the interactions distinguishing the null and full models are statistically supported. The results indicate that differential effects across sex and sociocultural group are present (Pillai’s Trace=0.59), but do not meet standard levels of statistical support ($p=0.22$). This suggests that simple, non-population-specific adjustments for contemporary environmental exposures would be adequate for stature and sex estimates. However, it is possible that the ANOVA failed to reach significance due to the small size of the sample. Univariate model summaries do suggest variable significance of interactions with sociocultural groups. For example, the interaction of sociocultural group and alcohol use and the interaction of sociocultural group and childhood socioeconomic status meet conventional, uncorrected significance thresholds ($p < 0.05$) as predictors of bi-iliac breadth, indicating that further investigation with a larger sample is warranted.

Skeletal Metrics, Environmental Factors, Biological Profile

A140 A Validation of Compatibility of the Median Sagittal Plane for 3D Metric Analysis of Facial Models: Cone Beam Computed Tomography (CBCT) and Multidetector Computed Tomography (MDCT)

Dong-Ho Kim, BSc, Department of Anatomy, Catholic Institute for Applied Anatomy, Seoul, Korea; Eun-Ju Jung, Department of Anatomy, Catholic Institute for Applied Anatomy, Seoul, Korea; Se-Hyun Oh, Department of Anatomy, Catholic Institute for Applied Anatomy, Seoul, Korea; Won-Joon Lee, PhD, Department of Forensic Medicine Investigation, National Forensic Service Seoul Institute, Seoul, Korea; Sang-Seob Lee, PhD, Department of Anatomy, Catholic Institute for Applied Anatomy, Seoul, Korea; Yi-Suk Kim, MD, PhD, Department of Anatomy, Catholic Institute for Applied Anatomy, Seoul, Korea; U-Young Lee, MD, PhD, Department of Anatomy, Catholic Institute for Applied Anatomy, Seoul, Korea*

Learning Overview: After attending this presentation, attendees will have gained an understanding of a measurement system designed for CBCT-based 3D models and its comparison with an MDCT measurement system.

Impact Statement: This presentation will impact the forensic community by providing information on the compatibility of two measurement modalities. With the increasing usage of cone-beam computed technology, a measurement system for CBCT-based models had been designed and its potential of exchangeability with the MDCT measurement system was tested.

The usage of CBCT in anatomical and anthropological studies has arisen.¹ Unlike MDCT using a fan-shaped beam, CBCT is an imaging modality taking a cone-shaped beam. Compared to MDCT, CBCT provides low radiation exposure and cost-effectiveness but a limited Field Of View (FOV). In cases of facial image acquisition, CBCT-based images could omit the occipital region due to smaller scanning areas.

The median sagittal plane of the measurement system for MDCT-based models was defined by three landmarks: nasion, prosthion, and lambda. The landmarks were selected to reflect the general anteroposterior shape of the skull. CBCT-based models, on the other hand, cannot utilize landmarks in the occipital region. Therefore, the median sagittal plane of the measurement system for CBCT-based models was defined with the nasion, prosthion, and bregma. It was necessary to validate the compatibility of standard planes due to the difference in the landmark composition of median sagittal planes.

This study analyzed 40 models of Korean adult males and females in total, with a random selection of five models in each decade of ages, from the 20s to 50s. This study measured the angle between standard planes using lambda and standard planes using bregma, and distance from landmarks and to each standard plane to measure the error between the CBCT measurement system and the MDCT measurement system. The landmarks were median landmarks (vertex, glabella, rhinion, nasospinale, gnathion) and lateral landmarks (frontotemporale, frontomale temporale, euryon, zygion, midmasseter, gonion).

The average angle between MDCT standard planes and their counterpart CBCT standard planes were 2.50 ± 2.02 degrees for median sagittal planes, 2.49 ± 2.01 degrees for coronal planes, and 0.29 ± 0.31 degrees for transverse planes. The distance between landmarks and standard planes was observed by paired *t*-test to verify whether the difference of standard planes exists. There was no statistical significance of the difference between MDCT standard planes and CBCT standard planes ($p < 0.05$, bilaterally).

The results exhibit that the CBCT measurement system is compatible with the previous MDCT measurement system. It would be preferable, however, to opt for lambda versus bregma with a subject with obvious facial asymmetry. The newly defined CBCT measurement system, nonetheless, will be useful for cases with incomplete scanning or damages of the occipital region.

3D, CBCT, MDCT

A141 A Validation of the Utilization of Automatic Placement of Anatomical and Sliding Landmarks on 3D Models for Shape Analysis of Human Pelves

Thandolwethu Mbonani, BSc, University of Pretoria, Pretoria, Gauteng, South Africa; Alieske Hagg, MSc, University of Pretoria, Pretoria, Gauteng, South Africa; Ericka L'Abbé, PhD, University of Pretoria, Pretoria, Gauteng, South Africa; Anna Oettlé, PhD, Sefako Makgatho Health Sciences University, Pretoria, Gauteng, South Africa; Alison Ridel, PhD, University of Pretoria, Pretoria, Gauteng, South Africa*

Learning Overview: After attending this presentation, attendees will better understand the utilization of automatic placement of anatomical and sliding landmarks on a 3D model for shape analysis of the human pelvis.

Impact Statement: This presentation will impact the forensic science community by suggesting the utilization of accurate 3D automatic anatomical information extraction and advanced statistical analysis for estimation of sex from whole and fragmentary pelvises.

Identification of unknown persons is a challenge in South Africa. For example, in 2014/2015, approximately 1,300 bodies were left unidentified in Gauteng mortuaries.¹ In response to this crisis, The Forensic Anthropology Research Centre's (FARC) forensic anthropologists collaborated with the South African Police Service (SAPS) to analyze skeletal remains and provide estimations on sex, population affinity, stature, age, and traumatic injury to bone and pathology. Sex estimation techniques focus directly on the pelvis's morphological variation and the long bones' metric variation.² However, the pubic bone, the most sexually dimorphic feature on the pelvis, is not often recovered intact. Therefore, it is necessary to improve our abilities to extract biologically meaningful information from other parts of the pelvis. To this end, in the past three years, researchers at FARC have become involved in developing morpho-phenotyping shape analysis tools using automatic landmarking and semi-landmarking for forensic case analysis.³ The purpose of this research was to validate the use of the automatic placement of anatomical and sliding landmarks shape analysis of the human pelvis using Computed Tomography (CT) scans.

CT scans of 88 adult pelvises (44 females and 44 males) from South Africans were collected from the Steve Biko Hospital, in Pretoria, South Africa. The 3D reconstruction generations were performed using the Avizo® 2019.3 software and pelvis shape data information was acquired using the MeVisLab v. 2.7.1 software. The automatic placement of anatomical and sliding landmarks approach used in this research is adapted from the procedure recently published by Ridel and colleagues.^{3,4} 3D reconstructions and anatomical and sliding landmark datasets were acquired using a manual and automatic approach and compared using reproducibility testing and Geometric Morphometric (GMM) analysis. To this end, 18 anatomical and 256 sliding landmarks (curve 1: *right greater sciatic notch*; curve2: *left greater sciatic notch*; curve3: *right ischiopubic region*; curve3: *left ischiopubic region*) were registered on 88 3D models of the same individuals using a manual and an automatic placement.

The anatomical and sliding landmarks reproducibility testing demonstrated minimal dispersion errors (<2mm) for both landmark datasets. The variance analysis showed that pelvis shape variation was statistically significant ($p < 0.001$) for the sex variable among all configurations collected using both procedures, including subspecific discriminate shape matrices separately. Furthermore, cross-validated linear discriminant function analysis yielded an accuracy between 84.09% and 97.72% using an automatic method and between 65.90% and 93.18% using a manual approach.

Several studies using GMM to analyze pelvic-related shape variation for sex estimation concluded that GMM and multivariate statistics are a reliable method to quantify pelvic shape differences between the sexes.⁵ The utilization of GMM for sex estimation using the pelvis is preferable to metric methods because they retain the objects' geometry and analyze subtle differences among structures.⁶ Furthermore, GMM could significantly overcome the exclusion of fragmented pelvises in the sex estimation analysis by creating discriminate shape matrices to analyze specific patterns not readily observed with a morphological approach. In a real-life application, using 3D imaging approaches is more reliable and efficient than traditional methods. However, researchers need a practical 3D scanning modality, such as a surface scanner, and an approach to extract 3D anatomical information, such as automatic landmark placements, along with advanced statistical analysis. All three of these tools will permit forensic anthropologists to estimate the sex from fragmentary remains in a more accurate and repeatable way.

Anatomical and Sliding Landmarks, Automatic Landmarking Approach, Sex Estimation

A142 A Validation Test of the Total Difference Technique for Assessing the Frontal Sinus

Jessica L. Campbell, PhD*, Des Moines University, Des Moines, IA; Lauren Butaric, PhD, Des Moines University, Des Moines, IA

Learning Overview: After attending this presentation, attendees will have a better understanding of how to accurately and efficiently apply the Total Difference technique for assessing the frontal sinus in personal identification.

Impact Statement: This presentation will impact the forensic science community by increasing evidentiary standards through the refinement and validation of an objective technique in frontal sinus identification.

While several quantitative methods evaluating frontal sinus morphology for positive identification exist, few have been rigorously tested for validity and repeatability following *Daubert* standards. This study specifically tests the reliability of the Total Difference technique for evaluating frontal sinus outlines.¹ This technique determines sinus uniqueness through 59 linear measures collected from the origin (cranial midline) to sinus outline at 3° intervals. While informative, this process can be time-consuming; thus, the current study also investigates whether measurement aids (i.e., an overlay) and/or semi-automation macros increase efficiency and repeatability.

Following Cox et al., frontal sinus outlines were collected on 244 adult radiographs from the American Association of Orthodontists Foundation (AAOF) Craniofacial Growth Legacy Collection in ImageJ.1-3 A randomly selected final sample (n=10 bilateral outlines, 590 data points) was required for significance testing with a 95% confidence level and 4% margin of error. Three methods for collecting the 59 linear measurements were tested: the original method's freehand; use of a 3° overlay; and a semi-automated macro. All radiographs were scaled by orbital breadth using the global average from Howell's dataset.⁴ Two observers collected data using the overlay and semi-automated macro; observer two collected a subsample using the original freehand method without an overlay, and observer one collected a second round of data two weeks after the first using the overlay and semi-automated macro. Methods for collecting measurements were evaluated on the ability to reproduce all 59 angles consistently, efficiency of data collection, and consistency in origin placement (measured as a midline ratio). Analyses ($\alpha=0.05$) were conducted in R.⁵

Time across the three modes was significant ($p<0.05$): the freehand mode averaged 11.4 \pm 4.1 minutes, the overlay mode averaged 8.9 \pm 2.6 minutes, and the semi-automated mode averaged 6.7 \pm 0.92 minutes. The maximum standard deviation of all midline ratios was 0.023, suggesting origin placement was consistent among and between all modes and observers. Placement of all 59 degrees had low overall bias (-0.04 \pm 0.47) and inaccuracy (0.30 \pm 0.36). There were significant differences between observers ($p<0.05$), and significance reached $p<0.001$ for both bias and inaccuracy for the overlay compared to the semi-automated method, as well as for the freehand method compared to either the overlay or semi-automated method; inaccuracy in the overlay method was greatest. Differences in lengths were significant between the overlay and semi-automated methods (bias, inaccuracy $p<0.001$) and between the freehand and semi-automated methods (bias, inaccuracy $p<0.001$). When results from observers were compared, inaccuracy was significantly different ($p<0.001$). Greater differences in length were observed in sinuses with convoluted outlines where minor deviations in angle precision or origin placement influenced the distal termination of a line (i.e., the furthest point of the outline at that angle extended into the adjacent arcade). Further differences could stem from placement of the orbital breadth scalar, which artificially affects linear dimensions.

These results suggest application of the Total Difference technique warrants caution, particularly with complex sinuses and scaling methods. However, placement of the 59 linear measures is highly repeatable using any collection mode tested here and the semi-automated macro was the most efficient. Ongoing research will continue to evaluate this technique and its applications for personal identification and compare its performance with alternate methods for assessing frontal sinus individuality.

This project contributes to a grant from the U.S. Department of Justice, Office of Justice Programs, National Institute of Justice Research and Development in Forensic Science for Criminal Justice Purposes. (Award No. 2020-75-CX-0013).

Frontal Sinus Outlines, Personal Identification, Radiographic Comparison

A143 The Precision of Standard Cranial Measurements in Dry Bones and Multi-Slice Computed Tomography (MSCT) Images: A Preliminary Study

Ivan Jerković, MSc, University of Split, University Department of Forensic Sciences, Split, Croatia; Tina Bareša, University of Split, University Department of Forensic Sciences, Split, Croatia; Elvira Krešić, Department of Diagnostic and Interventional Radiology, University Hospital Center Zagreb, Zagreb, Croatia; Anita Adamić Hadžić, Anthropological Centre of Croatian Academy of Sciences and Arts, Zagreb, Croatia; Željana Bašić, University of Split, University Department of Forensic Sciences, Split, Croatia; Krešimir Dolić, Clinical Department for Diagnostic and Intervention Radiology, University Hospital Center Split, Split, Croatia; Marija Čavar Borić, Clinical Department for Diagnostic and Intervention Radiology, University Hospital Center Split, Split, Croatia; Danijela Budimir Mršić, Clinical Department for Diagnostic and Intervention Radiology, University Hospital Center Split, Split, Croatia; Mislav Čavka, Department of Diagnostic and Interventional Radiology, University Hospital Center Zagreb, Zagreb, Croatia; Mario Šlaus, Anthropological Centre of the Croatian Academy of Sciences and Arts, Zagreb, Croatia; Dragan Primorac, MD, PhD, St. Catherine Specialty Hospital, Zagreb, Croatia; Šimun Anđelinović, Clinical Department for Pathology, Legal Medicine, and Cytology, University Hospital Center Split, Split, Croatia; Ivana Kružić, University of Split, University Department of Forensic Sciences, Split, Croatia*

Learning Overview: After attending this presentation, attendees will have gained insight into the issues that could arise from substituting documented skeletal collections with Computed Tomography (CT) images when developing standards for estimating biological profile.

Impact Statement: This presentation will impact the forensic science community by presenting evidence that cranial measurements from CT images may be equally valuable as direct skeletal measurements, but with particular caution for some cranial regions.

The osteometric analysis of skeletal remains is a fundamental step in reconstructing an individual's biological profile, especially when estimating ancestry, sex, and/or stature. The emergence of virtual anthropological methods bypassed the lack of documented skeletal collections but also raised the still unanswered question: Do the virtual measurements correspond to the physical ones? This question is essential when considering the requirements for admissibility of such evidence in court. Since those questions were still not completely considered, this study aimed to examine the repeatability of standard cranial measurements in a real and virtual environment.

The sample comprised 21 crania from the Early Medieval archaeological site Velim-Velišćak located in southern Croatia. CT scanning was done at the University Hospital Dubrava, Zagreb, Croatia, with an MSCT. Scanning parameters were 120kV and 320mA, respectively, with isometric slices using $16 \times 0.75\text{mm}$ collimation. Digital Imaging and Communications in Medicine (DICOM) data files were imported into the Stratovan Checkpoint software, version 2018.08.07. This study included 31 standard cranial measurements from Data Collection Procedures for Forensic Skeletal Material 2.0. (DCP 2).¹ Sliding and spreading calipers were used to take measurements on bones, while MSCT measurements were obtained as interlandmark distances. Four observers took part in the study. Two observers took measurements on crania, and two placed landmarks on MSCT images. For each measuring method, one of the observers repeated measurements/landmarking. MCST Images were viewed in 2D (axial, coronal, and sagittal view) and 3D using semi-transparent 3D volume rendering. On each cranium, a total of 47 landmarks were placed using both 2D and 3D views. R (version 3.6.2), Rstudio (version 1.2.5033), and geomorph package were used to read landmarks, calculate interlandmark distances, and obtain 31 standard cranial measurements.²

A paired-samples *t*-test was used to examine intra-observer and inter-observer variability and differences between dry bone and “virtual” measurements. Technical Error of Measurement (TEM) and relative Technical Error of Measurements (rTEM) were calculated for measurements that showed statistically significant differences. rTEM values lower than 1.5% were considered acceptable for intra-observer error, while this threshold was set at 2.0% for inter-observer error.³ The level of statistical significance was set at $P \leq 0.05$ with Bonferroni's adjustment for multiple comparisons.

The results showed high intra-observer agreement both for dry bone and virtual measurements. High inter-observer agreement was reached on bones and images for most measurements, except for several measurements that include sutural landmarks and minimum frontal breadth. When the dry bone and virtual measurements were compared, they showed consistency in most of the cases. The most pronounced discrepancies were noted for mastoid measurements and breadth measurements.

Per research, this is the first study that examined cranial measurements from novel data collection standards both in a real and virtual environment.¹ The results showed that most cranial measurements were repeatable and relatively consistent regardless of whether they were measured directly on crania or on CT images. Unlike previous studies that mostly used 3D reconstructions only, this study also employed traditional radiological views, which probably positively impacted precision; however, due to the limited sample size and number of parameters considered, further studies are needed to obtain additional confirmations.

A144 Uncovering Identities: A Case Study on Using Maxillary Sinus Morphologies in Human Identification

Teresa Runge, MSc, Liverpool John Moores University, Liverpool, Merseyside, United Kingdom; Joel D. Irish, PhD, Liverpool John Moores University, Liverpool, Merseyside, United Kingdom; Alicia Ventresca Miller, PhD, University of Michigan, Ann Arbor, MI; Matteo Borrini, PhD, Liverpool John Moores University, Liverpool, Merseyside, United Kingdom*

Learning Overview: After attending this presentation, attendees will understand the potential of using morphological evaluations of maxillary sinuses for identification purposes.

Impact Statement: This presentation will impact the forensic science community by presenting an identification case study on eight individuals utilizing maxillary sinus morphologies.

Introduction: Human identification from skeletal structures is a significant forensic procedure, and visual comparisons of radiographic images taken antemortem and postmortem can be used as a source for identification.¹ Previously, in forensic contexts, maxillary sinuses have been examined using measurements and volumes.² Besides those approaches, the maxillary sinus shows high morphological variability and can be used for identification by examining morphologies on antemortem and postmortem radiographs. Morphologies are easily comparable, and the availability of suitable X-ray images is granted from dental practices, as dental overview images often additionally cover the maxillofacial area of the skull.

This study aims to test the method of morphological evaluation on maxillary sinuses for human identification on a real-life scenario.

Materials and Methods: For this study, a total of eight individuals were made available from two collections of the American Association of Orthodontists Foundation (AAOF) Craniofacial Growth Legacy Collections Project.³ Within the framework of those longitudinal studies, radiographs were available of the same individuals on a semi-annual or annual basis to determine how the skull growths ranged from ages of 2 to 70 years.

For this study, an antemortem and postmortem situation was generated using two adult radiographic images. The first images, which simulate the antemortem dataset, were usually taken around the individual's 20th year of life, while the simulated postmortem image was taken later during the individual's life. Only standardized anteroposterior radiographic images were used for evaluations. Although the individuals were still alive at the time of the second radiograph, the passage of time during the images makes the images suitable for this case study.

In this study, method suitability was evaluated using elliptic Fourier Analyses. Correlations measuring Euclidean distances between the morphologies and neighbor joining clustering were applied to quantify method usability. The analyses were all performed and separated into left and right maxillary sinuses. Individuals with pathological changes in the maxillofacial area were excluded from the study.

Results: (1) Calculation of Euclidean distances between the morphologies for the antemortem and postmortem datasets show close Euclidean distances only for the antemortem and postmortem pair of one individual, while distances are greater between morphologies of different individuals. This is both visible in the right and left-sided morphologies. (2) Visualization through neighbor joining clustering validates the results.

With matching morphologies only between each antemortem and postmortem morphology of the same individual, this study supports and encourages the application of maxillary sinus morphologies on radiographic images for human identification.

Forensic Anthropology, Maxillary Sinus, Morphological Evaluation

A145 The Sociodemographic Composition of a Modern Juvenile Postmortem Computed Tomography (CT) Collection: Examining Trends in Body Size, Manner of Death, and Demographic Parameters

Julia Meyers, MA, Simon Fraser University, Burnaby, British Columbia, Canada; Natalie Adolphi, PhD, University of New Mexico, Albuquerque, NM; Hugo Cardoso, PhD, Simon Fraser University, Burnaby, British Columbia, Canada*

Learning Overview: After attending this presentation, attendees will have a better understanding of the make up of a modern postmortem CT sample, as well as the methods that can be used to examine and analyze sociodemographic composition in other similar populations.

Impact Statement: This presentation will impact the forensic science community by demonstrating the utility and value of examining trends in body size (weight and height), manner of death, and sociodemographic information (such as age, sex, race, and socioeconomic status) within modern juvenile forensic populations.

Body size, manner of death, and demographic data can be used to give researchers more in-depth and nuanced information, not only on the type of individuals who make up postmortem forensic samples, but also in predicting the composition of similar forensic populations in the future.

In this project, the forensic sample is composed of a subset of the New Mexico Decedent Image Database (NMDID). The individuals in the sample range from just under 1 year of age up to over 19 years of age and died between 2011 and 2017 in New Mexico.

A series of analyses were run to determine the frequency and proportion of each forensic variable that was listed in the database, including age at death, height (cm), weight (kg), Body Mass Index (BMI), manner of death, sex, race, and Hispanic ethnicity. Demographic information included in NMDID was obtained during the course of the death investigation, and additional information for some individuals was obtained from next-of-kin interviews. In addition, zip code information was used to pull socioeconomic information from United States Census data for the New Mexico region, including median income, poverty rates, and average educational attainment.^{1,2} Forensic variables and sociodemographic variables were contrasted to examine relationships.

The goal of this research is to create a more complete picture of the individuals who make up the juvenile subsample of the larger NMDID. Understanding the types of children who are represented within this sample can give us a better understanding of who has a higher mortality risk based on their demographic and socioeconomic parameters. This type of analysis can be taken and applied to other places and contexts to examine similar trends among forensic populations.

Juvenile Forensics, Demographic Analysis, Computed Tomography (CT)

A146 The Application of 3D Models in Age-at-Death and Sex Estimation of the Pubic Symphyseal Face

Anthony V. Lanfranchi, MS*, Department of Applied Forensic Sciences, Mercyhurst University, Erie, PA; Luis L. Cabo, MS, Department of Applied Forensic Sciences, Mercyhurst University, Erie, PA

Learning Overview: After attending this presentation, attendees will understand the emerging applications of 3D models for the study of morphological variation contributing to biological profile estimation in forensic and biological anthropology.

Impact Statement: This presentation will impact the forensic science community by introducing the utility of high-definition 3D models in data collection and analysis of spatial and morphological data contributing to biological profile analysis in forensic anthropological applications.

The pubic symphyseal face provides one of the most reliable areas for age estimation from maturity to the mid fourth decade of age. Phase methods based on the evolution of the morphology of this articular surface with age, and in particular different variations of the Suchey-Brooks method, are among the most trusted and utilized by forensic anthropologists.^{1,2}

However, quantifying the morphological traits utilized by traditional age estimation methods based on the pubic synchondrosis, in order to develop more objective metric methods also able to capture subtler morphological differences, beyond the rough ones between the more immediately identifiable traditional visual phases, has proven elusive. The most auspicious recent attempts to quantify the evolution of the pubic symphyseal face with age are based on capturing the geometry of the area from 3D scans, utilizing classic or modified Geometric Morphometry (GM) techniques.³⁻⁵ The available of increasingly precise 3D scanners, at much more affordable prices than classic micro-Computed Tomography (micro-CT) scan systems, have made them popular in anthropometric applications, making this approach even more promising.⁶

Among these, the Artec Space Spider is a high-resolution 3D scanner that utilizes blue light technology to produce point accuracies in the ± 0.1 mm range, which has caused it to become a particularly popular tool in anthropometric research, including studies on the evolution of the pubic face with age.^{4,5,7} However, studies discussing specific protocols for hardware and software configuration to allow for better inter-study comparisons are still very scarce. This study establishes the best practices and procedures for the Artec Space Spider and Artec Studio Professional software that produces the most accurate models for further analysis.

After establishing these protocols, this study tested the capabilities of Artec Studio Professional's Measure Tool and its use for age-at-death and sex estimation. The established protocols were used to produce models of the pubic symphyseal face. The surface area of these symphyseal faces were then calculated using the Measure Tool of Artec Studio Professional. No statistical significance was identified between the surface area of the pubic symphyseal face and age and sex of each individual. This suggests that another variable, such as perimeter or length of the face, may be useful to further investigate the morphological traits of the pubic symphyseal face. This presentation also discusses how a topological approach may be more useful than the geometric one to capture the type of variation encapsulated by the classic phase methods, not only to produce better age estimates, but also to infer and model the physiological processes underlying their age-related changes, including some of the main practical problems and challenges to capture and quantify that kind of information.

Biological Profile, 3D Models, Geometric Morphometrics

A147 The Accuracy of Topographical and Shape Analysis Using 3D Surface Scanning Compared to Micro-Computed Tomography (Micro-XCT)

Pearl Bothma, BSc, University of Pretoria, Pretoria, Gauteng, South Africa; Leandi Liebenberg, MSc, University of Pretoria, Pretoria, Gauteng, South Africa; Ericka L'Abbé, PhD, University of Pretoria, Pretoria, Gauteng, South Africa; Anna Oettlé, PhD, Sefako Makgatho Health Sciences University, Pretoria, Gauteng, South Africa; Alison Ridel, PhD, University of Pretoria, Pretoria, Gauteng, South Africa*

Learning Overview: After attending this presentation, attendees will better understand the utilization of 3D surface scanning and micro-XCT modalities for population affinity estimation using topographical and geometric morphometric methods.

Impact Statement: This presentation will impact the forensic science community by demonstrating that 3D surface scanning can be utilized for population affinity estimation. Furthermore, 3D scanning modeling and advanced geometric morphometric analysis allow forensic anthropologists to analyze shape-related skeletal variation in a more accurate and repeatable way toward a more efficient biological profile.

The high number of unidentified bodies recorded in South Africa annually combined with substantial heterogeneity within the population necessitates that innovative forensic analysis methods be developed that incorporate variation from South African groups.¹ Although a sizeable 3D scanning modality exists in osteology and anthropology, developing new advanced methods and techniques involving 3D scanning for real-life forensic applications requires that the accessibility, practicality, and, more importantly, the accuracy of the methods be taken into consideration. To this end, this study aimed to assess the reliability of 3D surface scanning modality-based topographical and shape analysis comparison to gold standard micro-XCT reconstructions for estimating population affinity.

Crania of Black ($n=22$) and White ($n=22$) adult South Africans were obtained from the Pretoria Bone Collection (PBC), which is housed in the Department of Anatomy at the University of Pretoria, South Africa.² Two sets of 3D reconstructions were acquired from each cranium, namely micro-XCT scans and 3D surface scans. A total of 41 craniometric landmarks were manually placed on the 3D meshes using Amira-Avizo® 2019.3 software. 3D reconstructions and landmark datasets were acquired from both scanning modalities and compared using reproducibility testing, geometric discrepancies, and shape analysis. The landmark reproducibility testing demonstrated minimal dispersion errors for both landmark datasets, indicating that the placement of landmarks on 3D reconstructions from both modalities is reliable and repeatable. The results of the topographical analysis showed that micro-XCT and 3D surface scanning yielded similar 3D reconstructions. There were slight differences between surface models on the maxilla, the postero-lateral margin of the zygomatic and frontal process areas. The minimal geometric discrepancies observed between the reconstructions suggest that both modalities provide similar shape landmarks datasets and can be used without compromising the accuracy of the analyses.

The statistical findings showed similar population affinity-related mid-facial shape variations analyzed across both modalities using Geometric Morphometric Methods (GMM). The Principal Component Analysis (PCA) revealed similar landmark configuration clustering between the two modalities, emphasizing that the two-scanning procedure provided relatively similar shape data and similar shape analysis for population affinity-related shape variations.

The results obtained in this study suggest that 3D surface scanning can be utilized for population affinity estimation using GMM. Incorporating 3D scanning modalities and advanced geomorphometric analysis into the existing biological profile estimation allows for an accurate and repeatable analysis of shape-related skeletal variation. 3D imaging and scanning modalities are useful for forensic anthropology laboratories as the methodologies are non-invasive, ethical, easily storable, and retrievable. In South Africa, digital repositories of cranial data of unidentified persons are far more manageable for storage and analysis than physical skeletal material. Furthermore, 3D analyses also open the possibility for analyzing a more significant number of cases each year.

3D Scanning Modalities, Population Affinity Estimation, Geometric Morphometric Methods (GMM)

A148 Myositis Ossificans Circumscripta: Evidence Contributing to the Reconstruction of a Life History

Jennifer Love, PhD, DC Office of the Chief Medical Examiner, Washington, DC; Deborrah Pinto, PhD, Harris County Institute of Forensic Sciences, Houston, TX; Julie Fleischman, PhD, Harris County Institute of Forensic Sciences, Houston, TX; Jason Wiersema, PhD, Harris County Institute of Forensic Sciences, Houston, TX*

Learning Overview: Accurate recognition and description of myositis ossificans circumscripta (traumatica) in human skeletal remains can be informative for the reconstruction of an individual's life history. After attending this presentation, attendees will understand the diagnostic features, pathophysiology, and occurrence rate of Myositis Ossificans Circumscripta (MOC). Several medical examiner cases will be presented to highlight the importance of recognizing and reporting various manifestations of MOC.

Impact Statement: In the field of medicolegal death investigation, thorough injury documentation is necessary for accurate cause and manner of death classification as well as appropriate case adjudication. When correctly identified, MOC may provide evidence of a traumatic history and assist in reconstructing the decedent's life history. The forensic science community will benefit from having a more in-depth understanding of the pathophysiology, occurrence rate, and presentation of MOC.

MOC, one form of heterotopic ossification, is a condition in which bone tissue forms within skeletal muscle, primarily after an injury or surgical intervention. Most often it occurs in young adults and athletes following an injury, but has been reported in all ages, including children as young as one year. The injury can result from a single event such as a hit sustained while playing a contact sport like football, or from repetitive injury such as within the thighs of a horseback rider. Although rare, MOC can occur following a severe muscle strain.

Typically, the clinical presentation of MOC is muscle pain that persists longer than would be expected for a simple muscle strain or contusion. The developing lesion can cause mechanical irritation of the surrounding bursa, tendon, or joint, but also paresthesia, weakness, lymphedema, and venous thromboembolic disease when the lesion compresses nearby neurovascular structures. The pathophysiology is incompletely understood; but, it is likely due to the mistaken differentiation of mesenchymal stem cells into chondrocytes and osteoblasts in the inflammatory-rich environment. The formation of the bone is gradual—often taking several weeks to develop after the injury or surgery—and results in a mass that often can be palpated. In most cases, MOC is a self-limiting and self-resolving process and surgical intervention is not needed; however, in extreme cases, surgery may be warranted.

In vivo, the features of MOC can be easily recognized radiologically, but possible mimics include osteosarcoma, synovia sarcoma, and parosteal osteosarcoma. In gross examination of the dry bone, MOC lesions are frequently adjacent to the cortical surface as a separate mass (although the lesions may eventually fuse to the adjacent bone) and are easily differentiated from other osteolytic or osteoblastic lesions.

The occurrence of MOC can be informative for reconstructing the life history of an individual and several publications have associated it with inflicted injury. In two cases investigated by the District of Columbia Office of the Chief Medical Examiner and Harris County Institute of Forensic Sciences, MOC was linked to the physical treatment of the decedent. One case involved a 6-year-old child abuse victim with bilateral MOC in the region of the *vastus lateralis* in the thigh. A second case involved a 33-year-old female who was found to have MOC on several long bones. Reportedly, the woman had a history of psychotic episodes during which her family would employ restraints. In both cases, the recognition of the MOC was important to demonstrating the history of inflicted injury.

During this presentation, these cases and others will be reviewed in depth as well as the pathophysiology and occurrence rate of MOC. The attendees will learn how to recognize MOC and gain an understanding of the value of the pathological condition in the development of a skeletal profile.

Myositis Ossificans Circumscripta, Trauma, Skeletal Profile

A149 The Effects of Gender Reassignment Surgery and Related Hormone Treatment on Morphological Sex Estimation in Forensic Anthropology

Shivani Sanger, MSc, Queen Mary University of London, London, England, United Kingdom; Heather Bonney, PhD, Queen Mary University of London, London, England, United Kingdom; Nikolas P. Lemos, PhD Queen Mary University of London, London, England, United Kingdom*

Learning Overview: After attending this presentation, attendees will understand the current status of research into the effects of gender reassignment surgery and related transgender hormone therapy in relation to human identification from skeletal remains.

Impact Statement: This presentation will impact the forensic science community by drawing together and evaluating the available evidence from the United Kingdom and elsewhere on the impact, if any, of transgender hormone therapy and gender reassignment surgery on the skeleton and how these procedures may impact human identification from skeletal remains.

In biological anthropology, prior to the 1990s, research was structured around dichotomous biological sex.¹ The acknowledgement of gender identity emerged more prominently in the late 1990s and is now increasingly being considered as an important part of the human identification process in forensic anthropology. Some research in this area has been published in the United States, but no literature was found relating to the medical pathways in the United Kingdom, or to their potential effects on identification of skeletal remains.

The aim of this study is to review the effects of gender reassignment surgery and related transgender hormone therapy in relation to sex estimation methods and identification in forensic anthropology in the United Kingdom. It was hypothesized that gender confirmation surgeries could affect skeletal remains and therefore impact on traditional non-metric sex estimation methods. The use of traditional sex estimation methods may be exclusionary of transgender individuals, especially those who have undergone gender reassignment surgery due to the binary allocation of biological sex derived from scoring of continuously variable skeletal traits. It can be further hypothesized that transgender-related hormone therapies may also influence skeletal remains, particularly if treatment is commenced prior to puberty and the ensuing development of sexual dimorphism in the skeleton. Peer-reviewed literature from the United Kingdom and elsewhere suggests that adult hormone therapy may impact bone density, but not the morphological appearance, and should not, therefore, affect non-metric sex estimation from skeletal remains.² On the other hand, gender confirmation surgery has been found to leave impressions, particularly on the facial region of the cranium and the mandible since metal plates, screws, and other biocompatible materials are sometimes used in facial gender confirmation surgery.³ Consequently, evidence of specific patterns of facial surgery may assist in confirming transgender identity in an individual, and serial numbers/manufacturer information from implants may further assist the identification process.⁴ It is concluded that further investigation is needed into the effects of pre-pubertal hormone treatment and gender confirmation surgery on skeletal remains to determine the impacts on the accuracy of non-metric sex estimation methods and to ensure that transgender identities are not excluded.

Forensic Anthropology, Transgender Hormone Therapy, Gender Reassignment Surgery

A150 Trotter's Tibia Error in Historical Context

Emily Wilson*, SNA International, under contract with DPAA, San Diego, CA

Learning Overview: After attending this presentation, attendees will have a better understanding of the historical context and details behind Trotter's tibia measurement error.

Impact Statement: This presentation will impact the forensic science community by providing previously unpublished historical details on the source of this error, which continues to affect stature estimation.

Mildred Trotter made a now well-known error in the tibia measurement for her stature estimation publication in 1952.¹ This has had longstanding repercussions for anthropological research and forensic applications that rely on the formulas, and the error is frequently revisited in the literature. This presentation provides novel historical details on the conditions under which Trotter made the error and how it evaded scrutiny for decades before being exposed.

Trotter measured the tibia without the medial malleolus, but described the technique as including the malleolus for her 1952 publication. This presentation addresses the variety of contemporary tibia measurement standards and the multiple measurement techniques Trotter simultaneously used for United States Army World War II casualty identification casework and for research. Details are also provided on Trotter's survey of prominent anthropologists for their opinions on tibia measurement techniques (regarding not just how the bone is measured in practice, but how they thought it should be measured) when beginning her stature research, including responses from T. Dale Stewart and Wilton M. Krogman.

The general problem with these 1952 stature formulas using tibia measurements was first acknowledged by Trotter and her co-author, Goldine C. Gleser, in their 1958 paper, which expanded to add data from Korean War remains.² This presentation provides information on how they continued to miss the source of the tibia problem. To Trotter and Gleser, it simulated secular change, populational variation, or age-related proportional changes. It got lost in the extensive noise in the data, and they never sorted out the source of the error. The problem was also widely acknowledged in many other research publications (even as early as 1958) and this presentation addresses possible explanations for why such a clear issue did not attract much attention for decades. Once this systematic error was made, it was insidious, unlike the easily correctible errors uncovered for bones such as the radius and ulna that resulted from simple typos.

The source of the error was first identified by the landmark work of Richard Jantz, David Hunt, and Lee Meadows Jantz in 1994 and 1995.^{3, 4} This presentation responds to suppositions made by Jantz et al., including questions of possible inexperience or intentional concealment, with details from Trotter's archival materials and relevant historical information.

The goal of this presentation is to provide further context for anthropologists using, modifying, and investigating this influential error.

Tibia, Mildred Trotter, Scientific Error

A151 Age Estimation From Cranial Suture Obliteration: A Computed Tomography (CT) -Based Evaluation

Mohammed Akbar, MBBS, All India Institute of Medical Sciences, Jodhpur, Rajasthan, India; Raghvendra Singh Shekhawat, MD, All India Institute of Medical Sciences, Jodhpur, Rajasthan, India; Vikas Meshram, MD, All India Institute of Medical Sciences, Jodhpur, Rajasthan, India; Taruna Yadav, MD, All India Institute of Medical Sciences, Jodhpur, Rajasthan, India; Tanuj Kanchan, MD, All India Institute of Medical Sciences, Jodhpur, Rajasthan, India; Rutwik Shedde, MSc, All India Institute of Medical Sciences, Jodhpur, Rajasthan, India*

Learning Overview: Cranial suture undergo obliteration in a predictable manner as the age of the individual progresses. The extent of obliteration can aid the medicolegal professionals in estimating age. This study employs the use of Acsadi and Nemeskri scoring method on the ectocranial suture closure on 3D CT images for the purpose of age estimation. Both linear and multiple linear regression models were applied for the purpose of age estimation. Attendees will learn about the degree of cranial suture obliteration in 3D CT scans of the skull, as well as how the Acsadi and Nemeskri scoring method can be applied to the ectocranial surface instead of the usual endocranial surface.

Impact Statement: This study used the Acsadi and Nemeskri scoring method to estimate age based on cranial suture obliteration in 3D CT images. When additional skeletal age markers are missing, such as in the case of mutilated or dismembered remains, the approach can be used alone or in conjunction with other well-established age estimate methods.

Age estimation is a critical aspect of human identification. Most of the common methods of age estimation include assessment of epiphyseal fusion of the long bones and the assessment of dental maturity. Most of these indicators of an individual's age attain complete maturation by the age of 25 years, therefore, age is routinely estimated using cranial suture obliteration and morphological changes of the pubic symphysis for adults. As an individual ages, their cranial sutures undergo obliteration in a predictable manner.

The present study investigated 3D CT scans of 262 individuals (182 males and 80 females), ranging in age from 18–85 years, to assess the extent of ectocranial cranial suture closure. The Acsadi and Nemeskri scoring method was used to evaluate the ectocranial suture closure and obliteration from the 3D images. The 3D CT images were obtained from the Department of Diagnostic and Interventional Radiology, All India Institute of Medical Sciences (AIIMS), Jodhpur, from patients who underwent CT examination of the head for diagnostic purposes. Patients suffering from any skeletal/bony deformities/injuries and congenital, acquired, metabolic, nutritional, and hormonal defects were excluded from the study.

A statistically significant correlation was observed between the chronological age and cranial suture obliteration scores ($P<0.05$). Simple and multiple linear regression models were developed using the cranial suture obliteration scores to estimate age. For females, the simple linear regression model developed using the coronal suture obliteration scores provided the least Standard Error of the Estimate (SEE) (SEE=11.218 years), while in males, the regression model developed using lambdoid suture obliteration scores showed the least SEE (SEE=15.021 years). When the sex of the sample was not considered, the least SEE was observed for the sagittal suture (SEE=14.554 years). The SEEs for multiple linear regression models developed for estimating age using obliteration scores of sagittal, coronal, and lambdoid sutures were 14.808 years in males, 11.131 years in females, and 13.956 years in the total study population. The study concluded that cranial suture obliteration, as scored using the Acsadi and Nemeskri scoring method, can be used to estimate age from 3D CT images. The method can be employed when other indicators of the skeletal age are absent, as in cases of mutilated or dismembered remains, or in adjunct with other well-established methods of age estimation.

Forensic Age Estimation, Cranial Suture Obliteration, Acsadi and Nemeskri Scoring Method

A152 Age Estimation From Pubic Symphyseal Morphological Changes: A Computed Tomography (CT) -Based Evaluation

Seshagiri Raju Vempalli, MBBS, All India Institute of Medical Sciences, Jodhpur, Rajasthan, India; Vikas Meshram, MD, All India Institute of Medical Sciences, Jodhpur, Rajasthan, India; Rutwik Shedge, MSc, All India Institute of Medical Sciences, Jodhpur, Rajasthan, India; Tanuj Kanchan, MD, All India Institute of Medical Sciences, Jodhpur, Rajasthan, India; Raghvendra Singh Shekhawat, MD, All India Institute of Medical Sciences, Jodhpur, Rajasthan, India*

Learning Overview: This study evaluates the utility of the Chen et al. method for age estimation by studying changes in the pubic symphysis using CT scan images.¹ It can be useful for forensic medicine and anthropology experts.

Impact Statement: In this study, the Chen et al. method, which is an autopsy study-based method for age estimation by studying changes in the pubic symphysis has been implemented using CT scan images in living individuals.

Age estimation is an essential component of the process of identification, both in living and deceased individuals. The pubic symphyseal surface consistently shows degenerative observational variations throughout the lifespan, making it a highly reliable feature for age estimation. The present study aims to establish an individual's age, based on the morphological changes observed on the pubic symphyseal surface, using criteria similar to the Chen et al. method using 3D reconstructed CT scan images of the pubic symphyseal surface.

The 3D CT images of the pelvis were obtained from the Department of Diagnostic and Interventional Radiology at the All India Institute of Medical Sciences in Jodhpur for this investigation. The study population consists of 154 male individuals who were 15 years and older. Morphological age indicators were assessed and scored following methods described by Chen et al. In the present study, both linear and multiple regression analysis were developed. It was concluded that the morphological changes occurring on the symphyseal surface were significantly correlated with the chronological age. Among all of the morphological indicators, bone density was the best predictor of chronological age, followed by the ventral rampart, ridges and furrows, and the lower extremity on the symphyseal surface. The ossific nodule was the least reliable parameter in estimation of age. The standard error of estimate of age in males was 7.19 years, which is relatively higher when compared to the study done by Chen et al., having a standard deviation of the age of 2.13 years. It is also observed that the standard error of estimation in the present study is relatively lower than that of the study done by Fleischman, having a standard deviation of 9.54 years.² Morphological features on the pubic symphyseal surface do not exhibit bilateral differences. From the present study, it was also concluded that the Chen et al. method is applicable to 3D CT images of the pubic symphyseal surface to estimate age.

Forensic Anthropology, Age Estimation, Pubic Symphysis

A153 Personal Identification of the L1-L5 Lumbar Vertebra Using Antemortem Computed Tomography (AMCT) and Postmortem Computed Tomography (PMCT) Scans

Summer Decker, PhD, USF Health Morsani College of Medicine, Tampa, FL; Guy Ruty, MBE, East Midlands Forensic Pathology Unit, University of Leicester, Leicester, Leicestershire, United Kingdom; Daniel Martin, BS, USF Health Morsani College of Medicine, Tampa, FL; Jonathan Ford PhD, USF Health Morsani College of Medicine, Tampa, FL*

Learning Overview: After attending this presentation, attendees will gain a deeper understanding of the usefulness of part-to-part comparison of anatomical features comparing AMCT and PMCT.

Impact Statement: This presentation will impact the forensic science community by providing the results of the initial findings of an ongoing study utilizing part-to-part comparison of the lumbar vertebra for personal identification. This presentation will examine the real-world application of using CT-derived 3D models of the L1-L5 vertebra of AMCT scans of known individuals and compare them against true PMCT scans to establish the validity of using this technology for personal identification.

The confirmation of identification for an unknown individual is a critical part of forensic practice especially in Disaster Victim Identification (DVI). The comparison of antemortem imaging for the purposes of personal identification is a common tool in pathology, odontology, and anthropology. A simulated version of this study was conducted successfully and served as a proof of concept of using 3D-rendered lumbar vertebra comparisons as a means for personal identification.¹ This study applies those findings to test true AMCT scans against true PMCT scans for the purposes of personal identification.

The University of Leicester, East Midlands Forensic Pathology Unit utilizes PMCT extensively in their daily practice and DVI situations. For the purposes of this project, Leicester acquired 23 matching AM scans for individuals that passed through their facility for PMCT scanning. The University of Leicester anonymized the scans so researchers at the University of South Florida Health Department of Radiology were blinded to the identities of the AM and PM scans. Each scan was imported into the Mimics® Innovation Suite v. 24. The L1-L5 vertebra were then isolated and modeled via segmentation and thresholding. Each series of 23 AM vertebra were registered with a target unknown PMCT-derived vertebra. A part-to-part comparison was conducted for each vertebra and a percent match was measured. A threshold of +/- 1mm was set for the part comparison.

Every unknown PMCT L1-L5 was correctly matched to the corresponding AMCT L1-L5, signifying complete accuracy for this sample. A Receiver Operator Curve (ROC) was calculated to determined 100% sensitivity and specificity with a cutoff point of a 0.735 match ratio. True identifications had an average match ratio of 0.945 +/- 0.048. Negative identifications had an average match ratio of 0.367 +/- 0.01.

With the increase usage of PMCT in the forensic sciences, there is an equal increase in the availability and opportunity to utilize 3D tools. This study has demonstrated the utility of 3D part-to-part comparison for successful personal identification.

Part-to-Part Comparison, Disaster Victim Identification, Forensic Radiology

A154 The Limitations of Sex Estimation: A Comparison of Osteological, Genomic, and Proteomic Methods

Glendon Parker, PhD, University of California-Davis, Davis, CA; Jane Buikstra, PhD, Arizona State University, Tempe, AZ*

Learning Overview: After attending this presentation, attendees will learn about molecular methods for skeletal sex estimation and their limitations.

Impact Statement: Skeletal sex estimation is critical in forensic anthropology, but the limitations of different anatomical and molecular methods are poorly delineated. The advent of proteomic sex estimation provides a counterpoint to establish osteological and genomic methods and allows the limitations of different approaches to be statistically developed.

Sex estimation of skeletons is fundamental to interpret and reconstruct many forensic contexts. Currently, three approaches are available to estimate sex: osteology, genomics, or proteomics, but little is known about the relative reliability of these methods in applied settings. In order to evaluate the forensic efficacy of respective methods this study evaluated degraded skeletal material in two settings, two ancestral Ohlone sites in Central California (2,440 and 100 cal BP, $n=55$), and the Lower Illinois River Valley (Late Woodland to Archaic horizons, $n=8$). Sex estimation was possible in 100% of both samples using proteomics, and the Californian context 91% using genomics, and in 51% using osteology. Agreement between the methods was high; however, conflicts did occur. Genomic sex estimates were 100% consistent with proteomic and osteological estimates when DNA reads were above 100,000 total sequences. However, more than half the samples had DNA read numbers below this threshold, producing high rates of conflict with osteological and proteomic data where 9 out of 20 conditional DNA sex estimates conflicted with proteomics, a rate close to random. No such pattern was clear when mapping conflicting sex estimates onto proteomic data where conflicting sex estimates occurred across different proteomic data quality levels. Together, these data imply that conflicting sex estimates are due to poor quality DNA and not proteomic data. This is supported by the finding that proteomic data quality is more stable compared to DNA. While the DNA signal decreased by an order of magnitude in these samples, there was no decrease in proteomic signal.

The study implies that sex estimates can be obtained from degraded material in forensic contexts. Osteological sex estimation is reliable (i.e., consistent with other techniques when sample signal is high), but has a high rate of indeterminate sex assignment when fragmentary and juvenile remains are assessed. Genomic methods help to extend sex estimation to many juvenile or fragmentary remains, but had a high rate of conflict with osteology or proteomic estimates for conditional sex assignments below the 100,000 mapped read threshold. In the event of a conflict in sex estimation, conditional DNA-based estimates should be disregarded in favor of osteological or proteomic methods. Proteomic sex estimation was the most sensitive technique, providing results in all remains tested for both Californian and Illinois contexts, due in part to the stability of the amelogenin peptide signal. These findings are contingent upon the preservation of dentition associated with each burial. To obtain the greatest coverage and confidence in sex estimates for degraded skeletal material, proteomic approaches should be combined with osteological and genomic methods.

Sex Estimation, Amelogenin, Enamel Proteome

A155 A Computed Tomography (CT)-Based Evaluation of the Acetabulum for Age Estimation in an Indian Population

Varsha Warriar, MSc, All India Institute of Medical Sciences, Jodhpur, Rajasthan, India; Tanuj Kanchan, MD, All India Institute of Medical Sciences, Jodhpur, Rajasthan, India; Pawan Kumar Garg, MD, All India Institute of Medical Sciences, Jodhpur, Rajasthan, India; Shilpi Gupta Dixit, MD, All India Institute of Medical Sciences, Jodhpur, Rajasthan, India; Rutwik Shedge, MSc, All India Institute of Medical Sciences, Jodhpur, Rajasthan, India; Kewal Krishan, PhD, Panjab University, Chandigarh, Punjab, India

Learning Overview: The present study highlights the significance of age estimation via a scored evaluation of the Calce method. Regression equations generated from the assigned scores can be used to estimate age more accurately in cases of forensic significance.

Impact Statement: The acetabulum is particularly advantageous for age estimation owing to its durability, slow development into maturity, and prolonged degeneration associated with old age. Computed tomographic (CT) evaluation of age-progressive degenerative morphological changes enables easier and quicker analysis without having to delve into the time-consuming and destructive process of maceration. The Calce method simplifies the process of age estimation through the scrutiny of defined morphological features within the acetabulum. A scored evaluation of these morphological features laid down by Calce can be used to generate population-specific regression models to allow for a more accurate age estimation using the acetabulum.

Age estimation constitutes an important aspect of forensic research and investigation.¹ Within the skeletal framework, dental development and mineralization, ossification changes, and degenerative morphological changes of various bones have often been relied on for the purpose of age estimation.^{2,3} Among these bones, age-progressive changes in the innominate bone are of particular importance when it comes to age estimation across varying age groups.⁴⁻⁶ Within the pelvis, the acetabulum presents as a durable and well-preserved feature, and the manifestation of characteristic age-related changes can be employed for age estimation.⁷ The present study analyzed CT scans in order to evaluate acetabular changes for the purpose of age estimation in an Indian population. CT images of 250 individuals aged 10-88 years were scrutinized according to the features defined under the Calce method of acetabular age estimation. Scores were allotted to the various features and a cumulative score was calculated. No significant bilateral and sex differences were observed. Significant correlation was obtained between the scores for these defined changes and the chronological age of individuals, and population-specific regression models were generated. Mean absolute error observed with the test sample was 9.24 years, with a mean difference of 0.45. Observations of the present study can be employed for age estimation from the acetabulum in cases of medicolegal significance.

A156 Toward a Model for Estimating Postmortem Interval (PMI) at High Altitude: Categorical Macromorphoscopic Changes Observed Throughout the Trajectory of Human Decomposition in the Colorado Rocky Mountains

Christiane Baigent, MSc, Southern Illinois University Carbondale, Carbondale, IL

Learning Overview: After attending this presentation, attendees will understand: (1) unique categorical changes observed along the continuum of human decomposition in a high-altitude environment, rendering the Total Body Score (TBS) model insufficient for use in this region; and (2) how this novel work provides the foundation for developing a region-specific predictive model for PMI estimation.

Impact Statement: This presentation will impact the forensic science community by addressing the environment-specific data gap pertaining to rate, pattern, and trajectory of decomposition in a high-altitude environment and supplement the growing body of knowledge pertaining to environment-specific patterns of decomposition.

Human decomposition is a dynamic process composed of several intercalated variables. The catalytic potential of individual and interacting variables exists along a continuum, rendering variable-interaction neither constant nor wholly predictable. Complexity is intensified in outdoor death scenes when the environment is not well understood from a holistic forensic-ecological perspective.

High-altitude environments are associated with interacting ecological, atmospheric, behavioral, and physiological variables. *In vivo* physiological adaptations include modified physiopathways to promote oxygen transport, hemoglobin production and concentration, nitric oxide synthesis, blood flow regulation, and increased respiration. Non-adaptive changes include higher-than-national-average incidence of suicide, exacerbation of pre-existing chronic conditions, and initiation of acute pathogenesis, including high-altitude cerebral and pulmonary edemas.¹⁻² Summarily, variables present at high-altitude are hypothesized to affect the suite of biophysiological changes presented throughout decomposition.

Controlled studies of decomposition in high-altitude environments are limited. Baigent et al. concurrently placed a small sample of porcine carrion at high-altitude (2,800 meters Above Mean Sea Level [AMSL]) and lower-altitude (1,200 meters AMSL) sites in Colorado.³ The TBS model was used to assess decomposition, and accumulated Degree Days (ADD) were used as indices of time and temperature.⁴ Results demonstrated that inter-site rate, trajectory, and pattern of decomposition varied significantly. Further, the TBS model was not sufficient for estimation of PMI at either site. However, controlled observation of decomposition within a human cohort is lacking and constitutes a critical analytical gap in high-altitude medicolegal investigation.

This longitudinal study seeks to address the lack of data pertaining to rate, pattern, and trajectory of decomposition at high-altitude with the ultimate goal of: (1) creating a holistic region-specific taphonomic profile; and (2) developing predictive models for the estimation of PMI. This study is currently conducted at Colorado Mesa University's Forensic Investigation Research Station high-altitude satellite facility (FIRS-TB40). FIRS-TB40 is located in the Rocky Mountain Region of Colorado at 2,900 meters AMSL. The environment is characterized by slopes, alpine forests, moraine grasslands, rapid weather shifts, concentrated incidents of heavy precipitation, high Ultraviolet (UV) exposure, and heavy annual snowfall. Placement of human remains began in March 2020; to date, ten human donors have been placed, unclothed, supine, at surface level in 10'x10' steel cages situated on a 45° slope. An onsite weather station is deployed to collect hourly data points for 13 environmental variables, including temperature and precipitation. Donors are photographed and decomposition changes are recorded daily using the TBS model. While TBS has not performed well as a predictive model in this region, it was employed throughout the first year to establish a baseline against which to identify divergent variables, as well as facilitate testing of the model among a human cohort at high-altitude.

Seven categorical changes have been observed throughout the cohort. These include: (1) pattern and spectrum of color change; (2) adipocere formation with late-stage interdigitated saponification of dermal layers; (3) fluid bloat leading to premature skeletonization of the affected tissue; (4) gravity-induced slope roll; (5) pseudoburial as a result of adhesion and slope wash; (6) anterior/posterior differential decomposition; and (7) peripheral dermal drying and retraction resulting in islands of fresh tissue surrounded by desiccated dermis. Additionally, the TBS model was not sufficient for estimation of PMI due in part to the unique suite of categorical changes observed within the high-altitude human cohort. In this case, model mimicry could not be achieved. While typically an analytical hazard, the inability to achieve model mimicry in this study demonstrates the critical need for environment-specific models for PMI estimation.

Future study will test these categorical variables for significance among environmental variables, with the goal of establishing predictive models for PMI estimation.

A157 Modeling Scavenging Patterns Within the Willamette Valley of Oregon to Inform Search Structure in Medicolegal Investigations

Cheyenne Collins, BS*, California State University-Chico, Chico, CA; Jeanne McLaughlin, PhD, Lane Community College, Eugene, OR; Ashley Kendell, PhD, California State University-Chico, Chico, CA

Learning Overview: After attending this presentation, attendees will understand how animal scavenging within the Willamette Valley of Oregon compares to previous research done in this region and beyond; how scavenging activities influence the decomposition process; and how differing sub-environments and seasonality influence scavenging behavior.

Impact Statement: This presentation will impact the forensic science community by increasing the data available on animal scavenging in an understudied region.

Forensic taphonomic research has indicated non-human animal scavengers play an important role in the decomposition, dispersal, and bone destruction of human remains in an outdoor environment.¹ Understanding the scavenging patterns of various animal species in regard to human remains can help forensic scientists locate and recover dispersed skeletal elements, understand the difference between scavenger damage and antemortem/perimortem trauma, as well as better inform estimates of the Postmortem Interval (PMI).² Wescott states that there is a gap in the literature focused on the behavior of animal scavengers.³ Understanding the intricacies of scavengers in a particular region allows professionals in the medicolegal field to more efficiently reconstruct the events occurring after death. Scavenging activities can vary depending on the region and climate due to differences in species presence, topography, seasonality, niche specificity, and available resources. Currently, there are few studies focusing on animal scavenging within West Coast states of the United States. Adding novel research to the body of literature will provide forensic investigators in the western United States more insight to accurately estimate PMI and construct a search structure that takes into account scavenging activity in medicolegal investigations.

In the current study, six whole hog (*sus scrofa*) carcasses were used as human analogs and placed on the ground surface in two separate outdoor environments (forested and open) in the summer of 2021 at the Multidisciplinary Oregon Taphonomy Investigative Studies (MORTIS) facility in Eugene, OR. Carcasses were purchased after ethical euthanasia via gunshot to the head and were animals destined for consumer use. The remains were distributed across an 80-acre forested parcel of land as well as a separate 4-acre disturbed meadow environment. Each environment had a control carcass that was caged in order to inhibit animal scavenging. The inclusion of a control carcass allowed researchers to record non-disturbed decomposition processes in order to analyze the effect that animal scavenging has on the pattern and timing of the decay process. Game cameras were utilized throughout the study to record scavenging behaviors and monitor dispersal of remains. Daily monitoring of the carcasses occurred from Day 0 to Day 21 of the observation period, followed by every-other-day observations from Day 22 to 33, and finally weekly observations from Day 34 to 60. Observational visits included scoring decomposition and noting any noticeable changes indicative of animal scavenging (i.e., disarticulation, dispersal, visible bite marks on soft tissue, mapping of dispersed remains, etc.).⁴⁻⁵

Observed scavengers included: turkey vultures (*Cathartes aura*), Virginia opossum (*Didelphis virginiana*), coyote (*Canis latrans*), gray fox (*Urocyon cinereoargenteus*), striped skunk (*Mephitis mephitis*), spotted skunk (*Spilogale gracilis*), unspecified small rodent species, and various small bird species. This study found notable differences between open and forested environments in both scavenging and decomposition. This included skeletonization occurring in open scavenged remains within 48 hours of placement and an extended period of mummification in forested and control carcasses. Data from this study was analyzed in conjunction with previous research from the facility in 2019 and results are consistent in patterns of seasonality and scavenger diversity that can be utilized by medicolegal professionals when constructing search protocols.

159 Testing the Efficacy of Bone Surface Swab Sampling of Microbial Colonization to Determine Postmortem Submersion Interval (PMSI) in Lentic and Lotic Environments

Sarah Rose, BSc*, Virginia Commonwealth University, Richmond, VA; Hannah Johnson, MSc, Virginia Commonwealth University, Richmond, VA; Claire Cartozzo, PhD, Virginia Commonwealth University, Richmond, VA; Jenise Swali, PhD, Virginia Commonwealth University, Richmond, VA; Tal Simmons, PhD, Virginia Commonwealth University, Richmond, VA; Baneshwar Singh, PhD, Virginia Commonwealth University, Richmond, VA

Learning Overview: This presentation will provide attendees with an understanding of microbial sequencing methods for estimating PMSI.

Impact Statement: This presentation will impact the forensic community by demonstrating that PMSI estimation of waterlogged skeletal remains can be achieved using surface swab sampling as an alternative to bone sampling.

In medicolegal death investigation, estimating the PMI contributes valuable information, and estimating the Postmortem Submersion Interval (PMSI) can specifically aid investigations involving victims discovered in aquatic environments.¹ Water-related deaths and homicide victim disposals often result in an increase in time required to discover the remains, causing loss of physical forensic evidence and potentially more advanced decomposition.

As demonstrated by Cartozzo et al., the succession of microbial communities found on skeletal porcine remains can be used to estimate the PMSI.^{2,3} This study effectively used bacterial structure from bone tissue to develop bacterial succession models for prediction of PMSI.^{2,3}

Though effective, direct bone sampling (bone powder) requires advanced processing techniques resulting in destruction of decedent tissue, this study investigates the use of bone surface swabbing as an effective alternative method to bone sampling that requires fewer technician hours, less sophisticated equipment, and simpler techniques for sampling.

Skeletal porcine (*Sus scrofa*) remains (rib and scapulae) were caged and submerged in both lentic (Henley Lake, Crozet, VA) and lotic (Rice Rivers Center, James River, VA) environments. In the Cartozzo et al. experiments, one cage, each containing five scapulae and five ribs, was pulled for sampling and water samples were collected every 250 Accumulated Degree Days (ADD).^{2,3} In this study, swabs and water samples from the original experiment were analyzed at 500 ADD intervals, from baseline (0 ADD) to 4,500 ADD. DNA was extracted from bone surface swabs using the ChargeSwitch® gDNA Plant Kit and protocol, and variable region 4 (V4) of 16S rDNA was amplified and sequenced using Illumina® MiSeq® Sequencing platform. Sequence analysis was performed with Mothur (v.1.39.5) using the Mothur MiSeq® SOP and R (v.4.04).

For the Henley Lake samples ($n=57$), Analysis of Molecular Variance (AMOVA) indicated a significant difference in beta diversity between the swab and bone samples ($p<0.001$) and the rib and scapula samples ($p<0.001$). These differences are likely explained by relatively greater Clostridia found in the bone samples compared to the swab samples, and by predominant Clostridia found in the rib samples compared to both Clostridia and Holophagae in the scapulae samples. ADD demonstrated a significant effect on alpha diversity ($p<0.001$) with alpha diversity increasing with ADD. Random forest models to predict PMSI were constructed using swabs for both ribs ($R^2=0.85$, RMSE=582.33 vs. $R^2=0.90$, RMSE=522.91 in bone) as well as scapulae ($R^2=0.85$, RMSE=588.19 vs. $R^2=0.96$, RMSE=533.48 in bone).

Similarly, for the James River samples ($n=32$), AMOVA indicated a significant difference in beta diversity between the swab and bone samples ($p<0.001$) and the rib and scapula samples ($p<0.001$). These differences are likely explained by predominant Clostridia and Gammaproteobacteria in the bone samples compared to the swabs and the overall variable presence and abundance of top taxa between rib and scapulae samples. ADD also demonstrated a significant effect on alpha diversity ($p<0.001$), with alpha diversity increasing with ADD. Random forest models to predict PMSI were constructed using swabs for both ribs ($R^2=0.74$, RMSE=675.47 vs. $R^2=0.94$, RMSE=476.61 in bone) as well as scapulae ($R^2=0.63$, RMSE=783.07 vs. $R^2=0.93$, RMSE=500.7 in bone).

Swab samples from both aquatic environments predicted PMSI, albeit less accurately than bone powder, though this may well be due to the reduced sample of swabs relative to bone used in this study. These results suggest that bone surface swabbing provides an accurate, less labor-intensive, and non-destructive alternative for sampling skeletal remains to perform microbiome-based PMSI prediction.

Aquatic Taphonomy, Bacterial Microbiome, Submerged Bone Degradation

A160 Improving Age-at-Death Estimation in Forensic Anthropology Applying a Translational Approach

Sara C. Zapico, PhD, New Jersey Institute of Technology, Newark, NJ; Quentin Gauthier, PhD, Florida International University, Miami, FL; Aleksandra Antevska, BS, University of Tennessee, Knoxville, TN; Bruce McCord, PhD, Florida International University, Miami, FL

Learning Overview: After attending this presentation, attendees will consider the possibility of applying knowledge acquired from biomedical research to improve age-at-death estimation in forensic anthropology.

Impact Statement: This presentation will impact the forensic science community by introducing a novel, innovative approach for age-at-death estimation, reaching accuracies of +1.7-2.05 years actual age.

As part of the biological profile, age estimation represents one of the key parameters toward the identification of human remains. This estimation is less accurate in adult individuals because it is based on degenerative changes in bones and teeth, being affected by endogenous and exogenous factors, pathological conditions, and fragmentary remains.

The application of biochemical techniques, based on the natural process of aging, may provide a potential solution to this problem. One of the current trends in aging research is epigenetics, the study of heritable changes in gene expression. Epigenetic DNA methylation, which involves the addition of a methyl group to a cytosine nucleotide in C/G regions, known as CpG islands, has led to the creation of “epigenetic clocks,” which are based on the correlation between methylation patterns and age. As a result of these studies, several authors have tried to accurately determine age from biological fluids (blood, saliva, semen), to apply to criminalistics. There have been scarce studies performed for forensic anthropological purposes. The latest methods have used the whole tooth for this analysis; however, DNA methylation is tissue-specific, and it is important to independently analyze the various types of tooth tissue in order to correctly apply the technique.

Teeth are the hardest structures in the human body, and they can survive after everything else has decomposed. The dental pulp is located in the central region of the tooth and protected from external insults by hard tissues. It is formed by a stromal tissue containing nerves, blood, and lymphatic vessels. This unique location and structure make it the preferred substrate for DNA analysis.

Based on these premises, the aim of this study was to analyze methylation patterns in pulp tissue from adult individuals and correlate these patterns with age, improving current age-at-death estimates.

Twenty healthy-erupted third molars, ages between 22 and 70, were used in this study. Pulp was isolated from the rest of the tissues. After DNA extraction, 200ng of pulp genomic DNA was bisulfite converted and later amplified by Polymerase Chain Reaction (PCR) for the following genes: ELOVL2, KLF14, SCGN, NPTX2, and FHL2. Pyrosequencing was performed to analyze DNA methylation levels of the CpG sites of these genes.

Six ELOVL2 CpG sites were found significantly correlated with age. In contrast, only one KLF14 CpG site, one NPTX2 CpG site, and two CpG sites of SCGN were found significantly correlated with age. None of the identified CpG sites of FHL2 were significantly correlated with age, although the correlation coefficients were high.

A multiple linear regression analysis was performed, and four models were developed for age estimation based on the assessment of these five genes. After leave-one-out cross-validation, models 2 and 3 produced the best accuracy, with Mean Absolute Error (MAE) between estimated and chronological age of +1.7 and +2.05, respectively (p -value <0.001). Additionally, Pearson correlations were carried out to compare predicted and chronological ages, obtaining $r=0.98$ in both models.

This research is the first to explore age-associated methylation in pulp tissue applying pyrosequencing and obtains higher accuracies than current methodologies. The findings from this study provide a new quantitative tool for estimating age at death, which, in combination with traditional age markers, should improve identification accuracy in forensic cases. Future research may be able to expand on these results, identifying new markers, using different types of teeth, and extending the age range.

Age-at-Death, Forensic Anthropology, DNA Methylation

A161 Reference and Target Sample Age Distribution Effects in Juvenile Dental Age Estimation

Valerie Sgheiza, MA, MS*, University of Illinois at Urbana-Champaign, Urbana, IL; Helen Liversidge, PhD, Queen Mary College of London, London, England, United Kingdom

Learning Overview: After attending this presentation, attendees will have learned about the effects of age distribution shapes and model types on point estimates of age. This presentation will provide an example procedure for applying machine learning theory to methods for estimating the biological profile and demonstrate the effect of model selection bias on error rates.

Impact Statement: This presentation will impact the forensic science community by providing steps for both reducing bias in age estimation methods and calculating representative error rates that will facilitate comparing methods in the literature.

There are many reasons why age estimation methods may perform differently. In order to understand the effects of individual factors such as population, age distribution, model type, or scoring system, it is important to vary each factor individually while holding the rest constant. In the specific context of juvenile dental age estimation, a single dataset and machine learning approach was used to systematically test three potential sources of difference: the age distribution of the reference sample, the age distribution of the target sample, and Bayesian vs. classical regression modeling. The hypothesis tested was that a Bayesian model with a uniform reference and target sample would provide the least biased estimates of age. This presentation is also a case study of the effects of model selection bias. Model selection bias occurs when error rates are used to select a best model from several options. Model selection attributes error entirely to the model when error is partially incidental to the data. Follow-up testing using new data may therefore produce larger errors than initially reported.

The age distributions considered were uniform, unimodal ($\sim\text{Chi}^2(10)$), and U-shaped ($\sim\text{Beta}(0.95,0.9)$). The models used were Bayesian Cumulative Probit (BCP) and Multivariate Adaptive Regression Splines (MARS). The initial dataset consisted of Moorrees et al. scores of left mandibular permanent teeth from 1,926 London children 6-19 years old.¹ One hundred replicates were performed for each of the 18 reference-target-model combinations with a reference sample size of $n=320$ and a target sample size of $n=80$. Since reference and target samples had varying shapes, true cross-validation was not possible. Instead, for each replicate, the reference and target sample were drawn randomly according to their corresponding distributional weights, then individuals duplicated in the reference sample were replaced in the target sample by randomly drawing individuals of the same sex and year of age from the larger dataset. True and estimated age in the target sample were compared for bias and overall error using loess smoothing of the residuals and Root-Mean-Square Error (RMSE).

BCP and MARS showed different patterns of age-specific bias, while reference sample distribution affected the magnitude of bias. BCP produced upward bias in the mid-teens, likely due to few age-informative stages at this time. MARS showed downward bias near 12 years depending on reference distribution, with the least from a uniform reference. RMSE was lowest for BCP models with a uniform reference (mean RMSE of three target distributions=1.0896 years) followed by bimodal reference (mean=1.0985) and unimodal reference (mean=1.1781). RMSE for MARS models was consistently an order of magnitude larger with a nine-model average RMSE of 12.6566. Target sample distribution had no consistent effect. True test error of the best model (BCP and uniform reference sample) was calculated using a holdout sample of 52 individuals. This RMSE of 1.2962 was larger than all nine initial BCP model RMSE values with the exception of unimodal reference with unimodal target (RMSE=1.3518).

In conclusion, a uniform reference sample and Bayesian model provided the lowest error in point estimates of age, but true test error for this model was larger than error rates found during model selection, demonstrating potential model selection bias.

A162 An Age-at-Death Estimation Using Cementochronology in Thermally Altered Teeth

Ryen Weaver, MS*, George Mason University, Fairfax, VA; Anthony Falsetti, PhD, George Mason University, Fairfax, VA; Timothy Gocha, PhD, Texas State University, San Marcos, TX; Joseph DiZinno, DDS, George Mason University, Fairfax, VA

Learning Overview: After attending this presentation, attendees will understand the impacts of thermal alterations on the ability to estimate age at death through cementochronology in human teeth.

Impact Statement: This presentation will impact the forensic science community by testing the validity of using cementochronology to estimate age accurately and objectively in unknown individuals whose remains have been thermally altered.

Macroscopic age-at-death estimations provide age ranges that give broad and often insufficient insight to an individual's chronological age. Accurate age estimations can become more complex for a forensic anthropologist if the unknown individual has been subjected to extreme heat from an assortment of scenarios that include but are not limited to structure fires, airplane crashes, automobile accidents, and attempts to conceal evidence of homicide. Due to their high mineral content and sequestered placement in the jaw, teeth have the ability to be one of the best-preserved human tissue remains in extreme heat situations.¹ Cementochronology utilizes the cementum, the mineralized covering of a tooth root, as an aid in estimating an individual's age.² The utilization of cementochronology is one of the most accurate ways to estimate age at death due to the countable cementum annulations found in the cross-sections of the tooth root, directly correlating to the individual's age.³

This study aims to provide an in-depth analysis of thermal alteration to human teeth by various accelerants when utilizing the cementochronology method to build a biological profile. The sample in this study consisted of 36 teeth from both male and female donors from all odontological positions, excluding third molars, ranging in age from 9-87 years. Three accelerants (acetone, lighter fuel, and 87 grade gasoline) with varied volumes were used to determine if the readability of cementum annulations can remain accurate after alteration. The 36 samples were separated into groups of three to represent one accelerant and were further separated into groups of four. Each accelerant had four groups of teeth, totaling 12 teeth per accelerant and 3 teeth per assigned volume. Results indicated that the type of tooth had significant impact on the ability to count annulations, with single-rooted teeth yielding better visualization of cementum annulations to that of multi-rooted teeth. Annulations were able to be read and estimated after alteration with all three accelerants used in this study. However, acetone yielded the lowest results with the most severe alterations.

A novel three-step formula was developed to help approximate the amount of cementum annulations found within each sample. This formula involves taking the width of the total area of cementum (X) and dividing it by the width of three sets of clear, dark, and light annulations (Y) to come to the total number of incremental lines (n). This value of "n" is then multiplied by "Y" to come to an estimated age (E). Once the "E" value is found, the estimated age of eruption for that particular tooth type is added to E to come to an accurate estimated age at death. A Pearson Correlation Coefficient test found this formula to yield estimated tooth cementum annulations that were highly correlated with the actual ages of the individuals from whom the samples were collected from $r=0.965$, $p<0.001$. After thermal alteration of teeth with accelerants, it was found that cementochronology remains an accurate and helpful tool for estimating age at death in unknown individuals.

Cementochronology, Thermal Alteration, Age Estimation

A163 Estimating Adult Age Using Radiographs of the Proximal Femur

Jong In Kim, HBS, University of Toronto at Mississauga, Mississauga, Ontario, Canada; Tracy Rogers, PhD, University of Toronto at Mississauga, Mississauga, Ontario, Canada*

Learning Overview: After attending this presentation, attendees will have learned the viability of estimating an unknown adult's age by assessing bone involution of the proximal femur.

Impact Statement: This presentation will impact the forensic science community by evaluating and improving a technique for skeletal age-at-death estimation.

In 2012, Pryce tested the reliability of the traits and variants associated with involution of the proximal femur that have been used to estimate physiological age. She examined 125 radiographs housed in the University of Toronto at Mississauga (UTM) radiograph collection and determined that the established variants could not accurately be used independently, or in conjunction, to estimate an individual's age.¹

The purpose of this research is to improve Pryce's age estimation method and to determine whether a Bayesian method is a more appropriate statistical approach to estimate age using bone involution of the proximal femur.¹ Pryce's method utilized five traits that had an accuracy rate of at least 80% and a precision of less than 10% error, criteria recommended by Rogers.^{1,2} The traits include: the density and thickness of the cortical bone; the density of the first trabecular structure; the density of the secondary trabecular structure; the location of the apex of the medullary cavity; and the degree of cavitation.¹ She also reduced the number of trait variants to four or five.¹ The final age estimation is calculated by averaging the age ranges of each variant, which was determined from the mean value plus one standard deviation.¹ The method was tested with 50 radiographs, which revealed an accuracy rate of 100% and an intra-observer error rate of less than 6%.¹

The current research tested Pryce's method using two different groups of radiographs: 29 were previously assessed by Pryce; and 50 were new images not included in Pryce's study.¹ All statistical analyses were performed using R (v. 4.1.0) software.³ The inter-observer error of Pryce's original criteria was calculated by using the first group of radiographs. A weighted kappa (K) revealed a minimal inter-observer agreement for the cavitation trait and a weak agreement for the remaining traits. All traits had a p -value<0.05. Intra-class Correlation Coefficients (ICC) showed that the medullary cavity has good reliability, while the remaining traits had moderate reliability. All traits had a p -value<0.05, indicating that the agreement between observers was not due to chance or bias. The Wilcoxon signed-rank test with continuity correction revealed that the distribution between the observers is the same for all traits (p -value>0.05).

Pryce's method was modified to improve the inter-observer error by combining several variants to create a 5-traits, 14-variants approach. By decreasing the number of variants, the inter-observer error decreased; improvements were seen in the weighted K for every trait (ranging from 0.54 to 0.76), as well as the ICC for every trait except for the secondary trabecular structure (ranging between 0.68 and 0.83). The Wilcoxon signed-rank test (p >0.05) indicates there are no differences between the two sets of data for all traits, except for the cortical bone (p =0.01073).

The success of utilizing Bayesian statistics to predict age will be evaluated using the data from group one radiographs to establish the posterior probabilities, and the second set of data will be used to test the Bayesian approach.¹

As the femur is one of the most recoverable skeletal elements, it is important for forensic anthropologists to develop techniques of age-at-death estimation specific to the femur.^{1,4,5}

Forensic Anthropology, Age Estimation, Proximal Femur

A164 From Subadult to Adult: Growth of the Cranial Complex and its Implications in Forensic Anthropology

Christopher Wolfe, MA, University of Nevada-Reno, Reno, NV; Briana New, MA, University of Nevada-Reno, Reno, NV; Louise Corron, PhD, University of Nevada-Reno, Reno, NV; Kate Spradley, PhD, Texas State University, San Marcos, TX; Kyra Stull, PhD, University of Nevada-Reno, Reno, NV*

Learning Overview: After attending this presentation, attendees will better understand the ontogenetic patterns of the cranial complex and be informed of the potential of craniometric techniques for estimating parameters of the subadult biological profile.

Impact Statement: This presentation will impact the forensic sciences community by thoroughly exploring ontogenetic cranial growth and identifying when the cranium can be confidently employed in biological profile methods.

Measurement of the human cranial complex is common in forensic anthropology to estimate parameters of the adult biological profile. However, it is unknown at what age the subadult cranium displays comparable levels of variation to the adult cranium. The purpose of this presentation is to bridge this gap by analyzing the patterns of ontogenetic variation in the subadult cranium. This presentation will address: (1) how variation of the cranial complex shifts from birth to adulthood, and (2) how subadult cranial variation compares to adult cranial variation. By doing so, this research is foundational for assessing the potential of craniometric data to improve subadult biological profile methods.

Thirty cranial Interlandmark Distances (ILDs) established from 36 craniofacial landmarks were collected on 3D virtual renditions of crania obtained from Computed Tomography (CT) scans of 571 subadults aged between birth and 20 years and of known biological sex from the Subadult Virtual Anthropology Database (SVAD). Individuals were assigned life history stage groups according to their age: infancy (birth to 2.99 years; $n=102$), childhood (3 to 6.99 years; $n=5$), juvenile (females: 7 to 11.99 years; males: 7 to 12.99; $n=66$), adolescence (females: 12 to 17.99; males: 13 to 17.99 years; $n=170$), and adulthood (>18 years; $n=178$). An adult sample ($n=1,035$) from the Forensic Anthropology Databank (FDB) was included for comparison. Linear Discriminant Analyses (LDA) were used to explore the variation between each life history stage and biological sex. Next, the data was split into training (75%) and testing (25%) sets and LDA with repeated 10-fold cross validation were run to determine if: (1) the subadult cranium could be used to estimate life history stage and/or biological sex, and (2) what subadult life history stage is most similar to adults in terms of classification accuracy and within-group (co)variation.

The LDA results demonstrate a clear ontogenetic trajectory in cranial variation. CV1 explains variation between each life history stage (89%), while CV2 explains variation between biological sex within each life history stage (4%). The overall classification rate using five life history stages is 65% for the pooled-sex sample. When looking at each life history stage separately, there is some overlap in cranial size variation between adjacent groups throughout ontogeny, with classification accuracy decreasing from 97% in infancy to 68% in adulthood, with almost superimposed ranges of variation in adolescence and adulthood. FDB adults share similar mean CV1 scores and ranges of variation to the SVAD adolescents and adults, while CV2 mainly captures population differences. Sex estimation is the least accurate during infancy (64%), but the most accurate in the SVAD adolescent and adult samples and in FDB adults with rates of 83%, 90%, and 93% respectively.

Final adult size is reached by adolescence as is the appearance of significant cranial sexual dimorphism and the expression of population affinity. The FDB adults share similar patterns of variation and classification accuracies with the SVAD adolescents and adults. Stabilization of the multivariate distribution of the cranial complex in adolescence indicates the cranium could accurately estimate features of the biological profile, such as population affinity and sex, for individuals older than 12 (F)/13 (M) years of age.

Interlandmark Distances, Ontogeny, Classification

A165 From Subadult to Adult: The Expression of Cranial Macromorphoscopic Traits Through Ontogeny

Kyra Stull, PhD, University of Nevada-Reno, Reno, NV; Elaine Chu, MA, University of Nevada-Reno, Reno, NV; Louise Corron, PhD, University of Nevada-Reno, Reno, NV*

Learning Overview: After attending this presentation, attendees will understand the ontogenetic patterns of cranial Macromorphoscopic (MMS) traits and the variation of trait expression according to age and population affiliation in subadult individuals.

Impact Statement: The results of this study will impact the forensic science community by providing knowledge on MMS traits in general and specifically the ontogenetic patterns of these traits, their frequency of expression according to age and population affiliation, and in particular the age at which they stabilize and are analogous to adult frequencies and could be employed in biological profile methods.

Cranial MMS traits are often used in forensic anthropology to study biological distance and estimate population affiliation as part of the biological profile for adult decedents. However, very little is known of their ontogenetic trajectories. Indeed, the current discussion over the use, or misuse, of these traits in forensic anthropology would benefit from additional knowledge regarding their patterns of expression throughout ontogeny. The aim of this study is to evaluate the growth trajectory of 13 cranial MMS traits commonly used in forensic anthropology.

Thirteen MMS traits were scored on the virtually reconstructed crania from Computed Tomography (CT) scans of 968 subadults aged between birth and 22 years from the Subadult Virtual Anthropology Database (SVAD). Scoring followed Hefner and Linde; definitions were slightly modified to fit virtual material.¹ To reveal the growth trajectory of each MMS trait, score frequencies were calculated according to population affiliation (American Black, American White, Hispanic, Native American) and for each Life History Stage (LHS) defined as: Infancy from birth to 2.99 years (N=294), Childhood from 3.00 to 7.99 years (N=89), Juvenile from 8.00 to 11.99 years for females (N=36) and 12.99 years for males (N=59), Adolescence from 12.00 to 17.99 years for females (N=92) and 13.00 to 17.99 years for males (N=160), Adulthood from 18+ years (N=238). Frequencies were compared across LHS to assess when the stabilization of trait expression occurred, which was achieved when the distributions were comparable to the adult sample in each population affiliation group.

The pattern of frequencies for MMS trait scores related to the orbital region, namely Inter-Orbital Breadth (IOB) and Orbit Shape (OBS), stabilize during Childhood. Three MMS traits relative to the nasal aperture stabilize during the Juvenile period: Anterior Nasal Spine (ANS), Nasal Aperture Width (NAW), and Nasal Aperture Shape (NAS). Traits relative to shape (INA, NBC, NBS, NO, PS, PBD) and size (PZT, MT) showed later stabilization during Adolescence.

There was a remarkable stability of all MMS traits by adolescence (12+ years) as well as clear patterns according to craniofacial regions. By exposing the developmental trajectories and patterns of MMS traits, anthropologists can be more informed regarding the continuum of phenotypic variation and can better understand the contribution of MMS traits to the biological profile in subadults.

This research was funded by the NIJ Award 2019-DU-BX-0039.

Phenotypic Variation, Growth and Development, Population Affinity

A166 From Subadult to Adult: Understanding Univariate Craniometric Growth Patterns

Briana T. New MA, University of Nevada-Reno, Reno, NV; Christopher A. Wolfe, MA, University of Nevada-Reno, Reno, NV; Louise K. Corron, PhD, University of Nevada-Reno, Reno, NV; M. Kate Spradley, PhD, Texas State University, San Marcos, TX; Kyra E. Stull, PhD, University of Nevada-Reno, Reno, NV*

Learning Overview: After attending this presentation, attendees will better understand the timing of ontogenetic shifts in cranial dimensions from birth to adulthood through an examination of univariate craniometric growth patterns by sex, regions, and life history stages.

Impact Statement: This presentation will impact the forensic science community by documenting the age at which males and females reach craniometric maturity for each Interlandmark Distance (ILD) and within regions, as well as providing measurable growth trajectories that can be broadly applied to forensic casework.

Although the general development of cranial regions is well-documented from clinical and evolutionary perspectives, quantifiable examinations of subadult cranial growth trajectories across the entire ontogenetic period (from birth to adulthood) are still needed within biological and forensic anthropology. This research investigates the timing of cranial growth and development for individual variables and their associated regions and assesses when cranial maturity in size is reached. By better understanding the complex univariate growth patterns of the cranium, anthropologists can better estimate the developmental timing of cranial pathologies or developmental defects and improve parameters of the subadult biological profile.

A sample of 571 male and female subadults aged between birth and 20 years was used from the Subadult Virtual Anthropology Database (SVAD). Twenty-six ILDs were derived from 36 3D cranial landmarks collected from virtual renditions of the cranium reconstructed from Computed Tomography (CT) scans.^{1,2} Results are discussed through the perspective of ontogenetic Life History Stages (LHSs) and three cranial regions: neurocranium, basicranium, and splanchnocranium. The LHSs are infancy (0–2.99 years; females=46, males=56), childhood (3.00–6.99 years, females=28, males=27), juvenile (7.00–12.99 years; females=29, males=41), adolescent (13.00–17.99 years; females=61, males=105), and adulthood (18.00+; females=78, males=100). Multivariate Adaptive Regression Splines (MARS) with ten-fold cross-validation were employed to capture the non-linear ontogenetic trajectory of each ILD and sexes were analyzed separately to account for differential timing in growth trajectories.

The majority of neurocranial measurements peak in size between 3–5 years (early childhood) and stabilize (i.e., plateau) thereafter regardless of sex. Some basicranial measurements (e.g., foramen magnum length, foramen magnum breadth) mimic the neurocranium with stabilization at a young age, while others (e.g., basion-nasion length, bauricular breadth) exhibit a secondary peak in size for the juvenile and/or adolescent LHSs. Splanchnocranium measurements exhibit the most complex, dynamic, and sexually dimorphic growth trajectories with measurements consistently increasing in size throughout ontogeny and stabilizing in late adolescence. For most measurements, males exhibit changes in growth trajectories between 4–5 years and again between 13–17 years. In contrast, females exhibit changes in growth trajectories between 7–13 years.

Males and females have comparable timing in growth trajectories for all three cranial regions prior to adolescence, illustrating the ontogenetic stability of early cranial growth. However, trajectories diverge based on sex during adolescence, reflecting well-known sex differences in the onset and duration of puberty. Overall, the variable and regional patterns observed here demonstrate earlier achievement of adult size for the neurocranium and basicranium when compared to the splanchnocranium. In understanding the growth trajectories and timing of stabilization for individual craniometric variables, forensic anthropologists can better mobilize these variables when estimating components of the subadult biological profile.

This research was funded by the NIJ 2019-DU-BX-0039 Award.

A167 Are Stable Isotopes Truly Stable Enough for Forensic Applications? Forensic Stable Isotope Research at a Human Decomposition Facility

Melanie Beasley PhD, Purdue University, West Lafayette, IN*

Learning Overview: After attending this presentation, attendees will have a better understanding of current forensic stable isotope research studies conducted at the Anthropology Research Facility (ARF), a human decomposition facility at the University of Tennessee, Knoxville, to address questions of postmortem alteration of stable isotope values in biological tissues.

Impact Statement: This presentation will impact the forensic science community by presenting results from forensic stable isotope studies at a human decomposition facility that provide unique research opportunities for innovative method development and validation of *in vivo* stable isotope values from biological tissues critical for region-of-origin applications of unidentified human remains.

Forensic stable isotope analysis is most beneficial to forensic investigations of unknown human remains in cases where standard methods of identification are unsuccessful. Stable isotope analysis capitalizes on the use of stoichiometric models to understand how elements on the landscape move throughout an entire ecological system, creating unique “fingerprints” of elements incorporated into human biological tissues.

Despite successful applications in forensic anthropology of stable isotope analysis, there are still basic research questions about alteration of biological samples after death and the offset between tissue types that needs to be addressed for wider adoption by the medicolegal community. The Forensic Anthropology Center’s (FAC) documented donors provide a unique opportunity for such research because of the biological tissues curated, varied scenarios for decomposition (buried vs. surface), and standardized documentation of life history movement.

The four tissue types (i.e., hair, fingernails, bone, and teeth) regularly curated by the FAC allows for basic geochemistry research on donors with known residential history. This is key for understanding how element signatures are incorporated and fractionate (i.e., offset in stable isotope values) between different tissue types with differential growth history. Additionally, as donors are placed in different scenarios at ARF, this allows for a wealth of knowledge to be gained about the diagenesis (i.e., alteration to element signatures due to post-depositional environment) of different stable isotopes in different tissues.

Current stable isotope research at the FAC surround research questions about the postmortem alteration of $\delta^2\text{H}$, $\delta^{18}\text{O}$, $\delta^{13}\text{C}$, $\delta^{15}\text{N}$, and $\delta^{34}\text{S}$ in hair and fingernails. This is of forensic importance because diagenesis of elemental signatures recorded in physical evidence may impact interpretations of region-of-origin predictions if isotope ratios are altered by the burial environment. Systematic alteration to stable isotope values can also be used in new innovative methods for determining Postmortem Interval (PMI). One research project at the ARF presented at the 2019 and 2020 AAFS annual meetings, investigated the use of systematic change in $\delta^{15}\text{N}$ values of decomposing muscle tissue and maggots feeding on decomposing tissue to test applications of diagenesis for determining PMI in recently deceased individuals.^{1,2}

Beyond questions of stable isotope diagenesis and fractionation research, the long-term curatorial efforts of the FAC serve as an ideal opportunity to investigate concerns in the field of forensic stable isotope geochemistry about the long-term storage impact to stable isotope values of tissue samples. One such study has been initiated on fingernails stored over two years in different scenarios to test the alteration in five isotope systems.

Stable Isotopes, Human Decomposition, Forensic Anthropology

A168 The Significance of Sociocultural Covariates in Stable Oxygen Isotope Analysis: Implications for Region-of-Origin Predictions for Global Populations

Taylor Lambrigger, BS, California State University-Chico, Chico, CA*

Learning Overview: After attending this presentation, attendees will have a better understanding of the significant role that sociocultural covariates such as poverty, indigeneity, and rurality play in local access to drinking water in Oaxaca, Mexico, and consequently how these factors influence the oxygen isotopic compositions of human bodily tissues used in forensic provenancing studies.

Impact Statement: As the forensic science community continues to develop methods in the United States and apply those methods to communities throughout the globe, it is increasingly important to consider how the lived realities for these different communities impact the assumptions used in stable isotope methods. The evaluation of isoscapes predictions for oxygen isotopes in Oaxaca provides an example of the need to investigate several assumptions that may affect region of origin predictions.

Stable isotope analysis involves a set of biogeochemical methods that have developed significantly over the past two decades. Specifically, forensic anthropologists and isotope experts have focused on oxygen isotopes because of its ability to help estimate probable regions of origin of unidentified individuals using tissues such as hair, nails, bones, and teeth. Prior research on this isotopic system in human populations has found that drinking water is geographically patterned and that tap water is often a reliable proxy for drinking water in assessing these geographical links between human tissues and geography. Though largely developed in the United States and areas of Europe, forensic anthropologists have begun to apply the method in a variety of global contexts, including assisting in identifying missing migrants at the United States-Mexico Border.

The focus of this presentation is to critically assess the assumption made that tap water is a reliable proxy for drinking water in oxygen isotopic systems as they are applied to global communities. Specifically, the development of isoscapes as tools to assist anthropologists in estimating region of origin rely on this assumption, which may not be appropriate for communities that do not have access to reliable or clean drinking water. However, little research has been done to date to explicitly test this assumption. The source of drinking water from 56 municipalities throughout the state of Oaxaca, Mexico, were recorded and compared with census data on indigeneity, rurality, and poverty. These census data indicate significant variation in the demographic makeup of the sampled municipalities, with six different categories of drinking water recorded throughout the sampled areas.

This wide range in drinking water sources indicates that further investigation into the isotopic systems of diverse global populations is necessary. Over 40% of the sampled municipalities rely on bottled water. The five most rural municipalities relied on stream water exclusively for drinking and cooking. One municipality relied exclusively on rain water during the wet season. Categorically, tap water is not an adequate representation of the sources of water consumed by local Oaxacans. The need to investigate if this conclusion extends isotopically is urgent. If the remains we seek to help identify are coming from various socioculturally diverse communities, we run the risk of missing these populations because of our assumptions.

Ultimately while the growth and development of isotopic methods, namely isoscapes, has been tremendous, it is imperative that anthropologists continue to question the assumptions made in our methods as we apply them to global communities. While recent isoscapes have mapped regions beyond the United States, these maps still largely rely on tap water data. A plethora of ethnographic evidence shows that sociocultural covariates have a direct impact on water insecurity in communities around the globe, and these data show that the sources of drinking water are variable across a single state in Mexico. Recognizing the varying sociocultural realities of the communities we seek to aid and identify is paramount as we grow and develop our methods moving forward.

Stable Isotope Forensics, Provenancing, Forensic Anthropology

A169 The Detection of Bone Particles in Non-Carbonate Soils

Angi Christensen, PhD, FBI Laboratory, Quantico, VA; Ian Saginor, PhD, FBI Laboratory, Quantico, VA*

Learning Overview: Attendees of this presentation will learn a new technique for determining whether a non-carbonate soil may contain bone particles.

Impact Statement: The forensic science community will be aware of a new, simple, cost-effective method for determining whether a non-carbonate soil may contain small particles of bone.

For many years, geologists have used a simple test to determine whether a soil contains carbonate minerals such as calcite and dolomite. This test involves the application of a weak Hydrochloric Acid (HCl) and observation for an effervescence reaction, the intensity of which can be graded on a qualitative scale.

This routine soil test was used in a recent forensic geology investigation. Based on the geographic recovery location, the soil was not expected to contain carbonates, but expressed effervescence in the presence of HCl. The soil was recovered from a location known to be in close proximity to human remains, and a collaborative assessment of the soil by a forensic geologist and forensic anthropologist confirmed the presence of small bone fragments in the soil that were visible microscopically. The question was then posed whether small, degraded bone particles in the soil could be causing the effervescent reaction rather than carbonates. This study therefore tested whether non-carbonate soils exhibit an effervescent reaction in the presence of HCl if bone particles are present in the soil.

A soil sample was collected from Quantico, VA, and tested for pre-existing carbonates. X-Ray Diffraction (XRD) failed to detect carbonate minerals, and the soil showed no effervescence in the presence of HCl solution. A portion of the soil was lightly ground with a mortar and pestle to break up the soil aggregates and to facilitate mixing. Five non-human bone samples were utilized, representing a variety of taphonomic alterations, including weathering, as well as one bone that was burned. The bones were ground using a ceramic mortar and pestle and sieved to achieve particle size fractions of <0.50mm and 0.50–0.85mm. A sample of powdered National Institute of Standards and Technology (NIST) hydroxyapatite standard was also used.

For each bone particle fraction as well as the hydroxyapatite standard, a 10:1 mixture by weight of soil:bone was prepared. A small sample of each mixture was placed into a crucible and positioned under a stereobinocular microscope at ~6.3X magnification. Several drops of 1 molar HCl (considered to be the standard for the geologic test) were applied, ensuring that soil and bone particles were covered/submerged. The observed reaction was categorized as being either non-effervescent or very slightly, slightly, strongly, or very strongly effervescent.

For all non-burned bone samples at both size fractions, the bone fragments in the soil were observed to be slightly effervescent. For the burned bone sample and hydroxyapatite standard, the particles were observed to be very slightly effervescent. In all cases, the bone particles could be easily identified within the soil based on the presence of small bubbles surrounding the bone particle. This is likely the result of calcium or phosphate in bone (as well as possibly organics) reacting with the HCl to yield a gas.

These results demonstrate that a simple, quick, cost-effective test can be used to determine whether soil may contain bone particles, even if they are too small to be identified morphologically. The possible forensic anthropological implications are significant since this method may be useful in identifying a possible burial (or previous burial) location. It also demonstrates that bone particles in soil can produce the same type of effervescence expected in carbonate soil and that additional tests (such as XRD) should be performed to determine the source of the reaction.

It is hoped that these results may form the basis for more sophisticated studies on using this type of test to detect the presence of skeletal material in soil. This study also highlights the insight that can be gained through interdisciplinary dialog and investigations.

A170 Longitudinal Effects of Prolonged Opioid Use on Cortical Bone Remodeling in a Rabbit Model: Part II—Intraskkeletal Histological Variability and Regional Differences

Janna Andronowski PhD*, Faculty of Medicine, Memorial University of Newfoundland, St. John's, Newfoundland, Canada; Mary Cole, PhD, Skeletal Biology Research Lab, Injury Biomechanics Research Center, The Ohio State University, Columbus, OH; Reed Davis, MSc, Department of Biology, The University of Akron, Akron, OH; Adam Schuller, BSc, Boise State University, Boise, ID; Gina Tubo, BSc, Northeast Ohio Medical University, Rootstown, OH; Abigail LaMarca, BSc, Department of Biology, The University of Akron, Akron, OH; Joshua Taylor, BSc, Memorial University of Newfoundland, St. John's, Newfoundland, Canada

Learning Overview: Attendees of this presentation will be introduced to novel histological data from a longitudinal live animal experiment documenting the effects of chronic opioid exposure on cortical bone remodeling. The ultimate goal is to describe how opioid agonists, particularly morphine sulphate and fentanyl, affect microscopic structures of cortical bone used in histological age-estimation methods in forensic anthropology. Related objectives include: (1) demonstrating intraskkeletal and regional variability in histologic parameters in the rabbit midshaft femur due to opioid exposure, and (2) presenting a novel toolkit (OsteoFlo®) for fluorescent osteon characterization.

Impact Statement: This presentation will impact the forensic science community by describing how opioid exposure dysregulates bone remodeling and the subsequent longitudinal impact on cortical bone microstructural parameters. Further understanding of such underlying biological processes will allow us to adapt histological age-estimation methods within the field of forensic anthropology for application to chronic opioid users.

Novel approaches to the study of changes in bone tissue are needed to explain the substantial variability observed in the pattern and pace of bone remodeling among diverse groups. Current histological age-estimation methods are limited by approaches that fail to account for underlying etiologies known to affect bone tissue (e.g., infection, stress, substance abuse, chronic alcohol use, medication regimes, hormones, among others). Previous studies have demonstrated that pathological conditions can affect bone remodeling and therefore age estimates.¹⁻⁴ Work by Karinen revealed that individuals who abuse methamphetamine were more likely to have their age underestimated (mean=-11.57 years) when evaluated using histological criteria.⁵

The purpose of this study was to develop a longitudinal model for evaluating the effects of prolonged opioid exposure on cortical bone remodeling in an animal model system. New Zealand White (NZW) rabbits were selected since they have a shortened remodeling period and relatively quick skeletal maturation. Male NZW rabbits were divided into three groups of seven animals each: morphine sulphate, fentanyl, and controls. In addition to eight weeks of experimental treatment, all animals underwent bi-weekly subcutaneous injection with a bone-labeling fluorochrome, calcein, to facilitate *ex vivo* dynamic histomorphometry following euthanasia. It was hypothesized that opioids would significantly alter microstructural features used in histological age-at-death estimation. Histomorphometric variables included mineralizing surface per bone surface, cross-sectional geometry, remodeling area, size and shape descriptors for vascular pores and osteons, intracortical remodeling activity, and activation frequency.

Mid-shaft bone blocks from rabbit femora were embedded in methyl methacrylate, and transverse thin sections were procured using a Well® diamond wire saw. Cortical bone microstructure was visualized using an Olympus® BX51 microscope, with cross-sectional images of each section acquired using Differential Interference Contrast (DIC) (200x), circularly polarized light (200x), and a Fluorescein 5-Isothiocyanate (FITC) filter cube for fluorescence (100x). A proprietary image processing toolkit (OsteoFlo®) was developed for FIJI software v.1.53k (6) that allowed for semi-automatic isolation, type classification, regional subdivision, and morphometric analysis of vascular pores and osteons. Statistical analyses were completed in R (v. 4.1.1), using Analysis of Variances (ANOVAs) to compare morphometric variables between drug groups and anatomical regions.

Whole bone analyses found that intracortical remodeling was significantly elevated in morphine rabbits and depressed in fentanyl rabbits, compared to controls. This pattern was observed in the cortical fraction of remodeled bone, active remodeling centers, and counts and population densities of osteon types. Regional subdivision additionally indicated that vascular pores and osteons were significantly concentrated posteriorly and reduced laterally. Osteons in lateral regions were also smaller. These results are consistent with repression of remodeling by high anterior and lateral strain during hopping. These results confirm the hypothesis that opioid exposure significantly dysregulates bone remodeling and its microarchitectural products.

Bone Remodeling, Opioids, Histomorphometry

A171 Post-Fire Modifications of Burned Human Remains

Elayne Pope, PhD, Fatal Fire Forensics LLC, Knoxville, TN; Chelsey Juarez, PhD, California State University-Fresno, Fresno, CA; Alison Galloway, PhD, University of California-Santa Cruz, Santa Cruz, CA*

Learning Overview: Attendees will understand some major factors that can alter burned human remains between the final moments of burning and the anthropological examination of the remains at the morgue.

Impact Statement: This presentation foregrounds several common post-fire changes that can occur to fragile burned human remains and bones during extinguishment, search and recovery, handling, transport, and the postmortem examination. Understanding these factors will allow the anthropologist to differentiate pre-fire trauma from post-fire defects.

Burned remains commonly seen by the anthropologist in the morgue have likely undergone post-fire changes due to activities from fire suppression, search and recovery, handling, transportation, and prior examination by the forensic pathologist and other personnel. By the time the anthropologist examines burned remains, it is essential to separate the damage due to: (1) pre-existing defects (pathology or trauma); (2) thermal changes; and (3) post-fire damage to burned bones. The San Luis Obispo Forensic Fire Death Investigation course has, over the past 12 years, utilized approximately 150 cadavers in realistic scenarios and provided the opportunity to identify these factors.

Fire suppression efforts focus on extinguishing the flames as quickly and safely as possible. One method to suppress the fire involves a pressurized column of water from the fire hose, which if the body is directly impacted, can cause the fragile charred and calcined bones to fragment and disperse within the fire scene, particularly for the head. Activities from heavy boot traffic and dragging fire hoses through the scene have the potential to cause damage if the body was in its path.

Search and recovery for fire victims often are premised on the belief that: (1) there is an intact body, and (2) this body is buried under the fire debris. One search technique is the “shuffle” method whereby the searchers shuffle through the debris in hopes of bumping into the body. If searchers are not trained to recognize charred and calcined human bone, it is likely that they could walk through the remains or focus on larger charred remnants and ignore or damage the surrounding bone fragments. Cadaver dogs alert to human remains by sitting or lying on the area of the greatest concentration of scent, often the pelvis. This can result in crushing of the spine or other adjacent skeletal elements.

Recovery of burned human remains from the fire scene involves safely gaining access, which may require extrication from vehicles with power tools or from heavily damaged structures with collapsed fire debris on and around the body. Excavation and removal of the fragile remains from their *in situ* context can produce additional fragmentation, especially from improper handling or untrained personnel (transport services). Recovery becomes challenging if charred tissues are fused to metal frameworks (car seat, bedsprings) or have adhering materials (melted glass, metal). Recovery can result in fragmentation if the body bag is placed next to the victim before sifting for bone fragments in the surrounding fire debris and from damage from boots of personnel moving the remains into the body bag. Body bags are flexible, which if lifted without a backboard, can produce pressure points against the fragile burned remains. Heavy-duty body bags can be flat and rigid, thus pressing against fragile bones of the face and teeth.

Transportation to the morgue involves strapping the body onto a gurney with 2- or 3-point belt restraints cinched against the fragile burned bones of the chest, flexed arms, and legs. Movements from loading, driving conditions, and unloading the gurney at the morgue can produce further fragmentation. At the morgue, the intake process can involve the transfer of the body to a new gurney/table, handling for radiographic images, removal of clothing/personal effects, and inherent damage from the invasive autopsy procedures that occur before the forensic anthropologist examines the remains.

Examples of damage from these factors will be presented to demonstrate the post-fire alterations that can occur to burned human remains from the fire scene to the morgue. Understanding these post-fire modifications will help isolate the areas of damage that may be most closely linked to the cause and manner of death.

Burned Bone, Fatal Fire, Burned Human Remains

A172 The Effects of Experimental Whole-Body Burning on the Cortical Bone Microstructure of Ribs, Femora, and Metatarsals

Lauren A. Meckel, PhD, Johns Hopkins, Baltimore, MD; Sophia Mavroudas, MA, Texas State University, San Marcos, TX; Justin Goldstein, MA, Texas State University, San Marcos, TX; Shelby Garza, MA, Texas State University, San Marcos, TX; Timothy Gocha, PhD, Texas State University, San Marcos, TX*

Learning Overview: This presentation will explain the effects of thermal alteration to the cortical microstructure and age-at-death estimates of ribs, femora, and metatarsals during whole-body burning experiments in simulated fire death scenarios.

Impact Statement: This presentation will impact the forensic science community by providing a better understanding of what to expect from histological analysis of thermally altered human remains at various temperatures based on realistic burning experimentation.

This project used will body donations (N=6) with known demographics from the Forensic Anthropology Center at Texas State (FACTS), all of whom had consented to advanced/traumatic research, in various realistic fire death scenarios to understand the effects of thermal alteration to whole-body donations at the microstructural level. Midshaft samples of the sixth rib, femur, and fifth metatarsal were taken from one side of each donor before burning. For the duration of the thermal alteration, thermocouples were placed both in the body near the regions of interest (thorax, thigh, and foot) and throughout each fire scene to record temperatures. Depending on the scenario, the fires were allowed to burn between 13-53 minutes and the average temperature for each region of interest ranged from 666.66-864.87 °F. Post-burning, the antimer of each bone sample was taken from the other side of the body, if available. This resulted in 18 pre-burn and 15 post-burn samples in total.

Histological slides were made from each sample using standard histological protocols and evaluated on a Leica® DM6M microscope for general histological data collection and age-at-death analyses.¹⁻⁴ Standard histological taphonomic alteration indices were applied to both pre- and post-burn samples, including the General Histological Index (GHI), the Cracking Index (CI), and the Birefringence Index (BFI) to quantify visible changes.⁵ A minimum of 40 osteons per sample were evaluated to compare changes in osteon area and Haversian canal area between pre- and post-burn samples.

Two-tailed *t*-tests were used to evaluate significant differences in index score, osteon area, and Haversian canal area within elements between pre- and post-burn samples. No significant differences in osteon area or Haversian canal area between pre- and post-burn samples were found. In the femur, significant differences in BFI were seen between pre- and post-burn samples ($p<0.05$). In the metatarsal, significant differences in CI were seen between pre- and post-burn samples ($p<0.05$). No significant differences in taphonomic indices were seen in the ribs. When pooling all elements, significant differences in BFI and GHI were seen between pre-burn ($p<0.01$) and post-burn samples ($p<0.05$).

The age estimate ranges from the femur across pre- and post-burn samples encompassed known age-at-death, provided enough cortical bone was preserved to include anterior width as an age estimate variable.² The age estimates for the rib were less accurate than the femur, but the point age estimates were not significantly different between pre- and post-burn samples.^{3,4}

Overall, the results of this study show that thermally altered remains can be used for histologic analysis, including age-at-death estimation, within certain burning parameters. These parameters and practical guidelines for evaluating whether burned samples can be successfully used for histological analysis will be discussed.

A173 Estimating Exposure Time From a Set of Burned Human Remains

Amanda Williams, PhD, Truckee Meadows Community College, Reno, NV*

Learning Overview: After attending this presentation, attendees will gain a better understanding of the variables that can contribute to the timing and development of heat-related changes on a human body.

Impact Statement: This presentation will impact the forensic community by introducing a new tool that can be used in analyzing fatal fire cases and aid investigators in building a legal case.

Questions regarding timing of death events are often ones that investigators look to have answered, as they are not readily known. Within anthropology, a series of methods have been developed to provide an estimate of time surrounding death events. A majority of these models are derived out of taphonomic studies that focused on developing a Postmortem Interval (PMI).¹⁻⁵ Experimental observations have found that a human body undergoes a series of physical alterations at death, making it possible to estimate time since death.¹⁻⁵ This study aims to employ a similar approach and create a model for estimating exposure time to a fire, which can provide additional insight and information to forensic investigators building a legal case.

This study involves observational experiments of the burning of 80 donated human cadavers. Data were collected as part of the Fatal Fire Death Investigation Course by the San Luis Obispo Fire Investigation Strike Team, Inc. Cadavers were placed in vehicles, structures, confined spaces, and outdoor fire contexts. All physical alterations to both soft and skeletal tissues were documented with digital photography. Temperature data was collected through use of thermal couples and thermal imaging devices placed on multiple locations and depths directly on the human remains. The remains were assessed by applying a Total Body Score (TBS) based on the affected body region (i.e., skull, upper and lower limbs, thorax, and hands/feet). Once the visual analysis was completed, all scores for each region were added together to form a TBS and used in a predictive model to estimate exposure time to a fire.

This study found the amount of thermal damage to remains was correlated with maximum temperatures and exposure times in each fire environment. TBS and maximum temperature were found to be the most significant variables in predicting time, with each having p-values less than 0.001, which is statistically significant (p-value <0.05). Given these results, a linear regression model was created for estimating exposure time. The model correctly predicted time in about 70% cases analyzed. The model misclassified on the testing dataset in approximately 30% of the cases analyzed. While it did not exactly pinpoint the exact time, it was within range of 2-3 minutes in some cases, and at most off by 8-9 minutes in others, which is still a fairly acceptable rate of error. On average, the model was found to be off by 5 to 6 minutes, which is within the range of standard error reported. Despite outliers and a limited comparable sample, the model correctly predicted time in approximately 70% of cases analyzed.

The results of this study demonstrate the possibility to estimate exposure time from burned human remains. The findings also lend support to the notion that it is a combination of both time and temperature that influence bodily conditions. Overall, this model provides a solid foundation for future researchers to build upon, as there is currently no model like this one described for fatal fire deaths.

Burned Human Remains, Taphonomy, Forensic Anthropology

A174 3D Analysis of the Microstructure of Heated Bone to Aid in Species Differentiation

Hannah Cross, MS*, Keele University, Newcastle-under-Lyme, Staffordshire, United Kingdom; Charlene Greenwood, PhD, Keele University, Newcastle-under-Lyme, Staffordshire, United Kingdom

Learning Overview: After attending this presentation, attendees will better understand the microstructure of bone, how it differs between species, and understand the changes that occur upon heating.

Impact Statement: This research will impact the forensic science community by discussing a non-destructive, inexpensive technique that can be implemented to analyze the internal microstructure of bone three dimensionally to aid in the species identification of bone

Species identification of bone is the foremost question posed to forensic anthropologists upon the recovery of remains. This can be an extremely challenging task if anthropologists are provided with compromised remains. Highly fragmented burnt bone, for example, is notoriously difficult to identify as it is confounded by factors including warping, the breakdown of the organic component, fragmentation, and commingling with debris and other remains. Therefore, there is a need for a new method that can reliably determine the species of compromised bone. Cortical bone is comprised of rod-shaped cells that are tightly packed into concentric circular structures called osteons. Haversian (longitudinal) and Volkmann (transverse) canals facilitates blood vessels and nerve fibers to pass through the osteon, providing the bone cells with nutrients and enabling waste removal.¹ Cattaneo et al. and Martiniaková et al. have demonstrated the success of using Haversian canal measurements via histological examination as a species differentiating parameter; however, this method relies on 2D measurements and therefore does not account for changes in 3D space.²⁻⁴ Further, the technique is destructive, with thin sections of specimens required for analysis. The project detailed in this abstract has utilized micro-Computed Tomography (μ -CT) to analyze the 3D microarchitecture of the canal network of bone from bone specimens of different species of origin. This has provided an understanding on how these networks differ between species and how these changes are impacted by thermal alteration.

Bovine, canine, ovine, and porcine femoral cortical bone were cut into 5 x 5 x 5mm sections and scanned using a Nikon® HMX ST 225 μ -CT operating at 65kV and 70 μ A with a resolution of ~14 μ m voxel size. Three repeats of each sample were tested for each temperature ($n=27$). The Haversian and Volkmann canals were separated from the cortical bone structure, and their volume and surface area were measured. The samples were then heated at 400°C, 600°C, and 800°C before being scanned again to compare any heat-induced changes. The results have shown significant differences ($p < 0.05$) in the morphometrics of the Haversian and Volkmann canal networks between species. Overall, there is a reduction in the diameter and the frequency of the canals after heat treatment that is correlated with an increase in temperature. Crucially, after heat treatment, it is still possible to differentiate between species. These findings suggest that μ -CT can potentially be implemented as a non-destructive tool to determine the species of origin of compromised bone.

Species Differentiation, Heated Bone, Bone Microarchitecture

A175 Do Bone Elasticity and Postmortem Interval Affect Forensic Fractographic Analyses of Bone?

Jessica Skinner, PhD*, Mayo Clinic, Scottsdale, AZ; Natalie Langley, PhD, Mayo Clinic, Scottsdale, AZ; Malin Joseph, MS, Mayo Clinic, Scottsdale, AZ; Peter Goguen, Arizona State University, Tempe, AZ; Loukham Shyamsunder, PhD, Arizona State University, Tempe, AZ; Subramaniam Rajan, PhD, Arizona State University, Tempe, AZ

Learning Overview: After attending this presentation, attendees will understand the effects of bone elasticity on fractographic features of bone fracture surfaces.

Impact Statement: This presentation will impact the forensic science community by demonstrating the utility of forensic fractography into the recent postmortem interval.

The timing of tissue injuries informs cause and manner of death in forensic cases. Distinguishing perimortem and postmortem injuries is straightforward when soft tissue is present but may be challenging with skeletonized remains. Taphonomic events may obscure or mimic perimortem trauma, particularly when bone is still elastic. The prolonged perimortem interval in bone limits macroscopic fracture pattern analyses' capacity to discern perimortem injuries from postmortem damage.¹ Bone fractography characteristics of fracture surface features reliably established crack propagation in perimortem injuries, especially when used in conjunction with overall fracture patterns. This study used the fractographic approach described by Christensen et al. to evaluate experimentally induced perimortem and postmortem fractures.² The hypothesis was that the expression of fractographic features may differ as bone elasticity decreases, elucidating perimortem and postmortem events.

Fourteen unembalmed, defleshed human femoral shafts from males and females aged 33 to 81 years were included in this study; the periosteum was left intact. The bones were stored at -22°C and thawed at ambient temperature (20°C) for two days. Five femora were used as the perimortem sample, and nine femora were placed in a ThermoFisher™ Heratherm™ gravity convection oven at 35°C to simulate six postmortem intervals ranging from 1,500–16,000 Accumulated Degree Hours (ADH). A data logger was used to monitor and record temperature and humidity. Bones were weighed before and after removal from the oven to estimate water loss, and a 1cm sample was cut from each shaft for histochemical analysis of collagen. Next, the shafts were fractured with a Columbus McKinnon (CM) Drop Test Frame using three-point bending and drop height of 100–275mm. Fracture tests were recorded with a high-speed camera and Digital Image Correlation (DIC) was used to calculate stress and strain across the bony geometry, as well as displacement and location of failure. Fracture surfaces were scored according to descriptions provided by Christensen et al.²

A Multivariate Analysis of Variance (MANOVA) and polyserial correlations were used to measure associations between the fractographic variables, ADH, and collagen and water content of the bone. The MANOVA showed that ADH ($F=0.99$, $p=0.50$) and water loss ($F=1.73$, $p=0.23$) did not affect fractographic scores significantly. The polyserial correlation showed a strong negative correlation between cantilever curl and ADH ($r=-0.86$, $p=0.067$), and a moderate positive correlation ($r=0.55$, $p=0.45$) between bone mirror and ADH. The correlations were not significant, likely due to the small sample size and uniformity of some variable scores. The effect size is 0.96 (80% power, $\alpha=0.05$), meaning that only a large effect would be observed with this sample size.

The hypothesis was rejected, demonstrating the potential utility of fractography into the recent postmortem interval (up to 16,000 ADH). The polyserial correlation results and the effect size indicate the need for further investigation with a larger sample and longer postmortem intervals.

Bone Fractures, Forensic Fractography, Accumulated Degree Hours

A176 The Value of Antemortem Skeletal Data in Interpretation of Acute Trauma: Context, Timing, Mechanism, and Likelihood Risk Assessment

Donna Boyd PhD, Radford University, Radford, VA*

Learning Overview: This research highlights the value of antemortem skeletal observations and data in understanding and interpreting acute (perimortem) trauma. Attendees will learn how antemortem conditions, including evidence for pathology and fracture, can inform our interpretations of acute trauma, its timing, mechanism, and context.

Impact Statement: Antemortem data can provide forensic anthropologists and other forensic practitioners with additional information beyond identification. Knowledge of these conditions can provide contextual understanding of perimortem traumatic events, their timing, and mechanism; they can also potentially be used to generate risk assessments for quantitative interpretation of the likelihood of such events.

Analysis of antemortem skeletal conditions has traditionally been of fairly limited use in forensic anthropology, primarily centered on identification of a decedent. This presentation highlights the value of antemortem conditions beyond the realm of forensic identification. Antemortem conditions, particularly those related to traumatic events like fracture and/or disease, typically exhibit evidence of a biological (osteological) response, and consequently hold much potential for understanding the context, timing, and mechanism of perimortem events. Pre-existing skeletal trauma, in some cases, reflects repeated (serial) traumatic episodes and, it is hypothesized, is associated with a higher risk of negative outcomes.

A review of 261 forensic cases from the Radford University Forensic Science Institute (RUFSCI) case files identified 12.63% ($n=33$) that were associated with antemortem conditions of probative value. These primarily fell into the following categories:

Suspicious child deaths for which a repetitive (serial) pattern of fracture was documented and its mechanism (non-accidental injury) supported. This patterned evidence was often only evident through microscopic documentation of a healing (i.e., osteoblastic, osteoclastic) response. It was the key to determination of the timing of events and, ultimately, accurate adjudication of these cases. This was also evident for adult and elderly domestic abuse cases, in which repetitive fracture events in the thorax, upper limbs, and face and even hyoid were prominent.

Documentation of antemortem comorbidities and pathological conditions (e.g., alcoholism, diabetes, osteoporosis) informed the interpretation of perimortem events with regard to susceptibility to accidental fracture.

Understanding the probability of these events based on these priors can increase their probative value and assist with perimortem interpretations of the context, mechanisms, and timing of acute trauma. The use of maximum likelihood ratios in estimating acute trauma mechanisms and quantifying trauma risk is explored. It is recommended that antemortem data in the form of observations of skeletal trauma and evidence of disease be collected and applied toward understanding, interpreting, and possibly predicting acute trauma.

Antemortem, Trauma, Acute Trauma

A177 tRauma: A New Application for Aiding in Blunt Rib Trauma Interpretations

Cortney Hulse, MA*, University of Nevada-Reno, Reno, NV; Elaine Chu, MA, University of Nevada-Reno, Reno, NV; Kyra Stull, PhD, University of Nevada-Reno, Reno, NV

Learning Overview: After attending this presentation, attendees will be familiar with a new Graphical User Interface (GUI), tRauma, which is available for aiding in analysis and interpretation of rib trauma through heat map analysis and robust statistical analyses.

Impact Statement: This presentation will impact the forensic science community by providing statistical substantiation of a practitioner's interpretations of rib trauma, which can help allow trauma analysis to adhere to the *Daubert* criteria and meet the suggestions of the National Academy of Sciences Report from 2009, which pushes for "good science."¹

Trauma analysis is the most common reason that forensic anthropologists provide expert witness testimony, which is continually increasing in demand.² Within a medical examiner's setting, the most common trauma observed is blunt force trauma, specifically to the ribs and cranium.³⁻⁵ However, trauma analysis methods and interpretations of blunt force trauma to the ribs remain heuristic and lack sufficient predictive methodologies.⁶

It is difficult to interpret rib fractures under the same paradigm used to interpret trauma in long or flat bones. First, ribs are structurally unique from all other flat bones and long bones, and therefore behave differently mechanically under strain. Second, ribs rarely are isolated at time of impaction, and their articulation with the rest of the rib cage causes interactions that can potentially mitigate applied strain. As a result, many practitioners forego interpretation of rib trauma, which may cause loss of information that could contribute to overall interpretation of the death event.

An open access GUI, called tRauma, was created to combat the difficulties associated with blunt force trauma to the ribs. The GUI utilizes a large-scale database of documented rib fractures from geographically diverse medical examiner offices. Each individual included in the database has documented Cause and Manner Of Death (COD, MOD), as well as demographic information, such as height, weight, sex, age, ancestry, and associated health variables (i.e., obesity, pathological conditions, etc.). Every fracture was documented for each individual and included associated details, such as rib number and location, completeness, and fracture type.

tRauma provides three main functionalities: (1) database manipulation that provides heat maps of rib trauma distributions and patterns, (2) fracture location input that provides database cases with similar trauma patterns, and (3) robust statistical analyses to classify a new case based on database information. Database manipulation functions include filtering by associated demographic, fracture, MOD, and COD-related information, or selecting which columns the user considers pertinent for a search. Fracture location input allows for documenting one or all fracture locations of a single case. Finally, statistical analyses provide substantiated statistical support for the user's own rib trauma interpretations.

tRauma can be utilized to help practitioners provide rib trauma interpretations with statistical substantiation, regardless of experience level. This open access resource has the potential to be used as an interpretive tool for rib trauma interpretation based on real-world scenarios that can be directly applied in most instances of forensic anthropological casework.

A178 The Frequency of Wedge Fractures in Experimental Bending of the Tibia

Angela Harden, PhD*, The Ohio State University, Columbus, OH; A Yun-Seok Kang, PhD, The Ohio State University, Columbus, OH; Alexander Bendig, MS, The Ohio State University, Columbus, OH; John Bolte, PhD, The Ohio State University, Columbus, OH; Carla Goldsmith, The Ohio State University, Columbus, OH; Amanda Agnew, PhD, The Ohio State University, Columbus, OH

Learning Overview: After attending this presentation, attendees will understand the importance of experimental research in skeletal trauma analysis and interpretation through an examination of fracture pattern frequencies in a single loading condition.

Impact Statement: This presentation will impact the forensic science community by presenting experimental skeletal trauma fracture characteristic data to evaluate current assumptions regarding fracture patterns and associated loading mechanisms.

The majority of expert testimony provided by forensic anthropologists is analysis and interpretation of skeletal trauma. However, there are still major gaps between current knowledge, skeletal trauma research, and judicial standards of scientific validity. General assumptions regarding fracture patterns and their association with specific loading mechanisms prevail within the field of forensic anthropology. As such, concepts such as wedge fractures are the result of bending and oblique fractures are the result of angled compressive loading are perpetuated without controlled experimental bone trauma data to support their reliability. In order to provide quantifiable methods to support expert testimonies regarding trauma analysis and reconstruction of traumatic events, experimental research conducted on large sample sizes of human specimens employing interdisciplinary methodologies must be utilized. The objective of this study was to test the assumption that a dynamic bending loading mechanism results in wedge fractures.

Fractures of the tibial shaft are the most common of all diaphyseal fractures, specifically, injuries are more common in the middle and distal portions.¹⁻³ The tibia is frequently fractured in pedestrian versus motor vehicle crashes, motorcycle crashes, sports injuries, and high-speed activities.^{2,4} Therefore, all controlled experimental blunt force trauma testing for this study was conducted on the diaphyseal region of the human tibia. The sample for this study consisted of 50 human tibiae (25 females, 66.6 years \pm 22.1; 25 males, 58.6 years \pm 21.2) collected from Postmortem Human Subjects (PMHS) and frozen in saline-soaked gauze until testing to prevent dehydration. Prior to testing, all tibiae were potted at the 20% and 80% sites using an anatomical coordinate system to ensure the same orientation across all tests. All tibiae were impacted dynamically in the lateral-medial direction at 6m/s at the 40% and 60% sites, simultaneously, in a four-point bending scenario. Fracture characteristics of each tibiae were recorded and fracture classifications were determined utilizing the Arbeitsgemeinschaft für Osteosynthesefragen/Orthopaedic Trauma Association (AO/OTA) Fracture and Dislocation Classification system.⁵

Of the 50 tibiae impacted, the following number of fractures per tibiae were observed: one ($n=23$), two ($n=16$), three ($n=6$), four ($n=4$), and five ($n=1$). To control for the possible influence of additional fractures, further evaluation of fracture groups and types was limited to tibiae that resulted in only one fracture. Fracture groups and types observed were simple oblique ($n=3$), intact wedge ($n=6$), fragmentary wedge ($n=5$), intact segmental ($n=2$), and fragmentary segmental ($n=7$). While wedge fractures (intact and fragmentary) were the most common fracture type observed (48%), more than half of the sample (52%) resulted in fractures other than wedge; segmental fractures (39%) and simple fractures (13%). Fifty human tibiae were impacted in precisely the same loading direction at the same rate, yet, there was variation in both the number of fractures per tibia and fracture classifications, demonstrating that loading mechanism should not be assumed based on fracture group and type.

Skeletal Trauma, Fracture Classification, Trauma Analysis

A179 Correlation or Causation? Concealing the Victims and Survivors of Domestic Violence

Micki David, MS*, Florida Gulf Coast University, Fort Myers, FL; Heather Walsh-Haney, PhD, Florida Gulf Coast University, Fort Myers, FL; Erica Baer, PhD, Florida Gulf Coast University, Fort Myers, FL

Learning Overview: After attending this presentation, attendees will have a greater understanding of domestic violence as it intersects and aligns with the Forensic Anthropologist's (FA's) role in a medicolegal death investigation.

Impact Statement: This presentation will impact the forensic science community by adding to the existing literature that supports the wider scope of the FA.

Forensic anthropology literature inconsistently defines the scope of FAs in their role in the identification of the Domestic Violence (DV) etiology with respect to trauma analysis. Historically, FAs remained "behind the curtain," solely evaluating the skeletal trauma, while neglecting the obvious, often pervasive, social problems and mechanisms that may be linked to such traumata. Opponents argued that correlation implies causation and that the FA should avoid opining specific antemortem changes consistent with DV.

However, more recently, researchers infer DV etiologies by evaluating skeletal trauma and circumstantial evidence from a holistic perspective.^{1,2} Proponents of the holistic perspective imply that correlation does not necessarily equate to causation, but that the correlation should be considered. Indeed, clinicians and medical examiners utilize circumstantial data to reveal clues relevant to diagnoses or cause and manner of death determinations. This study provides data to support and validate the FA's responsibility to identify DV etiologies in order to meet the expectations of a modern society and modernized science, especially mid- and post-COVID-19 pandemic, and with the recent dissolution of agencies such as the Florida Coalition Against Domestic Violence (FCADV).

In this study, 117 cases of blunt force trauma were evaluated and parsed between male and female cohorts. Generally, these data revealed that *only antemortem trauma* (e.g., to the exclusion of acute perimortem trauma) was the most common trauma category between male and female cohorts. However, when parsed by sex, the *only antemortem trauma* and *only perimortem trauma* categories were equally as common in females ($p=0.004901$). DV was identified through the FA and medicolegal death investigations and was more common in females ($p=0.001044$), consistent with clinical, psychological, forensic, and sociological literature.^{3,4} Of the 23 females represented in this study, 15% had medical documentation to inform the antemortem trauma, whereas 63% of males ($n=94$) had similar documentation. These statistical analyses were performed using R-Studio Statistical Analysis software.

These findings support the need for an investigation of antemortem injuries, especially when the cause of death is unknown. This study also highlighted that the FA tends to be called in for a focused perimortem trauma analysis by the legal authority rather than to conduct holistic trauma analysis that would include healed antemortem injuries on skeletal remains not included in the focused analysis. More specifically, the FA may be asked to evaluate a portion of a decedent's body, leaving the antemortem trauma either undetected or unexplained. This study also highlighted the potential for DV to remain hidden in the decedent's lifeways, carefully captured in their skeletal record. These findings suggested that full-body radiographs should be mandatory in death investigations and that FAs should more consistently acknowledge DV as an etiology. Otherwise, these latent, or simply unidentified, wounds can further silence and conceal a victim or survivor of domestic violence.

Domestic Violence, Blunt Force Trauma, Death Investigation

A180 Indirect Gunshot Trauma to the Skeleton: A Meta-Analysis and Experimental View

Samantha Coberly, PhD*, SNA International, Honolulu, HI

Learning Overview: The purpose of this research is to better understand the circumstances and frequency of indirect trauma in the skeleton. This presentation will allow attendees to recognize where indirect trauma from Gunshot Wounds (GSW) occurs and under what circumstances so that if elements of direct trauma are missing, it may be possible to still identify GSWs.

Impact Statement: This presentation will impact the forensic science community by allowing for better recognition of indirect trauma.

Indirect trauma occurs when the element was not hit directly by a projectile, but sustained damage due to the forces involved from the projectile.¹⁻⁴ As the projectile moves through the body, forces pulse through the tissue as a transfer of energy, taking several forms such as shock waves and temporary cavities. This cavity is thought to be responsible for indirect trauma.²⁻⁶ The temporary cavity, if strong enough, can cause tissue damage far removed from the area of impact.^{7,8} The purpose of this research is to better understand the circumstances and frequency of indirect trauma in the skeleton.

C.A. Pound Human Identification Laboratory (CAPHIL) cases between 1974 and 2020 were examined for indirect GSW trauma through case records/reports/photos and focused on cases with clear entrances and exits. Out of 263 total GSW cases, 29 (24.7%) had indirect trauma. Sixty-five total elements exhibited indirect trauma, with an average of 2.07 per case. Vertebrae, ribs, sternum, and scapula were represented in the sample; vertebrae (32; 49%) and ribs (31; 47.6%) were the majority. With the exception of one case, the indirect trauma was limited to articulating elements only. Twelve cases had known weapons; 58% (7) were handguns.

In addition, eight pigs were shot in the lateral thorax with a handgun; four with a .22cal bullet (one pig was shot twice making five shots in total) and four with a 9mm bullet (four shots in total). The pigs were defleshed, macerated, and analyzed for trauma. All the pigs shot with the .22cal had no indirect trauma. Three of the 9mm pigs had indirect trauma. The indirect trauma was near the element directly hit. The majority were ribs.

Elements with indirect trauma in the CAPHIL sample exhibited multiple trauma patterns: avulsion, incomplete fractures, damage to facets, processes, lamina, pedicles of vertebrae, and bisection of ribs. Comminution was not present in vertebrae but was in ribs. The indirect trauma was less than the elements that were hit directly. The same pattern can be seen in the pig experiment with the 9mm handgun; multiple ribs having clean, complete fractures to the sternal end. Several ribs had similar fractures to the head and neck as well.

Within the literature, indirect trauma is not often discussed in detail, but the possibility is mentioned.⁸⁻¹⁴ Indirect trauma tends to be simple; sharp with clean fractures and rarely comminuted. Oblique, spiral, and linear fractures can occur. Overall, indirect trauma is non-specific.^{2-4, 15-18} This was consistent with the findings of this study. Typically, vertebrae exhibit minor damage to processes and lamina and ribs have damage to neighboring ribs.¹⁷ Although not seen in this study, long bones can exhibit wedge-shaped fractures.^{3,4} One study found that projectiles that caused trauma passed on average 9.68mm from the bone during their trajectory.² Unfortunately, the limitations of the study do not allow for interpretation of distance, but it is logical that the closer to the bone, the more damage is present.

In the literature, indirect trauma has typically been associated with higher-powered weapons, especially rifles.^{9,11,12} The current study found indirect trauma with shotguns, handguns, and rifles. There were two cases in the CAPHIL sample where there was indirect trauma from a .22cal, although pigs shot with the .22cal did not exhibit this. Trauma was also not found far from the wound track or from where there was a direct hit from the projectile, except in one case. Fractures to adjacent bone may result from smaller waves of forces dispersing through the bone rather than directly from the temporary cavity. Further study is needed before conclusions can be drawn. With current research and future study, anthropologists can start to predict when and where indirect trauma will occur. Overall, indirect trauma is generally less than direct trauma, can occur in a variety of scenarios involving multiple types of elements, and can occur with different types of firearms.

Gunshot Wound, Indirect Trauma, Fractures

B1 Development and Validation of the InnoXtract™ DNA Extraction Method for Bone and Teeth Samples

Mah-Ro Khan, MS, Innoenomics Technology, LLC, New Orleans, LA; Hiromi Brown PhD, Innoenomics Technology, LLC, New Orleans, LA; Hailey Holt BS, Innoenomics Technology, LLC, New Orleans, LA; Joanne B. Sgueglia BA, Innoenomics Technology, LLC, New Orleans, LA; Sudhir K. Sinha PhD Innoenomics Technology, LLC, New Orleans, LA*

Learning Overview: After attending this presentation, attendees will understand the development and utility of a novel extraction and bead purification kit designed specifically for the extraction of degraded DNA from compromised bone samples, demonstrating the potential use of this new technology.

Impact Statement: This presentation will impact the forensic science community by providing a new tool for degraded DNA extraction from bone and tooth samples. The method can be automated for high throughput and help to provide further benefit in solving missing person and forensic cases.

InnoXtract is a nanoparticle magnetic bead-based DNA extraction method with optimized digestion and binding buffers for high recovery and reproducible DNA yield from highly degraded forensic samples such as hair shafts and bone. We report here an optimized method for demineralization and digestion of 40 mg of bone and tooth samples for purification of DNA utilizing the high yield InnoXtract DNA purification method. The InnoXtract method was developed to address challenges commonly seen in bone samples, including low-template, highly degraded, and/or inhibited DNA. Forensic crime laboratories receive bone and teeth as evidentiary samples and process them for DNA evidence as a means of identification of individuals. Oftentimes, nuclear DNA is too scarce and degraded to enable sufficient profile recovery from bone using standard methods. Even with current Short Tandem Repeat (STR) kits available on the market, the ability to obtain meaningful profiles may be limited due to the low amount of recovered nuclear DNA. In most cases, laboratories will potentially try to extract mitochondrial DNA (mtDNA) from the bone as there are hundreds or thousands of copies per cell compared to the nuclear DNA. However, the process of recovering, processing, and analyzing the mtDNA can be labor intensive and time consuming on resources in the forensic laboratory. This presentation presents an extraction kit with specially designed buffers and magnetic beads capable of recovering fragmented and low-level DNA from samples such as bone. This will save time and effort on the part of the lab as it fits into the standard workflows of forensic laboratories and has the capabilities of producing greater DNA quantities and more successful STR profiles for difficult sample types. Optimization studies included improved conditions to pretreat bone and teeth to allow for complete digestion. Validation studies were performed to evaluate sensitivity, stability, repeatability and reproducibility, non-probative case type samples, contamination and method comparisons adhering to the Scientific Working Group on DNA Analysis Methods (SWGDM) guidelines. The InnoXtract extraction method yielded ample DNA (over 800 pg) from severely insulted bone and teeth samples to produce interpretable autosomal STR and InnoTyper 21 profiles. The method is also amenable to automation and high-throughput sample processing.

DNA Extraction, Bone, InnoXtract™

B2 The Effects of Temperature and Precipitation on the Amount of Recoverable Human DNA From Soil During Decomposition

Wesley Wagner, Duquesne University, Pittsburgh, PA; Pamela Marshall, PhD, Duquesne University, Pittsburgh, PA*

Learning Overview: From this presentation, attendees can hope to learn about how environmental factors (temperature and precipitation) can affect the quality and amount of DNA that can be extracted from soil during human decomposition.

Impact Statement: This project hopes to impact the forensic science community by attempting to find a relationship between the amount of recoverable DNA and certain environmental factors: temperature and amount of precipitation.

When it comes to human decomposition, various studies have focused on any number of variables, including, but not limited to, temperature, soil pH, soil type, insect activity, medical conditions of deceased, soil moisture, weather patterns, scavenging activity, and many others. The two factors that are largely seen as contributing the most to the decomposition processes are temperature and soil moisture; however, these studies largely focused on the rates of decomposition of the sample.^{1,2} This project aims to expand the focus from the decomposing sample to the soil surrounding it. More specifically, this project prioritizes the presence of DNA that has leached into the soil by the decomposing sample, and what effect the two aforementioned variables, temperature and soil moisture, have on the amount and purity of recoverable DNA. To accomplish this, 18 equal sized human tissue samples will be buried into cloth grow pots and will be set to decompose outdoors. While decomposition is occurring, both temperature and soil moisture (in the form of precipitation) will be recorded at the experiment site. At one, three, five, seven, nine, and twelve months, three of the samples will be removed, and the soil immediately around the sample will be collected. The amount and purity of DNA extracted from the soil samples will be quantified using a Nanodrop. It is hypothesized that the amount of DNA recoverable from soil during human decomposition will rise along with increases in temperature and will also increase with higher amount of precipitation and humidity.

Decomposition, Soil, DNA Extraction

B3 Extraction Efficiency Testing of Degraded Bone Samples: Comparing Two Extraction Methods for Use in Downstream Massively Parallel Sequencing (MPS) Applications

Emily Deem, BS, Western Carolina University, Cullowhee, NC; Katie Zejdlik, PhD, Western Carolina University, Cullowhee, NC; Tiffany Saul, PhD, Middle Tennessee State University, Murfreesboro, TN; Frankie West, PhD, Western Carolina University, Cullowhee, NC*

Learning Overview: After attending this presentation, attendees will have a better understanding of the need for an extraction protocol that maximizes recovery of small fragments of DNA for compromised forensic bone samples for potential use with massively parallel sequencing applications.

Impact Statement: This presentation will impact the forensic science community by providing information on the differences in DNA recovery and performance of two DNA extraction methods.

In recent years, investigative genetic genealogy (IGG), which involves the use of genealogical methods combined with DNA analysis to generate potential familial matches, has become an important tool which applies massively parallel sequencing (MPS) in solving cold and active cases.¹ Traditionally, forensic DNA amplification methods have relied on the need to amplify large (150-500 base-pair) targets, specifically, short tandem repeats (STRs) for forensic profiles.² With MPS, smaller targets, such as single nucleotide polymorphisms (SNPs), have become useful for identification as well as ancestry and phenotype prediction.^{3,4}

Traditional commercial extraction protocols for forensic DNA have not focused on maximum recovery of small fragments, whereas ancient DNA (aDNA) research has shown evidence for increased recovery of even highly degraded samples in excess of one million years.^{5,6} When DNA yields are expected to be low from skeletonized remains, it is crucial that the implemented DNA extraction technique will maximize the quality and quantity of the DNA extracted. Given the new application of MPS in forensic DNA workflows, a comparison of forensic and ancient DNA extraction techniques was merited.

This study analyzed the quantity and quality of DNA recovered from two extraction methods involving degraded bone samples. A modified protocol as described in Rohland *et al.* was used for the aDNA extraction technique, while the PrepFiler® BTA Forensic DNA Extraction Kit from Applied Biosystems was used for the forensic extraction method.^{7,8} Seven humeri, obtained with permission from Western Carolina University's John A. Williams Human Skeletal Collection, were used in this study. A total of 100 mg of bone powder were collected from each bone sample, with 50 mg from each bone sample designated for each method. Samples were quantified using the Quantifiler™ Trio Quantification Kit from Applied Biosystems.⁹ All statistical analyses were performed in R (version 4.0.4) and Microsoft Excel.

One-way ANOVA tests were performed to compare small target DNA concentration and large target DNA concentration yields from both extraction methods. The results from the small target ANOVA test showed that there was no significant difference in the yields from both methods ($F_{1,12}$, $p = 0.418$). In addition, the results from the large target ANOVA test were similar, in that there was no significant difference in the yields from both methods ($F_{1,12}$, $p = 0.465$). Both methods performed similarly in their abilities to remove PCR inhibitors and in degradation indices. Further testing with a larger sample size is needed for more conclusive results.

The goal of this research is to determine the optimal DNA extraction method for maximum recovery of small DNA fragments in skeletal samples of forensic age for downstream MPS applications.

Massively Parallel Sequencing, DNA Extraction, Human Identification

B4 Evaluating the Effectiveness of Microbial DNA Extraction Kits for Intimate Samples

Grace Rutledge, BS*, Sam Houston State University Department of Forensic Science, Huntsville, TX; Aaron Lynne, PhD, Sam Houston State University Department of Biological Sciences, Huntsville, TX; Rachel Houston, PhD, Sam Houston State University Department of Forensic Science, Huntsville, TX; Sheree Hughes, PhD, Sam Houston State University Department of Forensic Science, Huntsville, TX

Learning Overview: After attending this presentation attendees will have a better understanding of the vaginal and penile microbiomes and how they can potentially relate to sexual assault cases.

Impact Statement: This presentation will impact the forensic science community by presenting foundational data for the potential use of microbial DNA as a complementary type of evidence in sexual assault cases when sperm is absent from the evidence.

When a sexual assault is reported, semen (containing sperm cells) collected via intimate swabs during a sexual assault kit examination can support a claim that a sexual act occurred and can potentially be tied to a specific individual using DNA typing.¹ However, collection and processing of sperm evidence may not be possible in cases such as when the sexual assault did not result in ejaculation, barrier contraception such as a condom is used, the perpetrator having a low sperm count, or has had a vasectomy.² In addition, potential victims may delay reporting an incident, or shower prior to the sexual assault exam, reducing the success of retrieving adequate amounts of biological evidence for DNA typing.³

Therefore, alternate types of evidence such as microbiota from male and female genital areas would be beneficial in the absence of sperm. In regards to sexual assaults and the human microbiome, the vaginal and penile microbiomes are the two most important body sites in heterosexual cases. However, little is known about the microbiome of these sites and their potential application in some sexual assault cases.

The aims of this research were to evaluate the effectiveness of five commonly used commercial DNA extraction kits used to purify DNA from a microbial biomass and to further establish the baseline vaginal and penile microbiomes. Five commercial microbial DNA extraction kits (Invitrogen® Purelink™ Microbiome DNA Purification Kit, PDQeX prepGEM Bacteria Kit, QIAGEN® QIAamp® DNA Mini Kit, QIAGEN® DNeasy® Power Soil Kit, and QIAGEN® QIAamp® DNeasy® UltraClean® Microbial Kit) were evaluated. The variation in bacterial composition across donors was also explored as well as identifying unique bacteria to donors.

Overall, the Invitrogen® Purelink™ Microbiome DNA Purification Kit was found to be the best performing DNA extraction kit as it recovered the highest amount of DNA across the representative microbial populations. This method was then used for a proof-of-concept study with male and female intimate samples (N = 10 of each) to demonstrate the microbiota normally present in the penile and vaginal microbiomes using next generation sequencing technology to target the V3 region of the 16S rRNA gene. A wide range of microbial genera and species were seen across all male donors. However, all the female samples had a very high relative abundance of the *Lactobacillus* genus (>90%). Additionally, unique genera and species were identified in most donors demonstrating the potential use of microbial evidence for identification purposes.

B5 The Development of a Fully Automated System Employing Parallel Processing for Highly Efficient Extraction and Purification of DNA From a Range of Challenging Samples

Matthew Ludeman, PhD, Thermo Fisher Scientific, South San Francisco, CA; Angela Chen, MS, Thermo Fisher Scientific, South San Francisco, CA; Leo Lai, BSc, Thermo Fisher Scientific, South San Francisco, CA; Julio Mulero, PhD, Thermo Fisher Scientific, South San Francisco, CA; William Hutchens, BSc, Hamilton Company, Reno, NV; Kevin Miller, PhD, Hamilton Company, Reno, NV*

Learning Overview: The work presented here will provide attendees an understanding of a newly developed DNA extraction and purification system that is capable of improving sample processing efficiencies in a range of potential settings.

Impact Statement: This work will impact the forensic community by introducing a new method for efficient and versatile extraction of DNA from samples.

A system that combines a highly robust extraction chemistry with medium/high-throughput automated liquid handling and a DNA extraction/purification workflow capable of efficiently processing a range of challenging samples is presented here. Key to this platform minimizing runtimes is its ability to execute liquid handling steps and extraction/purification steps in parallel -- 96 samples can be processed on this system in approximately 80 minutes. In addition to performance on challenging bone, tooth and adhesive containing samples, also demonstrated here is the ability of this combined system to effectively process certain frequently encountered case-type samples, particularly mock touch/trace samples.

In studies on challenging bone, tooth and adhesive-containing samples, this platform delivered results that were comparable to those seen with a well-established on-market automated DNA purification instrument that has significantly less throughput capacity (13 samples per run versus 96 samples per run, with both systems employing offline lysis). Good repeatability and reproducibility over two independent experiments on this platform was demonstrated with a challenging bone sample, as well as good correlation to performance seen on the existing lower throughput platform, with respect to DNA yields, and downstream STR profile quality and completeness. Additional experiments with tooth and adhesive-containing samples, as well, returned results very consistent with the above-described findings. Further evidenced in these studies was similar comparative performance capabilities with a range of mock touch/trace case-type samples. As a test of the sensitivity of this system on a common body fluid/substrate pair, a sample set consisting of a dilution series of dried blood spotted on cotton swabs was processed. Full STR profiles were consistently obtained with as little as 0.63 μ L of blood input, and either full or almost full profiles were seen down to 0.16 μ L blood input. Importantly, over the diverse sample set examined in this validation study, including swabs of blood stains on denim, there was no indication of inhibitory factor carry-through in any of the eluates.

In conclusion, on a set consisting of 96 case-type sample lysates, the combined system described here can deliver results highly comparable to those seen with a medium/low throughput platform in significantly less time and with output plasticware options, such as 96 well PCR plate, that are more efficient for typical downstream processing.

Automation, DNA, Extraction

B6 A Comparison of Five DNA Extraction Methods to Extract Genomic DNA From Human Body Fluid and Fly Artifact Samples

Alexis Garloff, Towson University, Towson, MD; Kelly Elkins, PhD, Towson University, Towson, MD; David Rivers, PhD, Loyola University Maryland, Baltimore, MD*

Learning Overview: After attending this presentation, attendees will better understand the impact of DNA extraction methods on DNA recovery and STR DNA profiling from human body fluid samples and fly artifacts deposited by flies fed on human body fluids.

Impact Statement: This presentation will impact the forensic science community by informing attendees about the results of a study comparing different methods of DNA extraction for human DNA typing success from body fluid samples and fly artifacts deposited by flies fed on human body fluids including blood and semen.

Human identification is integral to forensic investigation. Environmental conditions, surface porosity, and evidence type can influence DNA recovery from submitted evidence samples. Numerous methods have been shown to successfully extract high quality and sufficient quantity of DNA from human body fluids for STR DNA typing to aid in investigations. In this study we evaluated four methods to extract human DNA from human body fluid samples and *Calliphora vicina* fly artifact samples. The fly artifact samples include fly defecate and regurgitate after the flies fed on human blood or semen and were sampled over several days and weeks. This study analyzed the results of quantitative PCR DNA yield and degradation index, UV-Vis spectroscopy DNA quality estimate, and STR DNA profiles generated from four different DNA extraction techniques.

Methods and Discussion: This study obtained DNA from body fluid and fly artifact samples using four different DNA extraction methods: Qiagen EZ1® DNA Investigator® kit, Monarch Genomic DNA Purification Kit, Zymo Quick-DNA Miniprep Plus Kit, and the prepGEM Universal DNA Extraction Kit. Three 1.2 mm punches were isolated from filter paper and combined for the human body fluid blood and semen control samples and fly artifacts in triplicate. The DNA quantity and degradation index was measured using the Qiagen Investigator® Quantiplex® Pro RGQ Kit and the quality was estimated using the 260/280 nm absorbance ratio acquired using a Thermo Fisher NanoDrop spectrophotometer. The average and standard deviation of the DNA recovered from each sample type was tabulated. STR profiles were generated using Qiagen's® Investigator® 24plex QS kit, a kit designed to amplify 24 loci including the expanded Combined DNA Index System (CODIS) core loci and European Standard Set (ESS) loci for a total of 22 STR loci, amelogenin, SE33, and DYS391. STR amplicons were separated and analyzed on an Applied Biosystems 3500 capillary electrophoresis instrument. The analysis suggests that DNA extraction methods that perform best isolate the DNA from other cellular material and concentrate the DNA prior to elution. Substitution of different buffers can improve DNA yield in some cases. Careful selection of the DNA extraction method can improve the DNA yield and STR profile completeness in forensic case analyses where other methods have failed. Partial STR profiles were obtained from the *Calliphora vicina* fly artifacts. For future studies, whole genome amplification prior to STR typing may enable us to obtain more complete profiles.

DNA Extraction, STR Profiling, Fly Artifacts

B7 A Comparison of DNA Extraction Techniques for the Recovery of Bovine DNA From Maggot Crops

Cesar Cantu, BS, Sam Houston State University, Huntsville, TX; Sibyl Bucheli, PhD, Sam Houston State University, Huntsville, TX; Rachel Houston, PhD, Sam Houston State University, Huntsville, TX*

Learning Overview: This presentation will provide attendees with information regarding different DNA extraction methods that can be used to recover host DNA, in this case, bovine DNA, from the crops of maggots. Assessment of the DNA extraction methods was performed by measuring the bovine DNA, quantified by qPCR, and the quality of the extract by assessing inhibition. The relation between the recovery of DNA from maggots and the quality and quantity of extract is essential for using maggots as samples for forensic casework.

Impact Statement: The use of maggots as a potential sample for human identification has been shown to be possible to recover human mitochondrial DNA and short tandem repeats (STRs) from the crops of a maggot. This project aids in the implementation of maggots as a sample type that can be useful in unique cases in which a body is not present, or other samples are not available. However, to successfully use maggots in forensic laboratories, an optimal DNA extraction method must be determined. This study works toward that goal by evaluating different DNA extraction methods based on the quality and quantity of DNA recovered.

Forensic entomology aims to aid criminal investigations through the use of insects, and it is primarily associated with estimation of the postmortem interval (PMI). Another potential use of insects is the recovery of human DNA, for example, from the digestive tracts of larvae of Diptera (maggots) found on decomposing bodies. Studies have shown that human DNA can be recovered from the crops of maggots, making them useful in identification of individuals when tissue is not available or in establishing a link between a scene and a victim. While several factors regarding the recovery of human DNA from crops have been studied, DNA extraction methods have not been thoroughly assessed. Determining an optimal extraction method could aid crime laboratories in using human DNA extracted from maggot crops. In this study, four DNA extraction methods were chosen to extract bovine DNA from maggots: a silica-coated magnetic bead, silica column, enzymatic lysis, and a chelating agent method.

Bovine DNA was targeted as a substitute for human DNA to test the above listed DNA extractions kits. Fly traps with beef heart were placed at Southeast Texas Applied Forensic Science (STAFS) Facility and then moved to incubators once eggs and maggots were observed to rear maggots to the third larval stage (instar). Maggots were identified to the family level prior to DNA extraction. Four DNA extraction methods (Chelex®, PDQeX forensicGEM, EZ1® DNA Investigator, DNeasy® Powersoil® Pro Kit) were evaluated based on the quantity of bovine DNA and quality of extract. Extractions were performed on whole maggots and dissected crops. Quantification was performed using real-time PCR (qPCR) on a StepOne™ Real-Time PCR System with SYBR® Green using bovine specific cytochrome b primers. The quality of extracts was determined by checking for inhibition using commercial qPCR chemistries with an internal PCR control (IPC). When using whole maggots, Powersoil® Pro (n=10, 0.668± 0.458 ng/μL) yielded the highest average DNA yield, while EZ1® DNA Investigator (n=10, 0.605± 0.403 ng/μL) yielded the highest average from isolated crops. Chelex (Crops: n=10, 0.029± 0.033 ng/μL) and forensicGEM (Crops: n=10, 0.021± 0.032 ng/μL) yielded low amounts of bovine DNA, and DNA extracts were inhibited, unlike EZ1® and Powersoil® Pro, which have purification steps. It is recommended to use EZ1® DNA Investigator coupled with automation on EZ1® Advanced XL to recover DNA from maggot crops.

Forensic Entomology, Maggots, DNA Extraction

B8 Magnetic Bead Capture of Sperm Cells by Sperm-Specific Antibodies

Samantha Davis, MS, Sam Houston State University, Huntsville, TX; Julia Wang, MS, Sam Houston State University, Huntsville, TX; Rachel Houston, PhD, Sam Houston State University, Huntsville, TX; Sheree Hughes, PhD, Sam Houston State University, Huntsville, TX; Brendan Chapman, BSc, Murdoch University, Perth, Australia; Andrew Currie, PhD, Murdoch University, Perth, Australia*

Learning Overview: Upon attending this presentation, attendees will gain insight into the forensic applications of immunomagnetic cell isolation.

Impact Statement: This presentation will impact the forensic science community by presenting support for novel applications of sperm-specific antibodies in the use of testing sexual assault evidence.

Intimate swabs from sexual assault kits contain mostly female epithelial cells with relatively few sperm cells. Differential extraction, the established method of separating these cell types, is labor-intensive, time-consuming and often fails to improve sperm to epithelial cell ratios sufficiently to resolve a minor male DNA profile. This project investigated the use of antibodies specific to proteins expressed on the acrosome of human sperm cells. A cocktail of antibodies specific for acrosome proteins were previously shown to have a high affinity for spermatozoa in pilot flow cytometry studies.

Immunomagnetic beads (IMBs) conjugated with anti-SPAM1, anti-SPACA1 and anti-ZPBP antibodies were constructed and initial experiments showed that the highest quantity of sperm was isolated with anti-SPAM1 at 0.05 mg/mL, anti-SPACA1 at 0.025 mg/mL, or anti-ZPBP at 0.025 mg/mL. Coupling antibodies for each of these proteins individually to magnetic beads was shown to sufficiently isolate sperm for DNA extraction from single donor sperm cell concentrations at 10^3 cells/mL. The technique proved to be sensitive with full STR profiles being generated from sperm cell concentrations of 10^3 cells/mL using the anti-ZPBP antibodies and mixtures of all three antibodies. When sperm cells were mixed with female vaginal epithelial cells (4:1 female to male), a greater carryover of the female epithelial cell fraction was observed when sperm isolation by IMBs was performed prior to cell lysis compared to when preferential lysis of epithelial cells was performed before sperm isolation.

Initial experiments were performed with Dynabeads® M-270 Carboxylic Acid, but these beads were found to bind both sperm and female vaginal epithelial cells non-specifically. Blocking the beads with bovine serum albumin (BSA) reduced the non-specific binding of both sperm and epithelial cells. Given the reduced amount of isolated sperm and subsequently extracted DNA from the antibody-coupled, blocked magnetic beads, optimization of the cell isolation process requires further exploration to improve sperm selection.

Immunomagnetic Beads, Spermatozoa, Sexual Assault

B9 DNA Methylation of Decedent Blood Samples to Estimate the Chronological Age of Human Remains

Patrick Yew, MS, California State University-Los Angeles, Los Angeles, CA; Yessenia Anaya, MS*, California State University-Los Angeles, Los Angeles, CA; Katherine Roberts, PhD, California State University-Los Angeles, Los Angeles, CA and California Forensic Science Institute, Los Angeles, CA; Winters Hardy, PhD, Los Angeles County Department of Medical Examiner-Coroner, Los Angeles, CA*

Learning Overview: After attending this presentation, attendees will understand the strengths and current limitations when employing DNA pyrosequencing to predict the donor age of a blood sample.

Impact Statement: This presentation will impact the forensic science community by providing attendees with the statistical findings of our age prediction models based on the correlation between the methylation profile and chronological age. We will also provide data on the accuracy of the age predictions.

Chronological age estimation may offer valuable investigative leads in human identification cases. Bisulfite pyrosequencing analysis of single CpG sites on five genes (KLF14, ELOVL2, C1orf132, TRIM59, and FHL2) was performed on 264 postmortem blood samples from individuals aged three months to 93 years. The goals were to develop age prediction models based on the correlation between the methylation profile and chronological age and to assess the accuracy of the prediction. Linear regression between methylation levels and age at each CpG site revealed that the five markers show a statistically significant correlation with age.

The methylation data from a training set of 160 postmortem blood samples were used to develop an age prediction model with a correlation coefficient of 0.65, explaining 73.1% of age variation, with a mean absolute deviation from the chronological age of 7.60 years. The accuracy of the model was evaluated with a test set of 72 samples producing a mean absolute deviation of 7.42 years.

The training and test sets were also categorized by specific age groups to assess accuracy and deviation from chronological age. The data for both sets revealed a lower prediction potential as an individual increases in age, particularly for the age categories above 50 years.

DNA Pyrosequencing, Decedent Blood, Donor Age Estimation

B10 An Improved Method for the Analysis of Bisulfite Modified DNA Samples

Deborah Silva, PhD, Hofstra University, Hempstead, NY; Caitlin Lydon, Hofstra University, Hempstead, NY*

Learning Overview: After attending this presentation, attendees will have a better understanding of the importance of developing new and improved methods to analyze forensic samples that undergo harsh chemical treatments such as bisulfite modification.

Impact Statement: This presentation will impact the forensic science community by presenting a modified protocol that can be used to improve the analysis of samples that are bisulfite modified.

DNA is important evidence in forensic cases and the human genome has been used to identify persons involved in crimes since the 1980s. More recently, forensic analysts have begun to expand the study of DNA and its capabilities to aid in forensic investigations and started to explore the epigenome.

Throughout life, a person is exposed to the external environment and behavioral habits affect specific portions of the DNA. These changes affect gene expression without changing the DNA sequence. The epigenome is the “layer of information” on top of our existing genetic code, and it contributes to physical and behavior differences between individuals and complete human populations.¹

DNA methylation is the most studied epigenetic modification and different methylation patterns have been shown to be useful to identify body fluids and to estimate the age of a sample donor, for example.^{2,3}

When analyzing DNA methylation, bisulfite modification is a process often used to get information about a DNA strand’s methylation pattern since the methylated status of a DNA sample is lost during the process of PCR amplification.

However, the process of treating DNA with sodium bisulfite is harsh since it involves changes in the chemical structure of the DNA (unmethylated cytosines are converted into uracils). This treatment is not ideal to be used with forensic samples since DNA is damaged in the process, but it is necessary to make possible the analysis of methylation patterns.

The goal of this research was to use a modified method to bisulfite treat the DNA followed by a modified PCR to repair the damaged strands and to improve data generation. To achieve this goal, different DNA samples were tested using the modified protocol. These samples included standard DNA, DNA extracted from buccal cells without undergoing any further treatment, and DNA samples extracted from buccal cells that were exposed to UV light and heat treatment to mimic forensic samples.

First, the EZ DNA Methylation-Lightning™ kit was used to bisulfite modify all DNA samples. Then a modified PCR that involved adding repair enzymes to the reaction mix was performed and an extra step to thermocycling conditions was added to repair the damaged DNA before the start of the amplification process. The NanoDrop™ One was used to analyze the results of the modified protocol to confirm the quality and quantity of methylated DNA samples.

The results obtained in this study are important to show that it is possible to improve the quality of DNA samples after going through a harsh chemical modification, which will then provide better results in DNA amplification and other downstream methods and analysis.

Forensic Epigenetics, Damaged DNA, Modified Bisulfite Treatment

B11 The Use of a Mobile Fingerprint Identification Device in the Field and DNA Evidence: Benefits and Consequences

Amber Wetherbee, Ohio Northern University, Ada, OH; Hope Hardman, Case Western Reserve University, Cleveland, OH; Nasir Butt, DPhil, Cuyahoga County Medical Examiner's Office, Cleveland, OH; Dawn Schilens, BS, Cuyahoga County Medical Examiner's Office, Cleveland, OH; Thomas Gilson, MD, Cuyahoga County Medical Examiner's Office, Cleveland, OH*

Learning Overview: After observing this presentation, attendees will have a better understanding of the feasibility of collecting fingerprints at a death scene in cases where the decedent's hands may contain crucial evidence that needs to be collected and whether the risk of contamination outweighs the benefits that a mobile fingerprint device can provide.

Impact Statement: This presentation will impact the forensic science community and the evolving modern forensic science world by providing guidelines of proper handling and decontamination of a mobile fingerprint device when used in the field to expedite the identification and investigation and at the same time to protect the DNA evidence for downstream STR analysis. The evidence of DNA contamination on a mobile fingerprint device may affect the ability to implement its use in the field when using the simple decontamination methods like alcohol wipes etc.

Identifying a decedent is an essential element of death investigation. Mobile fingerprint devices could prove extremely beneficial in identifying decedents in the field so the investigation can begin. The mobile fingerprint identification device used in this study relies on the refractive indexes produced by the valleys and ridges within a person's fingerprint. The light passes through the area sensor of the device and into a lens which then focuses the light, and the camera converts it into a digital image. These devices can typically capture anywhere between 1-10 images which can then be sent to the AFIS database to perform a search of the ten-print database.

This study assessed whether alcohol wipes were sufficient to reduce DNA contamination on the device so that it could be used in the field by investigators for rapid identification. In order to do so, 20 subjects were selected for the study. Each subject was digitally fingerprinted by placing both index fingers on the area sensor of the device. Three swab sets were taken for each test case; the first set of the swab was of the entire device after the device had been handled by the operator, the second set of the swab was only of the sensor area of the device after fingerprinting the subject, and the third set was of the entire device after cleaning it with an alcohol wipe. In addition, a control fingerprint of the right index finger of each subject was taken onto an acetate fingerprint card.

DNA from all sets collected from each subject was extracted using Promega's Maxwell 48 extraction instrument and quantified using Promega's PowerQuant system on a QuantStudio 5. All qualified samples were amplified using Promega's PowerPlex Fusion using a ProFlex Thermal Cycler and amplified DNA was run on a 3500 Genetic Analyzer. The data was analyzed using GeneMapper-IDX software. The DNA obtained from 38 swabs out of 86 total swabs collected did not qualify for STR amplification as per the laboratory autosomal STR amplification guidelines. All the swabs (pre cleaning and post cleaning) collected from the device were successfully amplified with useable profiles. The data from these showed contamination from the operator in majority of the swabs. In some cases, contamination from the subjects was also seen on the device. Only 3 subjects out of 20 could be STR-typed positively from their fingerprints taken on the sensor area of the device. This implies that although these mobile fingerprint devices can rapidly identify decedents in the field and allow the investigation to begin, they pose a risk for contamination which can be harmful to the investigation if there is evidence that needs to be collected from the hands of the decedent.

This research is relevant to modern forensic science because it highlights that alcohol wipes on their own are not sufficient to prevent DNA contamination on mobile fingerprint identification devices and therefore other methods of decontamination and handling of the device should be explored before employing its use in the field by investigators. One such method could be to clean the device with a 10% bleach solution, only handle the device when wearing a mask and gloves. Another method may be to use a new device at each scene.

Mobile, Identification, Contamination

B12 Evaluating Different Collection Tools for Transfer DNA Deposited on Wooden Surfaces

Antonia Atkinson, BS, University of Indianapolis, Indianapolis, IN; Alba Craig, BA, University of Indianapolis, Indianapolis, IN; Krista Latham, PhD, University of Indianapolis, Indianapolis, IN; Cynthia Cale, MS, Houston Forensic Science Center, Houston, TX*

Learning Overview: After viewing this presentation, attendees will appreciate how collection tools can impact subsequent genetic testing.

Impact Statement: This presentation will impact the forensic science community by providing data that addresses the amount of biological material collected from wood surfaces by two different swabs and how that influences DNA profile composition.

The collection of transfer DNA from evidentiary items is an increasingly common and important part of many criminal investigations. A significant amount of research has been devoted to optimizing the collection and analysis of transfer DNA samples. Collection of transfer DNA typically utilizes a cotton swab, which has been shown to be the best choice for a variety of surfaces.^{1,2} However, as DNA extraction and amplification technologies continue to improve the ability to purify and analyze small quantities of degraded DNA, collection techniques should also strive for the maximum collection of biological material from item surfaces and the maximum release of cells during the extraction process. A smaller swab size to concentrate sample collection and a layered swab head to trap more cells might increase the amount of biological material obtained during the collection process in comparison to the traditional cotton tipped swabs utilized by many investigative agencies.

The goal of this study is to compare the results of two different swab types in the collection of transfer DNA to test for differences in the quantity of the DNA collected from the sampled item and the quality of the DNA profile obtained. The two types of swabs utilized for comparison were a traditional cotton-tipped swab with wooden handle (Swab A) (Puritan) and a cotton swab with a layered and ejectable tip from a plastic handle (Swab B) (Gentueri Inc.). Twelve wooden rulers were divided into two even sections and were decontaminated with a 10% bleach solution and exposure to UV light for 15 minutes. Three participants were asked to vigorously handle all surfaces of a ruler for one minute. Immediately after handling, one section of the ruler was wet-swabbed with Swab A, and the other section was wet-swabbed with Swab B. This was repeated on four different days, for a total of 24 samples (12 samples per swab type). The QIAamp DNA Mini Kit (QIAGEN) was used for purification of the DNA. The following Applied Biosystems™ products were used to process the samples through the DNA analysis workflow: samples were quantified with Quantifiler™ Trio DNA Quantification Kit on a 7500 Real-Time PCR System, amplified using Globalfiler™ Amplification Kit on a ProFlex™ PCR System, and analyzed on a 3500xL Genetic Analyzer. The following null hypotheses were tested: (1) the number of alleles detected will not vary between the two swabs and (2) the quantity of DNA collected will not vary between the two swabs.

During collection, it was noted that Swab B was easier to use, and the ejectable tip could help eliminate accidental contamination. The DNA quantity for the samples in this study ranged between 0.0006 ng/ul and 0.0123 ng/ul. No sample yielded alleles at all loci. T-tests were performed to investigate differences in the DNA quantities and number of alleles detected between Swab A and Swab B. A significant difference in DNA quantity ($p=0.004$) and number of alleles ($p=0.0007$) exists between the two swab types. Therefore, both null hypotheses are rejected since Swab A collected more DNA and more alleles were detected during amplification of Swab A samples. In conclusion, while Swab B was much easier to use than Swab A, Swab A performed better in collection and release of biological material from wooden surfaces.

B13 Extraction Techniques to Increase DNA Recovery From Touch DNA Samples

Ryan James Hinojosa, BS, Cedar Crest College, Allentown, PA; Jillian Conte, PhD, MicroGEM, Charlottesville, VA; Lawrence Quarino, PhD, Cedar Crest College, Allentown, PA; Janine Kishbaugh, MSFS, Cedar Crest College, Allentown, PA*

Learning Overview: After attending this presentation, attendees will understand how the method by which DNA is extracted from touch DNA samples greatly impacts DNA yields.

Impact Statement: This presentation will impact the forensic science community by advancing the knowledge of how processing multiple cuttings from touch DNA samples in multiple tubes versus a single tube can improve DNA yields. This work could help forensic biologists improve their workflow at the DNA extraction step to increase DNA yield from touch DNA samples.

Increasingly crime laboratories are receiving evidence with touch DNA. In this work, touch DNA is defined as the DNA that is recovered from a sample in which a person's skin has directly or indirectly come into contact with, composed of celled and cell-free DNA.^{1,2} One challenge that exists with recovering touch DNA from evidence is that it is not visible to the naked eye, thus locating a sample can be difficult and DNA analysts often must resort to making an assumption as to how the item was handled. Samples are then collected by swabbing, cutting, scraping, or vacuuming. In this research, sample collection was conducted by cutting and vacuuming.

Following visualization of touch DNA by a novel fluorescent detection method, three 0.5 cm² cuttings were taken from white cotton shirts that were grabbed by volunteers. The "standard method" consists of the three cuttings placed into one 2.0 mL microcentrifuge tube and extraction being conducted. The "combination method" consists of each of the three cuttings placed into separate microcentrifuge tubes and a portion of the extraction process being conducted and then combining these partial extracts into one tube to complete the extraction. Two extraction methods were used and compared – a solid phase extraction that utilizes columns and wash steps (QIAGEN) and a temperature driven, enzymatic extraction (MicroGEM). Samples were quantified for comparison of DNA recovery. Student t-tests and ANOVA statistics were conducted (with $p \leq 0.05$ as the level of statistical significance). The combination method for sample processing obtained up to four times more DNA in some donors. The minimum amount of DNA obtained was about 11 times higher with the combination method than the standard method. This research furthers the knowledge of the forensic community and helps forensic biologists recover higher DNA quantities through sample processing methods and extraction approaches.

Touch DNA, DNA Extraction, Sample Collection

B14 Modeling Assault From Touch DNA

*Jamie Fredericks, PhD, Eastern Kentucky University, Richmond, KY; Michael Lane, PhD, Eastern Kentucky University, Richmond, KY; Beighley Ayers, * Eastern Kentucky University, Richmond, KY*

Learning Overview: Attendees can expect to learn: (1) There is no correlation between the concentration of DNA collected and the average force applied (how hard the target was hit) or the contact time (the time of skin-to-skin contact between the participant's fist and target) of single strikes, and (2) It is possible to determine the sequence of participation when two participants strike a skin surface (one after each other).

Impact Statement: Our study demonstrates that touch DNA has the potential to determine the sequence of punches when a victim is subjected to multiple strikes by multiple individuals. This information can play a pivotal role in determining and corroborating eyewitness statements and establishing who struck a victim of assault and when.

Advances in DNA analysis have led to the ability to generate a DNA profile from minute amounts of DNA, such as 'touch' DNA. Touch DNA is biological material left behind when an individual has handled an object. Forensic medical examiners are often required to collect biological material from individuals that claim to have been assaulted and is playing an increasing role in solving crimes. Traditionally, when an assault has occurred, DNA is collected from hands or fingerprints; however, any area of skin that has made skin to skin contact between the victim and the alleged perpetrator could be swabbed. This aim of this study was to determine whether the forces applied during a mimicked aggravated assault scenario could be modeled from the DNA collected. We investigated the nature of touch DNA transfer, including DNA concentration and subsequent profile generated, when different measures of force are applied and multiple 'assailants' made skin to skin contact with a 'victim'. We wanted to determine whether primary and secondary DNA transfer could aid investigators in determining the sequence of events.

A novel apparatus was developed to mimic aggravated assault. A padded synthetic skin was placed on top of a force plate that would then be punched by participants. After each strike, the skin pad was swabbed, and the DNA concentration was determined before a DNA profile (using the PowerPlex Fusion kit) was generated. The force plate measures various parameters of the strike including, peak force, mean force, and time of force application. Each participant would strike the force plate once, either as an isolated event or as a combination with an additional individual.

Preliminary results have shown that although there was no correlation between the concentration of DNA collected and the average force applied (how hard the target was hit) or the contact time (the time of skin-to-skin contact between the participant's fist and target) of single strikes, it was possible to determine the sequence of participation when two participants strike the skin pad (one after each other). In 89 % of the samples, the second individual that punched the skin pad was observed to be the major contributor.

This study demonstrates that touch DNA has the potential to determine the sequence of punches when a victim is subjected to multiple strikes by multiple individuals. This information can play a pivotal role in corroborating eyewitness statements and establishing the 'by who and when' sequence of events.

Assault, Touch DNA, Force

B15 The Persistence of Transfer DNA on Touched Objects Over Time

Alba Craig, BA, University of Indianapolis, Indianapolis, IN; Krista Latham, PhD, University of Indianapolis, Indianapolis, IN; Cynthia Cale, MS, Houston Forensic Science Center, Houston, TX; Stephen Nawrocki, PhD, University of Indianapolis, Indianapolis, IN*

Learning Overview: The goals for this presentation include attendee appreciation for and increased understanding of: (1) the complexities of transfer DNA sampling and interpretation, (2) the effects of long-term storage on the quantity and quality of transfer DNA recovered from potential evidence items, and (3) how sampling location and timing can influence the DNA profile and interpretation.

Impact Statement: This presentation will impact the forensic science community by increasing the understanding of the persistence of DNA obtained from touched objects stored in a laboratory setting, by providing information on potential changes in DNA quantity and the quality of resulting DNA profiles over time. This will, in turn, provide information that may prove meaningful in terms of the urgency of processing DNA evidence in forensic laboratories experiencing backlogs.

The collection, analysis and interpretation of transfer DNA has been and continues to be highly studied in the forensic DNA community. However, there is a lack of studies that investigate the impact of long-term storage on the persistence of transfer DNA over time. For this study, 12-inch wooden rulers, divided into 9 equal parts for sampling, were handled by participants in order to monitor potential changes in the quantity of transfer DNA obtained and the quality of the resulting DNA profiles over time. Each participant was assigned one decontaminated ruler to handle for a two-minute period. Participants did not wash their hands prior to handling and were instructed to evenly contact the entire ruler surface. Using a single wet swab, one sample was collected from each section of each ruler every other week for fifteen consecutive weeks. To mimic evidence storage in forensic laboratories, the rulers were stored at room temperature in separate paper bags sealed with tape after each sampling event. The following null hypotheses were tested: (1) there will be no change in DNA quantity over time, (2) there will be no change in the quality of DNA profiles over time, and (3) no foreign DNA will be detected.

Samples were extracted using the QIAamp DNA Mini Kit (QIAGEN). Samples were further processed through DNA analysis workflow utilizing Applied Biosystems™ products: samples were quantified with Quantifiler™ Trio DNA Quantification Kit on a 7500 Real-Time PCR System; samples were amplified using Globalfiler™ Amplification Kit on a ProFlex™ PCR System and analyzed on a 3500xL Genetic Analyzer. Additionally, likelihood ratios were generated using STRmix™ v2.6.1.

The data collected in this longitudinal study provides insight into the effects of long-term storage on the recovery of DNA from touched objects. DNA quantity and DNA profile quality varied over time and between participants with some samples yielding no DNA profiles. Likelihood ratios ranged from uninformative to very strong support in favor of inclusion. Interestingly, one sample resulted in the exclusion of the ruler handler. Yet in another sample, a false exclusion of the ruler handler occurred because the apparent single-source profile was most likely a mixed DNA profile.

Based on the results obtained from this study, all null hypotheses were rejected. In conclusion, long-term storage of DNA evidence can have an influence on the persistence of transfer DNA over time which, in turn, can have an effect on forensic investigations.

Transfer DNA, STRmix™, DNA Persistence

B16 An Evaluation of Collection Methods for Direct Polymerase Chain Reaction (PCR) Amplification of Touch DNA Samples

Anna Salmonsens, MFS Bode Technology, Lorton, VA; Abigail Bathrick, MFS, Bode Technology, Lorton, VA; Jonathan Davoren, MS, Bode Technology, Lorton, VA*

Learning Overview: After attending this presentation, attendees will have a better understanding of direct polymerase chain reaction (PCR)-compatible collection methods and the use of direct PCR for touch DNA samples.

Impact Statement: This presentation will impact the forensic science community by recommending effective methods for collecting touch DNA from different substrates prior to direct PCR and presenting data comparing direct PCR and standard processing of touch DNA samples.

Improved methods for generating high-quality DNA profiles from touch DNA samples are of considerable interest to forensic DNA laboratories. Direct PCR amplification, a sample processing method in which a swab or substrate punch is added directly to an amplification reaction without prior extraction or quantification, has been identified as a method that may improve DNA profiles from low-yield touch DNA evidence samples. Direct PCR maximizes the amount of DNA template in a reaction by eliminating the DNA loss that occurs during DNA extraction, quantification, and concentration; however, the amount of DNA available for direct PCR can be affected by the method used for DNA sample collection. This study aimed to identify collection methods that maximize DNA recovery from common touch DNA substrates and to determine whether direct PCR or standard processing methods result in higher quality DNA profiles.

Nine direct PCR-compatible collection methods were used to collect touch DNA from cotton denim, wool, and polyester fabric; plastic microscope slides; metal tools; handgun grips; vinyl shutter samples; brass cartridge casings; foam cups; concrete bricks; and unfinished wooden tool handles. Collection was performed with Puritan® cotton swabs, Copan microFLOQ® direct swabs, and Whatman non-indicating FTA paper that were moistened with sterile water, moistened with 0.1% Triton™ X-100, or left dry. The fabric substrates were sampled via cutting. For each collection method, processing method, and substrate type, eight replicates were prepared from three donors. Samples were processed with two methods: 1) standard processing with DNA extraction and quantification and 2) direct PCR. Amplification for both the extracted and direct PCR samples was performed with the GlobalFiler™ PCR Amplification kit.

Direct PCR was successful for samples collected from plastic slides, polyester fabric, metal tools, handgun grips, vinyl shutters, foam cups, and unfinished wooden tool handles. The highest quality direct PCR results were obtained using microFLOQ swabs for collection. Direct PCR and standard processing produced generally comparable DNA profile results. Direct PCR of samples collected from metal tools and wooden tool handles with dry microFLOQ swabs and handgun grips with microFLOQ swab & water resulted in significantly higher quality DNA profiles than standard processing. Direct PCR was unsuccessful for samples collected from concrete bricks; cartridge casings; and denim, wool blend, and 100% wool fabrics, regardless of the method used for collection.

These results indicate that the success of direct PCR is highly dependent on the substrate from which samples are collected, whereas profile quality is affected by the efficacy of the collection method. In conclusion, direct PCR is an effective method for processing evidentiary touch DNA samples collected from certain substrates, and microFLOQ swabs were the most effective collection method for direct PCR of those tested.

Direct PCR, Touch DNA, Evidence Collection

B17 A Combined Extraction of Protein and DNA From Touch Evidence on Ammunition Cartridge Cases

Ashlee Lynch, BS*, University of California-Davis, Davis, CA; Glendon Parker, DPhil, University of California-Davis, Davis, CA

Learning Overview: After attending this presentation, attendees will have a better understanding of the options for retrieving touch evidence from ammunition bullet cases.

Impact Statement: This presentation will impact the forensic science community by presenting an alternative technique that helps to maximize biological information retrieved from challenging touch evidence.

DNA analysis of touch evidence on cartridge cases has proven difficult despite numerous attempts to improve collection and extraction methods for this important type of evidence. Numerous factors influence the variability of touch evidence such as shedder status, pressure and duration of contact, surface type, and collection and storage.^{1,2} Retrieval of biological information from cartridge cases are even more challenging since firing abrades the surface of the case, removing material, and metal in the case can react with DNA, resulting in oxidation and cleaving of the DNA backbone.^{3,4} Protein is more robust chemically than DNA, and contains genetic and contextual information that could be useful to investigators.⁵ Extraction and analysis of DNA and proteins from touch evidence can provide the maximum amount of information needed for probative results, especially when DNA is limited.⁶

This study evaluated the efficiency of transferring artificial DNA and protein from a glass microscope slide surface into the workflow for seven different collection and transfer methods: the standard wet-dry cotton swab was compared with alternative methods, a 'Copan microFLOQ® direct' swab, with and without lysing agent, and with and without extraction buffer, a cell scraper, and adhesive silicone gel-film sheets.

The results obtained determined that overall the 'Copan microFLOQ® direct' was the most efficient and consistent method with an average transfer of $58 \pm 22\%$ efficiency for DNA and $55 \pm 32\%$ for protein compared to $27 \pm 24\%$ and $2 \pm 27\%$ when using cotton swabs respectively. The evaluation was taken a step further to measure transferred DNA and protein from real fingerprints on a glass microscope slide. Results determined that the cotton swab and the 'Copan microFLOQ® direct' collected an average of 11.8 ± 20 ng and 15.7 ± 18 ng of total DNA, respectively, and 1200 ± 1200 RDU and 2300 ± 1600 RDU of total relative protein density, respectively. This level of relative variation is high but consistent with previous studies for fingerprint deposition.⁴ When normalized for individuals the 'Copan microFLOQ® direct' increased performance by 1.7-fold ($p=0.23$) for DNA and 1.9-fold ($p=0.02$) for protein.

Finally, real-life scenarios were mimicked where the cotton swab and 'Copan microFLOQ® direct' were used to transfer DNA and protein from unfired and fired cartridge cases into the workflow. The cotton swab and the 'Copan microFLOQ® direct' collected an average of 1.1 ± 1.5 ng and 2.8 ± 2.4 ng of total DNA, respectively, and 660 ± 380 RDU and 1200 ± 1500 RDU of total relative protein density, respectively for unfired cases. When fired there was a significant reduction in the amount of DNA material. The cotton swab and the 'Copan microFLOQ® direct' collected an average of 0.3 ± 0.5 ng and 0.5 ± 0.6 ng of total DNA, respectively, and 400 ± 340 RDU and 530 ± 450 RDU of total relative protein density. When normalized for individuals the 'Copan microFLOQ® direct' increased yields by 3.2-fold ($p=0.03$) for DNA and 2.0-fold ($p=0.06$) for protein when unfired and 3.7-fold ($p=0.09$) for DNA and 1.6-fold ($p=0.24$) for protein when fired. The firing process was harsher on DNA than on protein. Protein was 2.2-fold ($p=0.07$) more persistent than DNA on cartridge cases after firing.

We conclude that transfer of residual biological material from fingerprints is improved when using 'Copan microFLOQ® direct' swabs compared to the wet-dry cotton swab method, and that the improvement applies to both idealized surfaces such as microscope slides, and inadequate surfaces such as unfired and fired cartridge cases. We also observe that protein is more stable during the firing process and potentially can provide additional identifying and contextual information for investigators for this difficult type of evidence.

Touch Evidence, Cartridge Cases, Biological Material

B18 Can Variations in DNA Profile Composition Collected From Different Areas of the Same Handgun Inform Future Sampling Strategies?

Cynthia Cale, MS, Houston Forensic Science Center, Houston, TX; Jessica Miller, MS, Marion County Coroner's Office, Indianapolis, IN; Krista Latham, PhD, University of Indianapolis, Indianapolis, IN; Erica Cantor, MS, Indiana University School of Medicine, Department of Hematology and Oncology, Indianapolis, IN*

Learning Overview: After attending this presentation, viewers will be introduced to variations in DNA profile composition and statistical interpretation via likelihood ratios (LRs) calculated from samples collected in different locations of the same single-owner firearm.

Impact Statement: This presentation will impact the forensic science community by informing practitioners as to which specific area(s) of a handgun may be best suited for the recovery of DNA and the generation of informative profiles.

Handguns are a common piece of evidence associated with crimes and criminal activity. This study was designed to systematically test whether there is a detectable difference in the quality and quantity of DNA obtained from four locations (grip, trigger, slide, and magazine) sampled from a single-owner firearm that had been cleaned and briefly handled. Eleven handguns owned by eleven different law enforcement personnel were used in this study. A questionnaire was completed by each participant, which discerned length of ownership, length of daily contact, frequency of cleaning, time since last firing, and accessibility by other individuals. Each firearm was unloaded, wiped with a 10% bleach solution, reloaded, and handled in a way to simulate firing by the owner. Samples from the four designated areas of the firearm were collected separately using a single-swab technique. Each swab was moistened with 100 µL of sterile PBS before swabbing.

A total of 44 samples were extracted utilizing the QIAamp® DNA Mini Kit per manufacturer's instructions. Extracted DNA was amplified with the GlobalFiler™ PCR Amplification Kit and analyzed on an AB 3130xl genetic analyzer. STRmix™ v2.6.1 was utilized to aid in data interpretation. Deconvolution of any mixtures was completed before comparisons to known reference samples from the owners. The NIST1036 database was used to calculate LR. The SWGDAM scale of verbal qualifiers was used to express the degree of support for a specified proposition (H1 – owner of gun is a contributor) relative to an alternative proposition (H2 – unknown, unrelated individual is a contributor).

Data were obtained from all 44 samples. The average amount of DNA obtained from each area decreased in the following order: grip, magazine, slide, trigger. Single-source DNA profiles (36% grip, 27% magazine, 55% slide, 27% trigger) and mixed DNA profiles (64% grip, 73% magazine, 45% slide, 73% trigger) were observed. There was no discernable pattern as to the number of contributors based on swab area. The majority of the LR for all samples provided very strong support ($LR \geq 1,000,000$) in favor of H1. For Gun 5, the LR for the magazine sample provided limited support in favor of H2 ($0.5 \geq LR \geq 0.01$) while the LR for the slide and trigger samples provided moderate support ($100 \leq LR \leq 9,999$) and strong support ($10,000 \leq LR \leq 999,999$) in favor of H1, respectively. Likewise, the LR for the trigger samples from Guns 4 and 6 provided moderate support ($100 \leq LR \leq 9,999$) in favor of H1, while the LR for the trigger sample from Gun 8 provided strong support ($10,000 \leq LR \leq 999,999$) in favor of H1.

The results of this study demonstrate the complexity of DNA transfer. The detection of mixtures in the majority of the samples obtained from cleaned weapons suggests either “cleaning” of handguns is not effective or extraneous DNA is easily transferred via the owners' hands. Regardless, the LR for most samples strongly support inclusion of the firearm owner known to have touched the handgun. However, LR do vary within the samples collected for a single handgun suggesting some areas of a firearm might be more informative in the interpretation of relationships between DNA evidence and criminal acts.

Transfer DNA, Handguns, Probabilistic Genotyping

B19 The Quantification of Metal Ions Recovered During DNA Analysis of Brass Ammunition Using Inductively Coupled Plasma/Optical Emission Spectrometer (ICP/OES)

Natalia Czado, MSFS, Sam Houston State University, Huntsville, TX; Sheree Hughes, PhD, Sam Houston State University, Huntsville, TX*

Learning Overview: After attending this presentation, attendees will have a better understanding of the quantitative presence of copper and other metal ions during the recovery and analysis of touch DNA deposited on brass ammunition.

Impact Statement: This presentation will impact the forensic science community by informing them on the expected quantity of metal ions recovered during commonly used collection, lysis, and purification methods for processing DNA deposited on brass ammunition and providing guidance on improving downstream genotyping.

It is often challenging to obtain Short Tandem Repeat (STR) profiles from DNA recovered from the surface of ammunition, especially those comprising copper alloys. This problem is not only due to the low amount of DNA deposited, but also metal ions causing degradation and damage by interacting with the DNA, and/or inhibition during the polymerase chain reaction (PCR). Numerous studies have examined collection and extraction methods aimed at increasing genotyping success from these challenging samples.^{1,2} However, results have been inconsistent. Although there is consensus that metal ions, especially copper, can intercalate with DNA or cause PCR inhibition, to date, no study has quantified the amount of metal ions recovered during the collection of touch DNA on brass ammunition and that may persist after DNA purification.³⁻⁵

This study examines the presence and quantity of copper and zinc ions during DNA collection and purification and their possible effects on genotyping success. The effectiveness of various DNA collection and purification methods commonly used by forensic laboratories to process brass ammunition for DNA evidence was also investigated. The amount of copper, zinc, and other metals co-recovered from fired and unfired brass casings during DNA collection (using numerous soaking, swabbing, and direct PCR protocols) was quantified via Inductively Coupled Plasma - Optical Emission Spectrometry (ICP-OES). This same panel of metals was subsequently quantified after DNA lysis and purification.

As expected, the largest quantities of metal ions recovered with all collection methods were copper and zinc, for both fired and unfired casings. Although some differences were observed between the various DNA collection and purification methods tested, the quantity of metal ions were significantly reduced prior to STR amplification. Therefore, the results suggest that additional purification to remove more metal ions may not be necessary for increased genotyping success, but rather using alternative markers such as single nucleotide polymorphisms (SNPs) with next generation sequencing (NGS) technologies to examine the low amounts of damaged and degraded DNA.

Copper, Touch DNA, Brass Ammunition

B20 Validation of Lateral-Flow Immunoassay Test for Rapid Screening of Cocaine Samples

Corey Nida, PhD, Drug Enforcement Administration, Dulles, VA; Hunter Haddad, BS, Drug Enforcement Administration, Dulles, VA; Sandra Rodriguez-Cruz, PhD, Drug Enforcement Administration, Dulles, VA*

Learning Overview: After reviewing this poster, attendees will have a better understanding of the procedures used to complete an in-house validation of two commercial lateral-flow immunoassay (LFIA) tests for use during the analysis of suspected cocaine submissions.

Impact Statement: This poster will impact the forensic science community by providing information on how LFIA tests can be used as a rapid screening tool for samples containing cocaine and determine its fitness for purpose within the seized-drug laboratory analysis workflow.

The in-house validation requirements and results of two commercially available cocaine LFIA tests (Rapid Response™ Single Drug Test Strips [BTNX, Inc.] and Premier Identification Kits [Premier Biotech, Inc.]) are presented. Three primary characteristics were assessed to investigate the utility of the above-mentioned cocaine LFIA tests: selectivity, limit of detection (LOD), and repeatability (short-term precision).

Selectivity was evaluated by testing individual compounds and mixtures, in triplicate. In addition to the target analytes (cocaine hydrochloride and cocaine base) and other routine controlled substances, several of the most commonly encountered adulterants, diluents, and alkaloids in cocaine samples were individually tested. False-positives were observed with tropacocaine and benzoylecgonine for one of the cocaine-LFIA tests, while only benzoylecgonine was observed as a false positive in the other.

Mixtures containing varying amounts of (5%, 50%, 95%) cocaine hydrochloride or cocaine base with lactose, mannitol, levamisole, or phenacetin were also included as part of the scope of the selectivity. False-negatives were observed in 13 of the 72 prepared mixtures for one of the cocaine-LFIA tests, while no false-negatives were observed in the other.

LOD was evaluated by analyzing five replicates of cocaine hydrochloride and cocaine base reference materials at decreasing concentrations until at least one negative result was observed amongst the replicates. The experimentally determined LOD for one of the commercially available cocaine-LFIA tests was 1 milligram (mg), while that for the other was 2.6 microgram (µg).

Repeatability was assessed by performing thirty replicate tests of cocaine hydrochloride, cocaine base, levamisole, and phenacetin. Two separate lots of the commercially available cocaine LFIA tests were included in the scope of this study and no unexpected results were observed for the four compounds tested.

Validation, Cocaine, Immunoassay

B21 The Extraction and Identification of Illicit Compounds from Baked Goods Using Paper Spray Ionization Tandem Mass Spectrometry

Isabella Habershtock, BS, Duquesne University, Pittsburgh, PA*

Learning Overview: Attendees will learn about how the QuEChERS solid phase extraction method can be used to extract an illicit compound from a complex matrix containing proteins, carbohydrates, and lipids. Attendees will also learn about the versatility of paper spray ionization mass spectrometry in the rapid analysis of the QuEChERS supernatant for the presence of the illicit compound.

Impact Statement: Complex matrices like cookies and other baked goods have become common methods of consumption for illicit substances, and a rapid and accurate method for the extraction and detection of these substances is necessary for ongoing forensic investigations. Forensic toxicological analysis in drug-related cases often involve the detection of substances like MDMA, amphetamine, and methamphetamine, so an efficient solid phase extraction method would benefit time-sensitive investigations.¹ The paper spray ionization method can also be optimized and has the potential to advance the field of drug detection because of its versatility and rapidity.²

Attendees will learn about how the QuEChERS solid phase extraction method can be used to extract an illicit compound from a complex matrix containing proteins, carbohydrates, and lipids. Attendees will also learn about the versatility of paper spray ionization mass spectrometry in the rapid analysis of the QuEChERS supernatant for the presence of the illicit compound.

Complex matrices like cookies and other baked goods have become common methods of consumption for illicit substances, and a rapid and accurate method for the extraction and detection of these substances is necessary for ongoing forensic investigations. Forensic toxicological analysis in drug-related cases often involve the detection of substances like MDMA, amphetamine, and methamphetamine, so an efficient solid phase extraction method would benefit time-sensitive investigations.¹ The paper spray ionization method can also be optimized and has the potential to advance the field of drug detection because of its versatility and rapidity.²

The goal of this project is to couple the QuEChERS (Quick Easy Cheap Effective Rugged Safe) extraction method with paper spray ionization mass spectrometry to create an optimized extraction and detection method for illicit substances in baked goods. The QuEChERS method, although not typically used for baked goods, isolates the illicit compound from a complex matrix of carbohydrates, lipids, and proteins, allowing for accurate detection of the compound.³ Paper spray ionization is a versatile method that produces accurate quantitative and qualitative data for drug detection studies.⁴ Dough for individual sugar cookies was made using a basic recipe, and the cookies were spiked with 0µL, 1µL, 3µL, 5µL, and 10µL of phenethylamine. Each cookie was extracted in acetonitrile, magnesium sulfate, sodium chloride, and a lipid sorbent for the QuEChERS method.³ The supernatant was analyzed using the ThermoFisher LTQ-XL for the presence of the phenethylamine peak, which was confirmed through the use of tandem mass spectrometry and collision induced dissociation (CID). Using paper spray ionization mass spectrometry, the phenethylamine peak was seen in the 1µL, 3µL, 5µL, and 10µL phenethylamine cookies. CID on the phenethylamine peak confirmed these results for each cookie. The cookie with 0µL phenethylamine did not display the phenethylamine peak, which confirmed that the cookies were not cross contaminated. Because phenethylamine was successfully extracted and detected using QuEChERS and paper spray ionization, future experiments include the quantification of the illicit substance, the use of MDMA in place of phenethylamine, and the use of the LC-QQQ-MS to further perform targeted analysis on the extracted illicit substance.

Mass Spectrometry, QuEChERS, Baked Edibles

B22 A Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) Method Development and Validation for the Quantitation of Cannabinoids in Hemp and Marijuana Samples

Andrea Yarberry, PhD, National Institute of Standards and Technology, Gaithersburg, MD; Jerome Mulloor, MS, National Institute of Standards and Technology, Gaithersburg, MD; Melissa Phillips, PhD, National Institute of Standards and Technology, Gaithersburg, MD; Aaron Urbas, PhD, National Institute of Standards and Technology, Gaithersburg, MD; Walter Wilson PhD, National Institute of Standards and Technology, Gaithersburg, MD*

Learning Overview: After attending this presentation, attendees will learn about LC-MS/MS method development, validation, and application for cannabinoid quantitation.

Impact Statement: This presentation will impact the forensic science community by providing insight into LC-MS/MS method development and validation focused on the separation of cannabinoids for quantitation in marijuana and hemp samples.

Cannabinoids are a class of terpenophenolics found in *C. sativa* L. (cannabis), with cannabidiol (CBD) and Δ^9 -tetrahydrocannabinol (Δ^9 -THC) being the most studied compounds in the class. Prior to the Farm Bill (2018), cannabis was considered a Schedule I controlled substance under the Controlled Substances Act (CSA) and forensics laboratories were only required to determine presence/absence of Δ^9 -THC in a seized cannabis sample to determine legality. The Farm Bill amended the CSA, differentiating hemp from marijuana. Hemp is now defined as cannabis with a decarboxylated-THC (total THC) content less than or equal to 0.3 % by dry weight and marijuana is cannabis with a total THC content greater than 0.3 % by dry weight. Total THC considers the conversion of Δ^9 -tetrahydrocannabinolic acid (Δ^9 -THCA) into Δ^9 -THC through the heating of the cannabis sample or by using a calculation to mathematically convert the Δ^9 -THCA to Δ^9 -THC. While hemp is legal, marijuana remains a controlled substance, which places a new requirement on forensics labs to quantify the amount of total THC in seized cannabis samples. The requirement for total THC quantitation in forensic laboratories, along with the increase in consumer products containing therapeutic cannabinoids has created a need for a robust and selective method for quantitation of cannabinoids in cannabis extracts, oils, edibles, etc.

LC-MS/MS method development investigated selectivity using column chemistry and solvent choice for baseline resolution of the isomeric cannabinoids, where they were indistinguishable using the mass spec. Two C18 columns and three organic solvent mobile phases (B) were considered during method development. Separation using the three organic solvents (0.1 % formic acid in methanol (MeOH), 0.1 % formic acid in acetonitrile (ACN), and 0.1 % formic acid in 50:50 ACN:MeOH by volume) was optimized under isocratic and gradient conditions. The final method utilized a Raptor ARC-18 column (50 mm x 2.1 mm, 2.7 μ m particle diameter) with gradient separation using mobile phase A: 0.1 % formic acid in water and B: 0.1% formic acid in 50:50 ACN:MeOH. Method validation involved the measurements of up to 17 cannabinoids, total CBD, and total THC in hemp and marijuana plant samples. Reference materials were obtained from the University of Kentucky Proficiency Testing Program and NRC Canada. Cannabinoids were extracted from 500 mg samples via liquid-solid extraction using MeOH. In-house hemp and marijuana samples were analyzed as part of the Cannabis Quality Assurance Program (CannaQAP) at the National Institute of Standards and Technology. This poster will summarize the method development and validation results and highlight some of the challenges that occurred when transferring the method to a state crime laboratory.

Chromatography, Cannabis, Mass Spectrometry

B23 A Novel Approach for Quantitation of Total Tetrahydrocannabinol (THC) in *Cannabis* Plant Extracts by Isotope Dilution Gas Chromatography/Mass Spectrometry (GC/MS)

Jerome Mullor, PhD, National Institute of Standards and Technology, Gaithersburg, MD; Melissa Phillips, PhD, National Institute of Standards and Technology, Gaithersburg, MD; Aaron Urbas, PhD, National Institute of Standards and Technology, Gaithersburg, MD; Walter Wilson, PhD, National Institute of Standards and Technology, Gaithersburg, MD; Andrea Yarberry, PhD, National Institute of Standards and Technology, Gaithersburg, MD*

Learning Overview: After attending this presentation, attendees will learn about a new approach to quantifying total THC in *Cannabis* plant extracts using isotope dilution GC-MS.

Impact Statement: This presentation will impact the forensic science community by providing a novel quantitative GC-MS approach that does not require derivatization and instead utilizes deuterated internal standards to account for the decarboxylation of THCA to Δ^9 -THC.

Marijuana has been considered a Schedule I controlled substance since the 1970s. Forensic laboratories must evaluate the legality of seized evidence by the content of delta-9-tetrahydrocannabinol (Δ^9 -THC), the primary psychoactive substance in the *Cannabis* plant. Traditionally, qualitative methods were used to examine seized *Cannabis* plant material. However, the 2018 Farm Bill removed hemp from the controlled substances list and defined it as *Cannabis* containing less than 0.3 % decarboxylated Δ^9 -THC (total THC) content. The new threshold for differentiating between legal hemp and illegal marijuana implored forensic laboratories to implement new quantitative methods for total THC determination in *Cannabis* plant samples.

Forensic laboratories typically utilize liquid (LC) or gas (GC) chromatography with mass spectrometry (MS) detection as the “gold standard” techniques for quantifying illicit drugs of abuse. GC is usually favored over LC for its shorter separation times and use of carrier gas rather than solvents. Unfortunately, quantitation of *Cannabis* samples by GC is complicated by the decarboxylation of the acidic cannabinoids to their neutral form in the heated zones of the GC. The heat-induced conversion of tetrahydrocannabinolic acid (THCA) to Δ^9 -THC is incomplete and inconsistent since it depends on the type of liner used and the inlet temperature. Sample derivatization can remedy this issue, but it is time consuming and not feasible for most forensic laboratories.

In this research, a novel isotope dilution (ID) GC-MS method was developed for quantitation of total THC in sample extracts of *Cannabis* (hemp and marijuana) plant samples. The method accounts for the decarboxylation in the inlet by using two deuterated internal standards for THCA and THC (THCA- d_3 and THC- d_3) that have identical chromatographic properties but are differentiable by their mass spectra. The internal standards are added to the sample extracts and calibration standards prior to injection at a 1:1 ratio and a total THC concentration of 0.3 % to mimic a plant extract at the legal threshold. Previously, a GC method was developed to separate nine neutral cannabinoids in under ten minutes using a 35% phenyl column. This method was converted into a selected ion monitoring (SIM) method for total THC utilizing the most abundant ions for Δ^9 -THC and Δ^9 -THC- d_3 .

Quantitation was performed by extracting the ions for the analyte (m/z 299) and the internal standard (m/z 302) and plotting the mass ratio of total THC to total THC- d_3 in the samples. The quantitative ID-GC-MS method was evaluated using several *Cannabis* plant samples and compared with LC with photodiode array detection (LC-PDA) since LC can separately quantify THCA and THC without decarboxylation concerns. Additionally, the limits of detection and quantitation for total THC on the ID-GC-MS method were evaluated. The ID-GC-MS total THC values were in good agreement with the LC-PDA values, demonstrating its potential for use as a quantitative method.

Cannabis, Gas Chromatography, Mass Spectrometry

B24 The Classification of Cannabis Varieties Through Headspace Chemical Analysis and Transfer Learning

Ting-Yu Huang, MS, Sam Houston State University, Huntsville, TX; Jorn Chi-Chung Yu, PhD, Sam Houston State University, Huntsville, TX*

Learning Overview: The study provides attendees with an intelligent and rapid solution for cannabis classification by using headspace chemical analysis. A new idea of transforming GC/MS data into image representation to facilitate transfer learning will also be introduced.

Impact Statement: The impact of this study is to introduce a transfer learning technique for GC/MS data analysis. A new AI (artificial intelligence) powered framework for classifying cannabis evidence using headspace chemical analysis will be demonstrated.

Cannabis sativa L. (cannabis) has been known to produce cannabinoids that may have diverse bioactivities. The Agriculture Improvement Act of 2018 provided a new statutory definition of hemp, which defines the cannabis plant, and any part of it, with a delta-9-tetrahydrocannabinol (THC) concentration of not more than 0.3% on a dry weight basis. Therefore, the new law limits the definition of marijuana only to include cannabis containing more than 0.3% THC. While hemp is used in manufacturing versatile products, marijuana remains a Schedule I controlled substance under the federal Controlled Substances Act. To discriminate between hemp and marijuana, proficient analytical workflows for cannabis samples are essential in forensic laboratories.

Gas chromatography and mass spectrometry (GC/MS) is a commonly accepted analytical instrumentation to identify cannabinoids. However, due to the heterogeneity of cannabis samples, extensive sample preparation is required before instrumental analysis. To increase the throughput, we proposed a headspace sampling approach to extract cannabinoids before using GC/MS for chemical identification. Additionally, the interpretation of GC/MS data typically involves an analyst's operation. Considering the demands of marijuana analysis in forensic laboratories, an automated system to intelligently classify cannabis varieties can increase the throughput and decrease the turnaround time.

Deep learning (DL) model construction is an emerging AI technique to distinguish images for solving classification problems. Transfer learning is a more efficient learning approach and achieves higher performance than training a new DL model. This study aims to explore the transformation of GC/MS data into images to facilitate transfer learning. This approach was applied to construct an intelligent system for differentiating hemp from marijuana. In this study, 228 GC/MS data were collected from 14 standard cannabis varieties with known THC levels. Two varieties (30 data) were hemp, whereas twelve varieties (198 data) were marijuana. The data were resampled into 896x1471x1 arrays. The retention time region of cannabinoids was transformed into pseudo-color heat maps representing sample headspace cannabinoids signature. GoogLeNet, a pre-trained DL model, was retrained by using the standard dataset. Training parameters, including maximum epoch, learning rate, and mini batch size, were discussed.

The results indicated that the classifier could achieve 100% accuracy in classifying hemp and marijuana. The study demonstrates the feasibility of classifying cannabis varieties by training an AI model without collecting a large reference dataset. The probability-based classification outcome given by the proposed workflow also aids in statistical evaluations for interpreting forensic evidence. Moreover, pre-selection of cannabis botanical structures before GC/MS analysis are not required. Overall, combining image processing schemes and transfer learning offers great potential for forensic analysis of cannabis evidence. Our next step is to collect more comprehensive cannabis sources to cover more varieties in the dataset.

Cannabis, Transfer Learning, Pseudo-Color Heat Maps

B25 A Genetic and Chemical Characterization of the Cannabis Products Seized at the Croatian Cannabidiol (CBD) Stores

Slavena Cukrov-Bezbradica, PhD, Forensic Science Centre, Ivan Vučetić Ministry of the Interior, Zagreb, Croatia; Lucija Barbarić, PhD, Forensic Science Centre, Ivan Vučetić Ministry of the Interior, Zagreb, Croatia*

Learning Overview: Attendees will have an overview of the genetic and chemical data obtained from Cannabis product commercially sold in Croatia.

Impact Statement: This presentation will impact the forensic science community by presenting the challenges in differentiation of drug and hemp varieties in Cannabis seizures.

Cannabis sativa L. is the most commonly seized illicit drug in Croatia. Recent lifting of restrictions has led to a new problem for the law enforcement: prevention of illegal production and sale in a rapidly advancing cannabis industry that offers a wide range of commercial products. Croatian law allows production of cannabis plant varieties listed in the European Union Plant Variety Catalogue (EU PVC) with less than 0.2% w/w (weight/weight) of total Δ^9 -tetrahydrocannabinol (THC) content in the dry plant material. Hence, there is a particular need to study the commercial cannabis products. The aim of this study is to assess the genetic and chemical analyses of seizures obtained from CBD stores and to compare the results with the product declaration. Product declarations do not indicate the Cannabis variety, but state that the variety is listed in the EU PVC with the THC content less than 0.2%.

Cannabis samples were obtained from 46 seizures confiscated in the last year. Quantitative cannabinoids analysis was performed by GC-FID on Agilent 7890A GC System according to the accredited workflow. Extraction of DNA from plant material was performed using DNAeasy Plant Mini kit (Qiagen) following the manufacturer's protocol. DNA quantity was determined by Qubit™ dsDNA HS Assay Kit (Thermo Fisher Scientific). A portion of the tetrahydrocannabinolic acid synthase (THCAS) gene was amplified with primers "g" and "h" as outlined in (1) with the following modification. Briefly, protocol was optimized with duplex primer set using Qiagen Multiplex PCR kit. Furthermore, samples with detected THCAS marker were subjected to the D589 marker analysis with primers described in (2). PCR products were separated by capillary electrophoresis on AB 3500 GA. THCAS gene portion sequencing (265-1490bp) was conducted for samples with both markers detected along with two drug-type (positive controls) and two certified fiber-type varieties (negative controls). Sequencing was performed according to the laboratory standard operating procedures with primers described in (1) using Big Dye Terminator v.3.1 Cycle Sequencing Kit on AB3500xl GA (both from Life Technologies) and data analysis in Sequencher v.5.4.6. Sequences were aligned against the THCAS coding sequence of the drug-type cultivar Skunk (GenBank ID KJ469378).

Based on qualitative chemotype, 91.3% of samples were CBD (cannabidiol) predominant, and the remaining samples were CBG (cannabigerol) dominant. In 17 out of 46 tested samples, THC content was higher than 0.2 %. THCAS and D589 markers were detected in 12 analyzed samples. Eleven identical THCAS sequences were determined, which differed from the variants obtained in fiber-type except at the position 749. Moreover, G to A SNP at the 1064bp was observed. Moreover, one sample showed the sequence identical to the drug-type.

In 37% of total samples, THC content was above the value specified in product declaration. THCAS and D589 markers (specific for drug type varieties) were determined in 26.1% of tested samples. The complete concordance between abovementioned markers was observed, however their detection was not in agreement with the qualitative chemotype. Subsequent analysis demonstrated differences in THCAS sequences in comparison with the hemp sequences. Interestingly, 1064G→A substitution has been reported as a marker for THCA inactivation and CBGA dominance (3). However, this finding was not in correlation with the CBG content since it was found in only four tested samples. Hence, future studies will be focused on genetic analysis of complete THCAS and CBDAS genes in certified varieties and seizures.

B26 The Effects of Degradative Stress on the Headspace Profile of Fentanyl

Leann Forte, BS*, Florida International University, Miami, FL; Stephanie Vaughan, PhD, Naval Research Laboratory, Washington, DC; Ashley Fulton, PhD, Naval Research Laboratory, Washington, DC; Lauryn DeGreeff, PhD, Florida International University, Miami, FL and Naval Research Laboratory, Washington, DC; Howard Holness, PhD, Florida International University, Miami, FL; Kenneth Furton, PhD, Florida International University, Miami, FL

Learning Overview: After attending, this presentation, attendees will understand how thermal, oxidative, and hygro-degradation (degradation due to moisture – i.e., humidity) affects the formation of volatile compounds in the headspace of fentanyl.

Impact Statement: This project will impact the forensic scientific community by providing data to aid in both the development of a non-contact detection method as well as training aid mimics in order to unitize canines as a detection tool.

Vapor detection, such as by canine or electronic nose, has the potential to serve as a vital non-contact detection method. Understanding a substance's unique vapor profile is imperative for development of any vapor detection method. Knowledge of any controlled substance's headspace profile can also be utilized to develop safe training aids for canine detectors making it easier to detect controlled substances in the field. This research focused on determination of the degradation products making up the headspace profile of fentanyl in order to better determine the active odorant for the development of a canine training aid mimic. After attending, this presentation, attendees will understand how thermal, oxidative, and hygro-degradation (degradation due to moisture – i.e., humidity) affects the formation of volatile compounds in the headspace of fentanyl. This project will impact the forensic scientific community by providing data to aid in both the development of a non-contact detection method as well as training aid mimics in order to unitize canines as a detection tool.

Fentanyl is a Schedule II synthetic opioid with a potency 100 times greater than that of morphine. It was first synthesized in 1960 by Dr. Paul Janssen and is used to treat severe, short-term, and chronic pain in cancer patients, or as an anesthetic.¹ The thermal and oxidative degradation of fentanyl was studied by Garg et al.² Using hydrogen peroxide for the oxidation studies, researchers identified the formation of fentanyl N-oxide. Thermal degradation at 350°C yielded N-phenylpropanamide (NPPA) and norfentanyl. In the work discussed herein, we discuss the effects of oxidative degradation due to ambient oxygen, thermal degradation at 40°C, and the presence of humidity on the evolution of components in the headspace of fentanyl. This investigation will inform both the development of a non-contact detection method as well as training aid mimics to unitize canines as a detection tool.

Solid phase microextraction (SPME) with gas chromatography-mass spectrometry (GC-MS) were used to determine the VOCs in the headspace profile of fentanyl. To determine which VOCs in fentanyl's headspace profile can be attributed to degradation, a series of experiments were performed using field-relevant environmental condition, examining degradation due to exposure to air, humidity, and heat. Fentanyl samples were left open under varying conditions to measure the effects of degradation due to humidity, temperature, and oxidative stress. Samples were left open for one week increments in the following conditions, 40 °C and ambient (22°C), inert or ambient air, and dry (3 %RH) or humidified air (80 %RH).

Based on the results, NPPA was found to be the most notable product of degradation in all testing environments. There was also a notable increase in styrene after fentanyl was initially subjected to the 40°C environment for the first week, though this was followed by a decrease in styrene abundance in following weeks. Both styrene and NPPA were previously reported as a product of the thermal degradation of fentanyl.³ Other compounds identified include, benzaldehyde, aniline, N-phenethyl-4-piperidone (NPP), heptane, benzeneacetylaldehyde, benzyl alcohol and 1-phenethyl-4- propinoloxy piperidine, which were not attributed to degradation. All decreased steadily over time in all four environments, except NPP which showed a slight increase following the 7 days of degradation and then remained constant. Understanding the headspace of fentanyl and the compounds that make it unique will be utilized to create safe, non-contact field detection methods.

Fentanyl, VOCs, SPME-GC/MS

B27 Fentanyl Degradation in Syringes Obtained From Intravenous (IV) Drug Users in Washington, DC

Shayla Montalvo, BA, George Mason University, Fairfax, VA; Alexandra Evans, MFS, DC Department of Forensic Sciences, Washington, DC; Morgan Levitas, MFS, DC Department of Forensic Sciences, Washington, DC; Luke Short, PhD, DC Department of Forensic Sciences, Washington, DC*

Learning Overview: After attending this presentation, attendees will understand the degradation rate of fentanyl and common adulterants observed in used syringes in Washington, D.C. under natural degradation conditions following a data-drive approach. Additionally, attendees will be able to use the degradation rate to propose a time of use and improve testing methods for the detection of fentanyl in syringes collected from local needle-exchange programs and/or death investigations. Illicit fentanyl now drives the opioid epidemic and it is hypothesized herein that data from this research needs to be investigated to aid human health and can benefit analysis.

Impact Statement: This presentation will impact the forensic science community by providing an understanding of fentanyl degradation within used syringes, with and without the adulteration of xylazine, etizolam and eutylone; common fentanyl adulterants detected in Washington, D.C. This research will offer a timeline of fentanyl stability for used syringes, adapting analysis times and/or storage protocols, and enhance treatment programs.

Needle-exchange programs provide drug users clean needles in exchange for used needles which helps lower exposure to blood-borne illnesses and other diseases. Analyzing the residual content captures current drug abuse trends within the intravenous (IV) user population. Information obtained from syringes associated with death investigations supports medicolegal inquiries by discovering what might have led to a fatal overdose. Information from syringes obtained from needle-exchange programs provides drug trend monitoring.

Most recent data illustrate the high prevalence of fentanyl in used syringes in Washington, D.C. Adulteration of fentanyl is not uncommon, with xylazine, etizolam and eutylone being adulterants of concern often observed. In our experience, syringes related to death investigations arrive at our laboratory for analysis days or even several weeks after the event occurred while syringes obtained from needle-exchange programs are delivered weekly, but are not time-stamped and definitive time of use ultimately remains unknown. The stability of compounds within a syringe can weaken over time depending on the syringe's storage conditions. Fentanyl in combination with cutting agents, may degrade at different rates and the presence of 4-ANPP can affect the analytical results of drug residue testing. If the analysis of syringes cannot be performed immediately, understanding the thermal byproducts and degradation rate of fentanyl combined with other substances can improve analytical methods for the detection of used syringes.

For this study, polypropylene syringes were conditioned to mimic used syringes among intravenous drug users in Washington, D.C. The controlled dangerous substances analyzed from syringes include the following, individually and in combination: fentanyl, 4-ANPP, etizolam, eutylone, and xylazine. Syringes were stored at ambient temperature (20-25°C) and degradation was observed over a 3-month time span, with every 7-day measurements of each analyzed drug starting at day zero, one, three days followed by every seven days. Methanolic extraction of drug residue was performed on each syringe, followed by gas chromatography mass spectrometry (GC-MS). Linear standard curves were run prior to each analysis with correlation values >0.99. Degradation was measured by quantifying the analytes and calculating the percent changed over time based off of data collected on day zero.

This presentation serves as a tool to estimate the timeline of degradation in fentanyl and its common adulterants seen in Washington, D.C. and identify any matrix interference or ion suppression that can affect detection of residues within syringes. This research will help Forensic and Public Health Laboratories improve current extraction procedures for the identification of CDS in syringes.

Degradation, Syringes, Fentanyl

B28 The Use of Novel Gas Chromatography/Mass Spectrometry (GC/MS) and Gas Chromatography/Infrared Spectroscopy (GC/IR) Libraries for the Differentiation of Positional Isomers of Fentanyl-Related Substances (FRS)

Kimiko Ferguson, MSc, Florida International University, Miami, FL; Michael Gilbert, BS, Pinellas County Forensic Laboratory, Largo, FL; Reta Newman, MA, Pinellas County Forensic Laboratory, Largo, FL; Jose Almirall, PhD, Florida International University, Miami, FL*

Learning Overview: After attending this poster presentation, attendees will be able to better understand the difficulties of fentanyl analysis using electron impact GCMS and the benefits of using GC-IR in the identification and differentiation of fentanyl related substances (FRS).

Impact Statement: The forensic community will be presented with an alternative for the unambiguous identification of fentanyl related substances using GC-IR and the results of a validation study and database search exercise for fentanyl related substances using novel GC-MS and GC-IR libraries.

Forensic laboratories routinely use gas chromatography mass spectrometry (GC-MS) in the identification of controlled substances but certain drug classes, such as the positional isomers of fentanyl related substances, produce indistinguishable electron impact ionization mass spectra. The core structure of fentanyl, now the fourth most identified drug in the United States¹, consists of an amide group, a piperidine ring, an aniline ring, and an N-alkyl chain, each providing opportunities for points of substitution that create FRS and corresponding positional isomers.^{1,2} For this study, the analysis by GC coupled to a vapor-phase infrared spectroscopy detector (GC-IRD) was used as a complementary technique to GC-MS for the identification of positional isomers of FRS.³ The result is a novel fentanyl library consisting of more than 210 reference compounds. A collaboration among three different laboratories yielded 100% correct identifications of each of the 212 analogs when the new GC-IRD fentanyl library created at Florida International University was used. This compares to 15.1% correct identification when using another, more limited, GC-IRD library and 4.7% correct identification when using an existing and widely used GC-MS library alone. The results from interlaboratory studies among six different laboratories demonstrate the utility of the libraries in assisting forensic laboratories in the identification of fentanyl-related compounds. This newly created GC-IRD library and its GC-MS counterpart of 212 fentanyl-related substances will be made freely available to the forensic science community.

Positional Isomers, Fentanyl-Related Substances, Spectroscopy

B29 The Application of Electrospun Polymers with Metallic Nanoparticles for Use in the Detection of Fentanyl by Surface-Enhanced Raman Spectroscopy (SERS)

Daniel Rubin, BA, Florida International University, Miami, FL; Mario Vendrell-Dones, MS, Florida International University, Miami, FL; Ling Wang, PhD, Florida International University, Miami, FL; Bruce McCord, PhD, Florida International University, Miami, FL*

Learning Overview: After attending the presentation, attendees will see how combining electrospun nanofibers with nanoparticles can be used to enhance the surface-enhanced Raman spectra for fentanyls.

Impact Statement: This method will allow the forensic analyst to work quickly and efficiently, in order to identify the substances that pose a greater health risk to society.

The current opioid epidemic began in the 1990s with doctors prescribing opioids to help patients manage pain after surgical procedures.¹ From 1999 to 2019 it is estimated that around 500,000 people have died from overdosing on different opioids including prescription opioids and illicit synthetic opioids.² Fentanyl is a schedule II drug that is 50-100x more potent than morphine. Due its potency, it can only be prescribed by doctors as a painkiller in very specific situations. However, fentanyl is commonly subverted for recreational use. In 2019, it was estimated that more than 36,000 users died by synthetic opioids alone, which is 12 times the estimated amount from 2013.³

The rise in drug overdose has led the research community to produce new, and quicker detection methods. Sensors which can quickly detect structurally similar drugs and its concentration can be very instrumental in emergency room settings. One method suggested to do this has been to use Raman Spectroscopy to determine unknown drugs of abuse. Raman Spectroscopy works by detecting the interaction between inelastically scattered light and the polarizability of molecular vibrational bonds. The scattered light interacts with these molecular bonds resulting in a unique spectrum for each compound. The inelastically scattered light may be anti-Stokes or Stokes scattering in energy resulting in two separate but equivalent spectra.⁴ The problem with this method is that only a small proportion of the scattered light is inelastically scattered. Thus, Raman spectroscopy is not sensitive enough to detect drugs at the needed low concentrations (< ng/mL). To combat this relatively low sensitivity, gold, or silver metallic nanoparticles can be added to the surface to enhance the signal from the analyte. The metallic nanoparticles help enhance the signal through an interaction between the localized surface plasmon field of the metal, the adsorbed molecules, and the scattered light. This enhancement is referred to as Surface-enhanced Raman Spectroscopy (SERS).

Nanoparticles can be synthesized in a variety of methods. The method used in this project is the seed mediated method as it gives the most control over the final shape of the nanoparticle.⁵ The ideal shape for SERS is star shaped as it gives the greatest Raman enhancement.⁶ In order to make the nanostars Deionized water was reacted with H₂AuCl₄ 10⁻² M, AgNO₃ 10⁻² M, L-AA 10⁻¹ M, and Na₂CO₃ 1M. Recently, it has been proposed that nanofibers can be bound to metallic nanoparticles to be used as a surface to enhance the signal of organic compounds.⁷ In order to incorporate the nanostars, they are mixed into the nanofiber fiber solution at a 1:1 ratio. The nanofiber solution is polyvinylpyrrolidone dissolved in ethanol at 9-10% by weight. Once the solution has been made it will be electrospun. In this process a high voltage is used to draw a charged polymer through a syringe. The process gets its name from the fact that an applied voltage creates a magnetic field so when the polymer is pulled through a fine needle the viscous liquid spins creating nanofibers.

The present research project developed a method to incorporate nanoparticles into the electrospinning procedure to make nanofibers that can be used in SERS. This process will allow forensic analysts to detect benzylfentanyl, and fentanyl at the ng/mL concentration level. This method will allow the forensic analyst to work quickly and efficiently, in order to identify the substances that pose a greater health risk to society.

Electrospinning, Nanoparticles, SERS

B30 Identifying the Similarity Between In-Source Collision-Induced Dissociation (IS-CID) Fragment Ion Spectra and Tandem Mass Spectrometry (MS/MS) Product Ion Spectra for Seized Drug Identifications

Jared Sharp, BS, Sam Houston University, Huntsville, TX; Tyler Davidson, PhD, Sam Houston State University, Huntsville, TX*

Learning Overview: After attending this presentation, attendees will have learned about the mass spectral similarity between IS-CID fragment ion spectra and MS/MS product ion spectra of representative synthetic cathinones, synthetic cannabinoids, and fentanyl analogs. The audience will learn about the application of IS-CID for the generation of fragment ion spectra, and methods to assess mass spectral similarity including breakdown curves, Pearson product-moment correlations (PPMCs), and simple match factors (SMFs).

Impact Statement: This presentation will impact the forensic science community by providing a deeper understanding of the similarity between IS-CID fragment ion spectra and MS/MS product ion spectra and provide additional scientific basis for the use of IS-CID within the forensic science community.

The application of IS-CID for the generation of fragment ion spectra has become increasingly popular with soft ionization techniques, such as direct analysis in real time (DART®), when coupled to single-stage high-resolution mass spectrometers. The mass spectra generated by soft ionization techniques contain predominately protonated or deprotonated precursor molecules, which must be fragmented to gain additional selectivity and structural information. However, there is currently only limited information available about the similarity between IS-CID fragment ion spectra and MS/MS product ion spectra, which limits the reliability of IS-CID for the identification of seized drugs. The central hypothesis is that under optimized conditions, IS-CID fragment ion spectra can be generated that are highly similar to MS/MS product ion spectra, which is essential for the further development of IS-CID applications to seized drug identifications.

An Agilent 6530 quadrupole time-of-flight (Q-TOF) mass spectrometer was operated with direct infusion electrospray ionization (ESI) for the analysis of representative synthetic cathinones, synthetic cannabinoids, and fentanyl analogs. The combination of direct infusion with ESI and a Q-TOF mass spectrometer provided the capability to rapidly switch between different source voltages and collision energies to collect data for IS-CID and MS/MS under conditions as similar as possible. The IS-CID fragmentation was collected over a fragmentor voltage range of 150 V to 350 V in increments of 10 V with a constant skimmer voltage of 65 V. In comparison, the MS/MS activation was collected with collision energies ranging from 0 eV to 40 eV in 2 eV increments. The compounds analyzed in this study include: 4-chloroethcathinone (4-CEC), pentylone, 3-methoxymethcathinone (3-MeOMC), α -PVP, AB-PINACA, AB-FUBINACA, MAB-CHMINACA, AM-2201, fentanyl, carfentanil, α -methylfentanyl, and alfentanil.

The breakdown curves, PPMC, and SMFs were performed through Microsoft Excel. Breakdown curves provide a visual assessment of the relationship between the applied activation energy and the resulting mass spectra through a comparison of the major fragment ions and their corresponding abundances. In comparison, PPMC and SMFs are similarity metrics that provide a numerical assessment of the similarity between IS-CID fragment ion spectra and MS/MS product ion spectra under given conditions.

The results from the breakdown curve analysis generated from IS-CID and MS/MS data indicate a similar slope and overall shape between the majority of analyzed compounds, which highlights the similar fragmentation behavior observed between these two activation techniques. Likewise, the PPMC and SMF results for each possible comparison of IS-CID and MS/MS activation conditions indicate that there are conditions under which highly similar IS-CID fragment ion spectra and MS/MS product ion spectra are generated. For example, the average highest PPMC coefficient for each comparison between IS-CID and MS/MS activation conditions ranged between 0.9314 and 0.9567, indicating a high degree of spectral similarity. Additionally, the average SMF result for the highest similarity conditions between IS-CID and MS/MS activation conditions ranged from 687-829, indicating a good match between the resulting mass spectra.

Seized Drugs, Mass Spectral Similarity, Fragmentation Behavior

B31 Silver-Doped Nanofibers as Surface-Enhanced Raman Spectroscopy (SERS) Substrates for the Detection of Synthetic Cathinones

Mario Vendrell-Dones, MS, Florida International University, Miami, FL; Daniel Rubin, BA, Florida International University, Miami, FL; Ling Wang, PhD, Florida International University, Miami, FL; Bruce McCord, PhD, Florida International University, Miami, FL*

Learning Overview: After the presentation, attendees will understand the principles of Surface-Enhanced Raman Spectroscopy (SERS), how nanomaterials/nanofibers can be used to increase the sensitivity of the obtained signal and how it can be applied to rapidly detect synthetic cathinones.

Impact Statement: This work is intended to impact the forensic science community by the detection of substances that are a risk to society in a faster and more reliable way.

This work is intended to impact the forensic science community by the detection of substances that are a risk to society in a faster and more reliable way. In the distant past, indigenous people around the horn of Africa began chewing leaves of the khat plant for relief from daily toil. This habit has now resulted in the discovery of numerous compounds of medical use known as cathinones. Unfortunately, it has also resulted in the development of countless structural variations of addictive analogues. Research into the effects that these compounds have on humans is lacking due to the rapidity at which new compounds become available in the market, resulting in problems for policing and health agencies. Moreover, manufacturers synthesize these new synthetic cathinones in numerous and often amateur ways, causing variations in their purity and the presence of reaction by-products and additives, ultimately increasing the risk of overdose for users.¹ Therefore, there is a pressing need for a screening method that can assist authorities in recognizing various cathinones in a rapid, sensitive, and inexpensive way. Due to its molecular specificity and sensitivity, Surface enhanced Raman Spectroscopy (SERS), constitutes an ideal and flexible platform to detect newly developed compounds and differentiate analogs. This work describes the fabrication and optimization of nanofibers for use as enhancing substrates for the SERS detection of two model cathinones, 3,4-methylenedioxy-5-methylethcathinone and 4-methylethcathinone.²⁻⁴ The SERS substrate is developed by combining colloidal silver (Ag)-based nanoparticles with water soluble polymers, followed by electrospinning the solution into composite nanofibers, and finally crosslinking the nanofibers to reduce solubility and increase the density of hot spots on the surface.⁵ Since the intensity of SERS signal depends on the proximity of the analyte to the nanometallic surface and its vibrational interaction with the electromagnetic field generated by the oscillating electrons of the metal (i.e., LSPR), the quality of the analyte adsorption will affect the overall outcome of the experiment. pH experiments were performed to determine optimal charge states for both surface and analyte. Our results indicated that higher signal enhancements and lower detection limits were achieved at elevated pH. Additional experiments involving Density Functional Theory (DFT) calculations at the B3LYP/6-311G** level were utilized to predict the Raman frequencies of the studied compounds and assist in the assignment of their vibrational modes.⁶ In parallel, traditional Raman measurements on dried solid residues of the synthetic cathinones standards were examined and the resulting spectra were used as references to ensure concordance of the DFT-predicted frequencies with experimental values. Within this work, a rapid, sensitive, and alternative trace detection method of novel psychoactive substances, such as synthetic cathinones, is presented by combining the use of nanofibers and colloidal solutions.

Synthetic Cathinones, SERS, Nanofibers

B32 The Extraction of Cannabidiol (CBD) From Gelatin Edibles With Analysis by Paper Spray Ionization-Mass Spectrometry (PSI-MS)

Cheyenne Granger, BA, Duquesne University, Pittsburgh, PA*

Learning Overview: After viewing this presentation, the audience will have a better understanding of how the rise of cannabis products may impact Forensic Science, how we can significantly improve CBD edible analysis, and how paper-spray ionization mass spectrometry may be the future of rapid edible drug detection.

Impact Statement: This research project will impact the forensic science community by presenting a new and likely more efficient technique (SIPSI-MS) for CBD gelatin edible analysis in crime laboratories.

In the past two decades, the United States has observed a rise in the use and consumption of cannabis related products.¹ This rise comes as a result of increased popularity and 36 of the 50 states legalizing the use of these products.² With this observed increase, an influx of cannabis related evidence will likely be seen in crime laboratories across the country. This influx of evidence would likely cause a significant disruption to evidence intake and analysis leading to a greater chance of backlogging. For gelatin CBD (cannabidiol) edibles, a popular cannabis food product, the current methods of analysis may quickly become inhibitory due to their lengthy preparation and analysis times. The current methods include HPLC (high performance liquid chromatography) and GC-MS (gas chromatography mass spectrometry), the latter of which requires derivatization.³ While these methods are extremely useful, the use of PSI-MS (paper spray ionization mass spectrometry) may provide increased efficiency of identification and quantification of the CBD content in gelatin edibles. For this research project, a technique called SIPSI-MS (silver impregnated PSI-MS) was developed for the rapid detection and possible quantification of CBD content in CBD gelatin edibles. Through this technique, a more efficient identification of CBD extracted from a gelatin matrix was observed. The quantification of the extracted CBD from a gelatin matrix will likely have similar efficiency to identification as indicated by preliminary testing. Overall, this research may demonstrate that there could be significant improvement to CBD gelatin edible analysis via SIPSIMS, if the equipment is available at crime laboratories. This will allow for crime labs to lower the cost and time needed for CBD analysis from gelatin matrices, and in addition may provide a significant solution to offset any backlogging created by increased cannabis usage. This research may also be considered significant for the quality assurance and purity issues observed in cannabis edibles.⁴ Further research with SIPSI-MS for identification and quantification of THC (tetrahydrocannabinol) from edibles may further contribute to forensic analysis of cannabis products.

Cannabidiol, Edibles, Mass Spectrometry

B33 The Quantitation of Cannabinoids in *Cannabis Sativa* L. Plants from Pakistan Using Gas Chromatography/Flame Ionization Detector (GC/FID)

Tahir Jamshaid, MPhil*, Punjab Forensic Science Agency, Lahore, Punjab, Pakistan; Muhammad Chaudhary, MPhil, Punjab Forensic Science Agency, Lahore, Punjab, Pakistan; Muhammad Usman, MS, Punjab Forensic Science Agency, Lahore, Punjab, Pakistan; Zahid Mehmood, MPhil, Punjab Forensic Science Agency, Lahore, Punjab, Pakistan; Muhammad Irfan Ashiq, PhD, Punjab Forensic Science Agency, Lahore, Punjab, Pakistan; Muhammad Tahir, PhD, Punjab Forensic Science Agency, Lahore, Punjab, Pakistan; Amina Iqbal, Government College University, Lahore, Punjab, Pakistan

Learning Overview: The attendee will learn about the quantitation of cannabinoids in Cannabis and method development & validation using GC-FID technique specifically for forensic analysis. The study will also help in determining the Cannabinoid concentration in cannabis situated at various areas of Pakistan thus helping phenotyping and age determination.

Impact Statement: This study will provide forensic community an overview of the cannabis constituents present in Cannabis plant of Pakistan origin. It will also focus on, method validation, extraction & quantitation procedure for forensic analysis.

Cannabis (*Cannabis sativa* L.) and cannabis products are commonly abused in North Africa, South-West Asia, particularly Afghanistan and Pakistan. It belongs to Cannabinaceae family. It is given various street names/synonyms like Gardi, Charas, Ganja, hemp, marihuana, marijuana, pot, gandia, grass etc. Various psychoactive compounds called cannabinoids are produced in trichomes. The most common cannabinoids include Cannabidiol (CBD), Tetrahydrocannabinol (THC & D⁹-THC) and Cannabinol (CBN). D⁹-THC occur as 10-12 % in pistillate flowers, 1-2 % in leaves, 0.1-0.3 % in stalks and < 0.03 % in the roots. Prolonged use of cannabis may affect cardiovascular, respiratory and focal sensory systems.

The objective of conducting this study was to develop and validate method for quantitation of Cannabinoids (CBD, THC and CBN) that can be used in forensic analysis. The plants were collected from different regions of Pakistan and their concentration were calculated using internal standard (IS) method.

Materials and Methods: Samples of cannabis plants were collected from different regions of Pakistan like Azad Kashmir, Punjab KPK, Islamabad etc. Shade dried leaves & fruiting tops were used for extraction & analysis on GC-FID for cannabinoids determination. Validation studies were carried out using a known range (10, 20, 40, 60, 80 µg/mL) of each of ethanolic certified standards and unknown samples were extrapolated alongside using Phenanthroline as IS. An Agilent GC coupled with Flame ionization detector (7890B GC, ALS G4513A, Agilent Technologies, USA) was used for this purpose. Quality controls 25 µg/mL and 65 µg/mL & negative control spiked with 110 µL (55 µg/mL) IS solution were dried reconstituted with 200 µL of methanol were used. For validation, Linearity, Accuracy, Precision, Carry over, Interference, LOD and LOQ were evaluated. A mixture of different available drug standards containing GHB, Amphetamine, Starch, Phenaramine, PCP, and methadone, Fentanyl, Dextromethorphone and Methamphetamine with IS were analyzed to determine the absence of common interferences from the matrix. Accuracy and precision were determined by using 30 µg/mL of each standard containing IS & run replicates for five days.

Extraction: Dried leaves (100 mg) and fruiting tops (50 mg) were extracted with 2200 µL of 500 ppm of Phenanthroline (IS) & ethanolic (as solvent) extracts were dried on turbopap evaporator using N₂ gas at 40°C. Reconstituted the tubes with 200 µL of methanol and vortex.

GC-FID Parameters: Sample were injected (2 µL) in Agilent 30m x 250 µm x 0.25 µm DB.5 MS column in split mode (50:1). Oven temperature was programmed at 150 °C up to 300 °C with variable ramping & total run time of 10.5 minutes. The FID front detector with Heater at 250 °C & Nitrogen (99.999% pure) as carrier gas was used. The H₂ gas was used as igniting gas. The data was evaluated by Chem Station calculated regression coefficient with auto integration parameters.

Results and Conclusion: The cannabinoid concentration was calculated in leaves and fruiting tops of cannabis. The retention time (RT) for CBD, THC, CBN and Phenanthroline was determined as 7.942 ±0.2, 8.385±0.2, 8.701±0.2, and 6.628±0.2 minutes, respectively. Linearity was calculated with regression coefficient as 0.9992 (CBD), 0.9998 for THC and 0.9997 for CBN. The method showed no interference & LOD (10 µg/mL). The method was accurate and precise with <20 % acceptance criteria. The quantity of cannabinoids was expressed as the mean values of dry weight expressed as µg/mL.

Conclusion: The Cannabinoids content in cannabis plant of Pakistan showed marked variation. The validation and quantitation of the principal cannabinoids have great importance in pharmacological and forensic studies. The method is simple & reliable & has various applications, Future prospect of this study is to establish correlation between cannabinoid concentrations and age of plant.

Forensic Analysis, Cannabis, GC/FID

B34 The Quantitation of Opium Alkaloids in Seized, Crushed, and Mowed Plant Material

Muhammad Chaudhary, MPhil, Punjab Forensic Science Agency, Lahore, Punjab, Pakistan; Tahir Jamshaid, MPhil, Punjab Forensic Science Agency, Lahore, Punjab, Pakistan; Muhammad Irfan Ashiq, PhD, Punjab Forensic Science Agency, Lahore, Punjab, Pakistan; Mohammad Tahir, PhD, Punjab Forensic Science Agency, Lahore, Punjab, Pakistan; Atiq Asif, MPhil, Government College University, Lahore, Punjab, Pakistan*

Learning Overview: After attending this presentation, attendees will be able to learn: (1) how the contents of crushed *Papaver somniferum* L. can be extracted and confirmed using GC/MS after derivitization; (2) about challenges faced in confirmation using SIM mode; (3) use of alternative procedure of extraction instead of expensive solid phase extraction procedure.

Impact Statement: Forensic science community will be able to use this validated method for confirmation of opium alkaloids when conventional GC/MS or GC/FID give non reproducible results. This method will be particularly useful when concentration of alkaloids is low in mowed plant material from which juice has been extracted.

Papaver somniferum L. is herbaceous flowering plant. All or parts of the plants (except seeds) in any form are controlled as per law in Pakistan. Pakistan is poppy free country but being immediate neighbour to Afghanistan, there is continuous trafficking of poppy plant and opium alkaloids in Pakistan. Furthermore, use of crushed plant material is famous for its medicinal value as well. In Pakistan, opium and poppy plant seizure comprise of nearly 06% of total seizures per year. Author's laboratory routinely face problems in confirmation of opium alkaloids from crushed dried poppy plant materials from which alkaloids have already been extracted. Therefore, there was a need to develop and validate the robust method by which opium alkaloids can be confirmed and quantitated using GC/MS.

Agilent GC-7890A with MS-5975C (20m x 180um x 0.18um DB-5 MS UI column) was used in this study. Methanol (1 mL) was added in tube containing finely crushed poppy plant material (20 mg) along with 30 uL of IS solution (Phenanthroline 1mg.mL⁻¹). Calibrator solutions (1 ml in methanol) of codeine, morphine, thebaine and papaverine (5 to 50 ppm), positive control (25 ppm) and negative control were spiked with 30 uL of IS solution. Samples were sonicated for 30 minutes, centrifuged and methanol was evaporated after separation. Residue was derivitized with N,O-Bis(trimethylsilyl)trifluoroacetamide (BSTFA):ethyl acetate (25:75 uL) and heated in capped conical glass tube for 30 minutes at 70-80°C. Derivitized solutions were cool down to room temperature and 1 uL was injected to 10:1 split GC-inlet (250°C) using SIM mode (one quantifier and two qualifier ions of each analyte) and helium as carrier gas. Oven temperature was programmed initially at 150°C for 1 min, ramped at 25°C/min up to 250 °C and finally ramped at 10°C/min to 300°C (Total run time 10 min). Method was validated for linearity, selectivity, LOD, LOQ, bias, precision and matrix effect as per UNODC guidelines.

IS, codeine, morphine, thebaine and papaverine were detected with sufficient resolution having retention times of 4.9, 6.4, 6.6, 6.8 and 7.9 min, respectively. Separation of analyte peaks is dependent on oven temperature ramping. Response of all analytes is linear over calibration range (regression coefficient >0.995). Lowest calibrated was set as LOQ of method while LOD ranges from 31.25 to 125 ug/g. No interference is observed with common adulterants and controlled substances. Precision and bias are well below 20% for all analytes. Twenty four case samples were also analysed and produced reproducible results.

Based on the study, it is concluded that this method is sufficiently specific, selective and reproducible with enough LOQ for confirmation and quantification of opium alkaloids in challenging case samples.

Poppy, Opium, Confirmation

B35 The Use of Urine Rapid Response Fentanyl Test Strips to Detect Fentanyl in Seized Substances

Lauren Bishop, Ohio Northern University, Ada, OH*

Learning Overview: The learning overview in this presentation demonstrate that these lateral flow immunoassay strips work in non-laboratory settings for detection of fentanyl and fentanyl analogues mixed in seized substances. As well as a method for harm reduction to be distributed by social service agencies along with the test strips so it's easy to follow for people who use drugs.

Impact Statement: This study validates the use of urine Fentanyl test strips for detection of fentanyl and fentanyl analogues. This will impact the forensic science community by practically testing these strips and allowing them to be put in a real life setting to examine if the strips really work for a new intended use.

According to the Center for Disease Control (CDC), since 1999, nearly 841,000 people have died from a drug overdose.¹ In 2021 the Montgomery County Coroner's office in Ohio has recorded 235 overdose deaths until August 30th, 2021, and 323 overdose deaths in 2020, with 88% of those related to fentanyl.² Fentanyl is being mixed with other illicit substances according to the DEA.³ This study was designed to determine if Rapid Response™ urine fentanyl test strips would accurately detect fentanyl in seized substances and was set up to imitate the setting of people who use drugs, as opposed to a laboratory setting. Most of the published research surrounding the test strip efficacy has focused on testing the strips on pure standards or singular substances, which leaves uncertainty regarding true street substance samples that have been adulterated and whether mixtures routinely seen in casework would ultimately affect the results. Harm reduction agencies such as public health and coroner's offices in Montgomery County and Cleveland, Ohio, as well as in other states like Washington, along with organizations like Dance Safe, are proponents of user testing.^{4,5} All these agencies have attempted to implement different programs to help reduce fentanyl overdose deaths. The reason for the focus around fentanyl is because fentanyl about 100x more potent than morphine. The intent of the test strips is to detect fentanyl mixed in with a user's illicit substances before taking them. This then gives the user the knowledge and the ability to decide whether to take or not take the illicit substance. Harm reduction agencies are distributing the Rapid Response™ fentanyl test strip to people to test their various substances to determine if they contain fentanyl to avoid the potential for overdose. The samples tested in this study were from 76 cases submitted to the Miami Valley Regional Crime Lab in Dayton, Ohio. The detection of fentanyl and other illicit substances was qualitatively determined on a Gas Chromatography-Mass Spectrometry (GC/MS) to confirm the presence and abundance of each substance prior to strip testing. The manufacturer and supplier of the strips is BTNX Inc. located in Markham, Ontario, Canada. These test strips are based on the principle of lateral-flow immunoassay (LFIA), as a competitive assay between drug conjugates and free drug present. So, in this assay, the results are inversely related to the signal and have a sensitivity or a cutoff concentration of 20ng/mL.⁶ The variables investigated in the study included: the water type, (Dayton, Ohio city tap water), the seized drug substances (cases from Ohio and Indiana), mass of powder substance used (less than 0.01g) and the length of time the strips were exposed to the mixture and lastly the length of time lapsed prior to reading results (per the manufacturer instruction). The results from 73 of the 76 cases indicated positive detection demonstrating the presence of fentanyl, regardless of the abundance of each controlled substance versus adulterants. However, there were three cases that did not contain fentanyl as determined by GC/MS, but did contain heroin and/or methamphetamine, which gave unexpected results. Two of the cases were false positives, and one case was negative. These three cases were tested multiple times and it was concluded the results were accepted. This study demonstrates that the Rapid Response™ fentanyl test strips are sensitive about 96% of the time and as tested would be a reasonable method in the hands of people who use drugs to limit the exposure to fentanyl when using illicit drugs.

B36 Continuous Vapor Sampling of Volatile Organic Compounds (VOCs) Associated With Explosives and Cocaine Using Capillary Microextraction of Volatiles (CMV)

Jacqueline Rodriguez, MS, Florida International University, Miami, FL; Jose Almirall, PhD, Florida International University, Miami, FL*

Learning Overview: After attending this presentation, attendees will learn about a novel continuous vapor delivery and sampling system which can be implemented to rapidly sample the vapors of illicit drug and explosive analytes by using the CMV.

Impact Statement: This presentation will impact the forensic science community by demonstrating how the vapors of sub-nanogram amounts of VOCs, which are associated with explosives and cocaine, were capable of being rapidly recovered and detected by coupling the CMV device to portable instrumentations, indicating the potential for field applications.

The dynamic sampling and preconcentration device, capillary microextraction of volatiles (CMV), is coupled to portable instrumentation for the rapid field detection of volatile organic compounds (VOCs) associated with drugs and explosives. By coupling the CMV device to a portable gas chromatograph-mass spectrometer (GC-MS), sub-nanogram (ng) instrumental detection limits were achieved for VOCs associated with cocaine and VOCs associated with smokeless powder explosives, including 3-nitrotoluene (3-NT), 2,4-dinitrotoluene (2,4-DNT), diphenylamine (DPA), ethyl centralite (EC), dibutyl phthalate (DBP), and 2-nitrodiphenylamine (2-NDPA). Three different dynamic sampling methods were used with the CMV to sample and preconcentrate the volatiles prior to analysis. The headspace of a closed system was sampled over 10 minutes resulting in recoveries for the explosives analytes between 0.3 – 12% by subsequent GC-MS analysis using a field-portable Griffin G510 GC-MS. Simulated open-air vapor sampling was conducted using a previously described vapor source, which resulted in an improvement of analyte recovery (ranging from 1.6 – 25%), after sampling for 10 minutes. A novel, continuous vapor delivery and sampling system was used, for the first time, to facilitate the gradual delivery of sub-nanogram quantities of the VOC analytes of interest. The new continuous delivery system achieved significantly higher recoveries (between 3.0 – 89%) for all the analytes, while requiring less sampling time (~ 5 minutes) and sampling volumes. Each of the sampling methods presented attained an overall analytical precision of better than 14% relative standard deviation (RSD) for mass loadings as low as 100 ng/l. The VOCs that were studied for drug analysis derive from analytes that are commonly associated with the presence of cocaine, including methyl benzoate, methyl cinnamate, anhydroecgonine methyl ester (AEME), ecgonine methyl ester (EME), and benzocaine. Throughout this study, the rapid sampling and preconcentration of these VOCs followed by a ~ 10-minute portable GC-MS method, compared favorably to the analytical figures of merit achieved by laboratory instruments and the detection limits reported for canines. Another portable instrumentation, a hand-held ion mobility spectrometer (IMS), was also utilized for the application of field vapor detection of explosives and illicit drugs. The portable IMS possesses a rapid analysis time of only ~ 20 ms and was coupled to a planar solid phase microextraction (PSPME) disk to accommodate for the configuration of the IMS inlet. For vapor sampling, the circular PSPME disk was placed on top of the inlet to allow the analytes to adsorb onto the coated (phenyl-terminated polydimethylsiloxane) microfibers within the sampling device prior to analysis of the IMS. These new, fast, and sensitive sampling methodologies coupled to the rapid analysis of field-portable instruments expands the potential applications of the CMV for the field detection of trace analytes associated with illicit drugs and explosives. JL Rodriguez and JR Almirall, Continuous vapor sampling of volatile organic compounds associated with explosives using Capillary Microextraction of Volatiles (CMV) coupled to a portable GC-MS, 2021, For. Chem., submitted.

Capillary Microextraction of Volatiles (CMV), Volatile Organic Compounds (VOCs), Portable Instrumentations

B37 An Assessment of Robotic Solid Phase and Immunoaffinity Microextraction With Intact Mass Analysis for Saliva Identification in Forensic Samples

Catherine Brown, PhD, University of Denver, Denver, CO; Phillip Danielson, PhD, University of Denver, Denver, CO; Kevin Legg, PhD, Center for Forensic Science Research & Education, Willow Grove, PA*

Learning Overview: After attending this presentation, attendees will gain an understanding of the advances in protein analysis for the characterization of human saliva by intact mass spectrometry.

Impact Statement: This presentation will benefit the forensic science community by providing a rigorous scientific evaluation of two automated extraction techniques for the recovery of human statherin (a saliva biomarker) from forensic samples.

Alpha amylase is the most common target for salivary identification. While abundant in saliva, amylase is also detectable in vaginal secretions, sweat, and breast milk. Traditional enzyme-activity and immunochromatographic assays provide only a presumptive indication of saliva. In an effort to overcome these specificity limitations, several novel strategies have been explored including assays based on mRNA, epigenetics, Raman spectroscopy, and protein mass spectrometry.

Several previously established mass spectrometry-based approaches have been developed. While reliable, most are limited in throughput due to multi-step workflows that include protein extraction, quantitation, enzymatic digestion, solid phase cleanup, and nano/capillary-based chromatography. The work presented here has developed and assessed two “direct”, single stage, automated extraction strategies including immunoaffinity purification and reverse phase solid phase microextraction in conjunction with intact mass analysis of human statherin.

Swabs or cuttings were reconstituted in 500 μ L of PBS buffer at room temperature and centrifuged. Supernatant (125 μ L) was diluted 1:1 in 1 mg/mL BSA in PBS for immunopurification or 0.5% TFA in water for C18 solid phase extraction. All extractions were performed on an Agilent Technologies AssayMAP Bravo liquid handling platform with 5 μ L C18 or streptavidin cartridges. Biotinylated ProteinTech STATH polyclonal mouse anti-Statherin antibody was employed for immunoaffinity purification. Mass analysis was performed on the Thermo Q-Exactive mass spectrometer operated in positive Full-MS mode. Separation was carried out at 0.3 mL/min over an 8-minute gradient separation. Data analysis was performed with BioPharma Finder v4.1 using the Xtract algorithm to deconvolute intact statherin.

Two sample sets were analyzed including a population of 20 individuals to evaluate detection consistency as well as a series of casework samples to evaluate assay performance. Of 20 individuals sampled, statherin was identified in 18 samples by immunoaffinity purification and 17 samples by C18 extraction. A total of 26 casework type samples were assayed including mixed and single-source samples differing in age, substrate type, and type of chemical and environmental insult. All casework type samples were analyzed in duplicate for a total of 104 samples. Statherin was confidently identified in 94% of samples extracted using the immunopurification approach and 65% of samples by the C18 extraction. Both methods detected sub-microliter quantities of saliva applied to cotton swabs. Samples treated with a 10% bleach solution failed to be detected using either extraction method. This was the only sample type to fail with the immunopurification approach. All sample mixtures including saliva mixed with blood or semen as well as saliva fortified on menstrual swabs were not detectable using the C18 method.

Overall, immunoaffinity purification outperformed C18 extraction; especially when analyzing complex mixtures. This is likely due to the ability of immunoaffinity purification to generate highly purified extracts which circumvent the suppressive effects of non-target proteins. Conversely, while immunoaffinity purification performed well, these assays require a significant amount of development to identify appropriate antibodies, incubation periods, binding and wash conditions compared to SPE-based methods. In conclusion, robotic extraction and intact mass spectrometry can provide serological identification of human saliva from a variety of real-world sample types.

Serology, Intact Protein Analysis, Mass Spectrometry

B38 The Separation of Natural and Synthetic Hallucinogenic Tryptamines Using High-Performance Liquid Chromatography-Photodiode Array (HPLC-PDA) and Ultra-High Performance Liquid Chromatography-Photodiode Array/Mass Spectrometry (UHPLC-PDA/QDa)

Mia Fabbri, BS, Cedar Crest College, Allentown, PA; Marianne Staretz, PhD, Cedar Crest College, Allentown, PA; Matthew Wood, PhD, Ocean County Sheriff's Office, Toms River, NJ; Daniel Garrison, BS, Waters Corporation, Plymouth Meeting, PA; Peter Harrsch, PhD, Waters Corporation, Plymouth Meeting, PA; Thomas Brettell, PhD, Cedar Crest College, Allentown, PA*

Learning Overview: The goal of this presentation is to report the results of the development of a method to separate 12 natural and synthetic hallucinogenic tryptamines using high performance liquid chromatography-photodiode array (HPLC-PDA) and ultra-high performance liquid chromatography-photodiode array/mass spectrometry (UHPLC-PDA/QDa).

Impact Statement: This presentation will impact the forensic community by demonstrating that UHPLC-PDA/QDa can be a powerful and viable alternative tool in the analysis of natural and synthetic hallucinogenic tryptamines and that HPLC-PDA can also be used to separate 12 hallucinogenic tryptamines.

Every year new psychoactive substances (NPS) emerge on the illicit market and most end up being submitted to crime laboratories as seized drugs for analysis. Tryptamines are one of these common classes of NPS. Synthetic tryptamines are derived from natural tryptamines such as psilocybin and N,N-dimethyltryptamine (DMT). Since these natural tryptamines are altered to form new compounds, the NPSs are structurally similar and can therefore be difficult to distinguish and identify. The most used method for seized drug analysis is gas chromatography-mass spectrometry (GC-MS), however, this method requires that the compounds be thermally volatilized. This is not ideal for tryptamines since psilocybin can be dephosphorylated to psilocin in high temperature, acidic, or basic environments. Therefore, a more accurate method is necessary to detect the parent compound for tryptamine identification. HPLC-UV offers a non-degradative solution with adequate sensitivity for tryptamine analysis. The addition of mass detection enhances the capability of being able to identify seized drugs and should be very useful in the detection of tryptamines.

Twelve psychoactive tryptamine standards were prepared in methanol and studied using both HPLC-PDA and UHPLC-PDA/QDa. These included the three most common tryptamines: DMT, 5-methoxy-N,N-diisopropyltryptamine (5-MeO-DiPT), and N,N-diallyl-5-methoxytryptamine (5-MeO-DALT); and four natural psychoactive tryptamines: psilocybin, psilocin, bufotenine, and ibogaine. Additionally, 4-acetoxy-N,N-dimethyltryptamine (4-AcO-DMT), 5-methoxy-alpha-methyltryptamine (5-MeO-AMT), 5-methoxy-N-methyl-Nisopropyltryptamine (5-MeO-MiPT), N,N-dipropyltryptamine (DPT), and N,N-diethyltryptamine (DET) were analyzed. Retention time data, as well as UV spectra and selected ion recording (SIR) data were obtained for each individual compound using HPLC-PDA and UPLC/PDA-QDa. Both methods used binary mobile phases with gradients. The HPLC-PDA method mobile phase conditions consisted of 90% A (0.1% TFA in water) and 10% B (0.1% TFA in 2:1 acetonitrile to methanol) with a gradient elution up to 40% B at 0.4 mL/min using a Raptor® Biphenyl 5-μm column (100 mm x 3 mm) at 35°C. The UPLC-PDA/QDa method used a gradient elution starting with 95% A (5mM ammonium formate (pH 3)) and 5% B (0.2% formic acid in acetonitrile) to 55% B at 0.4 mL/min using an Acquity® UPLC HSS (high strength silica) C18 1.8-μm column (150 mm x 2.1 mm) at 50°C. A dilution series was analyzed to determine the limit of detection (LOD) for each method with the UPLC-PDA/QDa method giving a lower limit of detection (LLOD) of 5 ng/mL with a 3.0 μL injection volume for all compounds studied. Complete resolution was obtained for 10 of the 12 tryptamines by HPLC-PDA. Only two compounds could not be differentiated by UV given their co-elution and similar UV spectra. Separation and differentiation, however, was achieved using the UPLC/PDA-QDa which combined the high efficiency of UPLC with PDA and MS technology. Comparison of the biphenyl and C18 columns resulted in similar elution order.

UPLC/PDA-QDa is an excellent complement to standard instrumentation as it provides both chromatographic and mass spectral information without analyte degradation, while being sensitive and accurate for tryptamine analysis.

UHPLC-PDA/QDa, Tryptamines, Hallucinogens

B39 Community Resources and Updates from the Scientific Working Group for DNA Analysis Methods (SWGDM) Next Generation Sequencing (NGS) Committee

Katherine Gettings, PhD, National Institute of Standards and Technology, Gaithersburg, MD*

Learning Overview: Attendees will learn about the activities of the SWGDM NGS Committee, including currently available and forthcoming resources to support the adoption of new sequencing technologies for forensic DNA analysis.

Impact Statement: Impact to the forensic community is increased awareness of available resources; increased discussion will also impact future efforts of the committee.

The Scientific Working Group for DNA Analysis Methods (SWGDM) Next Generation Sequencing (NGS) Committee began as a working group in 2014 and formalized as a committee in 2018. This committee is tasked with identifying, evaluating, and researching issues relating to the forensic applications of next generation sequencing. On behalf of the committee members, this presentation will update the forensic community on past, current, and future efforts and work products. Past efforts include NGS-specific interpretation guidance for autosomal STR sequencing¹ and mitochondrial DNA analysis.^{1,2}

Two recent efforts/resources will be described in detail: 1) SNP interpretation guidance and 2) STR sequence mixture data intended to support the development of probabilistic genotyping methods. The SNP interpretation guidance document is focused on commercially available SNP assays most likely to be implemented in a forensic DNA laboratory. These assays target identity, ancestry, and/or phenotype informative SNPs; however, guidance is currently lacking regarding interpretation, statistical analysis, and reporting of this marker type. This document represents a first step in collating existing information and standardizing implementation across laboratories. The STR sequence mixture data project is steered by the SWGDM NGS committee, with mixture samples created and sequencing analysis performed by the NIST Applied Genetics Group. This mixture data set initially consists of 96 samples sequenced in several commercially available forensic STR sequencing assays. The mixture compositions were determined based upon feedback from probabilistic genotyping software developers. All mixture and single source contributor data are available in a NIST Public Data Repository.³

Future efforts of the SWGDM NGS Committee include an NGS-specific validation guidance document and additional support for probabilistic genotyping and bioinformatic software developers.

B40 Standards Development Activities in Human Forensic Biology

Kristy Kadash, PhD, Jefferson County Regional Crime Lab, Golden, CO; Beth Ordeman, MS, Pinellas County Forensic Laboratory, Largo, FL*

Learning Overview: After attending this presentation, attendees will have a better understanding of the status of discipline specific standards pertinent to the field of human forensic biology.

Impact Statement: The presentation will impact the forensic science community by creating greater awareness of standards development activities pertinent to human forensic biology. It will also increase awareness regarding training, tools and resources that support implementation, compliance monitoring, and broader understanding.

The Organization of Scientific Area Committees (OSAC) for Forensic Science was created to strengthen the nation's use of forensic science by promoting the use of discipline-specific forensic science standards. To this end, the OSAC drafts standards that are forwarded to standards developing organizations (SDOs) that further develop and publish them. The OSAC also reviews standards and recognizes them on the OSAC Registry, which serves as a central repository of high quality, consensus-based, technically sound standards. During this presentation, updates related to standards development in Human Forensic Biology will be discussed. These include:

Recent standards that have been added to the OSAC Registry:

- **ANSI/ASB Standard 023**, *Standard for Training in Forensic DNA Isolation and Purification Methods, First Edition, 2020.*
- **ANSI/ASB Standard 110**, *Standards for Training in Forensic Serological Methods, First Edition, 2020.*
- **ANSI/ASB Standard 115**, *Standard for Training in Forensic Short Tandem Repeat Typing Methods using Amplification, DNA Separation, and Allele Detection, First Edition, 2020.*
- **ANSI/ASB Standard 116**, *Standard for Training in Forensic DNA Quantification Methods, First Edition, 2020.*
- **ANSI/ASB Standard 018**, *Standard for Validation of Probabilistic Genotyping Systems, First Edition, 2020.*

OSAC proposed standards:

- **OSAC 2020-S-0004**, *Standard for Interpreting, Comparing and Reporting DNA Test Results Associated with Failed Controls and Contamination Events.*
- **OSAC 2020-N-0007**, *Best Practice Recommendations for the Management and Use of Quality Assurance DNA Elimination Databases in Forensic DNA Analysis.*

Published standards from the Academy Standards Board (ASB) pending Registry approval process:

- **ANSI/ASB Standard 038**, *Standard for Internal Validation of Forensic DNA Testing Methods, First Edition, 2020.*
- **ANSI/ASB Standard 077**, *Standard for the Developmental and Internal Validation of Forensic Serological Methods, First Edition, 2020.*
- **ANSI/ASB Standard 130**, *Standard for Training in Forensic DNA Amplification Methods for Subsequent Capillary Electrophoresis Sequencing, First Edition, 2021.*
- **ANSI/ASB Standard 131**, *Standard for Training in Forensic DNA Sequencing using Capillary Electrophoresis, First Edition, 2021.*

Documents currently in development at the OSAC or by the ASB:

- 9 training standards from the training standards suite
- *Standard for Internal Validation of Human STR Profiling on CE Platforms (and BPR)*
- *Standards for Prevention, Monitoring, and Mitigation of DNA Contamination*
- *Assigning Propositions for Likelihood Ratios in Forensic DNA Interpretations*
- *Best Practice Recommendation for Validation of Forensic DNA Software*
- *Standard for Internal Evaluation of a Laboratory's DNA Mixture Interpretation Protocol*
- *Standard for Reporting DNA Conclusions*
- *Standards for Determining Analytical and Stochastic Thresholds for Application to Forensic DNA Casework Using Electrophoresis Platforms*
- *Standards for Validation and Implementation of Familial Searching for Forensic Purposes*
- *Forensic Autosomal STR DNA Statistical Analyses –General Protocol, Protocol Verification, and Case Record Requirements*
- *Best Practice Recommendations for Testimony Regarding DNA Activity Propositions*

Other highlights:

- Provided subcommittee response to the NIST Foundational Review on DNA Mixture Interpretation.
- Forensic Biology Process Map
- Technical Report: Appendix Examples for Biology/DNA Reports
- 4Pilot audit document for **ASB Standard 040** *Standard for Forensic DNA Interpretation and Comparison Protocols.*
- New research needs.

Opportunities for supplemental training related to discipline-specific standards will be presented, as well as additional resources and tools designed to facilitate gap analysis, compliance monitoring, and outreach efforts.

B41 A Short Tandem Repeat (STR) Sequence Nomenclature Update From the Short Tandem Repeat: Align, Name, Define (STRAND) Working Group

Katherine Gettings, PhD, National Institute of Standards and Technology, Gaithersburg, MD; David Ballard, PhD, Kings College, London, United Kingdom; Martin Bodner, PhD, Medical University of Innsbruck, Innsbruck, Austria; Jonathan King, MS, University of North Texas Health Science Center, Fort Worth, TX; Walther Parson, PhD, Medical University of Innsbruck, Innsbruck, Austria; Christopher Phillips, University of Santiago de Compostela, Santiago de Compostela, Spain*

Learning Overview: Attendees will learn about the activities of the STRAND Working Group, including currently available and forthcoming resources on STR sequence nomenclature to support the adoption of STR sequencing technologies for forensic DNA analysis.

Impact Statement: Impact to the forensic community is increased awareness of available resources; increased discussion will also impact future efforts of this working group.

Since the 2016 publication of the ISFG DNA Commission Considerations on Minimal STR Sequence Nomenclature Requirements, the STRAND Working Group has been collaborating to harmonize related STR sequencing efforts across our respective laboratories: STRidER STR sequence quality control, STRSeq catalog of sequences, STRait Razor bioinformatic freeware, and the Forensic STR Sequence Structure Guide.¹⁻⁵ To expand and advance this discussion, in 2019 the STRAND working group hosted a meeting on STR sequence nomenclature with attendees across government, academic, and vendor sectors. Content from this meeting was disseminated to the community through publication and presentations.⁶

Following this meeting, an ISFG DNA Commission on STR Sequence Nomenclature was initiated in 2020 to develop recommendations for maintaining, formatting, and exchanging STR sequence data. These recommendations follow the tradition of autosomal STR allele designation guidance from earlier DNA Commissions of the ISFG which further evolved as the technology expanded into Y-STRs. The starting point for this DNA Commission was the 2016 *considerations* paper; now reevaluated in light of the intervening five years of published data and technology advancements.¹ This DNA Commission is composed of members of the STRAND working group and additional experts from international academic and government laboratories.

On behalf of the STRAND working group, this presentation will describe the aforementioned efforts of working group members, as well as the ISFG DNA Commission's progress toward STR sequence nomenclature recommendations covering: (1) sequence strings and minimum reporting range, (2) bracketed sequences, (3) resources for sequence formatting, (4) characterizing new loci, and (5) interlaboratory data exchange.

STR, Sequencing, Nomenclature

B42 An Evaluation of the Current Opinion of Next Generation Sequencing (NGS) Technology in Forensics Through a Global Survey

Megan Foley, MSFS*, Center for Forensic Science Research & Education, Willow Grove, PA and George Washington University, Washington, DC;
Fabio Oldoni, PhD, Arcadia University, Glenside, PA

Learning Overview: After attending this presentation, attendees will better understand the current status of next-generation sequencing (NGS) in crime laboratories around the world and the opinions of forensic DNA researchers/practitioners on the issues and future implementation of NGS in casework.

Impact Statement: This presentation will impact the forensic science community by exploring the opportunities for improvement and needs for implementation of NGS technologies into research and casework laboratories based on survey data.

Next-generation sequencing (NGS), also known as massively parallel sequencing (MPS), is gradually gaining traction in the forensic field as a few crime laboratories are beginning to validate and implement this new technology in casework.^{1,2} Forensically relevant research on NGS has been ongoing in the field and an increasing volume of data has been published that focuses on furthering the amount of information that can be generated from genetic material collected from crime scene evidence.^{3,4} However, the implementation and acceptance in the overall forensic community on the use of NGS on actual casework has been slow, especially in the United States. NGS data allows informative genetic information to be generated beyond traditional capillary electrophoresis (CE) practices that are widely used and accepted in the global community. Due to its enhanced multiplexing capability, hundreds of genetic markers can be targeted and processed simultaneously. Furthermore, individual sequences of STR markers are determined which enhances deconvolution of multiple contributors in a mixed profile or separation of true allelic peaks from artifactual data. Additional information can be obtained through the analysis of large SNP assays that can provide an analyst with more identifying information for kinship testing or predict physical traits through ancestral or phenotypic biomarkers.^{5,6}

This study was distributed to over 5,000 forensic DNA researchers and practitioners who are current members of the International Society for Forensic Genetics and the American Academy of Forensic Science through a Qualtrics survey. Data were collected from a 20-question online survey hosted by Arcadia University and The Center for Forensic Science Research and Education and approved by the Arcadia's IRB board. Questions included location and information about the laboratory of the responder as well as training/experience received in addition to current NGS technology applications, future technology usage, and opinions of issues of utilizing NGS in the field. The survey had a total of 367 respondents. The majority of respondents were from North and South America (69.75%), followed by Europe (21.25%), Asia (5.45%), Oceania (2.45%), and Africa (1.09%). A total of 187 respondents were practitioners, 115 researchers, and 65 performed both research and casework. About 38% of the responders currently have an NGS system in place in their laboratory and about 13% are planning to purchase an NGS instrument.

The results of the survey indicate that there is general knowledge of the application of NGS in forensics. Nonetheless, some of the major hurdles that many laboratories are presently facing in order to implement NGS into their analytical workflows include among others funding, staffing, limited value added, time and cost-effectiveness. Additionally, there are several technical concerns that respondents have even if they had the time and funding in their laboratory to purchase a massively parallel sequencing instrument. Some of the main concerns included training, no current statistical applications, bioinformatics support, lack of well-defined recommendations and guidelines, and court admissibility. Overall, the data displays that the respondents believe there will be a technology shift from CE to NGS in the next 5-10 years. In a nutshell, this presentation will illustrate the current usage of NGS technology throughout the world and will address strategies to overcome current analytical challenges for its implementation.

Next Generation Sequencing (NGS), Online Survey, Forensic DNA

B43 American Forensic Practitioners' Opinions on Activity-Level DNA Reporting

Yoon Yang, MS*, Arcadia University, Glenside, PA; Mechthild Prinz, PhD, John Jay College of Criminal Justice, New York, NY; Heather McKiernan, PhD, Center for Forensic Science and Research Education, Willow Grove, PA; Fabio Oldoni, PhD, Arcadia University, Glenside, PA

Learning Overview: By attending this presentation, attendees will have a better understanding of the status of activity level evaluative reporting in the United States.

Impact Statement: This presentation will impact the forensic science community by serving as a gap analysis of this area of research and give insight to any differing opinions among forensic practitioners in the U.S.

In criminal cases involving DNA evidence, it may not be the source of the DNA that is disputed in court, but rather how the DNA was deposited at the scene of crime.¹⁻³ Activity level propositions have been considered to address and answer this question.¹⁻³ However, there are many factors that should be included when formulating propositions at activity level, such as transfer, persistence, prevalence, and recovery (TPPR). Nevertheless, European laboratories have used evaluative reports under the hierarchy of propositions in court, and the European Network of Forensic Science Institutes (ENFSI) has issued specific DNA guidelines on the process. Despite this, the overall views of activity level DNA reporting in the U.S are not well known. Therefore, this study aimed at obtaining an overview on the opinions of using activity level reporting held by forensic DNA practitioners in the United States.

A seventeen-question survey was distributed through Qualtrics™ to members of the American Society of Crime Laboratory Directors (ASCLD) via the weekly Crime Minute and the International Society for Forensic Genetics (US members only) via email. The survey included multiple choice and open response questions and reached around 650 people.

Overall, there were 54 respondents to the survey in which 44 of them had over ten years of experience in DNA reporting at activity level. Of those 44 with over 10 years of experience, 72% agreed that despite having some concerns activity level reporting would be very (27%) or moderately (45%) useful. Only 31% believed that the current studies on DNA transfer were moderately adequate to provide empirical information on a case. A total of 41% of participants agreed that one year of training on activity level DNA reporting would be sufficient for a scientist to testify as an expert witness. There were six major concerns for implementing activity level DNA reporting in the U.S.: (1) the number of variables to be considered in activity level reporting such as shedder status, amount of starting DNA, or differing transfer rates based on surfaces; (2) educating practitioners and the legal system; (3) lack of controlled studies with realistic scenarios; (4) issues in court with admissibility. With this regard, some participants expressed concern that activity level propositions will have a difficult time passing a Daubert hearing because the approach is not as concrete or statistically sound as a DNA profile match. Moreover, (5) need for a standardized approach or guidelines in the U.S.; and (6) convincing the forensic community and reaching consensus.

These concerns expressed by U.S. forensic practitioners revealed a range of varying opinions on activity level reporting. Future research will involve expanding the participants to a global level.

B44 Microbial Dynamics of Human Decomposition Accurately Estimate Postmortem Interval

Zachary Burcham*, Colorado State University, Fort Collins, CO; Aerial Belk, Colorado State University, Fort Collins, CO; Alexandra Emmons, PhD, Colorado State University, Fort Collins, CO; Heather Deel, BS, Colorado State University, Fort Collins, CO; Amina Bouslimani, University of California San Diego, La Jolla, CA; Zhenjiang Xu, PhD, University of California San Diego, La Jolla, CA; Qiyun Zhu, Arizona State University, Tempe, AZ; Sibyl Bucheli, PhD, Sam Houston State University, Huntsville, TX; Aaron Lynne, PhD, Sam Houston State University, Huntsville, TX; Melissa Connor, PhD, Colorado Mesa University, Grand Junction, CO; Dawnie Steadman, PhD, University of Tennessee Knoxville, Knoxville, TN; Giovanna Vidoli, PhD, University of Tennessee Knoxville, Knoxville, TN; Sasha Reed, U.S. Geological Survey, Moab, UT; Michael Shaffer, Colorado State University, Fort Collins, CO; Kelly Wrighton, Colorado State University, Fort Collins, CO; Parsa Ghadermazi, Colorado State University, Fort Collins, CO; Joshua Chan, Colorado State University, Fort Collins, CO; David Carter, PhD, Chaminade University of Honolulu, Honolulu, HI; Rob Knight, PhD, University of California San Diego, La Jolla, CA; Jessica Metcalf, PhD, Colorado State University, Fort Collins, CO

Learning Overview: After attending this presentation, attendees will have a greater understanding on the importance of studying the microbiome associated with human decomposition for forensic purposes.

Impact Statement: This presentation will impact the forensic science community by conveying how the microbial response to human remains can be modeled to estimate the postmortem interval.

Nearly 64,000 cases (42%) of homicide and non-negligent manslaughter went unsolved in the United States from 2010 to 2019.¹ One approach to solving these cases is to accurately estimate the postmortem interval (PMI), or time since death, using decomposition processes. Estimating PMI can help solve death investigations because it can be used to identify people and establish the investigative timeline. One form of physical evidence that is always associated with decomposing remains is the postmortem microbiome. The postmortem microbiome has predictable characteristics that have proven to be useful for estimating PMI.²

This study provides the first analysis in using multiple ‘omic techniques for the accurate estimation of postmortem interval, leveraging three anthropological facilities to place 36 human bodies to decompose outdoors over multiple seasons. This study used amplicon DNA, metagenomic DNA, and metabolite datasets to build machine learning models with the goal of using ‘omic data feature abundance and geographic location as predictors of PMI. These results show that model accuracy was dependent on taxonomic resolution and site where the sample was derived. The models generated from 16S rRNA genes isolated from the corpse skin and classified at the species level provided the most accurate predictive power over the first 21 days of decomposition. Interestingly, in the gravesoil, taxonomic abundances predicted PMI more accurately than functional features (e.g., gene and metabolite abundances) suggesting either community structure correlates best with decomposition time or higher resolution is required for other ‘omic data types. Further, microbial abundance was more important for predicting PMI than geographic location suggesting shared trends between the three anthropological facilities exists which allow for the use of cross-facility models. This study shows that accurate, microbially-based models for aiding in the estimation of PMI for death investigations can be obtained from multi-omic data including cost-effective, amplicon sequencing data.

Postmortem Interval (PMI), Microbiome, Decomposition

B45 A Pilot Study of Microbial Succession in Human Rib Skeletal Remains During Terrestrial Decomposition

Heather Deel, BS, Colorado State University, Fort Collins, CO; Alexandra Emmons, PhD, Colorado State University, Fort Collins, CO; Jennifer Kiehl, BS, Sam Houston State University, Huntsville, TX; Franklin Damann, PhD, Defense POW/MIA Accounting Agency, Omaha, NE; David Carter, PhD, Chaminade University of Honolulu, Honolulu, HI; Aaron Lynne, PhD, Sam Houston State University, Huntsville, TX; Rob Knight, PhD, University of California-San Diego, San Diego, CA; Zhenjiang Xu, PhD, Nanchang University, Nanchang, China; Sibyl Bucheli, PhD, Sam Houston State University, Huntsville, TX; Jessica Metcalf, PhD, Colorado State University, Fort Collins, CO*

Learning Overview: After attending this presentation, attendees will learn about microbially-mediated decomposition of skeletal remains in a terrestrial environment. They will also learn how technologies (high throughput DNA sequencing of microbial communities) can be used to estimate the postmortem interval (PMI), and how microbial invasion into human rib bones during decomposition may be developed into a novel form of physical evidence for estimating PMI.

Impact Statement: This presentation will provide the forensic science community with a better understanding of novel microbiome tools that may be useful in investigations of unattended death scenes, in which PMI is unknown. In particular, this presentation will show how this approach can be applied to death scenes that are several weeks or months old in which only skeletal remains are found.

In crime scene investigations, estimating the PMI is critical for validating alibis and, in some cases, identifying the deceased. Although there are multiple methods to estimate PMI, there are few tools that are accurate after the first three weeks of decomposition. Therefore, a new tool for estimating PMI on the scale of weeks to months is needed. Microbes are major drivers of decomposition that could serve as evidence if microbial succession is similar across bodies during decomposition. Previous research has demonstrated that microbiome data collected from both mouse models and human bodies can be used to create an accurate “microbial clock of death.” We hypothesize that the invasion of microbes into bone is likely a slow process, and tracking the succession of microbes into bones after death may provide accurate estimates of PMI for longer timeframes of decomposition.

To test this hypothesis, we characterized the human bone microbial decomposer community to determine whether microbial succession is a marker for PMI. Six human donor subjects were placed outdoors to decompose on the soil surface at the Southeast Texas Applied Forensic Science facility. To also assess the effect of seasons, three decedents were placed each in the spring and summer. Once ribs were exposed through natural decomposition, a rib was collected from each body for 8 time points at 3 weeks apart for a total of 48 sampled ribs. After sample collection, samples were shipped to Colorado State University, where each of the rib samples were processed by excising a portion of the bone with a Dremel® drill, cleaning the newly excised piece with bleach and UV irradiation, then pulverizing into a fine powder. Each of the bone powders were demineralized, then DNA was extracted using the DNEasy Powersoil Isolation Kit following the Earth Microbiome Project standard protocols. The bacterial microbiome in each sample was then characterized using 16S ribosomal RNA (rRNA) amplicon sequencing on the Illumina Miseq platform at the University of California, San Diego.

We discovered a core bone decomposer microbiome dominated by taxa in the phylum Proteobacteria and evidence that these bone-invading microbes are likely sourced from the surrounding decomposition environment, including skin of the cadaver and soils. Additionally, we found significant overall differences in bone microbial community composition between seasons. Finally, we used the microbial community data to develop random forest models that predict PMI with an accuracy of approximately 34 days over a 1- to 9-month time frame of decomposition. Typically, anthropologists provide PMI estimates based on qualitative information, giving PMI errors ranging from several months to years. Previous work has only focused on the characterization of the bone microbiome decomposer community, and this is the first known data-driven, quantitative PMI estimate of terrestrially decomposed human skeletal remains using microbial abundance information.

Bone, Microbiome, Postmortem Interval (PMI)

B46 Forensic Microbiology of Human Cadavers in an Experimental Mass Grave

Noemi Procopio, PhD*, Forensic Science Research Group, Faculty of Health and Life Sciences, Northumbria University, Newcastle upon Tyne, England, United Kingdom and Forensic Anthropology Center, Texas State University, San Marcos, TX; Sarah Gino, MD, Department of Health Sciences, Università del Piemonte Orientale, Novara, Italy; Onengiye Ogbanga, MSc, Forensic Science Research Group, Faculty of Health and Life Sciences, Northumbria University, Newcastle upon Tyne, England, United Kingdom; Timothy P. Gocha, PhD, Forensic Anthropology Center, Texas State University, San Marcos, TX; Daniel J. Wescott, PhD, Forensic Anthropology Center, Texas State University, San Marcos, TX; Hayley L. Mickleburgh, PhD, Forensic Anthropology Center, Texas State University, San Marcos, TX and Department of Cultural Sciences, Linnaeus University, Kalmar, Sweden

Learning Overview: Attendees will learn about the impact of freezing and thawing on the postmortem human microbiome, and the implications this may have for experimental microbiome studies at human taphonomy facilities. Additionally, they will learn about metabarcoding experiments currently taking place as part of the Mass Grave Project and about their expected impact on the understanding of microbial successions over the course of time in an experimental mass grave context.

Impact Statement: This presentation will impact the forensic science community by highlighting the validity of microbiome analyses using donated bodies in simulated mass graves and the importance of routinely collecting microbiome samples from body donations prior to their freezing and/or deposition to maximize the chances of obtaining relevant microbiome results for the forensic population.

Microbiome studies are attracting increasing attention among forensic experts due to their potential to reveal valuable information related to individual identity, including geographical origin, health status, postmortem interval (PMI), and even lifestyle of the deceased.¹ To date, microbiome studies have mostly used animal proxies, allowing for large samples to increase statistical power of results.² However, to validate microbiome-based methods for application in forensic casework, further research on human cadavers is needed. Metabarcoding studies are currently being conducted on individual buried or exposed cadavers at human taphonomy facilities across the world, with the aim to map the microbial shifts associated with gross decomposition changes.^{3–5} It has been previously shown that microbial populations are still altered after four years post the deposition of multiple cadavers in a shallow burial.⁶ However, microbial shifts have not yet been studied via metabarcoding in the context of a mass grave, where the presence of multiple decomposing bodies could significantly alter the composition and development of the thanatomicrobiome. Additionally, it is relatively common for donated cadavers to be frozen prior to human decomposition studies, particularly when placement of multiple cadavers simultaneously is required. Previous studies have demonstrated that freezing and thawing can alter the thanatomicrobiome, but there is currently no consensus on the degree of alteration and/or the longer-term effects on its development throughout decomposition.

This project implements metabarcoding analyses on cadavers and soil samples in the first mass grave experiment conducted at Texas State University's Forensic Anthropology Research Facility (FARF). The Mass Grave Project includes a mass grave with six donated human cadavers, a control mass grave without cadavers, three individual graves with cadavers, and one (empty) individual control grave, all buried in May 2021. The experiments will be monitored for 18 months, after which the graves will be excavated. Human microbiome samples were collected by swabbing five different locations on the body (hand, foot, neck, mouth and rectum) prior to freezing, after thawing/before burial, and further samples will be collected upon excavation. The aims of this study are to: (1) examine the effect freezing donated cadavers has on microbiome sampling in taphonomic studies; (2) examine microbial shifts associated with increasing PMIs in a mass grave, how they differ from single burials and how they migrate within different areas of the grave; and (3) compare the microbiome of different body sites before and after the decomposition, to identify good microbial indicators that could be used for estimating prolonged PMIs.

Soil samples are being collected from the graves throughout the 18-month duration. Microbial DNA will be extracted using Qiagen DNeasy PowerSoil Pro Kit and will be analyzed via sequencing of the V4 region of the 16S rRNA gene using Illumina MiSeq platform. NGS data will be analyzed via R scripts normally used in metabarcoding ecology studies. The results on the first aim of the study will be presented and guidelines on microbiota sampling of willed body donations will be proposed for implementation in human taphonomy facilities worldwide.

(Thanato)microbiome, Mass Grave, PMI

B47 Bone Fluorescence, Taphonomy, and the Postmortem Interval (PMI)

Natalie Moss*, University of Georgia, Athens, GA and Forensic Investigation Research Station, Whitewater, CO; Alexander Smith, Forensic Investigation Research Station, Whitewater, CO; and Colorado Mesa University, Grand Junction, CO; Melissa Connor, PhD, Forensic Investigation Research Station, Whitewater, CO and Colorado Mesa University, Grand Junction, CO

Learning Overview: After attending this presentation, attendees will understand the influence of the decomposition microenvironment on the degradation of organic bone and subsequently, the limited potential of using alternate light sources (ALS) to determine general postmortem interval (PMI).

Impact Statement: This presentation will impact the forensic science community by challenging the use of bone fluorescence as a general indicator of PMI and provides experimental data suggesting that the decomposition microenvironment is too variable to allow for bone fluorescence to act as a reliable indicator of forensic relevance.

Bone fluoresces under short-wave visible light due to the presence of fluorophore amino acids in collagen. Phenylalanine, tryptophan, and tyrosine, all present in the organic portion of human bone, have aromatic side ring chains, allowing these amino acids to be optically active under short-wave visible light.¹ Postmortem, however, proteins containing these fluorophore amino acids degrade, subsequently causing a decrease in the fluorescence intensity of bone.² This has catalyzed interest in using fluorescence intensity as an indicator of general PMI.²

To test the potential use of fluorescence as a PMI indicator in an arid environment, the skeletons of eleven individuals placed in the outdoor facility at the Forensic Investigation Research Station (FIRS) in Whitewater, Colorado were examined. All individuals had a known PMI and remained outdoors between 101 and 1,876 days. Following their removal from the outdoor facility, all were cleaned using warm-water maceration, and stored in the FIRS Donated Human Skeletal Collection. On-site weather data was also incorporated into this study to determine if variables other than time had an influence on bone fluorescence. Bones from each individual were photographed under a 430-470 nm Crime-lite with the use of an orange filter. The photographs were then analyzed in ImageJ to determine the intensity of fluorescence, following a modified version of the methodology outlined by Swaraldahab and Christensen.²

All individuals included in this study displayed fluorescence values lower than the ancient samples analyzed by Swaraldahab and Christensen.² The single bone displaying the highest fluorescence intensity value was approximately equivalent to the ancient average described by Swaraldahab and Christensen, while the single bone displaying the lowest fluorescence intensity value was barely visible under the ALS.² Even when ambient temperature and solar radiation were considered in addition to time, no correlation existed between any single variable and bone fluorescence. Therefore, fluorophore degradation in collagen is not linear with respect to any single variable and likely depends on several factors, as it cannot be explained by UV exposure, ambient temperature, or time alone.

Furthermore, caution should be used when employing ALS searches in a forensic context, as suggested by some authors. Forensically relevant skeletal elements may not fluoresce even after a comparatively short time period, and in some environments, are unlikely to fluoresce at all. When an ALS search is used, a lack of discernable fluorescence should never be taken to mean that no bone material is present.

The results of this study highlight the importance of considering regional taphonomic processes in any skeletal study. Methodologies of estimating PMI, even on a general scale, may prove useful to buried populations or those in more temperate environments, but fail when introduced into more extreme climates. Bone fluorescence should only ever be used during ALS searches in a supplementary way and should never be used as an estimate of PMI due to its extreme variability.

Taphonomy , Alternate Light Source , Fluorescence

B48 Bone “Soft” Maceration Procedures at Human Taphonomy Facilities: How “Soft” Are They Really?

Noemi Procopio, PhD*, Forensic Science Research Group, Faculty of Health and Life Sciences, Northumbria University, Newcastle Upon Tyne, England, United Kingdom and Forensic Anthropology Center, Texas State University, San Marcos, TX; Luke William Gent, MRes, BSc, Forensic Science Research Group, Faculty of Health and Life Sciences, Northumbria University, Newcastle Upon Tyne, England, United Kingdom; Andrea Bonicelli, PhD, Forensic Science Research Group, Faculty of Health and Life Sciences, Northumbria University, Newcastle Upon Tyne, England, United Kingdom

Learning Overview: Attendees will understand the impact that different “soft” maceration processes commonly used by human taphonomy facilities for treating bones prior their inclusion in skeletal reference collections have on bone structure and on bone biomolecules, and how these procedures limit potential microscopic and molecular analyses of bone for in vivo and postmortem ageing studies.

Impact Statement: This presentation will impact the forensic science community in terms of competence, by showcasing the effects that “soft” maceration techniques have on bone biomolecules and on bone mineral structure, and performance, highlighting the potential biases caused by bone processing treatments can be avoided if alternative methods are sought by the community.

Bones are a precious reservoir of information on the identity of the deceased. Traditional morphological and metric anthropology approaches have been largely used for biological profiling of unknown skeletal remains.¹ In case of poor preservation, fragmentation or incompleteness of the skeletal remains, microscopic and molecular techniques represent important tools to aid human identification. Biomolecular and microscopic techniques can lead to individual identification via DNA analysis, or reveal information on age at death (AAD) and PMI using proteomics, metabolomics/lipidomics, and biophysical analysis.²⁻⁶ To successfully extract biomolecules without inducing decay, and to avoid the introduction of biases in data interpretation, the structural and molecular composition of bones must remain unaltered by thermal, chemical or mechanical treatments. However, in many human taphonomy facilities, bones undergo several cleaning steps, including “soft” maceration processes prior to long term storage, in order to remove remaining soft tissues after cadaveric decomposition. Depending on the harshness of the methods used, bone physicochemical and molecular properties can be moderately to severely impacted, resulting in a significant loss of information and limiting the usability of these remains in microscopic and molecular studies.

To comprehensively evaluate the extent of damage caused by maceration to bone biomolecules and biophysical properties, three complete right bovine tibiae were experimentally macerated using three different protocols routinely performed at Forensic Anthropological Center at Texas State (FACTS) (n=1) and at Southeast Texas Applied Forensic Science (STAFS) (n=2). These protocols differ by duration of the treatment, water temperature, and cleaning agents used. As part of the “ForensOMICS” project, DNA, proteins, lipids and metabolites were extracted and subjected to sample quality control (DNA) and full omics analysis (proteomics, lipidomics and metabolomics). In addition, a combination of Fourier-transform infrared spectrometry based on attenuated reflectance mode (ATR) and ATR microscopy were performed, to gain insight into mineral degradation induced by the three different treatment protocols. Results from macerated bones were compared to the untreated left tibiae, to take into account the existing biological variability among different animals.

A significant reduction in protein abundances and variety was observed in macerated bones in comparison with the untreated counterparts, particularly when using the protocol with the warmest water temperature. Similarly, metabolites and lipids showed a severe reduction in abundance and revealed a contamination caused by cleaning agents. Finally, mineral crystallinity and phosphate content were heavily affected by treatments, especially when high temperature was applied.

Overall, these findings suggest that caution should be taken when interpreting biomolecular and biophysical results from macerated bones, particularly when data are used to produce regression models for AAD and PMI estimation. Submerging bones at high temperatures (>60°C) for short times is more damaging than a prolonged submersion at lower temperatures, as it heavily affects mineral and organic bone matrix. Ideally, cleaning and maceration protocols should be standardized across human taphonomy facilities, to maximize the data comparability and facilitate comparative studies between taphonomic collections from different environments. Minimally damaging and invasive protocols are needed in order to prepare skeletal remains for long term storage and continued scientific analyses.

B49 The Optimization of the InnoXtract™ Extraction and Purification System for DNA Extraction From Skeletal Samples and Analysis of Subsequent Downstream Processing Methods

Jennifer Snedeker, BS*, Sam Houston State University, Huntsville, TX; David Russell, MS, Signature Science, LLC, Charlottesville, VA; Michelle Peck, MSc, Signature Science, LLC, Charlottesville, VA; Amy Holmes, PhD, Signature Science, LLC, Charlottesville, VA; Elayna Cuzio, MS, Signature Science, LLC, Charlottesville, VA; Christina Neal, MS, Signature Science, LLC, Charlottesville, VA; Carmen Reedy, PhD, Signature Science, LLC, Charlottesville, VA; Sheree Hughes, PhD, Sam Houston State University, Huntsville, TX; Rachel Houston, PhD, Sam Houston State University, Huntsville, TX

Learning Overview: This presentation will provide an overview of the optimization process of DNA extraction and purification from skeletal samples using InnoXtract™ methods. Additionally, a method for assessing which downstream process is better suited for skeletal extracts (on a case-by-case basis based on the quality and quantity of the DNA extract) will be examined.

Impact Statement: Improving human identification methods is an ongoing concern. The introduction of a new DNA extraction and purification method suited for challenging skeletal samples can improve the quantity and quality of DNA recovered. By analyzing a variety of extracts using STR typing, microarray SNP typing, and massively parallel sequencing methods, a procedure for assessing which downstream process is best suited based on the quantity and quality of the extract can be determined. This can provide analysts with a more streamlined process, limit the loss of DNA extract to unsuitable methods, and allow for the implementation of investigative methods such as genetic genealogy or phenotype/ancestry prediction methods.

Often, only skeletal remains are available in human identification cases, requiring challenging DNA typing methods on these samples for definitive identifications. The low-template nature, prevalence of inhibitors, and fragmentation commonly found in skeletal samples complicates this task of human identification through DNA typing and requires additional research on suitable DNA extraction, purification, and downstream processing techniques.^{1,2}

InnoXtract™ (InnoGenomics Technologies) extraction and purification system designed for DNA extraction from low-template samples, specifically rootless hair shafts.³ In addition, its ability to capture highly fragmented DNA suggested its suitability for use with skeletal samples³. However, the lysis and digestion parameters required modifications to optimize the method for this sample type.

Preliminary studies determined that InnoXtract™ purification parameters were most compatible with PrepFiler™ BTA (Thermo Fisher Scientific) lysis parameters; therefore, InnoXtract™ lysis parameters were designed similarly to this method. A two-part digestion was developed using a homebrew digestion buffer (0.5M EDTA, 0.05% Tween 20, and 100 mM NaCl) and a supplemental lysis with the hair digestion buffer included in the InnoXtract™ kit. The InnoXtract™ purification parameters were also modified to better suit skeletal samples by increasing the volume of magnetic beads allowing for maximal capture of DNA fragments. Following these modifications, the optimal volume of sample input was examined. The optimized InnoXtract™ method provided extracts with similar quality and quantity of recovered DNA compared to the commercial skeletal extraction method, PrepFiler™ BTA.

The optimized InnoXtract™ and PrepFiler™ BTA extraction methods were performed on various challenging skeletal samples (from surface decomposed, buried, embalmed, burned, and cremated remains). These extracts will be analyzed using three downstream processing methods; STR typing (Investigator 24plex QS; QIAGEN), microarray SNP typing (Infinium Global Screening Array; Illumina Inc.), and massively parallel sequencing techniques (ForenSeq Signature Prep Kit and ForenSeq Kintelligence Kit; Verogen). By examining the overall success of each method compared to each extract's DNA quantity/quality, a recommendation on the best-suited method will be determined. Initial data indicates several extracts have sufficient DNA recovery to yield complete STR profiles. Additionally, the Global Screening Array demonstrated sensitivity for DNA input down to 200 pg, indicating the improved sensitivity for forensically relevant SNPs. The ForenSeq Kintelligence kit provided an average total call rate of 9938 ± 258 SNPs at 1 ng input from challenging skeletal remains. These data indicate the potential success of this new extraction method with compromised skeletal remains utilizing a variety of downstream processing techniques.

This presentation will highlight the success of the newly optimized InnoXtract™ method for DNA extraction and purification from skeletal samples and demonstrate what downstream process should be implemented depending on each extract's DNA quantity and quality.

Skeletal Remains, Human Identification, DNA Extraction

B50 The Application of Ancient DNA Methodologies to Burned Forensic Samples and Their Potential to Aid in the Identification and Analyses of Difficult Samples

Cody Parker, PhD, School of Human Evolution and Social Change, Arizona State University, Tempe, AZ; Erin Rawls, BSc, School of Human Evolution and Social Change, Arizona State University, Tempe, AZ; Katelyn Bolhofner, PhD, Office of the Medical Examiner, Maricopa County, Phoenix, AZ; Laura Fulginiti, PhD, Office of the Medical Examiner, Maricopa County, Phoenix, AZ; Giovanna Vidoli, PhD, Forensic Anthropology Center, Department of Anthropology, University of Tennessee, Knoxville, TN; Joanna Devlin, PhD, Forensic Anthropology Center, Department of Anthropology, University of Tennessee, Knoxville, TN; Sree Kanthaswamy, PhD, School of Mathematical and Natural Sciences, Arizona State University, Tempe, AZ; Anne Stone, PhD, Arizona State University, Tempe, AZ and University of Arizona, Tempe, AZ*

Learning Overview: The purpose of this presentation is to present a generalized overview of the experimental design and preliminary data related to the potential gains expected from incorporating methodologies adopted from the analyses of ancient DNA regarding the efficacy of the isolation and analysis of degraded DNA from badly burned forensic samples.

Impact Statement: After completion, this research will provide a much-needed generalized set of suggested protocols for the isolation and analyses of burned forensic samples. This research will serve as an optimal sampling guide for basic sampling strategies and locations, DNA extraction methods, short tandem repeat (STR) profiling, and mitochondrial DNA (mtDNA) library preparation when dealing with degraded or burned forensic samples.

The ability to identify human remains using DNA analyses has revolutionized forensic science and become a standard procedure. However, most analyses generally rely on the presence of ample, minimally degraded endogenous DNA, which may not always be available. This is especially true when considering source material which may have compromised DNA retention due a variety of factors, including post-mortem decay and other alterations such as burning (thermal) and insect activity etc.

For temporally degraded remains, the breakdown of DNA molecules over time can drastically reduce DNA yields, DNA fragment length, and/or alter base composition via the conversion of cytosine to uracil through hydrolysis. As a result, the field of ancient DNA (aDNA) analyses has independently developed protocols for sampling, DNA extraction, and analyses optimized to take this degradation into account and maximize the quantity and quality of endogenous DNA recovered. In forensic DNA analysis, recent studies have shown that the adoption of aDNA techniques can lead to more successful outcomes in forensic samples having undergone minimal temporal degradation.

However, not all sample degradation is due to time or other environmental factors. The exposure of tissue to extreme temperatures, such as when burned, similarly affects DNA degradation in that much of the DNA is destroyed outright. Furthermore, the fragment length of recovered DNA may be drastically shorter, depending on the level of thermal exposure. Currently, the standard measure of the thermal alteration of remains is categorized based on severity along a scale of one to five. Tissue exhibiting low levels of alteration (e.g. superficial charring) being graded as a “one,” and the most severely altered tissues being graded at level “five” (fully burned cremains). Previous studies have shown that DNA recovery becomes increasingly difficult as the burn category of remains increases. The efficacy of aDNA techniques has only just begun to be explored. However, preliminary studies show that they may be more efficient than modern techniques, especially in regards to heavily altered samples in burn categories four and five. Presented here is a continuation of this research focusing on samples in burn categories three and higher, comparing forensic and ancient DNA laboratory protocols including the previously studied Dabney ancient DNA extraction protocol vs. the Lorielle modern forensic protocol as well as a new comparison of single-stranded next-generation sequencing (NGS) library preparation vs. double-stranded library techniques. In addition, a systematic analysis of DNA yields across a wide range of skeletal elements and associated sampling locations will serve as a basis for future sampling strategy formation.

Ten donor cadavers were burned under similar conditions at the University of Tennessee Research Center. From each of these individuals, the same twelve skeletal elements exhibiting the characteristics of burn categories three or higher were then collected and sent to Arizona State University’s School of Human Evolution and Social Change (SHESC) for DNA extraction and analyses. DNA extractions using both tested protocols are performed using the same source material for each sample. The DNA extracts are then analysed for both DNA yield and STR profile recovery. Next, each extraction will then be converted into both double and singlestranded DNA sequencing libraries and be enriched for both mtDNA and a set of diagnostic single nucleotide polymorphisms (SNPs) for further analysis. Casework samples from the Office of the Medical Examiner, Maricopa County, Arizona, are also processed alongside the controlled samples to establish a better sense of practical expectations. This study will serve as an optimal sampling guide for basic sampling strategies and locations, DNA extraction methods, STR profiling, and target enriched DNA library preparation from degraded or burned samples.

Forensic DNA, Method Development, Burned Remains

B51 Rapid DNA Profiling for Disaster Victim Identification (DVI)

Jeremy Watherston, MS, NSW Health Pathology Forensic & Analytical Science Service, Sydney, NSW, Australia; David Bruce, PhD, NSW Health Pathology Forensic & Analytical Science Service, Sydney, NSW, Australia; Dennis McNevin, PhD, University of Technology Sydney, Sydney, NSW, Australia; Jodie Ward, PhD, University of Technology Sydney, Sydney, NSW, Australia*

Learning Overview: Attendees can expect to learn about rapid DNA profiling protocols for decomposed human remains and disaster victim identification (DVI).

Impact Statement: This presentation has the potential to expedite the disaster victim identification (DVI) process, especially in remote locations.

Advances in forensic biology have increased options for the collection, sampling, preservation and processing of human remains for DNA-based identification. Targeting minimally-invasive post-mortem (PM) sample types that are simple to collect and do not require extensive preparation and testing protocols such as nail, distal phalanges (including whole digits) and femur drillings, is useful for DVI with sampling amenable to in-field collection.¹⁻³ Approaches which preserve sample, reduce analytical turnaround times and save resources, have the potential to expedite the identification process and provide answers to grieving families sooner.

At the Australian Facility for Taphonomic Experimental Research (AFTER), a human taphonomic facility, authentic PM samples in various stages of decomposition were collected from human cadavers and subjected to rapid collection, preparation and processing applications. A range of environmental conditions and deposition states were considered including surface and sub-surface decomposition, with post-mortem intervals (PMI) ranging from zero days to four years.

In 2019 and 2020, DVI simulations were conducted at AFTER. Whole and fragmented human cadavers were positioned to replicate a building collapse scenario and left to decompose for up to four weeks. This study evaluated the utility of the ANDE™ 6C Rapid DNA System and the RapidHIT™ ID System for DVI in the field and mortuary.² Applying PM nail and tissue biopsy samples showed promise, with the added benefit of minimally-invasive collection procedures and limited preparation requirements. Both platforms demonstrated utility for assisting with in-field identification and re-association of human remains.

Efficient DNA profiling approaches to PM samples were also developed for DNA-based identification. Incubating nail, distal phalanges and whole digits in 500 µL of PrepFiler™ Lysis Buffer for two hours was an efficient and simple method, limiting or removing sample preparation. A reduced 15-minute incubation also yielded DNA profiles, suggesting a shorter incubation may lyse sufficient DNA. These protocols have combined and modified previous work to develop a powder-free, rapid 15-minute PrepFiler™ Lysis Buffer incubation that is compatible with downstream automated processing; reducing sample preparation and extraction to two hours.³⁻⁵ Immersing whole digits in leaching and preserving solutions such as dimethyl-sulfoxide-ethylenediaminetetraacetic acid-salt saturated (DESS) solution is also a viable option for DVI.³ While the application of leached and preserved DNA to direct PCR on automated platforms was met with limited success⁶, swabs immersed in DESS were successfully applied to existing automated processes in an operational forensic laboratory.³

Optimal sample selection and collection can assist in facilitating downstream processing and can be combined with efficient DNA profiling protocols that involve minimal preparation and pre-treatment steps to expedite the identification of the deceased in mass fatality incidents. Furthermore, these protocols are compatible with existing DNA assays and automated instruments.

Taphonomy, Rapid DNA, Disaster Victim Identification

B52 The Identification and Characterization of Viral Biomarkers

Ema Graham, MS, University of Nebraska-Lincoln, Lincoln, NE; Michael Adamowicz, PhD, University of Nebraska-Lincoln, Lincoln, NE; Jennifer Clarke, PhD, University of Nebraska-Lincoln, Lincoln, NE; Samodha Fernando, PhD, University of Nebraska-Lincoln, Lincoln, NE; Joshua Herr, PhD, University of Nebraska-Lincoln, Lincoln, NE*

Learning Overview: After attending this presentation, attendees will have a better understanding of the development of the human skin virome and its potential use as an alternative genetic marker. This study presents research identifying human skin viral markers that have both stability and sufficient diversity across the study population to generate a profile that is appropriate for forensic human identification.

Impact Statement: The goal of this presentation is to demonstrate the applicability and development of human skin virome biomarkers that can be utilized in an accurate, reproducible, and highly discriminatory pattern profile for human identification. In situations of very low DNA template availability, degradation of DNA can lead to stochastic amplification and incomplete allele detection. As such, in situations where traditional short tandem repeat (STR) analysis of human DNA is not possible, novel methodologies and tools need to be developed to utilize alternative, stable, and robust genetic sources for human identification. The human virome is a stable source of rich genetic diversity that has the potential to be utilized as one of these alternative genetic sources. Previous studies have explored the skin bacterial microbiome for forensic application; however there is a lack of studies into the human skin virome. The study described in this presentation evaluated viral signatures for human identification.

In this study, human skin viromes of 42 study participants consisting of three anatomical skin locations (right and left hand and scalp) were evaluated over a 6-month period ($n=652$). Extracted skin virome samples were sequenced using the Illumina HiSeq 2500 platform to obtain a minimum depth of 12,000,000 reads per sample. The subsequent sequencing data was quality trimmed and filtered to remove low quality reads and Phi X contamination. All samples were mapped to the human genome to remove sequences of human origin. The resulting sequences were assembled on an individual sample basis. Additionally, all samples were pooled and assembled as a single dataset to improve assembly and annotation of sequences. The contigs generated were evaluated for viral gene presence and annotated using viral databases and were mapped back to each individual sample to measure viral presence and abundance. Statistical analysis was performed on annotated viral contigs and their abundance using relevant peer reviewed ecological statistic packages in R to assess virome stability, viral populations in the human skin virome, and to identify markers for human identification.

In total, 59 viral makers (38 viral species and 21 novel viral contigs) were identified as being significantly stable across four out of the five time points ($P=5.3 \times 10^{-15}$) within subjects in the study population, using both database and metagenome assembly dependent and independent methodologies. All identified makers displayed stability across the three anatomical skin locations tested within at least one individual. The diversity profile of these identified markers was significantly different between individuals on the basis of presence and absence of the makers as measured by using binary Jaccard dissimilarity distances between all subjects ($P=0.002$). Of these markers, seven of the identified viral species markers were present across the majority of samples and are thus proposed for future studies into genetic variation and single nucleotide polymorphisms comparisons for subject differentiation. Additionally, 21 of the established markers were novel viral genomes. This was determined by their genome containing at least one known viral gene. However, they had little to no sequence similarity to any viral or organism in current genome databases. The remaining 38 makers were all taxonomically annotated and were classified under the viral order *Caudovirales* and the viral families *Papillomaviridae*, *Genomoviridae*, and *Baculoviridae*. This presentation will discuss the utilization of the human skin virome for human identification purposes and introduce the development of an alternative genetic profile consisting of viral markers that can be used in conjunction with traditional human STR analysis to increase power of discrimination in resulting subject profiles.

Virome, Biomarker, Human Identification

B53 Seasonal Comparisons Between Soil Fungal and Bacterial Communities Impacted by Human Decomposition

Lois Taylor, PhD, University of Tennessee, Knoxville, TN; Allison Mason, BS, University of Tennessee, Knoxville, TN; Jennifer DeBruyn, PhD, University of Tennessee, Knoxville, TN*

Learning Overview: After attending this presentation, attendees will gain an understanding of seasonal (warm vs. cool season) fungal and bacterial successional patterns, how those patterns relate to prevailing soil chemistry during human decomposition over the long term (1 year), and their collective importance for time-since-death estimations.

Impact Statement: This work improves our understanding of both seasonal and long-term microbial community shifts observed during human decomposition and has implications for postmortem interval (PMI) estimation.

Terrestrial human decomposition creates localized hotspots of increased chemical activity, nutrient cycling, and microbial activity within the soil.^{1,2} While microbial communities (bacterial and fungal) have been evaluated during warm-weather decomposition experiments, few studies have evaluated patterns associated with cool weather when insects are less abundant or absent. Furthermore, there has been limited comparison between bacterial and fungal successional characteristics across seasons, and limited associations with changes in soil chemistry. Bacterial and fungal decomposers utilize different resource pools and respond to altered nutrient and environmental (e.g., soil chemistry) conditions.³ Since soil chemistry and nutrient profiles change dramatically during the decomposition process, this highlights a need for comparative study of these effects on bacterial and fungal communities as well as evaluating these changes by season.

The goals of this study were to reveal seasonal patterns in bacterial and fungal community structure during long-term decomposition (1 year) and to relate these changes to soil chemistry. Two year-long seasonal human decomposition trials were conducted at the University of Tennessee Anthropology Research Facility. A total of six donated human subjects (n=3 spring, n=3 winter) were placed at the facility and allowed to naturally decompose on the soil surface. Soil was subsampled at two depths: 0-1 cm (interface sample), and at 1-15 cm (core sample). 20 samples were taken annually for the spring study, and 19 for the winter study. Illumina amplicon sequencing was performed targeting the 16S rRNA and ITS2 gene regions in order to evaluate changes in bacterial and fungal communities. Soil chemical parameters measured included: pH, electrical conductivity (EC), respiration rates (evolved CO₂), dissolved oxygen (O₂) percentages, total carbon and nitrogen (TC/TN), and inorganic nitrogen concentrations (NH₄⁺, NO₃⁻).

Principal coordinates analyses (PCoA) showed that both bacterial and fungal community composition significantly changed over time and differed by morphological decomposition stage in both seasonal trials (PERMANOVA, $p < 0.05$). Irrespective of season, fungal community composition shifts exhibited two distinct inflection points coupled with changes in soil chemistry. The first occurred during the onset of advanced decay, corresponding to initial decreases in soil oxygen and pH, and increased NH₄⁺, EC, and CO₂. The second occurred during late advanced decay, corresponding to recovery of soil oxygen levels to >75%, decreased NH₄⁺, and elevated NO₃⁻ concentrations. Bacterial communities exhibited less clearly-delineated compositional shifts and higher variability (beta dispersion) during active and advanced decay. Additionally, bacterial communities stratified during late advanced decay, showing distinct community differences between cores and interface samples which remained differentiated at the end of the year-long study. Collectively, bacterial and fungal communities appeared to exhibit different successional driving mechanisms; while both responded to soil chemistry changes, fungal succession appeared more closely coupled with soil oxygenation. The magnitude of changes in soil chemistry parameters and microbial community structure was more pronounced in the spring study than in the winter study, as evidenced by a shorter-duration nutrient pulse with higher concentrations, and greater shifts in relative abundances of microbial taxa. After 1 year, soil communities remained altered and had not returned to their initial structure, regardless of season.

Funding for this project was provided by the National Institute of Justice GRF-STEM (2017-R2-CX-0008).

Human Decomposition, Soil Chemistry, Microbial Succession

B54 Body Mass Index (BMI) Impacts on Soil Chemical and Microbial Responses During Human Decomposition

Allison Mason, BS*, University of Tennessee-Knoxville, Knoxville, TN; Hayden McKee, MSc, University of Tennessee-Knoxville, Knoxville, TN; Katharina Hoeland, MS, University of Tennessee-Knoxville, Knoxville, TN; Sarah Schwing, MA, University of Tennessee-Knoxville, Knoxville, TN; Erin Patrick, MSc, University of Tennessee-Knoxville, Knoxville, TN; Shawn Campagna, PhD, University of Tennessee-Knoxville, Knoxville, TN; Dawnie Steadman, PhD, University of Tennessee-Knoxville, Knoxville, TN, Jennifer DeBruyn, PhD, University of Tennessee-Knoxville, Knoxville, TN

Learning Overview: After attending this presentation, attendees will understand how body mass index (BMI) influences chemical and microbial patterns in decomposition-impacted soil. This presentation will increase attendees' knowledge of human decomposition processes, including inter-individual variability in decomposition due to BMI, particularly as it relates to the soil environment.

Impact Statement: This presentation will impact the forensic science community by furthering the knowledge of cadaver-related factors (intrinsic factors), specifically BMI, and how they impact soil chemical and microbial response during decomposition.

Human decomposition is a complex process that is driven by the activity of decomposer organisms, including soil microbes.¹ Multiple factors can influence decomposer presence and/or activity, including extrinsic (e.g., temperature, moisture, etc.) and intrinsic, cadaver-related factors.^{2,3} To date, a majority of decomposition studies have assessed the importance of extrinsic factors in decomposition; however, the effects of intrinsic factors has received little attention.⁴ BMI, one intrinsic factor of interest, is the relationship between an individual's weight and height and is commonly used to estimate body fat. Body fat varies between individuals due to sex, age, and health status/medical conditions, thus, BMI of individuals in death investigations is expected to vary.⁵ The goal of this work was to assess the effect(s) of BMI on soil chemical and microbial patterns during human decomposition.

Decomposition of 19 deceased human donors was observed through the end of active decomposition (here defined by cessation of decomposition fluid purging from the abdomen). This study took place at the University of Tennessee Anthropology Research Facility between February 2019 – March 2020. BMI was calculated [weight(kg)/height(m)²] from reported values and individuals were sorted into BMI categories following CDC BMI levels (Underweight < 18.5, normal 18.5 – 24.9, overweight 25 – 29.9, obese > 30). Control and decomposition soil samples were taken at predetermined accumulated degree hours (ADH) intervals until the end of active decomposition. To understand soil chemical patterns, soil pH and electrical conductivity (EC) were measured. Soil microbial activity was assessed via heterotrophic respiration and extracellular enzyme assays. Co-extracted bacterial and fungal DNA was quantified, and community composition was examined using 16S rRNA gene and internal transcribed spacer (ITS) amplicon sequencing, respectively.⁶⁻⁸

Results indicate that an individual's BMI impacts both soil chemical and microbial responses during human decomposition. First, soil pH response is related to donor BMI. For underweight individuals, soil pH increased during decomposition, while decreasing for normal, overweight, and obese donors ($F = 9.647$; $p < 0.001$). This variability in soil pH impacted microbial community activity, specifically leucine amino peptidase (LAP) activity, whereby LAP activity increased with increasing soil pH ($F = 4.781$; $p = 0.032$). While LAP activity was related to soil pH, no relationship was found with donor BMI ($F = 2.444$; $p = 0.131$), suggesting soil pH acts as a control on LAP enzymatic activity. Soil microbial community compositional shifts over time were also impacted by donor BMI. The soil fungal class, Saccharomycetes, was found to increase in decomposition soils of normal, overweight, and obese individuals, but did not increase for underweight individuals ($F = 10.846$; $p = 0.014$).

Taken together, this study provides evidence that donor BMI influences chemical and microbial patterns in decomposition-impacted soil, resulting in inter-individual variability. These results highlight the importance of intrinsic factors in human decomposition and have considerable implications for soil chemical and microbial-based postmortem interval (PMI) models, which rely on consistent responses between individuals.

B55 Proteomic Genotyping in Compromised Skeletal Remains

Glendon Parker, PhD, University of California-Davis, Davis, CA; Jennifer Snedeker, BS, Sam Houston State University, Huntsville, TX; Trevor Borja, MSFS, University of California-Davis, Davis, CA; Rachel Houston, PhD, Sam Houston State University, Huntsville, TX

Learning Overview: This presentation will provide attendees a side-by-side comparison of proteomic- and DNA-based genotyping of degraded forensic anthropological samples.

Impact Statement: This presentation demonstrates novel ways by which genotypes can be obtained from degraded skeletons.

This presentation will provide attendees with information regarding a side-by-side comparison of proteomic- and DNA-based genotyping of forensic anthropological samples. This project examines the relative success of DNA and protein levels as well as standard short tandem repeat (STR) typing and GVP typing to identify skeletal remains subjected to a variety of insults including formaldehyde damage, burial, burning, and decomposition.

Skeletal material is often the only remaining evidence in missing persons cases, mass disasters, or mass burials. Nuclear DNA can be highly degraded in these samples making it difficult to recover quality profiles. This is especially true in the highly challenged remains from Ground Zero or the Punchbowl case. Conversely, proteins are chemically more stable than DNA and contain GVPs that can be used to infer a forensically useful autosomal SNP genotype and random match probabilities. Because human remains often undergo multiple stresses, it is important to determine if GVPs can be used to individualize bone samples under a variety of conditions. It is also necessary to examine and compare the quality of results with DNA and standard STRs.

In this study bone samples were subjected to five treatments: embalming, burning, burial and surface decomposition without and with extensive formalin treatment for 0, 0.25, 14, 24, and 66 hours. DNA extraction was performed using PrepFiler BTA chemistry followed by quantification via real time PCR using the Quantiplex Pro Kit and genotyping using the QIAGEN Investigator 24plex Kit. Formalin treatment decreased the overall DNA quantity by 98% percent ($p = 0.017$). Recovery of STRs was more stable with a reduction in alleles detected of only 23%, 26%, 25% and 64% with the increasing time points of formalin treatment. STR results showed a decrease of 82 ± 2 % alleles recovered to 30 ± 0 % after 66 hours. As expected, with the other challenging samples, DNA concentration ranged from 0.0055 ng/ μ L ng to 9.5539 ng/ μ L, and STR results ranged from 31% to 100%. After extraction of bone protein after demineralization and protease digestion and mass spectrometry a similar trend was seen when examining total peptide and unique peptide recovery. Total peptide recovery was consistent between the 24- and 66-hour mark and the unique peptides recovery only decreased slightly. Additionally, the DNA input for buried samples was lowest whereas the total peptide amount was highest for these samples. This suggests that with highly degraded samples, proteins are better preserved and can be more readily detected than STRs. There was also larger variation seen between DNA input and the percentage of STR alleles correctly called versus total peptide input and unique peptides called. This variation suggests that using GVPs for identification purposes can provide a more consistent result.

The preservation of peptide information in highly compromised skeletal material led to the hypothesis that the information from genetically variant peptides would also preserve well. GVPs were detected in all samples, the first example of proteomic genotyping in forensic anthropological samples. Depending on the individual 2 to 9 GVPs were detected in skeletonized material. Also, GVP-interpreted SNPs resulted in accurate allele calls. This suggests that in evidence where nuclear DNA is highly degraded protein-based human identification can be used to help determine a genetic profile from multiple sources. More GVPs identifications will occur as refinement and improvements are made in extraction methods of protein from skeletonized material. Proteomic information can then combine with nucleotide-based information to create complex genotypes with higher levels of discriminatory power and utility to forensic investigators.

Proteomic Genotyping, Human Identification, Single Nucleotide Polymorphisms

B56 The Use of Proteomic Genotyping to Estimate Genetic Ancestry for Intelligence Purposes

Zachary Goecker PhD, University of California Davis-Davis, CA; Noah Herrick, MSFS, Indiana University–Purdue University Indianapolis, Indianapolis, IN; Bailey Wills, MSFS, Indiana University–Purdue University Indianapolis, Indianapolis, IN; Susan Walsh, PhD, Indiana University–Purdue University Indianapolis, Indianapolis, IN; Glendon Parker, PhD, University of California-Davis, Davis, CA*

Learning Overview: After attending this presentation, attendees will have a better understanding of the potential of protein-based genetic information to estimate ancestry.

Impact Statement: This presentation will impact the forensic science community by demonstrating that protein can provide useful genetic information and investigative leads when DNA is compromised or provides ambiguous findings.

Forensic science often requires the generation of leads from trace evidence left at a crime scene. Hair shafts have been used historically for identification and ancestry determination, but these results have become controversial since they depend on pattern-based microscopic comparisons to determine identity and ancestry. Hair shafts do however contain genetically variant peptides (GVPs) with single amino acid changes, the result of non-synonymous single nucleotide polymorphisms (SNPs). Proteomic detection of genetically variant peptides (GVPs) therefore allows the inference of corresponding SNP alleles. Combinations of these particular genotypes can then be used to estimate random match probabilities and relative likelihood of an individual's genetic ancestry.

In this study, proteomic genotyping was conducted on human hair shafts to assess the ability of several GVPs found in order to classify individuals by biogeographic background. Matching hair and saliva were collected from a cohort of 174 individuals for proteomic and genomic genotyping. This cohort consisted of African, European, Asian, Middle Eastern, and admixed individuals. The study identified potential ancestry informative peptide biomarkers by assessing F_{ST} and H_o from a list of total observed GVPs ($n=408$), and 11 more when also incorporating sensitivity, linkage disequilibrium, and Hardy-Weinberg equilibrium. In addition, variable importance scores from partial least squares discriminant analysis identified over 50 more GVPs that contribute more heavily to the separation of data. Using a list of 408 validated GVPs, European, African, and admixed individuals were classified by three statistical methods: 1) multivariate analysis of GVP profile, 2) modeling using common population genetics software, and 3) calculation of likelihood ratios using estimates of random match probability.

Population genetics software programs such as STRUCTURE and ADMIXTURE resulted in a variance of 8% between the estimated values of ancestry using 53 discovered GVP SNPs versus 495 known ancestry informative markers using DNA-based SNP genotyping as a proof of concept. Likelihood ratios showed distinct distributions for each population, with a correlation between ratio and per cent African ancestry. Population estimates using proteomically-derived LR values were significantly correlated with genomically-derived per cent African ancestry ($p<0.01$). Improvements in discovery and detection sensitivity will further increase the resolution and statistical power of ancestry inference using GVP generated SNP information. These results indicate that methods of biogeographic classification from proteomic genotyping offer a valid alternative to current methods using hair shafts, particularly as proteomic genotyping becomes more a refined, sensitive and validated method. In sum, proteomics has the potential to provide actionable ancestry intelligence information about a deposited hair sample, regardless of the absence of the hair bulb structure.

Proteomic Genotyping, Ancestry Informative Markers, Genetically Variant Peptides

B57 The Development and Evaluation of Two DNA Collection/Extraction Techniques for Cartridge Cases

Kyleen Elwick, PhD*, Federal Bureau of Investigation, Quantico, VA; Quentin Gauthier, PhD, Federal Bureau of Investigation, Quantico, VA; Stephanie Rink, MFS, Federal Bureau of Investigation, Quantico, VA; Emily Cropper, MS, Federal Bureau of Investigation, Quantico, VA; Mark Kavlick, PhD, Federal Bureau of Investigation, Quantico, VA

Learning Overview: After attending this presentation, attendees will gain an understanding of how two different collection/extraction methods may be used to recover DNA from fired and unfired cartridge cases.

Impact Statement: This presentation will impact the forensic science community by demonstrating the utility of two DNA collection/extraction methods for the recovery of DNA from fired and unfired brass and nickel-plated cartridges.

For more than 10 years, studies have modified DNA collection, extraction, purification, and amplification with varying levels of success attempting to increase the recovery of DNA from ammunition; two studies were most notable. Montpetit & O'Donnell modified the method developed by Dieltjes et al. by adding DNA concentration following extraction, referred to as the "soaking" method.^{1,2} The second method, referred to as "rinse-and-swab" was developed by Bille et al.³ This method employs two different swab types and an additive solution to reduce the effects of copper degradation on DNA.

The purpose of this project was to compare these two promising DNA collection techniques for fired and unfired cartridge cases. First, cartridges from various manufacturers were tested for the presence of exogenous DNA. Then the two DNA collection methods were evaluated on an inert substrate that does not have metal ion interactions. Next, both methods were tested on brass and nickel-plated cartridges, both fired and unfired. Finally, the two methods were modified in an attempt to increase DNA yield and recovery.

For the exogenous DNA experiment, 210 cartridges derived from nine manufacturers were swabbed and processed using the laboratory SOP, which includes DNA extraction with the EZ1 Advanced XL, DNA concentration, and DNA quantification using Quantifiler Trio. Extracts for which the small autosomal target was quantified (44 of 210) were amplified and genotyped using the GlobalFiler PCR Amplification kit and 3500xL Genetic Analyzer. Of these, only one extract yielded two alleles concluding that the manufacturing process of ammunition is relatively DNA free.

Next, to identify a suitable amount of DNA to spot on cartridges and to obtain a baseline comparison of the two methods, 120 polypropylene 1.1 mL mini tubes were spotted with five concentrations (20ng, 10ng, 5ng, 2ng, and 1ng) of human adult epidermal keratinocytes (HEKa). Twelve mini tubes spotted with each DNA concentration were processed with both the soaking and rinse-and-swab methods. A final concentration of 5ng was chosen for DNA spotting of cartridges for the last two experiments.

Next, both collection methods were compared using brass and nickel-plated cartridges. Briefly, 600 cartridges (300 brass and 300 nickel-plated) were spotted with 5ng of HEKa cells and half were processed using the soaking method and half with the rinse-and-swab method. Each collection method processed 75 brass and 75 nickel-plated cartridges, both fired and unfired. The results show that the soaking method recovered an average of 0.25 ng of DNA or 5.1% recovery, and the rinse-and-swab method recovered an average of 0.28 ng of DNA or 5.8% recovery. Additionally, the results suggest that there is no significant difference in yield between the soaking and rinse-and-swab methods. However, significant differences were observed in fired vs unfired cartridges and brass vs nickel-plated cartridges.

Finally, seven experiments were performed using 25 fired brass cartridges each (n=175) to determine if a hybrid method could be used to increase DNA yield and recovery. These experiments included buffer, incubation, and extraction modifications to both the soaking and rinse-and-swab methods. However, the modifications presented did not result in increased DNA yield or recovery. It was determined that the soaking and the rinse-and-swab methods provided the highest DNA yield and recovery of all modifications tested, and the two methods, once again, did not produce significantly different results.

Cartridges, Soaking, Rinse-and-Swab

B58 A Comparison of the Effect of Manual Versus Robotic DNA Extraction Methods on the Microbial Communities Associated With Forensically Relevant Human Biological Samples

Denise Wohlfahrt, BS, Virginia Commonwealth University, Richmond, VA; Sarah Seashols-Williams, PhD, Virginia Commonwealth University, Richmond, VA; Paul Brooks, PhD, Virginia Commonwealth University, Richmond, VA; Baneshwar Singh, PhD, Virginia Commonwealth University, Richmond, VA*

Learning Overview: After attending this presentation, attendees will have a better understanding of the microbial DNA associated with various human biological samples and how manual and robotic extractions (common in crime laboratories) impact the bacterial structure associated with these samples. Attendees will also have a better understanding of the microbial taxa commonly associated with common DNA extraction reagents.

Impact Statement: This study will aid the forensic community in establishing more robust extraction protocols and methods, specifically regarding robotic extractions that may not be suitable for microbial evidence.

With the emergence of high-throughput sequencing, culture-independent microbiome analyses are being investigated for forensic applications. However, the forensic science biological sample workflow was not designed with microbial evidence in mind, so additional precautions must be clearly defined and implemented. Common forensic DNA extraction kits are not certified to be bacteria free, and it is therefore critical to identify how reagent-based microbes impact the microbial signatures associated with forensically relevant body fluids.^{1,2} This will not only define the reagent-based impacts on our previously developed microbiome-based body fluid identification method but will also define the impact of robotic extraction on these signatures.

This study was designed to investigate how the extraction methods influence the microbial signatures in body fluids. Saliva, feces, vaginal fluid, and menstrual blood were collected in duplicate using an IRB approved collection method. Ten samples of each body fluid were extracted using the standard Forensic Casework Sample protocol on the QIAcube, while the duplicate samples were extracted manually using the QIAamp DNA Investigator Kit according to manufacturer's protocol. All body fluid samples were extracted alongside body fluid specific reagent blanks to evaluate the differences between blank samples extracted robotically versus those extracted manually. This was to determine whether extraction methods impact the presence, absence, and abundance of bacterial taxa, as well as determine whether extraction methods impact the likelihood of cross contamination in reagent blanks.

Immediately after extraction, the V4 region of 16S rDNA was sequenced on MiSeq FGx sequencing platform following the dual-indexing protocol as described by Kozich et al.³ Sequences were then analyzed using mothur version 1.45.3, and statistical analysis was performed using R version 3.6.1.^{4,5}

With the exception of one robotically extracted reagent blank associated with fecal samples, all reagent blanks had DNA concentrations below the limit of detection. A preliminary Analysis of Molecular Variance⁶ comparing reagent blanks only, indicated that there was a significant difference between the reagent blanks extracted manually versus those extracted robotically.⁶

Findings from this study will help minimize errors associated with the accuracy of microbial signature-based method for body fluid identification, while enhancing current forensic protocols.

Body Fluid ID, Microbiome, Robotic Extraction

B59 Using Bone Biology to Optimize Forensic and Ancient DNA Extraction From Post-Cranial Skeletal Elements

Keith Biddle, MA, University of Montana, Missoula, MT*

Learning Overview: The overarching hypothesis of this project is that endogenous DNA levels in post-mortem human bone are primarily dependent on cellular and biochemical factors. More specifically, extraction sites on, or adjacent to, regions of *in vivo* bone remodeling will yield higher amounts of, and better quality, nuclear and mtDNA than extraction sites where cellular populations are minimal. Additionally, biochemical factors, such as increased crystallinity, will be reflected in extracted DNA quality and quantity and can be predicted using ATR-FTIR technology. The project also inspires an array of further research involving testing these methods, hypotheses, and theoretical underpinnings across multiple individuals and varying taphonomic conditions. This framework can also be used to test and track changes in cellular populations in different ages at death, as well as investigating the cellular and biochemical foundations of the various skeletal pathologies.

Impact Statement: Beyond expanding our knowledge, in many forensic and archaeological recoveries, or instances of remains surrendered to an ME/Coroner, the petrous and/or teeth are not present. Therefore, pinpointing the ideal sites for DNA extraction will reduce cost, improve efficiency, and aid in avoiding ethical dilemmas pertaining to destructive analysis of human remains. Research projects and paradigms across anthropology will benefit from an enhanced understanding of the reasons behind differential DNA preservation. This project also allows for an array of teaching opportunities. Undergraduates in both Anthropology and Chemistry Departments have already begun learning about the ethical treatment of human remains, proper drilling techniques, sampling protocols, aDNA and forensic DNA extraction and analysis, and experimental design.

The optimal site for DNA extraction from human skeletal remains lies primarily in the petrous portion of the temporal bone, and secondarily in the dental pulp, though the reasons for this primacy remain a mystery. Studies involving post-cranial remains, however, rely heavily on prior publications or experience, and less on foundational knowledge of cellular populations or biochemical processes and success rates vary widely. In fact, no current studies of skeletal remains exist that incorporate deep understanding of the cellular and biochemical components of bone as a potential reason for differential DNA preservation between or within post-cranial elements. Most of the current literature focuses on the primacy of taphonomic factors in differential DNA preservation. Many such studies do acknowledge and lament the lack of foundational understanding of the cellular and biochemical contribution to forensic and ancient DNA.

This research seeks to fill that void. In this project, over 400 extraction sites, representing cortical, trabecular, and lamellar bone tissue types, were sampled from across the post-cranial skeleton from a single individual, as were the petrous and the right, maxillary 1st molar (RM1). Since it is known that bone cell populations differ across the skeleton, these extraction sites were carefully selected for either their roles in skeletal homeostasis, visible trauma or pathology, or previously documented failure to routinely yield enough DNA for a full STR profile. Scanning electron microscopy (SEM) helped visualize areas of osteoclastic activity and Attenuated Total Reflectance Fourier Transform Infrared (ATR-FTIR) technology biochemically corroborated the presence of endogenous DNA in each sample prior to further destructive analysis. Each site will be run for both mitochondrial DNA (mtDNA) and the 21 CODIS STR markers. Oneway ANOVA testing will help clarify variance found in bone tissue types, skeletal element, and sites per element across the post-cranium as a whole and Chi-square analysis of independence may help clarify inter-element differences in endogenous DNA yields. Goodness of fit testing will compare post-cranial yields to the dental and petrous samples.

Results of ATR-FTIR analysis shows the presence of endogenous DNA in all 400 samples taken from the post-cranium as well as in petrous and dental samples. These results were also compared to ancient samples that had failed to yield endogenous DNA in previous studies. However, no statistical difference was found in biochemical component analysis between cortical and trabecular bone samples.

SEM imaging successfully indicated the presence of Howship's lacunae on both the auricular surface and the pubic symphysis, confirming the ante-mortem presence of multinucleated osteoclasts in the process of homeostatic bone resorption.

The use of a single individual (recovered from cold, fresh, water and professionally macerated at the Montana State Crime Lab in Missoula, MT, USA) for this study is ideal because it controls for many hidden and often confounding variables introduced by taphonomic and diagenetic processes. Such control allows for a purer analysis of the cellular and biochemical contributions to endogenous DNA extraction. Ethical concerns over destructive analyses involving human remains are also eliminated, as the individual (identified through CODIS by soft-tissue DNA extraction prior to maceration) had no familial obligations.

Uniquely, this project: (1) utilizes knowledge of the cellular components and biochemical processes specific to the growth and maintenance of bones to target specific sites on skeletal elements for optimal DNA extraction, (2) incorporates knowledge of cell types to investigate the specific type of bone (cortical or trabecular) that is best for sampling at that site, (3) will design and construct a visual "heat map" of the human post-cranial skeleton for use in both forensic DNA and ancient DNA (aDNA) laboratories.

Anthropology, DNA, Osteology

B60 Compositional Analysis of Human Skeletal Samples Using Raman Spectroscopy and Correlation to DNA Recovery

*Cody Silverman**, University of New Haven, West Haven, CT; *Brooke Kammrath, PhD*, University of New Haven, West Haven, CT and *Henry C. Lee* Institute of Forensic Science, West Haven, CT; *Angie Ambers, PhD*, University of New Haven, West Haven, CT and *Henry C. Lee* Institute of Forensic Science, West Haven, CT

Learning Overview: After attending this presentation, attendees will have a better understanding of the complexities associated with DNA extraction from bone, and how Raman spectroscopy may be used to understand the correlation between bone microstructure and DNA preservation.

Impact Statement: This presentation will impact the forensic science community by initiating an investigation into the use of Raman spectroscopy as a non-destructive screening tool for predicting the potential for DNA recovery from bone.

The purpose of this study is to determine if Raman spectroscopy can be used as a rapid and non-destructive screening tool to predict DNA recovery potential for bone, and to explore the correlation between the compositional structure of bone and preservation of DNA. The two primary structural components of bone are calcium hydroxyapatite and collagen.^{1,3,4,6-11} It is proposed that by analyzing bone using Raman spectroscopy, the presence, state, and distribution of hydroxyapatite and collagen can be measured, which may be useful in predicting if the sample is viable for genetic testing.

Currently, a reliable screening method for DNA extraction from bones does not exist. Previous studies demonstrate that certain skeletal elements (e.g., weight-bearing long bones, molar teeth) are preferred for forensic DNA testing; however, once these skeletal elements are selected, the sampling technique is blind.^{1,2,6,9} Moreover, the external physical appearance of bone has been proven to not be a reliable predictor of DNA recovery potential.² During postmortem diagenesis, the microstructure of bone decomposes in a non-uniform manner. The heterogeneous nature of bone diagenesis poses a challenge in determining which region(s) of the bone contain the most intact microstructure (and presumably the most DNA).⁵ The diaphysis of a long bone is the optimal area for sampling because it is comprised of very dense compact bone, which provides a strong physical barrier to environmental insult, and contains the highest concentration of osteocytes (nucleated bone cells that possess DNA).⁹ With Raman spectroscopy, it is proposed that the entire diaphysis can be sequentially scanned, and data collected from each scanned region can provide qualitative and quantitative information regarding bone microstructure (i.e., calcium hydroxyapatite, collagen), which may correlate to the quality and quantity of DNA present in each region. Forensic DNA analysis of human remains is time-consuming, labor-intensive, and expensive. This pre-screening tool has the potential to provide analysts with preliminary data to make informed decisions on the location of optimal sampling sites along the diaphysis of a long bone, thereby reducing the amount of bone consumed and destroyed in the testing process. Raman spectroscopy could offer a robust and reliable method to expedite and streamline the processing of unidentified skeletal remains in casework.

Analysis of results will be conducted to assess the relationship between the decomposition state of bone microstructure and DNA recovery, and to determine the reliability of Raman spectroscopy as a screening method. Preliminary research suggests that higher quantities of DNA (and better quality DNA) can be recovered from bone samples containing preserved hydroxyapatite and collagen versus samples taken from regions of the same bone that are in a more advanced state of diagenesis. DNA quantification using the Quantifiler™ Trio Human DNA Quantification Kit and the QuantStudio 5 Real-Time PCR System will provide data on total DNA recovery from each scanned bone section, as well as a quality index to indicate the degree of DNA degradation present.

B61 An Enhanced DNA Extraction Method for Charred Bone Remains Using Pressure Cycling Technology (PCT)

Kira Hurley, BS, Duquesne University, Pittsburgh, PA; Lisa Ludvico, PhD, Duquesne University, Pittsburgh, PA; Angie Ambers, PhD, Henry C. Lee Institute of Forensic Science, Henry C. Lee College of Criminal Justice and Forensic Sciences, West Haven, CT and University of New Haven, West Haven, CT; Pamela Marshall, PhD, Duquesne University, Pittsburgh, PA*

Learning Overview: After attending this presentation, attendees will understand a pressure cycling technology (PCT) enhanced DNA extraction method for working with charred bone remains.

Impact Statement: This presentation will impact the forensic science community by presenting a DNA extraction method that could yield a higher quantity and quality of results from charred bone remains.

Charred human skeletal samples may be submitted for forensic DNA testing from a variety of scenarios, including arson, wildfires, vehicular accidents, accidental fires, and terrorist attacks. Extraction of DNA from charred bones is particularly challenging. Exposure to heat damages DNA, thereby reducing the quality and quantity of genetic data that can be recovered to assist in making a positive identification. Bone itself presents a complicated matrix to work with for extractions, as minerals present within the bone microstructure can act as PCR inhibitors and create downstream issues in the analysis of the DNA.

In this study, the application of Pressure Cycling Technology (PCT) was used in an attempt to enhance the extraction of DNA from charred bone remains and increase yield. Metacarpal bones were burned at various, pre-defined incremental temperatures in a muffle furnace. After burning, half of the bones were subjected to standard DNA extraction protocols, while an additional PCT step was incorporated into the protocol for the other set of samples. DNA yield, as well as the quality of the profiles generated, were compared between the two experimental groups. A modified organic extraction was utilized for both sets of bones, with the additional PCT step occurring during lysis for the experimental group. Extracted DNA was quantified using the Quantifiler™ HP DNA Quantification Kit (ThermoFisher Scientific) and an Applied Biosystems QuantStudio 5 Real-Time PCR System. The samples suitable for typing were amplified using the GlobalFiler™ PCR Amplification Kit and a GeneAmp PCR System 9700 Thermocycler (Applied Biosystems). Amplified product was genotyped using an Applied Biosystems SeqStudio Genetic Analyzer and GeneMarker® HID Human Identity Software.

Pressure cycling has been shown to reduce the effect of inhibitors in the PCR process, generating cleaner profiles and higher yields from extracted samples.¹ By exploring and optimizing methods to extract DNA from charred bone remains, genetic recovery from bodies compromised by fire could be improved, thereby assisting in the resolution of a greater number of unidentified human remains (UHR) cases.

Pressure Cycling Technology, DNA Extraction, Charred Bones

B62 Alternative Sperm Cell Lysis Methods for Sexual Assault Samples

Sarah K Schellhammer, MS, Virginia Commonwealth University, Richmond, VA; Brittabny C. Hudson, MS, Virginia Commonwealth University, Richmond, VA; Jordan O. Cox, MS, Virginia Commonwealth University, Richmond, VA; Tracey Dawson Green, PhD, Virginia Commonwealth University, Richmond, VA*

Learning Overview: After attending this presentation, attendees will have a better understanding of alternative sperm lysis techniques that reduce the time and costs associated with processing sexual assault samples, as well as how those methods compare to traditional approaches.

Impact Statement: This presentation will impact the forensic science community by presenting data which demonstrate the availability of several alternative sperm cell lysis techniques that reduce time and cost of processing while providing high quality STR profiling results; thus, it will offer a tool to help combat the current backlog.

The prevalence of sexual assault kit backlogs in the United States has spurred research aimed at providing more efficient ways for handling associated samples. Traditional forensic DNA workflows for sexual assault samples include cell separation, cell lysis, and DNA purification, all of which are time and labor intensive, hindering the ability of forensic analysts to keep pace with evidence submissions.¹⁻⁵ These issues have prompted the recent exploration of new techniques for each of these steps, as well as new workflows that omit purification altogether. Thus, this study evaluated seven alternative techniques for cell lysis with the goal of developing a method for sexual assault samples that could allow for the omission of lengthy purification and transfer steps, efficiently lyse spermatozoa, consistently generate high quality STR profiles, and reduce reagent consumption, time, and associated costs.

Semen from ten donors was dried onto foam swabs, and 1/12th swab cuttings were tested in triplicate using commercial (e.g., SwabSolution™, Casework Direct, forensicGEM™ Sperm), “homebrew” (e.g., NP-40 buffer and alkaline lysis solution), and natural sperm decondensation (e.g., HEPES/Triton X-100 [HTX] and HTF media/glutathione/heparin [HGH]) approaches. Several volumes, reagent concentrations, and incubation times were evaluated with the goal of minimizing costs and sample loss/consumption. Samples lysed using forensicGEM™ Sperm served as the control group for all comparisons and statistical analyses. Quantification of human DNA yield using Investigator® Quantiplex HYres revealed that all lysis methods performed comparably to the control method of forensicGEM™ Sperm ($p > 0.06$). All internal PCR controls (IPCs) crossed the cycle threshold within the acceptable range; however, IPCs associated with all SwabSolution™ and some Casework Direct lysates were slightly delayed.

Following DNA quantification, lysates were amplified via the Promega™ PowerPlex® Fusion 5C System using two approaches: 1) a targeted DNA input (ng), based on quantification results and an internally validated protocol, and 2) a targeted volume input (μL) for situations in which quantification may not be performed ahead of “direct” amplification. Amplicons were separated using the ABI® 3130 Genetic Analyzer. Amplification of lysates with a target DNA input (0.25 ng) revealed samples that were lysed with Casework Direct, alkaline lysis, and NP-40 lysis buffer techniques produced DNA profiles with average STR peak heights comparable to the control method, as well as interlocus balance similar to or better than the control ($CV \leq 0.38$). STR amplification using a specified volume of lysate rather than a target DNA input generated similar results, with HGH cell lysis also providing high quality STR profiles.

Overall, this study demonstrated the ability of Casework Direct, alkaline, NP-40, and HGH methods to efficiently lyse spermatozoa and provide high quality STR profiles despite the absence of a purification step. Ultimately, based on the data reported herein, alkaline lysis is the most highly recommended and preferred alternative approach for sperm lysis, as it produces high quality profiles, saves time, and substantially decreases the cost per reaction when compared to traditional lysis methods. Further, this technique provided optimal results when using both a targeted DNA and targeted volume input, demonstrating its potential for other applications such as direct-to-PCR amplification and microfluidic devices.

Sexual Assault, Cell Lysis, Direct Amplification

B63 An Evaluation of a Body Fluid Identification Method Using MicroRNAs (miRNAs) Co-Extracted With DNA

Kelsey Price, BS, Virginia Commonwealth University, Richmond, VA; Carolyn Lewis, BS, Virginia Commonwealth University, Richmond, VA; Ciara Rhodes, BS, Virginia Commonwealth University, Richmond, VA; Anaya Valentine, MS, Houston Forensic Science Center, Houston, TX; Edward Boone, PhD, Department of Statistical Sciences and Operations Research, Virginia Commonwealth University, Richmond, VA; Sarah Seashols-Williams, PhD, Department of Forensic Science, Virginia Commonwealth University, Richmond, VA*

Learning Overview: After this presentation, attendees will understand how microRNA (miRNA) expression can be used for body fluid identification without the need for separate DNA and RNA extractions. The presentation will inform attendees about the limitations of the method, and attendees will understand why this molecular-based method may be a more reliable method for body fluid identification in forensic casework than current enzyme-based serological tests, which are prone to false positives.

Impact Statement: This presentation will impact the forensic science community by demonstrating that the evidence for using miRNAs for body fluid identification over current methods in forensic casework continues to grow.

MiRNAs are non-coding RNAs 18 to 25 nucleotides in length. Due to their smaller size, the absence of a poly-A tail, and protein encapsulation in vivo, miRNAs are less susceptible to degradation when compared to messenger RNAs. Additionally, previous studies have demonstrated that miRNAs co-elute with many DNA extraction methods, thus potentially eliminating the need for an additional RNA extraction and therefore simplifying the implementation of this method into the forensic laboratory workflow.

Several candidate miRNAs were previously identified using high-throughput sequencing (HTS) of the miRNome. The differential expression patterns of miRNAs were analyzed using quantitative PCR (qPCR) in forensically relevant body fluids. Candidate miRNAs and endogenous reference markers were identified using these data and validated with population sample sets of RNA extracts from each body fluid.

In this study, the candidate and endogenous reference miRNAs were evaluated using DNA extracts from dried venous blood, menstrual blood, saliva, vaginal secretions, feces, urine, and semen. The samples were deposited onto 50 swabs per body fluid, allowed to dry, and extracted using a silica-based DNA extraction method. Then, the miRNA levels were measured using reverse-transcription quantitative PCR (RT-qPCR). Next, differential expression of the miRNAs within each body fluids within the population set were analyzed, normalized, and evaluated with a quadratic discriminate analysis model. This model was adapted for miRNA expression from DNA extracts in the sampled biological fluids using this panel and demonstrated a correct classification accuracy rate of 91.36%. Finally, the relative stability of miRNA in dried body fluids under degrading chemical, heat, and environmental conditions meant to mimic a crime scene and over time within an individual was also evaluated in DNA extracts. These samples were classified using the same quadratic discriminate analysis model.

In conclusion, the panel of nine miRNA markers were shown to have a high specificity for identifying all biological fluids tested except for menstrual blood and vaginal fluid using quadratic discriminate analysis in DNA extracts and is a promising alternative to traditional serological tests for forensic casework.

Body Fluid Identification, MiRNA, MiRNA Stability

B64 A Demonstration of a Semi-Automated, Extraction-Free, MicroRNA (miRNA) Gene Expression Profiling Method for the Simultaneous Detection of Biofluids

Amy Brodeur, MFS, Boston University School of Medicine, Boston, MA; Frank Kero, PhD, HTG Molecular Diagnostics, Tucson, AZ; BJ Kerns, BS, HTG Molecular Diagnostics, Tucson, AZ*

Learning Overview: By attending this presentation, attendees will learn about the potential for microRNA (miRNA) profiling to be used for identifying body fluids present within a forensic stain.

Impact Statement: This presentation will impact the forensic science community by offering an alternative to traditional chemical and serological assays for identifying body fluids.

Biological stains recovered from crime scenes may be complex, limited in size and not always visually consistent with the body fluids of which they are comprised. The identification of specific body fluids can provide important contextual information, particularly in cases concerning sexual assault. Further, the presence or absence of certain biological material may help guide DNA analysis or impact its probative value.

Current forensic practice for body fluid identification is to employ colorimetric chemical tests and protein-based testing in the form of lateral flow immunochromatographic test strips. These assays are primarily presumptive in nature and are capable of detecting only one body fluid at a time, so multiple tests and samples are needed for a complete evaluation. A more specific, multiplex approach to forensic body fluid identification would be highly advantageous.

The HTG EdgeSeq miRNA Whole Transcriptome Assay (WTA) was developed to measure the expression of human miRNA within the HTG EdgeSeq system workflow. The HTG EdgeSeq system combines HTG's proprietary quantitative nuclease protection assay (qNPA) chemistry with a next-generation sequencing (NGS)-based platform to enable the quantitative analysis of a panel of targeted genes in a single assay. The HTG EdgeSeq miRNA WTA contains 2,102 nuclease protection probes (NPPs), including 13 housekeeping genes, one internal positive control, and five internal negative controls.

Human blood, semen, saliva, urine, menstrual blood, and breast milk were collected from various volunteers following an approved IRB protocol. Fifteen microliters of each fluid were added to an equal amount of HTG lysis buffer. Functional DNA nuclease protection probes (NPPs) were hybridized to target miRNAs. S1 nuclease was then added to digest excess non-hybridized DNA probes and non-hybridized miRNA, leaving only NPPs hybridized to miRNA fully intact and able to be barcoded. Lastly, the NPPs were quantified by NGS. Principal component analysis (PCA) was used to assess the global distribution difference across the various miRNAs and specimen types.

Following PCA analysis, a clear separation of the types of biofluids tested was shown. As an example, 187 miRNAs between saliva and aspermatic semen, 92 miRNAs between saliva and semen and 77 miRNAs between aspermatic semen and semen were found to drive this differentiation. Preliminary results suggest that the use of miRNA as a method for differentiating between body fluids is feasible and may be a suitable method for the forensic identification of mixed biofluid stains.

MiRNA, Body Fluid Analysis, Next Generation Sequencing (NGS)

B65 Direct Messenger RNA (mRNA) Sequencing for the Identification and Analysis of Human Body Fluids

Quentin Gauthier, PhD, Federal Bureau of Investigation, Quantico, VA; Patrick Rydzak, PhD, Federal Bureau of Investigation, Quantico, VA; Kyleen Elwick, PhD, Federal Bureau of Investigation, Quantico, VA; Mark Kavlick, PhD, Federal Bureau of Investigation, Quantico, VA*

Learning Overview: After attending this presentation, attendees will have a better understanding of advancements in nanopore sequencing technologies and how they can be applied to body fluid identification.

Impact Statement: This presentation will impact the forensic science community by demonstrating a novel method for body fluid identification using a straightforward analytical approach that can be adopted with relative ease in forensic laboratories.

Body fluid identification via analysis of differential expression of messenger RNA (mRNA) is well understood in the scientific community and particularly relevant to the field of forensics.¹ Source attribution of body fluid stains found on submitted evidence affords forensic DNA analysts' insight on which samples would provide the greatest evidentiary value for future processing after co-isolation of DNA and RNA.² Much of previous RNA body fluid identification work has commonly employed a reverse transcription (RT) reaction to generate complimentary DNA (cDNA), a step that may introduce bias in RT-qPCR assays and RNA sequencing assays.³ Recent advancements in RNA sequencing technology have bypassed the RT step and increased the lengths of reads for more streamlined and accurate data analysis.

This study employed Oxford Nanopore Technology's (ONT) direct RNA sequencing technology to identify and analyze mRNA markers within body fluids without a cDNA intermediary. TRIzol was used to extract RNA from saliva, blood, and semen, which was then prepped using Oxford Nanopore Technology's direct RNA sequencing protocol. RNA libraries were prepared from total extracted RNA standards directly, as well as post-polyadenylation, with External RNA Controls Consortium (ERCC) spike-in to act as an internal control. Sequencing was performed using MinION flow cells (R9.4.1) on the MK1C sequencing instrument. Data generated this way was analyzed for the presence of body fluid-specific mRNA markers corresponding to either saliva, blood, or semen, and for the absence of mRNA markers from other sources, such as vaginal fluid, menstrual blood, urine, and touch RNA. Reads from each sample were also queried against and aligned to the human transcriptomic reference GRCh38 using BLAST+ and Minimap2 respectively. Significant matches between sample reads and transcriptomic sequences were categorized and the top matches for each RNA standard were noted.

Of the RNA samples tested, mRNA markers unique to that tissue type were detected in the saliva, blood, and semen samples offering promising preliminary results for the use of direct RNA sequencing for body fluid identification. Ongoing research includes the analysis of total RNA extracted directly from additional tissue types, such as vaginal fluid, menstrual blood, urine and touch RNA, as well as the refinement of the bioinformatics data analysis pipeline to ensure that reads are matched to the correct transcripts with a high level of confidence.

Body Fluid Identification, Direct RNA Sequencing, Oxford Nanopore Technology

B66 The Development of Pyrosequencing-Based DNA Methylation Assay for Menstrual Blood Identification

Mirna Ghemrawi, MSFS*, Florida International University, Miami, FL; Nicole Fernandez-Tejero MS, Florida International University, Miami, FL; Valeria Castaneda BS, Florida International University, Miami, FL; Bruce McCord, PhD, Florida International University, Miami, FL

Learning Overview: After attending this presentation, attendees will be aware of the development of a novel and sensitive DNA methylation assay for menstrual blood identification using pyrosequencing chemistry.

Impact Statement: This presentation will impact the forensic science community by providing the analysts with a scientific tool to differentiate menstrual blood from peripheral blood as well as vaginal epithelial cells closer to menstruation.

In forensic casework, DNA is extracted from biological exhibits and compared to databases. Yet, in cases where an offender has regular access to a victim, a DNA profile may not be probative unless the source of the biological stain is known. For instance, a caregiver may claim that DNA found on their clothing results from an innocent transfer. However, if this DNA originates from vaginal epithelial cells, a crime may have occurred. Body fluid analysis thus can be critical in prosecuting violent crimes such as rape or child abuse.¹

Current tests used to identify body fluids are limited in specificity particularly when compared with DNA detection methods such as the PCR. Therefore, the forensic community is developing more advanced techniques, such as epigenetic methylation assays, to distinguish body fluids: blood, saliva, semen, and vaginal epithelia.^{2,3} Markers for menstrual blood, are challenging due to heterogeneity: blood, endometrial lining tissue, vaginal and cervical secretions may all be present. Thus, primers were designed for methylation markers within the SLC26A10 and MDFI genes.⁴⁻⁶ Menstrual blood was collected on cotton swabs daily from female volunteers, DNA was extracted, bisulfite converted, amplified, and pyrosequenced. Methylation data was then interpreted using hierarchical cluster analysis. Markers on the SLC26A10 showed significant methylation percent differences compared to peripheral blood whereas markers on MDFI showed hypermethylation mainly on days 2-3, suggesting a greater presence of endometrial lining tissue.

In this study we have examined swabs from a set of female volunteers to track changes in DNA methylation across the menstrual cycle. Our results demonstrate variations in methylation levels which are consistent with time-based variation in shed cells and further demonstrate the applicability of multiple epigenetic loci in the detection of menstrual blood.

Menstrual Blood, Pyrosequencing, DNA Methylation

B67 The Optimization of a Rotationally Driven Microfluidic Method for Forensic DNA Methylation Sample Preparation

Rachelle Turiello, MS, University of Virginia, Charlottesville, VA; Leah Dignan, BS, University of Virginia, Charlottesville, VA; Francine Garrett-Bakelman, MD, PhD, University of Virginia, Charlottesville, VA; James Landers, PhD, University of Virginia, Charlottesville, VA*

Learning Overview: After attending this presentation, attendees will have been introduced to a rotationally-driven microfluidic method for sodium bisulfite conversion of differentially-methylated DNA in preparation for forensic epigenetic analysis.

Impact Statement: This presentation will impact the forensic science community by contributing a robust analytical method for epigenetic sample preparation that is amenable to forensically-relevant amounts of input DNA.

In recent years, forensic genetics analysis has transcended comparative methods for human identification, such as short tandem repeat (STR) testing, to include DNA phenotyping.¹ In particular, the development of a molecular method for epigenetic age determination has garnered considerable attention, as it would not only contribute to the creation of a biological profile, but also inform other phenotypic traits including hair color and loss, stature, and general physical appearance.² However, these methods invariably require extensive sample preparation to extract, purify, and subsequently modify the DNA sequence for downstream analysis. The latter process, known as Bisulfite Conversion (BSC), preferentially converts unmethylated cytosines to uracil, thereby distinguishing age-associated methylation patterns within the genome for further genetic and statistical analysis.³ Unfortunately, current BSC techniques are known to result in extensive DNA fragmentation and loss, and are time-consuming, labor-intensive, and pose high risk for human contamination due to numerous open-tube pipetting steps.^{4,5}

The goal of this work is to design and optimize a robust microfluidic platform for silica superparamagnetic bead-facilitated BSC to enable rapid, efficient conversion of forensically-relevant DNA input masses in an automated, enclosed, and rotationally-driven microCD (μ CD) format. Leveraging microfluidics to facilitate BSC for forensic laboratories is ideal for several reasons. First, fluid volumes may be reduced significantly, decreasing the amount of input DNA required, reagent costs associated with sample preparation, and required incubation times. Second, the cost-effective fabrication of the enclosed μ CDs make them well-suited for implementation into the forensic genetics regime, as they may be discarded as consumables and are less susceptible to analyst contamination. Third, and finally, the integrated, on-board microfeatures ablated into the polymeric device accommodate all BSC-associated chemistries and sequential unit operations to permit comprehensive, automated BSC with no required user intervention. Ultimately, each μ CD is capable of simultaneous BSC of four samples, each with a minimum requirement of 2 μ L isolated input DNA. Reagent fluid volumes are also reduced to approximately 10% of the volume used in the traditional format, along with a decreased total analytical time.

Microfluidic architecture designed using AutoCAD software was tested for fluidic handling by pairing aqueous dye studies with objective image analysis using image analysis software. Early optimization of BSC chemistry was completed in-tube at both full-scale and using decreased fluid volumes to mimic volumes used in the microfluidic regime. BSC of both 0% and 100% methylated control DNA was assessed via real-time polymerase chain reaction (PCR) with an intercalating dye. In-tube BSC chemistry was then adapted to the μ CD, and optimized to decrease on-board heated incubation times, characterize BSC recovery, and confirm sample-to-sample reproducibility using both real-time PCR and pyrosequencing. To ensure forensic relevance of our BSC μ CD, all genetic regions interrogated during assay validation were extrapolated from human epigenetic aging literature and sample types, including process controls and extracted DNA from human K-562 erythroleukemia cell lines.

Continued work with this technology will focus on integration of on-board direct-from-swab DNA extraction upstream of BSC to comprehensively address sample preparation. Ultimately, development of a mechatronic platform for μ CD automation will limit manual user intervention for swab placement and initiating the sample preparation protocol via the corresponding mechatronic system to perform via a graphical user interface (GUI).

B68 A Quantiplex™-High Resolution Melt (HRM) Integrated Assay for Early Mixture Detection Using Support Vector Machine Modeling for “Whole Curve” Analysis/Proof-of-Concept Testing

Chastyn Smith, BS, Virginia Commonwealth University, Richmond, VA; Andrea Williams, MS, Bode Technology, Lorton, VA; Hannah Wines, MS, Houston Forensic Science Center, Houston, TX; Darianne Cloudy, MS, American Type Culture Collection, Manassas, VA; Jordan Cox, MS, Virginia Commonwealth University, Richmond, VA; Dayanara Torres, BS, Virginia Commonwealth University, Richmond, VA; Sarah Williams, PhD, Virginia Commonwealth University, Richmond, VA; Edward Boone, PhD, Virginia Commonwealth University, Richmond, VA; Tracey Dawson Green, PhD, Virginia Commonwealth University, Richmond, VA*

Learning Overview: After attending this presentation, attendees will be more aware of a new tool that allows for mixtures to be discerned earlier in the forensic DNA workflow.

Impact Statement: This research will impact the forensic science community by providing a qPCR-based quantitation method that produces additional information about an evidentiary sample, which could help shape or redirect the path of an investigation prior to the development of an STR profile.

Analysis of evidentiary samples containing DNA from multiple contributors (“mixtures”) is a time intensive process for a forensic analyst and one where the contributor nature of a sample is not revealed until the end of the traditional forensic workflow. Often, at this stage, retesting or additional testing of mixture samples may not be possible, particularly if only trace amounts of a contributor’s DNA is present. Thus, a new method that would allow for the quick and accurate, identification of single source (versus mixture) samples prior to the end-point of STR analysis would be beneficial. To meet this need, an HRM screening assay has been developed and integrated into an existing step in the laboratory evidence workflow - the real-time PCR-based DNA quantification step. Using the developed assay, resulting HRM data is coupled with prediction modeling approaches to allow for the contributor status of an evidence item to be identified and a genetic comparison to be made without additional steps or delays in processing. The developed integrated quantification-HRM mixture screening assay adds two new amplification targets (STR loci D5S818 and D18S51) and an intercalating dye to an existing commercial human DNA quantification chemistry, the Investigator Quantiplex® kit, which is used in combination with increased denaturation and annealing/extension times along with added transition and melt steps post-amplification. Initially, a subset of the resulting HRM data and a linear discriminant analysis (LDA) were used to predict whether a sample was a single source or a mixture, and if single source, the genotypes of each STR locus. Data was previously presented demonstrating that the modifications to the assay did not impede the accuracy of the quantification reaction nor alter the subsequent melt curves produced. However, accurate predictions of single source sample genotypes were lower than desired. Thus, alternate statistical approaches that incorporated the entire melt curve dataset, rather than key characteristic points, were subsequently investigated.

In the current study, 101 single source samples and 20 two-person mixture samples were tested using the Quantiplex®-HRM integrated assay and the entire HRM datasets were exported for prediction modeling using both LDA and support vector machine (SVM) algorithms in R Studio software. SVM was selected for evaluation as it has the ability to more accurately classify large datasets. For proof-of-concept, only 7 different genotypes were represented (for each locus) in testing. A portion of the samples tested was used to “train” the software and the remaining sample data was used as unknowns (or “validation”) samples for prediction. All samples were tested twice – once on the Rotor-Gene® Q platform and then on a more modern qPCR platform, the QuantStudio™ 6. When tested on the Rotor-Gene® Q the assay exhibited an overall accuracy of 89.39%, correctly classifying 87.5% of single source samples and 100% of mixture samples as such. When tested on the QuantStudio™ 6, the assay performed similarly, exhibiting an overall accuracy of 87.88%, correctly classifying 87.5% of single source samples and 90% of mixture samples. However, genotyping accuracy of the identified single source samples was lower than expected at 60.4% for D5 and 46.2% for D18 on the Rotor-Gene® Q and 16.0% for D5 and 22.6% for D18 on the QuantStudio™ 6. Thus, additional prediction modeling tools would need to be evaluated if one desires to use the resulting single source genotyping data for reliable early exclusionary information.

Overall, this work has successfully confirmed that the Quantiplex®-HRM qPCR-based integrated assay can be used for accurate prescreening identification of mixtures across two different qPCR platforms. Future work will seek to identify the limitations of this assay and to incorporate this HRM assay into more commonly used commercial quantification kits.

High Resolution Melt (HRM), Mixture Screening, Prediction Modeling

B69 The Integration of a High Resolution Melt (HRM) Mixture-Prescreening Assay Into the Quantifiler® Trio Quantification Chemistry Using the QuantStudio™ 6 Flex Real-Time Polymerase Chain Reaction (PCR) System

Dayanara Torres, BS*, Virginia Commonwealth University, Richmond, VA; Chastyn Smith, BS, Virginia Commonwealth University, Richmond, VA; Andrea Williams, MS, Bode Cellmark Forensics, Lorton, VA; Edward Boone, PhD, Virginia Commonwealth University, Richmond, VA; Tracey Dawson Green, PhD, Virginia Commonwealth University, Richmond, VA

Learning Overview; After attending this presentation, attendees will be informed of ongoing efforts to integrate a previously developed high-resolution melt (HRM) curve assay into the Quantifiler Trio™ kit. This assay, partnered with statistical analysis and prediction modeling, can provide crucial sample information and potentially exclusionary information earlier in the forensic DNA workflow.

Impact Statement: This presentation will impact the forensic community by providing a methodology that can detect and distinguish mixtures and single-source evidentiary DNA samples using a more widely adapted qPCR kit and real-time PCR platform. Currently, the forensic DNA workflow is not capable of providing conclusionary information about evidentiary samples prior to end-point analysis. This shortcoming can exacerbate the challenges inherent in mixtures and low-template DNA samples. Provided additional sample information earlier in the workflow, protocols could be implemented to mitigate these challenges. To this end, a proof-of-concept HRM assay of D5S818 and D18S51 STR loci using EvaGreen® intercalating dye was integrated into the Investigator Quantiplex® qPCR kit. When tested on the QuantStudio™ 6 qPCR platform, resulting melt curve datasets and sequential statistical analysis were capable of distinguishing single-source samples from mixtures at an 87.88% rate.^{1,2}

Given this initial success, integration of the HRM assay into a more commonly used chemistry, the Quantifiler Trio™ kit, was pursued. Unfortunately, the presence of EvaGreen® dye caused an 11.7% increase in the small autosomal (SA) and 35.8% increase in Y quantification values in both female and male samples, rendering this data unreliable. This is likely due to spectral emission overlap between the EvaGreen® dye and VIC™/FAM™ dyes used in the Quantifiler Trio™ assay. Additionally, melt products produced by the kit targets overlapped with the melt range of the STR products. Given these results, new fluorescent dyes were sought that least overlapped with the kit's quantification targets. However, since the kit utilizes all dye channels on the QuantStudio™ 6, the two candidate dyes (SYTO™ 17 and SYTO™ 64) shared a channel with the IPC. As predicted, both dyes interfered with the IPC, changing its expected Ct values, however, both dyes produced IPC Ct values that were consistent across samples and within an accepted range. Additionally, SYTO™ 64 was seen to inflate the large autosomal (LA) target while SYTO™ 17 was detected in the passive reference dye channel. Since these values are normalized to produce the final concentration values, and the standards used for quantification include the same integrated reaction components as the samples, it was less of a concern.

In order to keep the integrated assay chemistry at concentrations comparable to the Quantifiler Trio™ assay, two reaction conditions, at 11µL and 16µL, were tested. Inter-/intra-run quantification values when SYTO™ 17 and SYTO™ 64 were added to the assay were compared to those observed when using the standard Quantifiler Trio™ protocol. Intra-run variation of DNA concentration values (using both 11µL and 16µL reaction conditions) for LA and SA targets was approximately 50% lower when SYTO™ 17 and SYTO™ 64 were added. Similarly, intra-run variation improved by 25% and 80% for the Y quantification values when SYTO™ 17 and SYTO™ 64 were added to the assay, respectively. While inter-run comparisons of quantification data when SYTO™ 64 was added (using the 16µL reaction condition) also showed a decrease in LA targets across runs (2.5-fold less), there were major increases in variation across runs for the SA (4.8-fold) and Y targets (6.4-fold). Further, the actual quantification values obtained when either of the SYTO™ dyes were added (using the 11µL reaction condition) were higher than those obtained when the standard Quantifiler Trio™ protocol was used to quantify the same samples. This increase was more than the normal variation that is observed across runs using the traditional protocol, ranging from 10-28% higher with SYTO™ 17 and 18-31% higher with SYTO™ 64, depending on the target. In comparison, normal run-to-run variations observed using the Quantifiler Trio™ kit are less than 10% for each quantification target included in the assay. Fortunately, the increases in quantification values observed when the SYTO™ dyes were added occurred across all targets and not only in targets whose fluorophores overlapped with the spectral emission range of the added dye. Thus, these differences are likely due to the need to further optimize the QuantStudio™ 6 standard curve analysis settings used when each of the SYTO™ dyes are added. Once this issue is mitigated, the integrated HRM/Quantifiler Trio™ assay will be used to analyze the entire preliminary data set of single-source and mixture samples. If prediction accuracies are below 80%, the STR primers used for the HRM targets will be redesigned to better isolate the STR melt range.

High-Resolution Melt, Real-Time PCR, Mixture Detection

B70 Using Mitochondrial DNA (mtDNA) and the Y Chromosome to Estimate Population Affinity and Region of Origin

Andrew Schweighardt, PhD, Office of Chief Medical Examiner, New York, NY; Angela Soler, PhD, Office of Chief Medical Examiner, New York, NY*

Learning Overview: Attendees can expect to learn about a new concept for predicting the region of origin for an unidentified decedent. For challenging cases with decomposed remains, investigations traditionally rely upon an anthropological assessment, but recently developed and expanded databases for lineage markers have now made it possible to include a genetic component. The DNA-based side of the prediction is easily performed on publicly accessible databases and may be a valuable addition to investigations with an unidentified decedent.

Impact Statement: This presentation will impact the forensic science community by outlining a new paradigm for investigations with unidentified decedents. The need for a multidisciplinary approach to this process is underscored by the unique contribution that each makes to the investigation. Individually, the methods used for prediction of population affinity may be potentially inaccurate, but taken collectively, they offer a more holistic approach that draws on the strengths of each.

The EDNAP mtDNA Population Database (EMPOP) and the Y-Chromosome Haplotype Reference Database (YHRD) are the world's largest collections of lineage marker reference profiles for mitochondrial DNA (mtDNA) and Y chromosome haplotypes, respectively. These databases have primarily been used for computing haplotype frequencies but can also offer information about "population affinity" because the reference haplotypes are collected from known locations throughout the world. The population-specific reference samples of EMPOP and YHRD, together with anthropological interpretations and migration history, may assist in the prediction of population affinity for unknown decedents.

In medicolegal investigations, a case with an unidentified decedent deprives family members of answers and may be a barrier to understanding the circumstances of a suspicious death and resolving the case. Predicting population affinity may be helpful for cases in which the decedent is unidentified, because any small clue regarding the decedent may be the key that leads to identification and investigative progress. When decomposition precludes visual assessment, population affinity has traditionally been predicted using an anthropological analysis that evaluates characteristics such as craniometrics and cranial morphology. More recently, a multidisciplinary approach has paved the way for collaborative efforts in which anthropologists and molecular biologists pool their resources. In addition to an anthropological assessment, a DNA-based component can now be included. This has been made possible by databases such as EMPOP and YHRD, which complement each other by providing population-specific samples for maternal (EMPOP) and paternal (YHRD) lineages.

Seventy individuals consented to having their mtDNA profile searched in EMPOP. The findings indicated that the region of origin predicted by EMPOP aligned with the self-identification for 61% of individuals. For almost a third of these individuals, the region of origin predictions was extremely specific and precise, without the inclusion of any other regional predictions.¹ A sample of ten consenting male participants were also recruited to grant permission to search their Y-STR profile in YHRD. The YHRD results were then compared to the participant's own self-identification for the purpose of determining how well the two align. The predicted metapopulation was accurate for all participants, and the specific paternal country of origin was correctly predicted for 30% of the sample.

Both EMPOP and YHRD have been applied to cases of unidentified decedents being investigated by the NYC OCME. Several case studies will be highlighted which illustrate instances where the EMPOP and YHRD results have been utilized with anthropological assessments. The results emphasize the importance of using a multidisciplinary approach to predict population affinity, and the need to understand the benefits and limitations of each method.

Population Affinity, Haplotype, Unidentified Remains

B71 Solving Cold Cases With Databases: Considerations for the Application of Advanced DNA Searching Methodologies

Ashley Rodriguez, RTI International, Research Triangle Park, NC*

Learning Overview: After attending this presentation, attendees will have a better understanding of the searchable databases associated with familial DNA searching (FS) and forensic genetic genealogy (FGG) and will understand how limitations of these databases can influence the application of these methodologies to forensic investigations.

Impact Statement: Familial DNA searching (FS) and Forensic Genetic Genealogy (FGG) are advanced DNA searching methodologies that have demonstrated their value in solving cold case violent crimes. It is necessary for the forensic community to understand that both methodologies are limited by the sample populations within their respective searchable databases in order to avoid the inappropriate application of the technology and possible consumption of evidence.

Both familial DNA searching and forensic genetic genealogy have been used to solve challenging cold cases, yet these techniques differ from each other in the information they can provide as investigative leads based on the limiting factors of the databases they use. This presentation will discuss the differences between these techniques and will recount recent successes to demonstrate the value of these types of searches. The presenters will describe how the database populations and limitations associated with the searchable databases play a role in the type of information that can be obtained, will highlight how the application of these techniques can be streamlined for the identification of missing persons or victims as compared to suspects and will provide suggestions for how stakeholders can evaluate the forensic evidence in a cold case to align it with the technique most likely to provide an investigative lead. Lastly, suggestions will be made for identifying possible challenges when applying these methodologies, solutions to overcome such challenges and how the crime laboratory is a valuable partner when considering these searches.

Familial Searching, Forensic Genetic Genealogy, Databases

B72 FauxDIS: An Interactive Online Forensic DNA Profile Database

Ashley Hall, PhD, University of Illinois at Chicago, Chicago, IL; Jonathan Bisson, PhD, University of Illinois at Chicago, Chicago, IL*

Learning Overview: After the presentation, attendees will understand the theory and function of a tool that can be used by forensic science educators in reinforcing critical thinking and the scientific method.

Impact Statement: The presentation will impact the forensic science community with the demonstration of an online tool useful in educating future forensic scientists.

Forensic Science has captured our collective imagination for generations, whether it be in the medical examiner's room with Quincy, examining blood spatter with Dexter, or in the crime lab with Forensic Files. With the right tools and applications, educators can take advantage of this popularity and use forensic science as a vehicle to teach critical thinking skills and the scientific method, both of which are integral in the collection and analysis of forensic evidence. The forensic scientist makes observations, formulates hypotheses about the probative value of evidence, and tests these educated guesses by submitting crime scene samples to an operational forensic laboratory for analysis. With a DNA profile generated from crime scene evidence, the forensic scientist can conduct direct or indirect database searches in hopes of finding a match and learning the identity of the donor of the questioned sample. The U.S. national DNA database system, CODIS, contains millions of offender DNA profiles, but its use is restricted to authorized operational labs.

FauxDIS is an interactive online forensic DNA profile database that is available to educators for use in learning exercise, such as mock crime scenes, that require students to apply critical thinking skills in the analysis of forensic evidence. The FauxDIS workflow incorporates instrumentation and protocols analogous to those employed in U.S. operational crime laboratories. The database can be used to simulate both direct and indirect profile searches, demonstrating principles of genetics. It also supports experimentation with partial profiles, which can be useful in simulations of degraded and damaged samples commonly found at a crime scene. Further, with a successful database search, random match probabilities can be calculated using either observed or predicted allele frequencies. These experiential exercises teach valuable skills, and the practical experience that students gain may be attractive to potential employers.

FauxDIS currently contains 151 autosomal profiles. Growing the database with additional profiles will increase its utility. DNA profiles will be generated in-house, and will be accepted profiles from other educators, ensuring that the DNA profiles they use in mock crime exercises will be found in the database. FauxDIS is a dynamic entity; it can be expanded to accommodate new marker systems in response to advances in forensic science. In the future, additional indices will include Y-STRs, single nucleotide polymorphisms and massively parallel sequencing data. With this database, the hope is to provide a tool for experiential exercises and contribute to a collaborative network of educators.

DNA Database, Forensic Science Education, Critical Thinking

B73 Using Mitochondrial DNA (mtDNA) and the Y Chromosome to Estimate Population Affinity and Region of Origin

Andrew Schweighardt, PhD, Office of Chief Medical Examiner, New York, NY; Angela Soler, PhD, Office of Chief Medical Examiner, New York, NY*

WITHDRAWN

B74 The Interpretation of Y-Chromosome Short Tandem Repeats (Y-STRs) for Missing Persons Cases

Jianye Ge, PhD, University of North Texas Health Science Center, Fort Worth, TX; Benjamin Crysip, PhD, University of North Texas Health Science Center, Fort Worth, TX; Dixie Peters, MS, University of North Texas Health Science Center, Fort Worth, TX; Meng Huang, PhD, University of North Texas Health Science Center, Fort Worth, TX; Bruce Budowle, PhD, University of North Texas Health Science Center, Fort Worth, TX*

Learning Overview: After attending this presentation, attendees will have a better understanding of the interpretation methods and guidelines of Y chromosome STRs for complex kinship analysis cases with mutations and/or multiple references.

Impact Statement: This presentation will impact the forensic science community by providing more sophisticated interpretation methods and guidelines on Y chromosome STRs for missing person identifications and kinship analysis in general.

Y chromosome STR haplotypes have been used in assisting forensic investigations primarily for identification and male lineage determination. The Scientific Working Group on DNA Analysis Methods (SWGDM) Lineage Marker Committee published interpretation guidelines for Y-STR typing, which provide helpful guidance. However, these guidelines do not address the issue of kinship analysis with Y-STR haplotypes. Because of the high mutation rate of Y-STRs, there are complex missing person cases in which inconsistent Y-STR haplotypes between true paternal lineage relatives will arise and cases with two or more male references in the same lineage and yet differ in their haplotypes. Therefore, more useful guidelines are needed for interpretation of Y-STR haplotype data. Computational methods and interpretation guidelines have been developed specifically addressing this issue, either using a mismatch based counting method or a pedigree likelihood ratio method. However, these methods and guidelines have not been adopted by forensic laboratories, likely because of a lack of specific procedures and software to facilitate analyses.

The Missing Persons Unit under the Center of Human Identification at the University of North Texas Health Science Center (UNTCHI) specializes in the DNA analysis and identification of missing persons cases and processes >50% unidentified human remains of the missing persons cases in the US. It is common within UNTCHI to encounter complex cases that would be better served with enhanced Y-STR interpretation procedures. With the experiences and resources at UNTCHI, more sophisticated interpretation methods and guidelines for Y-STR applications are implemented, which include pairwise comparison with a mismatch-step-based counting method to quickly determine if two profiles are from the same male lineage, and a pedigree likelihood ratio (PLR) based method to evaluate the evidence weight of Y-STR profiles, particularly for complex missing persons cases. A software program is under development and will be validated to facilitate Y-STR haplotype interpretation, and the software will be made accessible to the forensic community free of charge.

Y-STR, Missing Persons, Interpretation

B75 An Evaluation of a 74 Microhaplotypes (MHs) Assay for Kinship Testing in Four Major United States Population Groups

Fabio Oldoni, PhD, Arcadia University, Glenside, PA; Chiara Della Rocca, MS, Sapienza Università, Rome, Italy; Daniele Podini, PhD, The George Washington University, Washington, DC*

Learning Overview: After attending this presentation, attendees will understand the use of microhaplotype (MH) markers in kinship testing.

Impact Statement: This presentation will impact the forensic science community by describing the potential use of MHs in addition to conventional STRs as an additional biomarker for kinship analysis.

MHs are new biomarkers consisting of more than two single nucleotide polymorphisms (SNPs) displaying various allelic combinations within an expanse of ~300bp. The multi-allelic nature of MHs makes these alternative loci suitable for massively parallel sequencing (MPS) and more informative than individual SNPs. Forensic applications include human identification, mixture deconvolution and biogeographical ancestry inference. Due to the low mutation rate of SNPs, MHs can also be useful in kinship analysis.¹ This work evaluated the performance of a new MH assay in kinship analysis under different case scenarios.

A newly developed bioassay of 74 MHs was tested on the Ion S5™ sequencing System for kinship analysis. In particular, a large set of families from four distinct U.S. population groups (i.e., 117 Afro-Americans, 68 European-Americans, 105 Southwest Hispanics, and 82 East-Asian Americans) was genotyped.² These included both family trios and families with multiple children. Allele frequencies of each U.S. family group were estimated using the recently published U.S. database of 74 MHs.³ To input MH data and determine the likelihood ratio (LR) distributions under parent-child, full-siblings, half-siblings, and first-degree cousin scenarios, Familias software v.3.2.8 was used.⁴ A dataset of 29 short tandem repeats (STRs) from the same U.S. populations obtained from the National Institute of Standards and Technology was also run on Familias and results compared to MH data.

A total of 1,000 simulation tests were performed per each U.S. family group. For parent-child scenarios, the LR distribution curves of parent-child pairs vs unrelated pairs were well separated for both the 29 STRs and 74 MHs, which showed higher median LR distribution values across the four U.S. population groups and stronger support for true related vs unrelated scenarios. Similarly, this was observed in full-siblings scenario vs unrelated case scenario; however, some overlap of the LR distributions were observed with STRs. For half-sibling scenarios, some overlap of the LR distribution curves of half-sibling scenario vs unrelated scenario was observed for both STRs and MHs, although the latter displayed higher median LR distribution values. For first degree cousin scenarios, high level of overlap of the LR distributions were observed for both STR and MH markers.

This study indicated that the 74-MH assay is promising and reliable in clearly solving paternity and full-sibling cases. When testing half-sibling and first-degree cousins versus unrelated case scenarios, some overlaps of the LR distributions were observed, which may lead to inconclusive results. In a nutshell, these results further support the use of this comprehensive and versatile MH tool in solving complex family pedigrees.

Microhaplotypes, Kinship Testing, Massively Parallel Sequencing

B76 Microwave Pre-Processing for Enhanced Rapid DNA Analysis of Forensic Samples

Nicole Fernandez-Tejero, MSc, Florida International University, Miami, FL; Fabiana Taglia, MSc, Florida International University, Miami, FL; Casandra Hernandez-Setser, PhD, Florida International University, Miami, FL; Ling Wang, PhD, Florida International University, Miami, FL; Robert O'Brien, BS, National Forensic Science and Technology Center, Largo, FL; Kevin Lothridge, MS, National Forensic Science and Technology Center, Largo, FL; Bruce R. McCord, PhD, Florida International University, Miami, FL; Steven B. Lee, PhD, Florida International University, Miami, FL*

Learning Overview: After attending this presentation, attendees will understand how a microwave can be used to rapidly extract DNA.

Impact Statement: This presentation will impact the forensic community by demonstrating how microwave pretreatment extraction can increase allele recovery for conventional DNA analysis and Rapid DNA analysis in low template samples.

In recent years, there have been efforts to develop and implement automated, rapid DNA analysis systems that can process biological samples from swab to profile in 90 minutes. This has proven effective for high-quality samples and known references, but complete DNA profiles are difficult to obtain from less than pristine forensic evidence samples. Since microwaves can disrupt cell membranes, their use prior to rapid DNA analysis provides a quick and inexpensive method to augment the recovery of DNA. We have found that this can be achieved with an off-the-shelf microwave at 300W with a total of 40 seconds run time.

Microwaving samples prior to capillary electrophoresis conventional DNA analysis resulted in a 340% increase in allele recovery from 1% blood, 55% increased recovery from 1% saliva, and 96% increased recovery from 0.5% semen samples. In 1:9 saliva/semen mixtures, the total number of detected alleles increased from 20 to 25 alleles with microwaving, with the minor donor allele peak heights increasing 106% to 130% after microwaving. Rapid DNA processing of mock gun samples produced 11 ± 2 alleles when microwaved in comparison to 7 ± 6 alleles by conventional processing.

We focused on the ability to develop DNA profiles from samples in the stochastic range since this presents one of the main challenges to introducing rapid DNA to routine forensic casework. We empirically determined this was best represented by 0.05% dilutions of saliva where there was > 85% enhancement in allele recovery with microwaving before Rapid DNA analysis. The original sample collection method also profoundly impacts the downstream allele recovery with wet swab collection resulting in 5-6 alleles which increased to 12-13 alleles with dry swab collection. Interestingly, we found that simply removing the original swab from the cartridge (where 7 alleles were developed), allowing it to dry between runs, and then reprocessing permits the recovery of additional alleles when rerun. The microwaved rerun samples resulted in a total of 12 additional alleles vs only 11 in the non-microwaved samples.

A set of samples, sent out to two separate forensic casework laboratories, showed similar enhanced results for microwaved samples. We have developed a simple method that permits calibration of microwave power and sample placement to facilitate the calibration and use of a wide variety of instruments. Overall, our findings demonstrate that results from low copy DNA samples run on Rapid DNA systems can be improved using microwave pre-processing of forensic samples.

Microwaves, DNA Analysis, Rapid DNA

B77 Touch DNA Recovery to Inform Activity-Level Propositions: Fingerprints in the Wild and Their Domesticated Counterparts

Ashley Hall, PhD, University of Illinois at Chicago, Chicago, IL; Ray Wickenheiser, DPS, New York State Police Crime Laboratory System, New York, NY; Megan Tyahla, BS, University of Illinois at Chicago, Chicago, IL; Nivida Shete, MS, University of Illinois at Chicago, Chicago, IL*

Learning Overview: After attending this presentation, attendees will understand the scientific basis informing “activity-level propositions,” addressing how the sample got there, rather than simply who it belonged to. This understanding will improve the attendee’s potential for objective scientific validity as their opinions will be backed by data obtained from well-designed trace DNA transfer experiments. The presented flexible model permits the scientific expert to adapt to a wide variety of potential scenarios to meet defense and prosecution hypotheses, improving their evaluation of evidence, interpretation, opinions, and testimony.

Impact Statement: This presentation will impact the forensic community with the presentation of a scientifically neutral basis for evaluating alternate scenarios for explanation of why a suspect’s DNA is located at a crime scene. Opinions based on novel experiments using standardized mock fingerprints and hands will support a model to predict various scenarios posited by either defense or prosecution. Improved data to support the evaluations of hypotheses on transfer will provide improved evaluations, interpretations, and testimony in the field of trace DNA transfer. Improved scientific thought based on data will in turn result in improved justice system outcomes.

Interpreting forensic evidence has long been a challenge for forensic scientists as they are asked to evaluate, interpret and testify upon evidence using experimental data designed to maximize the probative value of evidence. Expert’s opinions include a variety of scenarios representing both prosecution and defense perspective. Alternate scenarios to explain why a suspect’s DNA is found at a crime scene is a common form of defense. Evaluating each scenario provides tremendous value when it can be backed by objective data. Touch samples are becoming increasingly informative sources of this data. In many cases, the strength of the DNA evidence is such that the identity of the donor can’t be reasonably disputed, rather the activities surrounding the DNA transfer become the subject of intense debate. Evaluations of the evidence given the donor’s activities inform “activity-level propositions,” addressing how the sample got there, rather than simply who it belonged to.

DNA transfer and recovery are two factors useful in addressing activity-level questions. Quantification of DNA recovery can be a useful tool in defining primary, secondary, and tertiary DNA transfer events. However, there are numerous variables to consider in a crime scenario and controlling for as many of them as possible is critical to generating informative objective data. First, deposition of a touch sample standard with a known DNA content is necessary to produce quantitative recovery data. A mock eccrine fingerprint containing a known quantity of DNA was previously reported.¹ An improvement on this protocol has been the incorporation of sebaceous components, such as amino acids and lipids, into the mock (domesticated) fingerprint chemistry. Using the domesticated sebaceous fingerprint, DNA recovery can be used to more closely approximate the behavior of fingerprints in the wild.

Next, to normalize DNA delivery in the primary transfer, a mock hand has been optimized. Three artificial epidermal formulations were evaluated: (1) a water-responsive, gelatin-based model; (2) a Lorica leather surrogate; and (3) a mixture of polyvinyl alcohol and polydimethyl siloxane.²⁻⁴ The artificial skin was constructed on a nitrile glove supported on a plaster cast of the researcher’s hand. To complete a transfer, the researcher put on the epidermis-glove, a domesticated fingerprint was placed on the skin, and it was transferred to a different surface. DNA recovery was quantified by real-time PCR. By controlling for DNA deposition variables, DNA recovery can be used to inform activity-level propositions.

B78 A Responsive Academy Seeing the Modern Forensic World Through the Lens of Its History: Lessons Learned From the Pioneering Jan Bashinski

Sandra Sachs, PhD, Oakland Police Department, Oakland, CA*

Learning Overview: The importance of the modern forensic world keeping history in mind when moving forward.

Impact Statement: Historical issues laboratories faced remain topics that forensic organizations wrestle with to this day.

The Modern Forensic World is faced with enormous challenges: Sexual Assault Kit backlogs, maintaining accreditation, inadequate funding, onboarding emerging technology, legal challenges, training analysts, publishing/sharing research, certification, scope of expertise, standards development and more.

It is worth taking a look back through the last five decades to see where the field of forensic science has been. Indeed, "A generation which ignores history has no past and no future."¹

In the 1970s a heightened awareness about Sexual violence against women was emerging. Jan Bashinski, the first woman hired at the Oakland Police Department Criminalistics Laboratory, and her collaborators moved the needle by investigating ways in which this type of evidence could be handled and processed to its fullest potential. She conducted this work in the tiny municipal laboratory servicing the residents of Oakland. Jan initiated research relationships with local talent at UC Berkeley to make this happen. She did this with no extra funding for such efforts.

Jan received master's degree in Criminology from UC Berkeley in 1974 for work evaluating Gunshot Residue for lead.

In 1977 Jan inherited the helm of the Oakland PD as the first female forensic laboratory director in the State of California. In 1983, she led the charge to have the Oakland Laboratory become the first in California and the fourth in the nation to be accredited.

In addition to these accomplishments, Jan provided leadership in a multitude of ways:

- Early adopter and advocate of Accreditation through ASCLD/LAB
- Strong regional forensic science association (CAC) attendance and collaboration
- President in 1977
- Presenter of technical papers on many occasions
- National leadership
- AAFS Criminalistics Section Chair, 1984-85
- Certification of forensic scientists – CAC which assisted to launch ABC
- Generalist approach
- Founded the California State DNA Laboratory Program and DNA Database
- DNA Laboratory in Richmond named after her through CA legislation
- Cold hit program – sought and received funding for California municipal labs
- More than 10,000 cases reopened and 366 cold hits were achieved
- Mentorship
- Training forensic practitioners
- Oversaw the California Criminalistics Institute (CCI)

This presentation is not intended to be hagiographic. Instead, it is simply to set the stage of the special session for discussion and reflection on the ways past figures in our forensic profession blazed trails and, in so doing, what lessons can be learned about how to proceed tackling the innumerable emerging issues at our collective forensic door: Recognition of vicarious trauma, mitigation of bias, forensic management certification, black box studies to address error rates, next generation sequencing, cutting edge instrumentation, method development. Which will we tackle? How will we do so?

Laboratory Issues, Certification/Accreditation, Working Group Standards

B79 The Important Role of Generalists in the Modern Forensic Science World of Specialists

JoAnn Buscaglia, PhD, FBI Laboratory, Quantico, VA; Jack Hietpas, PhD*, Microtrace, Elgin, IL; Peter De Forest, DCrim, John Jay College of Criminal Justice, New York, NY*

Learning Overview: Attendees will learn the value of generalists in meeting and surpassing the challenges in the modern forensic science world, which is overwhelmingly dominated by specialists.

Impact Statement: In keeping with the conference theme, this presentation will impact the forensic science community and honor the legacy of Jan Bashinski by exploring the value of generalists and their impact on the modern forensic science world, particularly in the areas of research, mentoring, quality assurance, and administration.

Historically, the role of the criminalist has been as a forensic science generalist – a competent scientist with sufficient breadth and depth to define the appropriate investigative scientific questions, and to recognize, recover, examine, and interpret traces. However, as early as 1969, Kirk reported the trend toward specialized scientists confined to the laboratory “without the basic principles of scientific crime investigation” – a trend that has continued up to today with few exceptions.¹ De Forest has tirelessly advocated for “recapturing the essence of criminalistics” and the importance of the role of the scientist at the crime scene.² Similarly, an international group of scientists recently presented the Sydney Declaration, which defines forensic science as “... a case-based (or multi case-based) research-oriented endeavour (sic) using the principles of science to study and understand traces....”³ Although there is certainly a need for specialists for highly technical methods and advanced instrumentation, there remains a need for the proactive generalist not only in scientific crime investigation but also in research, quality assurance, mentorship, and administration of crime laboratories.

In keeping with the spirit of the historical criminalist, forensic scientists should strive for a forward-thinking, research orientation regardless of whether their work is scene- or laboratory-based. One can be highly specialized in one or more areas yet still be a generalist by keeping casework and research interests wide and asking the appropriate questions that are based on sound science. As technological advancements continue, there is no doubt that certain areas will become more highly specialized, requiring more specialists to analyze a single item of evidence. However, in such a situation, the role of the generalist will be even more critical – in ensuring that the right questions are asked, the appropriate tests are conducted to answer them, and the significance of their results are properly interpreted within the context of the case. Without this holistic understanding, there may very well be highly specialized tests done that give the *right* answers to the *wrong* questions, wasting precious (evidentiary, financial, and human) resources and failing to serve the criminal justice system and society as a whole.

Although research in support of the forensic sciences often requires highly specialized knowledge in a particular area, it is also likely multidisciplinary, for which it is most appropriate for a generalist to lead the research effort. “Chance favors the prepared mind” – a quote attributed to Pasteur – exemplifies the important role of the generalist in research; success in research requires grounding in the scientific approach to problem-solving. Similarly, successful implementation of research into practice often requires a broad knowledge of the forensic sciences and criminal justice system as a whole – reasons to have a strong and broad educational foundation in science and applications in Criminalistics.

This session honors Jan Bashinski, who was wholeheartedly a generalist – forward-thinking, problem-solving, and research-oriented. From GSR and drug chemistry to forensic biology, to accreditation and laboratory management, Jan’s education and knowledge in Criminalistics and her generalist approach provided the strong foundation for her diverse career, which had a profound impact on forensic science and the criminal justice system.

Generalist, Criminalist, Specialist

B80 Taking the Lead: Jan Bashinski and the Development of Modern Analytical Methods for the Chemical Detection of Gunshot Residues

Michelle D. Miranda, PhD, Farmingdale State College, SUNY, Farmingdale, NY*

Learning Overview: After attending this presentation, attendees will have learned about the history, chemistry and present approaches to GSR analysis, specifically the detection of lead residues using the sodium rhodizonate test. During the course of the presentation, attendees will learn about Bashinski's contributions to GSR analysis, which includes techniques still routinely employed in crime laboratories conducting GSR analysis.

Impact Statement: The presentation will impact the forensic science community by providing a review of the history and chemistry of GSR analysis, the contributions of Bashinski to the discipline, and their continued relevance today.

GSR examinations consist of visual, microscopical, chemical and spectroscopic examinations of the residues that result from the discharge of a firearm and ammunition. The major contributors to the deposition of GSR on a surface proximal to a discharge event include the projectile (bullet, shot), propellant (gunpowder), and the primer. Primer GSR (pGSR) analysis is largely concerned with examinations of "shooter's hands" samples utilizing SEM-EDS to detect inorganic residues derived from the primer (barium, antimony, and lead). pGSR interpretations address whether or not an individual may have recently fired, handled, or was in the vicinity of a discharged firearm. Supplemental analysis for the detection of organic components (propellant) may be conducted in conjunction with pGSR testing. Alternatively, the broad analysis of firearm discharge residues is often associated with color tests for the residues exiting from the muzzle end of the firearm and being subsequently deposited, often in a pattern, on a target or intervening object. The sequence of color tests is selected in order to detect the presence of both organic (nitrites) and inorganic (copper, lead) traces. Detection and interpretation of these residues can aid in determining the passage of a bullet; the discharge of a firearm; the approximate distance between the shooter and the target (muzzle-to-target distance determinations); and the maximum distance at which a particular firearm with particular ammunition will cease to deposit residues on a target (maximum distance determinations).

Presently, the most common color tests employed in such GSR testing are the dithiooxamide test for copper, the modified Griess test for the detection of nitrites, and the sodium rhodizonate test for lead. This presentation will focus on the history and chemistry of the sodium rhodizonate test and the research of Jan Bashinski in the 1970's which resulted in the technique referred to as the *Bashinski Transfer Method*. The sodium rhodizonate test has its roots as a general spot test for trace metal detection in analytical chemistry, and was eventually recognized for its application to matters of forensic significance—notably, the colorimetric detection of lead residue resulting from the passage of a bullet. The utility of the sodium rhodizonate test extended beyond a spot test indicating presence or absence of lead to a test that could provide information *in situ* about lead deposition based on the pattern deposited on the target, lending itself to making approximations about the distance between the firearm and the target surface. Bashinski *et al.* reviewed the chemistry and methodology of sodium rhodizonate in a forensic context to provide the forensic community with a test that was useful and robust for distance determinations, supporting the utilization of the sodium rhodizonate test for routine GSR examinations in crime laboratories.¹ Moreover, Bashinski *et al.* brought attention to the importance of well-informed approaches to interpreting GSR results.¹ Despite modern advances in technology and application of spectroscopic and chromatographic methods to identify and classify gunshot residues, the analytical methods and interpretation considerations addressed by Jan Bashinski in her research endeavors are still of critical importance to how forensic scientists approach GSR cases presently.

B81 Jan Bashinski's Progressive Approach to Crime Lab Management: The Development of the Systematic Approach for the Analysis of Semen Evidence From 1978 to 1985

George Sensabaugh, DCrim, University of California Berkeley, Berkeley, CA; Edward Blake, DCrim, Retired, Oakland, CA*

Learning Overview: This presentation honors Jan Bashinski's contribution to the development of a systematic approach to the analysis of evidence in sexual assault cases.

Impact Statement: This presentation illustrates how crime labs can benefit from creating an environment marshaling the efforts of the public, private, and academic sectors to work together on forensic problems of the day.

Sexual violence against women emerged in the 1970's as a major public issue: police investigations of rape were often superficial, prosecution rates were low, and conviction rates even lower. Two consequences with immediate forensic relevance were calls for better treatment of victims in emergency rooms and greater utilization of physical evidence in supporting investigations and prosecutions.

Jan was director of the Oakland Police Department Criminalistics Laboratory as these issues were coming to a head. Jan recognized that the path to increasing the crime lab's contribution to the utilization of physical evidence began with better procedures for the collection of evidence in the ER and preservation of evidence prior to analysis in the lab. She also appreciated a need to improve the information yield provided by the then-current protocols used for the analysis of sexual assault evidence.

To address these objectives, Jan initiated a working consortium involving her lab with an academic research lab and a private practitioner, both with research experience with sexual assault evidence. She was successful in obtaining research grants to support the work of the consortium and administered the grants with a firm hand to keep the research objectives in sight.

As the potential value of sexual assault evidence came to be appreciated in the 1970s, the collection of evidence from sexual assault victims typically involved collection of vaginal swab samples according to clinical sterile practice: wet swabs were placed in sealed tubes for submission to the crime laboratory. These conditions were hypothesized to lead to degradation of the genetic markers of forensic interest, specifically the ABO blood group substances and polymorphic enzyme markers that might be present. Basic research on protein and blood group stability demonstrated that both markers were very stable in the dried state. Follow-up research demonstrated that markers on dried vaginal swabs persisted longer than on wet vaginal swabs even when frozen. Finally, it was demonstrated that rapid drying was better than drying under ambient conditions. This led to the development of the drying box, a box to be placed in the ER to dry freshly collected swabs in a stream of moving air. This body of research laid the foundation for the current practice of storing biological evidence in the dry state to maintain marker stability.

By the end of the 1970's, the analysis of vaginal swab evidence in sexual assault cases was limited to presumptive testing for the presence of semen and/or detection of sperm by microscopy followed by, if semen was detected, genetic testing for ABO blood group antigens and the genetically polymorphic enzymes phosphoglucomutase (PGM) and peptidase-A (PepA). Because these genetic markers are also expressed in vaginal fluids, genetic testing of vaginal swab extracts is nominally informative as to the semen donor only when markers foreign to the victim's types are detected. To address this limitation, a systematic scheme for the analysis of semen evidence was devised which entailed estimating the amount of semen present in a vaginal swab extract by quantitative acid phosphatase analysis supported by microscopic assessment of the sperm content. This quantitative variable could then guide the interpretation of genetic typing results: genetic types detected under this scheme can be attributed to the semen donor if the semen content of the vaginal swab extract exceeds the upper limit of the genetic markers normally present in vaginal fluids.

These examples illustrate Jan's progressive approach to crime laboratory management - by creating an environment in which the efforts of public, private, and academic sectors were marshaled to work together, significant progress was made in addressing an important forensic problem of the day.

Criminalistics, Sexual Assault, Crime Lab Management

B82 Examining the Analytical Threshold (AT) Methods Used in Interpreting Capillary Electrophoresis (CE) - Based Short Tandem Repeat (STR) Profiles

Sarah Riman, PhD, National Institute of Standards and Technology, Gaithersburg, MD; Hari Iyer, PhD, National Institute of Standards and Technology, Gaithersburg, MD; Peter Vallone, PhD, National Institute of Standards and Technology, Gaithersburg, MD*

Learning Overview: After attending this presentation, attendees will gain valuable insight into the methods used to select analytical thresholds (ATs) and the impact of AT values on downstream analysis.

Impact Statement: This presentation will benefit the forensic science community by discussing a framework to assess an AT(s) and their impact on casework interpretations.

Continuous probabilistic genotyping software (PGS) model true allelic peaks with their associated PCR byproducts. PGS also model drop-in and drop-out events. Most PGS require STR profile information with an AT pre-applied to remove baseline noise and similarly setting these AT values within the PGS to model drop-in and drop-out peaks during Likelihood Ratio (LR) assignment. Therefore, setting an AT to help distinguish an allelic signal from electronic noise remains a critical step and is still to be determined until noise models are incorporated into PGS.

There is no ‘perfect’ AT for all situations. This is the reason there are different methods and equations that provide guidance to establish AT and none of the formulas are normative. Higher AT values will prevent erroneously labeling non-alleles as alleles decreasing drop-in events (false positives). However, a high AT value can lead to drop-out events (false negatives). Therefore, an established AT value should provide a satisfactory balance point between drop-ins and drop-outs.

Here, we first give an overview of: (1) different factors that affect the peak heights of both the noise and true alleles, and (2) various published methods and equations that are used to determine AT values. We then examine the performance of these different AT approaches and their effect on: (1) rates of false positives (false labeling of electronic noise peaks as true alleles), (2) true positives (correctly labeling peaks as true alleles), (3) number of contributor (NOC) assessment, and (4) LR assignment. To illustrate these ideas, we derive AT using single-source profiles of varying DNA quality and DNA quantity obtained from the GlobalFiler 29 cycles 15s PROVEDIt dataset. We then evaluate the performance of ATs derived from single-source samples when applied to unknown samples by using a set of PROVEDIt mixture profiles of varying quality, quantity, NOCs, and mixture ratios.

Analytical Thresholds, DNA Mixture, True and False Positive Rates

B83 Lessons Learned From a 40-Year Career in Forensic Science

Barry Fisher, MS, MBA, LAPD Crime Lab, Retired, Indio, CA

Learning Overview: There is no substitute for experience. This presentation relates the professional experiences of a senior forensic scientist that may aid younger professionals.

Impact Statement: The biblical statement that nothing is new under the sun is partially true in a forensic science career. No two days or cases are ever exactly alike. Drawing on the experience of senior practitioners can give forensic scientists newer to the profession ideas of how to handle situations unfamiliar to them or perhaps that they have never considered.

During my career, I learned a number of useful qualities that can guide forensic scientists. These include:

- Forensic science is not static and requires continuing education.
- Be skeptical. Don't believe the first explanation you develop when obtaining from tests.
- Always consider alternative theories even when presented by adversaries.
- Add as many professional colleagues as you can from all areas and cultivate those individuals.
- Work to improve your communication skills and consider your audience when explaining technical matters.
- Join and become involved in professional societies. Attend conferences.
- When able, present papers at professional conferences and publish your work in peer-reviewed journals.
- When a superior asks for a volunteer to take on a project, volunteer.
- Remember, that when life hands you lemons, make lemonade.
- Maintain a positive attitude.
- Be willing to say, "I don't know." It is impossible to be an expert in all things. Ask for assistance.
- Be willing to assist subordinates when possible.
- Be honest and ethical in all your professional conduct.
- Learn the importance of outreach to groups such as the press, crime victims, senior personnel, judges, and lawyers.
- Keep a journal.

Mentoring, Experience, Coaching

B84 Fixing Forensic Science by Learning How to Learn from Our Mistakes

Brian Gestring, MS, 4n6Services, Guilderland, NY*

Learning Overview: Attendees will learn about failure analysis in forensic science and how to improve their response to when things go wrong.

Impact Statement: This presentation will highlight a critical weakness in how forensic science is practiced and provide a phased implementation plan describing how to fix it.

The introduction of Forensic Science has forever changed the criminal justice system. Despite how good forensic scientists are at their respective disciplines, inexplicably, they are bad at looking at themselves and learning from when things go wrong with the work they do.

In part, this is due to the many divergent educational paths that lead to a career in forensic science. Examiners can enter the field with a forensic science degree, a traditional science degree, or in some cases, no degree at all. While there is a voluntary accreditation available for academic programs in forensic science, there is no requirement that any failure analysis methodology be discussed.

This weakness is further compounded by existing practitioner's lack of awareness and training. For the most part, forensic science did not start to embrace root cause analysis until the greater forensic community started to migrate to the international accreditation standards (ISO/IEC 17025:2005). 17025 required a process of root cause analysis and corrective action, but there was no training requirement for the forensic scientists who had to develop or carry out these procedures for their laboratory.

To this day, there is no requirement for forensic scientists working in accredited laboratories to receive any root cause analysis training. As a result, the experience levels of the people charged with this responsibility varies from some external training to no formal training at all.

The challenges faced by accredited laboratories are dwarfed in comparison to their non-accredited counterparts who essentially have no requirements at all. As of this writing there is no universal requirement for government run forensic laboratories to be accredited despite calls for this for over a decade.

Lack of formal guidance and training on failure analysis combined with immersion in the adversarial system of justice often leads to rushed assignments of blame and the development of "quick fixes." Failing to understand the full scope and true nature of a problem before coming up with a solution virtually guarantees that the problem will occur again. The apprehension that comes from having no "safe space" to discuss failures often leads to silos of information precluding even other sections of the same laboratory from learning from a mistake, let alone other laboratories or the broader forensic community.

As daunting as this sounds, it is not too late to recognize this Achilles heel and take steps to address this critical weakness. This presentation will outline the current challenges associated with this vulnerability and describe a phased implementation plan demonstrating a path to not only learn from the mistakes that we make, but those of others within the field.

Root, Cause, Analysis

B85 Reclaiming Forensic Science: A Closer Look at the Sydney Declaration

Michelle D. Miranda, PhD, Farmingdale State College, SUNY, Farmingdale, NY; Sheila Willis, PhD, Leverhulme Research Center for Forensic Science, Dundee, United Kingdom; Patrick Buzzini, PhD, Sam Houston State University, Huntsville, TX; Rebecca Bucht, PhD, NBI Forensic Science Laboratory, Vantaa, Finland*

Learning Overview: After attending this presentation, attendees will learn about the collaborative effort to define forensic science and articulate its fundamental principles in an effort to unify and improve the status and application of forensic science.

Impact Statement: The presentation will promote and encourage discussions concerning the fundamental principles of forensic science in order to effectively address education and training, research and development, laboratory practices, and quality of forensic science services.

Forensic science, forensic sciences, forensics.

Forensic scientists, criminalists, generalists, specialists, academics, practitioners, “experts,” “others.”

Prosecutors, defense attorneys, judges, law enforcement officers, administrators, policymakers.

Who are we? What do we do? Who (and what) defines what we are and what we do?

Where have we been? Where are we going? What is our history and what is our future?

In 2021, an international group of forensic scientists drafted and presented “the Sydney Declaration” in response to years of discussions and debates concerned with fundamental matters related to forensic science.¹ Many of these conversations arose from publications and media accounts addressing the effectiveness and reliability of forensic science. The group opted to approach forensic science from its foundation, thereby establishing fundamental principles with the goal of unifying the purpose of forensic science in order to effectively address matters of education and training, research and development, and laboratory operations as forensic science moves into the future.

This presentation begins with a brief history of criminalistics and is then divided into two sections. First, aligned with the principle that forensic science relies on scientific knowledge and logical reasoning, a discussion of scientific methodology is presented and expanded upon by considering the importance of observation and inferential reasoning within forensic science education and training. The second section emphasizes the principle that forensic science requires meaning in context, which necessitates knowledge of the nature of traces.

A core element of the Sydney Declaration is the trace, or vestige of an activity that occurred in the past under uncontrolled conditions. Traces undergo a process that qualifies them to a status of evidence. This process requires a rigorous methodology that goes beyond the deployment of specialized techniques to include defined scientific principles and human cognition. A reliable methodology intended to determine the contributing value of traces recovered in a case should include the proper use of the scientific method, but where does the scientific method fit in practice? At the laboratory? At the crime scene? Who defines the working hypotheses? Is the scientific method integrated into the transition of traces from the scene to the court, and through the lab? Moreover, can the scientist communicate their observations, interpretations and reasoning processes to others?

Forensic science has been the subject of much criticism in recent years, making it easy to imagine that its use causes more problems than it solves. Yet even the most ardent critics could not imagine a criminal justice system without physical evidence. We need to acknowledge that context has an impact on the scientific process and that findings do not have a stand-alone value. Relevance is sometimes considered to be the concern of the court or the lawyers and not the scientist. But, if the science is to make a useful contribution to an investigation, the knowledge the scientist has on trace activity, persistence and detection needs to be made available to guide scientific methodology and assigning meaning to the results obtained. Forensic science takes some norms from other disciplines, but it is a mistake to confine the contribution to the analytical results of comparisons without consideration of the nature of the source, trace and environment in the context of the case.

Trace, Context, Sydney Declaration

B86 Case Contextual Information and Its Variation Among Forensic Laboratories

Taylor Hopkins, Duquesne University, Pittsburgh, PA; Lyndsie Ferrara, PhD, Duquesne University, Pittsburgh, PA*

Learning Overview: The goal of this presentation is to inform attendees about the information that different forensic disciplines and laboratories collect through evidence submissions forms as well as their established bias mitigation techniques.

Impact Statement: This presentation will impact the forensic science community by cultivating a continuous dialogue about the impact of contextual bias within the workplace.

One of the challenges in the modern forensic science world is acknowledging and mitigating bias in all of its forms. Contextual bias, in particular, is a challenge as it can unintentionally cause scientists to let case contextual information guide their decisions as opposed to the actual evidence. This bias can arise simply through the use of laboratory submission forms and a study concluded that such forms could contain irrelevant information relating to the examination required.¹ This project investigated the amount of information requested by forensic laboratories, via their submission forms, and how they vary between forensic disciplines.

A survey was created asking participants about their laboratory, laboratory submission form, and laboratory procedures as it relates to case contextual information and how it is transmitted. Participation was completely voluntary and not all questions had to be completed to submit it. The survey was transmitted via email to accredited forensic-testing laboratories according to the ANSI National Accreditation Board (ANAB) website and sent out to members of several regional and national forensic organizations including the American Academy of Forensic Sciences Criminalistics section. Data was collected during the summer of 2021.

A variety of disciplines and laboratories were represented in this data set including forensic biology, chemistry, and firearms/toolmarks. The majority of participants indicated their job position as an analyst as opposed to a laboratory administrator. Most participants also answered that their laboratory used a general laboratory submission form instead of a discipline-specific form. Of the items listed on the survey, the top four reported items on the laboratory submission form were investigating officer, evidence description, suspect name, and offense type. Responses showed that while many laboratories implement bias training, there are still many laboratories that do not have a protocol in place to guard an analyst from potential biasing effects of case contextual information. Overall, the data provided a comprehensive outlook on information collected through evidence submission forms and what different laboratories and disciplines are doing, or not doing, to mitigate the effects of contextual bias.

Bias, Contextual Information, Submission Form

B87 The Development of an *In Situ* Sampling Interface for Thermal Desorption Direct Analysis in Real-Time Mass Spectrometry (TD/DART®-MS) Analysis of Ignitable Liquid Residues (ILRs) in Fire Debris Samples

Briana Capistran, PhD, National Institute of Standards and Technology, Gaithersburg, MD; Matthew Staymates, MS, National Institute of Standards and Technology, Gaithersburg, MD; Edward Sisco, PhD, National Institute of Standards and Technology, Gaithersburg, MD*

Learning Overview: After attending this presentation, attendees will be familiar with a new sampling chamber designed for ILR analysis *via* (TD)-DART®-MS to achieve direct sampling, ionization, and detection of sample components.

Impact Statement: This presentation will impact the forensic science community by providing a sampling tool for ILR analysis that eliminates sample preparation procedures and enables *in situ* sampling of volatile components.

After attending this presentation, attendees will be familiar with a new sampling chamber designed for ILR analysis *via* (TD)-DART®-MS to achieve direct sampling, ionization, and detection of sample components. This presentation will impact the forensic science community by providing a sampling tool for ILR analysis that eliminates sample preparation procedures and enables *in situ* sampling of volatile components. The identification of ignitable liquid residues (ILRs) in fire debris samples can serve as an indication of an intentionally set fire. Gas chromatography-mass spectrometry (GC-MS) is the standard method for ILR analysis because of its ability to separate and identify individual sample compounds. Such analysis requires sample preparation procedures (e.g., passive-headspace extraction), which can be time-consuming (up to 24 hrs), involve the risk of competitive adsorption, and require the use of hazardous solvents (e.g., carbon disulfide). Additionally, GC-MS analysis times can be lengthy (e.g., 30 – 60 min per sample), and ILR identifications can be challenging due to the presence of substrate interferences in the resulting chromatograms and extracted ion profiles. Direct Analysis in Real-Time Mass Spectrometry (DART®-MS) has become increasingly popular in forensic laboratories because of the ability to rapidly analyze samples in their native states.

The identification of volatile and nonvolatile compounds is also possible using DART®-MS, which is advantageous for identifying nonvolatile fuel additives that are otherwise undetectable using GC-MS. Coupling DART®-MS with temperature-programmed Thermal Desorption (TD) compensates for the lack of separation component and provides time-resolved mass spectra for particularly volatile samples, such as ILRs in fire debris. Use of TD has also shown to improve sensitivity and ionization efficiency. Thus, the use of (TD)-DART®-MS for ILR analysis eliminates time-intensive sample preparation, reduces the risk of competitive adsorption and exposure to hazardous solvents, and minimizes sample and data analysis times. However, there exists a need for a sampling chamber to accommodate for *in situ* sampling from commonly used sample containers (e.g., paint cans). This work presents a newly developed TD interface amenable to ILR analysis that enables direct sampling of compounds and introduction into the mass spectrometer. The sampling chamber has been constructed to accommodate sample containers of varying sizes. Containers are loaded into the chamber and enclosed with temperature-controlled heating elements for homogeneous heating of the entire sample unit. A temperature program is used to desorb compounds with a wide range of volatilities. Subsequent ionization of desorbed compounds and direction into the mass spectrometer is achieved using a heated junction. Optimization of programmed heating parameters, such as initial and final temperatures, hold times, and ramp rates, was performed specifically for ILR analysis to enhance spectral reproducibility, especially for highly volatile compounds. A range of samples was used to assess the efficacy of the sampling chamber, including standard test mixtures of n-alkanes and aromatic compounds (common ILR components) and simulated fire debris samples.

This work will introduce a novel sampling chamber for (TD)-DART®-MS analysis of fire debris samples in their original sample containers. The development of such an interface not only eliminates sample preparation and increases sample throughput but enhances sensitivity and reproducibility for ILR identification in highly complex samples.

Fire Debris, DART®-MS, Thermal Desorption

B88 A Sensitivity Analysis of Dynamic Vapor Microextraction with Simulated Fire Debris

Jennifer Berry*, National Institute of Standards and Technology, Boulder, CO; Mary Gregg, National Institute of Standards and Technology, Boulder, CO; Amanda Koepke, National Institute of Standards and Technology, Boulder, CO; Chris Suiter, National Institute of Standards and Technology, Boulder, CO; Reta Newman, Pinellas County Forensic Laboratory, Largo, FL; Kavita Jeerage, National Institute of Standards and Technology, Boulder, CO

Learning Overview: Attendees will learn about the application of dynamic vapor microextraction (DVME) to the extraction and concentration of ignitable liquid (IL) from simulated fire debris, its challenges, and how sensitivity analysis can be used to evaluate this emerging forensic method.

Impact Statement: This presentation will impact the forensic scientific community by describing a sensitivity analysis of dynamic vapor microextraction (DVME), an alternative headspace concentration method that may find application in fire debris analysis. DVME employs a safer solvent than typical headspace concentration methods and vapor distortion can be monitored; however, the relative influence and interaction of sample and instrumental variables remains unexplored. Challenges associated with sample packaging will also be addressed.

Debris from structural fires is typically investigated for ignitable liquid (IL) residue using headspace concentration methods. The most common method in the United States is passive concentration onto activated carbon strips (ACSs), which requires the use of carbon disulfide, a dangerous neurotoxic solvent, and is known to have challenges with vapor distortion.^{1,2} Dynamic vapor microextraction (DVME), in which a carrier gas pushes vapors from the sampling container headspace through a chilled adsorbent capillary, is a potential alternative. The adsorbent phase of the capillary, along with the cold temperature, enhances the trapping efficiency of vapors and stabilizes reactive species in the sample. DVME was originally developed to identify compounds in the headspace of low volatility explosives and has been applied to the extraction of ILs including gasoline and diesel fuel in preliminary studies.³⁻⁵ This emerging method has promising features for fire debris analysis including the use of a relatively benign elution solvent (acetone) and the ability to monitor vapor distortion. However, the current DVME procedure involves many high-precision controllers (e.g., to control the inlet flowrate and the capillary temperature) using equipment not standard in forensic laboratories. Furthermore, the relative effect of many sample and instrumental factors on the resulting IL extraction remains unknown.

To address this research gap and assess potential instrumental requirements, a sensitivity analysis was conducted with 5 sample and 6 instrumental factors. Simulated fire debris was created by adding weathered gasoline (50% or 80%) to a 32 oz glass sampling container partially filled with burned or unburned wood chips; some samples were spiked with water. DVME was used to collect vapors from the headspace of these containers, varying the adsorbent phase, oven temperature, capillary trap temperature, inlet flowrate, and collection volume. Collected samples were eluted with acetone, analyzed using gas chromatography with mass spectrometry, and compared to reference samples using covariance mapping of the retention time-ion abundance data matrix.⁶ Statistical analysis was conducted to determine significant first-order effects and interactions between variables.

This study is an essential step in validating the DVME method for application in forensic practice. Instrumental factors that significantly influence extraction of IL vapors direct future research on optimization, while non-significant instrumental variables identify elements of the procedure that may be modified to facilitate laboratory adoption. The results also provide a better understanding of the robustness of the DVME method to realistic differences in sample composition.

B89 Gasoline Identification by Pattern Recognition: Facts and Myths

Reta Newman, MA, Pinellas County Forensic Lab, Largo, FL; Brenda Christy, MS, Virginia Department of Forensic Science, Norfolk, VA; Kelsey Winters, MS, Virginia Department of Forensic Science, Norfolk, VA; Michael Gilbert, BS, Pinellas County Forensic Lab, Largo, FL*

Learning Overview: Attendees will learn about the results of a study that included a detailed comparison of chromatographic patterns associated with gasoline and negative sample matrices in fire debris analysis with an emphasis on the facts and myths associated with data interpretation of key diagnostic features.

Impact Statement: This presentation will impact the forensic scientific community by addressing inconsistencies in the emphasis placed on specific chromatographic patterns in the identification of gasoline in fire debris samples

The identification of ignitable liquids (ILs) is primarily made using pattern recognition techniques comparing key diagnostic features (KDFs) between forensic unknown samples and known ignitable liquids. When complex matrices, especially those that include pyrolyzed synthetic materials, are present, the interpretation becomes increasingly subjective. This presentation will focus on the KDFs of gasoline, providing the facts and debunking the myths on the importance and uniqueness of specific KDFs in the identification of gasoline based upon analyses of 150 gasoline reference samples (acquired from various geographic locations and tested in multiple laboratories) and the analysis of 56 negative debris samples.

Extracted ion profiling (EIP) is used to emphasize chromatographic patterns and isolate KDFs associated with specific compound types (alkylbenzenes, polynuclear aromatics, indanes, alkanes, cycloalkanes). Historically, greater emphasis has been placed on specific KDFs (for example C3 alkylbenzenes) and less on others in gasoline identification. This presentation will include a comprehensive and objective look at various peak patterns, and in some cases, specific compound identification, used in the forensic community to differentiate gasoline from matrix contributions. Pattern uniqueness was evaluated by comparing closely eluting peak pair ratios in KDF peak patterns.

Ultimately, it was determined that many of the KDFs that analysts currently rely on, were less unique than anticipated, other features including features not commonly reported in literature as being diagnostic, were found to be highly consistent in the reference gasoline samples and less common in matrix samples. The study reiterates the importance of having concordance among many KDFs when differentiating gasoline from complex matrices.

This work was supported by the National Institutes of Justice grant number 2018-DU-BX-0174.

Fire Debris Analysis, Ignitable Liquids, Pattern Recognition

B90 Standards Development Activities Related to Ignitable Liquids, Explosives and Gunshot Residue

Brenda Christy, MS, Virginia Department of Forensic Science, Norfolk, VA*

Learning Overview: After attending this presentation, attendees will have a better understanding of the status of discipline specific standards related to ignitable liquids, explosives (ILE) and gunshot residue (GSR).

Impact Statement: The presentation will impact the forensic science community by creating greater awareness of standards development activities related to ILE and GSR.

The Organization of Scientific Area Committees (OSAC) for Forensic Science was created to strengthen the nation's use of forensic science by promoting the use of discipline-specific standards. To this end, the OSAC drafts standards that are forwarded to standards developing organizations (SDOs) that further develop and publish them. The OSAC also reviews standards and recognizes them on the OSAC Registry, which serves as a central repository of high quality, consensus-based, technically sound standards.

During this presentation, ignitable liquids, explosives, and gunshot residue standards development activities will be discussed. These include recent standards that have been added to the OSAC Registry:

- ASTM E1388-17 Standard Practice for Static Headspace Sampling of Vapors from Fire Debris Samples
- E1412-19 Standard Practice for Separation of Ignitable Liquid Residues from Fire Debris Samples by Passive Headspace Concentration with Activated Charcoal
- E1413-19 Standard Practice for Separation of Ignitable Liquid Residues from Fire Debris Samples by Dynamic Headspace Concentration onto an Adsorbent Tube
- E3189-19 Standard Practice for Separation of Ignitable Liquid Residues from Fire Debris Samples by Static Headspace Concentration onto an Adsorbent Tube
- E3245-20 Standard Guide for the Systematic Approach to the Extraction, Analysis, and Classification of Ignitable Liquids and Ignitable Liquid Residues in Fire Debris Samples – drafting documents to submit for registry approval
- E3197-20 Standard Terminology Relating to Examination of Fire Debris
- E1588-20 Standard Practice for Gunshot Residue Analysis (GSR) by Scanning Electron Microscopy/Energy Dispersive X-Ray Spectrometry (SEM/EDS)

OSAC proposed standards:

- Standard Classification for Ignitable Liquids Encountered in Forensic Fire Debris Analysis
- Standard Test Method for Interpretation of Gas Chromatography-Electron Ionization Mass Spectrometry
- Data for the Identification of Ignitable Liquid Classes in Forensic Fire Debris Analysis
- Standard Guide for Analysis of Ignitable Liquids by Gas Chromatography Electron Ionization Mass Spectrometry
- Standard Practice for the Analysis of Organic Gunshot Residue (oGSR) by Gas Chromatography - Mass Spectrometry
- Standard Practice for the Analysis of oGSR by Liquid Chromatography - Mass Spectrometry
- Standard Practice for the Collection of Primer Gunshot Residue (pGSR) Particles from Clothing, Vehicles, and Other Objects using Adhesive Lifts
- Published standards from the ASTM that have yet to go through the Registry approval process
- Standard Practice for Reporting of Forensic pGSR Analysis by SEM/EDS
- E2451-13 Preserving Ignitable Liquids and Ignitable Liquid Residue Extracts from Fire Debris Samples
- Standard Terminology Relating to the Examination of Explosives
- Documents currently in development at the OSAC or by the SDO
- Revision to E1386-15 Standard Practice for Separation of Ignitable Liquid Residues from Fire Debris Samples by Solvent
- WK75150 Standard Practice for Training in the Forensic Examination of Fire Debris
- Standard Guide for the Forensic Analysis of Explosives by PLM,
- Standard Practice for the Characterization of Solid Oxidizer/Fuel Explosive
- WK72856 Standard Practice for Collection and Preservation of oGSR
- WK72526 Standard Practice for Expert Opinions on the Interpretation of pGSR by SEM/EDS
- WK58457 Standard Practice for Training in the Forensic Examination of GSR Using SEM/EDS
- Priorities for new documents or work products
- Fire Debris and Explosives annexes for ASTM E2549
- Standard Practice for Validation and Verification of Analytical Methods for Forensic Science
- Service Providers Performing Forensic Chemistry Analysis
- Standard Guide for the Performance of Automated pGSR Analysis by SEM/EDS
- Standard Guide for Reacquisition of pGSR Particles by SEM/EDS
- Standard Guide for the Classification of pGSR particles by SEM/EDS analysis

B91 Standards Development Activities in Firearm and Toolmark Examination

Jennifer Floyd BS, Arkansas State Crime Lab, Little Rock, AR*

Learning Overview: After attending this presentation, attendees will have a better understanding of the status of discipline specific standards related to the examination of firearms and toolmarks.

Impact Statement: The presentation will impact the forensic science community by creating greater awareness of standards development activities pertinent to firearm and toolmarks.

The Organization of Scientific Area Committees (OSAC) for Forensic Science was created to strengthen the nation's use of forensic science by promoting the use of discipline-specific forensic science standards. To this end, the OSAC drafts standards that are forwarded to standards developing organizations (SDOs) that further develop and publish them. The OSAC also reviews standards and recognizes them on the OSAC Registry, which serves as a central repository of high quality, consensus-based, technically sound standards. The Academy Standards Board (ASB) was formed by the American Academy of Forensic Sciences (AAFS) to accomplish the task of completing and publishing Standards, Best Practice Recommendations, and Technical Notes. To that end, the Firearms and Toolmarks Consensus Body was created.

During this presentation, updates related to firearm and toolmark evidence will be presented. These include i) recent standards that have been added to the OSAC Registry; ii) OSAC proposed standards; iii) published standards from the Academy Standards Board (ASB) that have yet to go through the Registry approval process; iv) documents currently in development at the OSAC or by the ASB; v) priorities for new documents or work products, and other highlights.

Firearm and Toolmarks, Standards, OSAC

B92 Bullet Ricochet of Polymer Coated Bullets

Stephen Daly, John Jay College of Criminal Justice, New York City, NY; Peter Diaczuk, PhD, John Jay College of Criminal Justice, New York City, NY*

Learning Overview: After attending this presentation, attendees will have a better understanding of the bullet ricochet of polymer coated bullets off of various substrates.

Impact Statement: This presentation will impact the forensic science community by providing a better understanding of the unique characteristics of one brand of polymer coated bullets.

Polymer coated bullets were designed to limit a shooter's exposure to lead as well as to limit the amount of lead that would be released into the environment. However, despite the advantages that these bullets give there are still difficulties which may arise in a forensic firearms examination. Unlike in a typical metal coated bullet, individualizing striations will typically not be imparted to a polymer coated bullet making it unable to be linked to a specific firearm. In fact, the only striations that are typically imparted to the polymer coated bullets are those of the general rifling characteristics which cannot be used to link a bullet to a specific firearm. Despite the difficulties that may arise there is still little known about these polymer coated bullets and there have been few published works regarding these bullets. Due to this difficulty any information that can be gained at the scene of a shooting could be crucial in a forensic firearm examination. Some obtainable information includes the angle of ricochet and the angle of incidence of the discharged bullet as well as traces from the polymer coating found at the impact mark. With this information, details such as the location of the shooter, the angle at which the shot was taken, or the angle at which the bullet ricocheted from the substrate are obtainable. In this project the ricochet angle and angle of incidence, utilizing the ellipse method, were calculated using trigonometric equations. The velocity of the shots was also measured using a chronograph.

The data was collected using 9 mm Luger Federal brand total synthetic jacket (TSJ) bullets and 9 mm Luger Federal brand full metal jacket (FMJ) bullets, which were used as a comparison point. The selected substrates were sheetrock[®], sheet metal, and durock[®] cement boards. Upon the collection of the velocity data, the TSJ bullets had a significantly lower average velocity (p-value of <0.00001), by a difference of 257 ft/s (feet per second) when compared to the FMJ average velocity. When the angles of ricochet were calculated each FMJ average angle was lower than the corresponding TSJ average angle, except in two instances. The ellipse method was found to still be an accurate method to determine the angle of incidence when applied to impact marks from TSJ bullets. In many of the impact marks there was also a red residue left behind which would have to be from the red polymer coating of the bullets.

Bullet Ricochet, Polymer-Coated Bullets, Syntech Ammunition

B93 A Forensic-Related Study on AK Bullet (7.62mm X 39mm) Holes on 1mm Sheet Metal and the Designing of the First Android-Based Field Investigation Tool for AK Gun-Related Bullet Trajectory Reconstructions

Bandula Nishshanka, MSc, Centre for Defence Research and Development, MOD, Sri Lanka, Colombo, Western, Sri Lanka; Randika Ariyaratna, MSc, Centre for Defence Research and Development, MOD, Sri Lanka, Colombo, Western, Sri Lanka; Chris Shepherd, PhD, University of Kent, Canterbury, United Kingdom*

Learning Overview: The presentation introduces a new method to identify the trajectories of AK bullets using the size of the bullet hole on 1 mm sheet metal and automotive sheet metal. The participant can learn the new theory and practically employ the theory and the new android tool for future AK gun related vehicle shooting incidents.

Impact Statement: The presentation introduces a new method and an android based field investigation tool to identify the trajectories of fired AK bullets using the size of the AK bullet hole on automotive sheet metal. This is a new method with proved success in field trials and wishes to introduce it to the shooting investigators worldwide. This new method can be used for AK investigations worldwide and introduce a novel method to the existing methods for trajectory determination of bullets from bullet holes. As AK guns have become a threat to the world peace with the increase reporting in recent crime scenes worldwide, this study will have a considerable impact to the field of AK gun related shooting investigations.

Bullet holes play a major role in the trajectory determination of fired bullets, potentially suggesting where the shots were fired from. Few methods are currently employed to estimate the angles of incidence of fired bullets using bullet holes. The study presents the findings of an empirical study and the design of the first android-based field investigation tool for AK gun-related vehicle shooting incidents, based on the relationship identified with the angle of incidence and length of the bullet hole in automotive sheet metal.

In the field experiment, AK bullets (7.62 mm x 39 mm) were fired into 1 mm sheet metal placed at different angles from 90 to 15-degrees and the results demonstrated a strong inverse relationship (Figure 1). This relationship has not been used as a method to estimate the angle of incidences of fired bullets and the findings confirmed that, the lengths of the bullet holes *l* can be used as a viable indicator to estimate the angle of incidence of fired bullets to vehicle bodies in real crime scenes. The full paper published in this study is available at AAFS Journal; *Journal of Forensic Sciences*; <https://onlinelibrary.wiley.com/doi/abs/10.1111/1556-4029.14717>¹

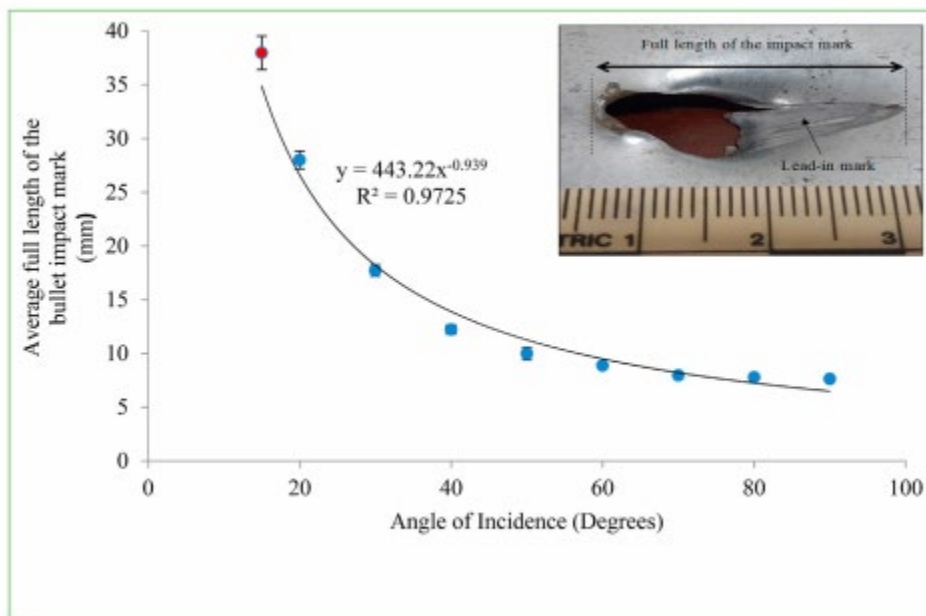

Fig 1. The relationship identified between the angle of incidences of Ak bullets and the length of the bullet hole on 1 mm sheet metal.

Continuing the study and utilizing the study's findings to a greater particle use, the team developed a mobile-based software tool, based on the formula identified on the correlation of the incident angle of AK bullets and length of the bullet hole. The designed software tool: "Bullet Trajectory Plotter" could estimate the potential trajectories of perforated AK bullets in 1 mm sheet metal surfaces. The software tool proved to be a viable, quickly employable, user-friendly, and fully mobile field investigation tool that can be installed on investigators' mobile phones to identify the approximate angles of incidence of perforated AK bullets on 1 mm sheet metal surfaces.

The tool was field-tested using a van door with a 1 mm sheet metal body. The new tool and the commonly used ellipse method were employed to estimate the angles of incidence of fired AK bullets, and the estimated values were recorded. The results of the estimated trajectory from the new tool and the comparison of the mean differences reported in the two methods compared to the real angles of incidence of fired AK bullets are illustrated in Fig. 2.

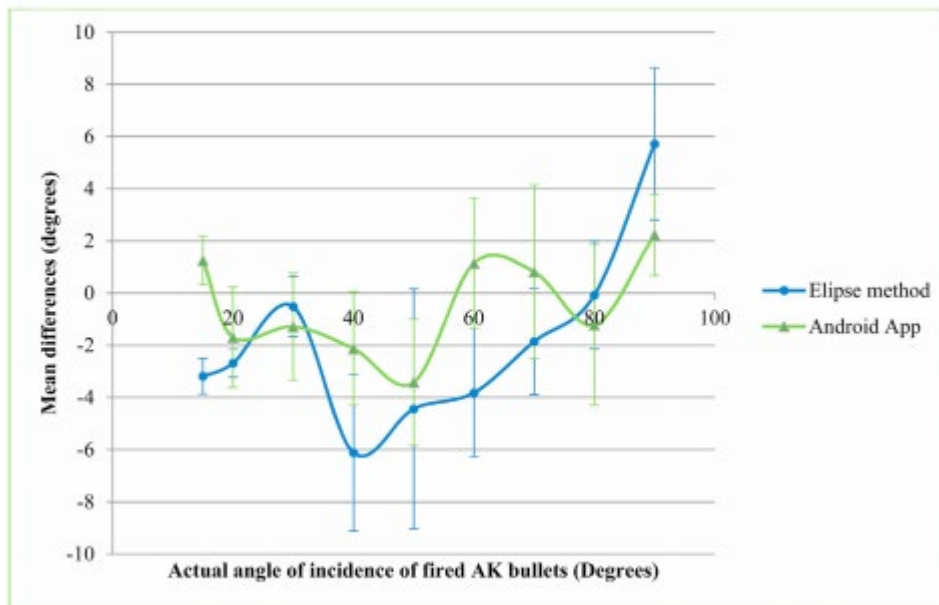

Fig 2: A comparison of the mean differences reported in the estimated angles of incidence, using two methods compared to the real angles of incidence of fired AK bullets.

The results of the field tests highlighted the employment of the new method in AK-related investigations. It is also significant to highlight that, the estimated incident angles by the new software tool were within ± 5 - degrees universally accepted error margin to the actual incident angles in bullet trajectory reconstructions. Some of the screen captured image of the developed software is given at Fig 3 and the full content of the published paper in this regard is available at: <https://www.sciencedirect.com/science/article/abs/pii/S2666281721001840>.²

AK Guns, Shooting Reconstruction, Android™ Tool

B94 Forensic Discrimination of Aluminum Sources in IEDs using Quantitative Trace Elemental Analysis

Anjuli Bhandari, PhD, ORISE/FBI Laboratory, Quantico, VA; Michelle Jordan, PhD, Carnegie Institute for Science, Washington, DC; Christopher Saunders, PhD, South Dakota State University, Brookings, SD; Danica Ommen, PhD, Iowa State University, Ames, IA; JoAnn Buscaglia, PhD, FBI Laboratory, Quantico, VA*

Learning Overview: Attendees of this presentation will gain a comprehensive overview of trace elemental profiles via ICP-MS from a variety of aluminum-based sources, understanding the ability of the developed method to discriminate between sources.

Impact Statement: Research presented will help the community understand the value in using ICP-MS to quantitate trace element compositions for discriminating between aluminum-based sources to further characterize IED component sources.

Improvised explosive devices (IEDs) often contain inexpensive, easily accessible materials. Metallic aluminum (Al) is commonly used as the fuel base in IEDs to increase the heat of reaction. Al powders can be produced from commercially available Al sources including foils, pastes, pyrotechnics, spray paints, Al cans and components of binary exploding targets. At AAFS 2020, method development and proof-of-concept research was presented¹. Further method refinements as well as new data evaluating the discrimination of Al sources using trace element concentrations by inductively coupled plasma mass spectrometry (ICP-MS) will be presented.

Koons, et al.² initially investigated ten trace element concentrations in Al foils in 1993 and demonstrated that trace elemental profiles allowed for discrimination between the 12 manufacturers studied, as well as between two lots of the same manufacturer for the 30 rolls analyzed. Research presented here builds on these initial findings and analyzes a larger, more diverse sample set using instrumentation with greater sensitivity, which permits analysis of additional elements.

The current Al source collection contains approximately 381 sources from different starting materials and final manufactured powders, a variety of global manufacturers, as well as materials from both the same and different production lots of the same manufacturer.

Twenty-nine elements of interest are quantitated via ICP-MS using two states: standard (STD) and kinetic energy discrimination (KED) depending on the isotope and potential interferences. To ensure and verify accuracy and stability, external calibrations are used, a multielement internal standard covering the analyzed mass range is added to all samples to correct for instrumental drift, and a NIST-certified standard reference material is analyzed with all samples.

Previously reported homogeneity tests¹ were conducted using a 250-foot Al roll sampled every 10 feet. Based on these results, it was concluded that the roll was likely not significantly heterogeneous and that the trace element profile was independent of the sampling location. Preliminary tests also confirmed that trace element profiles were distinct among two different manufacturers, allowing for between-source discrimination. Based on these initial findings, a statistical subsampling scheme was implemented using nine locations along the length of each Al foil roll. Specific subsamples of paired sources were analyzed over the course of two-day analytical runs in a designated pattern. Forty-six sources from 39 distinct manufacturers were analyzed in this manner. Statistical analysis failed to detect significant within-roll heterogeneity; therefore, subsequent sampling was reduced to the first 18 inches of the roll using the same sampling scheme.

Trace element concentration data from Al sources were analyzed statistically, assessing points of variability in both the analytical measurement and within/between Al sources. Statistical analysis methods are used to determine which specific analytes or suite of analytes, if any, offer the greatest discrimination between sources from different manufacturers or products/lots of the same manufacturer. Information learned from analysis of this sample collection will assist in providing further characterization of Al powder sources used in IEDs and may provide valuable lead information for investigations and intelligence.

Trace Elements, Aluminum, ICP/MS

B95 Loading Artificial Fingerprints onto Brass Shell Casings for Improved Method Development and Proficiency Testing

Curt Hewitt, Signature Science, Austin, TX; Danielle LeSassier, Signature Science, Austin, TX; Benjamin Ludolph, Signature Science, Austin, TX; Kathleen Schulte, Signature Science, Austin, TX; Myles Gardner, Signature Science, Austin, TX*

Learning Overview: After attending this presentation, attendees will have a better understanding of challenges of DNA analysis using brass shell casing samples and emerging methods to improve and standardize DNA analysis from this challenging matrix.

Impact Statement: This presentation will impact the forensic science community by presenting novel approaches to generate standardized brass shell casing samples for DNA collection method development or for potential use in proficiency testing shell casing extraction methods.

No two human touch samples are the same. This variability complicates research focused on DNA collection and extraction methods. To this end, artificial fingerprints containing precise amounts of DNA and sebaceous material have been utilized to prepare highly standardized samples for method development purposes.¹ However, these approaches are not extensible to one of the most challenging forensic matrices: brass shell casings. While heat and pressure play a role in DNA degradation on shell casings, chemical damage by reactive oxygen species (ROS) containing copper molecules has perhaps a greater effect on stability. This is illustrated by high rates of DNA degradation observed from unfired brass shell casings and on other copper surfaces that exhibit similar properties. These limitations lead to exaggerated DNA degradation in artificial fingerprint samples when compared to human donor samples, likely due to the contrived environment caused by the addition of naked genomic DNA to the metal surface in an aqueous solution.

To assess whether the formulation of artificial fingerprints could be modified and optimized for use on brass shell casing samples, various additives and workflow alterations were evaluated. Creating physical separation between the DNA and shell casing surface by first applying a layer of synthetic sebaceous material was not successful. Depositing a hydrophobic layer onto the shell casing did reduce DNA degradation but created an environment that was overly contrived.

Next, various additives, such as chelators, were evaluated to determine whether they could protect the DNA during the artificial fingerprint drying process. EDTA increased degradation as observed by green discoloration on the shell casing surface over time. Other protein additives, such as BSA or a tripeptide mixture previously reported to aid in DNA recovery from shell casings, also failed to prevent excessive DNA degradation.²

Finally, rapid desiccation and storage methods were assessed with the aim of limiting the amount of time that solubilized ROS molecules could come into contact with hDNA. By placing shell casings containing artificial fingerprints directly into a SpeedVac following preparation, DNA stability increased 50-90% over a 48-hour time period. Degradation Index (DI) values using a commercial DNA quantification kit also decreased to < 5, as opposed to DI values > 10 for non-dried samples. Storage under desiccation further extended DNA stability, suggesting that moisture from the air can act to rehydrate a sample over time.

Taken together, our findings establish a method for the deposition of artificial fingerprints on brass shell casings that mimic human deposits. Critically, by rapidly drying the artificial fingerprint samples, it is possible to avoid excessive degradation caused by prolonged exposure of naked genomic DNA in an aqueous environment to the copper and other reactive molecules on the shell casing surface. This data may also inform shell casing forensic analysis, suggesting that samples should be stored under desiccating conditions to reduce exposure to moisture and damage caused by ROS.

Brass Shell Casings, DNA Analysis, Artificial Fingerprints

B96 Standards Development Activities Related to the Examination of Friction Ridge Detail

Heidi Eldridge, PhD, RTI International, Research Triangle Park, NC*

Learning Overview: After attending this presentation, attendees will have a better understanding of the status of discipline specific standards related to the examination of friction ridge detail from the hands and feet.

Impact Statement: The presentation will impact the forensic science community by creating greater awareness of standards development activities pertinent to the examination of friction ridge detail.

The Organization of Scientific Area Committees (OSAC) for Forensic Science was created to strengthen the nation's use of forensic science by promoting the use of discipline-specific forensic science standards. To this end, the OSAC drafts standards that are forwarded to standards developing organizations (SDOs) that further develop and publish them. The OSAC also reviews standards and recognizes them on the OSAC Registry, which serves as a central repository of high quality, consensus-based, technically sound standards.

During this presentation, updates related to friction ridge standards development activities will be presented. These include i) recent standards that have been added to the OSAC Registry; ii) OSAC proposed standards that are currently published on the OSAC website in draft form; iii) published standards from the Academy Standards Board (ASB) that have yet to go through the Registry approval process; iv) documents currently in development at the OSAC or by the ASB; and v) priorities for new documents or work products. This presentation will also highlight how the process of moving documents back and forth between the OSAC and ASB works for the friction ridge discipline, challenges and successes that process has encountered, and what the near future looks like for the promulgation of friction ridge standards and guidelines.

Friction Ridge, Standards, OSAC

B97 Understanding and Generating Close Non-Matches in Latent Prints for Training, Testing, and Research

Heidi Eldridge, PhD, RTI International, Research Triangle Park, NC; Christophe Champod, PhD, University of Lausanne, Lausanne, Vaud, Switzerland*

Learning Overview: After attending this presentation, attendees will be aware of the creation of an International Close Non-Match Library (ICNML) for latent prints and the results of testing that was done to validate expert consensus-based criteria for predicting the marks that are more likely to produce close non-matches.

Impact Statement: This presentation will impact the forensic science community by informing them of a new resource that can be used to create known ground truth exercises for training, testing, and research that will include challenging close non-match pairings. It will also present the results of research to validate criteria used to predict those marks that are likely to produce close non-matches, which will aid latent print examiners in training to avoid false identifications due to close non-matches.

Close non-matches (CNMs) (marks that look similar but originated from different sources) present a challenge for examiners because they are the most likely to lead to false-positive errors. As the size of Automated Fingerprint Identification Systems (AFIS) increases, the chance of encountering a CNM in casework also increases. Yet there is little training available in avoiding these errors because there are few known cases available to study.

The authors have leveraged an international team of collaborators to create the first known International Close Non-Match Library (ICNML), which is populated with known ground truth same source, different sources, and CNM pairings. This database will be made available free of charge to trusted law enforcement partners for testing, training, and research purposes. Access to such a database will allow for challenging exercises to be built that will help train examiners to avoid making false identification errors due to CNMs.

The CNMs collected in this study were found by searching clusters of minutiae through multiple AFIS according to selection criteria developed by an expert panel of latent print examiners with background and expertise in CNMs. Once the database was populated with CNM pairs, research was conducted to validate these criteria by testing whether different sources pairings located using the criteria resulted in higher false positive error rates than different sources pairings that were found through AFIS searches on random configurations of minutiae (thus demonstrating that more examiners were misled into false identifications by the pairings found through targeted searches according to CNM criteria). Results of this research will be presented along with a presentation of the developed criteria and whether they should be incorporated into training on CNMs. Finally, attendees will be informed of how to access the ICNML to download comparison packets for use in their own agencies.

Latent Prints, Close Non-Match, AFIS

B98 How Do Latent Print Examiners Perceive Blind Proficiency Testing? A Survey of Practicing Examiners

Brett Gardner, PhD, University of Virginia, Charlottesville, VA; Sharon Kelley, PhD, University of Virginia, Charlottesville, VA; Maddisen Neuman, MA, Houston Forensic Science Center/CSAFE, Houston, TX*

Learning Overview: This program will educate attendees about preliminary findings from a survey administered to practicing latent print examiners. This presentation will describe beliefs regarding blind proficiency testing commonly held by examiners, explore how beliefs differ between examiners who do and do not work for a laboratory with such procedures, and detail the importance of understanding examiner perceptions when attempting to implement blind proficiency testing.

Impact Statement: This presentation will describe examiner perceptions of blind proficiency testing and identify differences among examiners who currently participate in such testing. Audience members will be encouraged to reflect upon their own perceptions of blind proficiency testing and discuss how concerns raised by examiners can inform attempts to implement blind testing procedures in laboratories.

Introduction: In the wake of criticism regarding traditional proficiency testing, there has been an increased focus on implementing blind proficiency testing (BPT) in crime laboratories.¹⁻⁴ Indeed, landmark reports have strongly recommended the pursuit of BPT in crime laboratories.^{5,6} To date, the implementation of BPT in latent print units has remained limited.⁷ Scholars have reviewed obstacles for implementation, and one identified challenge has been the “cultural history in the field,” i.e., examiner preconceptions about proficiency testing.⁸

The current study sought to explore perceptions of BPT among practicing latent print examiners and determine whether such beliefs varied between examiners who work for laboratories with and without BPT.

Method: Researchers administered an online survey to practicing latent print examiners about their typical work practices and perceptions of BPT. Specifically, examiners indicated their opinion of the value of BPT beyond non-blind proficiency testing in accurately assessing examiner proficiency, on a scale of 0 = *Completely Unnecessary* to 10 = *Absolutely Necessary*. They also indicated their agreement with statements that BPT: (1) is a valuable use of time/resources, (2) increases examiner diligence, (3) improves testimony experiences, and (4) reveals laboratory areas most vulnerable to errors. Finally, examiners indicated their agreement with statements suggesting that they are/would be glad to work in a laboratory with BPT, and that examiners in their laboratory feel positively about BPT. The final sample included 338 latent print examiners. Although most examiners practiced within the United States (88.5%), participating examiners practiced in at least 11 other countries.

Results: Overall, opinions regarding the value of BPT to accurately assess examiner proficiency varied widely. On a scale from 0 to 10, some examiners described BPT as “completely unnecessary” and others described BPT as “absolutely necessary,” with most examiners considering such testing to be somewhat necessary ($M = 6.3$).

The presentation will provide detailed results describing examiner beliefs. In brief, examiners “somewhat disagreed” with the notion that BPT would increase examiner diligence but endorsed ambivalent beliefs about other aspects of BPT. On average, examiners slightly disagreed with the notion that BPT would improve their testimony experience, and that examiners feel positively about BPT. Examiners slightly agreed that BPT is a valuable use of time/resources and that they are/would be happy to work in a laboratory with such procedures.

Approximately 14.8% of examiners indicated that their laboratory implements BPT in latent print comparison. Examiners who work within a laboratory with BPT endorsed more positive beliefs about all aspects of blind testing. As a primary example, examiners who work in a laboratory with BPT view such testing as significantly more valuable in accurately assessing examiner performance than other examiners, $t(269) = 5.93, p < .001, d = 1.04$.

Results will also describe the benefits and downsides of BPT. In brief, examiners often indicated that BPT would reduce bias in testing procedures, provide more representative and accurate assessment, and enhance court testimony. On the other hand, many examiners indicated that BPT is logistically challenging and consumes limited time and resources. Results will present differences in identified benefits and downsides among examiners who do and do not work in a laboratory with BPT.

B99 What Types of Information Can and Do Latent Print Examiners Review? A Survey of Practicing Examiners

Brett Gardner, PhD, University of Virginia, Charlottesville, VA; Sharon Kelley, PhD, University of Virginia, Charlottesville, VA; Maddisen Neuman, MA, Houston Forensic Science Center/CSAFE, Houston, TX*

Learning Overview: This program will educate attendees about findings from a survey administered to practicing latent print examiners. This presentation will identify what types of information examiners can access during routine work, and what types of information examiners typically choose to review. Results will describe how patterns in information access and review vary by unit size and examiner roles within the laboratory.

Impact Statement: This presentation will describe common examiner work practices in routine latent print comparisons regarding what information is typically accessed and reviewed. Audience members will be encouraged to reflect upon their own work practices and contemplate what types of information should and should not be reviewed while completing latent print comparisons.

Introduction: Understanding typical work practice is important to understanding latent print comparison and ultimately improving the reliability of the discipline. ACE-V procedures provide general structure, but research suggests that adherence to ACE-V standards is unknown and examiner decisions continue to vary within every phase of work procedures.¹⁻³

Reducing exposure to task-irrelevant information is one way to reduce bias and improve inter-examiner reliability in latent print comparison.^{4,5} But research shows that examiners disagree regarding what information is task-relevant.⁶ Further, some examiners have indicated that implementing large-scale procedures (such as linear sequential unmasking) is unfeasible in small laboratories due to personnel and resource restrictions.⁷ For example, examiners in small laboratories sometimes must fulfill administrative roles in addition to their analytical duties. Expanding upon the limited task-relevance literature, the current study surveyed practicing latent print examiners about their routine work practices. This study specifically sought to review what types of information examiners typically review when conducting their analyses and explore whether access and inclination to review different information vary according to examiner role (i.e., supervisory/managerial examiner vs. nonsupervisory examiner) and unit size.

Method: Researchers administered an online survey to practicing latent print examiners. The survey requested information regarding examiners' current position, laboratory details, and typical work practices. Specifically, examiners indicated which types of information (of 14 listed information types; e.g., suspect age, victim name) they had access to in their daily work, and which types of information they routinely reviewed. The final sample included 284 latent print examiners that provided complete responses. Of these, most examiners practiced within the United States (91.5%), although participating examiners practiced in at least 10 other countries.

Results: The final presentation will provide detailed demographic information about surveyed examiners and their laboratories. Although results are only briefly summarized here, the presentation will present comprehensive information and tables about all analyses. In short, results revealed significant variability in the types of information to which examiners have access and review. Most examiners (i.e., ~75% or higher) have access to information regarding evidence description, method of evidence collection, offense type, suspect name, and victim name. However, only evidence description and method of evidence collection are routinely reviewed by most (i.e., >50%) examiners. In fact, approximately half of examiners (51.4%) indicated that they did not review offense type information despite having access to such information.

Differential patterns in accessing and reviewing information types also emerged according to the size of an examiner's latent print unit and their role within the laboratory. These patterns will be detailed and discussed. In brief, examiners from small latent print units (i.e., ≤3 examiners) were more likely to have access to every type of information listed, and they more often indicated that they routinely reviewed 11 of 14 information types compared to examiners from large units (i.e., ≥10 examiners). However, examiners from smaller units were also more likely to indicate that they actively did not review 11 of 14 accessible types of information compared to examiners from larger units. Thus, results indicate that examiners in larger units do not review information as often as those from smaller units because they do not have access; examiners from smaller units must actively decide to not review available information (and often do). Examiners in supervisory/managerial roles differed from other examiners in that they were less likely to review all information types compared to other examiners. Implications for practice and laboratory operating procedures will be discussed.

Latent Print Comparison, Task Relevance, Contextual Effects

B100 Does Image Editing Improve the Quality of Latent Prints? An Analysis of Image-Enhancement Techniques in One Crime Laboratory

Brett Gardner, PhD, University of Virginia, Charlottesville, VA; Maddisen Neuman, MA*, Houston Forensic Science Center/CSAFE, Houston, TX; Sharon Kelley, PhD, University of Virginia, Charlottesville, VA

Learning Overview: This program will educate attendees about findings from a study examining the prevalence of image-editing during routine casework in the Latent Prints section at the Houston Forensic Science Center. Additionally, this presentation will detail the impact of image-editing techniques upon the quality and clarity of latent prints, and explore how this information can be used to improve and standardize laboratory procedures.

Impact Statement: This presentation will evaluate typical image-editing procedures within one latent print unit and examine the impact of such procedures on print quality and clarity. Audience members will be encouraged to reflect upon their practice and any guidance that their laboratory may provide on image-editing given the observed variability in routine practice.

Introduction: In the wake of calls for reform and additional empirical research in many forensic science disciplines, the literature describing latent print comparison has significantly increased in recent years.^{1,2} Indeed, scholars have examined basic cognitive processes involved in latent print comparisons (e.g., eye tracking studies and contextual bias studies), examiner reporting practices, and juror perceptions of resulting latent print testimony.⁴⁻⁷ However, most of the extant latent print research relies on highly controlled experimental designs that are not always representative of actual casework. Field studies, or studies assessing examiner behavior during the course of actual casework, are necessary to increase understanding of basic processes associated with latent print comparison.

One recent field study revealed that print quality (as measured by objective quality metrics) is associated with sufficiency determinations, examiner conclusions, and examiner accuracy.⁸ “Good” quality latent prints were more than twice as likely to result in correct conclusions as were “Ugly” quality prints.

The current study addressed an important, but under-studied aspect of the latent print comparison process: the practice of digitally editing latent print images. Anecdotally, examiners often alter the images of latent prints, but image-editing behavior is inconsistent among examiners. There are no standards mandating or restricting the editing of latent print images. This study therefore sought to: (1) provide information on the prevalence of latent print image editing within one laboratory (i.e., Houston Forensic Science Center; HFSC) and (2) examine the potential effect of image editing on objective print quality and clarity, as well as analyze potential examiner differences in editing effectiveness.

Method: This study reviewed digital images of 378 latent prints analyzed by examiners as part of 144 blind cases. Researchers obtained images of latent prints that had been edited and uploaded into the case management system and retrieved original copies of the edited images to obtain unedited images of the same prints. Both the original and edited images of each print were then scored using the FBI’s Latent Quality Metrics (LQMetrics) software to obtain objective measures of print clarity and quality.⁹

Results: The vast majority of collected latent print images (98.9%) had been edited in some fashion as part of routine casework. Excluding cropping and rotation edits, 91.0% of images had been enhanced in some manner. A review of the editing histories suggested that common editing techniques included: Tonal Reversal, Brightness/Contrast Adjustment, Color Alteration, and Shadow and Highlight Adjustment.

A paired-sample *t* test revealed that, on average, edited latent print images ($M = 53.4$) were of slightly higher quality than raw latent print images ($M = 50.8$), $t(371) = 4.77$, $p < .001$, $d = .13$. Although edited images were only slightly higher quality than raw images, another paired-sample *t* test revealed that, on average, edited latent print images ($M = 34.3$) were of meaningfully higher clarity than raw latent print images ($M = 27.6$), $t(373) = 19.96$, $p < .001$, $d = .55$.

Additional results indicated that examiners did not significantly vary in their ability to increase the quality of print images but did vary significantly in their ability to increase the clarity of edited print images. The presentation will provide detailed analyses and tables describing examiner differences. Ultimately, findings identify a source of variability in examiner behavior and emphasize a need for laboratory guidance regarding image-editing procedures.

Latent Print Comparison, Image Editing, Quality Metrics

B101 Validation of a Systematic Method for Duct Tape Physical Fits Through Inter-Laboratory Studies

Meghan Prusinowski, West Virginia University Department of Forensic and Investigative Science, Morgantown, WV; Evie Nguyen, North Carolina State Crime Laboratory, Raleigh, NC; Tatiana Trejos, West Virginia University Department of Forensic and Investigative Science, Morgantown, WV*

Learning Overview: After attending this presentation, attendees will learn about the results of two inter-laboratory studies designed to validate a developed systematic method for reporting the quality of a physical fit of duct tape edges.

Impact Statement: This presentation will impact the forensic science community by demonstrating the value of developing systematic methods for conducting physical fits in trace evidence. This presentation will also demonstrate the utility of the developed method for duct tape and highlight how the documentation of critical features and a quantitative similarity score can offer additional support to inform the examiners' expert opinion.

Physical fit examinations involve analyzing separated items to determine if the compared edges re-align with distinctive features. In trace evidence, physical fits are considered the highest degree of association between two items of evidence. Currently, there is an effort by the OSAC Trace Subcommittee to develop consensus-based criteria and methods to provide a more standard approach to physical fit examinations. Previously, our group developed a systematic method for physical fits of duct tapes, utilizing an edge similarity score as a quantitative metric of the quality of a fit to support the examiner's opinion.¹ In this study, the developed method was evaluated by forensic practitioners under two interlaboratory studies. In both studies, a set of seven duct tape pairs were provided to each participant. Before distribution to participants, the samples were examined by an expert panel to determine a baseline consensus similarity score. The tests were designed as a Round Robin, including fracture edges of true fits and true non-fits of different difficulty levels to resemble casework items. Participants were asked to provide their opinion on a potential fit between each pair of tape edges, as well as report the respective edge similarity score. The feedback received from the first study was applied to refine the instructions, training, and reporting tools. As a result, the second interlaboratory study added more focus to the documentation of the type and location of critical features each examiner used to make their decision and added an option of reporting inconclusive on each comparison sub-unit. The reporting template was simplified with autofill cells, automatic calculations of the ESS, and a code that automatically colored a fit, non-fit or inconclusive cell with green, red, or yellow, respectively, for ease of visualization of the aligning patterns. Features such as scrim pattern weave, aligning warp and weft fibers, severed dimples on the backing, and distortion of the backing and adhesive were documented at each pair's macroscopic and microscopic levels. Also, participants were required to participate in an instructional training session before taking the test. The video was also made available for review at any time. The participants generally reported the overall determination of fit or non-fit for each pair accurately and were able to document which features contributed to that decision at each comparison step. A high level of agreement between participants and the consensus ESS values was observed, demonstrating the utility of the comparison approach. The performance rates showed no false positives and low false negatives (<5%), with scores above 80 providing strong support for a fit and scores below 30 providing strong support for non-fits. Overall, the two interlaboratory studies demonstrated that the proposed comparison method provides examiners with support for their decisions with consistent documentation of observed features and a quantitative score to help describe the quality of the fit.

Moreover, the approach can be leveraged to provide different measures of the evidentiary value of fracture matches in duct tape evidence, as demonstrated in a previous population study of over 3000 duct tape comparisons using score likelihood ratios.¹ One of the main benefits of the ESS method is that it is systematic, facilitating standardization of comparison criteria and data-driven conclusions. An added value of this approach is its ability to transparently demonstrate the thought process in peer-review and as a training tool. And finally, because qualitative and quantitative descriptors are documented, it helps not only in the standardization of protocols but also in the demonstration of scientific validity that can serve as a foundation for supporting the value of physical fits and a better understanding of the factors that can influence accuracy.

Physical Fits, Interlaboratory Studies, Systematic Comparison

B102 Student Perceptions of the Forensic Science Major at Middle Tennessee State University

Cole Buffalini, BS, Middle Tennessee State University, Murfreesboro, TN; Frank Bailey, PhD, Middle Tennessee State University, Murfreesboro, TN; Karen Reed, PhD, Middle Tennessee State University, Murfreesboro, TN*

Learning Overview: After attending this poster presentation, viewers will have a greater understanding of currently enrolled Middle Tennessee State University Forensic Science Program students' perceptions of program performance and curriculum collected from both quantitative and qualitative survey questions.

Impact Statement: This presentation will impact the forensic science community by sharing the responses of currently enrolled students in the MTSU forensic science program, granting faculty members insight on the drawbacks and benefits of current program mechanisms and how to influence them for the better.

This work was undertaken to better understand what the currently enrolled students in Middle Tennessee State University's (MTSU's) Forensic Science Program desire in their curriculum and their opinions on how to strengthen the program. In the Spring 2021 semester, a total of 46 students out of 180 students currently registered in the program (-25.5% response rate) took a survey created by the authors, designed to address these questions. The survey was created through a survey instrument named Qualtrics. Survey questions debriefed participants beginning with demographical questions, including such questions as enrollment status, age, employment status, gender, and current class qualification. Furthermore, the survey also collected qualitative data with opportunity for survey participants to elaborate. After Qualtrics reported the survey data received from the participants, the authors interpreted the results within Excel documents.

For quantitative data, the survey participants responded to questions among topics such as preference of field work versus lab work in forensics, perception of level of support from faculty advisors as well as from the advising department for the program, and their preferences on mentoring for currently enrolled students. Moreover, they were asked their likelihood to participate in extracurricular activities, whether MTSU was the participants first choice in school, student comfort level in interactions with professors, among other questions. Qualitative survey questions addressed items such as student interest in potential new forensic-based upper-division electives and perceptions of whether the program met their expectations with the opportunity to elaborate.

Overall, the majority of students who took the survey found the program challenging and felt that it properly prepared them for their post-graduation careers. However, the results indicated that the program has not met all the students' expectations, nor have students gained all of the experiences they anticipated. Perceptions of currently enrolled students are provided in this report from an even array of freshman through seniors. A theme discovered from responses regarding expectations of the program was the lack of forensic significance among some coursework in the program, which was unexpected by participants. An expectation met was the balance provided between science and criminal justice classes within the program. Detailed feedback was received about the forensic-based upper-division electives the students desired for the program, with twenty-two potential options provided in the survey. "Death Investigation", "Bloodstain Pattern Analysis", and "Forensic Fingerprinting" were the three most common interests among survey participants with the initial ranking the highest with twenty-seven interested participants. Understanding the perceptions of currently enrolled students may shed new light on the program for the forensic science faculty at MTSU which will allow them to heighten the academic experiences of the students participating in the program. Moreover, the students' thoughts on the benefits of the program give just as much insight as the drawbacks, and all should be considered by the MTSU forensic science faculty.

Forensic Science, Education, Perceptions

B103 Optimization Parameters of Fragmentary Voltage and Collision Energy for Identification and Separation of RDX (1,3,5-Trinitro-1,3,5-Triazinane) From Other Explosives with Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS)

Blerim Olluri, Kosovo Agency on Forensic, Pristina, Kosovo; Milazim Tahirukaj, Kosovo Agency on Forensic, Pristina, Kosovo; Andriana Surleva, University of Chemical Technology and Metallurgy, Bulgaria, Sofia, Bulgaria; Xhemajl Ademaj, University, Pristina, Kosovo; Herolind Krasniq, Msc, Kosovo Agency on Forensic, Pristina, Kosovo*

Learning Overview: After participating in this presentation, participants will present with the Kosovo Agency for Forensic achievements the development and optimization of the parameters for the creation of a new method for identification and separation of organic explosives.

Impact Statement: This presentation will affect the scientific community of forensics by describing the current capabilities of the Kosovo legal science lab in the development of new methods for the identification and separation of organic explosives by chromatographic methods and the impact on the identification of source (s) explosives and interconnections to identify terrorists.

Explosives are classified in several ways, based on different criteria. Thus, the explosives are divided into high and low explosives based on the type and speed of the action they are doing. Explosives are also classified according to their chemical structure. The most important group is that of organic compounds containing the nitro (NO₂) group. They are further subdivided based on the site where NO₂ is attached to the atomic structure. Nitrogen compounds contain C-NO₂ groups, a group of C-O-NO₂ nitrate ethers and C-N-NO₂ nitrite nitriles.

There are different methods for identifying and separating organic explosives, especially RDX (1,3,5-Trinitro-1,3,5-triazinane), but recently, double-mass spectrometric detector chromatography has begun to accommodate numerous scientific research by forensic scientists to find appropriate parameters for the identification and separation of organic explosives in low concentrations in pg (pictograms) or even in fg (fentogram).

Therefore, considering the needs reasonable we have begun to create optimal parameters for CE (collision energy) and FV (fragmentary voltage) for identifying and dividing RDX from other explosives by using the Liquid chromatography instrument with double-mass spectrometric detector (LC-MS/MS) with the Atmospheric pressure chemical ionization (APCI) model, Zorbox SB - C18 column 600 bar 3 x 50 mm 3.5 µm and mobile phase: Methanol / Isopropanol / Water (1: 3: 6) as well as 0.1% chloroform.

In our studies we have found optimal "CE" and "FV" values for the identification and separation of RDX from other explosives, the change of fractional energy values greatly influences the fragmentation of the molecule we are studying, the fragmentation fractions molecule at all levels and this facilitates the identification of the molecule of unknown explosive and all fractions comply with our preliminary knowledge of the RDX structure and knowledge of its potential fragmentation, in addition to the excellent division achieved with this technique and the limit of detection up to fg.

At the end of this study, optimized parameters for identification and separation of organic explosives with LC-MS/MS we have the following conclusions:

- In our study the samples analyzed were organic explosives: HMTD (3,4,8,9,12,13-Hexaoxa-1,6-diazabicyclo[4.4.4]tetradecane), HMX (1,3,5,7-Tetranitro-1,3,5,7-tetrazocane), RDX, TATB (1,3,5-triamino-2,4,6-trinitrobenzene), EGDN (1,2-dinitroxyethane), 1,3,5-TNB (1,3,5-Trinitrobenzene), 1,3-DNB (1,3-Dinitrobenzene), TETRYL (N-Methyl-N-(2,4,6-trinitrophenyl)nitramide), 4A-DNT (4-amino-2,6-dinitrotoluene), NB (Nitrobenzene), NG (Nitroglycerin), 2A-DNT (2-amino-2,6-dinitrotoluene), TNT (2,4,6-Trinitrotoluene), 2,6-DNT (2,6-Dinitrotoluene), 2,4-DNT (2,4-Dinitrotoluene), 1,3,5-Trinitro-2-[2-(2,4,6-trinitrophenyl)ethenyl]benzene (HNS), 2-Nitrotolueni (2-NT), 4-Nitrotolueni (4-NT), PETN (2,2-Bis[(nitrooxy)methyl]propane-1,3-diyl dinitrate), 3-NT (3-Nitrotolueni), TATP (3,3-Dimethyl-1,2-dioxacyclopropane) and CARBAMITE, creation of methods for identification and separation of explosives doing the optimization of parameters on LC and MS/MS.
- Parameter optimization for both methods done as follow: flow of mobile phase 0.5 ml/minute, temperature of colon 35°C and the length of colon 3x50 mm, diameter 3.5 µm, ionization source multimode (MMI), ionization model (APCI), volume of sample injected 20 µl. Mobile phase was suitable for both above methods.

RDX, Collision Energy, Fragmentary Voltage

B104 Automated Particle Micromorphometry and Statistical Scoring for Improved Characterization of Aluminum (Al) Powders in Improvised Explosive Devices (IEDs)

Kayla Moquin, BS, ORISE/FBI Laboratory, Quantico, VA; Cami Fuglsby, MS, South Dakota State University, Brookings, SD; JenaMarie Baldaino, MS, FBI Laboratory, Quantico, VA; Danica Ommen, PhD*, Iowa State University, Ames, IA; Christopher Saunders, PhD, South Dakota State University, Brookings, SD; Jack Hietpas, PhD, Microtrace, Elgin, IL; JoAnn Buscaglia, PhD, FBI Laboratory, Quantico, VA*

Learning Overview: Attendees will better understand the various statistical methods currently being applied for the interpretation and discrimination of aluminum particles, commonly associated with improvised explosive devices (IEDs). Further, attendees will have a deeper understanding of how automated imaging with measurement of morphological features may aid in forensic science investigations.

Impact Statement: This presentation will impact the forensic science community by providing an objective, statistically sound method for the identification of source of aluminum powder evidence in IEDs, providing crucial information for forensic science investigations.

Improvised explosive devices (IEDs) are often composed of commercial or readily available materials. One such material is aluminum (Al) powder; a common metallic fuel, Al powder has many legitimate uses and applications, making it easily accessible from a variety of sources. Although many of these sources are marketed in powder form, other types of sources can be easily and inexpensively manipulated and turned into powder via simple methods found online. This increased circulation of amateur methodologies, as well as their ease of availability, has put dangerous and destructive tools in the hands of amateur bomb makers. For this reason, it has become increasingly important to further characterize Al powder sources beyond identification, in order to differentiate between sources of Al powder for additional investigative and intelligence value.

Building upon the work that has been previously presented at AAFS, it has become increasingly evident that additional discrimination of Al powder sources is possible by modeling the distribution of particle size and shape parameters within a subsample. The analysis of more Al powder samples of different types and from a variety of manufacturers has generated a more robust data set for testing the scoring algorithms. Further, additional statistical approaches have been developed and tested on these high-dimensional, large data sets, which are not only suitable in the discrimination of Al powder sources, but which may be applicable to the interpretation of other high-dimensional forensic data, such as those encountered with trace evidence analyses.^{1,2}

Using a variety of statistical approaches (various machine learning methods applied to summary statistics of subsamples and score-based methods for measuring the dissimilarity between distributions of particles), empirical tests have thus far shown that the applied methods have the ability to characterize the type of powder based upon the 17 measured size and shape parameters. Further, results have shown that, in most instances of incorrect classification of a subsample to a specific source, the misclassification is attributed to another source of the same general type (e.g., ball-milled foil subsample from source A is misattributed to ball-milled foil subsample from source C). The performance of the pairwise scores are evaluated based on the performance of the corresponding 1-nearest neighbor classifiers; various trials utilizing different portions of the collected data were implemented to determine which factors affected results and how those findings may allow for improvement of the analytical and interpretative methods. The use of automated microscopical techniques, in combination with image processing and various statistical methods, will allow for more efficient characterization and source discrimination of Al powders in IEDs, thereby providing valuable investigative lead and intelligence information.

Aluminum Powder, Improvised Explosive Devices, Micromorphometric Analysis

B105 The Impact of Ultraviolet (UV) Radiation and Plane Polarized Light (PPL) Microspectrophotometry (MSP) in the Characterization and Differentiation of Deeply Colored Automotive Fibers

Andra Lewis, MSFS, Sam Houston State University, Huntsville, TX; Patrick Buzzini, PhD, Sam Houston State University, Huntsville, TX*

Learning Overview: After attending this presentation, attendees will gain knowledge and understanding about the strengths of light microscopy in combination with different capabilities of microspectrophotometry (MSP) including ultraviolet (UV) and plane polarized light (PPL) in the examination of deeply colored automotive carpet fibers which appear macroscopically similar in color.

Impact Statement: This research will impact the forensic science community by providing an understanding of the combined strengths of light microscopy and variants of MSP in the ability to differentiate deeply colored textile fibers. Studies have shown the inclusion of ultraviolet (UV) radiation as well as plane polarized light (PPL) provides greater discriminatory capabilities beyond the visible range.

The examination of textile fibers can be time consuming and tedious. However, they continue to prove their effectiveness in addressing questions about source attributions and the development of investigative leads in serious criminal cases. Fibers from carpeting and rugs found in homes and vehicles are commonly recovered as evidence because they are easily transferred between the scene(s) and both the victim and suspect. Although most carpet fibers found in homes are made of either nylon, polypropylene, or polyester, with differing cross-sectional shapes, automotive carpet fibers found in the trunk and passenger compartments of vehicles are made from a variety of substances. Due to demands to lower CO₂ emissions by reducing vehicle weight, automotive carpet fibers are being made from lighter substances known as nonwovens. Nonwovens in combination with other woven or knitted textile materials provide a significant contribution in this area. Many automotive carpet fibers are made from recycled polyester derived from plastic bottles as well as automotive carpet samples which are blends of several types, including polyamides (nylon 6, nylon 6,6, etc.), polypropylene (PP), polyester (PET), and polyolefins which can make the spectral analysis of these fibers challenging. A typical fiber examination starts with light microscopy for identification purposes followed by visible MSP and/or TLC. It has been shown incorporating ultraviolet radiation can provide further discriminatory factors and more recent studies have shown the discriminating potential of dichroism (plane polarized light or PPL) in conjunction with visible MSP. Furthermore, dichroic ratio measurements have the advantage of being independent of uncertainties due to optical path length (sample thickness) and pigment or dye concentration differences. Considering the current trends in the forensic science community toward method standardization and standards development, this research aims to determine the most efficient methodology for the application of microspectrophotometry (MSP) to the forensic differentiation of textile fibers applied to challenging fiber samples. The purpose is to identify objective criteria to develop a protocol for the capture, processing, and interpretation of spectral patterns for fiber specimens encountered in casework. In this research, forty (40) dark colored and macroscopically similar automotive carpet fibers were analyzed using microscopical examinations including color assessment, cross-sectional shape, and fluorescence followed by few alternative applications to visible MSP. The microspectrophotometer used in this research was not only equipped with full polarizing capabilities (i.e., polarizing filter and a rotating stage), but the analyzer and polarizer transmitted UV radiation down to 240nm, making pairing of the ultraviolet with plane polarized light a reality. The results of this research showed ~70% of the samples provided further discriminatory information through the combination of both ultraviolet radiation and plane polarized light to the characterization and differentiation of these fibers.

Trace Evidence, Fiber, Ultraviolet-Visible Microspectrophotometry

B106 Using Capillary Columns for Measurements of Relative Distribution Constants of Vaporized Hydrocarbons Between Headspace and Polydimethylsiloxane (PDMS) Solid-Phase Microextraction (SPME) Fibers for Quantitative Chemical Analysis of Ignitable Liquids

Joonyeong Kim PhD, Buffalo State College, Buffalo, NY*

Learning Overview: Attendees will expect to know a method of the estimation of true compositions of volatile compounds such as ignitable liquids in headspace via solid phase microextraction (HS-SPME) and capillary column gas chromatography (CCGC). The compositions of volatile compounds in headspace (HS) analyzed by a solid phase microextraction (SPME) sampling method usually differ from true compositions due to the difference in the distribution constants of these compounds between headspace and a polydimethylsiloxane (PDMS) SPME fiber are not equal. In this presentation, an analytical strategy to estimate relative distribution constants of vaporized hydrocarbons between air and PDMS using capillary column gas chromatography (CCGC) will be presented.

Impact Statement: This presentation will impact the forensic science community by proposing a way to estimate true compositions of vaporized hydrocarbons in headspace using relative distribution constants via capillary columns. The results produced in this work and future studies can be applied to the quantification of target volatile/semi-volatile compounds such as gasoline residues and other ignitable liquids present in headspace containing various types of forensic samples. This is important to identify the nature of ignitable liquids as well as their origins in forensic fire investigations.

For a quantitative chemical analysis of vaporized hydrocarbons in headspace via solid phase microextraction (SPME), distribution constants (K_D) of these hydrocarbons between a SPME fiber and air are required. Recently, the relative distribution constants of three vaporized hydrocarbons between air and polydimethylsiloxane (PDMS) were determined by packed column gas chromatography (PCGC) in order to calculate headspace hydrocarbon compositions. However, preparation of packed columns is a cumbersome process in order to prevent possible experimental errors. Especially, a solid substrate should be completely and uniformly covered with a proper thickness of PDMS layer. In this regard, commercially available capillary columns with evenly coated polymeric stationary phases are proposed as alternatives to packed columns despite the limited selection of stationary phase.¹⁻³

This study focused on the measurements and validity of relative distribution constants of vaporized hydrocarbons between air and polydimethylsiloxane (PDMS) using commercially available capillary columns. Capillary column gas chromatography (CCGC) measurements, using two columns containing a PDMS stationary phase with different film thicknesses (1 and 4 μm), were conducted to determine the relative distribution constants of *n*-heptane, toluene, *n*-octane, *p*-xylene, *n*-nonane, and 1,2,4-trimethylbenzene between air and PDMS at 90 and 120 °C. To validate the accuracy of the relative distribution constants via CCGC, the compositions of three headspace samples containing different amounts of hydrocarbons were calculated using the relative distribution constants via CCGC and extracted amounts via PDMS solid phase microextraction (SPME) at 90 and 120 °C.

To validate the relative distribution constants via CCGC, calculated headspace hydrocarbon compositions were compared to true headspace hydrocarbon compositions via the Wilcoxon signed-rank test (the significance level of 5%). A calculated *p*-value greater than 0.05 indicates there is no difference between the two compared data sets. All *p*-values calculated from the two data sets were greater than 0.05 and ranging from 0.5625 to 1. Therefore, calculated hydrocarbon compositions were close to experimental hydrocarbon compositions for all three samples at both 90 and 120 °C. In addition, calculated headspace hydrocarbon composition via two sets of relative distribution constants measured using two different capillary columns (1 and 4 μm film thickness) were comparable as indicated by the *p*-values.

Finally, relative errors of calculated hydrocarbon compositions in absolute forms from two methods, CCGC and PCGC, were compared via the Mann-Whitney-Wilcoxon test with the bootstrap samples where the bootstrap method was considered to avoid any statistical parametric assumptions. The averages for absolute relative errors (%) in calculated hydrocarbon compositions via CCGC with 1 μm PDMS film thickness, CCGC with 4 μm PDMS film thickness, and PCGC were 3.1, 3.2, and 4.7, respectively. The bootstrap *p*-values are 0.914 and 0.902 from testing CCGC (1 μm) and PCGC and testing CCGC (4 μm) and PCGC, respectively. These results strongly indicate that relative errors of calculated headspace compositions measured via capillary columns are comparable to those via PCGC in the previous work. The results suggest that CCGC can provide a convenient and reliable method for measuring the relative distribution constants for the quantification of headspace containing various hydrocarbons via a HS-SPME sampling method using PDMS fibers.

Distribution Constants, Solid Phase Microextraction, Quantitative Chemical Analysis

B107 Evaluation of a Thermodynamic Model to Predict the Weathering of Ignitable Liquids at Different Temperatures

Hannah L. McMillen, West Virginia University, Morgantown, WV; Glen P. Jackson, PhD, West Virginia University, Morgantown, WV*

Learning Overview: After attending this presentation, attendees will understand how to apply fundamental principles of physical chemistry to mathematically model the weathering of ignitable liquids like gasoline.

Impact Statement: The thermodynamic model will help analysts to make more informed decisions about the temperatures and timeframes under which casework samples are likely to have been exposed. For example, the model can help tell the difference between liquids that have undergone slow evaporations at room temperature versus fast evaporations at elevated temperatures. The model can also be applied to predict a wide range of weathered chromatograms from a single chromatogram of an unweathered sample, which can facilitate the detection of ignitable liquid residues in casework samples without the need to collect an extensive GC-MS database of weathered samples.

Analyses involved the use of a local E85 gasoline that was weathered to a variety of different percentages. An aluminum block with a pre-weighed, clean aluminum weigh boat in the center was heated in an oven to the desired temperature, such as 30.0°C or 120.0°C. A volume of 1 mL of gasoline was transferred into the aluminum weigh boat, in the oven, and allowed to evaporate at a constant temperature for the desired duration(s). No air stream or vacuum was used to facilitate evaporation. A cold aluminum block was used to cool the aluminum weigh boat after being removed from the high temperature block. Weathering times ranged from 0.2 to 25 minutes.

The ignitable liquid residue (ILR) samples, diluted to a 1:200 dilution factor, were run on a Gas Chromatography-Mass Spectrometer (GC-MS). These results corroborated the current understanding of the weathering process at both low (30%) and high (95%) weathering percentages. The results were then compared to the thermodynamic model based on Raoult's and Dalton's laws.

Pearson Product Moment Correlations (PPMCs) determined the chromatographic similarity between the experimental data and the modeled data. For example, at 30.0°C, the best PPMC values between the modeled and measured chromatograms are on the order of 0.98 or better. However, the modeled chromatograms that provided the best (largest) PPMC values are not always the modeled chromatogram with the same percent weathering as the measured chromatogram: the average difference between the experimental and modeled extent of weathering using PPMC as the measure of fitness is 6.4% percent weathering (N=21 chromatograms predicted between 20-99% weathering). When using the PPMC values between experimental and modeled chromatograms, the error in predicting the extent of weathering of gasoline ranges from 0.37% to 11.2%, depending on the extent of weathering. The model works equally well at the elevated temperature of 30.0 °C.

The mean of absolute residuals between measured and modeled total ion chromatograms (TICs) were also calculated to determine the dissimilarity between the experimental data and the modeled data. The range of absolute differences between experimental and modeled weathering percentages is 1.06% to 18.06% at 30.0°C, and the mean error is 8.0%. In summary, the approach using PPMCs instead of mean absolute residuals provided more accurate predictions about the extent of weathering of the gasoline sample. Additional details in the presentation will include the accuracy of weathering predictions at elevated temperatures (120.0°C) and in the presence of porous substrates, which act to suppress the evaporation of volatile components in the gasoline and make the residues appear to be less weathered than would ordinarily be expected.

Ignitable Liquids, Weathering, GC/MS

B108 Quantitative Ballistic Cartridge Case Analysis using Micro-CT

Kirsty Alsop, MSc, Forensic Centre for Digital Scanning and 3D Printing, Coventry, West Midlands, United Kingdom; Danielle Norman, PhD, Forensic Centre for Digital Scanning and 3D Printing, Coventry, West Midlands, United Kingdom; Guillaume Remy, PhD, Forensic Centre for Digital Scanning and 3D Printing, Coventry, West Midlands, United Kingdom; Paul Wilson, PhD, Forensic Centre for Digital Scanning and 3D Printing, Coventry, West Midlands, United Kingdom; Mark Williams, Forensic Centre for Digital Scanning and 3D Printing, Coventry, West Midlands, United Kingdom*

Learning Overview: After attending this presentation, attendees will have a better understanding of the application of micro-CT to ballistic analysis of cartridge cases

Impact Statement: This presentation will impact the forensic science community by introducing a new methodology for forensic ballistic analysis

Forensic ballistic analysis requires the examination of fired ballistic components to try to establish information on the weapon that fired them. One feature on cartridge cases which is known to be representative of the weapon is the firing pin impression. This poster proposes micro-CT as an imaging technique for the 3-dimensional visualization of cartridge cases and quantification of firing pin impressions. The study consists of two parts: assessment of the applicability, reliability, and repeatability of micro-CT for cartridge case analysis; and comparison of cartridge cases fired from three weapons to establish the magnitude of variation within and between weapons.

A total of 72 cartridge cases fired by three distinct weapons were collected and micro-CT scanned to 5 µm resolution. One randomly selected cartridge was scanned ten times under the same conditions to ensure repeatability of the scanning conditions. Following this, part two of the study introduced two cylindrical measurements are proposed to assess how repeatable the method is, and three functional firing pin impression measurements are proposed to establish the variability within and between weapons.

Micro-CT was found to be an effective and highly repeatable method for 3-dimensional imaging and measurement of ballistic cartridge cases. Furthermore, high agreement for inter-rater reliability was found between five raters. Quantitative micro-CT analysis of the functional firing pin impression measurements showed a significant difference between the studied weapons using Welch's t-test ($p < 0.01$). Combination of the three measurements also showed a visible clustering separation between weapons suggesting a high applicability of the method should a large foundational database be pursued.

This study shows the advantage and reliability of utilizing micro-CT for firing pin impression analysis. Quantitative analysis of the firing pin impression allows distinction between the weapons studied. With expansion to further weapons, application of this methodology could complement current analysis techniques through classification models or statistical prediction.

Ballistics, Micro-CT, Quantification

B109 An Internal Validation Study of the TopMatch 3D Scanner for Cartridge Cases

Kayli Carrillo, BS*, Sam Houston State University, Huntsville, TX; Alexis Moser, BS, Harris County Institute of Forensic Sciences, Houston, TX; Jennifer Turner, MS, Harris County Institute of Forensic Sciences, Houston, TX

Learning Overview: After attending this presentation, attendees will be familiar with the TopMatch 3D Scanner's ability to obtain topographical details from cartridge cases.

Impact Statement: This presentation will impact the forensic science community with emphasis on firearms and toolmark examiners by demonstrating the application of virtual comparison microscopy through use of the TopMatch system in firearms identification laboratories.

The emergence of 3-dimensional (3D) surface topographies and computer algorithms for fired ammunition comparison has been termed Virtual Comparison Microscopy (VCM). VCM shows potential advantages over traditional microscopy when archiving and comparing evidence, training examiners and documenting comparisons and verifications.¹

Currently, the TopMatch™ system is the fastest and highest resolution 3D scanner for VCM applications. It is also the first and only 3D scanner and analysis system to be validated for VCM by the FBI.² One of the goals of high-resolution 3D acquisition technologies is to overcome limitations associated with traditional comparison microscopy, especially those related to lighting conditions. To address challenges with lighting and reflection, TopMatch™ system utilizes GelSight™, a gel of optically clear elastomer with a thin layer of elastic paint on one side. The thin layer of paint conforms to the shape of the surface and removes unwanted surface reflectance properties to observe the head of the cartridge case. Several regions of interest such as the breech face and aperture shear are used by novel feature-based scoring algorithms to yield match scores between 0-1.²

Internal validation was conducted before using a TopMatch™ system in casework. This 3D surface topography technology has already gone through several validations and has demonstrated to meet or exceeded the performance of equipment used in traditional light microscopy.¹⁻³ The internal validation at Harris County Institute of Forensic Sciences included three phases. In Phase I, eleven previously analyzed proficiency tests were scanned and completed by analysts. In Phase II, three test fires shot from a Hi-Point Model C-9 were collected from a series of ten known consecutively manufactured slides were analyzed. In Phase III, eight lab generated test fires from the laboratory reference gun collection were evaluated. The breech face impression and aperture shear marks were measured at approximately 1.8 micron/pixel lateral resolution and sub-micron depth resolution. The ability for the analysis software to be remotely installed on each examiner's computer allowed for ease of use. With past proficiency tests, all examiners answered correctly.

B110 The Assessment of Modern Glass from Portable Electronic Devices and Their Accessories by μ -XRF for Their Use in Forensic Investigations

Oriana Ovide, BS, West Virginia University, Morgantown, WV; Ruthmara Corzo, PhD, National Institute of Standards and Technology, Gaithersburg, MD; Tatiana Trejos, PhD, West Virginia University, Morgantown, WV*

Learning Overview: During this presentation, attendees will learn about the μ -XRF elemental profile of modern glass from portable electronic devices (PED) and their glass accessories that can become valuable evidence in crime scenes.

Impact Statement: Given the high use of PEDs in modern lifestyles, this type of glass is anticipated to be found more often in crime-related incidents. Therefore, this study aims to expand the limited knowledge about their elemental composition and sources of variation within and between items. The forensic science community can use this study as a basis for further research into the potential value of glass from PEDs in casework.

Glass is a common type of trace evidence often found at crime scenes that can provide important information about the type and origin of the broken glass. Glass items that are commonly involved in crimes are typically soda lime glass, which has been studied extensively and for which there are current consensus standards available. Over the past decade, the prevalence of portable electronic devices (PED) such as phones, electronic watches, and tablets has increased. Since PEDs are designed to be kept close to a person, there is the potential for the transfer of broken glass from PEDs to become relevant evidence.

The recent demand for PEDs has led to constant upgrades to their components, including the glass screens of most PEDs. Currently alkali aluminosilicate glass is common and is defined by high alkali (typically Na) that will be replaced by a larger alkali element (typically K) to increase the strength and scratch resistance of the glass. To provide additional protection to their devices, individuals may also apply a tempered glass screen protector or, more recently, a liquid glass screen protector to their device.

In this study, both glass surfaces (inner and outer) from 30 different original PED screens, 15 different tempered glass screen protectors, and 5 PED screens to which 3 brands of liquid glass had been applied were analyzed using μ -XRF following some modifications to the ASTM E2926 method (e.g., adapted to different elements of interest and comparison method due to the substantial difference to soda lime glass). A micro-XRF with two Silicon Drift Detectors (SDD) was used, taking 5 replicates per sample.

Examination of the 30 PEDs revealed high potassium, and the samples were classified into 5 groups based on their distinctive elemental profiles. Group one and two both had low zirconium and either had phosphorus or sulfur present in addition to aluminum, and iron. Group three and five had higher zirconium but group five also had titanium. Finally, group 4 had significantly higher Zn levels. Further examination of within-group samples through spectral overlay demonstrated good discrimination power (>99%), and for most samples, the top and bottom of the fragment could not be differentiated (76%). When the top and bottom of the fragment were deemed different, this was only by a slight difference in K, while the remaining relative elemental composition was indistinguishable. Additionally, spectral angle contrast (SAC) ratios were used as a more objective means to estimate the similarity between samples. Overall, SAC ratios between the top and bottom fragments of the same screen were low, ranging from 1 to 9. Conversely, ratios within groups were higher (ranging from 1 to 80) and ratios between different groups were much higher ranging from 10 to 460. The use of SAC ratios provides a proxy for the level of similarity between spectra rather than a binary decision.

The spectra from the 15 tempered glass screen protectors were differentiated into 4 groups based on their elemental composition. While group two represented samples most similar to soda lime glass, the remaining groups showed spectra similar to the PED glass. Additionally, spectra of just the liquid glass residues indicated that the major elements present within the sample were silicon, sodium, calcium, and potassium. However, the increase of the overall elemental profile for these elements in PED fragments with liquid glass was not significant.

This study provided support that PEDs and tempered glass screen protectors have the potential to be discriminated between different sources. This study provides a preliminary understanding of the elemental composition of these modern glasses and explores the discrimination capability of μ -XRF for the forensic analysis of PEDs.

PED Glass, Screen Protector Glass, μ -XRF

B111 A Microscopical Examination and Elemental Analysis of Automotive Lubricating Greases

Jared Esteveanes, BS, Sam Houston State University, Huntsville, TX; Rajesh Balaraman, PhD, Vironova, Cambridge, MA; Patrick Buzzini, PhD, Sam Houston State University, Huntsville, TX; Geraldine Monjardez, PhD, Sam Houston State University, Huntsville, TX*

Learning Overview: After attending this presentation, attendees will gain a greater appreciation for the expansion of potential evidential value to automotive greases.

Impact Statement: This presentation will impact the forensic science community with emphasis to the trace evidence community by expanding the consideration of new types of trace materials to automotive greases and show their potential contribution to forensic investigations.

Automotive greases may be recovered as stains on the ground at a road accident scene or on the garments of a suspect or victim allegedly involved in events under investigation. Numerous studies have been performed differentiating automotive motor oil for forensic applications, however little research was conducted to characterize or differentiate automotive greases. This study aims to determine the physical and chemical properties that allow a reliable identification and differentiation of automotive lubricating greases. It also aims to expand the consideration of potential trace materials that could help investigators or forensic laboratory personnel in the commission of crimes involving vehicles.

Thirty-five brand new commercially available grease samples were examined using light microscopy for potentially discriminating features. This initial microscopical examination showed the presence of microscopic particles that were part of the original formulation of the grease samples. These particles differed considerably in terms of shapes, sizes, and concentration between the different grease samples: Three particle types were identified and consequently classified as opaque, isotropic, and anisotropic.

Initially, the use of Fourier Transform Infrared (FTIR) spectroscopy yielded less than ideal data for these grease particles. Attempts were then made to characterize the observed particles using scanning electron microscopy coupled with energy dispersive x-ray spectroscopy (SEM/EDS), and this also did not yield informative results due to sample charging and oversaturation of the detector. Hence, an extraction procedure of these particles from the grease medium was necessary and an oil-solid separation method was developed based on the investigation of three solvents.

The solvents chosen were two petroleum solvents (hexane and pentane) and one green solvent (D-limonene). The ability of these solvents to dissolve the greases was studied by submerging chosen greases with an appropriate amount of each solvent for 15 minutes. These solutions were then gravity filtrated to separate out the particles, and air dried. Microscopy on the dried separation products revealed that the extraction achieved the removal of most of the base oil and left all three particle types intact. Based upon the results of the extraction, microscopy, and other green chemistry concerns, the solvent chosen for further extractions was D-limonene.

The visualization of these particles and the determination of their elemental composition was completed after extraction proved successful. Targets were selected for EDS analysis based upon SEM images using the backscatter detector and the particle size. It was discovered that the opaque particles analyzed are solid lubricant additives within the greases, containing various amounts of molybdenum and niobium. Greases within the sample set that do not contain opaque particles, are missing these heavy elements. These differences in composition display potentially discriminating properties for automotive greases.

This study demonstrates the efficiency of the extraction method developed and shows that automotive lubricating greases have high discriminating capabilities due to the variation of the elemental composition of the particles in the samples analyzed.

Forensic Science, Automotive Lubricating Greases, SEM/EDS

B112 Rapid Spectrochemical Mapping Techniques for Enhanced Detection and Visualization of Gunshot Residue Patterns

Courtney Vander Pyl, MS, West Virginia University, Morgantown, WV; Korina Menking-Hoggatt, PhD, West Virginia University, Morgantown, WV; Tatiana Trejos, PhD, West Virginia University, Morgantown, WV*

Learning Overview: The attendees will learn about the capabilities of LIBS and LA-ICPMS to offer rapid and reliable elemental information in the analysis of firearm-related evidence. Furthermore, they will learn the advantages of using laser-based methods for the visualization of GSR patterns of multiple crime scene substrates compared to the other methods currently in use.

Impact Statement: Utilizing rapid, laser-based methods for detection and interpretation of gunshot residues is anticipated to modernize current methods and aid fast decision making and more objective evidence assessment needed during the investigation and interpretation of firearm-related crimes.

Upon discharge of a firearm, microscopic particles consisting of inorganic species from the primer cap, known as inorganic gunshot residue (IGSR) are deposited on several surrounding surfaces. Likewise, some visible partially burn propellant flakes and other organic compounds (OGSR) are transferred. Receiving surfaces can include the shooter's hands and face, as well as target materials such as clothing, a wall, or a window. Conventional methods used in these investigations include Scanning Electron Microscopy-Energy Dispersive X-ray Spectrometry (SEM-EDS) for single particle analysis and colorimetric assays that react with organic and inorganic components of ammunition for distance determination. However, these techniques have some limitations. SEM-EDS is reliable, but it is time-consuming and costly. Colorimetric assays have severe drawbacks regarding limited selectivity and sensitivity, it is invasive, requires hazardous reagents and is highly subjective.

As a result, this study aimed to develop rapid chemical mapping methods for GSR pattern visualization using two laser-based methods: Laser-Induced Breakdown Spectroscopy (LIBS) and Laser Ablation-Inductively Couple Mass Spectrometry (LA-ICPMS). LIBS methods were developed and validated for shooting distance determination and bullet hole identification on complex substrates commonly found at firearm-related crimes. Residues were analyzed off 133 fabrics (white, dark colored, patterned, bloody), glass, drywall, and wooden samples. Spectrochemical data produced permanent 3D heat maps to visualize GSR patterns on surfaces. For shooting distance estimation, calibration curves were created for items shot at known distances (contact, 6 inches, 12 inches, 24 inches, and 36 inches). Additional test samples were shot at known distances but the ground truth was kept blind to the examiners. Principal Component Analysis (PCA) and Regularized Discriminant Analysis (RDA) were used to determine the distance. For comparison purposes, clothing samples were subjected to colorimetric testing (sodium rhodizonate and Griess). Color tests resulted in a misclassification rate of 26%, particularly on bloody and dark fabrics, while the LIBS method correctly classified the distance range of all unknown testing samples. For bullet hole identification, 21 difficult substrate materials were shot from a close distance, and the resulting GSR were transferred to an adhesive sheet, then mapped by LIBS to identify if a hole as produced by a bullet.

Additionally, a micro-spatial mapping method using combined LIBS and LA-ICPMS was developed for micro-bulk detection of IGSR collected from a suspected shooter's hands, providing simultaneous elemental profiles for particle(s) identification in the stub, at 25 discrete micro-regions. First, characterized IGSR suspensions (*p*GSR) created using 8 different primer types, 4 leaded and 4 non-leaded were used as "ground truth" compositions to test the methods. Sixty-four known-shooter samples (37 leaded and 27 non-leaded), and 60 non-shooter samples were then analyzed to test the mapping methods' abilities to correctly identify IGSR from shooter samples. Furthermore, correlation and covariance matrices were created using elemental intensities collected from *p*GSR, shooter, and background samples to assess the relationship of IGSR elements relative to the population of interest and as a means to describe the confidence the elemental profile originated from GSR as opposed to other sources. LA-ICPMS' enhanced sensitivity resulted in 94% classification accuracy, while LIBS resulted in 88% accuracy.

Overall, laser-based methods applied in this study demonstrated the feasibility of rapid techniques to be used for elemental mapping of GSR substrates often submitted as evidence in crime laboratories. Laser-based methods provided enhanced detection and visualization of GSR patterns on difficult substrates as compared to conventional colorimetric methods and allowed for the application of multivariate statistical interpretations. Continued development of rapid techniques for enhanced detection and visualization of gunshot residues could aid fast decision making and objective assessment of the evidence needed during the investigation of firearm-related crimes and interpretation of evidence in court.

Gunshot Residue (GSR), Laser Ablation, Multivariate Statistics

B113 Combining Novel Sampling Techniques and Electrochemical Detection in Gunshot Residue Analysis for Bullet Hole Identification and Distance Determination

Kourtney Dalzell, BS, West Virginia University, Morgantown, WV; Courtney Vander Pyl, MS, West Virginia University, Morgantown, WV; Tatiana Trejos, PhD, West Virginia University, Morgantown, WV; Luis Arroyo, PhD, West Virginia University, Morgantown, WV*

Learning Overview: After attending this presentation, attendees will understand the gaps in knowledge regarding bullet hole identification and shooting distance determination, which the presented alternative sampling methods and electrochemical analysis aimed to address.

Impact Statement: This presentation will impact the forensic community by describing innovative sampling and electrochemical methods for bullet hole identification and distance determination for screening in shooting related crimes. The sampling technique combined with electrochemical detection of inorganic and organic gunshot residue provide 3D chemical and spatial information.

Bullet hole and distance determination are two examinations under the large umbrella of firearm discharge residue (FDR) analysis that aid in a shooting event's reconstruction. The distributions of FDR around target surfaces can help answering questions like how far away the shooter was standing from the target or if a given orifice was created by a bullet. The current approaches for bullet hole identification and distance determination rely on visual and physical examination followed by colorimetric methods. The modified Griess and sodium rhodizonate tests assess the presence of some organic and inorganic GSR (OGSR and IGSR) such as nitrites and lead, respectively. While these examinations are straight forward, there are some challenges with performing these tests due to their subjectivity, lack of specificity and sensitivity, and difficulty to apply to larger or complex substrates.

A series of sampling strategies were investigated using the universal collection method of carbon adhesive stub. Method development of sampling techniques focused on different approaches that permitted a 3D chemical mapping of residues for bullet hole identification and distance determination applications. Two sampling techniques were compared for bullet hole identification: (1) a single carbon stub was utilized to sample in 4 spots around the bullet wipe and (2) handpicking approximately 5 GSR flakes from the surface for microscopic examination and electrochemical analysis. For distance determination, we investigated four types of sampling methods: (1) a single stub lifted multiple times in a 8 cm line moving away from the entrance orifice, (2) four stubs, each sampling a 2 cm interval area from the bullet wipe to 8 cm in a single line direction, (3) four stubs, each sampling a 2 cm interval from bullet wipe to 8 cm in a circular direction, and (4) four stubs, each sampling four spots in diamond shape around the bullet wipe a 2cm intervals from the bullet wipe to 8 cm away. For comparison purposes, five replicates were collected per sampling technique (30 samples total) on 100% white cotton fabric (8 ½ by 11 inches) which were shot at a fixed distance of 6 inches with a Springfield XD9 9mm pistol and manufactured leaded ammunition. Electrochemical analysis was utilized as the main analytical technique for evaluation of target organic compounds and metals. The electrochemical method adapted from Ott et al. allows for the simultaneous detection of lead, antimony, copper, 2,4-dinitrotoluene, diphenylamine, nitroglycerin, and ethyl centralite.¹

Electrochemical technique for detection reached detection limits of 0.012 µg/mL for IGSR and 0.147 µg/mL for OGSR. The bullet hole identification method resulted in positive identification of IGSR (lead, antimony, and copper) and OGSR (nitroglycerin, diphenylamine, and ethyl centralite) analytes in addition to visualizing the partially burnt flakes. Distance determination methods provided accurate identification of GSR analytes as well as spatial information of the distribution of residues around the entrance hole using heat maps. Sampling method results demonstrated that the line method cannot extrapolate spatial information, the circle method collected too much FDR on the stub oversaturating the electrochemistry signal, while the interval line provided the best visualization of the FDR distribution pattern. Electrochemical detection yielded combined signatures of at least one IGSR and OGSR compound in every sample, increasing the reliability for identifying the residues as originating from GSR. This work provides a good proof of concept that electrochemical detection using these sampling methods can provide forensic laboratories with a more sensitive, specific, and reliable method that can be used at the crime scene and laboratory. Future work will focus on method implementation on authentic samples, interference testing, and confirmatory analysis of samples by other analytical methods.

Electrochemistry, Distance Determination, Bullet Hole Identification

B114 A Characterization of Mounting Media for Hair and Fiber Microscopy

Maria Lawas, MS, Oak Ridge Institute for Science and Education/Federal Bureau of Investigation Laboratory Division, Quantico, VA; Linda Otterstatter, BS, Trace Evidence Unit/Federal Bureau of Investigation Laboratory Division, Quantico, VA; Joshua Friedman, MS, Trace Evidence Unit/Federal Bureau of Investigation Laboratory Division, Quantico, VA; Joseph Donfack, PhD, Research and Support Unit/Federal Bureau of Investigation Laboratory Division, Quantico, VA*

Learning Overview: After attending this presentation, attendees will understand various mounting media used for hair and fiber forensic analyses and how these different media compare in terms of color, setting time, media autofluorescence, hair and fiber sample autofluorescence suppression or enhancement, and mounting media absorption in the ultraviolet range.

Impact Statement: This presentation will impact the forensic science community by providing forensic trace examiners an updated and diverse pool of commercially available media from which to consider alternatives.

Currently, Permount™ is being used by several forensic laboratories as a semi-permanent mounting medium for hair and fiber samples, mainly because of its ideal refractive index and of its performance as a matrix for long-term storage.¹⁻⁴ In some cases, visible region (VIS-MSP, about 380nm – 700nm) spectral data is not sufficient to distinguish fibers. Microspectrophotometry in the ultraviolet region (UV- MSP, about 240nm – 380nm) must be conducted. To analyze the full ultraviolet spectrum, fibers must be removed from the Permount™-glass setup, washed, and remounted in non-permanent glycerin on expensive quartz slides. Since this significantly increases the risk of sample damage and loss, hair and fiber examiners prefer to avoid remounting and observing UV signals below 380nm to the best of its ability.

Possible alternatives to the mounting medium Permount™ were evaluated and characterized for suitability in the use of sample preservation, imaging, and color discrimination. Through the use of examiner surveys, vendor inquiries, and previous research articles, a literature review was performed to identify commercially available mounting media since the publication of a previous evaluation study by Wiggins and Drummond (2007).⁵ Evaluation of features such as toxicity, handling, setting time, ease of retrieval, media autofluorescence, fiber autofluorescence suppression, refractive index, media absorption in the ultraviolet (UV) range and sample preservation were conducted on final candidate mounting media. Additionally, color of mounting media themselves as well as color discrimination of embedded fibers were characterized for each candidate.

In all evaluative tests, multiple candidates performed as well as or outperformed control mounting media. Aqueous mounting media overall performed well in the UV spectral range, but glass was the major limiting factor. The evaluated mounting media exhibited different advantages and disadvantages. Before any firm recommendations can be made, further comprehensive validations must be done to evaluate the long-term conditions and stability of water-based mounting media after several months of storage at room temperature and under highly non-temperature control conditions.

Fiber Analysis, Light Microscopy, Mounting Medium

B115 A Diagnosis of Abusive Head Trauma (AHT): The Role of Immunohistochemistry in a Multidisciplinary Approach

Eleonora Mezzetti, MD*, Institute of Legal Medicine, Department of Surgical Pathology, University of Pisa, Pisa, Italy; Andrea Costantino, MD, Institute of Legal Medicine, Department of Surgical Pathology, University of Pisa, Pisa, Italy; Andrea Scatena, MD, Institute of Legal Medicine, Department of Surgical Pathology, University of Pisa, Pisa, Italy; Giacomo Visi, MD, Institute of Legal Medicine, Department of Surgical Pathology, University of Pisa, Pisa, Italy; Paola Santoro, MD, Department of Anatomy, Sapienza University, Rome, Italy; Fabio Del Duca, MD, Department of Anatomy, Sapienza University, Rome, Italy

Learning Overview: Because of the difficulty in making the diagnosis AHT, this case appears useful because it comprehends the current methods of investigation based on a necessary multidisciplinary approach. It provides an objective post-mortem confirmation of the hypothesis made by the clinicians while the patient was alive. The immunohistochemical analysis was a fundamental step of the diagnostic process.

Impact Statement: This case will have an impact on the forensic science community because it represents the complete diagnostic process that every pathologist will face when working on a similar image during their career. By attending this presentation, the audience will gain insight into performing the technical assessments necessary to make the diagnosis of abusive head trauma.

Introduction: The diagnosis of abusive head trauma (AHT) represents a challenge for the Pediatrician and Forensic Pathologist. Because AHT is not characterized by pathognomonic signs, the diagnostic process must necessarily be supported by a multidisciplinary approach. Retinal hemorrhages are one of the core manifestations in maltreated children and are found in about 85% of cases.^{1,2} Several pathogenetic mechanisms of retinal hemorrhages have been described, of which vitreoretinal traction is the most credible.³ Second, retinal venous obstruction represents another etiologic mechanism.⁴ However, it has been associated with accidental head trauma and may not be related to abusive head trauma. Therefore, to make a differential diagnosis between accidental head trauma and AHT, some specific characteristics of retinal hemorrhages should be evaluated, such as the localization, subtype, and number, as well as the presence of retinoschisis and retinal folds. In AHT cases, different types of hemorrhages have been described. In less severe cases they occurred within the posterior retinal region and were single layered, while in more severe cases the hemorrhages were multi-layered and spread to the ora serrata. Thus, the severity of hemorrhage is directly related to the severity of trauma.^{5,6} Although in AHT the hemorrhages are usually bilateral, monolateral hemorrhage does not exclude the diagnosis. If the ophthalmoscopic evaluation reveals many, severe, multilevel hemorrhages distributed over peripheral areas of the retina, the etiology of which cannot be verified, the diagnosis AHT should be made until proven otherwise.⁷

Case Report: A 3-month-old girl was admitted to the emergency department of the local hospital in a state of cardiopulmonary arrest; external examination revealed no pulse, apnea, pallor, mydriasis, and cutaneous hematomas. The child was then intubated and transferred to the Intensive Care Unit, where a CT scan revealed skull fractures and cerebral edema associated with diffuse cerebral hemorrhage. The diagnostic framework was completed by examination of the fundus of the eye, which showed multiple retinal hemorrhages. After 12 days, the child died, and an autopsy was ordered. The examinations confirmed the lesions found during the diagnostic tests and allowed histological analysis of tissues. Histology of the encephalon showed diffuse axonal damage (DAD) and encephalomalacia, and immunohistochemical analysis of the eye showed strong positivity for glycophorin A antibodies.

Discussion: In the presented case, the autopsy was performed to confirm the diagnosis of AHT made before the death. Together with the histological examination, all the signs typically described for AHT were found. In particular, retinal hemorrhage was easily detectable on microscopic examination of the eye. Moreover, the medical history provided by the parents was unclear and could not explain the severity of the clinical findings. The evidence of retinal hemorrhage, alongside multiple skeletal and brain injuries, allowed health care providers to make a quick and accurate diagnosis of physical child abuse.

B116 Visualizing Shed Skin Cells in Fingerprint Residue using Dark Field Microscopy

Shin Muramoto, PhD, National Institute of Standards and Technology, Gaithersburg, MD*

Learning Overview: In evidence samples that contain a limited amount of DNA such as latent fingerprints, proteins in the form of cells may be used to supplement individual identification using single amino acid polymorphisms. This study explores the practical aspects of such investigation by examining how much proteins are present in a typical latent fingerprint.

Impact Statement: Everyday tools such as dark field microscopy can be effective for the visualization of skin cells in latent fingerprints, which can be used to non-destructively quantify the amount of proteins. These proteins can then be used to supplement STR profiling through single amino acid polymorphisms that infer SNPs.

This proof of concept study shows that dark field microscopy provides sufficient contrast for cell visualization in fingerprints with high sebum content. Although the application is limited to smooth surfaces that do not scatter light, such as polyethylene terephthalate (PET), it was able to measure the number of cells deposited within a fingerprint residue and the reduction in cell transfer with repeated skin contact. On a PET surface, at roughly 5 N of contact force, a typical finger transfers several hundred cells onto the surface. Over subsequent finger contacts onto a clean PET surface, this number decreased exponentially until a steady state was reached, which is characterized by the transfer of (78 ± 36) cells, or (0.46 ± 0.21) cells/mm² when normalized for fingerprint area. High uncertainty in cell transfer was due to: the highly variable nature of a human finger (where the number of loose cells vary from person to person and from day to day depending on what they touch); and difficulties in controlling the contact force and finger movement such as twisting during deposition (where twisting of the finger can expose a new patch of skin to the substrate, increasing the number of cell transfer). Plasma etching was also explored as an effective way to validate dark field microscopy for cell counting. Although limited to inorganic substrates due to etching effects, exposing the fingerprint for less than 10 min can remove a majority of the sebum while keeping the cells intact for a before-and-after comparison using light microscopy.

Cell Visualization, Fingerprint, Microscopy

B117 An Evaluation of the Stability and Durability of an Inkless Method for Fingerprint Recordings

Sihai Li, BS, University of New Haven, West Haven, CT; Josep De Alcaraz-Fossoul, PhD, University of New Haven, West Haven, CT*

Learning Overview: After attending this presentation, attendees will learn about the proposed inkless method that utilizes commercial thermal paper and alcohol-based hand sanitizer gel to obtain reference (exemplar) fingerprints and how environmental variables over time, such as temperature, affect the visual quality (clarity) of the resultant fingerprints.

Impact Statement: This presentation will impact the forensic science community by demonstrating the stability and durability of the proposed inkless method as a potential safer and inexpensive alternative to the conventional ink method.

Fingerprint identifications have been used in criminal investigations for decades due to their reliability.¹ The legibility and uniqueness of friction ridge skin recordings are critical for subsequent comparisons to questioned fingermarks located at crime scenes. Also, for discarding other impressions deposited by victims and personnel who have had legitimate access to the scenes as well as for the identification of deceased persons.² When practicing the conventional inking method, ridge skin patterns will be coated with black ink and then transferred on standard tenprint cards, leaving inconvenient stains on the donor's skin. On the other hand, when utilizing inkless electronic equipment, such as Live Scan, the financial cost may be too high for certain agencies. As a result, a low-cost, cleaner, and safer inkless method to obtain reference (exemplar) fingerprints is recommended.

Previous research has proposed and proven the potential of an inkless method for obtaining exemplars with commercial thermal paper and alcohol-based hand sanitizer gel.³ The visual quality (clarity) of the resultant fingerprints was comparable with those obtained from the conventional inking method as assessed with two different systems: an adapted quality score (QS) scheme and a set of metric data provided by the FBI's Universal Latent Workstation (ULW).³ Results demonstrated that the ridge clarity produced by the new method was influenced by the biological sex of donors (female vs. male). Most importantly, it could be used as an alternative for obtaining exemplars.³

In order to further explore the viability of the proposed inkless method, it was necessary to examine additional factors that may affect the degradation of the thermal paper substrate. The purpose of this project was to determine whether environmental factors, i.e., temperature (°C) and relative humidity (%RH), in combination with biological sex could influence the quality of ridges over time. In a practical setting, it was important to evaluate whether the expected degradation of thermal paper could influence the quality of fingerprint ridges and be mitigated by preserving it under colder temperatures. A total of 120 fingerprints were obtained from 9 females and 11 males. Inkless impressions of the index, middle, and ring fingers were deposited in duplicate, and each set was stored under different environmental conditions. One set was stored at an average room temperature of 21.4°C with a %RH of 42.5%; while the other was exposed to an average temperature of 2.9°C with a %RH of 12.2% for the first 22 weeks (fridge) and later moved to room temperature and %RH as with the other set. After aging over 72 weeks, impressions were photographed, images were standardized using image processing software and then analyzed with ULW. The clarity metric provided by ULW was used as reference to evaluate any visual differences between the two aging sets.⁴ All samples were examined and compared in relation to time, temperature/relative humidity, and biological sex.

This research provided empirical evidence that the storage at colder temperatures and the time interval between depositions did not affect the quality of ridges on thermal paper significantly. Statistical tests proved the stability and durability of the proposed inkless method for fingerprinting purposes regardless of temperature and time. A biological sex effect was again identified where males showed better ridge clarity. This was consistent with the literature in which males and females have shown differences in the morphology of friction skin ridges that could affect the quality of ridges. In future work, longer storage periods, different temperatures and relative humidity may provide more insightful information on the validity of the proposed inkless method.⁵

B118 Standards Development Activities in Trace Materials

Celeste M. Grover, MSFS, Oregon State Police, Forensic Science Division, Clackamas, FL*

Learning Overview: After attending this presentation, attendees will have a better understanding of the status of discipline specific standards pertinent to the examination and interpretation of trace materials.

Impact Statement: The presentation will impact the forensic science community by creating greater awareness of standards development activities related to trace material examination and interpretation. It will also increase awareness regarding training, tools and resources that support implementation, compliance monitoring, and broader understanding.

The Organization of Scientific Area Committees (OSAC) for Forensic Science was created to strengthen the nation's use of forensic science by promoting the use of discipline-specific forensic science standards. To this end, the OSAC drafts standards that are forwarded to standards development organizations (SDOs) that ballot and publish them. The OSAC also reviews standards and recognizes them on the OSAC Registry, which serves as a central repository of high quality, consensus-based, technically sound standards.

During this presentation, updates related to standards development activities in trace materials will be discussed. These include:

Recent standards that have been added to the OSAC Registry

- *E3260 Standard Guide for Forensic Tape Analysis and Comparison*
- *E3272 Standard Guide for Collection of Soils and Other Geological Evidence for Criminal Forensic Applications*
- *E2808 Standard Guide for Microspectrophotometry in Forensic Paint Analysis*

Published ASTM standards that have yet to go through the Registry approval process

- *E2224/WK58028 Standard Guide for Forensic Analysis of Fibers by IR*
- *E2225 Standard Guide for Forensic Examination of Fabrics and Cordage*
- *E2227 Standard Guide for Forensic Examination of Non-reactive Dyes in Textile Fibers by Thin Layer Chromatography*
- *E2228 Standard Guide for Microscopic Examination of Textile Fibers*
- *WK70035 Standard Practice for Determination and Comparison of Color by Visual Observation in Forensic Soil Examination*
- *WK72837 Standard Guide for Analysis of Forensic Geological Materials by Powder X-Ray Diffraction*
- *WK72932 Standard Guide for Forensic Glass Analysis and Comparison*
- *WK56743 Standard Practice for Training in the Forensic Examination of Hair by Microscopy*
- *WK72597 Standard Guide for the Forensic Examination of Hair by Microscopy*
- *E2809/WK57479 Standard Guide for Using Scanning Electron Microscopy/X-ray Spectrometry in Forensic Polymer Examinations*
- *WK74138 Standard Guide for Using X-ray Fluorescence in Forensic Polymer Examinations*
- *WK75180 Standard Guide for Using PyGC-MS in Forensic Polymer Examinations*

Documents currently in development at the OSAC

- *Standard Guide for Interpretation and Reporting in Forensic Comparisons of Trace Materials*
- *Standard Guide for Forensic Physical Fit Examinations*
- *Standard Practice for a Forensic Fiber Analysis Training Program*
- *Standard Guide for Forensic Fiber Analysis and Comparison*
- *Standard Guide for Forensic Analysis of Fibers by Microspectrophotometry*
- *Standard Practice for a Forensic Glass Analysis Training Program*

Priorities for new documents or work products

- *Standard Guide for Physical Fit Training Program*
- *Standard Guide for Using X-ray Diffraction in Forensic Polymer Examinations*
- *Standard Guide to Raman Spectroscopy in Forensic Polymer Examinations*
- *Standard Guide for Accessing Physical Characteristics in Forensic Tape Examinations*
- *Standard Guide for Using Light Microscopy in Forensic Tape Examinations*
- *Standard Guide for Using Scanning Electron Microscopy for Morphology and Energy Dispersive Spectroscopy in Forensic Soil and Geological Materials Analysis*
- *Standard Guide for the Use of Polarized Light Microscopy in the Forensic Examination and Comparison of Sands and Soils*

and other highlights. Opportunities for supplemental training related to discipline-specific standards will be presented, as well as additional resources and tools designed to facilitate gap analysis, compliance monitoring, and outreach efforts.

Trace Materials, Standards, OSAC

B119 Five Years Since the President’s Council of Advisors on Science and Technology (PCAST) Report: The Value of Materials Science and Tribology as Foundational Science for Transfer and Persistence

Michael Aberle, BA, National Centre for Forensic Studies, University of Canberra, Bruce, ACT, Australia; Hilton Kobus, PhD, National Centre for Forensic Studies, University of Canberra, Bruce, ACT, Australia and Flinders University, Bedford Park, SA, Australia; James Robertson, PhD, National Centre for Forensic Studies, University of Canberra, Bruce, ACT, Australia; Caroline O'Driscoll, PhD, National Centre for Forensic Studies, University of Canberra, Bruce, ACT, Australia and Australian Federal Police, Canberra, ACT, Australia; Jurian Hoogewerff, PhD, National Centre for Forensic Studies, University of Canberra, Bruce, ACT, Australia and Australian Federal Police, Canberra, ACT, Australia*

B120 Forensic Discrimination of Copper Metal by Laser Induced Breakdown Spectroscopy (LIBS)

Chase Notari, BS, University of New Haven, West Haven, CT; Brooke Kammrath, PhD, University of New Haven, West Haven, CT and Henry C. Lee Institute of Forensic Science, West Haven, CT*

Learning Overview: After attending this presentation, attendees will gain an understanding of the capabilities and limitations of LIBS for the comparative analysis of copper metal, specifically the copper jacketing of bullets, and its capabilities as an investigative tool for use in forensic casework.

Impact Statement: This presentation will impact the forensic science community by presenting a novel application of LIBS for the discrimination of copper metal, specifically the copper-jacketing of bullets.

Copper metal has great potential as forensic evidence due to its presence in a range of cases from thefts of copper wiring and pipes, the use of copper wiring in IEDs, and its common function as jacketing for bullets. Copper has already been proven to be able to be discriminated through trace element profiles collected from ICP-MS, although there are instruments with faster analysis and no sample preparation that are being investigated use in forensic analysis, not only for copper, but for glass, paint, and other types of evidence as well.

LIBS is an analytical technique that has continued to gain prominence in the scientific community as a valuable tool for elemental profiling. In addition, it is advantageous when compared to other similar instruments due to the fact that it is rapid, requires no sample preparation, is able to simultaneously provide information on multiple elements at once, and is less expensive than other instruments used for elemental analysis. Furthermore, LIBS has already been tested to have value in the analysis of other types of forensic evidence such as paint, soil, and ink.

The goal in this research is to evaluate LIBS for its ability to comparatively analyze copper, focusing primarily on the copper-jacketing of different bullets. The study first explored the detection capabilities of the instrument, while also determining an appropriate element menu, and outlining the optimal parameters for the LIBS. Parameters were tested and optimized using a copper density block; parameters included laser pulse energy, spot size, pattern size, gate delay, number of pulses per shot, and repetition rate. Once determined, the optimal parameters were applied to the analysis of the copper jacketing from the different bullets, and results were analyzed using multivariate statistical methods (Principle Component Analysis, Canonical Variance Analysis, and Partial Least Squares Discriminant Analysis).

This research showed that there is great potential for LIBS to provide a novel method for the forensic analysis of copper metal, and specifically copper-jacketed bullets. The results demonstrate that elemental analysis by LIBS has the ability to differentiate bullets based on the elemental profile of their copper jacketing. Discrimination of bullets is improved when combined with LIBS elemental analysis of bullet lead. This research also provides evidence that other sources of copper may be able to be analyzed and discriminated using LIBS, thus extending this powerful tool to additional items of forensic relevance, such as pipes and wiring.

Copper Metal, Bullets, LIBS

B121 The Transfer of Metal Traces by Human Touch Detected Using a Scanning Electron Microscopy with Energy-Dispersive X-ray Spectroscopy (SEM/EDS) Technique: A Pilot Study

Sofia Bodini, MD, Department of Public Health, Experimental Medicine and Forensic Sciences - University of Pavia, Italy; Alberto Amadasi, PhD, Institute for Forensic Medicine - Berlin, Berlin, Germany; Giacomo Govoni, University of Bologna, Bologna, Italy; Giacomo Belli, MD, Department of Public Health, Experimental Medicine and Forensic Sciences - University of Pavia, Pavia, Italy; Elena Cavriani, MD, Department of Public Health, Experimental Medicine and Forensic Sciences - University of Pavia, Pavia, Italy; Paola Braga, MD, Department of Public Health, Experimental Medicine and Forensic Sciences - University of Pavia, Pavia, Italy; Matteo Moretti, MD, Department of Public Health, Experimental Medicine and Forensic Sciences - University of Pavia, Pavia, Italy; Silvia Damiana Visonà, PhD, Department of Public Health, Experimental Medicine and Forensic Sciences - University of Pavia, Pavia, Italy*

Learning Overview: After attending this presentation, attendees will understand more about the transfer of metal traces by touch.

Impact Statement: This presentation will impact the forensic science community providing experimental data that can be extremely useful in a forensic setting, for instance when it is necessary to establish, for example, if a victim has been touched by someone who held a weapon or another metal object found on the scene.

The transfer of metal particles could be extremely useful in a forensic setting, for example metal residues can be transferred from metal weapons on the victim's skin. The presence of metal traces can be assessed using SEM-EDS (scanning electron microscope equipped with energy dispersive spectroscopy) analysis.¹ The studies in literature about metal traces detected using SEM-EDS focus especially on gunshot residues, metal particles in the "current mark", and traces on bone tissue after blunt and sharp injuries.²⁻⁶ The transfer of metal particles between different surfaces hasn't been investigated until now. Aims: this pilot study aims to assess the entity of the transfer of metal residues by human fingertips from metal objects to different surfaces. Materials and methods: the experiment have been carried out as follows: (1) FIRST TOUCH SAMPLES: subject 1 (a volunteer) touched ten different metal items (8 things of everyday usage, 1 gun, 1 cartridge case) using both the thumb fingertips, applying pressure but no rubbing. Then, for each item a metal stub covered by a carbon tape has been applied on the fingertips and then analyzed using SEM-EDS. (2) SECOND TOUCH SAMPLES: after touching the ten items as explained above, subject 1 touches three different surfaces: glass, plastic and the skin of a second volunteer (subject 2). One sample has been taken from each touched surface, obtaining in total 30 "second touch" samples. The 40 samples have been observed using EM30X (COXEM), as well as fragments of the metal items used for the experiment. The observation was carried out using backscattered electrons, in order to detect only the inorganic particles; metal fragments appear bright using this setup, due to the higher atomic number. Results: the metal residues were found in the totality of the examined samples. The semiquantitative analysis shows a lower amount of traces in the "second touch" samples. The EDS analysis showed a high correspondence between touched items and primary metal fragments. Conclusions: the results above summarized allowed to demonstrate that, after touching a series of different metallic items, traces of them persist on the fingertip's skin and can be detected using SEM-EDS. Moreover, such traces can be transferred on a second surface and detected using the same technique. This presentation will impact the forensic science community providing experimental data that can be extremely useful in a forensic setting, for instance when it is necessary to establish, for example, if a victim has been touched by someone who held a weapon or another metal object found on the scene.

Transfer by Touch, SEM/EDS Analysis, Metal Particles

B122 A Comparative Study on the Background Presence of Glass and Paint in Various Populations and Seasons in the United States

Lauryn Alexander, PhD*, West Virginia University, Morgantown, WV; Oriana Ovide, MS, West Virginia University, Morgantown, WV; Olivia Duffett, BS, West Virginia University, Morgantown, WV; Andra Lewis-Krick, PhD, Sam Houston State University, Huntsville, TX; Patrick Buzzini, PhD, Sam Houston State University, Huntsville, TX; Tatiana Trejos, PhD, West Virginia University, Morgantown, WV

Learning Overview: After attending this presentation, attendees will gain knowledge about the background presence of glass and paint in two U.S. cities and different seasons, according to the type of clothing and footwear worn, along with their retention characteristics.

Impact Statement: This presentation aims to fill the current gap of knowledge concerning the random presence of glass and paint within the United States' general population, and how different demographics and geographical aspects can impact the overall background levels of traces.

Glass and paint particulates are often recovered from crime scenes as a primary form of trace evidence that can provide information about how the events took place. Baseline background presence of these traces in the general population are essential in assessing their evidential value. Although studies have been performed on the background presence of glass and paint in areas such as Canada, Australia, the United Kingdom, and Northern Ireland, surveys are limited within the United States.¹⁻⁹ The available studies have drastically different demographics, socioeconomic statuses, and/or geographical circumstances, as well as methodologies, sample types, and experimental designs, making the use of background data challenging.

As a result, this collaborative study between West Virginia University and Sam Houston State University focuses on collecting glass and paint residues from volunteers with different demographics and socioeconomic backgrounds in various U.S. cities during two different seasons. The study provides valuable information on the chance of randomly finding glass and paint particles in the general population, as well as the recovery location from the type of clothing and footwear worn.

This presentation discusses the findings from samples collected in Morgantown, WV during the winter and summer seasons, as well from samples collected in Huntsville, TX during the spring season. One hundred volunteers with up to 6 separate garment areas per volunteer were sampled utilizing taping and scraping methods. Each sample was systematically searched, and any paint or glass particulates were identified. Glass fragments were analyzed via SEM-EDS and/or μ XRF, as well as refractive index, while paint particulates were analyzed via micro-FTIR and micro-ATR techniques. The Morgantown set collected in the winter consisted of 511 items, in which 10 glass fragments (~2% of the sampled items) and 118 paint fragments (~20% of the items) were identified. In total, approximately 50% of the individuals sampled had paint fragments recovered from their clothing, while only 7% of individuals had glass on them. The Huntsville set collected in the spring consisted of 398 items, with 8 glass fragments (~2% of the items) and 93 paint fragments (~20% of the items) identified. In total, approximately 46% of the individuals sampled had paint fragments recovered from their clothing, while only 8% of individuals had glass on them. No individuals had both particle types on their garments. In both subpopulations, the majority of the paint fragments were recovered from the upper garments while most of the glass was recovered from the footwear sole. Overall, both Morgantown and Huntsville sets yielded close proportions of background presence of glass and paint particles.

The baseline data presented in this study will increase the background knowledge on the background presence of glass and paint in the United States and aims offering valuable information for the assessment of the evidential value of trace evidence in the US court system.

B124 Interlaboratory Studies to Evaluate the Forensic Analysis and Interpretation of Glass Evidence

Katelyn Lambert, MS*, Florida International University, Miami, FL; Shirly Montero, PhD, Arizona State University, Tempe, AZ; Jose Almirall, PhD, Florida International University, Miami, FL

Learning Overview: After attending this presentation, attendees will have a better understanding of the importance of utilizing likelihood ratios (LRs) for the interpretation of forensic glass evidence.

Impact Statement: This presentation will impact the forensic science community by presenting an accessible way to calculate LRs, an alternative method for the interpretation of multivariate LA-ICP-MS data comparisons.

The results of two interlaboratory exercises involving 20+ operational and research laboratories employing laser ablation inductively coupled plasma mass spectrometry (LA-ICP-MS) and using a standard test method (ASTM E2927-16e1) for the forensic analysis and comparison of glass evidence are presented.¹ The overall aims of the first exercise were to evaluate the performance of a newly reported calibration standard (CFG2) for the quantitative analysis of simulated casework samples and to evaluate the use of a qualitative determination of the strength of association or non-association (as recommended by the ASTM E2927) and the use of a likelihood ratio (LR) as an objective and quantitative determination of the strength of any association found.²⁻⁵ Ten (10) laboratories determined an LR for the comparisons to report the significance of glass source comparisons for a set of glass samples of known origin. Both the ASTM E2927 match criterion and previously reported LR calculations were used to interpret the results of the comparisons reported by the 10 different laboratories. Two different background databases were used for the calculation of the LR to gauge the effect of the size and nature of the databases on the calculation of the LR.^{6,7} As expected, glass that originated from the same windowpane was found to be indistinguishable using the ASTM E2927 match criteria and result in a high LR value (suggesting strong support for an association between the glasses) and glass that originated from different vehicles are distinguished (resulting in a low LR, suggesting strong support for an exclusion).^{6,8,9} Glass samples that originated from different vehicles but that were the same make, model, and year (comparisons between the inner and outer pane of the same windshield) were found to exhibit chemical similarity that is sometimes reflected in a low LR. Good agreement among the laboratories was also reported for the analytical data collected using the standard test method of analysis for reference materials and the samples analyzed with relative standard deviations < 5 % RSDs among all labs participating in the study with few exceptions.² The overall aims of the second exercise were to allow for all participants to gain proficiency in the free-available Shiny App, created by our group, to facilitate the calculation of likelihood ratios (LR), compare the likelihood ratios from different scenarios using a wide range of background databases from across the world, and interpret the data to provide recommendations to create a standardized interpretation method for the use of likelihood ratios for glass analysis, which will be submitted to ASTM.¹⁰ The 20+ laboratories determined an LR for the three (3) different scenarios. Both the ASTM E2927 match criterion and previously reported LR calculations were used to interpret the results of the comparisons reported. Five (5) individual databases were used to gauge the effect of different sized non-local databases on LR calculations. Glass that originated from the same pane was found to be indistinguishable using the ASTM E2927 match criteria and result in a high LR value and glass that originated from different windows are distinguished.^{6,8,9} Glass samples that originated from chemically similar windows were found to be reflected in LRs between the maximum and minimum.^{6,8,9}

B125 A Chemical Approach to Tire Mark Analysis—Preliminary Protocols From Collection on Scene to Elemental Profiling

John Lucchi, MS, National Center for Forensic Science, University of Central Florida, Orlando, FL; Veronica Flores, BS, National Center for Forensic Science, University of Central Florida, Orlando, FL; Matthieu Baudelet, PhD, National Center for Forensic Science, University of Central Florida, Orlando, FL*

Learning Overview: After attending this presentation, attendees will have an understanding of using lifting procedures, Raman microscopy, and Inductively-Coupled Plasma Mass Spectrometry (ICP-MS) to collect, extract, and analyze tire marks from road crime scenes.

Impact Statement: This presentation will impact the forensic science community by providing preliminary protocols to collect tire marks on the road, separate tire trace material from skid mark lifts, and establish their elemental profile with the potential to be analyzed for tire and skid mark association.

Road crime is an ever-present aspect of the forensic community, with a lack of quantitative tools in the investigation. One such area that is lacking is in tire mark investigations, where traces of tire evidence are present. Previously tire patterns have been used for linking tire and skid mark and thus car, but anti-lock braking systems making readily visible skid marks rare. However, tire traces are still left where the tire mark was made, meaning that they can be chemically or elementally analyzed to get information about the tire which left them.

In the United States between 2004 and 2018, 5% of fatal vehicle incidents were fatal hit and runs, where knowledge of the tire of the car is sometimes the only evidence available.¹ Even in cases where vehicles are still present, attribution of a tire mark can assist in accident reconstruction.

One challenge present with this route of analysis is that tire trace material must be collected from the road. Lifting the material from the road has many options, including gel lifting tapes, different casting compounds, or collecting trace material with tweezers directly from the road. These methods were tested and compared to give the best results for later analysis. Field tire marks evidence were created and lifted in collaboration with the Florida Highway Patrol.

Current methods of analysis for attribution involve either molecular or elemental signatures using a few different analytical techniques. Of particular interest to us, laser induced breakdown spectroscopy has been shown to be able to attribute bulk tires.² Both these methods need a reliable way to separate tire trace material from the lift while also differentiating what is just road material.

Once the lift is performed, separating those tire materials from other contaminants, mainly the asphalt, is a challenge that needs to be addressed. Some chemical separation methods have been tested, but ultimately present possible contamination of their own. In this study, Raman microscopy was used to differentiate the tire trace material from the asphalt. This was shown to easily differentiate asphalt from tire materials, allowing manual separation of the tire material from the tire mark lift.

After the tire trace is separated from the lift, the material was analyzed for elemental profiling using ICP-MS. By comparing the elemental signature of the tire trace and the bulk tire, the effect of transferring bulk tire to tire mark was examined. This step is important in knowing how the bulk tire will correlate with the tire trace when attribution of a skid mark to tire is desired.

Tires, Trace Evidence, Raman Microscopy

B126 Evaluating the Discriminating Power of Hair Amino Acid Ratios for Distinguishing Individuals Using Gas Chromatography/Mass Spectrometry (GC/MS)

Timothy Yaroshuk, MS*, University of New Haven, West Haven, CT; Alyssa Marsico, PhD, University of New Haven, West Haven, CT

Learning Overview: To understand the variability of amino acid ratios between different hair samples in order to differentiate individuals.

Impact Statement: This presentation will demonstrate the capabilities and limitations of using amino acid ratios in hair to differentiate individuals in cases where DNA analysis cannot be conducted.

Currently, the conventional methods of analyzing hair include microscopic hair comparison (MHC) and DNA analysis (nuclear and mitochondrial), with nuclear DNA analysis being individualizing. However, MHC is subjective and nuclear DNA analysis is not always possible if not enough adequate cells are present.¹⁻³ Non-synonymous amino acid changes in the hair protein sequence – resulting from single nucleotide polymorphism profiles that differ between individuals – can be exploited to offer supplemental or alternative routes for hair analysis. Currently, proteomics has successfully exploited genetically variant peptide (GVP) content in hair to differentiate at least non-related individuals.⁴⁻⁷ However, proteomics is complicated and requires the GVPs to remain intact. Analyzing amino acids is an alternative method that may simplify the analysis. It has been demonstrated that analyzing amino acid quantities has abilities to differentiate people based on general class characteristics (sex, age group, and geographical origin).⁸ A study by Macri et al., analyzing amino acid ratios of two individuals with morphologically similar hair, discovered 15 amino acid ratios that differed.⁹ Expanding on this study, this research will evaluate the discriminating power of using hair amino acid ratios to differentiate individuals with a focus on increasing the sample size and diversity to develop a method that can supplement MHC in cases when DNA analysis cannot be conducted.

Hair samples were obtained from consenting individuals and were anonymized. Brushed hair, plucked hair or cut hair samples were obtained from 10 individuals, including a sample from one individual before and after dying their hair. Hairs were thoroughly washed with deionized water and methanol to remove surface contaminants. They were then cut into smaller pieces, hydrolyzed with hydrochloric acid for protein digestion in triplicate and subsequently filtered to remove unhydrolyzed hair pieces. An aliquot was then taken to dry under a gentle stream of nitrogen and L-norvaline was added as an internal standard. The sample was then reconstituted in ethyl acetate, and N,O-Bis(trimethylsilyl)trifluoroacetamide (BSTFA) was added for amino acid derivatization. The samples, in addition to a set of 11 standard derivatized amino acids in ethyl acetate, were analyzed using gas-chromatography mass-spectrometry (GC/MS).

Eight derivatized amino acids were detected from the hair samples in addition to a glutamic acid derivative. Identification confirmation was conducted by comparing sample retention times to standards as well as mass spectra library comparison. Quantitation relative to the internal standard was completed and 36 amino acid ratios were constructed from these quantities. Outliers for each ratio were determined by the Grubbs test and these were discarded. Based on preliminary comparisons of means and standard error of the ratios between individuals, individuals can be differentiated using hair amino acid ratios. Between the 10 hair samples analyzed, one-way ANOVA for all 36 ratios had $p < 0.05$ indicating the ratio is different between at least 2 individuals. Most individuals were differentiable using the post-hoc Tukey test for all ratios. For the samples that could not be differentiated with this method, 3D-PCA plot showed distinct clustering of individuals, therefore allowing differentiation. Ratios between dyed hair samples were also differentiable from undyed hair from the same donor.

B127 Standards Development Activities in Seized Drugs

Agnes D. Winokur, MS, Drug Enforcement Agency, Southeast Laboratory, Miami, FL*

Learning Overview: After attending this presentation, attendees will have a better understanding of the status of discipline specific standards pertinent to examination of seized drugs.

Impact Statement: The presentation will impact the forensic science community by creating greater awareness of standards development activities pertinent to the examination of seized drugs. It will also increase awareness regarding training, tools and resources that support implementation, compliance monitoring, and broader understanding.

The Organization of Scientific Area Committees (OSAC) for Forensic Science was created to strengthen the nation's use of forensic science by promoting the use of discipline-specific forensic science standards. To this end, the OSAC drafts standards that are forwarded to standards developing organizations (SDOs) that further develop and publish them. The OSAC also reviews standards and recognizes them on the OSAC Registry, which serves as a central repository of high quality, consensus-based, technically sound standards.

During this presentation, updates related to standards development in seized drugs will be presented. These include i) recent standards that have been added to the OSAC Registry (E1968-19 Standard Practice for Microcrystal Testing in Forensic Analysis for Cocaine, E1969-19 Standard Practice for Microcrystal Testing in Forensic Analysis for Methamphetamine and Amphetamine, E2125-19 Standard Practice for Microcrystal Testing in Forensic Analysis for Phencyclidine and Its Analogues, E2882-19 Standard Guide for Analysis of Clandestine Drug Laboratory Evidence, E2548-16 Standard Guide for Sampling Seized Drugs); ii) OSAC proposed standards (Standard Guide for Assessment of Fourier Transform Infrared (FTIR) Spectroscopy Data During the Qualitative Analysis of Seized Drugs, Standard Guide for Assessment of Gas Chromatography and Electron Ionization Mass Spectrometry Data During the Qualitative Analysis of Seized Drugs, Standard Guide for The Development of Electron Ionization-Mass Spectral Libraries for the Analysis of Seized Drugs, Standard Guide for Intra-laboratory Blind Quality Control Programs for Seized Drug Analysis); iii) documents currently in development at the OSAC or by the SDO (Standard Practice for the Differentiation of Marijuana and Hemp in Seized Drug Analysis, Standard Guide for Court Testimony in Seized-Drug Analysis, Revision of E2549 Practice for Validation of Seized Drug Analytical Methods into an Interdisciplinary Standard, Revision of E2764-11 Standard Practice for Uncertainty Assessment in the Context of Seized-Drug Analysis); iv) priorities for new documents or work products (Standard Guide on Reporting in Seized-Drug Analysis, Standard Practice for the Analysis of Opioids and Emerging Drugs, Standard Guide for the Assessment of Liquid Chromatography (LC) Data During Qualitative Analysis of Seized Drugs); and other highlights. Opportunities for supplemental training related to discipline-specific standards will be presented, as well as additional resources and tools designed to facilitate gap analysis, compliance monitoring, and outreach efforts.

Seized Drugs, Standards, OSAC

B128 A Comparison of Analytical Workflows for Seized Drug Analysis

Edward Sisco, PhD, National Institute of Standards and Technology, Gaithersburg, MD; Amber Burns, MSFS, Maryland State Police - Forensic Sciences Division, Pikesville, MD; Elizabeth Schneider, BS, Maryland State Police - Forensic Sciences Division, Pikesville, MD; Charles R. Miller IV, MSFS, Maryland State Police - Forensic Sciences Division, Pikesville, MD; Laurel Bobka, MSFS, Maryland State Police - Forensic Sciences Division, Pikesville, MD*

Learning Overview: After attending this presentation, attendees will have an understanding of the qualitative and quantitative differences between two analytical workflows for seized drug analysis. One workflow incorporated color tests and generic GC-FID and GC-MS methods and the second incorporated DART®-MS and targeted GC-MS methods.

Impact Statement: This presentation will impact the forensic science community by providing both qualitative and quantitative measures of different screening and confirmatory approaches. This information can be used to make data-driven decisions on changes to workflows or adoption of new technology.

As the challenges presented by the continued presence of synthetic opioids, novel psychoactive substances, and other emerging drugs persist, laboratories are continuing to look for new analytical approaches or techniques to ease the burdens. These solutions range from modifications to existing methods or techniques to implementation of entire new technologies. Laboratories often must estimate the benefits of implementing changes making adoption difficult because there may be an incomplete understanding of how, and even if, these changes will address the challenges a laboratory is facing. One way to mitigate this issue is to develop metrics that compare different analytical approaches to provide laboratories and personnel with tangible data to make decisions.

In this study we attempt to compare, qualitatively and quantitatively, two analytical workflows for seized drug analysis using adjudicated and mock case samples containing synthetic cannabinoids, cathinones, and opioids. The first workflow, an existing workflow, employed color tests for screening followed by general-purpose gas chromatography flame ionization detection (GC-FID) and general-purpose gas chromatography mass spectrometry (GC-MS) analyses for confirmation. The second workflow was an experimental workflow that combined direct analysis in real time mass spectrometry (DART®-MS) for screening with targeted GC-MS methods for confirmation. Four forensic chemists were asked to analyze a subset of samples on each workflow and at each step in the analysis scheme, recorded metrics such as the time required, and level of information obtained.

Using the information from the study, the two workflows could be compared. A scoring system was developed to allow for comparison of the two screening approaches – DART®-MS and color tests. DART®-MS required the same amount of time as color tests but yielded significantly more accurate information. Confirmation of samples using GC-FID and GC-MS general purpose methods required more than twice the amount of instrument time and data interpretation time compared to targeted GC-MS methods. There were also several analytical challenges that prevented compound confirmation in some samples using the existing workflow. Targeted GC-MS methods were found to simplify data interpretation, reduce consumption of reference materials, and address almost all limitations of general-purpose methods. The results of this study highlight how rethinking processes for seized drug analysis could assist laboratories in reducing turnaround times, backlogs, and standards consumption.

Seized Drugs, GC/MS, DART®-MS

B129 Evaluating the Robustness and Ruggedness of a Statistical Method to Compare Mass Spectra

Andrew Sacha, BS, Michigan State University, East Lansing, MI; Victoria McGuffin, PhD, Michigan State University, East Lansing, MI; Ruth Waddell Smith, PhD, Michigan State University, East Lansing, MI*

Learning Overview: After attending this presentation, attendees will have a better understanding of the robustness and ruggedness of a method developed to statistically compare mass spectra, with a focus on differentiating structurally similar novel psychoactive substances.

Impact Statement: This presentation will impact the forensic science community by further demonstrating a more objective method that can be used toward seized drug identifications.

Identification of seized drugs in submitted samples often involves a visual comparison of mass spectra as one part of the analytical scheme. However, with the increasing prevalence of novel psychoactive substances (NPS), identification based on visual comparison of spectra can be challenging due to the high degree of structural similarity among compounds within given NPS classes.

Previous work in our laboratory developed a statistical method to compare two mass spectra and, thereby, increase objectivity in the comparison. The method is based on the unequal variance *t*-test, which is performed to compare the mean intensities of corresponding *m/z* values in the two spectra at a user-specified confidence level. The null hypothesis states that the difference in mean intensities at that *m/z* value is equal to zero, whereas the alternative hypothesis states that the difference is not equal to zero. If the null hypothesis is accepted at all *m/z* values in the spectral range, the two spectra are considered to be statistically equivalent. In contrast, if the null hypothesis is not accepted at any *m/z* value, the two spectra are considered to be statistically distinct. In these cases, the *m/z* values for which the null hypothesis is not accepted are termed 'discriminating ions' and the number of such ions is determined. The method has been applied previously to demonstrate successful association and discrimination of structurally similar seized drugs and positional isomers.

The next step is to demonstrate the robustness and ruggedness of the statistical comparison method, which is essential prior to future implementation in forensic laboratories. In the current work, three sets of structurally similar compounds were investigated: six synthetic cathinones, six synthetic cannabinoids, and six fentanyl analogs. Compounds were prepared at different concentrations and analyzed by gas chromatography-mass spectrometry (GC-MS). Spectra of compounds within each set were statistically compared to evaluate the robustness of the method by taking into account the effect of reduced spectral intensity on the association and discrimination of spectra. Compounds were analyzed on two different GC-MS instruments over several months, with the resulting comparisons used to evaluate the ruggedness of the method.

Preliminary results indicate the potential to successfully associate corresponding compounds while discriminating from structurally similar compounds even as spectral intensity decreases. For example, at a concentration of 1 mg/mL, spectra of pentylone are associated (zero discriminating ions) but discriminated from spectra of dibutylone, eutylone, and propylone, with 7 – 12 ions responsible for discrimination (99.9% confidence level). At lower concentrations, corresponding to 50% and 10%, discrimination is maintained, with 3 – 11 discriminating ions. Initial comparisons also demonstrate the potential to identify reliable discriminating ions, despite differences in spectral intensity and the instrument used to collect spectra. For example, for comparison of dibutylone and pentylone, *m/z* 44, 57, 71, 121, 149, and 150 are common discriminating ions at the three spectral intensity levels investigated and on both instruments tested thus far.

In this presentation, statistical comparison of the synthetic cathinones, cannabinoids, and fentanyl analogs will be presented in more detail and reliable ions for discrimination of structurally similar compounds will be highlighted.

B130 The Analytical Challenges of Distinguishing Between Pentylone and Its Positional Isomers

Sally Ho, PhD, Drug Enforcement Agency, Chicago, IL

WITHDRAWN

B131 Development of an Expert Algorithm for Substance Identification (EASI) of Fentanyl Analogs using Mass Spectrometry

Alexandra Adeoye, BS, Department of Forensic and Investigative Sciences, West Virginia University, Morgantown, WV; Glen P. Jackson, PhD, Department of Forensic and Investigative Sciences, West Virginia University, Morgantown, WV and C. Eugene Bennett Department of Chemistry, West Virginia University, Morgantown, WV*

Learning Overview: At the end of this presentation, attendees will learn how correlated ion abundances within replicate mass spectra can be used to improve confidence in compound identification for fentanyl analogs, especially those sharing structural and spectral similarities.

Impact Statement: This presentation will provide the forensic community with a flexible multivariate model that can minimize the risk of false-positive and false-negative identifications and enable confident identifications without the need to analyze contemporaneous drug standards. The goal of the algorithm is to provide sufficient confidence to obviate the need for laboratories to analyze their own drug standards at all.

Hypothesis: Our central hypothesis, supported by an extensive database of replicate fentanyl analog spectra, is that relative ion abundances of replicate mass spectra are not independently variable, as has been assumed for more than 70 years, but are in fact highly correlated and anticorrelated. We use the measured correlations that exist between spectra in a series or general linear models to make accurate predictions of ion abundances within spectra.

Methods/Results: Most existing search algorithms for electron ionization-mass spectrometry (EI-MS) data use a ‘consensus’ approach when making unknown identifications. These algorithms compare unknown spectra to discrete, fixed spectra of standards in a library. However, the inter-day or inter-laboratory variance in the abundance of each fragment in a spectrum is known to vary by $\pm 20\%$, so compounds with somewhat similar EI mass spectra, like many fentanyl analogs, can be difficult to distinguish using only the EI spectral comparison. The multivariate algorithm discussed in this presentation takes a more informed approach and uses an algorithm to effectively interpolate between replicate spectra and provide a continuously variable model of ion abundances for each compound in the database. The model explains most of the variance in replicate mass spectra and enables very confident mass spectral identifications.

A database containing approximately 57,000 replicate mass spectra of 76 fentanyl analogs was compiled from gas chromatography-electron ionization-mass spectrometer (GC/MS) data from 9 different laboratories by extracting every mass spectrum across the eluting chromatographic peaks of interest. The ion abundances for each spectrum were normalized to the base peak in each spectrum. As examples, nine compounds were chosen as known positives (KPs) for model building, and the remaining 75 analogs served as known negatives (KNs). The 20 most abundant ions were extracted, and the abbreviated spectra were randomly divided into training and testing sets. Twenty general linear regression models (GLM) were built for each compound by sequentially using the abundance of each ion as the dependent variable and the abundance of the 19 remaining ions as the independent variables. The models for each compound were then used to predict the ion abundances for various KPs and KNs. The predicted abundances were compared to the measured abundances using various similarity and dissimilarity metrics, like the Pearson product-moment correlation (PPMC) and mean absolute residual. Each metric was then used as a binary classifier to determine the true-positive and false-positive rates over a range of threshold values. These classifications were used to plot a receiver operating characteristic (ROC) curve from which we could calculate the area under the curve (AUC) to determine the strengths of each model.

PPMC values between the measured and predicted spectra of known positives of the selected drug models exceeded 0.9666 for the training and testing sets. Known negatives in the validation set typically had smaller PPMC values than the smallest PPMCs for known positives, resulting in AUCs of 0.999 or better in the ROC plots for binary classification. The residuals in the predictions for the known positives were typically improved by a factor of 3 over the traditional consensus approach. In short, the new algorithm outperforms existing algorithms for accurately identifying fentanyl analogs from their mass spectra.

This project was supported by a grant awarded by the National Institute of Justice, Office of Justice Programs, United States Department of Justice. The opinions, findings, and conclusions or recommendations expressed in this presentation are those of the authors and do not necessarily reflect the views of the Department of Justice.

General Linear Model, Mass Spectrometry, Fentanyl Analogs

B132 Extracted Volatiles from Cannabis Smoke: A Potential Source for the Determination of Detectable Exhalable Breath Components in Users

Katherine E. Zink, PhD, National Institute of Standards and Technology, Boulder, CO; Kavita M. Jeerage, PhD, National Institute of Standards and Technology, Boulder, CO; Tara M. Lovestead PhD, National Institute of Standards and Technology, Boulder, CO*

Learning Overview: This presentation will describe a novel method developed at NIST for the isolation, detection, and characterization of volatile compounds in cannabis smoke that may serve as exogenous markers of recent use in the exhaled breath of cannabis users for law enforcement, public health, and workplace safety.

Impact Statement: This project will provide evidence to support further development of a roadside cannabis breathalyzer, an instrument that so far has produced many challenges.

As medical and adult recreational cannabis continues to be legalized across the nation and the world, the need for a rapid roadside detection method to determine recent use is critical. A cannabis breathalyzer has become an intriguing option; in-lieu of blood sampling, the presence of 9 Δ -tetrahydrocannabinol (9 Δ -THC) in biological fluids does not provide an indication of last use. Frequent use can result in build-up of 9 Δ -THC in adipose tissue that may be released over time, even after sustained abstinence.¹ Furthermore, 9 Δ -THC detection in breath presents challenges due to its low volatility and low concentration.²

Cannabis plants have been examined for decades to document the natural products generated by plant metabolism.³ Most often, this work has been done by solvent extraction of solid plant material, and datasets have generated informative profiles of cannabis compounds. Similarly, volatile molecules from cannabis strains have been profiled for the forensic detection of cannabis by canines.⁴ To target detection of cannabis compounds that may be present in breath, this work aims primarily to characterize the volatile components of cannabis that survive combustion in a similar method that users employ while smoking.

An in-house apparatus was designed to burn dried plant samples, collect the volatilized components in the form of smoke, and condense them into both an aqueous fraction and an organic fraction. Flower samples from four hemp strains have been evaluated. The volatiles extracted from these smoke samples were analyzed using liquid chromatography-(LC-UV) and LC mass spectrometry (LC-MS) using a high-resolution instrument, an LTQ Velos Orbitrap (Thermo Fisher). The Orbitrap method measures their intact mass as well as their fragmentation patterns, which provide important structural information. Large datasets were uploaded to the Global Natural Products Social Molecular Networking database (GNPS), an online collection of over 200,000 fragmentation spectra from natural products, including plant compounds. Experimental spectra are compared to annotated spectra in the database both to identify known compounds as well as provide structural information for unknown compounds.

This approach to compound identification has indicated the presence of the cannabinoids 9 Δ -THC, cannabidiol (CBD), cannabigerol (CBG), and cannabinol (CBN) in four distinct types of hemp. Additionally, a terpene, nerolidol, has been detected in two of the four strains of hemp. Compounds detected across all samples are candidates for the consideration for the design of a cannabis breathalyzer.

B133 Gas Chromatography-Mass Spectrometry of Phencyclidine (PCP) Analogues

Alexandra Kuchinos, BS, Cedar Crest College, Allentown, PA; Thomas Brettell, PhD, Cedar Crest College, Allentown, PA; Lawrence Quarino, PhD, Cedar Crest College, Allentown, PA; Jennifer Bonetti, MS, Virginia Department of Forensic Sciences, Norfolk, VA*

Learning Overview: This presentation will report the chromatographic and mass spectrometric data for phencyclidine (PCP) and ten of its analogues on two gas chromatographic columns of different polarity.

Impact Statement: This presentation will impact the forensic community by reporting the mass spectral fragmentation patterns and characteristics of PCP and ten of its analogues as well as reporting the retention times (RTs) and linear retention indices (RIs) for these compounds.

Goal of Project: The goal of this project was to develop to a gas chromatographic-mass spectrometric method that would separate PCP and ten of its most common analogues and report the retention data (RTs and RIs) and mass spectral information.

Phencyclidine (PCP) and its analogues belong to a class of new psychoactive substances (NPSs) whose prevalence continues to rise. Though these analogues share similar chemical structures to illicit substances, slight modifications can produce unpredictable effects, and limited knowledge of their potential poses a serious threat. Rapid synthesis and distribution of these compounds severely complicates the critical task of analogue identification in forensic laboratories due to lack of reference materials and available standards. Additionally, isomeric distinction may be challenging or even impossible for certain analogues depending on the chosen instrumentation. Contribution to the analytical profile of PCP analogues is necessary so that forensic analysts have the essential resources to make accurate and efficient identifications. Gas chromatography-mass spectrometry (GC-MS) remains a reliable technique for analogue discrimination requiring limited sample preparation and can be optimized for reproducible analysis. In this work, GC-MS was implemented to simultaneously detect and identify PCP and ten of its most common analogues including 3-methoxyphencyclidine (3-MeO PCP), 3-Methoxyeticyclidine (3-MeO PCE), 4-methoxyphencyclidine (4-MeO PCP), diphenidine, methoexetamine (MXE), eticyclidine (PCE), 1-phenyl-N-propyl-cyclohexanamine (PCPr), tenocyclidine (TCP), rolicyclidine (PCPy), and methoxphenidine (MXP). Individual standards were first analyzed to compile their mass spectra, interpret and elucidate their fragmentation patterns, and confirm their identity. A mixture of these compounds was then prepared for analysis on two different column stationary phases of varying polarity, HP-1 MS and Rxi-5Sil MS. Both columns had the same configuration (30 m x 25 mm x 0.25 μ m). Split injection (25:1) was used for all analyses. Separation of up to ten standards was achieved, though baseline resolution of TCP and PCP was only attained on one column, the non-polar 100% dimethylpolysiloxane (HP-1 MS). Retention data including retention times and calculated linear retention indices showed good reproducibility ($CV \leq 0.1\%$) over the course of ten days for each column. Averages of these values were reported with their corresponding relative standard deviation for each analogue. Of the standards, 4-methoxyphencyclidine (4-MeO PCP) experienced degradation appearing to decrease with lowered inlet temperatures. The artifact peak could not be completely eliminated even with decreased inlet temperatures. The base peak for 4-MeO PCP tended to shift, likely influenced by the abundance of the degradation, and leading to varied ion intensities in the mass spectrum. While general fragmentation patterns were followed, all analogues produced distinct mass spectra capable of distinguishing all compounds studied. Supplementation of comprehensive data such as elucidation of mass spectral fragments and retention data (RT and RI) for a large set of PCP analogues will help bridge the gap between drug synthesis and identification by offering comparable reference material to aid in more productive forensic drug analysis and combat the challenges of NPS identification.

GC/MS, PCP, Retention Indices

B134 HPTLC Separation of Tryptamine Based Hallucinogens

Kelsey Patterson, BS, Cedar Crest College, Allentown, PA; Matthew Wood, PhD, Ocean County Sheriff's Department, Toms River, NJ; Jeanne Berk, PhD, Cedar Crest College, Allentown, PA; Thomas Brettell, PhD, Cedar Crest College, Allentown, PA*

Learning Overview: This presentation will report the evaluation of seven thin-layer chromatography (TLC) mobile phase systems to separate 12 natural and synthetic hallucinogenic tryptamines using high-performance thin-layer chromatography (HPTLC).

Impact Statement: This presentation will impact the forensic community by demonstrating that HPTLC can be a useful and viable alternative tool in the seized-drug analysis of natural and synthetic hallucinogenic tryptamines.

Goal of Project: The goal of this project was to evaluate TLC mobile phase systems to determine the optimum conditions for the separation of 12 natural and synthetic hallucinogenic tryptamines using HPTLC.

Traditional thin-layer chromatography (TLC) has been one of the analytical techniques used for the analysis of common hallucinogenic tryptamines for many years. However, novel psychoactive substances (NPSs) are constantly being synthesized and these compounds need to be incorporated into existing laboratory procedures. Using traditional TLC does not always provide a satisfactory level of sensitivity, resolution, or documentation to analyze all of these compounds, many of which may be closely related structural isomers/analogues. In this study high-performance thin-layer chromatography (HPTLC) was used to separate 12 tryptamine hallucinogens, including the commonly analyzed psilocybin, psilocin, and bufotenine. The other nine tryptamines included in the study were 4-acetoxy-N,N-dimethyltryptamine (4-AcO-DMT), 5-methoxy- α -methyltryptamine (5-MeO-AMT), 5-methoxy-N,N-diallyltryptamine (5-MeO-DALT), 5-methoxy-N,N-diisopropyltryptamine (5-MeO-DiPT), 5-methoxy-N-methyl-N-isopropyltryptamine (5-MeO-MiPT), N,N-diethyltryptamine (DET), N,N-dipropyltryptamine (DPT), N,N-dimethyltryptamine (DMT), and 12-methoxy-ibogamine (ibogaine). The visualization reagent p-dimethylaminobenzaldehyde (p-DMAB) was sprayed on each plate to derivatize the compounds so they could be more easily detected by the naked eye. Seven different mobile phase systems which included 100:1.5 methanol/ammonium hydroxide, 2:1:1 n-butanol/water/glacial acetic acid, 75:15:10 cyclohexane/toluene/diethylamine, 2:1 n-propanol/5% ammonium hydroxide, 4:1 chloroform/methanol, 75:10:15 methanol/glacial acetic acid/water, and 100:1.5 methanol/glacial acetic acid were investigated to determine which produced optimal separation for all the compounds. Six of these mobile phases were based on previous literature and one was developed from ratios and solvents of previously tested mobile phases. The mobile phases evaluated were considered successful based upon whether the compounds interacted with the mobile phase and migrated up the plate ($R_F > 0.1$), the number of pairs of compounds that could be resolved from each other ($R_s > 1$), reproducibility ($CV < 10\%$), and if the visualization reagent resulted in a visible color reaction. Out of the seven mobile phases, 100:1.5 methanol/ammonium hydroxide (mobile phase 1), 2:1:1 n-butanol/water/glacial acetic acid (mobile phase 2), and 100:1.5 methanol/glacial acetic acid (mobile phase 7) produced the most successful results. Mobile phases 1, 2, and 7 were able to provide R_F values that spanned the majority of the plate. These mobile phases also provided good resolution between almost all of the compounds. Although mobile phase 1 provided resolution between some of the tryptamines, the reproducibility of the R_F values was unsatisfactory compared to mobile phases 2 and 7. Taking both resolution and color into consideration, 66 pairs of tryptamines were compared. Mobile phase 2 was able to differentiate between 56 out of 66 possible comparisons between compounds and mobile phase 7 can differentiate between 60 pairs of compounds. Using either of these mobile phases in conjunction with p-DMAB shows promising results when trying to distinguish between psilocin, psilocybin, bufotenine, and 9 other tryptamine compounds. The results suggest that HPTLC is a suitable method for separating common tryptamine hallucinogens while incorporating adequate sensitivity, good resolution, along with providing proper documentation, and ecofriendly science.

HPTLC, Tryptamines, Hallucinogens

B135 Interpreting DNA Mixtures With Extreme Allele Overlap

Tim Kalafut, PhD, Sam Houston State University, Huntsville, TX; Jo-Anne Bright, PhD, Institute of Environmental Science and Research, Mt Albert, Auckland, New Zealand; Duncan Taylor, PhD, Forensic Science SA, Adelaide, SA, Australia*

Learning Overview: After attending this presentation, attendees will have a better understanding of the interpretation process and outcomes for mixtures where non-donors (H2 True) have a high level of allelic overlap with the true donors (H1 True).

Impact Statement: This presentation will impact the forensic science community by discussing appropriate ways to approach mixtures where there is a concern about the presence of non-donors that are related to donors.

There is considerable interest in the effect of relatives on the interpretation of mixed forensic DNA samples using probabilistic genotyping. Recent examples of interest are found in the NISTIR 8351 draft report and a promised report by the Brooklyn Defender Services.^{1,2} There are two situations where it would be helpful to differentiate: 1) where a relative of a true donor or donors is falsely considered to be a donor to the mixture, and 2) where the true donors are themselves related.

It is known that relatives of true donors have a higher rate of adventitious support than unrelated false donors. It is also known that the high degree of allelic overlap by relatedness of the true donors can make assignment of number of contributors (NoC) and deconvolution difficult. This was noted at least 30 years ago by Evett, yet there is a call “to bring these troubling analytical findings out of the shadows and issue a clear public warning about the unconscionable risk of falsely including a non-contributor relative in a DNA analysis.”^{2,3}

Theory suggests that mixtures of two relatives (dyads), although showing a degree of allelic overlap, should not present extreme difficulties. Lin et al. showed that mixtures of two parents and a child did present such difficulties.⁴ We hypothesize that no dyads should present extreme difficulties to assignment of NoC or deconvolution but that some triads will do so. Specifically, we hypothesize that PPC, PCC, SSS mixtures will present difficulty.

We present here the results of 177 H1 true, 42,419 H2 true unrelated, and 14,053 H2 true related tests on in-vitro constructed mixtures and 1,150 H1, 128,850 H2 true unrelated, and 50,300 H2 true related tests on in-silico constructed mixtures of dyads and triads. No dyads presented difficulty for NoC assignment or deconvolution. We detected no instances of false exclusion or support in our in-vitro set. The in-silico set showed a considerable rate of false support especially for the related non-donors. The likelihood ratios (LRs) for this false support were of considerable magnitude. There was a considerable difference in template with the in-vitro samples having much higher template.

All balanced triads in our in-vitro set presented difficulty in the assignment of NoC and deconvolution. The most likely outcome of an uninformed examination of such a triad is an incorrect assignment of NoC = 2. This provokes false exclusion but does not appear to provoke false support. When the balanced triads were examined as NoC = 3, the deconvolution struggled to find a third contributor. This is expected, as three equally contributing full siblings look like a 2:1 mixture of unrelated persons. Due to an incorrectly low assigned proportion for a third donor, both false exclusionary LR and false support for related and unrelated profiles were obtained. When allele overlap to the mixture is considered for false related inclusions, the LR is often not intuitive for such high allele sharing.

The work described here explored ways to improve the deconvolution and minimize false exclusions and false inclusionary support for unrelated and related donors. The effects of conditioning profiles and use of pre-determined donor proportions was examined (Mx prior). Together, these strategies show an improvement in the LR for donors and decrease false support for both related and unrelated nondonors. This shows that the deconvolution and LR calculation should not be done in a vacuum. Relevant case information is necessary to minimize both false exclusions and false inclusionary support. It is recommended that references from all relatives, especially first order relatives be tested if there is concern about close relatives in a case.

B136 The Effect of Pull-Up on the Allele Peak Heights and the Weights of Genotypes for Minor Donors

Damani Johnson, BS, Sam Houston State University, Huntsville, TX; Tim Kalafut, PhD, Sam Houston State University, Huntsville, TX*

Learning Overview: After attending this presentation, attendees will have a better understanding of how spectral pull-up can affect low-level data peaks and the subsequent genotype weights used to calculate a probabilistic likelihood ratios (LR).

Impact Statement: This presentation will impact the forensic science community by discussing a method that has the potential to give more weight to the ground truth genotypes of trace donors in a mixture.

Capillary Electrophoresis of fluorescently labeled PCR products is the most common form of forensic DNA analysis in crime laboratories today. A fluorescent tag is applied to the PCR product, and after traveling through the capillary, a laser is used to excite the tag and a camera reads the signal that is produced and measured as relative fluorescence units (rfu). One issue that needs to be addressed is that these tags do not fluoresce at a single wavelength, and there is spectral overlap between them. An attempt to compensate for this is done by the use of a spectral calibration where an algorithm is applied that is intended to correct for the overlap.

When the fluorescence signal is strong, such as for a sample with a high amount of DNA, it is common to reach the limit of this spectral correction. This results in a signal from a PCR product in one channel (primary pull-up peak) causing so-called “pull-up” peaks in one of the other dye channels. The primary pull-up peaks in the dye channel of the PCR product and the resultant pull-up peaks in the affected channel are closely correlated in time. If the pull-up is strong enough, these artifactual pull-up peaks can be sized like an actual PCR product signal, as they can be above the analytical threshold. Often the pull-up peaks do not correspond to any peak on the ladder and are relatively easy to identify as artifactual in nature. Occasionally, due to the lay out of the loci in the PCR kit, the pull-up peaks can be “on ladder” and show all the characteristics of an actual PCR product peak.

This can complicate the deconvolution of major/minor mixtures if the height of a minor donor peak is taller than expected due to the summation of the actual minor donor PCR product rfu and the additional rfu from the pull-up effect. If a pull-up peak is added to a stutter peak, it can result in a stutter PCR product to be labeled as an allele because of the additional pull-up rfu. If an unshared peak of a minor donor is enhanced by the pull-up effect, the minor genotype might appear to be a homozygote, when really the sister allele is masked by an allele of the major donor.

The OSIRIS software program (NIH) has some ability to correct for pull-up when a pattern is recognized across channels. ArmedXpert™ (NicheVision, LLC) has the ability to pull the corrected value out of the data, and then use that value in the preparation of data tables. This allows for a corrected peak height to be used in STRmix™ (ESR, Ltd) for probabilistic genotyping. We prepared mixtures of major and minor donors using the Investigator 24plex QS kit (QIAGEN) where primary pull-up peaks from the major donor correspond to actual peaks from the minor donor, resulting in a higher rfu value. We investigated if using the corrected rfu value for the minor peak (subtracting out the pull-up contribution) gave more weight to the known genotype of the minor donor and made the LR more informative (larger) for those affected loci.

Pull-Up Peaks, Genotype Weights, Corrected RFU

B137 The Detection and Analysis of DNA Mixtures With the MiSeq® FGx™

Rachel Houston, PhD, Sam Houston State University, Huntsville, TX; Timothy Kalafut, PhD, Sam Houston State University, Huntsville, TX; Ryan Gutierrez, PhD, Sam Houston State University, Huntsville, TX*

Learning Overview: This presentation will address the advantages and disadvantages of implementing Next Generation Sequencing (NGS) to detect and deconvolute DNA mixtures.

Impact Statement: Continued research and evaluation of NGS platforms for forensic casework will promote further adoption of this technology in operational crime labs.

It is often necessary to process samples that contain biological material from more than one donor in forensic cases. This can include evidence from sources such as sexual assault kits to property crime. Mixed samples are variable and can have limited input samples and various combinations from major and minor donors. To successfully process these samples, it is necessary to identify the presence of low-level mixture alleles as well as the number of mixture contributors before further interpretation.

NGS may help analysts by providing distinct advantages in allele recovery leading to better estimations for the number of contributors (NoC), including multiple male and female donors. In addition, NGS may provide more confidence in relation to NoD due to the potential for different isoalleles between donors. This research analyzed mock forensic and mixture samples with the ForenSeq™ DNA Signature Prep kit Primer Set A for sequencing on the MiSeq FGx®. In addition, all samples were compared with complimentary amplification using the GlobalFiler™ Kit for capillary electrophoresis. Metrics tested for both chemistries included concordance, limits of detection, and mixture analysis. Data analysis for mixture samples was completed with the MixtureAce™ plug-in and ArmedXpert™ software. NGS offered distinct advantages in determining the numbers of male contributors, limits of detection, and iso-allele heterozygosity but suffered from increased variability in stutter and peak height ratios compared to capillary electrophoresis.

Any new forensic techniques that are implemented must be able to handle the challenges of mixed forensic samples. NGS offers advantages over capillary electrophoresis in amplicon multiplexing and degraded sample analysis. However, advantages with mixture samples will rely heavily on the advancement of user-friendly analysis software to supplant current probabilistic genotyping pipelines that are available for use with capillary electrophoresis data.

Next Generation Sequencing (NGS), Mixture Analysis, Isoalleles

B138 Enhanced Mixture Interpretation With Macrohaplotypes Based on Long-Read DNA Sequencing

Jianye Ge, PhD, University of North Texas Health Science Center, Fort Worth, TX; Jonathan King, MS, University of North Texas Health Science Center, Fort Worth, TX; Sammed Mandape, MS, University of North Texas Health Science Center, Fort Worth, TX; Bruce Budowle, PhD, University of North Texas Health Science Center, Fort Worth, TX*

Learning Overview: After attending this presentation, attendees will have a better understanding of the latest development on long-read DNA sequencing technologies, how the macrohaplotypes are designed based on the long-read data, and how these macrohaplotypes can be used to enhance DNA mixture interpretation.

Impact Statement: This presentation will impact the forensic science community by providing a new set of forensic markers that substantially outperform CODIS STRs for mixture interpretation, particularly for mixtures with a high number of contributors.

Deconvoluting mixture samples is one of the most challenging problems confronting DNA forensic laboratories. Efforts have been made to provide solutions regarding mixture interpretation. The probabilistic interpretation of Short Tandem Repeat (STR) profiles has increased the number of complex mixtures that can be analyzed. A portion of complex mixture profiles, particularly for mixtures with a high number of contributors, are still being deemed uninterpretable. Novel forensic markers, such as Single Nucleotide Variants (SNV) and microhaplotypes, also have been proposed to allow for better mixture deconvolution. However, these markers have both a lower discrimination power compared with STRs and are not compatible with CODIS or other national DNA databanks worldwide. The short-read sequencing (SRS) technologies can facilitate mixture interpretation by identifying intra-allelic variations within STRs. Unfortunately, the short size of the amplicons containing STR markers and sequence reads limit the alleles that can be attained per STR. The latest long-read sequencing (LRS) technologies can overcome this limitation in some samples in which larger DNA fragments (including both STRs and SNVs) with definitive phasing are available.

Based on the LRS technologies, this study developed a novel CODIS compatible forensic marker, called a macrohaplotype, which combines a CODIS STR and flanking variants to offer extremely high number of haplotypes and hence very high discrimination power per marker. The macrohaplotype will substantially improve mixture interpretation capabilities. Based on publicly accessible data, a panel of 20 macrohaplotypes with sizes of ~8k bp and the maximum high discrimination powers were designed. The statistical evaluation demonstrates that these macrohaplotypes substantially outperform CODIS STRs for mixture interpretation, particularly for mixtures with a high number of contributors, as well as other forensic applications. Based on these results, efforts should be undertaken to build a complete workflow, both wet-lab and bioinformatics, to precisely call the variants and generate the macrohaplotypes based on the LRS technologies.

Macrohaplotype, Long-Read DNA Sequencing, DNA Mixture

B139 Results From a Probabilistic Genotyping Software for the Continuous Interpretation of Next Generation Sequencing (NGS) Autosomal Short Tandem Repeat (aSTR) Mixtures

Kevin Cheng, MSc*, Institute of Environmental Science and Research (ESR), Auckland, Auckland, New Zealand and The University of Auckland, Auckland, New Zealand; Jo-Anne Bright, PhD, Institute of Environmental Science and Research (ESR), Auckland, New Zealand; James Curran, PhD, The University of Auckland, Auckland, New Zealand; John Buckleton, DS, Institute of Environmental Science and Research (ESR), Auckland, Auckland, New Zealand and The University of Auckland, Auckland, New Zealand

Learning Overview: The aim of this presentation is to show the deconvolution results of NGS aSTR mixtures using published biological models implemented into a prototype probabilistic genotyping software.

Impact Statement: This presentation will impact the forensic science community by demonstrating a possible probabilistic genotyping solution for the interpretation of mixtures generated using sequencing technology.

There has been increasing interest from forensic laboratories to evaluate the use of next-generation sequencing (NGS) technologies or massive parallel sequencing (MPS) technologies. For example, the use of sequencing technology for genetic genealogy, missing-persons identification, or paternity testing.¹ One particular area of interest is the use of this technology to interpret autosomal short tandem repeats (aSTRs) in forensic mixtures. This is because, unlike contemporary capillary-electrophoresis (CE) methodologies for the analysis of aSTRs, NGS can detect sequence variations in a stretch of STRs. Several publications have demonstrated that this sequence-level information can increase the power of discrimination in single-source profiles.

Over the past few years, there have also been a number of publications describing the behavior of STRs in NGS-DNA profiles including publications around potential quantitative models to describe an expected NGS-DNA profile.²⁻²² This increasing body of knowledge has facilitated the development of probabilistic genotyping solutions for the interpretation of aSTR mixtures generated using sequencing technologies. Using the biological models described by Cheng et al., models that were adapted from Bright et al. and Vilsen et al., a prototype probabilistic genotyping solution was created.^{10,22,23}

This presentation will present the results of the continuous interpretation of aSTR mixtures that were generated using a sequencing technology with this prototype probabilistic genotyping solution. This will include the assignment of likelihood ratios (LRs) to known donors and non-donors to more than one-hundred DNA profiles that were experimentally designed to contain up to four-contributors. The results demonstrate the behavior of the LRs, the changes in the LR when a known donor to the mixture is assumed, and the effect of under- or over-assigning the number of contributors to a mixture. The presentation will also describe some of the limitations in this prototype solution such as degradation and the assignment of the number of contributors, and possible solutions to address these limitations.

NGS, Probabilistic Genotyping, Mixture Interpretation

B140 The Recovery of Probative DNA Information From Complex Mixtures Involving First-Degree Relatives or Marginally Detectable Minor Donors Using Direct Single Cell Subsampling (DSCS) and Probabilistic Genotyping (PG)

Kaitlin Huffman, MS, University of Central Florida, Orlando, FL; Erin Hanson, PhD, University of Central Florida, Orlando, FL; Jack Ballantyne, PhD, University of Central Florida, Orlando, FL*

Learning Overview: Attendees will learn of a DNA mixture deconvolution tool that relies on subsampling of individual or few cells by physical capture, subsequent high sensitivity DNA typing and quantitative computer interpretation to extricate probative single source and mixed DNA genotypes.

Impact Statement: The DSCS approach could permit forensic scientists to analyze and recover probative evidentiary information from complex mixtures not only from those with excessive overlapping alleles such as those seen with related individuals, but also from marginally detectable minor donors.

DNA mixtures are one of the more difficult sources of biological evidence to deconvolute and interpret. This is particularly troublesome as current STR typing kits have increased sensitivity increasing the prevalence in which DNA mixtures are seen. Probabilistic genotyping (PG) has greatly aided in mixture analysis. However, even with PG, standard bulk mixture approaches do not always result in probative results.

One such instance is a mixture in which there is an extreme minor contributor resulting in a virtually undetectable donor even when large quantities of DNA are present. An example of this is a 2-person mixture where a weight ratio of ~1:50 is seen. Furthermore, mixtures with significant allele overlap can lead to inaccuracy in determining the number of donors within a mixture potentially resulting in missed contributors. This can notably be seen with mixtures comprising of related individuals which also increases the probability of false inclusions from other non-contributor relatives.

To aid in mixture deconvolution and genotype information loss seen in these especially complex mixture scenarios, a simple micromanipulation technique referred to as Direct Single Cell Subsampling (DSCS) has been applied. DSCS allows for physical separation of subsets of cells (typically 1-5 cells) from mixtures prior to DNA typing. Low template DNA techniques (LTDNA) and probabilistic genotyping validated for use with few cells was applied. PG software systems, STRmix™ and EuroForMix, were utilized to compare the information loss (in bans) of the standard 'bulk' mixtures to that of the contributor single source reference profiles. Comparison to the analyzed DSCS samples obtained indicated instances in which the DSCS method resulted in a substantial gain of probative information.

The feasibility of this approach will be presented firstly using a complex two-person 1:51 buccal cell mixture in which one donor is nearly undetectable. By taking multiple 5-cell samplings, the probability of obtaining genetic information for that minor donor is increased. Instances in which the minor donor is retrieved results in new mini mixtures with a 1:4 weight ratio and a significant increase in LR's. This approach will further be applied to mixtures comprised of donors, some of whom are first degree relatives.

Mixtures, Micromanipulation, Single Cells

B141 Automated Familial Search Using a Probabilistic Genotype Database

Matthew Legler, BS, Cybergenetics, Pittsburgh, PA; Kevin Miller, PhD, Hamilton Robotics, Reno, NV; Mark Perlin, PhD, MD, Cybergenetics, Pittsburgh, PA; Garrett Sugimoto, MS, Kern Regional Crime Laboratory, Bakersfield, CA*

Learning Overview: To evaluate a workflow for the automatic development and comparison of probabilistic genotypes from complex evidence for the purpose of inferring a perpetrator genotype that may not be previously known.

Impact Statement: Forensic laboratories may use local DNA databases to develop automated familial searching workflows that yield impactful increases in investigative leads for law enforcement.

Familial searching can find suspects by searching a DNA database that contains their relatives. Genotypes from people who contributed their DNA to crime scene evidence are compared with reference profiles in the DNA database. Even when the contributor genotypes are not in the database, genetic similarities to contributor relatives who are in the database can help find investigative leads.

Earlier familial search strategies were based upon partial allele matches and simple allele inclusion statistics. Cybergenetics TrueAllele® technology provides a more sophisticated approach using information-preserving probabilistic genotypes, and likelihood ratio (LR) information.

The TrueAllele database automatically generates probabilistic familial genotypes from reference genotypes, using them for automated comparison with probabilistic genotypes from complex evidence. LR match statistics are calculated automatically. This general computer method allows any DNA evidence (e.g., mixtures of up to ten contributors) to be easily compared with automatically inferred familial genotypes.

The Kern Regional Crime Laboratory (KRCL) conducted three validation studies prior to deploying their information driven automated TrueAllele familial search system.

An *Accuracy Study* demonstrated the software can provide informative match statistics to evidence items when compared to inferred kinship genotypes from relatives of true contributors. DNA profiles from 26 individuals from four different family trees were typed and included in the accuracy study. There were 676 pairwise comparisons made for each assumed genotype group (PCH, SIB and HAS) for a total of more than 2,000 comparisons. The evidence to parent/child (EVI-PCH) and evidence to sibling (EVI-SIB) searches were shown to be informative.

A *Sensitivity and Specificity Study* examined LR comparison of PCH and SIB inferred genotypes when the mixture weight of the true contributor's DNA varied. Thirty-one single source profiles and 36 mixture samples (2 to 5 contributors) were compared to the inferred genotypes of 44 single source known reference profiles. The EVI-PCH searches were more specific for inferred genotypes of closely related relatives of known contributors. The EVI-SIB searches were more sensitive for inferred genotypes of more distant relatives of known contributors. The EVI-PCH false positive rate was ~0.02% (1/6512), with $\log(\text{LR}) = 2.117$ ban. The EVI-SIB false positive rate was ~0.25% (16/6512), having $\log(\text{LR})$ values from ~2.0 to 4.5 ban.

A *Known and Nonprobative Evidence Study* compared kinship inferred genotypes in a larger database comparable to the KRCL's local DNA database. This study included known reference samples from known matches, used to compare to EVI profiles in the laboratory's local database of over 5,000 profiles. The EVI-PCH and EVI-SIB searches accurately matched to the inferred genotypes of known contributors, as well as the inferred genotypes of the true contributor's son. The EVI-PCH comparisons were more specific than EVI-SIB, resulting in fewer false positives. EVI-PCH search did not result in any match scores above 1,000, while EVI-SIB search gave 25 false positives with match scores greater than 1,000. The false positive rate (for a $\log(\text{LR}) \geq 2$) was ~.0001% for EVI-PCH searches, and ~.0006% for EVI-SIB searches.

Familial search is a powerful tool for finding investigative leads from DNA evidence when other avenues have not produced suspects. The KRCL has conducted validation studies and developed protocols to bring automated TrueAllele familial searching into routine forensic practice. This forensic science advance can make more identification information available to criminal justice by reusing data from existing DNA evidence.

B142 Using DNA Mixtures for Relationship Inference and Missing Persons Identification

Maarten Kruijver, PhD, Institute of Environmental Science and Research, Auckland, Solid, New Zealand*

Learning Overview: After attending this presentation, attendees will have a better understanding of how probabilistic genotyping can aid missing persons identifications.

Impact Statement: This presentation will impact the forensic science community by explaining novel methods at the intersection of probabilistic genotyping and relationship inference.

Recent theoretical advances in probabilistic genotyping enable relationship inference when one or more of the observed DNA profiles are mixed or low-level.¹ This bridges the fields of probabilistic genotyping and kinship testing unlocking new applications in both fields. This presentation focuses on how probabilistic genotyping can be used to draw inferences about blood relationships and discusses applications in missing persons identification.

In missing person cases, DNA may be used to establish a link between unidentified remains and a missing person. When a preliminary link is not already available from non-genetic evidence, a DNA database search can be used to compare a reference of the missing person to profiles obtained from unidentified remains. These cases can be complicated if a reference profile from the missing person is not (yet) available.

Exploiting theory from probabilistic genotyping, the presentation explains how a list of weighted genotypes can be obtained for the missing person based on other relevant DNA profiles. These profiles may be mixed DNA profiles to which the missing person is a contributor but also include any profiles to which close relatives of the missing person are a contributor. These weighted genotypes can be used for database searching combining all available DNA data just like how mixture deconvolutions can be used for database searching in criminal casework.² The use of weighted genotypes makes it possible to compare large numbers of profiles at little computational cost. With modern multiplexes, the power to identify a person based on DNA of their relatives can be substantial. It is explained how case-specific false positive rates and true positive rates can be estimated using simulation. The simulation results can be used to evaluate whether the DNA data is sufficiently informative for identifications or that further data is needed.

The presentation emphasizes how theory from probabilistic genotyping has further applications besides criminal casework.

Probabilistic Genotyping, Relationship Testing, DNA Mixture

B143 “Essentially, All Models Are Wrong, but Some Are Useful”—A Comparison of Likelihood Ratios Obtained From EuroForMix and STRmix™

Kevin Cheng, MSc*, Institute of Environmental Science and Research (ESR), Auckland, New Zealand and The University of Auckland, Auckland, New Zealand; Øyvind Bleka, PhD, Forensic Genetics Research Group, Oslo University Hospital, Oslo, Norway; Peter Gill, PhD, Forensic Genetics Research Group, Oslo University Hospital, Oslo, Norway and Department of Clinical Medicine, University of Oslo, Oslo, Norway; James Curran PhD, The University of Auckland, Auckland, New Zealand; Jo-Anne Bright PhD, Institute of Environmental Science and Research (ESR), Auckland, New Zealand; Duncan Taylor, PhD, Forensic Science SA, Adelaide, South Australia, Australia and School of Biological Sciences, Flinders University, Adelaide, South Australia, Australia; John Buckleton, DSc, Institute of Environmental Science and Research (ESR), Auckland, New Zealand and The University of Auckland, Auckland, New Zealand

Learning Overview: The aim of this presentation is to show the comparison of likelihood ratios obtained between two probabilistic genotyping software. Similarities and differences between probabilistic genotyping software were assessed with single-source profiles and 129 mixtures.

Impact Statement: This presentation will impact the forensic science community by demonstrating that even though there are differences between the software both can be useful in assigning a likelihood ratio (LR). The inclusion of two sets of developers as collaborators and developers within this study should alleviate the concern that the work will be biased towards a single model and provide an in-depth understanding of the two software.

The British statistician, George Box, has been famously quoted as saying “Essentially, all models are wrong, but some are useful.” By saying that “all models are wrong” is to say that every model makes some fundamental assumptions about reality, no model can ever hope to cover all the intricacies of a real-world system.¹ This is applicable to all probabilistic genotyping (PG) software used to assist with the interpretation of forensic DNA profiles, where there are many modelling assumptions made about the interpretation of forensic DNA profiles. With a good understanding of each software, the differences arising from these assumptions can be predicted; and in some cases, software options or workarounds allow these differences to be minimized.

Although making these assumptions, or simplifications of reality, means that the models are “wrong” they can be very useful for better understanding of what is being modelled and predicting the outcome given certain inputs. The use of models within PG software allows forensic practitioners to evaluate DNA profiles and assign LR to a pair of propositions. The question is then whether the LR from different PG software are “equally reliable” or “equally useful.”

It is known that different models implemented in different software can produce divergent results. This thinking is reflected in the 2016 PCAST (President’s Council of Advisors on Science and Technology) report, where the authors called for (amongst other things) an investigation into “Under what circumstances – and why – does the method produce results (random inclusion probabilities) that differ substantially from those produced by other methods?”² This presentation aims to summarize the results from a comparison of LR obtained from the interpretation of more than 120 PROVEDIt profiles using two probabilistic genotyping software – EuroForMix and STRmix™.^{3,4} The results from both software show similar LR behavior, suggesting that even though the models in the two software are different, both can be useful in assigning an LR. Any difference in the assigned LR between the software were investigated to try and identify the driving factor(s). This body of work was carried out concurrently with the independent comparison work published by Rimen et al. and reinforces their findings.⁵

B144 Peeling Away Uncertainty: A Probabilistic Approach to DNA Mixture Deconvolution

*William Allan MS1, Hajara Chaudhry MS2, John Donahue MA3, Dr Mark Perlin PhD, MD, PhD1, Dr Mark Wilson PhD2
Cybergenetics, Pittsburgh, PA, USA. 2George Mason University, Fairfax, VA, USA. 3Beaufort County Sheriff's Office, Beaufort, SC, USA*

Learning Overview: After attending this presentation, attendees will understand how genotype conditioning improves DNA mixture separation, decreases genotype uncertainty, and increases DNA match information.

Impact Statement: This presentation impacts the forensic science community by describing how the genotype conditioning method increases the identification information that can be obtained from complex DNA mixtures.

Complex mixtures contain DNA from multiple contributors in differing amounts. Unlike older manual methods, probabilistic genotyping (PG) can use all of the peak data to separate the DNA contributors out of these mixtures into their component genotypes. Once the genotypes are inferred, they are compared to reference genotypes (relative to population allele frequencies) to calculate likelihood ratio (LR) match statistics. These statistics can be inclusionary or exclusionary.

Genotype comparison LR values scale with inferred genotype certainty, where more definite genotypes show higher probability allele pair possibilities. More definite genotypes lead to larger (i.e., more informative) match statistics, whether inclusionary or exclusionary.

Uncertainty in the inferred genotypes – seen as a diffuse allele pair probability distribution – reduces this match information. Genotype uncertainty can be due to incomplete separation of the DNA contributors, low DNA amounts, or biological relatedness between contributors. More genotype uncertainty leads to less LR information. Therefore, identification information can be increased by reducing genotype uncertainty.

Genotype conditioning, or ‘peeling’, assumes a statistically established contributor genotype in genotype inference. This conditioning ‘locks down’ a contributor genotype, focusing the inference on the other unknown contributor genotypes. Conditioning can improve the genotype mixture separation, reducing uncertainty in the other genotypes, and increasing match information.

This study demonstrates the utility of genotype conditioning using the TrueAllele® PG system. Mixture samples (genotypes and their amounts) were randomly designed. Two, three, four and five DNA contributors were examined. Initial computer processing established the most informative DNA contributors. Subsequent computer runs used these statistically established genotypes to reduce uncertainty in the remaining unknown genotypes. Multiple rounds of processing ‘peeled away’ the unknown contributor genotypes until one remained. Assuming all contributor genotypes as known gave highly accurate contributor mixture weights.

Inferred genotypes were compared with 70 references to calculate LR match statistics. The log(LR) information increased linearly with contributor DNA amount, until reaching a maximal information plateau for major contributors.

Genotype conditioning improved separation for overlapping contributors, overall doubling their match information. For example, a five-contributor mixture contained two 11% components. Initially, the LRs for these overlapping contributors were in the thousands. Peeling these contributors away from the major contributors increased their LR values into the billions, while peeling the contributors away from each other increased the LRs to almost a quintillion.

An adjudicated quintuple homicide case demonstrated how genotype conditioning works to support criminal justice. Prosecutors used a probative five-person mixture sample, taken from a spot of blood on a garage floor, to establish victim family members’ presence at a suspect’s home. The forensic question was to determine which family members left their DNA in the blood spot. While initial computer results were informative, more analysis could be done.

Through multiple rounds of genotype conditioning, TrueAllele separated the garage floor mixture into component family member genotypes. Peeling away DNA contributors statistically showed the presence of both parents, their children, and another relative. Conditioning also showed that another family member, whose DNA was not in the evidence, was statistically excluded from the mixture. While family allele sharing had initially indicated an inclusionary match statistic, genotype peeling factored away genotypes of relatives to show her DNA was not in the mixture.

This presentation demonstrates both the laboratory and real-world utility of genotype conditioning, and how the method reduces DNA mixture uncertainty by increasing information.

Genotype Conditioning, Peeling, Mixture Deconvolution

B145 How Forensic Genetic Genealogy (FGG) Is Supporting the Combined DNA Index System (CODIS) and the Criminal Justice System

Colleen Fitzpatrick PhD, Identifinders International LLC, Fountain Valley, CA*

Learning Overview: After attending this presentation, attendees will have a better understanding of how Forensic Genetic Genealogy (FGG) supports conventional means of human identification through CODIS.

Impact Statement: This presentation will impact the forensic science community by describing the overlap and compatibility of FGG identification methods with those of CODIS.

CODIS has been the backbone of human identification for 30 years and will continue to be the legal form of human identification for the foreseeable future. In the meantime, Forensic Genetic Genealogy (FGG) has moved from a miracle cure for the common cold case to its recognition as a practical tool that can be used to generate investigative leads.

Due to the broader reach of crowd-sourced data, FGG is helping to identify perpetrators of decades-old cold cases that have not achieved CODIS hits; unlike CODIS, FGG does not require an offender to be in the database. Consequently, FGG is often the only means to identify offenders who do not otherwise have a criminal record, as well as offenders who died before CODIS was in place.

Even if an individual has committed other offenses, however, there are still reasons why he may not be in CODIS yet may be identified through FGG. States vary widely on the type of crimes for which DNA collection is required and when that collection can take place; only a few states practice familial searching. There have also been lapses in the criminal justice system where “lawfully owed DNA” should have been collected but was not.

FGG benefit CODIS in other ways. FGG has shown useful to provide exclusions via target testing and information on ethno-ancestry and phenotype, and to identify witnesses using crime scene DNA that is ineligible for CODIS upload. It has also been used successfully to identify unidentified remains where family members were not in the CODIS Missing Persons Database.

There are additional relevant comparisons that can be made between genetic genealogy in general, FGG in particular, and CODIS, that draw a larger picture of the public’s attitude towards the criminal justice system. While the expansion of DNA collection laws and the use of familial searching has caused push-back on the side of privacy versus public safety, commercial Direct-to-Consumer DNA testing company databases have grown to be enormous in size, backed only by testing company privacy policies and terms of service agreements that can change unilaterally and without notice. Ironically, CODIS has approximately 20 million entries from convicted offenders and arrestees while Direct-to-Consumer (DTC) DNA testing databases have topped about 40 million entries. Of the approximately 1.4M GEDmatch users, only about 400,000 have opted-in to allow law enforcement use of their data.

This presentation explores how FGG supports CODIS and the criminal justice system, through a draft survey of FGG casework that has provided insight into the synergy between the two methodologies. The presentation briefly mentions issues with the use of crowd-sourced DTC consumer DNA data for forensic applications, and ends with a discussion on what the future holds for FGG as it continues to develop as a game-changing investigative tool.

FGG, CODIS, DNA

B146 Development and Implementation of Forensic Genealogy Casework Acceptance Criteria and Testing Guidelines and Their Impact on Developing Valuable High-Density SNP Datafiles.

Robert Bever, PhD, Bode Technology, Lorton, VA; Teresa Vreeland, BS, Bode Technology, Lorton, VA*

Learning Overview: Attendees will learn how to develop casework acceptance criteria for forensic genealogy casework and how the acceptance criteria impact the ability to generate valuable high-density SNP datafiles.

Impact Statement: The presentation will impact the forensic community by demonstrating the value of establishing acceptance criteria for forensic genealogy casework. It will also provide data that demonstrates that low quantity and poor-quality DNA can generate valuable SNP datafiles that can be utilized in forensic genealogy investigations.

Developing a casework acceptance criteria is particularly important for forensic genetic genealogy (FGG) casework due to the age, low quality, and low amount of the evidentiary material associated with cold casework evidence. Therefore, to efficiently process criminal casework and conserve the evidence samples, an acceptance criteria was developed for FGG casework to be processed via micro-array or genomic sequence analysis. The acceptance criteria were established associated with the amount of DNA. Varying amounts of DNA (100 ng to 0.25 ng) extracted from each sample type were analyzed using either the Illumina GSA V2 chip or Illumina NovaSeq 6000 Genome Sequencing workflow to produce high density SNP datafiles to search for matches in the third-party databases. The results indicate that valuable high-density SNP datafiles with call rates > 60% generated from either microarray analysis or genomic sequence analysis can be produced from DNA templates as low as 0.25 ng from blood and 2 ng from sperm. Genomic testing guidelines were developed based on the Degradation Index (DI), to decide whether to process the evidentiary DNA using micro-array analysis or genome sequencing. DNA was degraded from a DI of 1.0 to >20 and then processed via micro-array or genome sequence analysis. DNA degraded to DI of > 6.0 and analyzed via microarrays produced high density SNP files with failed call rates 60% when the datafile was generated by genome sequencing; therefore, the Degradation Index of 6.0 was used as the testing guideline metric to decide whether to process a sample by micro-array or genome sequencing. The acceptance criteria and testing guidelines were further validated by demonstrating the high-density SNP datafiles with call rates > 60% could be uploaded into GEDmatch to search and identify reliable matches with direct-to-consumer datafiles based on shared centimorgan regions of similar chromosomes. These results served as the criterion for developing initial acceptance criteria for FGG casework. The fore-mentioned casework criteria were used as guidelines to accept forensic genealogy casework, and the casework evidence samples were processed to develop high-density SNP datafiles to upload into GEDmatch or Family Tree DNA(FTDNA). Using casework blood samples with a minimal acceptance criteria of 0.5 ng DNA, over 90 % of blood casework samples produced valuable SNP datafiles with call rates >60% that could be successfully uploaded to third party databases and produce reliable matches that share at least 20 cM between the experimental datafile and direct to consumer datafiles. Similar pass rates are observed using DNA from spermatocytes and bone evidence samples. Pass rates were slightly higher from microarray case work then genomic sequencing analysis. Analysis of 170 casework samples demonstrate that DNA samples with 1.0 ng DNA and degradation indices >10 did generate valuable SNP datafiles with call rates >60% and capable of identifying valuable matches in the third-party databases. The observation that useful SNP datafiles can be generated from low quantity or low-quality DNA indicate the importance of establishing casework acceptance criteria and genome testing guidelines.

Forensic Genealogy, SNPs, Case Acceptance Criteria

B147 Internal Validation of the ForenSeq™ Kintelligence Kit for Application to Forensic Genetic Genealogy Cases

Michelle Peck, MFS, Signature Science, Charlottesville, VA; Stephen Turner, PhD, Signature Science, Charlottesville, VA; V. Peter Nagraj, MS, Signature Science, Charlottesville, VA; David Russell, MS, Signature Science, Charlottesville, VA; Jessica Bouchet, BS, Signature Science, Charlottesville, VA; Amy Holmes, PhD, Signature Science, Charlottesville, VA; Rachel Houston, PhD, Sam Houston State University, Huntsville, TX; Jennifer Snedeker, BS, Sam Houston State University, Huntsville, TX; Carmen Reedy, PhD, Signature Science, Charlottesville, VA; Christina Neal, MS, Signature Science, Charlottesville, VA*

Learning Overview: After attending this presentation, attendees will understand the performance of the ForenSeq Kintelligence Kit in an internal validation, its compatibility with challenging forensic samples, and how it can be applied to forensic genetic genealogy (FGG) cases.

Impact Statement: This presentation will impact the forensic science community by demonstrating how a laboratory can validate the ForenSeq Kintelligence Kit and implement it for forensic genetic genealogy cases.

The ForenSeq Kintelligence Kit (Verogen), a targeted amplification approach for SNP genotyping, was specifically designed for forensic genetic genealogy cases.^{1,2} The design took into consideration compatibility with the most challenging forensic samples (i.e., low input and degraded samples) and does not include medically relevant SNPs due to genetic privacy considerations. The 10,230 SNP markers in the panel can be used for distant kinship matching, phenotype, and ancestry inference.

Initial optimization testing identified modifications to improve performance and efficiency, particularly with low input samples. First, a decreased final library elution volume increased library yields and subsequently total SNP calls, while maintaining sufficient library volume. Secondly, a modified pooling and dilution strategy was applied to maximize molarity input and better normalize pooled samples. Finally, a range of sample pool multiplexing levels was evaluated to best use the flow cell capacity, while balancing cost and time considerations.

Internal validation testing in accordance with SWGDAM standards demonstrated sensitivity down to 0.05 ng of DNA, high precision and accuracy, the ability to detect mixtures, negligible contamination, and high performance with nonprobative samples.

Within sensitivity testing, calls rates of over 95% and 97% were observed with inputs of 0.05 ng and ≥ 0.1 ng (up to 1.0 ng) with control DNA, respectively. Concordance rates were $92.8 \pm 0.8\%$ for 0.05 ng, $97.0 \pm 0.3\%$ for 0.1 ng, and $99.0 \pm 0.15\%$ for 0.25 ng and 1.0 ng. The majority of discordance observed was due to allelic drop-out attributable to low DNA input. To help overcome these stochastic effects, combining replicate FASTQs was evaluated to determine the impact on both call rates and concordance. Further, multiplexing levels of both 2-plex and 4-plex were assessed to maximize performance and efficiency.

Nonprobative testing evaluated the ForenSeq Kintelligence Kit with extracts from bones, shell casings, and tape collections. Bones were tested at range of input from 0.1 to 1.0 ng, including samples extracted with two different methods and replicates at different inputs. Six bone samples (i.e., burned, cremated, surface decomposition, and embalmed), starting as low as 0.042 ng/ μ L, were evaluated at 1.0 ng DNA input. These samples resulted in $9,934 \pm 258$ called SNP sites, equivalent to a $97.1 \pm 2.5\%$ call rate, when sequenced in a 4-sample multiplex. Further, a tape collection extract at 1.0 ng input yielded 9,873 total SNPs, including 77 of 78 ancestry and phenotype markers.

The ForenSeq Kintelligence Kit demonstrated robust performance in this internal validation testing. As the laboratory seeks to apply this method, implementation considerations include compatible sample types, likelihood of informative database results, cost, and time. One of the major advantages of the workflow, particularly for challenging samples, is the large sample volume it can accommodate; up to 25 μ L of a sample. The multiplexing level will be assessed for each case to determine the optimal processing strategy to maximize data recovery while balancing cost and time considerations. The ForenSeq Kintelligence Kit will serve as a viable option for FGG cases, particularly for cases with low input.

SNP Genotyping, Massively Parallel Sequencing, Forensic Genetic Genealogy

B148 An Analysis of the Genealogy Process in Investigative Genetic Genealogy

Su Erturk, BS, Stanford University, Stanford, CA; Lawrence Wein, PhD, Stanford University, Stanford, CA*

Learning Overview: The goal of this presentation is to provide attendees with an understanding of the genealogy process in investigative genetic genealogy (IGG), to learn how this process can be mathematically modeled and optimized, and to gain new insights into how the genealogy process can become more effective (solve more cases) and efficient (take less time).

Impact Statement: This presentation will impact the forensic science community by: 1) showing for the first time how the genealogy process within IGG can be mathematically modeled and optimized, 2) estimating key model parameters (e.g., the probability of identifying a match, someone's parents or someone's children) from data on 17 cases, 3) computing the probability of solving a case as a function of the amount of work invested, and 4) introducing a new strategy that attempts to optimize the tradeoff between solving more cases and doing less work.

The genealogy process is typically the most time-consuming part of (and a limiting factor in the success of) IGG. The objective of this study is to develop a systematic approach to efficiently perform the genealogy portion of investigative genetic genealogy.

The genealogy process is formulated as a two-stage mathematical model: an ascending stage that attempts to find the most recent common ancestors (MRCAs) between the unknown individual and each investigated match, and a descending stage that searches for a marriage among the descendants of the MRCAs. For any given set of investigated matches (and their genetic distance to the unknown individual), the probability of identifying the unknown individual and the expected amount of work (i.e., size of the final family tree) are computed. We consider three strategies, each operating under three informational scenarios. Two of the three strategies descend only from known MRCAs, and differ by how they seek MRCAs: one seeks MRCAs directly between the unknown individual and the match, while the other seeks MRCAs between two different matches.

The third strategy is a greedy policy that myopically chooses the next action (i.e., which match to investigate, which MRCA to descend from, or whether to terminate the investigation) by maximizing the marginal benefit-to-cost ratio (i.e., the increase in probability of finding the unknown individual divided by the expected additional work required) given the current system state. The three informational scenarios relate to what is known about an identified match: unobserved cluster (e.g., cannot determine which groups of matches descend from the same set of great-grandparents) and relationship to the unknown individual, observed cluster and unobserved relationship, and observed cluster and relationship.

Data from 17 unidentified remains cases (eight solved, nine unsolved) from DNA Doe Project are used to estimate the model's parameters and compare the three strategies under the three informational scenarios.

Our study highlights the benefits achieved by the proposed greedy strategy; of aggressively descending from a match's ancestor that is not known for certain to be a MRCA with the unknown individual. It also assesses the value of the AutoCluster and AutoKinship tools used in GEDmatch, and reveals how our proposed greedy strategy exploits these tools.

Crime Solving, Forensic Genealogy, Probabilistic Analysis

B149 A Theft of Consent: How FGG solved one the most difficult unsolved serial rapist cases in Texas and Louisiana

Leighton D'Antoni, JD, Dallas County District Attorney's Office, Dallas, TX*

Learning Overview: Attendees can expect to learn about Forensic Genetic Genealogy (FGG) and advances in DNA as applied to criminal investigations of unsolved cold cases.

Impact Statement: This presentation will educate attendees and highlight the fact that FGG is the future to solving the most difficult cold cases that have been previously unsolvable.

David Hawkins was a serial rapist who committed over 30 violent home invasion rapes all across north Texas and north Louisiana from 1980-1985. It wasn't until the FBI teamed up with the Dallas County DA's Office to use FGG to identify Hawkins, arrest him, persuade him to confess to over 30 cases, and ultimately accept 4 Life Sentences for his crimes.

"David Hawkins is a monster and deserves every single second of those four life sentence he was sentenced to today," said prosecutor Leighton D'Antoni.

In court, one survivor from a 1985 aggravated sexual assault asked the judge to let Hawkins remove his face mask.

"I have never seen his face. He had on a ski mask that night," the woman told the judge. The judge told Hawkins he could remove his mask. "I have been searching for you for 35 years," the woman said. "I always wanted a face and a name for the sicko who raped me." "I would not let it define me," she said of the assault. "The search for you has empowered me."

December 18, 1982: A woman woke up to Hawkins pulling the covers off her and pointing a gun to her face. Hawkins raped the woman and then stole money and jewelry. At one point, the woman's roommate came home.

Hawkins held the roommate at gunpoint and told her to undress. He then raped the other woman again. He left after telling both women to be quiet.

January 3, 1983: At 3:00 a woman was asleep in her bed when she was awakened by Hawkins lying on top of her saying "If you scream, I'll kill you." Hawkins was wearing a ski mask, gloves and had a gun. Hawkins tied the woman to her bed, covered her head, and sexually assaulted her by penetrating her vagina with his penis. The suspect then demanded the complainant's money and jewelry but did not take anything. Hawkins untied the woman and forced her to douche. Hawkins told her to not to call the police "if she knew what was good for her."

August 18, 1983: A woman was asleep in her bed when she heard her door open. A masked man came in and forced her to lay on her stomach. The man tied her hands behind her back. He raped her, while threatening to shoot her if she didn't cooperate, according to a police report.

Afterward, the man untied the woman and told her to wash up. He then took some jewelry and said, "Don't tell anyone this happened. Just forget about it."

April 27, 1985: A woman woke up to Hawkins wearing a turquoise ski mask with pink around the eyes and dark blue gloves. Holding a gun, he told her, "Either get [expletive] or get killed."

Hawkins put the woman on her stomach and tied her hands behind her back. He then threatened to gag her if she didn't stop crying and stay quiet."

The woman called 911. She underwent a sexual assault exam at the hospital. The rape kit, the woman's bedsheets and another washcloth she used were collected and tested for DNA. A profile was identified, but not matched to a suspect for over 30 years.

Went cold again: The 4 DNA profile from the 4 Dallas rapes matched 2 unsolved cases in Shreveport, LA. Though the six rapes were linked through DNA testing in 2005, the cases went cold again.

The investigation was re-opened in 2020. The FBI teamed up with Dallas County DA SAKI team to use FGG to identify a family tree, which led investigators to Hawkins. It was the first time in Dallas history, FGG had been used to identify a suspect.

D'Antoni, the lead prosecutor, said "It was truly the only way these cases were going to be solved." "FGG is the future of solving previously unsolvable cold cases. I am excited that here in Dallas County, we will be national leaders using this tool to solve violent cold cases."

FGG , Serial, DNA

B150 Nuclear DNA Single Nucleotide Polymorphism (SNP) Profiles Derived From a Human Hair Shaft

Daniele Podini, PhD, George Washington University, Washington, DC; Elaine Lewis, PhD, George Washington University, Washington, DC*

Learning Overview: Attendees of this presentation will learn of a new approach to obtain nuclear DNA SNP profiles from hair shaft using the power of massively parallel sequencing (MPS).

Impact Statement: The ability to obtain a nuclear DNA SNP profile from hair found at crime scenes or from unidentified individuals would improve our ability to identify the contributor through DNA analyses.

Shed hair is a frequent item found at crime scenes, and yet has not been reliably useful in DNA analyses. The shed hair is usually lacking the root, containing the nuclei. The remaining hair shaft contains both mitochondrial and nuclear DNA, but in low amounts. In addition, the DNA is frequently degraded, leaving fragments of approximately 100 bases, and in otherwise poor quality for analyses. The small size of the DNA fragments precludes analysis of standard short tandem repeats.

This study describes our steps to overcome the difficulties inherent in obtaining a nuclear DNA profile from hair shaft. DNA is extracted from 5-10 cm of hair shaft using the method of Brandhagen et al.¹ The DNA recovered is quantified for both mitochondrial and nuclear DNA using a qPCR assay derived from an assay described by the C. Calloway laboratory.² Recovery of DNA is highly variable among hairs, ranging from 0-10 pg nuclear DNA per cm of hair. The DNA hair samples have been used successfully to detect and identify nuclear SNPs using Snapshot assays developed in our laboratory, demonstrating the presence of nuclear DNA.

DNA samples from the same donor are combined to reach several hundred picograms and are used as templates for DNA library construction. In library construction, adapters compatible with the Ion Torrent S5 MPS system are ligated onto the ends of the hair DNA, followed by 18-20 rounds of PCR amplification. The libraries are analyzed by a bioanalyzer and have an average fragment size of ~140-160 bases.

The libraries are subsequently used in capture hybridization enrichment assays. The target sequences are a panel of 238 SNPs and microhaplotypes selected for high discrimination power. The regions surrounding and including the variants were used as templates for synthesis of RNA “baits” which specifically hybridize to the corresponding DNA segments of the hair-derived libraries. Following hybridization reactions, the hybridized hair-derived DNA is recovered, amplified, and sequenced with the Ion Torrent S5 MPS system. Analysis of the sequences reveals the genotype of the donor DNA for the variants included in the original panel.

The further development of the techniques described in this study should provide a new strategy for human identification from hair.

B151 A Comprehensive Evaluation of the ForenSeq™ DNA Signature Prep Kit on the MiSeq® FGx™ Next Generation Sequencing (NGS) System

Chelsea Jones, BS*, Arcadia University, Glenside, PA; Megan Foley, MSFS, Center for Forensic Science Research & Education, Willow Grove, PA; Thomas Walsh, MSFS, Center for Forensic Science Research & Education, Willow Grove, PA; Justina Nichola, BS, Center for Forensic Science Research & Education, Willow Grove, PA; Fabio Oldoni, PhD, Arcadia University, Glenside, PA

Learning Overview: After attending this presentation, attendees will have a better understanding of the performance of the ForenSeq DNA Signature Prep Kit on the MiSeq Next-Generation Sequencing (NGS) platform.

Impact Statement: This presentation will impact the forensic science community by presenting an evaluation of the ForenSeq DNA Signature Prep Kit Primer Set B and comparison to gold standard capillary electrophoresis (CE) instrument. The information from this presentation can be used by others to help determine possible important points of information, such as limit of detection, for the MiSeq FGx NGS system.

CE is the gold standard and is a widely used platform in forensic DNA laboratories for human identification purposes. While CE enables fragment analysis, NGS technology, also known as massively parallel sequencing (MPS), has grown in popularity among crime and research DNA laboratories. This is due to its enhanced capability to multiplex and run in parallel hundreds of forensically relevant markers including identifying short tandem repeats (STRs) and phenotypic and ancestral marker single nucleotide polymorphisms (SNPs). In addition, it allows information to be obtained on individual sequences of STR markers. MiSeq FGx (Illumina) system is currently one of the most used platforms in forensic DNA practice along with the ForenSeq DNA Signature Prep Kit (Verogen). This kit contains Primer set B, which offers more forensic insight into phenotypic and ancestry information of individuals than Primer set A which includes only STR and SNP markers. In this study, the ForenSeq DNA Signature Prep Kit Primer set B will be evaluated on the MiSeq system and compared to the performance of the CE system.¹⁻⁴

In this study, male and female reference samples were collected from buccal swabs, extracted using the EZ1 Advanced XL (Qiagen), and quantified on 7500 Real-Time PCR (Applied Biosystems™) system using the Quantifiler Trio DNA Quantification Kit. All single-source and mixed samples are to be amplified with the GlobalFiler™ PCR Amplification Kit and run on the 3500 Series Genetic Analyzer (ABI) for DNA typing. The same samples will then be run on the MiSeq FGx Sequencing System, the results will be compared, and stutter analysis was performed. The evaluation of the ForenSeq DNA Signature Prep Kit primer set B included concordance, sensitivity, reproducibility, the limit of detection, and mixtures studies. The sensitivity of this NGS kit will be tested at 1,000 pg, 500 pg, 250 pg, 125 pg, 63 pg, and 31 pg. An assay of mixtures representative of commonly encountered mixed samples at 1 ng of total input DNA will be prepared. These include two-person, three-person, and four-person mixtures. A total of 18 mixtures are to be prepared for this research. For two-person mixtures, male:female and male:female mixtures at 1:1, 1:5, 1:10, 1:20, 1:50 and 1:100 ratios will be prepared. Three-person mixtures will be simulated as female:male:male at four different ratios of 1:1:1, 5:1:1, 10:5:1, and 20:5:1. Four-person mixtures will be prepared as female:female:male:male mixtures at ratios of 1:1:1:1, 5:5:1:1, and 10:5:1:1.

The reference samples will be the first run on the CE and then on the NGS using the standard flow cell kit. Quantification and CE typing results of the single-source DNA samples are to no contamination issues and that mixture ratios are correct. Preliminary sequencing results on these samples showed a higher level of sensitivity and detection limit of the MiSeq system than that of the CE platform. Moreover, an initial set of mixture samples at 1:1, 1:5, 1:50, 1:1:1, and 10:1:1 ratios were prepared and first run on the CE to help determine the actual ratios of the mixtures before the NGS run. CE mixture results confirmed the expected ratios of all mixed samples, which were then run on the MiSeq. Overall, the preliminary NGS data showed a higher sensitivity to that of the CE.

In conclusion, these preliminary results highlighted an enhanced capability of the ForenSeq DNA Signature Prep Kit primer set B to detect and deconvolute mixture contributors on the NGS platform in comparison to CE fragment analysis. A comprehensive mixture and stutter analysis is ongoing to fully evaluate this sequencing kit.

B152 Developmental Validation of the Illumina® Infinium™ Assay Using the Global Screening Array (GSA) on the iScan® System for Use in Forensic Laboratories

David A. Russell, MS, Signature Science, LLC, Charlottesville, VA; Carmen Reedy, PhD, Signature Science, LLC, Charlottesville, VA; Stephen D. Turner, PhD, Signature Science, LLC, Charlottesville, VA; Stephanie Guertin, PhD, Signature Science, LLC, Charlottesville, VA; Mary Heaton, MS, Signature Science, LLC, Charlottesville, VA; Jessica Bouchet, BS, Signature Science, LLC, Charlottesville, VA; Michelle Peck, MFS, Signature Science, LLC, Charlottesville, VA; Erin Gorden, MFS, Signature Science, LLC, Charlottesville, VA; Elayna Cuzio, MS, Signature Science, LLC, Charlottesville, VA; Christina Neal, MS, Signature Science, LLC, Charlottesville, VA*

Learning Overview: This presentation will provide an overview of the developmental validation of the Infinium Global Screening Array-24 v3.0 Kit [GSA] on the iScan array system; a microarray-based genome-wide SNP genotyping workflow. It will provide valuable insight into what forensic practitioners can expect from microarray-based genotyping data.

Impact Statement: This presentation will provide valuable insight into what forensic practitioners can expect from microarray-based genotyping data.

This developmental validation study aimed to provide the forensic community with a validated microarray-based genome-wide SNP genotyping workflow for DNA inputs consistent with forensic sample types. Most labs performing microarray-based SNP genotyping are clinical and lack a forensic framework. Our approach was to evaluate the Infinium Global Screening Array-24 v3.0 Kit [GSA, Illumina] on the iScan array system [Illumina], focusing on shifting applicability from clinical laboratories to the forensic community. To date, there is no existing guidance on how to validate microarray-based genome-wide SNP genotyping within the forensic community. This validation was performed guided by standards (FBI QAS, SWGDAM) accepted by the forensic community with the intended application to challenging cases crime labs encounter. This will allow greater confidence in the investigative leads developed by law enforcement agencies, as the data used to develop such leads will have been generated under the same scientific standards already established within other human identification methods.

The following studies were performed as part of the developmental validation: sensitivity, precision, and accuracy (repeatability and reproducibility), mixtures, degradation, species specificity, contamination, case-type samples, and array stability-post processing. Throughout all studies, except for the case-type study, extensively characterized human genomes for which high-confidence variant calls are known were used. Concordance was assessed using the NIST/Genome-in-a-bottle (GIAB) sample call sets as truth data for each sample.

For the sensitivity study DNA inputs from 200 to 0.2 ng were assessed using NA12878 [Coriell]. This evaluation demonstrated call rates of >99% and >95% for inputs ≥ 1 and 0.2 ng, respectively. Additionally, results were highly concordant at DNA inputs as low as 0.2 ng: <0.001% discordance for all replicates down to 1 ng, and <0.5% discordance at 0.2 ng. For the precision and accuracy (repeatability and reproducibility) studies, when comparing sample genotypes to the NIST/GIAB sequencing data, average concordance rates were 99.2% across all samples. Comparing duplicate samples to each other showed a concordance rate of >99.8% across all samples. The repeatability and reproducibility studies demonstrated reliable and consistent call rates and high concordance, regardless of operator.

In the mixture study, the profile generated from samples of a 3:1 mixture of NA24631 to NA12878 (major to minor contributor) was on average 98.85% concordant with gold standard data for NA24631; the 9:1 mixture ratio was on average 99.99% concordant. This demonstrated that at a mixture ratio of 3:1 or greater between the major and minor contributors, the resulting major contributor's profile is accurate. The data generated during the degradation study was unexpected; samples known to have been severely degraded produced genotyping data with call rates similar to pristine samples. However, examination of concordance data showed that the genotype calls were less accurate as the samples became more degraded. Lower heterozygosity was observed in the degraded samples (average of 7%) compared to the GIAB population set (average of 17.3%). This suggests that allelic dropout is responsible for the noticeable shift to false homozygous calls, accounting for the high call rate yet discordant SNP data.

This validation characterized the performance of forensic samples on the GSA platform, providing valuable insight into what forensic practitioners can expect from microarray-based genotyping data. Thresholds for call rate, heterozygosity, and overall signal (fluorescence) were established to assess the data and determine suitability of samples for the workflow.

Developmental Validation, Forensic Genetic Genealogy, SNP Genotyping

B153 Joint Data Analysis of DNA Mixtures Using Probabilistic Genotyping

Sara Antillon, MS, George Mason University, Fairfax, VA; Jennifer Hornyak Bracamontes, MS, Cybergenetics, Pittsburgh, PA; Kevin Miller, PhD, Hamilton Robotics, Reno, NV; Mark Perlin PhD, MD, PhD, Cybergenetics, Pittsburgh, PA; Mark Wilson, PhD, George Mason University, Fairfax, VA*

Learning Overview: After attending this presentation, attendees will understand how probabilistic genotyping (PG) methods can conduct joint data analysis of multiple DNA data samples to produce more informative genotypes and likelihood ratio (LR) match statistics.

Impact Statement: This presentation will impact the forensic science community by showing how joint data analysis can obtain more information by analyzing multiple DNA data samples at the same time, particularly helpful for interpreting mixed or low template DNA (LT-DNA) samples.

Polymerase chain reaction (PCR) is a random DNA amplification process that inherently produces unequal amounts of amplified allele amplicons. Scientists can extract all the DNA identification information from complex mixtures of several people, or from just a few cells in the sample, only by probability modeling of the short tandem repeat (STR) PCR experiment. This forensic innovation is called “probabilistic” genotyping, since it has a computer assign accurate probabilities to all genotype possibilities, instead of discarding DNA evidence as inconclusive, or reporting inaccurate LR values.

When analyzing one DNA sample, PG computer analysis usually yields more information than human review of the same STR data. However, a joint likelihood function can simultaneously examine multiple data items. This joint analysis can extract even more information from DNA evidence data. Information was quantified here by the magnitude of log(LR) match statistic, measured in ban units.

The study examined DNA mixture samples containing two, three, four, and five contributors, at both high and low amounts of DNA. The selected samples were interpreted using the TrueAllele® PG method, comparing single and joint analysis. There were three sample groupings: complementary mixture weight (MW), template concentration, and complex mixtures. The combined joint analysis showed an overall increase in genotype and match information, relative to single analysis of individual evidence samples.

For samples with complementary MWs, on average joint analysis gave 10 ban more information than single analysis, when a contributor was uninformative or a minor component. For example, single analysis of a 50% two-person mixture contributor produced a log(LR) of 11 ban, and analysis of a four-person 5% contributor mixture gave a log(LR) of 3 ban. Joint analysis produced a log(LR) of 18 ban for this shared contributor, which is a 7 ban and 15 ban respective increase in identification information over the single analysis for the 50% and 5% fractions.

Single sample analysis of LT-DNA gave minor contributors having log(LR) values as low as 3 ban. Jointly analyzing three LT-DNA data experiments for a minor 10% component produced a log(LR) around 14 ban, increasing match information 11 ban relative to single analysis.

In a terrorist case, a matchstick was recovered from the scene of a torched getaway car. Human review of the low copy number (LCN) amplifications was uninformative. TrueAllele computer review of each individual LCN amplification gave LR values around ten. However, joint TrueAllele data analysis of the three LCN amplifications produced a higher LR value of a million, which brought the DNA evidence back into the case.

Joint data analysis generally increases genotype and DNA match information. Two common scenarios are when (a) contributor mixture weight is different across the samples, and (b) a small amount of the same contributor is present in multiple samples. In these scenarios, joint data analysis may be the only way to obtain informative LR results for a suspect from the DNA evidence.

Collecting more LT-DNA samples up front can lead to more informative joint analysis downstream. Separate STR analysis of the samples permits joint computer analysis, whereas a pooled sample PCR does not. Planning for joint data analysis can constructively change initial sample collection and laboratory procedures.

Probabilistic Genotyping, Joint Data Analysis, Forensic DNA

B154 An Evaluation of the QIAamplifier® 96 Thermal Cycler

Madeline Roman, PhD, Signature Science, LLC, Austin, TX; Josh Abernathy, MSFS, QIAGEN, Germantown, MD; Bryan Davis, BS, QIAGEN, Germantown, MD*

Learning Overview: After attending this presentation, attendees will have a better understanding of how different thermal cyclers perform with forensic STR chemistries and what studies are necessary to ensure that new thermal cyclers are performing comparably to existing ones.

Impact Statement: This presentation will impact the forensic science community by introducing a new thermal cycler for STR amplification in crime laboratories.

A typical forensic DNA workflow consists of DNA extraction, quantification, amplification of STRs, and capillary electrophoresis. Multiple STR amplification chemistries are commercially available, and the quality and accuracy of STR results is affected by the thermal cycler used for amplification. The purpose of this study was to test the compatibility of a newly available thermal cycler, the QIAamplifier® 96 (QIAGEN), with STR multiplexes used for human identification. Sensitivity, accuracy, reproducibility, and inhibition studies were performed using the Investigator® 24plex QS kit (QIAGEN), and results from the QIAamplifier® 96 were compared to results from the Veriti 96-Well Thermal Cycler (Thermo Fisher Scientific). In addition, compatibility with direct PCR was tested using the Investigator® 24plex GO! Kit.

The sensitivity study consisted of two male reference samples amplified in triplicate at each input ranging from 63 pg to 1 ng. For both thermal cyclers, dropout occurred at 63 and 125 pg for one sample, and full profiles were recovered for the other sample throughout the entire range of DNA inputs. No differences were observed in profile completeness, average peak heights, average peak height ratios, or intra-color balance between the QIAamplifier® and Veriti thermal cyclers using the F statistic (95% confidence interval). The reproducibility study involved amplification of twelve replicates of positive control DNA on each thermal cycler at 0.5 ng. All replicates resulted in 100% profile completeness, and there was no significant difference between average peak heights, average peak height ratios, and intra-color balance between thermal cyclers (F-test). Inhibition was tested by addition of three concentrations of hematin to positive control samples prior to amplification. All samples resulted in 100% allele recovery, with no significant differences between average peak heights, average peak height ratios, and intra-color balance between thermal cyclers (F-test). Finally, direct amplification was assessed using three buccal swabs amplified in triplicate with the Investigator® 24plex GO! kit. All samples and replicates resulted in 100% allele recovery using both thermal cyclers. There was no significant difference between average peak heights or average peak height ratios, and all genotypes were concordant with the reference profiles (F-test). Throughout all studies, all negative controls resulted in no allele calls, and no new reproducible STR artifacts were observed.

The concordance of results between the QIAamplifier® 96 and Veriti 96-Well Thermal Cycler indicates that the QIAamplifier® 96 is compatible with STR amplification chemistries and may be used as an alternative to other thermal cyclers in forensic casework laboratories. Though only two QIAGEN STR chemistries were analyzed during this study, it is likely that other STR chemistries would perform similarly well and generate comparable results using the QIAamplifier® compared to other thermal cyclers commonly utilized by forensic laboratories.

STR, PCR, Thermal Cycler

B155 Toward a *Sample In-Answer Out* Centrifugal Microfluidic Platform for Nucleic Acid Detection

Leah Dignan, BSc*, University of Virginia, Charlottesville, VA; Michael Woolf, PhD, University of Virginia, Charlottesville, VA; Will Treene, University of Virginia, Charlottesville, VA; James Landers, PhD, University of Virginia, Charlottesville, VA

Learning Overview: After attending this presentation, attendees will have been introduced to a novel, rotationally-driven *sample in-answer out* microdevice that integrates and expedites nucleic acid extraction, amplification, and detection.

Impact Statement: This presentation will impact the forensic science community by introducing a microfluidic platform for comprehensive integration of nucleic acid preparation and detection that is amenable for use outside of traditional laboratory settings.

Nucleic acid amplification tests (NAATs) are ubiquitous, yet complex, multi-step processes encompassing liberation (e.g., cell disruption), extraction, quantification, amplification, and ultimately detection of nucleic acids (NAs). Despite an increasing demand for portable NAATs, the majority of existing techniques remain tethered to centralized laboratories, where their time-consuming and labor-intensive workflows must be conducted by trained analysts.¹ Microfluidic systems offer rapid, cost-effective, and portable alternatives to laboratory-based analyses that are readily amenable to use by non-technical personnel. Ideally, fully automated *sample in-answer out* platforms would permit comprehensive NA processing, from sample preparation through interpretation of results, with no user intervention.¹ Here, we describe our work towards one such portable, automatable centrifugal microfluidic platform to integrate and expedite detection of human DNA.

Although there has been much focus on microfluidic adaptations of NA amplification and detection, the advancement of NA extraction has lagged behind.² Thus, initial work was centered on developing and characterizing on-disc enzymatic direct-from-swab DNA extraction. The resulting genetic material was compatible with 'gold standard' real-time and multiplexed polymerase chain reaction (PCR) techniques. In addition, extracted DNA was amenable to loop-mediated isothermal amplification (LAMP), which is especially well-positioned for point-of-need use due to simplified hardware requirements (e.g., no thermal cycling) and compatibility with visual, colorimetric detection.³ Following initial in-tube pilot studies showing successful colorimetric LAMP, the associated chemistry was adapted to a centrifugal microfluidic format. Specifically, by targeting and amplifying the thyroid peroxidase (TPOX) locus, the presence of human DNA was visually detected.

The ability to perform all NA processing operations on a single centrifugal microdevice is enabled by laser-actuated valve opening and channel closures, as well as a novel method for fluid displacement towards the center of rotation using reagents stored on-board.⁴ The latter technique is beneficial for such multi-step assays because it acts counter to centrifugal force, allowing for continued on-disc processing without integration of bulky external hardware. By leveraging gas generation from an on-board acid-base reaction, fluid can be driven radially inward without incorporating additional hardware (e.g., pneumatic pumps). Previous work demonstrated proof-of-concept but relied on highly corrosive reagents and complex fabrication methods.⁵ Here, an alternative strategy leveraging simple, on-board storage of safe-to-handle reagents that exhibits compatibility with amplification-based NA detection is demonstrated. Subsequent on-board coupling of NA preparation, inward fluid displacement, and colorimetric LAMP represents significant progress towards a fully automated *sample in-answer out* system for fieldable genetic analysis.

Nucleic Acid Amplification Tests (NAATs), Microfluidics, Forensic DNA

B156 Using a Non-Destructive Method to Estimate the Number of Contributors and Predict DNA Yield in Touch DNA Mixtures

Susan Greenspoon, PhD, Virginia Department of Forensic Science, Richmond, VA; Christopher Ehrhardt, PhD, Department of Forensic Science, Virginia Commonwealth University, Richmond, VA; Christin Lee Master, Department of Forensic Science, Virginia Commonwealth University, Richmond, VA; Sarah Ingram, PhD, Department of Forensic Science, Virginia Commonwealth University, Richmond, VA*

Learning Overview: After this presentation, attendees will become more familiar with the application of antibody probes for DNA casework. Specifically, antibody probes can hybridize known target proteins in a cell sample without destroying cell structure. Applying antibodies to target proteins/hormones in human epithelial cells, the individualized signaling peaks can represent each contributor, and the shift/intensity of fluorescent can predict the amount of DNA to each person in a mixture sample.

Impact Statement: This project investigates a new pre-DNA-profiling method that can screen for touch DNA in epithelial cell mixtures rapidly and in a non-destructive manner. This new approach applies fluorescent-tagged intra-cellular molecules to estimate both contributor number and DNA content, preserving the DNA from touch evidence, while still providing information about the samples before STR analysis. This technique has the potential to increase the information available for mixture touch evidence prior to DNA profiling, which may assist with sample triaging as well as data analysis and interpretation.

DNA deposited by handling an item is also referred to as touch DNA. It can play an important role in forensic science since it is an extremely common form of evidence left at crime scenes. However, most touch DNA obtained from an object is low template and has been contacted by multiple individuals. Touch DNA samples are very frequently difficult to interpret and distinguish contributors, and these challenges can decrease the success rate of casework. Currently, the most common method to estimate the number of contributors and the amount of DNA for each contributor from touch DNA mixture samples is based on DNA quantitation and short tandem repeat (STR) analysis; however, there are some limitations, making a definitive interpretation difficult. Therefore, applying a non-destructive pre-DNA analysis technique that can differentiate cell populations and predict DNA yield may improve the casework process and increase success in interpretation.

Recent published research demonstrated that antibody probes can differentiate cell populations in mixture samples, however, little has been published applying this technique to epithelial touch cell mixtures. Cholesterol-based hormones such as testosterone and dihydrotestosterone (DHT), and proteins including cytokeratins (CK) inside epidermal cells have been demonstrated to be a personalized signature in human populations. Both hormone and cytoskeletal targets are stable for long periods of time, making them feasible candidates to act as a marker to differentiate cell populations. The binding efficacy of testosterone and DHT for each individual in an epithelial mixture sample and the correlation between predicting DNA yield versus actual DNA yield still remains unknown. Furthermore, there are a small number of reports on CK in the forensic field. Thus, much remains to be discovered regarding its potential applications.

In this study, swabs of epithelial cells collected directly from each volunteer's hands were cut in half, with one-half stained with fluorescently tagged anti-testosterone and anti-DHT antibodies or stained with anti-cytokeratin antibody. The other half of the swabs were extracted for DNA. Fluorescence histograms were generated for the stained sample of each epithelial cell population using flow cytometry. Staining patterns in the fluorescent histograms were observed that differed among the contributors in mixture samples. This result demonstrated that cholesterol-based hormones were able to differentiate cell populations and thereby distinguish each contributor. Furthermore, in the DNA quantitation experiment, the remaining half of the epithelial cell swabs were extracted for DNA and quantitated using a qPCR assay. The quantitation data showed that the DNA amount correlated with the shift in fluorescence in the histograms; those samples with a higher concentration of DNA showed a larger shift in the fluorescent signal (greater fluorescence). This finding suggested that using antibody probes can be used to predict DNA yield before any DNA has been extracted. Moreover, the cell staining and flow cytometry is a non-destructive method of cell analysis. Thus, these findings indicated that antibody hybridization has the potential to serve as a non-destructive technique prior to STR analysis to enhance the probative value of biological evidence.

Touch DNA, Testosterone and Dihydrotestosterone, Cytokeratins

B157 An Evaluation of Microhaplotype Markers in Kinship Analysis in a Korean Population

Sohee Cho, PhD, Institute of Forensic and Anthropological Science, Seoul, Korea; Soong Deok Lee, MD, PhD, Institute of Forensic and Anthropological Science, Seoul, Korea and Department of Forensic Medicine of, Seoul, Korea*

Learning Overview: After attending this presentation, the attendees will understand the potential of microhaplotypes for use in kinship analysis, and their power of resolution in analysis for distinguishing true relatives from the unrelated compared to when using the current genetic markers, STRs and SNPs.

Impact Statement: This presentation will impact the forensic science community by serving the statistical values of relatedness evaluated based on likelihood ratio (LR) for various familial relationships from actual Korean pedigrees, including parent-child, full-siblings, uncle-nephew, grandparent-grandchild, and first cousins, which can be considered for kinship determination.

Microhaplotypes are a novel-type of genetic markers emerging in forensic genetics recently, which may supplement existing markers for different forensic purposes. A microhaplotype, also known as a microhap, is defined by two or more closely linked SNPs associated in multiple allelic combinations. Microhaplotypes have advantages of both STRs and SNPs, including lower mutation rates, absence of stutter peaks, small amplicon size less than 300 bp usually, and multiple alleles. Those features can provide usefulness for human identification, relationship identification, and mixture deconvolution.

Here, we present the distributions of likelihood ratio for different familial relationships by analyzing 51 microhap markers using massively parallel sequencing technology. The markers analyzed were selected from the literature, data were analyzed using STRait Razor 3.0, and each kinship was assessed against unrelated pairs based on likelihood ratio using Familias 3 software. For comparison of the usefulness of microhaps in kinship analysis, tested pairs were also analyzed using two different genetic marker systems consisting of 22 STRs and ~160 SNPs from commercial kits, respectively. In the results, all pairs in kinship of parent-child and full-siblings were clearly resolved from the unrelated with a high sensitivity. For distant relationships, uncle-nephew or grandparent-grandchild, the number of pairs within the 'grey zone' where uncertainty exists due to overlapping of the LR distribution curves of true relatives and the unrelated were decreased compared to when using STRs. Compared to when using SNPs, the resolution somewhat was similar, which may be due to the total number of SNP similar in analysis in each system. A higher resolution for distant relationships can be expected with more microhap markers on a single panel with the current set of markers, and it is believed that these microhaplotype markers have a potential for use in kinship analysis of various familial relationships for forensic application.

Microhaplotypes, Kinship Analysis, Korean

B158 Examining the Ancestry of the Spring Street Presbyterian Church Burial Vault Population Using Mitochondrial DNA (mtDNA) Analysis

Stephanie Gladys, PhD, Madonna University, Livonia, MI; Shannon A. Novak, PhD, Syracuse University, Syracuse, NY; Jodi Lynn Barta, PhD* Madonna University, Livonia, MI*

Learning Overview: Attendees will learn about DNA extraction, amplification, and analysis that effectively allows for ancestry identification of aged, degraded bone samples.

Impact Statement: This presentation will outline methods that have been implemented to extract genomic DNA from challenging, low copy number bone samples in order to amplify, analyze, and determine maternal ancestry of individuals based on mitochondrial DNA. Aged and degraded bone samples are some of the most difficult to analyze and sharing successful methods within the forensic science community helps lead to improvements in forensic science practice.

During the winter of 2006, where SoHo Towers in New York City now stand on the corner of Spring and Varick Streets in Manhattan, construction crews uncovered four underground burial vaults. The vaults belonged to the historic Spring Street Presbyterian Church and subsequent excavation yielded the commingled remains of over 200 individuals ranging from infants to the elderly. The Spring Street Presbyterian Church (SSPC) was a prominent abolitionist institution from the early to mid-19th century. Church pastors were known for admitting to the congregation African Americans, the working poor, and immigrants despite accusations and backlash from members of the community, including riots that resulted in the burning of the church and one pastor's home. Few archival records remain, though New York City burial records suggest that two "Blacks" were interred in the church vaults. Burial practices in New York City at the time were more commonly segregated, and it remains unclear if there was differential access to burial in the SSPC vaults or if segregation occurred within them. Therefore, we ask: did the church practice what they preached in their burial practices? The goal of this project is to answer this question through the analysis of DNA for ancestry determination. Despite the age of the bones and the likelihood that the DNA was subject to degradation during freeze-thaw cycles in the burial environment, methods traditionally used for ancient DNA analysis were performed on the remains of these individuals in an attempt to identify the geographical origin of their maternal ancestors. This research successfully utilized whole genomic extraction, polymerase chain reaction amplification, sequencing, and analysis of mitochondrial DNA from the skeletal remains of 13 individuals to determine the ancestry of members of this population. Results of these analyses reveal that a diverse group of individuals found their final resting place in the SSPC burial vaults.

MtDNA, Degraded DNA, Ancestry Determination

B159 Contemporary Population Genetics Data and Haplogroup Prediction Using 27 Y-Chromosomal Short Tandem Repeat (Y-STR) Loci in the Croatian Population

Dragan Primorac, MD, PhD, St. Catherine Hospital, Zagreb, Croatia Vedrala Skaro, Molecular Anthropology Laboratory, Center for Applied Bioanthropology, Institute for Anthropological Research, Zagreb, Croatia; Petar Projic, Molecular Anthropology Laboratory, Center for Applied Bioanthropology, Institute for Anthropological Research, Zagreb, Croatia; Sasa Missoni, Molecular Anthropology Laboratory, Center for Applied Bioanthropology, Institute for Anthropological Research, Zagreb, Croatia; Ivana Horjan Zanki, Forensic Science Centre, Ivan Vucetic, Zagreb, Croatia; Sinisa Merkas, Forensic Science Centre Ivan Vucetic, Zagreb, Croatia; Jelena Sarac, Molecular Anthropology Laboratory, Center for Applied Bioanthropology, Institute for Anthropological Research, Zagreb, Croatia; Natalija Novokmet, Molecular Anthropology Laboratory, Center for Applied Bioanthropology, Institute for Anthropological Research, Zagreb, Croatia; Andrea Ledic, Forensic Science Centre, Ivan Vucetic, Zagreb, Croatia; Adela Makar, Forensic Science Centre, Ivan Vucetic, Zagreb, Croatia; Gordan Lauc, DNA Laboratory, Genos Ltd, Zagreb, Croatia; Simun Andjelinovic, Clinical Department for Pathology, Legal Medicine, and Cytology University Hospital Center, Split, Croatia; Zeljana Basic3, Ivana Krucic, University Department of Forensic Sciences, University of Split, Split, Croatia; Marijana Neuberg, University North, Varazdin, Croatia; Martina Smolic, Faculty of Medicine, University of Osijek, Osijek, Croatia; Robert Smolic, Faculty of Medicine, University of Osijek, Osijek, Croatia; Irena Hratic, General Hospital Pula, Pula, Croatia; Dragan Trivanovic, General Hospital Pula, Pula, Croatia; Rijad Konjodovic, Alea Genetic Center, Sarajevo, Bosnia and Herzegovina; Lana Salihefendic, Alea Genetic Center, Sarajevo, Bosnia and Herzegovina; Naida Babic Jordamovic, Department of Genetics and Bioengineering, International Burch University, Sarajevo, Bosnia and Herzegovina; Damir Marjanovic, Department of Genetics and Bioengineering, International Burch University, Sarajevo, Bosnia and Herzegovina*

Learning Overview: This presentation will offer attendees a better understanding of how analysis of increased number of STR loci can expand informativeness of Y chromosome haplogroups, offering more accurate results as well as higher probability of detecting all (including rare) Y haplotypes.

Impact Statement: This presentation will provide an update of forensic and population genetic parameters regarding Y chromosome markers which is important for forensic scientists.

Almost 50% of the Y chromosome consists of repetitive sequences.¹ When it comes to more mutable repetitive elements, prominent examples are short tandem repeats (STRs), with an average mutation frequency of ~0.2% per generation.² These markers are representing important genetic tools for various studies; therefore, Y chromosome has an important role in forensic analyses, in cases of paternity testing, in the process of human identification, but also in human migration studies.³ Therefore, updating of all forensic and population genetic parameters regarding Y chromosome markers is mandatory for forensic scientists. Y chromosome haplogroups can be successfully predicted from Y-STR haplotypes using different software packages.

Buccal swab samples were collected from 518 unrelated male individuals from five Croatian cities and their close surroundings: Hvar (island Hvar, Split-Dalmatia County) n=104, Split (Split-Dalmatia County) n=105, Varazdin (Varazdin County) n=100, Osijek (Osijek-Baranja County) n=110, Pula (Istria County) n=99. Y-STR genotyping was performed using Yfiler™ Plus PCR Amplification Kit (Applied Biosystems) targeting 27 Y-STR loci.⁴ The number of alleles and different haplotypes, allele and haplotype frequencies, and gene and haplotype diversity were estimated in order to assess the intrapopulation diversity. The evolutionary history was inferred for both set of markers using the neighbor-joining (NJ) method of phylogenetic tree construction in MEGA, whereby the optimal tree is shown.^{5,6} Genetic distances between groups of males and between populations were quantified by R_{st} using AMOVA online tool from the Y Chromosome Haplotype Reference Database – YHRD.⁷ In addition, associated probability values (P values) with 10,000 permutations were included for the studied populations. Genetic distances were used to generate MDS plots for the comparison of population haplotype data from YHRD. AMOVA analysis was done with two population groups. The first comparison for analysis was made using the original number of the Yfiler Plus kit. The second comparison was made with a reduced number of markers using the Yfiler marker set. Y-chromosomal haplogroup prediction using allele frequencies on 518 Yfiler Plus profiles was performed using Whit Athey's Haplogroup Predictor v5, an algorithm based on Bayesian-allele-frequency approach.⁸ The Y chromosomal STR data of the present study are submitted to Y-STR Haplotype Reference Database (YHRD).

A total of 513 different haplotypes were detected in the study, with 508 unique haplotypes and 5 haplotypes appearing twice. In addition, the largest number of alleles was recorded on DYS481 with 14 detected alleles. Three loci had the smallest number of alleles, namely DYS393, DYS437 and Y-GATA-H4 with 4 alleles each. Average genetic diversity for the study population was 0.656 across all loci, ranging from 0.251 at the locus DYS392 to 0.886 at DYS481. Eleven haplotypes with possible new (not confirmed within YHRD) microvariants are detected, requiring additional sequencing.

Both population comparisons point towards a general conclusion that geographically closer populations show higher degree of genetic relatedness. Population comparisons using comparative analysis methods presented above show very low genetic differentiation between the currently analyzed population in this part of the Europe. The results revealed the existence of 15 different haplogroups, with I2a, R1a and E1b1b being the most prevalent with frequencies of 39.00%, 24.32% and 10.81% respectively. Compared to the previously published studies on Croatian population based on Y-SNP and Y-STR data, this study represents an upgrade of molecular genetic data with increased number of loci, thus offering more accurate results as well as higher probability of detecting all (including rare) Y chromosome haplogroups.

B160 Rapidly Mutating Y-Chromosomal Short Tandem Repeats (RM Y-STRs) in Punjabi Deep-Rooted Endogamous Pedigrees From Pakistan

Shahid Nazir, PhD, University of Health Sciences, Lahore, Punjab, Pakistan*

Learning Overview: Attendees will learn: (1) in sexual assault cases it is very tricky to separate male relatives of the same family but using RMSTRs we can differentiate between them, (2) the diffraction power of RM Y-STR loci in Pakistani populations, (3) population genetic analysis of Pakistani population using RM Y-STRs allele frequency data, and (4) this data will be very valuable to law enforcement agencies and criminal justice system.

Impact Statement: The overall objective of this exploration is to validate a single plex assay, which can validate 13 RM Y-STR loci in the Pakistani population till fourth generation. Such assay will aid a breakthrough in human population's studies as well as forensic applications.

The objective of the study was to explore the discrimination power of RM Y-STRs in Pakistani population till four-generation. This study can be utilized effectively in the following ways: (1) In sexual assault incidents, it is very tricky to separate male relatives of the same family but using RMSTRs we can differentiate between them, (2) to investigate the RM Y-STR loci in Pakistani populations, (3) leading a population genetic study of Pakistani inhabitants using RM Y-STRs allele frequency data, (4) assist the Pakistan justice system and law enforcement agencies.

Short tandem repeat polymorphisms on the male specific portion of the human Y-chromosome (Y-STRs) are important in many areas of human genetics. Y chromosomal STRs being normally utilized in the field of forensic exhibit low haplotype diversity in endogamous populations and fail to discriminate among male relatives from same pedigree. Rapidly mutating Y-STRs (RM Y-STRs) have been paid much attention in last decade. These 13 RM Y STRs have high mutation rates ($>10^{-2}$) and have considerably higher haplotype diversity and discrimination capacity than conventionally used Y-STRs showing remake-able power, when it comes to differentiation in paternal lineages in endogamous populations. Separation of male relatives is usually impossible with standard Y-STRs. Previously, we have analyzed 2–4 generation, 99 pedigrees covering 1568 pairs of men covering 1–6 meioses from all over Pakistan and 216 male relatives from 18 deep rooted endogamous Sindhi pedigrees covering 1–7 meioses.

Here we are presenting 861 pairs of men from 63 endogamous pedigrees covering 1–6 meioses from Punjabi population of Punjab, Pakistan. Mutations were frequently observed at DYF399 and DYF403 while no mutation was observed at DYS526a/b. The rate of differentiation ranged from 29.70% (first meiosis) to 80.95% (fifth meiosis) while overall (1 to 6 meiosis) differentiation was 59.46%. Combining previously published data with newly generated data, an overall differentiation rate was 38.79% based on 5176 pairs of men related by 1–20 meioses, while Y-filer differentiation was 9.24% based on 3864 pairs. Using father-son pair data from the present and previous studies, we also provide updated RM Y-STR mutation rates.

Rapidly Mutating, Short Tandem Repeats, Y-Chromosome

B161 Developing Effective and Sustainable Teaching Labs for Forensic DNA Courses

Catherine Cupples Connon, PhD, Virginia Commonwealth University, Richmond, VA*

Learning Overview: After attending this presentation, attendees will be aware of some of the challenges involved with (and solutions to) developing forensic DNA laboratories for teaching purposes. These laboratories should be robust enough for students with little to no laboratory experience, offer an introductory level of analysis, and be sustainable long-term from a cost perspective.

Impact Statement: This presentation will impact the forensic science educational community by offering a low-cost assay for human-specific DNA quantitation, as well as a cost saving approach to STR profiling via robust quarter PCR reactions for blood and buccal samples.

Developing forensic science laboratories for educational purposes can be challenging for a variety of reasons. Robust protocols that work well for the average, relatively inexperienced student are a necessity, and fortunately, there are a number of quality options to choose from. However, many of these come with a hefty price tag, especially for forensic DNA analysis. Sustaining these costs long-term presents additional challenges. One remedy is to only process a small number of samples to keep costs low, but this is often not the best option as students will have a more well-rounded experience if they can process more than one or two samples. Other options include utilizing robust homebrew assays and/or consuming less reagent per sample. This talk will address some specific solutions to these issues, including the adoption of low-cost, human-specific qPCR assays and quarter reactions for STR profiling. The methods employed here also take into account the inexperience of most students, both from a laboratory technique perspective, as well as from a data analysis perspective.

Studies were conducted to assess the effectiveness of a low-cost human-specific qPCR assay utilizing Alu repeats and SYBR Green detection.¹ Two PCR master mixes (Power SYBR® Green and PowerUp™ SYBR® Green) were evaluated using full (25µL) and half (12µL) reactions in combination with eight versus five DNA standards processed in singlicate and duplicate. For each combination of variables, three standard curves were generated and used to quantify five DNA extracts (loaded in duplicate) of varying quantities. Evaluations included assessing the standard curves (R², slope, y-intercept, and degree of manipulation needed to pass) and reproducibility of quantitation. PowerUp™ SYBR® Green outperformed Power SYBR® Green on all combinations of standards for full reactions. Half reactions were not viable under any circumstance. From the successful qPCR setups, amplification of 0.7-1.1ng of DNA yielded high quality full profiles using the AmpF/STR® SGM Plus™ PCR Amplification Kit.

The other area of our teaching laboratory that was altered was amplification of STR profiles. Low volume quarter reactions (6.2µL) based on an earlier study were applied to the AmpF/STR® COfiler® and SGM Plus™ PCR Amplification Kits for buccal swabs and blood on FTA cards.² Resulting STR profiles were analyzed from 143 student-generated amplifications. These were assessed for overall interpretability (interpretable, uninterpretable, or no results) and basic metrics. Of all student-generated profiles, 76% were interpretable and, of those, 71% had full profiles. Interpretable profiles exhibited average peak heights of 1872 rfu, average PHR of 87.7%, and an average of seven artifacts per sample, the vast majority of which were pull-up.

These studies demonstrate that a low-cost qPCR assay and a lower cost quarter reaction for STR amplification are viable options for students in a forensic biology teaching laboratory. These assays are robust enough that even students with little to no laboratory experience can be successful and have data to evaluate. Furthermore, though these are not the top-of-the-line options for analysis of casework, they provide students with a nice introduction to forensic DNA analysis that is not as overwhelming as qPCR assays with numerous detectors and/or STR profiles with >20 loci.

B162 The Evaluation of Cannabinoid Synthase Polymorphisms for Distinguishing Between Marijuana and Hemp

Ya-Chih Cheng, MS, Sam Houston State University, Huntsville, TX; Rachel Houston, PhD, Sam Houston State University, Huntsville, TX; Sarah Kerrigan PhD, Sam Houston State University, Huntsville, TX; Madeline Roman, PhD, Signature Science, Austin, TX*

Learning Overview: After attending this presentation, attendees will understand the limitation of a previous method utilizing tetrahydrocannabinolic acid synthase (THCAS) polymorphisms to differentiate marijuana and hemp and the potential of high-throughput analysis of three synthase genes to reveal novel polymorphisms to identify cannabis crop type or strain.

Impact Statement: Cannabis *sativa*, which can be cultivated as hemp or marijuana, has been one of the most controversial plants in the United States. The recent passage of the Agriculture Improvement Act of 2018 that legalized hemp charges law enforcement with differentiating the two crop types. This presentation will impact the forensic science community by demonstrating the applicability of the previously reported single nucleotide polymorphism (SNP) marker system and the importance of expanding sample varieties and performing more robust sequencing to evaluate genetic markers for the differentiation of hemp and marijuana.

Genetic markers are desirable for determining crop type in sample types inconducive to chemical analysis, such as trace residues, small leaf fragments, immature crops, aged samples, seeds, and root material. Cannabinoid synthase genes are considered the key enzymes that determine a particular cultivar's chemical composition or chemotype. The use of cannabinoid synthase genes to predict *C. sativa* chemotype has been proposed in several studies. However, existing methods for crop type differentiation based on the past theory could lack specificity and accuracy, and a broader range of cannabis varieties must be considered when examining cannabis-based genetic markers.

This study optimized and evaluated a previously reported SNP assay for determining *C. sativa* crop type (marijuana or hemp).¹ In order to achieve the most accurate results, the assay was first optimized to ensure sufficient amplification. The method was then applied to reference *C. sativa* samples from NIDA (National Institute on Drug Abuse) and NIST (National Institute of Standards and Technology), hemp samples from the USA and Canada, and marijuana samples from USA-Mexico and Chile. The SNP assay correctly identified crop type in most seized samples and commercial hemp based on the original model with active versus inactive isoforms of THCAS. However, nine out of eleven marijuana reference samples appeared to be classified as hemp. In addition, several hemp seeds, which generally have low levels of cannabinoids, were classified as marijuana, and two strains of legal CBG hemp flowers were classified as marijuana. The results demonstrated the inaccuracy of the model assuming active- and inactive-THCAS. This suggested that the reported THCAS SNP markers might not represent the genetic variation of the synthase gene (including gene expression at the time of harvest) and are not directly related to the cannabinoid content in the cannabis plant. This study also performed qualitative chemical analysis on hemp and reference samples to better understand the relationship between the chemotype and genotype.

In order to develop more robust genetic markers, sequencing of the three synthase genes of the cannabis reference materials was performed. This data serves as a preliminary design for a future next generation sequencing custom panel targeting cannabinoid synthase genes. This custom panel will serve as a comprehensive analysis of the three synthase genes in order to discover novel polymorphisms between crop types and/or strains.

Overall, this presentation highlights the limitation of a previously published method for the differentiation of marijuana and hemp and the potential to find novel polymorphisms between crop types and strains with a high throughput sequencing technique.

B163 An Evaluation of Chloroplast DNA Barcoding Markers to Individualize *Papaver Somniferum* for Forensic Intelligence Purposes

Kari Graham, BS, Sam Houston State University, Huntsville, TX; Rachel Houston, PhD, Sam Houston State University, Huntsville, TX*

Learning Overview: After attending this presentation, attendees will understand a novel research project which seeks to: (1) provide a comprehensive screen of chloroplast DNA barcoding markers for the individualization of *Papaver somniferum* samples, and (2) show how these regions can be used for source attribution and case linkage of seized opium poppy and heroin samples.

Impact Statement: This presentation will impact the forensic science community by providing an overview of regions within the chloroplast genome of *Papaver Somniferum* that can be used for investigative leads for law enforcement to help link cases, distributors, growers, or individual samples

Papaver somniferum, commonly known as opium poppy, is the source of natural opiates like morphine and other alkaloids that produce analgesic and psychotropic effects. These compounds can be chemically separated and modified to produce opioids of varying strength and effectiveness as pain relievers in modern medicine. Unfortunately, the widespread use of these medications has resulted in an epidemic in the United States that causes over 40,000 deaths a year.

The Drug Enforcement Agency (DEA) has recently developed the Heroin Source Program (HSP). One goal of this program is to chemically analyze and identify the impurities of heroin to track and source seized heroin samples. While this program is moderately successful, using genetic information from *P. somniferum* could strengthen the program. Until recently, it was hypothesized that usable DNA could not be obtained from heroin due to the high temperatures and pH ranges used in heroin production. However, a study by Marciano et al. demonstrated that *P. somniferum* DNA suitable for genetic analysis could be extracted from heroin samples.¹ This demonstrated the possibility of utilizing DNA to individualize heroin samples to determine origin. In addition, chloroplast DNA (cpDNA) markers may help to provide the investigative leads needed for source attribution or case linkage.

This project aims to evaluate various chloroplast markers for intraspecific variation from various sources of *P. somniferum*. The chosen barcoding regions were previously shown to distinguish between the closely related *P. somniferum* and *P. setigerum*.² *P. somniferum* seeds were obtained from a variety of sources and extracted. Primers were designed to target various barcoding regions of the *P. somniferum* chloroplast genome: *psbA-trnH*, *trnL-trnF*, *trnE-trnT*, *rpl32-trnL*, *ndhF-rpl32*, *rps16-trnQ*, and *petA-psbJ*. These barcoding regions were then sequenced using Sanger sequencing and screened against published cpDNA sequences for polymorphisms between the varieties of *P. somniferum* samples. Of the barcoding regions screened, two markers, *trnH-psbA* and *petA-psbJ*, showed promise in differentiating samples of *P. somniferum*. This presentation will discuss the process of screening the barcoding regions and designing and optimizing custom Sanger sequencing to identify the cpDNA barcoding markers most helpful in distinguishing between *P. somniferum* samples of different origins. This is an ongoing project, and future research will focus on investigating other promising cpDNA barcoding markers, developing and validating a comprehensive analytical tool used for biogeographical determination and case linkage where opium poppy and its various derivatives are seized.

B164 Development and Validation of Rapid Color Test for Acetic Anhydride

Muhammad Chaudhary, MPhil*, Punjab Forensic Science Agency, Lahore, Punjab, Pakistan; Tahir Jamshaid, MPhil, Punjab Forensic Science Agency, Lahore, Punjab, Pakistan; Rabia Naveed, MPhil, Punjab Forensic Science Agency, Lahore, Punjab, Pakistan; Muhamamd Irfan Ashiq, PhD, Punjab Forensic Science Agency, Lahore, Punjab, Pakistan; Mohammad Tahir, PhD, Punjab Forensic Science Agency, Lahore, Punjab, Pakistan

Learning Overview: After attending this presentation, attendees will be able to know the method validation protocol and economical identification of acetic anhydride samples using simple color test.

Impact Statement: Forensic science community will be able to overcome the challenging identification of acetic anhydride by using this color test in laboratories. Forensic science community will prefer to use this simple and cost-effective test with suitable degree of reliability rather than use of Hi-Tech expensive methods.

Acetic anhydride (AA) $(\text{CH}_3\text{CO})_2\text{O}$, is a colorless liquid with pungent vinegar like odor. It is the largest commercially produced carboxylic acid anhydride.¹ Its use in illegal synthesis of heroin from morphine is important in illicit drug market. The United Nation (UN) has implemented the control of AA as essential precursor around the world.² About 100-250 liters of AA can be used in conversion of opium to about 100 kilograms of heroin.³ Pakistan is also a key market for AA trafficking and its use in heroin production. Various seizures have been carried out in Pakistan during last years which were identified by using UNODC precursor identification kit.

AA can be identified in forensic samples using various chemical spot test and quantified. In 1925, Whitford et al reported a method for rapid and accurate determination of acetic anhydride using anhydrous oxalic acid in the presence of Pyridine as catalyst.⁴ Other method include titration for determination of AA in samples. Rosenbaum's macro procedure was adapted in first method involving 10-25 mg sample with known amount of oxalic acid and titrating with permanganate. The other method involved reaction of 10-15 mg sample with pyridine-oxalic acid mixture in vessel and ultimately determining carbon dioxide gravimetrically using sodium hydroxide-coated asbestos.⁵ All such method are laborious and demand the use of various chemicals in controlled manner. AA is identified using Drug and Precursor Identification Kits developed by UNODC which is expensive.

The method is based on reaction of anhydrous Citric acid (few milligrams) with suspected acetic anhydride sample (more than 20 uL) in the presence of pyridine solvent (two drops) producing yellow to orange red color which on heating turns purple/violet using water bath at 80-90°C. It is pertinent to mention that acetic acid (major degradation product) did not react to produce any color change. Furthermore, various liquids and solvents (similar to acetic anhydride) were tested for selectivity and did not produce any color change. When common drugs of abuse were tested in the presence of acetic anhydride, none of those interfered with the reaction. LOD of this method was found to be 20 uL which is equivalent to 21.6 mg of AA. Furthermore, method was found reproducible when used by different analysts in the laboratory. This method is suitable for screening of acetic anhydride in suspected samples.

Based on the validation study, it is concluded that this test is selective, robust and fit for use in the casework for presumptive screening of acetic anhydride.

B165 A Journey: The International Organization for Standardization/International Electrotechnical Commission (ISO/IEC) 17020: 2012 Accreditation for Crime Scene Units in Latin America

Alejandro Madrigal, BS, Pacific Architects and Engineers, Arlington, VA; Abraham Aysa, JD, Pacific Architects and Engineers, Arlington, VA; Domingo Villarreal, BA, Houston Forensic Science Center, Houston, TX; Ramon Diaz, MS, Pacific Architects and Engineers, Arlington, VA*

Learning Overview: After attending this poster presentation, attendees will have a better understanding of the importance of pursuing accreditation for Crime Scene Investigation Units applying ILAC G19:2014, ISO/IEC 17020:2012 and accreditation requirements from an accrediting body.

Impact Statement: This poster presentation will impact the forensic science community by presenting the journey of Crime Scene Investigation Units toward accreditation and the correction actions of non-conformities detected during the process.

Over decades, there have been many discussions in different countries in Latin America regarding standards for crime scene investigations. The main reason for requiring such standards is primarily due to the critics and review of this activity and the results within respective judicial systems and stakeholders. In these countries, none of national accreditation bodies have been intervening on this issue under the International Laboratory Accreditation Cooperation (ILAC) Guide 19: Module for Forensic Science Process, and the progress had been relatively slow. In USA, accreditation bodies have been in the accreditation process for Crime Scene Units (CSU) under ISO/IEC 17020 with the first units accredited in 2012; Puerto Rico in February 2012 and Texas in March 2012. Outside the USA, Mexico obtained their first accreditation of CSI in September 2015 and Panama in July 2021.

To determine the best way forward for Central and South America, and to ensure that a common approach would be adopted, International Narcotics and Law Enforcement Affairs (INL) and the International Criminal Investigative Training Assistance Program (ICITAP) from the US Department of Justice agreed in a joint venture to prepare Crime Scene Units for accreditation throughout Central and South America, to ensure common interpretation of the international standards and to obtain valid, reproducible and quality of results. The outcome was an understanding between INL and ICITAP USDOJ, recommending the international quality standard for inspecting bodies, ISO/IEC 17020:2012, as the most appropriate standard for crime scene investigation. At the same time, a working group composed of forensic advisors from USA and Mexico, with experience in Quality Systems, Crime Scene Investigations (CSI) and other Forensic Disciplines, aided in the interpretation of ISO/IEC 17020 for processing crime scenes. These forensic advisors help in the development of framework of quality standards for forensic science to meet the needs of the Criminal Justice System and is designed to give the public confidence that forensic science used in the investigation and prosecution process is fit for purpose.

The Forensic Advisors contracted by federal contractors are working with INL and ICITAP to support the development of quality standards framework inclusive of the quality management system: development and review of technical procedures, instructions, guides, manuals, forms; GAP analysis, training, consultation, advice towards validation, verification, equipment (instruments, reagents, certified materials, consumables, etc.) corrective actions, and continued education toward accreditation. This framework from INL and ICITAP USDOJ, together with the contracted Forensic Science Advisors sets out the quality requirements for providers of forensic science services into the criminal justice system. It is a firm understanding that all forensic science providers shall gain accreditation to ISO/IEC 17020:2012 and/or ISO/IEC 17025:2017, as appropriate, for their scope of work, and that individual practitioners are able to demonstrate a level of competence commensurate with the requisite of the forensic discipline and country legislation. The scope of this poster presentation is focused on crime scene investigation, restricted to ISO/IEC 17020:2012 and how to obtain the accreditation of this field.

Crime Scene Investigation (CSI), Accreditation, ISO/IEC ISO 17020:2012

B166 The Effect of Household Cleaning Agents on the Fluorescein Presumptive Blood Test

River Williams, University of Findlay, Findlay, OH; Jaymee Kim, PhD, University of Findlay, Findlay, OH*

Learning Overview: After attending this presentation, attendees will have an increased understanding of the impact that cleaning agents can have on blood detection using fluorescein.

Impact on the Forensic Science Community: This study contributes findings regarding the impacts of common cleaning agents on the accuracy of presumptive blood detection.

Blood evidence found at crime scenes can often provide valuable information to investigators. To detect the presence of blood, presumptive blood tests are performed at the scene. One common test uses a fluorescein reagent. When in contact with blood, oxidation of the hemoglobin causes the sample to fluoresce under ultraviolet light.¹ Because household cleaning agents may be used to obscure evidence of a crime, investigators need to ensure that the fluorescent reaction in this test is not impeded with cleaning agents.

Building on studies conducted by Adams, Rancourt, and Christensen and Signaevsky, this project uses ten common household cleaners selected to undergo the fluorescein test with synthetic human blood present.^{2,3} After a preliminary trial, all samples had a positive reaction with the fluorescein, including the negative controls containing only cleaning agents. This indicates that these cleaning agents have components with inherent fluorescent capabilities, which could disrupt the determination of the presence of blood at crime scenes. In a second phase of the experiment, the same cleaning agents were prepared at 5%, 25%, and 50% dilution with deionized water. These dilutions were used as samples for carrying out the fluorescein procedure without blood being present and evaluated for the presence of absence of fluorescence under UV light. In this trial, the samples all exhibited fluorescence including negative controls. This is consistent with the original findings by Signaevsky, which showed abnormalities in some negative controls; however, the findings are inconsistent with Adams, Rancourt, and Christensen, which did not have any abnormal negative controls.^{2,3}

Future applications of this study would be to test more cleaning agents to determine if they have fluorescent capabilities.

Blood Detection, Fluorescein, Cleaning Agents

B167 Soil Mineral Analysis by Particle Correlated Raman Spectroscopy (PCRS): Optimized Dispersion and Double-Pass Raman Analysis

Savannah Brown BS, University of New Haven, West Haven, CT; Gabrielle Messe, BA, University of New Haven, West Haven, CT; Hannah Garvin, MS, University of New Haven, West Haven, CT; Nicholas Gogola, MS, University of New Haven, West Haven, CT; Chase Notari, BS, University of New Haven, West Haven, CT; Virginia Maxwell, PhD, University of New Haven, West Haven, CT; John Reffner, PhD, John Jay College of Criminal Justice, New York, NY; Peter De Forest, PhD, John Jay College of Criminal Justice, New York, NY; Christopher Palenik, PhD, Microtrace LLC, Elgin, IL; Peter Harrington, PhD, Ohio University, Athens, OH; Deborah Huck-Jones, PhD, Malvern Panalytical Ltd, Malvern, Worcestershire, United Kingdom; Bridget O'Donnell, PhD, HORIBA Scientific, Piscataway, NJ; Andrew Whitley, PhD, HORIBA Scientific, Piscataway, NJ; Brooke Kammrath, PhD, University of New Haven, West Haven, CT*

Learning Overview: After attending this presentation, attendees will gain knowledge of the optimized parameters for the PCRS analysis of soil minerals to achieve maximized discrimination, through particle dispersion and Raman microspectroscopy.

Impact Statement: This presentation will impact the forensic science community by detailing the optimized methods for soil mineral particle dispersal and PCRS analysis, which are necessary for maximizing the discriminating power of PCRS for forensic soil analysis.

The analysis of soils has become a neglected field in forensic science due to the perception of current practices as being overly time-consuming, subjective, and ineffective. The potential value of soil evidence is incontrovertible, and thus several analytical approaches are being researched which can revitalize the use of soil as forensic evidence. Particle Correlated Raman Spectroscopy (PCRS) is a recently developed technique that has demonstrated value for forensic soil analysis, as it combines particle size distribution and morphological measurements with chemical identification by Raman spectroscopy. This technique is non-destructive, rapid, and can be automated; thus, PCRS may provide more detailed information than traditional methods about a soil sample.

Previous research identified optimized parameters for the identification of soil minerals via PCRS. Such parameters included the laser wavelength and power, magnification, exposure time, and grating. These parameters, which were initially optimized using 10 diverse minerals, have been applied to the 60 most commonly encountered minerals. Traditional figures of merit and response surface modeling of a multi-level experimental design were used to confirm the optimized Raman collection parameters. It was concluded that a double-pass Raman analysis, using two laser wavelengths, is needed to identify the majority of the soil minerals. Further, total Raman acquisition times of 1 second per particle were achieved which would enable a large number of mineral grains to be identified in a reasonable time period, thus making it possible to have robust datasets for subsequent statistical analysis.

Prior research also began the process of parameter optimization for the vacuum dispersion of soil samples. Proper dispersion must be attained to minimize overlapping or clustered particles so that data can be accurately obtained for individual particles. Soil samples were prepared for analysis by washing alone, washing and sieving, or analyzed with no further preparation. Each sample was then dispersed onto glass analytical plates with various combinations of vacuum dispersion parameters (sample volume, vacuum pressure, and time for dispersal and settling). The dispersion was assessed microscopically via PCRS for reproducibility, uniformity, dispersion density, and the maintenance of particle morphological characteristics throughout the processing. PCRS was also used to analyze four morphological characteristics of these dispersed samples – area, diameter, ellipse ratio, and circularity – at three points on the analytical plate – center, 2 cm from center, and 3.5 cm from center.

The results from this research, optimized PCRS analysis parameters, will next be applied to a large collection of soil samples to create a robust database combined with statistical analysis to support the evidentiary significance of soil. Optimization of sample preparation, dispersal, and Raman analysis parameters are necessary to take full advantage of the discriminating power of PCRS for soil analysis.

Forensic Soil Analysis, Vacuum Dispersion, Raman Spectroscopy

B168 Feature Occurrence and Error Rates in Textile Physical Fit Comparisons

Zachary Andrews, BS, West Virginia University, Morgantown, WV; Colton Diges, West Virginia University, Morgantown, WV; Tatiana Trejos, PhD, West Virginia University, Morgantown, WV*

Learning Overview: After attending this presentation, attendees will gain a better understanding of the error rates in physical fit comparisons of textiles and the occurrence rate of specific features that influence the decision-making process.

Impact Statement: This presentation will impact the forensic science community by responding to calls for research into the development of standardized methods and identification of error rates in physical fit comparisons.

Textiles are a frequently encountered form of evidence at crime scenes. Textiles can take the form of clothing, bedding, carpeting, and more. This type of evidence is particularly useful in physical fit comparisons. A physical fit directly links two items of evidence as originating from the same common source and is considered as the highest degree of association between two items due to the belief that it is extremely unlikely that two unrelated fractured items fit together as one. Despite the potential value of this evidence, the validity and reliability of physical fit comparisons has not been widely studied, and there are no consensus-based standard protocols or criteria for conducting these types of comparisons.

Due to the common nature of textiles at crime scenes, and the potential value in identifying a physical fit between two separated items, a study was designed to evaluate performance rates in textile physical fit comparisons. A systematic method was adapted for use with textiles where the analyst divides the length of the textile edge into ten comparison areas.¹ The analyst then examines the quality of the physical fit between the two textiles in question at each comparison area and classifies each individual area as a “fit” or a “non-fit” using a score of 1 (fit), 0 (non-fit), or 0.5 (inconclusive), respectively, along with documenting the observed features. The numbers assigned to each area are then summed and divided by 10 (the total number of comparison areas) to reach an overall edge similarity score. Variability in the construction and composition of textiles also required the identification of factors that affect the suitability of specific types of textiles to undergo a physical fit comparison. Specific features that either enhance or diminish the quality of a physical fit between textiles are also documented in a systematic method.

A textile comparison set of 200 samples was created using five clothing articles of 100% cotton knit clothing. Three fabrics were solid colored, while two items exhibited a multi-colored pattern in their construction. The sample set was evenly split between hand-torn and stabbed separation methods to represent two common ways that textiles can be separated in a crime. The ground truth of the comparisons was kept blind to the analyst, who then conducted all 200 comparisons using the systematic method described previously. The analyst documented specific features throughout the comparison process that either increased or decreased their confidence in either a fit or non-fit decision.

The analyst completed the stabbed textile subset with 100% accuracy, and therefore no misclassifications. The hand-torn textile subset was completed with 96.84% accuracy. The analyst reported that 2 comparisons were inconclusive, while one true positive comparison was reported as a non-fit, resulting in a false negative. Moreover, five comparisons in the hand-torn subset, not included in the above performance rates, were identified as not suitable for comparison due to extreme distortion from the tearing process masking potential features that could have informed the analyst’s decision-making process. These performance rates are comparable to a previous study in our group using the same method on a subset of 100 sample of varying compositions, which all exhibited inter- and intra-examiner accuracies between 87.20% and 98.00%.

Several prominent textile features were identified throughout the comparison process, including weave direction alignment, pattern/print alignment, fiber gap alignment, curling, secondary tearing, fluorescence, and extreme distortion, that were all influential in the decision-making process. Weave direction proved to be an especially informative feature, as it affects the alignment or misalignment of the direction of the fiber construction at the comparison edge.

Physical Fits, Textiles, Error Rate

B169 Detection of Animal Blood Using Green Synthesized SERS

Geraldine Monjardez, PhD, Sam Houston State University, Huntsville, TX; Erin Bruner, MSc, Texas DPS Houston Crime Lab, Houston, TX; Rajesh Balaraman, PhD, Vironova, Cambridge, MA; Patrick Buzzini, PhD, Sam Houston State University, Huntsville, TX*

Learning Overview: After attending the presentation, attendees will gain a better understanding of the practical use of green synthesized SERS to collect and identify body fluids from crime scenes.

Impact Statement: This presentation will impact the forensic science community by presenting an efficient and rapid method to detect non-human blood.

While DNA profiling is commonly used to identify individuals, identifying the type of body fluid recovered from crime scenes before it can be used for DNA typing may be critical to help qualifying its relevancy to the case. While typical approaches that rely on biochemical tests to detect and identify body fluids already exist, they present several drawbacks. Surface-enhanced Raman spectroscopy (SERS) has been used to detect trace level of chemical and biological analytes using their characteristic vibrational signatures. This study aims to develop a method of collection and identification for non-human blood using green synthesized SERS swabs.

Following a general movement in the natural sciences to move toward more sustainable practices, silver nanoparticles were successfully synthesized directly on nylon evidence swabs using a biosynthesis reaction and curcumin as the reducing agent to form the nanoparticles. The nanoparticles were characterized on the swabs by Scanning Electron Microscopy coupled with Energy Dispersive X-Ray Spectroscopy (SEM-EDS). The SEM images confirmed the presence of the nanoparticles adhering to the fibers of the swabs and their rough surface texture. The nanoparticles were observed to be dispersed on the fibers, which led to the creation of random hot spots

The detection of bovine blood was investigated by analyzing decreasing volumes of the blood swabbed with the SERS swabs. While swabbing 30 μ L and 20 μ L of blood resulted in the most resolved spectra, swabbing 10 μ L of blood still produced identifiable peaks, with a much lower intensity. Wetted swabs were used to analyze dried bovine bloodstains on two different substrates, 100% cotton fabric and glass microscope slides. The results suggest that the surface on which the dried bloodstain is found may determine whether a wet or a dry SERS swab should be used to collect the sample.

Following the analysis of bovine blood, the SERS swabs were used to collect and analyze horse and sheep blood. The spectra showed that the peak intensity differed between the three species. Dominant bands in some spectra also displayed a shift in dimensions of both left/right. This could be due to several factors, including the complexity and heterogeneity of blood, which could be further increased by the swabs, and the degree of dryness of the sample. Raman bands characteristic of blood were identifiable for each specie, showing that the SERS swabs allowed the successful detection of the three animal blood species.

This study demonstrates the efficiency of the green synthesis to grow the nanoparticles on the swabs and shows their viability to be used as SERS substrates to collect and identify animal blood using Raman spectroscopy.

Forensic Science, Animal Blood, SERS

B170 The Visualization of Bruises Using an Alternate Light Source (ALS)

Wan Yu, Tan, BSc*, Boston University, Boston, MA; Karen Kelly, MD, East Carolina University, Greenville, NC; Ann Marie Mires, PhD, Anna Maria College, Paxton, MD; Sabra Jones MSc, Boston University, Boston, MA

Learning Overview: Attendees can evaluate the effectiveness of using different ALS wavelengths for the visualization of blunt force injuries (i.e. contusions) to the skin. Since ALS is a standard crime scene equipment, there would be no added cost and this documentation technique could be considered for use in the field prior to transporting the victim to either the hospital or the morgue setting.

Impact Statement: With the rise in domestic abuse, victims are usually subjected to physical abuse. This study will enable forensic officers to make use of existing crime scene equipment to enhance the visualization and documentation of bruises on victims of abuse.

With the global pandemic, there has been mandatory movement restrictions by countries around the world. There has also been an increase in domestic abuse; such violence often presents in many forms with physical abuse heading the list.¹⁻⁴ This study was conducted to enable forensic officers to make use of existing crime scene equipment to enhance the visualization of bruises on victims of abuse.

When a case of abuse is reported, evidence of the abuse must be documented. Traditional methods of investigation involve questioning the victim or abuser, followed by documentation using photography and note-taking which may not accurately represent the injuries. In addition, the amount of force used, area of injury and the age of the injuries could affect the appearance of blunt force trauma including bruising. At times only redness is observed on the victim's skin making the injury difficult to document; such injuries would constantly be overlooked.^{5,6} Alternate Light Source (ALS) is a common, cheap, and effective piece of equipment used by forensic examiners at the crime scene to reveal objects missed by the naked eye. With the use of ALS, the documentation of existing bruises can be enhanced, while bruises that are missed by the naked eye can be revealed.

In this study, the effectiveness of visualization of blunt force injuries (i.e., contusions) to the skin at different ALS wavelengths was evaluated to determine the optimal wavelength for documentation of bruises.⁷⁻¹⁰ Bruises were inflicted on 57 participants with no known medical conditions following institutional approval. The participant was in a seated position while a cylindrical ball of ~465 grams was dropped at a height of 1.5 meters through a vertically positioned tube onto the ventral surface of the participant's forearm. The injury site was then observed and documented under white light, 415nm, 460nm and 550nm. Photographs of the forearm were taken under at all wavelengths prior to bruising, immediately after bruising, 3 hours after bruising, and at specific time points over a period of 21 days. The results showed better visualization of the injury observed at a wavelength of 415nm and 460nm.

A blind study was conducted using the same methodology to determine the validity of the experiment. A colleague was briefed and tasked to conduct a blind trial on 12 participants following institutional approval where the researcher has no knowledge on which participant the bruise was inflicted on. Photographic documentation and observations were recorded with the results only made known to the researcher at the end of the experiment. The results showed that the methodology is accurate at about 75%.

This study shows that the use of ALS provided an effective alternative with the visualization and documentation of blunt force traumatic injuries in the form of bruising compared to traditional documentation methods without added cost and should be considered for use in future cases involving trauma and physical abuse. Additionally, since ALS is the standard crime scene equipment, the documentation of bruising by forensic examiners can be initiated in the field prior to transport of victim to either the hospital or morgue setting.

B171 The Case of a Ferocious Double Homicide: When Your Home Hides the Killer and the Murders' Weapon

Matteo Scopetti, Department of Anatomical, Histological, Forensic and Orthopaedic Sciences, Sapienza University of Rome, Italy; Martina Padovano, Department of Anatomical, Histological, Forensic and Orthopaedic Sciences, Sapienza University of Rome, Italy; Federico Manetti, Department of Anatomical, Histological, Forensic and Orthopaedic Sciences, Sapienza University of Rome, Italy; Martina Zanon, Department of Medicine, Surgery, and Health, University of Trieste, Trieste, Italy; Alessandro Santurro, Department of Medicine, Surgery and Dentistry, University of Salerno, Salerno, Italy; Stefano D'Errico, Department of Medicine, Surgery, and Health, University of Trieste, Trieste, Italy

Learning Overview: After attending this presentation, the attendees will be able to better appreciate the methodological approach adopted in a case of double murder performed with multiple different improper weapons.

Impact Statement: This presentation will have an impact on the forensic science community by describing an extremely ferocious double murder carried out by associating the use of blunt means with the action of improper piercing objects used to penetrate the victims' neck and abdomen.

Both murders occurred in the same building. The first victim was a 65-year-old woman, mother of the killer, a 34-year-old man with a history of substances abuse. The woman was found near the entrance door of her home at the second floor, prone, in abundant blood, with evident bruising and extensive lacerations at the level of the head and the face, with a broken leg of a chair still inflicted in her abdomen. The walls and the ceiling of the room were extensively smeared with bloodstains; many umbrellas and fragments of wood were found on the floor. The second victim, a 77-year-old woman, lay two floors below. The woman was found on the stairs, half-seated with her neck pierced by two foreign bodies still in site: a wooden one, attributable to a fragment of a chest, and a second metallic one, referable to a candlestick arm. A bloody and deformed umbrella stand, identified as the possible blunt object used to hit the first woman, was found in another apartment, whose door was broken down, together with the remaining parts of the candlestick.

On the basis of the collected testimonies the murderer, once out of the building, stole a car, ran a group of cyclists over, assaulted two elderly people, to finally end his escape by swimming in a lake until being arrested by the police.

The Prosecutor ordered the execution of a judicial autopsy for both corpses, in order to determine the cause of death and obtain further useful information for evidential purposes. The two bodies were PMCT-scanned prior to autopsy and the 3D reconstruction allowed to better define of the foreign bodies' location and the presence of multiple fractures in both cases.

In the first case, external examination allowed to appreciate discontinuity and detachment of a portion of scalp, and the presence of figured lesions depicting the surface of the chair leg on her back. At autopsy, it was possible to clarify the structures damaged by the piercing object, which caused the laceration of the vascular structures of left renal hilum.

Also, in the second case it was possible to identify figured lesions depicting, this time, the tip of the candlestick arm. At autopsy, the dissection of the neck according to Adams technique revealed the laceration of main vascular structures and fractures of mandible and cervical vertebral corpses caused by the metallic means.

The investigations performed, completed with histopathological assessments, allowed to clarify the mechanisms behind the death: in the first case, cause of death was identified in the hemorrhagic cardiovascular collapse due to the laceration of renal hilum, while in the second one asphyxial death because of external compression of airways by hemorrhage and piercing means was supposed.

Blunt Force Injury, Forensic Pathology, Double Homicide

B172 Effects of Improper Ammunition Storage

Victoria Andre, MS, John Jay College of Criminal Justice, New York, NY; Peter Diaczuk, PhD, John Jay College of Criminal Justice, New York, NY; Patrick McLaughlin, MS, John Jay College of Criminal Justice, New York, NY*

Learning Overview: After attending this presentation, attendees will become familiar with the effects of improper ammunition storage and the consequences to discharging the compromised ammunition in a firearm.

Impact Statement: This presentation will impact the forensic science community by revealing the detrimental nature of outside contaminants permeating cartridges, causing them to malfunction.

Firearms are commonly used by law enforcement, hunters, and civilians either for protection, sport or criminal activity. A firearm is a device used to aim and discharge projectile(s) from a barrel towards a target at high velocity due to gases produced through rapid and confined burning of propellant.¹ The projectiles previously mentioned are one of the four components of ammunition. Ammunition is used in traditional firearms such as rifles and handguns, and consists of a cartridge case, propellant, a bullet (projectile), and primer.² The two types of priming systems within the cartridge that are commonly used today are rimfire and centerfire cartridges.

For research purposes, cartridges can be fired to observe and record their performance. To obtain velocity measurements, optical chronographs or a Doppler radar unit such as the LabRadar are commonly used. As with all ammunition, there are malfunctions that can occur. The types of malfunctions that are commonly seen in ammunition are misfire, stovepipe, hang fire, double feed, squib load and misfeed.³ Improper ammunition storage is also a major factor that plays a role in ammunition failure. Work stress and environmental factors can cause ammunition failure to occur as well.

Another form of improper ammunition storage is where the storage environment being used abruptly changes due to an external liquid or solid material submerging the ammunition. In this scenario, the external liquid or solid material may be able to permeate the ammunition if it is submerged over an extended period of time. As a result, ammunition failure and damage to the firearm may occur if used. While this situation can commonly happen, little research is seen if and how ammunition would function when used in a compromised condition. This study observed how ammunition function is affected when it is improperly stored in the following materials: water, soil, Hoppes 9 Solvent (a gun bore cleaner that contains kerosene, ethyl alcohol, and ammonium hydroxide), and WD-40, (a water-displacing spray that contains aliphatic petroleum distillates and petroleum base oil).

This research showed that although there were distressed cartridges that fired successfully with an expected average velocity measurement obtained, the majority of the cartridges exhibited changes such as ammunition failure, low velocity and anomaly velocity measurements. The types of ammunition failure such as misfires, stovepipe, and double feed were observed with misfires being the most common. All of the distressing materials used had an adverse effect on the cartridges, with Hoppes 9 Solvent being the most detrimental on all cartridge sets. These findings encourage future work to be done to observe any additional detrimental effects of improper ammunition storage in an external liquid or solid.

B173 The Forensic Utility of the ForenSeq™ MainstAY Kit With Challenging Samples

Lucio Avellaneda, BS, Sam Houston State University, Huntsville, TX; Ryan Gutierrez, PhD, Sam Houston State University, Huntsville, TX; Rachel Houston, PhD, Sam Houston State University, Huntsville, TX*

Learning Overview: After attending this presentation, attendees will better understand the improvements and challenges of implementing Next Generation Sequencing (NGS) in a forensic setting, focusing on the ForenSeq MainstAY kit compared to electrophoresis techniques.

Impact Statement: This presentation will impact the forensic science community by presenting data from challenging samples using NGS and comparing this data to results obtained by capillary electrophoresis methods. It will also compare the workflow and discuss the ease of adapting the instrument/method to a crime laboratory workflow.

Most DNA profiles are generated using a standard workflow: extraction, quantitation, amplification, and detection using capillary electrophoresis (CE). For many years, this workflow has provided results for most DNA case working laboratories. However, there continue to be examples where recovered DNA is insufficient to produce complete STR profiles due to low quality, degradation, or mixtures.¹ In these cases, the need to recover more information has grown, and one technique that is more sensitive and yields more genetic data is NGS. Unlike CE platforms, NGS platforms are not limited by dye channel real-estate, and as a result, more amplicons can be simultaneously sequenced and analyzed.² In addition, this increased number of amplicons provides analysts more power of discrimination to analyze samples more effectively.

This study focuses on a new NGS assay from Verogen, the ForenSeq MainstAY kit. This kit contains approximately one-fourth the number of markers available in the ForenSeq DNA Signature Prep kit, which has shown to be a powerful tool for recovery in bone samples.³ The MainstAY kit focuses on identification, including only autosomal STRs and Y-STRs. The decrease in marker complexity increases sensitivity compared to the Signature Prep Kit and may provide more robust data. In this study, we evaluated the MainstAY kit compared to CE data previously collected from challenging samples using GlobalFiler (Thermo Fisher) and Investigator 24plex QS (QIAGEN) kits. A sensitivity study consisted of varying concentrations of control DNA between 1ng – 8pg.

Results showed that the MainstAY kit had similar or improved recovery compared to the capillary electrophoresis methods for the challenging samples. Overall, quality testing with the MainstAY chemistry demonstrated the chemistry to be highly sensitive and reproducible, with consistent results observed in four repetitions of 12 samples, including controls. Dropout was seen starting with input DNA of 31pg, but approximately 50% of loci were still recovered at 8pg. With challenging samples, the NGS method improved or obtained comparable results to CE in 73% of samples. The most extreme example of recovery improvement was 4% from GlobalFiler to 42% with MainstAY. However, eight samples, including bone, touch, muscle, hair, and saliva extracts, did not obtain a higher recovery percentage of STRs as CE methods. For this reason, these samples will be included for testing with an enhanced PCR buffer for challenging samples.

MiSeq® FGx™, Next Generation Sequencing (NGS), Degraded DNA

B174 A Modified ForenSeq™ DNA Signature Prep Kit Protocol for Increased Allele Recovery From Low DNA Quantities

Sana Enke, BS, NBACC, Fort Detrick, MD; Kimberly Eskey, MS, NBACC, Fort Detrick, MD; Tracy Ferguson, MS, NBACC, Fort Detrick, MD; Rebecca Just, PhD, NBACC, Fort Detrick, MD*

Learning Overview: After attending this presentation, attendees will understand how optimizing post-PCR steps of a next generation sequencing protocol can recover additional alleles amplified using a human DNA typing assay.

Impact Statement: This presentation will provide the forensic science community with a ForenSeq Signature Prep methodology that can help to obtain probative information from low DNA input samples and minor contributors to mixtures.

The next generation sequencing (NGS) based ForenSeq™ DNA Signature Prep kit (Verogen, Inc.) using DNA Primer Mix B targets 58 total autosomal, Y-chromosome and X-chromosome short tandem repeat (STR) markers, plus identity, ancestry and phenotype-informative SNPs in a single multiplex PCR reaction. Similar to traditional size-based STR typing assays, the recommended DNA input for PCR for the Signature Prep kit is 1 ng, though developmental validation indicates complete profiles can potentially be recovered down to 62.5 pg input DNA using the manufacturer's protocol.¹

To improve the likelihood of recovering probative results from very low template single-source samples and minor contributors in mixtures, we have developed a modified protocol for the Signature Prep kit. The laboratory portions of the modified protocol incorporate multiple post-PCR changes, including: concentration of PCR products at the post-indexing purification step; replacement of the manufacturer's bead-based normalization with equimolar pooling; an additional purification step following library pooling; use of freshly diluted NaOH in place of kit reagent HP3 for consistency in denaturing; addition of HCl to account for a higher concentration of NaOH and fully neutralize the denaturing reaction; and sequencing from loading concentrations ranging from 12-20 pM.^{2,3} The modified protocol also utilizes optimized data analysis parameters that aim to retain authentic low-level alleles in mixtures (via a low 1.7% dynamic analytical threshold for most loci), while still filtering error sequences (noise) and stutter (when desired).

This presentation will include empirical data demonstrating the efficacy of the modified protocol as compared to the standard (manufacturer's) protocol for the Signature Prep kit for the recovery of alleles from DNA quantities equal to or less than 50 pg input DNA. In addition, the presentation will demonstrate the value of the increased information recovery on the interpretation of mixtures. The modified protocol produces high quality data from both the assay target template quantity of 1 ng and low template samples, and helps to realize the potential of increased sensitivity to low quantities of DNA using NGS technologies.

Next Generation Sequencing (NGS), Low Template Samples, Mixtures

B175 Predicting Short Tandem Repeat (STR) Genotypes From Identity-Informative Single Nucleotide Polymorphisms (SNPs) Across Three Ancestry Population Groups

Anjalika Balasuriya, HBS, University of Toronto, Mississauga, Ontario, Canada; Nicole Novroski, PhD, University of Toronto, Mississauga, Ontario, Canada; Frank Wendt, PhD, Yale University, New Haven, CT*

Learning Overview: After attending this presentation, attendees will have a better understanding of a novel approach to genotyping highly compromised/degraded human remains.

Impact Statement: This presentation will impact the forensic science community by presenting the use of identity-informative single nucleotide polymorphisms (iiSNPs) genotypes to statistically predict genotypes at short tandem repeat (STR) loci across the genome.

In forensic investigations, highly heterozygous STRs are the gold-standard genetic tool for attributing the source of biological evidence to a suspect. STR genotyping is considerably more difficult when studying compromised evidentiary substrates, skeletonized human remains, and other historical biologicals due to the degraded nature of available DNA.^{1,2} Furthermore, once the average DNA fragment length is reduced to sizes smaller than 300 bp, the template DNA may no longer be suitable for current STR typing methods which rely on the amplification of STR markers by polymerase chain reaction (PCR).³ When processing degraded DNA, numerous PCR amplification issues can occur, such as heterozygous peak imbalance, allelic drop-out, and artifact signals, all contributing to an incomplete and/or low-quality DNA profile.³

Relative to STRs, single nucleotide polymorphisms (SNPs), which represent single base changes, can be genotyped using smaller sections of DNA and are not subject to PCR artifacts. Therefore, in suitable numbers, SNPs may be comparably powerful source attribution loci. As SNPs require nearly triple the loci to match STR match statistic power, their applicability to degraded DNA is still limited. In other words, it remains difficult to successfully genotype a full iiSNP profile.⁴ Utilizing samples from the 1000 Genomes Project, genotypes of 94 iiSNPs from the ForenSeq™ DNA Signature Prep Kit (Verogen, San Diego, CA, USA) were used to statistically predict genotypes at STR loci across the genome. We report relatively low accuracy of STR genotypes derived from SNP data and discuss the limitations of predicting highly polymorphic STR genotypes for source attribution statistics.

Forensic Genetics, Single Nucleotide Polymorphisms, Short Tandem Repeats

B176 The Development of an Enhanced Buffer to Overcome Polymerase Chain Reaction (PCR) Inhibition for DNA Typing by Targeted Next Generation Sequencing (NGS)

Shan-Fu Wu, Verogen, San Diego, CA; Keenan Fleming, Verogen, San Diego, CA; Richelle Barta, Verogen, San Diego, CA; June Snedecor, Verogen, San Diego, CA; Samantha Snow, Verogen, San Diego, CA; Joana Antunes, Verogen, San Diego, CA; Sarah Radecke, Verogen, San Diego, CA; Juan Perez, Verogen, San Diego, CA; Gothami Padmabandu, Verogen, San Diego, CA; Kathryn Stephens Verogen, San Diego, CA*

Learning Overview: After attending this presentation, attendees will gain information on an option to overcome PCR inhibition in challenging casework samples for DNA typing by targeted Next Generation Sequencing.

Impact Statement: This presentation will impact the forensic science community by presenting studies for improved DNA typing of challenging samples using targeted Next Generation Sequencing with highly multiplexed STR and SNP amplicons.

Targeted Next Generation Sequencing (NGS) or massively parallel sequencing (MPS) has recently emerged as an efficient approach in forensic DNA analysis to profile both short tandem repeat (STR) and single nucleotide polymorphism (SNP) markers at a relatively high plexity.^{1,2} Yet, current NGS-based approaches, unlike capillary electrophoresis-based ones (CE), are susceptible to PCR inhibitors.^{3,4} Common inhibitors in forensic samples including humic acid (from soil) and hematin (from blood) have been shown to negatively impact library preparation PCR amplification yield and consequently lead to lower sequencing reads and allele detection rate. The sequencing results also show that larger amplicons tend to drop out in the presence of inhibitors.

Approaches to overcome inhibition in forensic samples include dilution or further purification of samples, adjusting polymerase, bovine serum albumin (BSA), and magnesium concentration, and the use of smaller amplicons in PCR reactions. Addition of 10 ug BSA alone to the initial PCR reaction in ForenSeq DNA Signature Prep Kit has been shown to improve inhibitor tolerance significantly.⁴ However, developing NGS assays for DNA typing encounters challenges not only on PCR inhibition, but also with PCR and sequencing fidelity. Additional challenges for ForenSeq DNA Signature Prep Kit are to target both large and small markers at a high plexity. Here an enhanced PCR buffer (ePCR1) utilizing PCR additives, such as BSA, PEG, glycerol, and DMSO with the high-fidelity polymerase was developed and verified.

The verification of ePCR1 was performed following the revised guidelines for developmental validation from the Scientific Working Group on DNA Analysis Methods (SWGDM, December 2016), with addendum on STR typing to address NGS (April 2019). Two multiplexes of markers were tested with ePCR1: 1) DNA Primer Mix B (DPMB) targets 27 autosomal STRs (aSTRs), 24 Y-STRs, 7 X-STRs, and 172 SNPs; 2) DNA Primer Mix C (DPMC) targets 27 aSTRs and 25 Y-STRs.

Comparing to the original PCR1 buffer, the inhibitor tolerance with ePCR1 is improved by 50-fold for humic acid, 3.3-fold for hematin, and 8-fold for tannic acid for DPMC. In the absence of inhibitors, metrics such as allele balance, locus coverage, and sequencing noise remain comparable between PCR1 and ePCR1 buffers. Stutter, however, is slightly elevated with ePCR1 buffer compared to PCR1 buffer. Other studies such as species-specificity, sensitivity, accuracy and precision, stability, and casework-type samples such as bone extracts will be discussed. PCR1 buffer is suitable to profile regular DNA samples while ePCR1 buffer is an option for challenging, inhibited samples for targeted NGS assays.

DNA Typing, PCR Inhibition, Next Generation Sequencing (NGS)

B177 Evaluating Library Preparation Improvements of Short Tandem Repeats (STRs) Using the PowerSeq™ 46GY System for Massively Parallel Sequencing (MPS)

Kyleen Elwick, PhD, Federal Bureau of Investigation, Quantico, VA; Patrick Rydzak, PhD, Federal Bureau of Investigation, Quantico, VA; James Robertson, PhD, Federal Bureau of Investigation, Quantico, VA*

Learning Overview: After attending this presentation, attendees will gain an understanding of how different library preparation methods, purification beads, and quantification kits affect the results of the PowerSeq™ 46GY System.

Impact Statement: This presentation will impact the forensic science community by demonstrating the utility of testing a variety of library preparation methods to obtain the best quality results for forensic-type samples using a commercial STR panel.

Massively parallel sequencing (MPS) provides an alternative to Sanger sequencing and CE-based analysis for DNA typing. It provides increased sequencing throughput and sensitivity capabilities, as well as the ability to sequence multiple markers simultaneously (i.e., SNPs, STRs). This project evaluated the PowerSeq™ 46GY System, containing 22 autosomal loci, 23 Y-STR loci, and Amelogenin, using male and female control DNA and casework-type bone and hair samples.

The goal of this study was to determine which library preparation kit, bead purification method, and quantitative PCR (qPCR) kit provided the highest coverage and best quality results for these samples with the PowerSeq™ 46GY System. The male and female control samples (DNA input amounts from 6.3pg to 1ng) and casework-type samples were amplified with the PowerSeq™ 46GY System and prepared with either the TruSeq® DNA-PCR Free HT Library Preparation Kit (TruSeq®), or the KAPA HyperPrep Kit (KAPA). The library preparation kits were evaluated unmodified, as well as by substituting Agencourt® AMPure® XP beads for the beads of each respective kit. Two qPCR kits were also evaluated with all libraries including the PowerSeq™ Quant MS System (PowerSeq™) and the KAPA Library Quantification Kit (KAPA). The prepared libraries were sequenced using the MiSeq® FGx and data were analyzed with Battelle ExactID® software.

The first experiment in this study evaluated the TruSeq® kit with TruSeq® Sample Preparation Beads using five concentrations of male and female control DNA. The KAPA kit resulted in quantities 2.6-8.7X higher than the PowerSeq™ kit. Post sequencing, coverage was high for all DNA input concentrations, averaging ~3000X-5500X coverage. Samples with a total DNA input of 0.5ng demonstrated the highest read depth. Furthermore, all loci amplified and demonstrated high coverage for each sample.

The second experiment in this study evaluated the KAPA kit with KAPA Purification Beads using five concentrations of male and female control DNA. Again, KAPA quantified libraries were 6-9.2X higher than the PowerSeq™ kit. The sequencing results demonstrated an increase in coverage as the DNA input concentration increased. Average coverage ranged from ~150X-675X, with 1ng samples producing significantly higher ($p < 0.05$) coverage than all other DNA concentrations. In addition, unequal amplification was observed among loci.

The third experiment in this study evaluated the TruSeq® kit with AMPure® beads using five concentrations of male and female control DNA. The PowerSeq™ and KAPA kits resulted in a large range of quantification values for all libraries. Moreover, the KAPA quantified libraries were 10-20X larger than the PowerSeq™ libraries. Coverage ranged from ~4500X-6700X with the highest coverage at 0.25ng of DNA input. Additionally, all STR loci amplified and demonstrated high coverage.

The final experiment in this study evaluated casework-type samples ($n=12$ bone/hair) using the TruSeq® kit with AMPure® beads in place of kit-provided beads. Bone and hair quantities prior to amplification ranged from 0.01ng - 0.51ng DNA input. Using the PowerSeq™ and KAPA library quantification kits, hair samples resulted in quantities up to 7X higher than bone samples. Average sample coverage was ~2800X and coverage ranged from ~1200X (0.01ng) to ~4300X (0.42ng). Additionally, all loci amplified and demonstrated coverage over 1000X using casework-type samples.

Overall, the samples amplified with the PowerSeq™ 46GY System produced the highest quality results when libraries were prepared using the TruSeq® library preparation kit and purified with AMPure® beads.

Massively Parallel Sequencing, STR, Mitochondrial DNA

B178 Forensic Autosomal Short Tandem Repeat (STR) Profiling Using the Promega® PowerSeq™ Kit on Oxford Nanopore® Technologies' MinION Device

Courtney Hall, MS, UNTHSC, Fort Worth, TX; Rupesh Kesharwani PhD, Baylor College of Medicine, Houston, TX; Nicole Phillips, PhD, UNTHSC, Fort Worth, TX; John Planz, PhD, UNTHSC, Fort Worth, TX; Fritz Sedlazeck, PhD, Baylor College of Medicine, Houston, TX; Roxanne Zascavage, PhD, UNTHSC, Fort Worth, TX and UTA, Arlington, TX*

Learning Overview: Attendees will learn about a successful approach to forensic STR profiling using Promega PowerSeq46 kit on the MinION device when data is assessed with our novel program; STRspy.

Impact Statement: This presentation will demonstrate that nanopore sequencing platforms are capable of revealing an additional level of variation in and around STR loci with sufficient read coverage. As the first method to successfully profile the entire panel of autosomal STRs amplified by a commercially available kit using an ONT platform, STRspy significantly increases the feasibility of using Nanopore sequencing in forensic applications.

The high variability characteristic of short tandem repeat (STR) markers is harnessed for human identification in forensic investigations. Despite the power and reliability of current typing techniques, sequence-level information both within and around STRs are masked in the length-based profiles generated. Forensic STR profiling using next generation sequencing (NGS) has therefore gained attention as an alternative to traditional capillary electrophoresis (CE) approaches.

In this proof-of-principle study, we evaluate the forensic applicability of the newest and smallest NGS platform available, the Oxford Nanopore Technologies (ONT) MinION device. Although nanopore sequencing on the handheld MinION offers numerous advantages, including on-site sample processing, the relatively high error rate and lack of forensic-specific analysis software has prevented accurate profiling across STR panels in previous studies. Here we present STRspy, a streamlined method capable of producing length- and sequence-based alleles designations from noisy, long-read data. To demonstrate the capabilities of STRspy, seven reference samples (female: n = 2; male: n = 5) were amplified using the Promega PowerSeq 46GY System and sequenced on the ONT MinION device in triplicate. Basecalled reads were processed with STRspy using a custom STR database containing alleles reported in the STRSeq BioProject NIST 1036 dataset. Resultant STR allele designations and flanking region SNP calls were compared to the manufacturer-validated genotypes for each sample. STRspy generated robust and reliable genotypes across all autosomal STR loci using 500pg of input DNA amplified with 30 PCR cycles, achieving 100% concordance based on both length and sequence. Furthermore, we were able to identify flanking region SNPs with >90% accuracy.

These results demonstrate that nanopore sequencing platforms are capable of revealing an additional level of variation in and around STR loci with sufficient read coverage. As the first method to successfully profile the entire panel of autosomal STRs amplified by a commercially available kit using an ONT platform, STRspy significantly increases the feasibility of using Nanopore sequencing in forensic applications.

Forensic DNA Analysis, STR, Nanopore® Sequencing

B179 GeoFOR: An Innovative Geographic Information Systems (GIS) -Based Application and Accumulated Degree Days (ADD) Calculator

Cristina Tica, PhD, Clemson University, Clemson, SC; Katherine Weisensee, PhD, Clemson University, Clemson, SC; Patrick Clafin, Clemson University, Clemson, SC; Patricia Carbajales-Dale, MS, Clemson University, Clemson, SC*

Learning Overview: Attendees will learn about the newly developed, Geographic Information Systems (GIS)-based application created with the aim of generating a large and representative database of forensic cases. The main goal for collecting a robust dataset is to integrate it with embedded georeferenced information and other curated environmental data, in order to develop accurate models, with known error rates, for calculating time since death.

Impact Statement: This presentation will show how all death investigators, coroners, coroner deputies, medical examiners, forensic educators, and any members of the forensic science community studying and recording deaths can contribute to this project. As the application is already available for use by investigators from across the country and internationally (~40 users thus far), it brings the forensic community together in the creation of an extensive reference database (~ 200 cases and growing) of decomposition and environmental variables, reflective of the realities of forensic casework.

GIS software provides an ideal system from which environmental variables from a local area can be easily obtained from available databases and overlaid on the location of the scene. The current application prototype was developed in Survey123 for ArcGIS software. ArcGIS provides a secure system that is currently utilized by multiple industries and governmental organizations for securely storing sensitive data.

The GeoFOR application provides a framework for data acquisition which minimizes interobserver error and maximizes efficiency. In order to encourage practitioners to submit data from casework, the application has a built-in calculator that provides practitioners with immediate benefits: it calculates the accumulated degree days based on the location the remains are recovered. Accumulated degree days is a commonly used variable for many of the available methods for estimating the postmortem interval (PMI). However, it is a time-consuming process for forensic investigators to recover information from nearby weather stations so as to calculate accumulated degree days. Using the GeoFOR application, the investigator inputs the information about the case and the application automatically compiles information from the National Oceanic and Atmospheric Administration (NOAA), with weather stations available worldwide, in order to quickly determine the accumulated degree days. This addition to the application uses spatial analysis techniques to locate the nearest weather station. Using a Python script, the application gathers historical weather information from the station's RSS feed and calculates average temperature until it reaches the accumulated degree days needed. By providing investigators with this information in a simpler and faster format compared to currently available methods, it provides an immediate incentive for practitioners to contribute their data beyond the long-term goal for improving time since death estimates.

Many statistical and machine learning methods exist which could significantly improve determinations of time since death; however, all these methods depend on the availability of known reference or training sets to develop new methods. In the absence of improved data, it will be difficult to develop improved methods for estimating time since death. This reference set must reflect the reality of forensic casework in order to be applicable to future cases. This means it needs to be geographically diverse and encompass the various scenarios in which human remains are discovered in forensic casework. The goal of this project is to develop this reference data set which will be used to train new models, validate methods, and suggest future experimental studies to refine the understanding of decomposition.

Postmortem Interval (PMI), Decomposition, Taphonomy

B180 The Billey  Johnson Homicide

Bryan Burnett, MSc, Meixa Tech, Cardiff, CA*

Learning Overview: After attending this presentation attendees will understand that for unexpected deaths where the official manner of death is disputed by any party, an examination of the evidence by an independent, experienced death scene analyst should be required.

Impact Statement: Local law enforcement and district attorneys for both the county and state of Mississippi ignored the evidence of homicide and declared the victim committed suicide without any supportive physical evidence.

In the early morning of December 8, 2008, seventeen-year-old Billey Joe Johnson allegedly committed suicide by discharge of his 12-gauge shotgun to the left side of his head at the ear. The death occurred in George County, a rural county in southern Mississippi, USA. Johnson was beside his truck on the driveway to a small business park at the time of his death. According to the only witness to the shooting, a police officer, “I walked back to my vehicle got down my glasses to read the driver’s license [of the victim] and I heard a gunshot and glass break. I looked up, the black male fell on the ground and the gun he had in his hand fell on top of him.”

Johnson was officially determined to have committed suicide but the death scene, processed as a homicide, indicated otherwise. The manner of death was changed to accident by a Mississippi Grand Jury in a decision published February 2009. In April 2011 a letter from the United States Department of Justice, Civil Rights Division to the parents of Billey Johnson supported the suicide death.

Images of the scene were taken by five digital cameras at different times over an eleven-hour span. All of these images appeared to have relatively accurate timestamps in their metadata files.

Blowback from the penetrating 12-gauge shotgun discharge to the victim’s head was substantial, propelling tissue as much as 14.3 m (47 feet) from the victim. The victim’s head was within 30 cm (1 foot) of the interior truck door’s window when the shotgun discharged, a position not possible for either suicide or accident scenarios. The victim was not the shooter by a shotgun that was not his.

The bloodstains show the body was moved twice following the discharge of the shotgun and prior to law enforcement, other than the police officer witness, arriving on scene. The shotgun was placed on the body to stage suicide. A scene processor or a person with access to the scene continued the staging of the scene by placing a handwritten love note (3 x 5 inch card), apparently to the victim, on the dash of his vehicle and moving the card twice during the scene processing. The card was not put into evidence. It was either removed from the truck’s dashboard prior to the victim’s family taking possession of the truck or it was left for the family.

There were multiple assailants involved in Johnson’s death. The person who fired the shotgun (not the victim’s shotgun) was standing near the exterior of the open driver side door. He thrust the shotgun barrel through the closed window breaking it. Two or more persons held the victim and positioned him to be shot near the interior side of the open truck door.

Lynching: “...a killing by a group. It is often used to characterize informal public executions by a mob in order to punish ... or intimidate.” - Wikipedia. Billey Joe Johnson was lynched.

Crime Scene Reconstruction, Staged Suicide, Image Metadata

B181 The Application of Artificial Intelligence (AI) Image Analysis Techniques to Bloodstain Pattern Analysis

James Creecy, PhD, University of Central Oklahoma, Edmond, OK; Jicheng Fu, PhD, University of Central Oklahoma, Edmond, OK; Craig Gravel, MA, University of Central Oklahoma, Edmond, OK*

Learning Overview: After attending this presentation, attendees will have a better understanding of the uses of artificial intelligence and the role it can play in assisting a trained bloodstain pattern analyst.

Impact Statement: This presentation will impact the forensic science community by presenting evidence on the application of artificial intelligence to the field of bloodstain pattern analysis.

The forensic discipline of Bloodstain Pattern Analysis (BPA) has played a crucial role in the reconstruction of countless crime scenes. The shape, size, distribution, and location of bloodstains at a crime scene have aided trained analysts in locating potential murder weapons, estimating the origin of attacks, and determining if a body had been moved or relocated from the original crime scene. Despite well-established legal precedent, there continue to be aspects of BPA that can be improved upon. To date, BPA relies primarily on manual methods of analysis to process a crime scene. As with most forensic disciplines, BPA analysts require rigorous training on the use and application of these manual methods before applying them at a crime scene. It is therefore imperative to have forensic analysts who can accurately produce consistent and reliable results. However, human error has been known to occur under challenging case scenarios, and analysts have been known to interpret the same body of evidence differently. Commonly, errors in identifying blood spatter evidence arise when the crime scene has large amounts of bloodstains which can yield less information during analysis. Based on the overwhelming success of artificial intelligence (AI) image analysis in other areas of science and medicine, it is logical to infer that automated and computer-assisted analysis methods can be employed successfully to analyze bloodstain patterns. The goal of this study was to utilize AI algorithms to assist the analyst in the analysis of bloodstain patterns. To achieve this goal, a few AI algorithms were employed to estimate the angle of impact for a large data set of controlled spatter pattern samples. This study focused on the analysis of photos taken from a single impact angle as the primary input data. Bloodstain patterns were experimentally constructed using controlled conditions, and a single variable was altered at a time. This study determined that the AI-assisted approach accurately assigned the correct angle of impact for 78.64% of all data analyzed. Interestingly, the angle range that the AI was unable to resolve accurately, 80°-60°, is the same angle range that the manual methods of analysis struggle to resolve. In conclusion, AI-based analysis of bloodstain patterns is a promising area of study to improve the forensic discipline of bloodstain pattern analysis.

Artificial Intelligence, Bloodstain Pattern Analysis, Image-Processing Method

B182 Determining the Minimum Size of Soil Samples For Forensic Geological Analysis

Brittany Claassen, BS, Cedar Crest College, Allentown, PA; Emma Redman, Cedar Crest College, Allentown, PA; Ted Schwartz, MS, Westchester County Forensic Laboratory, Valhalla, NY; Thomas Brettell, PhD, Cedar Crest College, Allentown, PA; Lawrence Quarino, PhD, Cedar Crest College, Allentown, PA*

Learning Overview: Attendees will learn that the minimum amount of soil needed for result reliability varies according to method and soil type.

Impact Statement: This research will impact the forensic science community by contributing to the understanding of the minimum soil techniques before divergent and spurious results occur.

Goal of Project: The goal of this project is to analyze and determine the sensitivity of several common soil techniques and to determine the minimum sample needed for robustness of method.

Although not widely practiced in most forensic laboratories, numerous case studies exist in literature showing the evidentiary value of the forensic comparative analysis of soil.¹ Soil in a forensic context can be of limited size and although numerous comparative techniques exist, the minimum sample size required for reproducible and accurate data in each of these techniques is not well known. In fact, determining the minimum sample size for visual color determination of soil samples has been identified as an OSAC research need. In this study, 15 surface layer soil samples from different geologic areas were collected and homogenized for analysis. Various techniques including digital color determination, particle size distribution, d-space ordering by x-ray diffraction (XRD), and loss on ignition (organic content) were applied to sample sizes ranging from 2 to 0.25 grams. Differences in color between samples was measured using the Nix Color Pro QC Sensor and calculated using Delta E. It was found that color differences between samples and sample sizes was highly dependent on particle size components within samples. Locations that consisted of higher portions of silt and clay fractions reported low Delta E values between sample sizes and among sample sizes, compared to samples with higher coarse fractions which reported low Delta E values between sizes and among sample sizes. Descriptive statistics were utilized on particle size distribution and loss on ignition data. The use of correlation analysis and Kolmogorov–Smirnov D statistic suggests that samples below 1 gram begin to show diverging results. Analysis of variance performed on loss on ignition determined that samples with lower carbon content lost showed statistical differences between sample sizes. In addition, confidence intervals indicate that 0.25-gram samples do not often overlap with other sample sizes within each location. D-space ordering via x-ray diffraction was done on 2- and 0.25-gram samples of each location and it was determined that both were visually different. To determine where the differences in sample sizes begin to diverge via XRD, further analysis will be performed on 1- and 0.5-gram samples. Overall, based on preliminary data findings and analysis, samples smaller than 0.5 grams begin to give divergent results compared to larger sample sizes.

Comparative Soil Examination, Sample Size, Sensitivity

B183 The Development of a Technique for the Forensic Identification of Carrion Beetles

Amy Osborne, BS, University at Albany, SUNY, Albany, NY; Jennifer Rosati, PhD, John Jay College of Criminal Justice, New York, NY; Rabi Musah, PhD, University at Albany, SUNY, Albany, NY*

Learning Overview: Attendees can expect to learn about the use of DART®-HRMS for the generation of unique insect species-specific metabolome profiles, and how statistical analysis can be applied to these profiles to enable insect species identification that is useful for postmortem interval determination.

Impact Statement: The use of metabolome profiles as unique chemical fingerprints that enable differentiation between species of insects will be presented. Attendees will also learn about the application of statistical analysis for processing of insect chemical profiles for differentiation and classification, as well as about methods for handling specimens.

One of the most important aspects of a death investigation is estimation of time since death or postmortem interval (PMI). This can be difficult to assess for remains that have advanced to such a state of decay that traditional methods for determining PMI are no longer applicable. One approach that can be employed in such cases is the use of carrion insects found on or near the body, as there is a well-established correlation between a given stage of decomposition, and the insect species that colonize the remains. Since the species-dependent timeline associated with insect progression through various life stages is well established, knowledge of the species of the retrieved entomological evidence can be used to calculate PMI. For this reason, accurate species identification is critical. However, while this may seem straightforward, it is often a time-consuming, resource-intensive process that requires high levels of specialized expertise and laboratory facilities, among other elements. This is because traditional insect species identification is accomplished by rearing collected immature life forms to maturity so that positive identification based on the gross physical features of the adult can be achieved. Furthermore, the insects most likely to be found colonizing remains that are in the advanced stages of decay are beetles. Yet, there is a limited amount of research on methods that can be used to quickly identify beetle species.

It is demonstrated here that chemometric processing of direct analysis in real time mass spectrometric data acquired from analysis of insects can be used to rapidly accomplish species identification. In order to mimic field collection practices, all specimens were suspended in 70% aqueous ethanol prior to analysis by DART®-HRMS. It was established that consistent results were obtained when samples were suspended in aqueous ethanol for at least 24 hours, and that suspending the samples for more than 24 hours did not result in added advantage, nor was an advantage seen in rehydrating dried insect specimens with steam prior to placing them in suspension. Furthermore, it was determined that insect specimens could be resuspended in aqueous ethanol after several months in dry storage while still yielding results similar to what would be obtained from analysis of fresh specimens. Overall, the results showed that the ethanol suspensions of each species exhibited a unique chemical fingerprint, and that these fingerprints were consistent for members of the same species but different between species. The application of Kernel Discriminate Analysis (KDA) to the data revealed that clear differentiation was possible between insect species based on the chemical fingerprints generated by DART®-HRMS analysis of insect-ethanol suspensions. Furthermore, the separation occurs even between insects belonging to members of the same family, such as the Silphidae family. Thus, the use of DART®-HRMS and statistical analysis to differentiate between species of insects can circumvent some of the challenges faced when dealing with entomological evidence, thereby increasing the utility of this evidence.

Forensic Entomology, DART®-HRMS, Chemometric

B184 Human Scent Biometrics: A Pilot Study in Source-Origin Determination

Vidia A. Gokool, MS, International Forensic Research Institute, Florida International University, Miami, FL; Howard K. Holness, PhD, International Forensic Research Institute, Florida International University, Miami, FL; Kenneth G. Furton PhD, International Forensic Research Institute, Florida International University, Miami, FL*

Learning Overview: After attending this presentation, attendees will understand the application of a combined targeted and untargeted approach to gas chromatography-mass spectrometry (GC-MS) data analysis as applied to the interpretation of profile variability in same-donor human hand odor samples.

Impact Statement: This presentation will impact the forensic science community by sharing newly cultivated fundamental knowledge regarding the variability of human hand odor and equipping attendees with techniques for extrapolating similarities in GC-MS profiles through a pattern recognition approach.

Human scent is commonly implemented as an individualizing feature used to associate a suspect with an object, location, or path of travel. Human scent evidence is commonly identified by and utilized in conjunction with human scent detection canines. Human scent detection canines are employed to follow a scent trail left by a person of interest or to associate a questioned item with one of known origin.

Previous studies in the field of human scent analysis have worked to explain the procedures carried out by these canines when associations are performed; however, these works have largely focused on describing the differences between separately sourced samples. The presented work builds upon previous research in the field while providing insight into the under-evaluated fundamental theory regarding the intra-subject variability of human scent. The presented work evaluates the volatile organic compounds (VOCs) present in the headspace of human hand odor samples collected from 8 donors over variable time periods ranging from 5-weeks to 1-year. These profiles were collected over the course of multiple weeks, utilizing headspace-solid phase microextraction- gas chromatography-mass spectrometry (HS-SPME-GC-MS) to capture and analyze the gaseous organic compounds present in the equilibrated sample headspace. With the headspace composition serving as a representative depiction of the donor's hand odor composition, both targeted and untargeted approaches to profile interpretation and association were investigated.

This research evaluates a combined approach to analyzing VOCs, incorporating Spearman's rank correlation, 3-D covariance, and automated peak matching as chemometric techniques for analyzing 3-D and 2-D components of human hand odor profiles. This combined approach provides a mechanism for predicting the source-origin of human scent samples collected using HS-SPME-GC-MS. Intra-subject variations in human scent, including inter-day changes, are explored. A discussion will be lead on the observed diversity in human scent, its impact on the developed technique performance, and the plans for further refining of the developed methodology.

This study reflects an active effort towards the creation of a model for the formal discrimination of human scent profiles collected using GC-MS. Further application of the advances made in this study will aid in the understanding of same-donor human scent similarity and inform thresholds when discriminating between different-donor samples. Additionally, this work will provide greater context to canine performed human scent associations while continuing to build toward a quantitative laboratory test for confirmation of in-field, canine performed human scent associations.

Human Scent, Chemometric, HS/SPME-GC/MS

B185 Volatile Organic Compounds (VOCs) Produced by Bacteria Associated With Decomposition

Veronica Cappas, BS*, The Pennsylvania State University, State College, PA; Megan Morris, The Pennsylvania State University, State College, PA; Dan Syles, PhD, The Pennsylvania State University, State College, PA; Reena Roy, PhD, The Pennsylvania State University, State College, PA

Learning Overview: Attendants can expect to learn how the microbiome and VOC profile are connected throughout the complex process of decomposition.

Impact Statement: This presentation will provide the potential origin of VOCs observed throughout decomposition, giving further insight to impact of microorganisms on the process, and improving techniques for locating remains.

Microorganisms play an important role in decomposition and are known to produce volatile organic compounds (VOCs) that contribute to the odor of decomposition. Although microorganisms and VOCs have been studied independently regarding decomposition, few studies have linked the two subject matters. As the number of decomposition studies increases, a clearer picture of the temporal evolution of VOC profiles is emerging. However, identifying the origin(s) of specific VOCs remains elusive (i.e., microbial processes, general chemical decomposition, insects, environmental effects). The volatile organic compounds produced by specific species of bacteria associated with decomposition were characterized in order to determine origins of VOCs detected during decomposition. In the present study, the volatile organic compounds produced by specific species of bacteria associated with decomposition were characterized. Overall, researching the VOCs produced by bacteria will help to understand the complex process of decomposition. It also helps improve techniques used to search for remains in missing person cases or natural disasters, such as through improved training of cadaver-detection canines or the creation of VOC detection devices. Microbial communities were sampled at various time points during decomposition of a swine placed in an indoor enclosure and sequenced using NextGen Illumina sequencing. Because the indoor enclosure inhibited insect activity and colonization by extrinsic microorganisms, the VOC profile likely reflects the intrinsic microbial community and autolysis. Over 1,000 taxa at the genus level were identified and over 600 taxa at the species level. Prevalent phylum includes Bacteroidetes, Firmicutes, Tenericutes, and Spirochaetes, which are seen in other swine decomposition studies.¹ Further analysis of the swine's microbiome succession is discussed with an emphasis on the potential correlation of the microbiome succession and decomposition as seen in other studies like Hyde et al. and Metcalf et al.^{2,3} Based on the relative abundance of sequenced reads, *Alcaligenes faecalis*, *Lysinibacillus fusiformis*, and *Lactobacillus gasseri* were selected. They were independently cultured in headspace vials on a modified chopped meat medium created from ground pork broth and sheep blood, to provide similar nutrients to the decomposing swine. Solid Phase Microextraction (SPME) fibers were used to sample the VOCs produced by the bacterial species. The VOC profiles produced by each bacteria species are compared with the overall VOC profile collected from the same decomposing swine to distinguish the VOCs associated with bacterial decomposition from those originating from the general break-down process. *A. faecalis* produced VOCs categorized as sulfides and carboxylic acids. *L. fusiformis* generated sulfides and hydrocarbons, while *L. gasseri* was seen to produce just one VOC. However, this may be due to the nutrient source and growth conditions. To investigate how interactions between species could affect VOC production, *A. faecalis* and *L. fusiformis* were cultured together. Different VOCs versus in the independent cultures were produced, like nitrogen-containing compounds that have been seen in other decomposition studies.⁴ This may support that species interactions can have an extraordinary effect on VOC production.

B186 Analyzing the “Cross-Hatch” Patterns of Clear Biaxially Oriented Polypropylene (BOPP) Tapes

Walter Rowe, PhD*, The George Washington University, Washington, DC

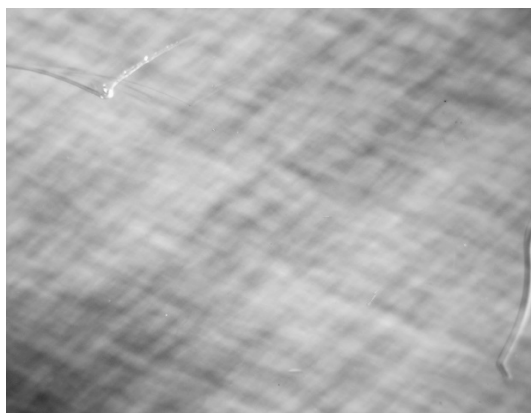

Learning Overview: After attending this presentation, attendees will understand how to analyze the “cross-hatch” patterns observed when clear biaxially oriented polypropylene (BOPP) tapes are examined with a polarizing microscope.

Impact Statement: This presentation will impact the forensic science community by providing a process for the comparison of “cross-hatch” patterns of questioned and known tape samples.

Clear biaxially oriented polypropylene (BOPP) tapes are widely used pressure-sensitive tapes. These tapes are marketed as mailing tapes, shipping tapes, packaging tapes or storage tapes and are sold at hardware stores, office supply stores, supermarkets, and pharmacies. When examined with a polarizing microscope with crossed polarizing filters, clear BOPP tapes show complex “cross-hatch” patterns when oriented close to extinction. As shown below, the patterns may differ from one tape sample to another.

3M Shipping Tape

Duck EZ Start Heavy Duty Tape

Twenty-four clear BOPP tape samples representing twenty brands were purchased online and at a variety of retail outlets in the Washington, DC, area. The brands included national brands, as well as store brands. Samples of the tapes were placed on standard microscope slides and their “cross-hatch” patterns observed with a polarizing microscope. The patterns were recorded as 8-bit grayscale images using a digital eyepiece camera. The images were pre-processed by application of a diffuse gaussian edge detection filter followed by conversion to binary. These steps preserved the salient features of the “cross-hatch” patterns and removed variations in illumination (vignetting) from most of the patterns.

The binary images were analyzed in two ways.

The fractal dimensions of the binary images were determined using a box-counting algorithm which determined the number $N(\delta)$ of boxes with edges of length δ required to cover completely the white or black areas of a binary image. Generally

$$N(\delta) \sim \delta^{-D}$$

where D is the box-counting fractal dimension of the image. The box-counting algorithm determines $N(\delta)$ for a series of values of δ . The relationship between $N(\delta)$ and δ can be expressed as a linear equation:

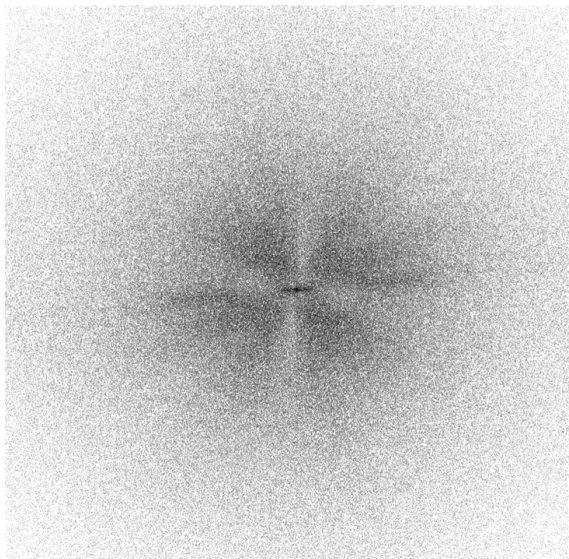

$$\log[N(\delta)] = A - D \log(\delta)$$

Linear regressions were applied to the data from the box-counting algorithm to obtain the best-fit values of A and D . The A and D values of the tape samples were compared pair-wise using the Student’s t test.

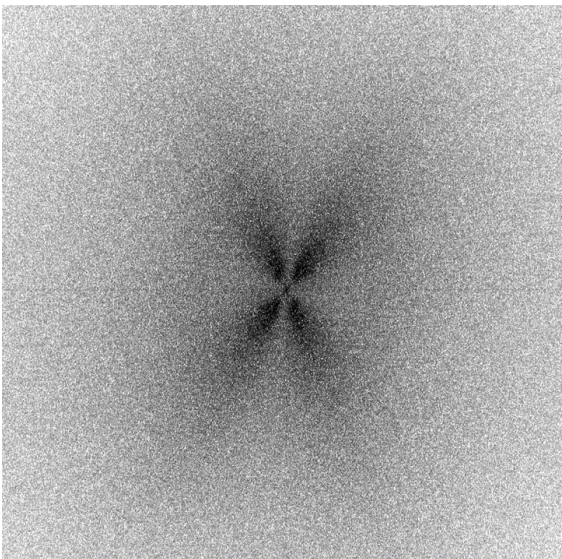

Two dimensional discrete Fourier transforms (2DDFT) were calculated for each binary image. These transforms detect repetitive features in images and have been useful in the forensic analysis of surface texture patterns on sheets of paper created by the fine metal meshes used in paper manufacture.

Analysis of the data for the box-counting fractal dimensions of the binary images of the tape samples revealed that the fractal dimensions D of the binary images of the tape “cross-hatch” patterns were similar and provided only limited discrimination of tape samples. The intercepts A provided a greater degree of discrimination than the fractal dimensions. Many of the tape samples had indistinguishable A and D values.

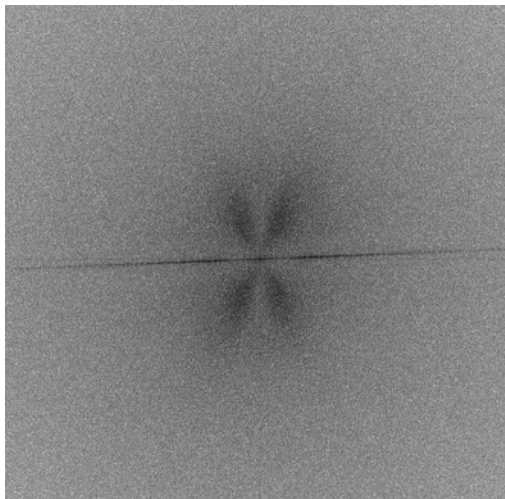

Examination the 2DDFTs of the tape samples revealed that one tape sample had a unique 2DDFT. The remaining 2DDFTs could be placed in three distinct groups, as shown below. The 2DDFTs detected additional subtle repetitive patterns in the “cross-hatch” patterns (e.g. Group 3); they also allowed a more accurate determination of the angles of the “cross-hatch” patterns.

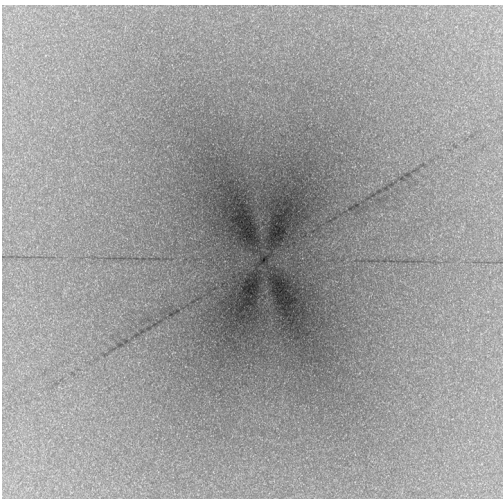

Unique Tape Pattern

Group 1 Fourteen Tapes

Group 2 Seven Tapes

Group 3 Two Tapes

Clear Bixially Oriented Polypropylene Tapes, Polarized Light Microscopy, Digital Image Analysis

B187 “Leaf” It to DART®-HRMS and Multivariate Statistical Analysis for the Forensic Identification of Illegally Traded Timber

Mónica Ventura, BS, University at Albany, SUNY, Albany, NY; Samira Beyramysoltan, PhD, University at Albany, SUNY, Albany, NY; Meghan Appley, MS, University at Albany, SUNY, Albany, NY; Edgard Espinoza, PhD, National Fish and Wildlife Forensics Lab, Ashland, OR; Rabi Musah, PhD, University at Albany, SUNY, Albany, NY*

Learning Overview: Attendees will be introduced to the development of a method to identify illegally traded timber to be used in wildlife forensics laboratories. An understanding of multivariate statistical analysis to aid in the classification will be gained.

Impact Statement: This presentation will impact the forensic science community by providing a new and efficient methodology for the identification of illegally traded timber. This approach will contribute to the enhancement of techniques that enable law enforcement to distinguish between endangered wood species at crime scenes.

One of the concerns of wildlife forensics is the identification of endangered species, the trade of which is illegal. The Convention on International Trade of Endangered Species (CITES) was created to address the conservation of imperiled wildlife by controlling their trade. Regulation status is defined by appendices: CITES Appendix I species are threatened with extinction and trade of any kind is outlawed; CITES Appendix II species are threatened in the wild and international trade is controlled to aid in their survival; and CITES Appendix III species are regulated in a particular region. While trade in fauna, including elephant parts (such as tusks), rhinoceros horns, and pangolin scales, are well-known examples of wildlife crimes, there are a host of flora that are also heavily trafficked. *Dalbergia* genus trees serve as a case in point. *Dalbergia* species fall under the Leguminosae family, with most species commonly known as rosewood. Illegal trade of these species is common because they are highly prized for making exclusive furniture, cabinetry, musical instruments and artifacts. Depending on the species, trade is either totally or heavily restricted. A current technique used by law enforcement to differentiate species of wood is direct analysis in real time-high resolution mass spectrometry (DART®-HRMS), coupled with multivariate statistical analysis. Here, the added dimension of wood headspace analysis featuring solid phase microextraction (SPME) was used to generate data to complement that acquired using the conventional wood analysis technique. This could facilitate the development of “stand-off” approaches to the differentiation of wood species based on their volatile profiles. Seventeen *Dalbergia* species, including *D. baronii*, *D. cearensis*, *D. oliveri*, *D. occulta*, *D. madagascariensis*, *D. latifolia*, *D. melanoxydon*, *D. normandii*, *D. purpurascens*, *D. retusa*, *D. nigra*, *D. decipularis*, *D. stevensonii*, *D. tucurensis*, *D. spruceana*, *D. maritima*, and *D. cochinchinensis* were provided by the U.S. Fish & Wildlife Forensic Lab, all of which are listed as CITES Appendix II species, except for *D. nigra*, which is listed as a CITES Appendix I species. The headspace volatiles of the wood samples were concentrated on SPME fibers for thirty minutes and analyzed by DART®-HRMS. Multivariate statistical analysis processing of the DART®-HRMS data revealed intraspecies similarities and interspecies differences that resulted in the ability to assign species attributions to the chemical signatures. The classification model that was developed could therefore be used for forensic identification of species based on simple analysis of the headspace of the wood. The results show that this approach can be used as a technique for species identification of these illegally traded timber.

Endangered Wood, DART®-HRMS, Illegally Traded Timber

B188 Evaluation of Organic and Inorganic Gunshot Residues in Various Populations using LC-MS/MS

William Feeney, BS, West Virginia University, Morgantown, WV; Korina Menking-Hoggatt, PhD, West Virginia University, Morgantown, WV; Luis Arroyo, PhD, West Virginia University, Morgantown, WV; James Curran, PhD, The University of Auckland, Auckland, New Zealand; Suzanne Bell, PhD, West Virginia University, Morgantown, WV; Tatiana Trejos, PhD, West Virginia University, Morgantown, WV*

Learning Overview: After attending this presentation, attendees will understand the importance of utilizing IGSR and OGSR components and advanced algorithms for interpreting presented evidence.

Impact Statement: This presentation will impact the forensic science community by presenting findings of IGSR and OGSR occurrence from various subpopulations.

Differentiation and classification of trace materials are critical tasks in many criminal investigations yet still present a challenge for forensic science practitioners.¹ The formation of GSR is entropic in nature and yields varying and sometimes time-dependent analytes. GSR evidence is categorized into two constituents – inorganic particulates (IGSR) and organic compounds (OGSR). These analytes are formed after a firearm's firing pin strikes the primer of the ammunition, igniting the propellant and expelling a projectile at high velocities.

Two approaches evaluated the evidence for additional interpretation and understanding – classification via machine learning algorithms and estimation of the strength of the evidence via likelihood ratios. Neural network models can predict responses when exposed to large data sets through rigorous training measures such as backpropagation and cross-validation. Likelihood ratios are used to evaluate the evidence given two mutually exclusive hypotheses.

This work investigates the prevalence of organic and inorganic gunshot residue within two main subpopulations: (1) non-shooters, including groups with low- and high-risk of potentially containing GSR-like residues, and (2) individuals involved in a firing event (shooters, bystanders, and shooters performing post-shooting activities). The study analyzes over 400 samples from individuals via a recently validated liquid chromatography-tandem mass spectrometry (LC-MS/MS) methodology with complexing agents.²

Exploratory statistical tools and neural networks evaluated the quantitative data of the subpopulations. We report lower occurrences of OGSR compounds in the non-shooter (high- and low-risk) population compared to IGSR elemental profiles. By utilizing different strategies on the observed OGSR and IGSR traces, the presence of GSR from shooters from other potential sources, such as bystanders and some professions, can be further assessed. Additionally, the low-risk background sample set allowed documentation of GSR occurrence in the general population.

The probabilistic outputs of the neural network models were utilized to calculate likelihood ratios (LR) as a proxy for the significance of evidence. Through rigorous training of the model with combining IGSR and OGSR profiles, the false-positive rates obtained from the neural network were less than 5%. This evidence further suggests that this approach can be effectively used for a probabilistic interpretation of GSR evidence.

B189 The Association of Smokeless Powders and Lab-Generated Residues to Organic Gunshot Residue (OGSR) Using Gas Chromatography/Mass Spectrometry (GC/MS) and Direct Analysis in Real-Time High Resolution Mass Spectrometry (DART®-HRMS) Analysis Followed by Chemometrics

Emily Lennert, MS, University of Central Florida, Orlando, FL; Candice Bridge, PhD, University of Central Florida, Orlando, FL and National Center for Forensic Science, Orlando, FL*

Learning Overview: After attending this presentation, attendees will understand how organic gunshot residues (OGSR) may be analyzed via direct analysis in real time – high resolution mass spectrometry (DART®-HRMS) and gas chromatography – mass spectrometry (GC-MS), and subsequently the application of chemometrics in determining the effectiveness of classification of OGSR within smokeless powder models.

Impact Statement: This presentation will impact the forensic science community by providing insight regarding how organic gunshot residue (OGSR) may be best analyzed via DART®-HRMS, as well as by traditional means of analysis using GC-MS, and how those residues may be associated with the intact smokeless powder (SP) particle. This study may provide a basis for potential evidentiary links between the residue recovered from a crime scene and a suspected SP from which the evidence may have originated.

Following a shooting, gunshot residues (GSR) settle on areas such as the shooter's hands and face, the shooter or victim's clothing, and other nearby surfaces. Organic gunshot residue (OGSR), which primarily originates from the smokeless powder (SP) contained in the ammunition, accounts for a portion of the GSR in addition to the inorganic GSR that is more commonly analyzed. Additionally, in explosive events such as the use of an improvised explosive device in which SP serves as the main charge, smokeless powder residues (SPR) may serve a similar purpose as OGSR as evidence.

In this study, SP samples were extracted following a modified version of the extraction protocol set forth by the National Center for Forensic Science.¹ Extracts were analyzed via GC-MS, a gold standard of analysis available in many operational crime labs, as well as DART®-HRMS, a newer technique. In both analyses, key organic components of the SP were easily identified in the extracted material. Subsequently, classification models were generated from a series of chemometric analyses. Then, SPRs were generated in-lab through a small-scale burning method in which SP samples were individually ignited within foil packets and extracted similarly to the intact SP. Resulting data from each instrument was classified within the respective SP model using linear discriminant analysis with the SPR as an external test set. Results indicated generally low classification accuracy, and thus SPR models were also generated.

Finally, 9 mm ammunition was loaded with known SP and fired to collect OGSR from cloth targets and cartridge casings. The OGSR was extracted and analyzed via DART®-HRMS and GC-MS and tested against the SP and SPR models to determine the association of OGSR to its intact SP to allow for narrowing the source of evidence, as well as lab generated SPR for the assessment of the representativeness of the burn method. The ability to characterize a SP, SPR, or OGSR and successfully associate these to one another may be helpful in determining the origin of a suspected sample and aid investigators in linking a suspect to a crime scene.

Organic Gunshot Residue, GC/MS, DART®-HRMS

B190 Elemental Profiling of Total Gunshot Residue (tGSR) Using Total Reflection X-Ray Fluorescence (TXRF) Spectrometry

Samantha Gong, BS*, Hofstra University, Hempstead, NY; Ling Huang, PhD, Hofstra University, Hempstead, NY; Jason Berger, MS, Hofstra University, Hempstead, NY and Police Laboratory, NYPD, Queens, NY; Nicole Homburger, BS, Police Laboratory, NYPD, Queens, NY, USA

Learning Overview: The aim of this presentation is to help attendees understand the utility of total reflection X-ray fluorescence spectroscopy in producing elemental profiles of total gunshot residue produced from the firing of different ammunition.

Impact Statement: This presentation will present a novel approach to qualitative and quantitative analysis of total gunshot residue found on cloth, and in differentiating various ammunitions based on their elemental profiles.

The aim of this presentation is to help attendees understand the utility of total reflection X-ray fluorescence spectroscopy in producing elemental profiles of total gunshot residue produced from the firing of different ammunitions.

This presentation will present a novel approach to qualitative and quantitative analysis of total gunshot residue found on cloth, and in differentiating various ammunitions based on their elemental profiles.

Gunshot residue (GSR) is composed of combustion products from the various components of firearm ammunition cartridges. These components include propellant powder, primer, grease, lubricants, and the different metals that make up the bullet.¹ Traditionally blasting particles are the main type of investigated GSRs, most commonly found on the shooter hands. This type of GSR can present as whole particles, flattened particles, or partially splattered, which is usually collected by swabbing or tape-lifting and analyzed by a scanning electron microscope and energy dispersive X-ray spectroscopy (SEM-EDS).^{1,2} SEM-EDS, while simultaneously imaging and identifying GSR particles, only analyzes approximately one square millimeter worth of GSR and does not analyze other types of GSR such as impact deposition residue.³ Other studies have used instrumentation such as inductively coupled plasma mass spectrometry (ICP-MS) to quantify GSR deposited on surfaces such as wood and metal, but the methodology only involved swabbing the interior surface of the bullet hole. total reflection X-ray fluorescence spectrometry (TXRF) is a highly sensitive qualitative and quantitative method that for elemental analysis.^{3,4} Absolute quantities can be determined with a spiked internal standard such as gallium or yttrium. This instrumental technique employs a molybdenum or tungsten X-ray source to eject an inner shell electron before an outer shell electron fills the resultant void and emits X-ray fluorescence with energy that is characteristic to elemental identity. The X-ray fluorescence intensity or photon counts can be used for quantitation. In contrast to SEM-EDS, TXRF can quantify a greater number of elements in each run with lower energy consumption. Different from ICP-MS, TXRF is a type of elemental analysis often free from complex ion interference, without bulky and noisy vacuum pumps. In this study, TXRF was used to study total gunshot residue (tGSR), the collection of all deposits on a target. Six types of ammunition were fired at targets of plain cotton using two firearms from a fixed distance of six inches. The samples were individually digested in concentrated nitric acid for a minimum of 24 hours to dissolve the GSR particles prior to analysis.

Through TXRF analysis, different types of ammunition were found to produce different and unique elemental profiles of tGSR. The focus of the elemental analysis was on lead, copper, barium, antimony, iron, and zinc. Other detected elements were excluded as they were found in similar quantities between the environmental blank and the samples. Lead, as the main element composing the bullet, was the primary element of interest and was found to corresponds to the amount of a traditional bullet that is exposed to the target and the combustion heat upon discharge of the firearm. For example, the unjacketed bullet had a lead concentration of 239.25 ± 1.32 ppm while the full covered total metal jacket ammunition had a concentration of 4.56 ± 0.02 ppm. The second element of interest was copper, which corresponded to the composition of the bullet and the amount of jacketing on the different ammunitions. For example, the unjacketed ammunition had the lowest concentration of copper at 0.23 ± 0.44 ppm, as expected. The TXRF analysis produced repeatable and reliable elemental profiles in which the information could be used as the basis as a predictive tool to associate ammunition types and the impact deposition on a close-range target.

B191 A Pilot Study of Lead Isotopes and Trace Element Utility in Shooting Investigations

Aaron Hernandez Flores, AS*, Arizona State University, Tempe, AZ; Gwyneth Gordon, PhD, Arizona State University, Tempe, AZ; Shirley Montero, PhD, Arizona State University, Tempe, AZ

Learning Overview: After attending this presentation, attendees will understand the potential for chemically associating bullet fragments and impact marks with specific bullets by ICP-MS and MC-ICP-MS for shooting investigations.

Impact Statement: This presentation will impact the forensic science community by introducing a new method to associate bullet impact marks identified with sodium rhodizonate lifts with a specific bullet from a limited pool of possibilities.

Previously, the FBI testified that a bullet could be determined from a specific box of bullets. Due to manufacturing and packaging practices, testimony using this technique was not scientifically supported according to the National Research Council and has been discontinued.¹⁻³ However, inferences from lead isotopes combined with trace elements in bullets may still prove useful in forensic shooting investigations.⁴⁻⁶

Bullet manufacturers use inexpensive sources of lead, which vary with time, shipping costs and the development cycle of lead mines.² During packaging, bullets in a specific box may come from multiple lots of lead. Hence, associating a single bullet with a specific box of bullets is highly problematic. However, it is demonstrated here that single bullets are relatively homogenous in both element ratios and lead isotope compositions, and residue from the bullet can be probabilistically associated with the main bullet fragment. The hypothesis was, given a shooting incident with a limited number of projectiles (a “limited universe”), most of the projectiles can be eliminated from consideration as having made a specific ricochet mark or left a specific fragment in a wound track.⁷

Six bullets and five evidence lifts made from ricochet marks were anonymized and sent by Luke Haag of Forensic Science Services to researchers at Arizona State University. Six bullets were provided, ensuring associations between lifts and bullets were not made by process of elimination. Bullets were swabbed using dilute nitric acid, minimizing damage to the evidence.⁷ A method to solubilize the lead from evidence lifts was developed, and an optimized method for measuring low concentrations of trace elements (Cu, As, Ag, Sn, Sb, Ba, Bi) in the presence of very high lead concentrations using ICP-MS. This method optimization included use of (1) a custom in-house internal standard (Sc, Ge, In); (2) developing a matrix-matched calibration curve to quantify very low trace elements despite interferences from the high lead matrix; (3) maintaining constant lead concentrations for samples ensuring high quality trace element data close to the limit of quantitation; and (4) optimization of sample concentration to avoid impact of high lead samples on substantial lower concentration lead samples. This method uses element ratios, rather than absolute concentrations of trace elements, because the initial mass of bullet lead recovered by solubilizing material from an evidence lift cannot be determined. Samples were then diluted and measured for lead isotopes by MC-ICP-MS. Lead isotopes were superior to trace elements to accurately discriminate between similar possible lift-bullet pairs. Associations between the blinded lifts and bullet pairs made by the researchers were confirmed to be 100% accurate to the known associations by Luke Haag.

Overall, this pilot study concluded this new method was reliable and effective at correctly associating evidence lifts with bullets, using elemental/isotopic ratios and isotopic plots. This research is continuing in collaboration with Luke Haag and Chris Gunsolley, a Forensic Scientist Firearms Supervisor at Mesa Police Department. In a series of shooting experiments, the accuracy and specificity of this method for associating GSR from cotton shirts, bullet fragments recovered from ballistic soap, and bullets from a single shooting event is being evaluated. If successful, this technique could be widely used in shooting investigations.

Shooting Investigations, Bullets, Lead Isotopes

B192 A Study on the Longevity of pGSR in an Outdoor Environment.

Christopher Chany, MS, Texas DPS Crime Lab Austin, Austin, TX; Thomas White, BS, Texas DPS Crime Lab Austin, Austin, TX; Juan Rojas, BS, Texas DPS Crime Lab Austin, Austin, TX; Rebekah Lloyd, BS, Texas DPS Crime Lab Austin, Austin, TX; Marcos Rivera, BSA, Texas DPS Crime Lab Austin, Austin, TX*

Learning Overview: After attending this presentation, attendees will have a better understanding of how long pGSR will last in an outdoor environment.

Impact Statement: This presentation will impact the forensic science community by providing practitioners insight into whether pGSR remains in an outdoor environment after approximately 13 years. The presentation also describes the methods used to test this theory.

Gunshot primer residue (GSR) is produced by a firearm when it is discharged. The primer for centerfire cartridges is mainly composed of lead styphnate, barium nitrate and antimony sulfide. The residue from the primer explosion escapes from openings in the gun and is deposited on nearby surfaces including a person's hands and clothing. These particles can be collected and analyzed using automated scanning electron microscopy energy dispersive x-ray spectrometry (SEM/EDS). Characteristic gunshot residue primer particles have a molten appearance and are composed of barium, antimony, and lead.

There have been numerous studies addressing the longevity of pGSR on hands and clothing. There have not been any studies on whether pGSR can be kicked up from the surface of the ground onto a person's clothing. The laboratory was fortunate enough to be able to access the department's old outdoor firing range which had not been in service since 2008. GSR stubs were taken not only of some of the surfaces but an analyst wearing clean clothes, walked and kicked up the ground in the range. Stubs were taken from multiple areas of his shoes, clothing and hands. These stubs were analyzed using scanning electron microscopy energy dispersing x-ray spectroscopy instrumentation using standard laboratory procedures for the analysis of gunshot primer residue.

The presentation will detail the results of a study on gunshot primer residue found in an outdoor environment transferring to an individual walking through that environment. This research takes a novel approach by investigating the likelihood of transfers from the ground to other surfaces including hands.

Gunshot Residue (GSR), Longevity, SEM

B193 Probabilistic Interpretation of a Large Population Study of Gunshot Residue and Background Profiles Using LIBS, Electrochemistry, and SEM-EDS

Korina Menking-Hoggatt, PhD, West Virginia University, Morgantown, WV; Colby Ott, MS, West Virginia University, Morgantown, WV; Courtney Vander Pyl, MS, West Virginia University, Morgantown, WV; Kourtney Dalzell, BS, West Virginia University, Morgantown, WV; James Curran, PhD, University of Auckland, Auckland, North Island, New Zealand; Luis Arroyo, PhD, West Virginia University, Morgantown, WV; Tatiana Trejos, PhD, West Virginia University, Morgantown, WV*

Learning Overview: After attending this presentation, attendees will understand the strength of orthogonal methods for identification of gunshot residue (GSR) and improved classification and evidential value when using probabilistic interpretation.

Impact Statement: The findings on IGSR and OGSR in various populations and the use of probabilistic interpretation are anticipated to provide a significant leap in knowledge in the field of gunshot residue.

This study aims to address some research needs identified in the field of GSR, such as studying the prevalence of OGSR and IGSR in the general population and evaluating the feasibility of using organic and inorganic data for more comprehensive analysis and interpretation approaches.

To address these gaps, we conducted a large population study of over 3,000 samples originating from various sources of known shooters' hands ("shooter") and background populations ("non-shooter"). A large study of both "shooter" and "non-shooter" samples assists with understanding the trends of elemental combinations present in authentic specimens, along with environmental residues that could be misidentified as GSR.

Five subpopulations were studied. The known shooter samples originated from firing pistols and revolvers using various ammunition types: leaded (set 1), lead-free (set 2), and a mixture of both (set 3). Background samples were collected from individuals who had not fired a gun in the past 24-hours, separated by low-risk (set 4) and high-risk (set 5). Low-risk samples were collected from volunteers who did not have hobbies or professions that could mimic GSR, while high-risk included firearm researchers, agriculture workers, mechanics, and police officers/administrators. Samples were first analyzed by LIBS, which can detect multiple elements of interest and provides 25 spectra in less than 2 minutes with spatial information. Then electrochemistry was completed on the same sample, simultaneously detecting both IGSR and OGSR (Pb, Cu, Sb, 2,4-DNT, DPA, nitroglycerin, and ethyl centralite) in under 3 minutes. Lastly, a subset from each population was analyzed by SEM-EDS for morphological and elemental information, demonstrating SEM-EDS could confirm GSR after screening with the novel methods. The sole presence of Pb was found in the low-risk, high-risk, and leaded shooter populations at occurrences of 26.8%, 64%, and 83%, respectively. Barium is highly prevalent (94% in low risk, 100% high risk, 100% in shooters). Conversely, some GSR elemental combinations, such as PbBaSb were present in 100% of the leaded shooter samples, in 16% of the high-risk, and only 1.8% in the low-risk background. The presence of lead-free elements was more frequent in background sets (up to 64% TiZn or 92% Cu). OGSR compounds such as NG were detected in shooter sets while remained absent in the background populations. Finally, combinations of OGSR and IGSR were absent in background sets, indicating enhanced certainty when observed in GSR.

The data was classified using a categorical exploratory method (critical threshold) to estimate positive and negative rates, and the performance was compared to machine learning algorithms. Regardless of the classification method, accuracy of 87% or higher was observed for individual techniques and 92% or higher when combined (LIBS and EC). The machine learning probabilistic outputs were used to calculate log₁₀ likelihood ratios which were typically between -2.5 to -5 for non-shooters and >5 for shooters, demonstrating good discrimination between the overall populations and the viability of using LR as a proxy for reporting the weight of the evidence. Tippet plots were used evaluate LR and the rates of misleading evidence (RME <3.7%).

The probabilistic interpretation and use of likelihood ratios provide additional support to examiners and the trier of fact to better inform their decisions about the weight of the evidence. The incorporation of fast emerging methods, and the information derived from this large population study of IGSR and OGSR, combined with probabilistic interpretation, will contribute strengthening GSR evidence.

Analytical Methods, Gunshot Residue (GSR), Probabilistic Interpretation

B194 Acid Phosphatase Detection in Food Products and Mold

Katrina Ostapovic, MS, Boston University School of Medicine, Boston, MA; Amy Brodeur, MFS, Boston University School of Medicine, Boston, MA*

Learning Overview: After attending this presentation, attendees will understand that many food items and fungi, including mold, contain detectable levels of endogenous acid phosphatase (AP) and will yield positive results using the forensic AP Spot test.

Impact Statement: This presentation will impact the forensic community by demonstrating that the AP Spot test for semen can yield positive results in the presence of certain foods and fungi, even though semen is absent.

Semen is frequently encountered on sexual assault evidence and is often detected using a colorimetric test for acid phosphatase (AP). Other substances that are known to contain detectable levels of AP include vaginal secretions, saliva, urine, certain foods, plants, and other miscellaneous material including fungi. Fungi are spore-producing, eukaryotic organisms that include a wide variety of species such as molds, yeasts, and mushrooms. Medications, illicit drugs, bread, alcohol, fermented foods, food colorants, vitamins, preservatives, and pesticides are derived from fungi, and may come into contact with or contaminate an object of forensic relevance. Food and other items are susceptible to fungal growth when left in improper conditions, such as damp spaces and warm temperatures. Fungi also grow unwanted in human spaces, notably in the form of mold in damp, enclosed areas. Thus, it is possible that evidentiary items exhibiting mold growth or those that have been in contact with mold or food (such as items recovered from a trash receptacle) could test positive for the presence of AP, even in the absence of semen.

This study had three primary goals: (1) to determine whether known cultured molds and unknown home-grown molds would produce positive results with an AP spot test; (2) to determine whether the presence of mold on non-semen biological stains would produce positive results with an AP spot test; and (3) to determine whether any AP-positive mold samples would produce positive p30 or Semenogelin (Sg) results in the absence of semen.

Numerous non-moldy food items, moldy food items, cultured mold spores, and semen-free body fluid stains were obtained and deposited onto individual filter papers or tested directly using AP Spot reagent (SERI, Richmond CA). Of 26 non-moldy food and yeast samples tested, 16 showed a positive violet color change result within the 5-minute observation period; 4 of those items (butter bread, banana, pear and cremini mushroom) showed a strong positive reaction within 1 minute. Following mold growth on 25 food items, AP-positive results were obtained for six yeast-based bread products, five vegetables, three unknown foods from a shared refrigerator, one dairy product, and one fruit. Further, a tree fungus specimen and 13 of 15 mold culture samples had detectable levels of AP, many with a reaction time under 2 minutes.

A total of 17 fresh or frozen urine, saliva, and vaginal fluid samples were tested for AP. Two saliva samples showed a strong positive result and were excluded from further study. Of the remaining samples, 1 vaginal sample was negative, and 14 samples gave a faint positive reaction occurring at the 1-minute mark or later. All samples but one subsequently developed visible mold spores over a 2-month period. Following mold growth on these semen-free samples, all gave a positive reaction for AP, with two urine samples, one saliva sample, and one vaginal fluid sample showing a more intense color change than before mold growth, with some developing as quickly as 30 seconds. A total of 27 AP-positive samples were tested using both ABACard® p30 immunoassay cards and RSID™-Semen immunoassay cards. All p30 and Sg testing yielded negative results.

This study demonstrates that a variety of foods, yeast and mold have detectable levels of acid phosphatase using the AP Spot test; however, semen-free moldy samples with detectable levels of AP did not yield positive p30 or Sg testing results. Thus, evidence that has developed mold or comes into contact with mold spores or certain food products should be interpreted with caution when positive AP Spot test results are obtained, particularly when subsequent protein testing and microscopic analysis for sperm is negative.

Acid Phosphatase, Mold, AP Spot Test

B195 Reducing Interference in the Ultraviolet/Visible (UV-Vis) Spectra of Blood Samples to Detect Ethylenediaminetetraacetic Acid (EDTA) Via the Reverse EDTA Detection Using Eriochrome® Black T (EBT) and UV/Vis (RED-BLEU) Assay

Kristen M. Atkinson BS, Virginia Commonwealth University, Richmond, VA; Brittany C. Hudson, MSFS, Virginia Commonwealth University, Richmond, VA; Catherine Cupples Connon, PhD, Virginia Commonwealth University, Richmond, VA*

Learning Overview: After attending this presentation, attendees will understand how to reduce interference from blood proteins in a UV-Vis spectrum as part of the RED-BLEU (Reverse EDTA Detection in Blood using EBT and UV-Vis) assay.

Impact Statement: This presentation will impact the forensic science community by contributing to the authenticity of blood evidence via a presumptive test for EDTA.

Assertions of false blood evidence are not unheard of in the courtroom. Thus, developing a rapid method to refute or support these claims would contribute to increased transparency in criminal cases. When blood is drawn as a reference sample, it is typically preserved with the anticoagulant ethylenediaminetetraacetic acid (EDTA). EDTA is not found naturally in blood; therefore, its presence in an evidentiary sample could indicate planted blood.

A colorimetric test for the presence of EDTA in blood using Eriochrome® Black T (EBT) indicator (Reverse EDTA Detection or RED) has been developed. To reduce false positives and enhance the robustness of this presumptive test, it was coupled with ultraviolet-visible spectroscopy (UV-Vis) immediately following the colorimetric reaction, and has therefore been collectively termed the RED-BLEU assay.^{1,2} While the use of the NanoDrop™ 2000 spectrophotometer also enabled quantification of EDTA within samples, other components within blood exhibited substantial interference with this portion of the assay.^{1,2}

The primary goal of this research was to develop a treatment for blood samples to reduce interference in the UV-Vis spectrum to the point that detection of EDTA is possible. Several efforts were attempted to reduce this interference, including protein precipitation and protein denaturation. Protein precipitation was attempted using ammonium sulfate and trichloroacetic acid (TCA), both of which are used in blood sample preparation for other analytical techniques.^{3,4} Proteinase K was also explored in an attempt to denature the interfering blood proteins. To evaluate these, mock samples were created with HPLC-grade water, calcium and magnesium ions, and EDTA (positive samples only). Blood samples with and without EDTA were also used for testing each method. Blood samples were treated both before and after processing with the EBT indicator test to identify any interference(s) with the color changes, as well as to observe the impact of the colorimetric reagents on the precipitation method.

When used prior to the RED assay, ammonium sulfate produced a blue color (positive result) in all samples, regardless of the presence/absence of EDTA, and did not yield an observable reduction in the amount of inference from blood in the UV-Vis spectra. When a TCA treatment was applied prior to the RED test, the expected results were achieved for the colorimetric portion of the assay; however, this treatment also did not afford observable changes in the UV-Vis spectra. Although a Proteinase K treatment applied prior to the RED test interfered with that portion of the assay, this treatment did reduce interference from blood components in the UV-Vis spectra. Therefore, a Proteinase K treatment between the colorimetric and UV-Vis portions was evaluated and demonstrated the most promise for removing the blood protein interference without compromising the colorimetric test. Additional studies are needed to optimize this Proteinase K treatment for integration into the RED-BLEU assay.

RED-BLEU, Blood, Ethylenediaminetetraacetic Acid (EDTA)

B196 Volatile Organic Compounds (VOCs) Associated With Diseased Human Blood

Megan Morris, The Pennsylvania State University, University Park, PA; Veronica Cappas, BS, The Pennsylvania State University, University Park, PA; Dan Sykes, PhD, The Pennsylvania State University, University Park, PA; Virginia Greenberger, PhD, The Pennsylvania State University, University Park, PA

Learning Objective: Those attending this presentation will have a better understanding of the volatile organic compound (VOC) profile throughout decomposition and how health conditions of the deceased can affect the profile.

Impact Statement: Characterizing the differences between the volatile organic compounds (VOCs) produced by healthy and diseased blood may enhance our understanding of the body's health-state on decompositional processes.

According to the CDC, 6 in 10 adults are living with a chronic disease.¹ Blood serves as a repository of information regarding one's health state. One means of datamining this "blood bank" is to identify the VOCs that are present in fresh blood as well as those produced by decomposing blood.² Indeed, disease-specific blood VOCs are of interest in clinical settings for rapid disease diagnosis and may provide insight on cadaveric state.^{3,4} A number of factors influence VOC composition of decomposing blood such as temperature, moisture, soil composition, and health of the individual among other factors.^{2,5} Each of these factors influence the post-mortem interval (PMI) estimation by forensic pathologists and may interfere with search efforts by human cadaver dogs.² Previous research has focused on environmental factors, drug use, and blood alcohol levels, but there is little information regarding diseased human blood VOC composition.⁶

Headspace solid-phase microextraction (SPME) paired with gas chromatography-mass spectrometry (GC-MS) was used for the detection and characterization of the volatile components of decomposing blood samples. Nondiseased, anemic, and diabetic blood samples were placed in uncapped glass vials and allowed to stand for two weeks. VOCs were collected at 0, 24, 96, 168, and 336 hours. Thirty minutes prior to collection, the vials were capped with pressure-tight teflon caps to trap released gases. An SPME fiber was then inserted into a vial's headspace for sample adsorption. After fiber removal, the vials were then left uncapped until the next sample cycle. The SPME fiber was then sampled using the GC-MS to identify the volatile organic compounds. Throughout this research, diseased and nondiseased blood VOC profiles consistently differed. Overall, nondiseased blood produces more abundant and more varied VOC emissions compared to anemic and diabetic human blood.

Decomposition, Volatile Organic Compounds (VOCs), Blood

B197 Stages of Heat Damage to Fabrics Encountered in Forensic Clothing Examination: Microscopic Examination

Cheyenne Smith, Ohio Northern University, Ada, OH; Chesterene Cwiklik, BS, Cwiklik & Associates, Seattle, WA; Braeden Camarota, Seattle University, Seattle, WA; Lauren Bouoju Davies, Seattle University, Seattle, WA*

Learning Overview: Attendees will gain awareness that microscopically observable evidence of types and degrees of heat damage to fabrics provides information that can be correlated with conditions at a scene or exposure of a wearer to a heat source.

Impact Statement: Findings of different stages of thermal damage to fabrics can provide evidence of exposure to different temperatures and degrees of heat, such as from polymer softening due to heat generated upon impact friction, from exposure to flame, contact with a hot surface, or from sticky residues from cellulose pyrolysis of nearby materials.¹ The types and degrees of damage can be useful in answering case questions.

Effects of heat exposure can be found on clothing items as either thermal alteration to the clothing itself, or deposits of other heat-altered materials. The latter may occur when fabrics are damaged together or were removed and burned together to destroy evidence. In this study, fabrics comprising a single type of fiber were exposed to flame and conduction heating both singly and paired with another fabric.² Transfer demonstrated in prior heat studies using cotton blue jeans and t-shirts includes ash/char fragments and amber residues produced as aerosols during cellulose combustion; the droplets can drift to a person standing nearby.³

To provide a basis for correlating observed damage with the conditions that produced it, the stages of heat damage observable with a stereomicroscope (6x to 40x magnifications) were described, classified and photographed. Follow-up examinations of fabric fragments and constituent fibers were conducted using polarized light microscopy (PLM).

For description of stages of damage, fabric and fiber types were divided into three categories: cellulosic, i.e., plant fibers and regenerated cellulose; animal (protein-based) fibers; and synthetics. Stages of heat damage in cellulosic fibers include scorching, charring; and pyrolysis with thermal decomposition as described earlier. Damage to proteinous fibers such as wool and silk is characterized by discoloration followed by melting and thermal decomposition; bubbles produced by gasses during pyrolysis are observed in individual fibers; and finally, hard dark crusts are formed. Loss of birefringence is observed. In wool, as in other hair, initial swelling results from expansion of air spaces. Most synthetic fibers soften, melt, then undergo thermal decomposition with hardening. Acrylics typically decompose before melting. All exhibit loss of birefringence upon softening in the polymer transition temperature region.

A match held to the side of each fabric test swatch produced a temperature gradient from edge to interior; other swatches were heated uniformly in tins on a hot plate. Selected fabrics were wrapped in aluminum foil and heated with a butane utility lighter to produce higher temperatures. Isolated areas of each fiber type are more readily observed at higher magnifications (100x, 250x and 400x). Preliminary tests of blended fabrics, comprising more than one type of fiber, also suggest that areas individual fiber types can be found. Both these topics will be the focus of future studies.

Correlations of visually observed stages of heat damage with underlying chemical changes, studied via FTIR, are reported in a companion study.

Thermal Damage, Forensic Clothing Examination, Fibers

B198 The Effect of Washing on the Transfer and Persistence of Fiber Evidence

Madison Carter, BS, University of New Haven, West Haven, CT; Brooke Kammrath, PhD, University of New Haven, West Haven, CT; John Reffner, PhD, John Jay College of Criminal Justice, New York, NY; Virginia Maxwell, DPhil, University of New Haven, West Haven, CT*

Learning Overview: After attending this presentation, attendees will gain an understanding of (1) primary, secondary, and tertiary transfer of fiber evidence via washing and drying; and (2) persistence of fibers on clothing after washing and drying.

Impact Statement: This presentation will impact the forensic science community by providing insight as to how washing affects the transfer and persistence of the two most common fiber types, cotton and polyester, which can be used to inform the evidentiary significance of fiber evidence.

Fiber evidence has proven to be valuable forensic evidence in a plethora of cases by providing associations between a suspect, victim, and/or location. This can most readily be seen in the Wayne Williams murder trial of 1984, where unique fibers served as linkages between victims and the suspect's home.¹ Specific characteristics of fibers such as shedability, cross-sectional shape, colorant (dye or pigment), and fiber type (natural versus synthetic) can be observed in order to determine the rarity of the fiber, which can be used to assess the evidentiary significance of an association.^{2,3}

A gap in the literature has been identified regarding the effect of different variables, specifically washing, on the transfer and persistence of fibers. This research has been based on the underlying assumption that a perpetrator will wash clothing that was worn during the crime in an attempt to remove any evidence. Four different scenarios were displayed in this research, with target fibers on the donor garments being fluorescently dyed for means of easy identification. These scenarios included washing a single donor garment, washing the donor garment with a recipient garment, washing the donor garment with two recipient garments, and finally washing a single donor garment, taking it out, and washing a single recipient garment. These sets of washes were run for both cotton and polyester donor fibers. After washings were complete, the individual garments were bagged, labeled, and stored for examination using fluorescent photography.

Whether it be a primary, secondary, or tertiary transfer, after examination and documentation, fibers were observed to have been transferred in all scenarios from donor to recipient garments as well as secondary locations such as the inside of the washer and/or dryer. There were also major differences noted in the quantity, location, and size of the recovered fibers based on the number of garments washed as well as the donor fiber type. By understanding how washing affects transfer and persistence of different fibers, forensic scientists can be better informed of the recovery potential and location, as well as evidentiary significance of fibers from washed garments.

B199 The Identification of Toxic Adulterants in Seized Drug Material Around the World

Judith Rodriguez Salas MSFS, The Center for Forensic Science Research and Education, Willow Grove, PA; Amanda Mohr, MSFS, The Center for Forensic Science Research and Education, Willow Grove, PA; Thom Browne, MA, Colombo Plan, Colombo, Sri Lanka; Barry Logan, PhD, The Center for Forensic Science Research and Education, Willow Grove, PA and NMS Labs, Horsham, PA*

Learning Overview: After attending this presentation, attendees will have a better understanding of the importance of identifying toxic adulterants in seized drug material.

Impact Statement: This presentation will impact the forensic science community by bringing awareness of the potential health risks that adulterants can create and how is important to report them.

The International Adulterant Database (ITAD) was created in 2018 as a result of the first Symposium of Forensic Drug Testing Lab Directors held in December 2017, where 33 laboratories from 22 different countries attended. The creation of the database resulted from discussions related to problems with toxic adulterants and diluents found in seized drug materials, and the public health risks associated with their use. Toxic adulterants, pharmacologically active substances and diluents, pharmacologically inactive substances, are regularly used as cutting agents and intentionally added to illicit drugs. Toxic adulterants are of concern because potential increased toxicity related to their actions on the central nervous system.

For the past four years, laboratories from all over the world have collected and sent in data that they gathered from their analysis of seized drug samples. Submitted data included information on illicit drugs, toxic adulterants and diluents identified within seized material. To date, 16 different countries have submitted data to the ITAD database. Countries provided data either monthly, quarterly, yearly or biannually. The data was collected and analyzed using Microsoft Excel®.

The toxic adulterants reported to ITAD can vary between countries and the illicit drug type, but many adulterants are reported with some frequency. Seized cocaine samples have been reported to contain caffeine, levamisole, lidocaine, phenacetin and benzocaine, alone, and in a in various combinations of these substances. Toxic adulterants identified in seized heroin samples included caffeine, acetaminophen, dextromethorphan, lidocaine, phenacetin and diltiazem, along with other by-products related to illicit manufacturing process. MDMA pills have been identified mostly with caffeine, levamisole and acetaminophen.

Looking specifically at individual countries, in Argentina, 46% of cocaine samples were unadulterated, 36% contained caffeine, 24% lidocaine and 5% phenacetin. In Brazil, all cocaine samples were identified with an adulterant. The most commonly encountered one was phenacetin in 48%, followed by levamisole (31%), and hydroxyzine (22%). With respect to heroin samples, samples from Saudi Arabia were adulterated with caffeine (36%), dextromethorphan (26%) and acetaminophen (8%). Comparatively in Singapore, 92% heroin samples were found with caffeine, followed by chloroquine in 78% and acetaminophen in 45%.

Most of the time, these toxic adulterants do not pose significant health risks when ingested in small amounts or used as prescribed. However, the unknown concentration of these adulterants and the mixture of one or more with the illicit drugs and chronic use can results insignificant. Caffeine, at small doses is innocuous but at toxic levels it can create convulsions and cardiac arrhythmias. Levamisole, a drug approved by the FDA in 1990 for the treatment of cancer, was withdrawn of the market a decade later due to the severe side effects such as, agranulocytosis (lowered white blood cell count) and skin necrosis (skin death). These are some of the most severe side effects of this drug.

The identification of toxic adulterants is important because there are risks associated with unknowingly ingesting these compounds. Based on the data available in the ITAD database, a wide variety of adulterants and combinations are commonly detected in seized material across several countries for the same illicit substance. Further, adulterants likely to be detected are largely dependent on the country of origin and countries that may be close in proximity can have differences in the adulterants that are used. It is important to bring awareness related the different adulterants that can co-ingested with the illicit substances as they can contribute to adverse effects that may lead to health complications for the users or even death.

Toxic Adulterants, Seized Drugs, Health Risks

B200 X-Ray Powder Diffraction: A Unique Approach for Identifying and Differentiating Controlled Substances

Hillary Culbertson, PhD, Defense Forensic Science Center, Forest Park, GA*

Learning Overview: After attending this presentation, attendees will have an understanding of XRPD analysis of controlled substances as well as its benefits and drawbacks.

Impact Statement: This presentation will inform the forensic community about how x-ray powder diffraction (XRPD) can identify and differentiate controlled substances, how to create a high-quality XRPD library of controlled substances and cutting agents, and how an XRPD library of controlled substances is beneficial to a forensic lab.

X-Ray Powder Diffraction (XRPD) is non-destructive and yields highly discriminatory data characterizing the crystalline structure based on a chemical's composition. The Scientific Working Group for the Analysis of Seized Drugs (SWGDRUG) categorizes XRD as a Category A technique for the analysis of controlled substances based on its level of selectivity. Additionally, XRPD is rapid, compatible with mixtures, and requires minimal sample preparation. However, despite all of these analytical advantages, its use for the identification of controlled substances in the forensic drug chemistry field has infrequently been applied historically. The aim of this work was to assess the discriminating power of XRPD and its ability to identify controlled substances, and, if suitable, create an internal spectral library.

Proof of concept and method robustness were first established using codeine (sulfate), amphetamine (sulfate), methamphetamine (HCl), and cocaine (sulfate). Amobarbital (Na) and secobarbital (Na) were analyzed to demonstrate that controlled substances of similar chemical structures could be differentiated by XRPD. Additional analyses demonstrated that co-drugs and their constituents, positional isomers, homologs, and diastereomers could be differentiated by XRPD. XRPD was able to differentiate absolute enantiomers, but only when they had different salt forms.

Follow-on work involved creating a high-quality spectral library of controlled substances and common cutting agents. High-quality diffractograms of forty-three pure standards were acquired over the course of three hours. Each standard was analyzed three times, with the standard being removed and reapplied to the same zero background holder each time to ensure sample preparation did not influence the diffractograms. The resulting library has allowed drug chemistry examiners to detect and differentiate commonly encountered controlled substances and cutting agents in pure form or mixtures without sample degradation or consumption.

Controlled Substances, XRPD, Library

B201 Evaluation of Two Portable Devices for the Detection of Common DFC Drugs

Hannan Latif, MSc, Queen Mary University of London, London, England, United Kingdom; Nikolas Petros Lemos, PhD, Queen Mary University of London, London, England, United Kingdom*

Learning Overview: In attending this presentation, the attendee can expect to learn about drug facilitated crimes, particularly drug facilitated sexual assaults, and about two currently available portable devices that could potentially be used to decrease the incidence of such crimes. After attending this presentation, attendees will be able to appreciate the fact that the devices that claim to be able to detect drugs in drinks need to be further configured for this purpose before routine use in forensic settings can be allowed.

Impact Statement: This presentation will impact the forensic community by introducing the idea of using portable devices to detect drugs mixed in drinks, which are characteristic of crimes such as drug facilitated sexual assaults. By evaluating currently available devices, and configuring them for this purpose, they could be used in forensic fieldwork settings in cases where drugs have been used to facilitate the crime.

Drug Facilitated Crimes (DFC) such as Drug Facilitated Sexual Assaults (DFSA) are a growing public health concern with presumed underrepresentation due to underreporting. Several testing devices for the detection of drugs typically encountered in DFSA are commercially available to the public but need to be evaluated for their effectiveness so that there is no cause for concern regarding their use, degree of accuracy, result falsehood, and other factors encountered in forensic work.

Our study evaluates one such device consisting of a handheld NIR spectrophotometer. SCiO®, developed by Consumer Physics®, is a handheld pocket-sized device operating in the NIR. This device was used to scan drinks before and after the addition of a drug. 12 different drugs were tested in 12 different drinks. The drink without the addition of the drug was used as the negative control. Additionally, CYD® paper test strips were used to screen for the presence of ketamine and GHB in 10 of the 12 drinks.

Average NIR spectra were generated using the SCiO® handheld device and were evaluated using the SCiO® Lab application available of the world wide web. 6.3% (9/144) of the samples had a noticeable spectral shape difference only when compared to the negative control, 10.4% (15/144) had a noticeable intensity difference only when compared with the negative control and 22.2% (32/144) had both a noticeable spectral shape as well as intensity difference from the negative control. Collectively, 38.9% (54/144) of the samples had at least one noticeable difference between the spectra generated with and without the addition of drugs within the drinks. CYD® strips gave negative results for the presence of GHB and ketamine in all 10 of the drinks tested for.

Our study results suggest that although there was low efficiency of this device in detecting drugs within the drinks, SCiO® could potentially be optimized to be used for screening of drugs, particularly in drinks with low alcohol content. Additionally, SCiO® was deemed better able to detect drugs found in higher concentrations within the drinks but this scenario is often incompatible with the modus operandi of DFC perpetrators who aim to achieve the biggest effect with the smallest dose administered.

In summary, neither CYD® nor SCiO® are effective in the fight against DFCs in their current configurations and we propose that further research be conducted before these devices are marketed to the public for DFC detection/prevention.

Drug-Facilitated Crimes (DFC), Drug-Facilitated Sexual Assault (DFSA), Portable NIR Spectrometer

B202 Understanding Research Methods, Limitations, and Appropriate Applications of Drug Data Collected by the National Forensic Laboratory Information System (NFLIS-Drug)

Wayne Pitts, PhD, RTI International, Research Triangle Park, NC; David Heller, BS, RTI International, Research Triangle Park, NC; Hope Smiley-McDonald, PhD, RTI International, Research Triangle Park, NC; BeLinda J. Weimer, MA, RTI International, Research Triangle Park, NC; Megan Grabenauer, PhD, RTI International, Research Triangle Park, NC; Katherine Bollinger, RTI International, Research Triangle Park, NC; Jeri Roper-Miller, PhD, RTI International, Research Triangle Park, NC; DeMia Pressley, MS, RTI International, Research Triangle Park, NC*

Learning Overview: After attending this presentation, attendees will have a better understanding of the limitations and appropriate applications of NFLIS-Drug data.

Impact Statement: This presentation will impact the forensic science community by presenting the most common pitfalls associated with using NFLIS-Drug data, including the reasons why these issues are problematic from a methodological perspective.

The National Forensic Laboratory Information System (NFLIS) is a drug surveillance program of the U.S. Drug Enforcement Administration that systematically collects data on drugs that are seized by law enforcement and submitted to and analyzed by the Nation's forensic laboratories (NFLIS-Drug). The NFLIS-Drug component represents all 50 U.S. State systems as well as scores of local and municipal laboratory systems that cumulatively account for more than 98% of the national drug caseloads among forensic laboratories with drug chemistry sections.

This presentation provides an overview of NFLIS-Drug data, which are increasingly being used in predictive modeling and to examine drug use patterns. Based on analysis of 428 unique, refereed article citations published between January 2005 and April 2021, eight concerns that have important implications for proper interpretation and limitations of NFLIS-Drug data were identified. The concerns pinpointed are 1) NFLIS is a voluntary program with varied reporting coverage. Users of NFLIS-Drug data obtained through request outside of NFLIS reports are not privy to the details of partial or interrupted reporting or other coverage issues. 2) Not all drugs are tested by crime laboratories. 3) NFLIS-Drug counts reflect "drug reports." Not all drugs that are seized or submitted for testing are assessed. 4) There are differences in laboratory reporting and timing. The timeliness of surveillance data is complex, and delays in time between the drug seizure, drug testing at the laboratory, and results reporting could be underestimated by researchers. 5) NFLIS geo-location data has limitations. For some laboratories, location information data is not systematically provided. 6) NFLIS-Drug data represent co-reported drugs. Presenting NFLIS-Drug data as "drug combinations" or "drug mixtures" misrepresents what the NFLIS-Drug data show. 7) Varied testing procedures exist at the laboratories. Laboratories also use different criteria to detect drugs in their samples. 8) Overgeneralization and inferential errors can occur. As DEA moves forward with releasing the publicly available data via the Data Query System (DQS), it will be critical for data users to understand that logical inconsistencies and subsequent inferential errors can pose challenges. Knowing the limitations of data sets and considering these limitations during analysis promotes proper comparison of complementary data sets, consistency, accuracy, and usability of the data set.

This study should not be considered a structured systematic literature review and the authors recognize the subjective decisions that were used in drawing our convenience sample. The points included here are intended to serve as illustrative examples to better describe the purposes and limitations of NFLIS data.

NFLIS, Research Methods, Drug Surveillance Reporting

B203 Project REMEDY: Providing Emerging Drug Data and Materials to the Community

Edward Sisco, PhD, National Institute of Standards and Technology, Gaithersburg, MD; Aaron Urbas, PhD, National Institute of Standards and Technology, Gaithersburg, MD; Sara Driscoll, BS, Drug Enforcement Administration, Special Testing and Research Laboratory, Dulles, VA; Hunter Haddad, MS, Drug Enforcement Administration, Special Testing and Research Laboratory, Dulles, VA; Rebecca Jones, BS, Drug Enforcement Administration, Special Testing and Research Laboratory, Dulles, VA; Trinette Spratley, BS, Drug Enforcement Administration, Special Testing and Research Laboratory, Dulles, VA; Sherri L. Tupik, BS, Drug Enforcement Administration, Special Testing and Research Laboratory, Dulles, VA*

Learning Overview: After attending this presentation, attendees will understand how the REMEDY project, which is being jointly run by NIST and the DEA, aims to provide reference data and materials of emerging drugs to the community.

Impact Statement: This presentation will impact the forensic science community by providing a mechanism for forensic laboratories to obtain reference data and materials, free of charge, for emerging drugs while also assisting with detection of new substances.

The constantly changing emerging drug landscape presents a major need for seized drug chemists to have improved access to standards and reference data in a timely and cost-effective manner. Oftentimes when new substances are encountered in casework, chemists may not be able to identify a substance due to lack of available physical material for comparison purposes. To address this need, Project REMEDY has been established with the goal of providing no-cost reference data and materials to seized drug chemists in such cases where there are no commercial standards available.

Project REMEDY is a joint effort between the National Institute of Standards and Technology (NIST) and the Drug Enforcement Administration Special Testing and Research Laboratory (DEA-SFL1). The goal of the project is to decrease the time lag that can exist between the first appearance of an emerging drug in the United States and the time a viable physical standard is available. Project REMEDY reduces this time lag by rigorously characterizing seized material provided by one of the laboratories within a collaboration network. Characterization of the material occurs independently at both NIST and DEA-SFL1 using a suite of analytical tools including gas chromatography mass spectrometry, liquid chromatography mass spectrometry, nuclear magnetic resonance spectroscopy, direct analysis in real time mass spectrometry, Raman spectroscopy, polarimetry, thermal gravimetric analysis, differential scanning calorimetry, and both solid phase and vapor phase Fourier transform infrared spectroscopy. Once characterized, the resulting data, as well as aliquots or direct forms of the physical material, are made available to the community. Laboratories can then request a portion of the characterized material to better understand the specific responses of the new compound on their instrumentation. The entire process is expected to take three to four weeks.

This presentation will outline the Project REMEDY goals, workflow, and examples of materials that have been characterized. Mechanisms for laboratories to receive and send materials will also be discussed.

Emerging Drugs, Standards, Seized Drug Analysis

B204 Using DEA's Forensic Laboratory Drug Chemistry Report Data to Validate the FBI's Law Enforcement Drug Seizure Data

Nick Richardson, PhD, RTI International, Research Triangle Park, NC; Wayne Pitts, PhD, RTI International, Research Triangle Park, NC; David Heller, BS, RTI International, Research Triangle Park, NC; Hope Smiley-McDonald, PhD, RTI International, Research Triangle Park, NC; Megan Grabenauer, PhD, RTI International, Research Triangle Park, NC; DeMia Pressley, MS, Drug Enforcement Administration, Springfield, VA*

Learning Overview: After this presentation, attendees will have a broader understanding of the NFLIS-Drug and NIBRS data overall, which can show estimates of drugs in the U.S. illicit drug market.

Impact Statement: This presentation highlights how the Drug Enforcement Administration's NFLIS-Drug data can help validate the Federal Bureau of Investigation's National Incident-Based Reporting System (NIBRS) data to provide a reliable and valid estimate of the types of drugs seized to measure the illicit drug supply.

Understanding and measuring the illicit drug supply market is critical to effectively responding to the drug epidemic. Data systems to monitor and track the licit drug supply exist, but no standardized data collection system monitors the illicit supply network. Some studies have used law enforcement drug seizures as a proxy by which to monitor the illicit drug supply, but little is known about the quality and validity of law enforcement drug seizure data.

This study compared trends across a 12-month period in 2018 across two important law enforcement drug seizure data sets: NFLIS-Drug and NIBRS. NFLIS-Drug systematically collects drug identification results and associated information from drug cases submitted to and analyzed by Federal, State, and local forensic laboratories. These laboratories analyze controlled and noncontrolled substances secured in law enforcement operations across the country. As of January 2021, NIBRS replaced the FBI's Uniform Crime Reporting Program's Summary Reporting System. NIBRS captures information on drugs seized by law enforcement, including the suspected drug type and the quantity of the drug seized. Although it is a valuable data set, resource, and tool for researchers interested in examining the relationship between the illicit drug market, virtually nothing is known about the quality of NIBRS drug seizure data.

The primary study goal was to examine how closely the trends from both data sets align from month to month, examining heroin, methamphetamine, and cocaine. Methamphetamine, cocaine, and heroin were used because they have played a key role in fueling the drug epidemic. The study premise is that the drug reports in the NFLIS-Drug data are from drugs tested in a laboratory setting and would yield more accurate and reliable data than would other types of presumptive positive tests that are used by law enforcement in the field and reported in NIBRS.

The authors focused on these drugs seized by law enforcement in Michigan and Tennessee during 2018 based on three NIBRS-related criteria: (1) agency response rate, (2) crime incident coverage, and (3) population coverage. Because NIBRS data are not yet nationally representative, and not all agencies in a state submit data to NIBRS, it was important to ensure that selected states had adequate coverage. For NIBRS, Michigan and Tennessee have greater than 99% coverage for each criterion. All NFLIS-Drug laboratories in Michigan and Tennessee submitted 2018 data.

The results for each of the three drug categories for both states across both data sources exhibit similar longitudinal trends, with the number of drugs seized being higher in NIBRS than in NFLIS-Drug laboratories. Spikes in law enforcement drug seizures in NIBRS are shadowed by spikes in NFLIS-Drug case counts. Similarly, declines in drug seizures in NIBRS mirror drops in NFLIS-Drug cases. These general trends, as well as the few exceptions to these trends, which will be highlighted in the presentation.

Although further work should be done to further validate NIBRS law enforcement drug seizure data, this is the first study to show the correlation between these two important data sets and how they can be used by the forensic, law enforcement, and public health communities to measure the illicit drug market.

NFLIS, NIBRS, Drug Surveillance Reporting

B205 The Effect of Modifications to the Core Fentanyl Structure on the Observed Product Ion Spectra

Alia Hacker, BS, West Virginia University, Morgantown, WV; Tyler Davidson, PhD, Sam Houston State University, Huntsville, TX; Glen Jackson, PhD, West Virginia University, Morgantown, WV*

WITHDRAWN

B206 An Evaluation of the Physical and Chemical Variation in Tablets Found to Contain Fentanyl

Emily Lockhart, MS, U.S. Drug Enforcement Administration, Dulles, VA; James Jordan, PhD, U.S. Geological Survey, Reston, VA*

Learning Overview: Attendees will gain a fundamental understanding of the physical characteristics and chemical properties of clandestine fentanyl tablets.

Impact Statement: This presentation will impact the forensic science community by presenting data from the testing of individual tablets within batches of seized clandestine fentanyl tablets and investigating sources of variation within seizures and across different seizures as potential indicators for routes of introduction into the illicit US opioid market.

Fentanyl in the United States' illicit drug market has been a prolific concern since circa 2014. According to internal studies by the DEA Intelligence Division, which included data from the Center for Disease Control and Prevention (CDC), the prevalence of illicit tablets containing fentanyl available to the public is a national health threat as deaths involving synthetic opioids continue to increase.¹ The National Forensic Laboratory Information System (NFLIS) reported a 12% increase in fentanyl-related incidents in 2019 when compared to the previous year.¹

Illicit tableting operations occur domestically and are especially prolific in Mexico. A report from the Partnership for Safe Medicines states that as of October 2020, all 50 US States have reportedly identified fentanyl in clandestine tablets.² Tablets bearing the mark "M 30" (normally indicative of 30 milligram oxycodone tablets) are consistently observed in the illicit market.¹ Other tablet markings such as "A 215" are also seen. Mexican authorities have reported an increase in illicit opioid tableting operations assuring that fentanyl will continue to be observed in the illicit market.¹

The goal of this research is to characterize individual clandestine fentanyl tablets from physical and chemical perspectives. Analysis of individual tablets versus bulk composites provides valuable data pertaining to within seizure and seizure-to-seizure variation which is necessary to gain insight to the level of sophistication in illicit manufacturing operations. Physical characterization included measurements of sample mass, diameter, thickness, and markings. Additionally, high resolution photos of the tablets were collected using a camera coupled to a microscope. Tablet color (normally a subjective call) was more fully characterized by fiber-optic spectrophotometry in diffuse reflectance mode. Chemical characterization included qualitative identification and quantitation of all components via nuclear magnetic resonance (NMR) and profiling of elemental impurities using X-ray fluorescence (XRF) and/or laser ionization breakdown spectroscopy (LIBS).

Seized Drugs, Fentanyl, Tablets

B207 An Analysis of Fentalogs and Illicit Fentanyl Vapor Profiles

Stephanie Vaughan, PhD, Naval Research Laboratory, Washington, DC; Ashley Fulton, PhD, Naval Research Laboratory, Washington, DC; Lauryn DeGreeff, PhD*, Formerly Naval Research Laboratory, Washington, DC*

Learning Overview: After attending this presentation, attendees will understand the methods used for headspace analysis, as well as the relationship between pharmaceutical-grade fentanyl, fentalogs, and illicit fentanyl.

Impact Statement: This presentation will impact the forensic science community by identifying target analytes that can be used to detect fentanyl in the vapor phase.

Fentanyl is a Schedule II synthetic opioid that possesses strong euphoric and analgesic properties, as well as high potency. With its immense potency and availability, fentanyl poses great danger to users and law enforcement personnel. The risk of overdose is extremely high, with as little as 2 mg milligrams capable of a lethal dose. In 2019, there were 36,359 synthetic opioid deaths, with most caused by fentanyl or fentanyl-related substances.¹ Availability of fentanyl has been consistently on the rise with a 180% increase of seizures from 2016 to 2019.² Due to this hazard, most agencies advise personnel to avoid direct handling of fentanyl or related materials.

To avoid the dangers of fentanyl in the field, a non-contact detection method would be ideal; however, due to the low vapor pressure of fentanyl it is not likely to be detected in the vapor phase. Thus, it is necessary to identify other compounds in the headspace that can be used as target analytes for vapor detection. In this regard, the vapor profile of fentanyl can be determined by identifying volatile organic compounds (VOCs) found in the headspace that are specific to fentanyl. This presentation will describe the research used to determine the vapor profiles of pharmaceutical-grade fentanyl, fentalogs (fentanyl analogs), and illicit fentanyl, as well as identification of target analytes for vapor detection of fentanyl.

A solid phase microextraction (SPME) coupled with gas chromatography and mass spectrometry (GC-MS) method was used to assess the vapor profiles. Several semi-VOCs and VOCs were identified in the headspaces, with each having a unique vapor profile. A comparative analysis of all vapor profiles was completed, which included a total of 20 illicit fentanyl samples and fentalogs. The analysis revealed two targets of interest for detection of fentanyl and related substances in the vapor phase: N-phenylpropanamide (NPPA) or N-phenethyl-4-piperidone (NPP). It was determined that NPPA is formed through fragmentation of fentanyl through β -elimination, while NPP is a constituent of the synthetic route for fentanyl and many fentalogs. The identification of NPPA or NPP in 75% of these samples is an essential component in the development of a non-contact vapor detection method for fentanyl.

Fentanyl, SPME, Vapor Detection

B208 The New National Institute of Standards and Technology/National Institute of Justice (NIST/NIJ) Direct Analysis in Real-Time Mass Spectrometry (DART®-MS) Data Interpretation Tool (DIT)

Arun Moorthy, PhD, National Institute of Standards and Technology, Gaithersburg, MD; Edward Sisco, PhD, National Institute of Standards and Technology, Gaithersburg, MD; Stephen Tennyson, BS, National Institute of Standards and Technology, Gaithersburg, MD and University of Maryland, College Park, MD; Ruthmara Corzo, PhD, National Institute of Standards and Technology, Gaithersburg, MD*

Learning Overview: After attending this presentation, attendees will know how to employ the new NIST/NIJ Direct Analysis in Real Time Mass Spectrometry (DART®-MS) Data Interpretation Tool (DIT) for seized drug analysis.

Impact Statement: The NIST/NIJ DART®-MS DIT is a freely available and open-source software tool developed in collaboration with practicing local, state, and federal forensic laboratories doing seized drug analysis. This tool simplifies DART®-MS analysis of seized drugs for forensic chemists, and the open-source nature of the software allows for further customization and expansions.

DART®-MS is an analytical chemistry technology being increasingly employed in forensic applications.¹ This form of mass spectrometry rapidly yields rich structural information about an analyte with minimal sample preparation. The challenge with DART®-MS data, much like other data generated with high throughput technologies, lies in the data interpretation; this is especially true when the analyzed samples are multi component mixtures like seized drug evidence.

The NIST/NIJ DART®-MS DIT is a freely available and open-source software tool developed to support the interpretation of DART®-MS data. The NIST/NIJ DART®-MS DIT can be used to view reference mass spectra from DART®-MS spectral libraries, search query DART®-MS mass spectra of mixtures against reference libraries using the Inverted Library Search Algorithm, and generate printable reports from search results.^{2,3} Several of the features, including the formatting of generated reports, were iteratively designed with input from local, state, and federal forensic practitioners, ensuring that the program is intuitive and usable for the expected users.

This presentation will discuss the process of creating the NIST/NIJ DART®-MS DIT, including how feedback was solicited and incorporated through the development process, as well as demonstrate how new users can employ DART®-MS and this new software to analyze seized drug evidence.

DART®-MS, Software, Seized Drugs

B209 Best Buds—Ambient Ionization Coupled with Mass Spectrometry for the Forensic Analysis of Cannabinoid-infused Complex Matrices

Megan Chambers, BS, University at Albany - SUNY, Albany, NY; Rabi Musah, PhD, University at Albany - SUNY, Albany, NY*

Learning Overview: In this presentation attendees will gain an understanding of how ambient ionization coupled with mass spectrometry can be utilized for the rapid analysis of various Cannabis-derived and cannabinoid-infused samples, including plant material, edibles, beverages and personal-care products.

Impact Statement: This presentation will impact practices in the fields of forensic science and criminal justice by providing protocols for the rapid detection and quantification of cannabinoids in complex matrices, as well as an approach to differentiate hemp and marijuana varieties of *Cannabis sativa*.

Exploration of new methods for the analysis of Cannabis-derived materials has exploded in recent years. This is primarily a result of the ever-evolving sample types that require analysis. In the field of forensic science, crime laboratories can receive Cannabis and cannabinoids as evidence in a variety of forms, and the complexity of these matrices can cause numerous problems when analyzed by traditional forensic methodologies. However, also in recent years, a technique termed direct analysis in real time – high-resolution mass spectrometry (DART®-HRMS) has been utilized in several areas of forensic science, including seized drugs. This technique confers several potential benefits that can be leveraged in the analysis of Cannabis evidence, as described herein.

The primary difficulty when it comes to analyzing edibles infused with cannabinoids is how complex the matrices are. In this study, a variety of cannabinoid-infused food and beverages were prepared in-house, while personal care-products were purchased from local vendors. The two primary cannabinoids of interest are psychoactive Δ^9 -tetrahydrocannabinol (THC) and non-psychoactive cannabidiol (CBD). When screened by DART®-HRMS, samples containing one or both of these cannabinoids produced a mass spectrum containing a peak at m/z 315, which is consistent with the protonated mass $[M+H]^+$ of THC and CBD. Control samples (blank samples that do not contain cannabinoids) were also analyzed in this study. Despite the complexity of their matrices, none of the controls exhibited peaks that overlapped with those consistent with cannabinoids. The successful detection of cannabinoids in complex matrices prompted research towards the development of quantification protocols using DART®-HRMS, including the quantification of CBD in traditionally challenging edible matrices (i.e., gummies, chocolates). Extraction protocols and the DART®-HRMS method for quantification are being optimized for integration into current forensic laboratory workflows.

Another challenging aspect of analyzing Cannabis evidence is the differentiation of hemp and marijuana plant material, which are two varieties of *Cannabis sativa*. Although both varieties contain THC, they differ in the amount of this molecule that is present. Federal law currently states that *C. sativa* that contains $>0.3\%$ THC is marijuana, while plant material that contains $\leq 0.3\%$ THC is hemp. This definition imposes severe challenges on crime labs. Therefore, in addition to the detection and quantification of cannabinoids, a DART®-HRMS method combined with statistical analysis was developed for the rapid differentiation of hemp and marijuana plant material. Marijuana samples from DEA-registered suppliers and hemp plant material from licensed vendors were obtained and analyzed by DART®-HRMS. Preliminary statistical analysis of the small-molecule profiles of these samples revealed the potential for differentiating these varieties by DART®-HRMS. These results prompted the application of advanced statistical processing to the data, which revealed diagnostic m/z values for distinguishing between hemp and marijuana with a high level of certainty. The identities of several m/z values have been confirmed, while the identification of the remaining masses is currently underway.

DART®-HRMS has demonstrated successful applications to the investigation of seized *C. sativa* plant material and derived products. Overall, the methods described would greatly improve forensic science and criminal justice practices in the United States.

B210 A Retrospective Review of Hemp/Marijuana Decision Point Assays in Operational Laboratories

James Miller, MA, Houston Forensic Science Center, Houston, TX; Kay McClain, BS, Harris County Institute of Forensic Sciences, Houston, TX; Charles Cline, BS, Texas Department of Public Safety Crime Laboratory Service, Tyler, TX; Ya-Chih Cheng MS, Sam Houston State University, Huntsville, TX; Sarah Kerrigan PhD, Sam Houston State University, Huntsville, TX*

Learning Overview: After attending this presentation, attendees will have a greater understanding of the practical and scientific considerations associated with the deployment of decision-point assays for the differentiation of hemp from marijuana in a high-throughput operational setting.

Impact Statement: The presentation will impact the forensic science community by highlighting important concepts and considerations associated with the use of decision-point assays related to hemp/marijuana differentiation.

Decision-point assays are frequently used to differentiate illegal marijuana from legal or commercial hemp in many jurisdictions. We previously reported an interlaboratory validation at a 1% $\Delta 9$ -tetrahydrocannabinol ($\Delta 9$ -THC) administrative threshold using gas chromatography/mass spectrometry (GC/MS), deuterated internal standard and dual selected ion monitoring (SIM)/scan acquisition. This threshold far exceeds the legal threshold of 0.3% $\Delta 9$ -THC by dry weight. Although multi-agency collaborations and interlaboratory validations are extremely beneficial, they do not supplant the need for there to be a full, independent, and rigorous validation. Prior to deployment, the method was fully validated in accordance with published standards in seized drug analysis. This included limit of detection, selectivity, precision, accuracy, dilution integrity, carryover, extract stability, decarboxylation efficiency, measurement uncertainty, and potential interference from cannabidiol (CBD). Certified reference materials and secondary controls were employed during validation and routine casework.

In this presentation we share data and the experience of three independent agencies and fifteen laboratories following deployment of the method for over one year. Practical challenges, maintenance, sample throughput, reporting practices, operational workflow and resource sharing are discussed.

Using the decision-point approach, the relative peak area (RPA) of the unknown ($\Delta 9$ -THC/ $\Delta 9$ -THC- D_3) is measured relative to the positive control at the administrative cutoff (1% $\Delta 9$ -THC by weight). This ratio of RPAs establishes the decision-point ratio (DPR) whereby samples with a DPR of 1.0 or more exceed the reporting cutoff. Although not quantitative in nature, the spread of decision-point ratios among exhibits provides an estimate of how close a large population of seized drug specimens across laboratories and jurisdictions are to the administrative cutoff. Data between laboratories are correlated, and interesting (outlier) data are discussed.

Differences in instrument performance and strategies for routine maintenance are addressed. Workflow issues and the use of a customized macro among laboratories are presented. Finally, reporting strategies that reflect differences in laboratory approach, jurisdictional and policy-based preferences are also discussed. Data and experiences across multiple agencies highlight the utility and efficiency of the approach, while maintaining a strict regimen for instrument maintenance and performance monitoring.

Hemp, Marijuana, GC/MS

B211 Factors Influencing the *In Situ* Formation of Psychoactive Cannabinoids from Cannabidiol During GC-MS Analysis

Student Ya-Chih Cheng, MS, Sam Houston State University, Huntsville, TX; Sarah Kerrigan, PhD, Sam Houston State University, Huntsville, TX*

Learning Overview: After attending this presentation, attendees will understand the potential for CBD to Δ 9-THC conversion in the GC inlet and strategies for mitigation.

Impact Statement: This presentation will impact the forensic science community by creating greater awareness regarding the potential for in-situ formation of psychoactive cannabinoids, and the role of instrument conditions, preventive maintenance, and liner selection to mitigate issues.

Cannabis sativa (*C. sativa*) can be broadly classified as hemp or marijuana. While marijuana yields a higher concentration of the psychoactive compound, Δ 9-tetrahydrocannabinol (Δ 9-THC), industrial or commercial hemp products are typically rich in cannabidiol (CBD). Gas chromatography/mass spectrometry (GC/MS) is the most widely used instrumental technique for the identification of Δ 9-THC in seized plant materials. As a consequence, it is commonly deployed for the differentiation of hemp from marijuana in the United States and Europe. However, the potential for CBD conversion to Δ 9-THC and other cannabinoids exists under certain conditions. This conversion is exploited in e-cigarettes due to their extremely high operating temperatures. Although temperatures in the GC inlet are typically much lower than e-cigarette devices, the potential for conversion must be carefully evaluated during GC/MS method development and validation. Other mitigating factors, such as active sites, and absence of routine maintenance could potentially exacerbate formation.

We previously developed and validated a GC/MS assay to differentiate hemp from marijuana using an administrative threshold of 1% Δ 9-THC by weight. Plant extracts containing CBD concentrations equivalent to 50% (w/w) were evaluated during the validation. Instrumental conditions were selected to minimize in-situ formation. Anecdotally, differences in assay performance were observed following routine maintenance.

In this study, seven GC liners with different deactivation chemistries and geometries were evaluated. The effect of deactivation chemistry was compared using four cyclosplitter liners with standard deactivation, base deactivation, Siltek deactivation, and premium deactivation. The influence of liner geometry was also evaluated using liners with the same surface deactivation chemistry. In order to produce detectable Δ 9-THC, no preventive maintenance was performed (including column maintenance or source cleaning) for several months.

Significant differences in CBD to Δ 9-THC production were observed between liner type. In many instances it was not possible to produce sufficient Δ 9-THC to meet reporting criteria (typically ion ratios). Three of the liners evaluated were capable of producing reportable Δ 9-THC from CBD. Although inlet temperature had been previously optimized (250°C), the effect of temperature (230 – 290°C) was also investigated. Due to extreme differences in abundance, temperature dependence was observed for some liners but not others. However, a two-way ANOVA confirmed inlet temperature had a significant effect on Δ 9-THC production at $p=0.05$ [$F(3, 32)=16.04$, $p<0.0001$]. ANOVA was also used to show that differences between instruments operating under the same conditions were significantly different [$F(1, 32)=244.31$, $p<0.0001$]. The results confirmed that the original deactivated liner that was used for the validation was resistant to the formation of Δ 9-THC under the operating conditions of the assay. However, some liners, including those packed with glass wool were more susceptible to in-situ production of Δ 9-THC. Using the least favorable liner, CBD to Δ 9-THC was found to be 20 times higher. Moreover, using this liner it was also possible to identify Δ 8-THC from CBD at high concentrations (40%).

Under forceful conditions and in the absence of routine preventive maintenance, measurable quantities of Δ 9-THC can be produced in-situ. Careful selection of instrumental conditions, liner selection and routine preventive maintenance can mitigate this. Differences between instruments highlight the need for full, independent and rigorous validation, as well as appropriate safeguards during routine analysis.

Marijuana, Hemp, CBD

B212 Analysis of Cannabis Plant Materials by Infrared Spectroscopy for Differentiating Hemp and Marijuana

Aaron Urbas, PhD, National Institute of Standards and Technology, Gaithersburg, MD; Ewelina Mistek-Morabito, PhD, University at Albany, SUNY, Albany, NY; Igor Lednev, PhD, University at Albany, SUNY, Albany, NY; Walter Wilson, PhD, National Institute of Standards and Technology, Gaithersburg, MD; Melissa Phillips, PhD, National Institute of Standards and Technology, Gaithersburg, MD*

Learning Overview: The goal of this presentation is to provide forensic scientists with an overview of the potential utility of mid-infrared and near-infrared spectroscopic analysis for the rapid evaluation of Cannabis plant materials for distinguishing hemp and marijuana.

Impact Statement: This presentation will impact the forensic community by summarizing near-infrared (NIR) spectroscopic analysis of cannabis conducted on a benchtop FTIR system as well as an evaluation of several commercially available portable cannabis analyzers, based on IR (ATR) or NIR (reflectance) spectroscopy, for the quantification of THC and differentiation of Cannabis samples as hemp or marijuana.

Identification and quantification of seized drugs are important aspects of current forensic practices. With the passage of the 2018 Farm Bill, the analysis of cannabis samples has become more challenging for forensic practitioners. There is an urgent need for rapid and reliable methods to differentiate between legal hemp and illegal marijuana samples. There are no taxonomical differences between hemp and marijuana and current field tests to distinguish them are limited. The term hemp is used to refer to strains of cannabis that have low levels of tetrahydrocannabinol (THC). However, the new federal legislation defined legal hemp as containing 0.3% or less total-THC, estimated as decarboxylated- Δ^9 -THC, on a dry weight basis. This designation requires that forensic practitioners quantify the total-THC content in seized cannabis samples.

In this work, we explored the use of near-infrared (NIR) reflectance spectroscopy to analyze a wide variety of ground cannabis plant materials on a benchtop FTIR spectrometer system. A total of 85 samples were analyzed for different aspects of the investigation. The data was analyzed using multivariate analysis methods to both qualitatively discriminate between cannabis strains/samples designated as hemp or marijuana and to develop quantitative models for predicting total-THC content. Classification models, based on partial least-squares discriminant analysis (PLS-DA), showed clear differentiation between hemp and marijuana strains. However, numerous hemp samples were found to contain levels of THC above 0.3% based on reference THC content obtained using a high-performance liquid chromatography with ultraviolet detection (HPLC-UV) method for a large subset of the subsamples. Partial least-squares (PLS) regression models were developed on this sample set to quantify total-THC content and determine whether sufficient accuracy could be obtained for forensic or regulatory purposes.

In addition to our own spectroscopic investigations, a subset of cannabis samples was evaluated on four commercially available small footprint, portable cannabis analyzers based on either mid-IR (ATR) or NIR reflectance spectroscopy. These systems came with built-in calibrations that provided quantitative estimates of total-THC content as well as other cannabinoids (e.g., CBD). The results from these commercial systems were compared to the total-THC values obtained from the reference HPLC-UV method and will also be presented.

Cannabis, Infrared Spectroscopy, Seized Drug Analysis

B213 The National Institute of Standards and Technology (NIST) Cannabis Quality Assurance Program (CannaQAP): A Tool for Improving Quantitative Measurements in Cannabis

Melissa Phillips, PhD, National Institute of Standards and Technology, Gaithersburg, MD; Walter Wilson, PhD, National Institute of Standards and Technology, Gaithersburg, MD*

Learning Overview: To increase understanding about CannaQAP, the impact participation in a QAP can have on a forensic laboratory, and consideration of how future QAPs could be instrumental in standardizing forensic testing approaches.

Impact Statement: CannaQAP is the first large-scale interlaboratory study to investigate quantitative measurements of cannabinoids and other constituents in Cannabis. CannaQAP, and future similar programs, will generate a wealth of information for the forensic community.

Accurate and precise measurements are critical for enforcement of laws and regulations. Many tools are available to help laboratories critically evaluate performance, including standard methods, reference materials, and interlaboratory studies. The National Institute of Standards and Technology (NIST) uses interlaboratory studies as a tool to establish scientific validity of a method, to uncover method specific results, to evaluate fitness-for-purpose of candidate reference materials, and to gather multi-laboratory testing data to support method standardization.

The NIST Cannabis Quality Assurance Program (CannaQAP), an ongoing educational interlaboratory comparison, launched in 2020 as a mechanism to improve the comparability of analytical measurements in forensic and Cannabis (hemp and marijuana) testing laboratories. CannaQAP operates similarly to traditional proficiency testing schemes but without pass/fail implications. Results from CannaQAP participants are evaluated with respect to the consensus of submitted results as well as to NIST results, and all studies are summarized in publicly available NIST Reports. Exercise 1 of CannaQAP offered opportunities for participants to demonstrate proficiency in the determination of cannabinoids in two hemp oils. Exercise 2 offered studies for determination of cannabinoids in Cannabis materials both above and below the US federal limit for total THC (0.3 %), as well as moisture and toxic elements in hemp plant materials. Exercise 3 repeated studies previously offered in Exercises 1 and 2 as an opportunity for laboratories to demonstrate improved performance. Over 200 laboratories have participated in CannaQAP, including Cannabis product developers, contract research organizations, regulators, and forensic laboratories. Involvement of stakeholders from across the Cannabis community has contributed to the impact of CannaQAP, allowing laboratories from different sectors to learn from one another's experience.

This presentation will summarize the goals and impact of CannaQAP, including results from the first three exercises. These studies have revealed the overall performance of Cannabis testing laboratories in quantitative evaluation of cannabinoids, toxic elements, and moisture in Cannabis plant and oil materials. In addition, method information collected via CannaQAP participation has identified potential areas for improvement of in-house methods and directions for standard methods currently in development. Future studies of CannaQAP will engage additional standards development organizations and include studies for other Cannabis-containing samples, building upon lessons learned and providing a tool for laboratories to demonstrate comparability.

Cannabis, Seized Samples, Δ9-THC

B214 Testosterone as an Internal Standard in Qualitative Decision-Point Assays for the Differentiation of Hemp From Cannabis: Optimization and Limitations in High CBD Matrices

Jose Gonzalez, BS, Los Angeles Police Department, Los Angeles, CA*

Learning Overview: An attendee can expect to learn how to best optimize and understand the limitations of Testosterone as an internal standard in qualitative decision-point assays used to differentiate Hemp from Cannabis.

Impact Statement: My presentation will present information which will shed light on chromatographic and sample preparation approaches to handle sample matrices which have proven difficult to analyze in the past where testosterone was/is utilized as an internal standard.

Background: Traditionally government laboratories at the local, state, and federal level tasked with analyzing plant material for the presence of Cannabis used a two-tier testing approach: One a morphological examination and the other a chemical color test known as the Modified Duquenois-Levine test. These controlled substance laboratories have historically been focused on qualitative work- the identification and weight of a controlled substance. Quantitatively determining the amount of controlled substances has typically been left to toxicologists where such analysis is routine. However, with the passage of the Farm Bill in 2018, control substance laboratories now had to come up with methodologies to differentiate Hemp from Cannabis.

There are various ways to tackle the issue ranging from spectrophotometric techniques to high pressure liquid chromatography to name a few. In an effort to provide a solution to the analytical challenge, some laboratories settled on a decision-point assay technique which relies on one of the techniques utilizes a common instrument in controlled substance laboratories - a gas chromatograph/mass spectrometer (GC/MS).^{1,2} Decision-point assays look at the ratio of a known amount of delta-9 THC to the amount of delta-9-THC in the sample utilizing an internal standard technique.

This work looks at the use of Testosterone¹ as an internal standard in various sample matrices. The challenge of utilizing Testosterone in such matrices will be discussed as well as the inhibition of Testosterone in certain high CBD profile samples.

C1 The Validation of Imagery Enhancement Tools

James Zjalic, MSc, Verden Forensics, Birmingham, Birmingham, United Kingdom; Jake Harrison, BSc, Verden Forensics, Birmingham, Birmingham, United Kingdom*

Learning Overview: After attending this presentation, attendees will better understand the importance of validating tools relied upon as part of a wider method and the need to exercise caution when selecting said tools. Attendees will be presented with the methodology, results, and conclusions from research performed in relation to the validation tool testing of imagery enhancement tools that are marketed at different sectors (including forensics and graphic design) and thus fall into different price brackets.

Impact Statement: The study aims to increase awareness of the requirement for tool validation and to assist examiners in making informed decisions about the tools they use for the enhancement of images.

The validation of methods is an essential component of forensics to aid in improving consistency and is also one of the core requirements of the International Organization for Standardization/International Electrotechnical Commission (ISO/IEC) 17025:2107 standard.^{1,2} This reliability is based on two principles: accuracy (will the method/tool produce the expected [and thus reliable] results?), and precision (will the method/tool produce the same results repeatedly?). In order to validate a method, it is vital that the tools used within the said method are reliable, and thus, the validation of tools forms a vital part of the overall validation exercise.

During validation of the imagery enhancement method, results were obtained using a tool that is marketed specifically for use in forensics. Curiosity then drove further tool testing into the consistency of results against other imagery enhancement solutions. As the focus of the research is tool validation, and not the performance of specific tools, all software tested has been anonymized.

The overarching research questions were: (1) do the tools apply processes as expected?, and (2) what is the degree of inter-variability between the results of processes applied by different software?

Hypotheses stemming from such are that the processes would be applied as expected, and thus the inter-variability would not significantly impact the overall result of the method. This is based on the premise that imagery enhancement tools would apply similar processes to the imagery based on fundamentals of image processing.

In order to test the proposed hypothesis, the same images were processed using the same settings with each tool. The processes applied included: cropping, look up table adjustments, brightness, contrast, sharpening, and rescaling.

C2 Score-Based Likelihood Ratios for Camera Device Identification Using Cameras of the Same Brand for the Alternative Device Population

Stephanie Reinders, PhD*, Center for Statistics and Applications in Forensic Evidence, Ames, IA and Iowa State University, Ames, IA; Danica Ommen, PhD, Center for Statistics and Applications in Forensic Evidence, Ames, IA and Iowa State University, Ames, IA; Alicia Carriquiry, PhD, Center for Statistics and Applications in Forensic Evidence, Ames, IA and Iowa State University, Ames, IA

Learning Overview: After attending this presentation, attendees will have a better understanding of the benefits and limitations of using score-based likelihood ratios to quantify the weight of evidence in camera device identification and how the alternative cameras used in the analyses can affect the rates of misleading evidence.

Impact Statement: A digital image (questioned image) is involved in a crime and investigators want to determine whether the image was captured by a person of interest's camera. This presentation will impact the forensic science community by explaining how score-based likelihood ratios can quantify the strength of the evidence in this scenario. The presentation will also explore how the set of alternative cameras used in the analyses can affect the results.

Score-based likelihood ratios are a statistical method for quantifying the weight of evidence and have been used in many areas of forensics, including camera device identification.¹⁻³ Small sensor imperfections caused during manufacturing, called photo response non-uniformity, leave identifying features, called a camera fingerprint, in the images that a camera takes.⁴ The sample correlation measures the similarity (or dissimilarity) between the camera fingerprint from the person of interest's camera and the camera fingerprint in the questioned image. On its own, it is difficult to know how to interpret this score. Is a score of 0.25 evidence that the questioned image originated from the person of interest's camera? What about a score of 0.5? To make sense of the score, it is compared with two different reference sets of scores: matching and non-matching. Matching scores are sample correlations between two fingerprints known to come from the person of interest's camera. Non-matching scores are sample correlations between two fingerprints known to come from two different cameras. An alternative set of cameras that does not include the person of interest's camera is used to build the set of non-matching scores.

It turns out that researchers have not agreed upon a best method for constructing the alternative population for score-based likelihood ratios.^{5,6} Recently, researchers calculated score-based likelihood ratios for camera device identification using 48 cameras representing 26 models.⁷ This present research explores whether the rates of misleading evidence can be decreased by restricting the alternative device population to cameras of the same brand as the person of interest's camera.

C3 The Influence of Compression on Forensic Deepfake Detection

Meike Kombrink, MFS, Netherlands Forensics Institute, The Hague, South Holland, Netherlands; Zeno Geradts PhD, Netherlands Forensics Institute, The Hague, South Holland, Netherlands and University of Amsterdam, Amsterdam, North Holland, Netherlands*

Learning Overview: After attending this presentation, attendees will have learned more on deepfake detection algorithms in relation to compression algorithms used.

Impact Statement: This presentation will impact the forensic science community by giving more direction of research, as well as handling issues with deepfakes on social media.

Many videos are shared on online platforms every day. Yet it is becoming increasingly difficult to determine the authenticity of these videos due to the increased popularity and availability of deepfake creation software. Deepfake videos are videos that have been manipulated using deep learning. Although many different types of deepfakes exist, the current, most popular type of deepfake is a face swap between a target person and an individual in a video. The quality of deepfake videos has improved drastically, to the point where deepfake videos and genuine videos are becoming harder to distinguish with the human eye. While the analysis of single, high-impact videos for evidence of manipulation is possible, this can only be performed properly by experts (making this method of detection limited in its applicability) for whom the process is time consuming. The limited number of experts available to distinguish between deepfakes and genuine videos means that we cannot analyze all videos that are uploaded daily given this current speed of detection. In order to review each of the hundreds of thousands of videos uploaded to internet or social media platforms every day, automation of the process is needed.

Recently, the automated detection of deepfake videos has experienced a surge of interest, which led to a lot of improvements in the performance of algorithms to detect deepfakes. Yet these improvements have been made on either largely abstracted datasets or on datasets without annotation of complexities. One such complexity that always occurs is compression, which launders manipulation traces from images. As many deepfakes are shared on social media, where any upload will always first be compressed, it is vital to understand the influence of compression on the detection of deepfake videos. Therefore, this research will investigate the influence of compression on the ability of two promising detection algorithms to distinguish between deepfake videos and genuine videos. The results of this research suggest that the effect of compression on the detection of deepfake is positive at first, but turns negative when too much compression is added. The studied algorithms show almost identical effects to compression. The study also suggests similar effects of compression are seen for H.265 and AV1, though this result is only gathered on a limited dataset and needs more research before any conclusions should be drawn. Also, other approaches such as lip-reading with Artificial Intelligence (AI) have been tested, and the combination of different methods for detection both for audio, speaker and video artifacts seem to be the way forward.

Compression, Deepfake, Video Manipulation

C4 The Performance of Automated Age Assessment Methods in Images of Subadults

C5 Methods for Evaluating and Optimizing Automated Detection/Classification Systems in the Forensic Environment

Jeff Smith, MS, MITRE, McLean, VA*

Learning Overview: After attending this presentation, attendees will better understand the foundational principles underlying detection/classification systems used in forensics, such as biometric recognition and multimedia manipulation detection, considerations for their operational use, and novel techniques for implementing these systems in a forensic environment.

Impact Statement: This presentation will impact the forensic science community by increasing baseline knowledge in the operating principles behind automated systems and by proposing best practices and new methods for their implementation in a forensic environment.

It is necessary to implement automated systems in forensics and intelligence in application areas such as biometric recognition and multimedia manipulation detection. These analytics leverage machine learning techniques that output a confidence value or posterior probability of classification given the evidence input.¹ This probability is typically a value between 0 and 1. A threshold, set to 0.5, would assign samples of outputs larger or equal 0.5 to the positive class, and the rest to the negative class.² While this arbitrary threshold can work well in many cases, as will be shown in this presentation, an optimal threshold can be found by evaluating performance against known data.

The results of these systems when evaluated against known data can be summarized with a Confusion Matrix (example in Figure 1) of True Positives (TP), False Positives (FP), True Negatives (TN), and False Negatives (FN).

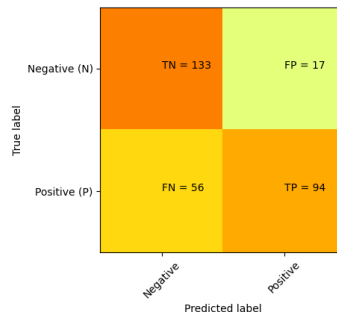

Figure 1: Example Confusion Matrix at an arbitrary threshold shows count of False Positives, False Negatives, True Positives, and True Negatives.

The most common evaluation technique is the area under the Receiver Operating Characteristic (ROC) curve in order to establish overall system performance. The ROC curve (example seen below in Figure 2) is a plot of the system's True Positive Rate (TPR):

$$TPR = \frac{\text{true positives}}{\text{true positives} + \text{false negatives}}$$

over its False Positive Rate (FPR):

$$FPR = \frac{\text{false positives}}{\text{false positives} + \text{true negatives}}$$

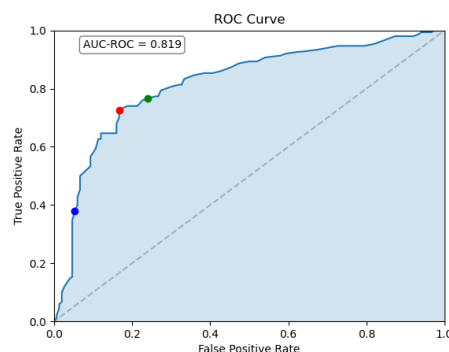

Figure 2: Example ROC curve with AUC, shaded blue, of 0.819. The point where False Positive Rate = 0.05 is labeled with a blue dot, the red dot where MCC is maximum, and the green dot shows TPR and FPR with the threshold at 0.5.

The utility of this plot comes from observing the Area Under the Curve (AUC). This is the definite integral of the ROC curve across all thresholds; a value of 0.819 in example Figure 2. An AUC of 1 would be perfect performance—no false positives, no false negatives. An AUC of 0.5, the dotted line where $x=y$, is performance that is no better than chance. In reality, no system is expected to perform perfectly, so an acceptable rate of error must be determined and achieved prior to implementation against unknown, or real, data. By comparing the AUC of detection/classification systems, one can determine the best or most appropriate system given the performance on known data. While the area under the ROC curve is useful for evaluation across all thresholds, the task of selecting one operating threshold is still required prior to implementation in a forensic environment.

During this presentation, the range of optimal thresholds where the TPR and FPR counts are maximized will be explored to develop a novel method of evaluating and selecting a forensically sound operating threshold considering the rate of change between critical thresholds (where the Matthews Correlation Coefficient [MCC] is highest and where the False Positive Rate reaches a desired level).³

C6 A Quantitative Analysis of Video Software Frame Extraction Methods for Use in Forensic Science

Gregory Wales, MSc, University of Colorado Denver, National Center for Media Forensics, Denver, CO; Christopher Lemon, BA, University of Colorado Denver, National Center for Media Forensics, Denver, CO; Gregory Savage, BSc, University of Colorado Denver, National Center for Media Forensics, Denver, CO; Stephen Wells, BA, University of Colorado Denver, National Center for Media Forensics, Denver, CO; Jesus Valenzuela, BSc, University of Colorado Denver, National Center for Media Forensics, Denver, CO*

Learning Overview: After attending this presentation, attendees will better understand factors affecting frame/image quality when extracting a video frame for forensic use.

Impact Statement: This presentation will impact the forensic science community by providing the community with cross hardware and software test results of some commonly used open-source and commercial video software tools (including some video forensic tools) used to extract frames/still images.

The Video/Image Technology and Analysis (VITAL) Subcommittee of the Organization of Scientific Area Committees for Forensic Science published research needs associated with factors affecting image quality when extracting a still from a video that was approved February 26, 2021. VITAL noted images extracted from videos appear to differ in quality when the same video data is viewed on different computer systems using the same extraction technique as well as different methods. VITAL specifically noted research was needed to determine if computer hardware was a factor affecting image quality when extracting images from video.¹

The fundamental principle of forensic science and in the handling of digital and multimedia evidence is to ensure the integrity of evidence through the collection and analysis stages of an investigation. As noted in the VITAL research needs document, changes to the video frames have been detected during the extraction process to still images or frames. It is important to gain a better understanding of hardware and software influences in the alteration process for further research. This study expanded on the quantitative comparison of frame extraction methods for Motion JPEG video that were unpublished research previously presented in American Academy of Forensic Sciences conference proceedings in 2014.²

The study used five different quantitative analysis methods to test the frame extractions using the various software and hardware compared to carved JPEG frames (ground truth) from the Motion JPEG test data set videos. The testing hardware included multiple operating systems and multiple hardware manufacturers.

This presentation continued the previous research, followed the testing methods in the previous research, and used some of the same quantitative evaluation methods as well as adding additional methods for more granularity of possible changes in the exported frames.² The findings address some specific VITAL research interests and revealed trends in frame changes in exported video files. In addition, the study was able to successfully export frames from the same test videos using different test hardware repeatedly without alteration of the exported frames.

C8 The Use of Electric Network Frequency Presence Due to Rolling Shutter Effect in Video Material for Time Estimation

Zeno Geradts, PhD, Netherlands Forensics Institute, The Hague, South Holland, Netherlands and University of Amsterdam, Amsterdam, North Holland, Netherlands; Guus Frijters, MSc, Netherlands Forensics Institute, The Hague, South Holland, Netherlands*

Learning Overview: After attending this presentation, attendees will better understand that based on the rolling shutter effect of a Complementary Metal-Oxide Semiconductor (CMOS) in combination with the Electric Network Frequency (ENF), it is possible to determine the time when a recording was made.

Impact Statement: This presentation will impact the forensic science community by informing attendees of the validation of a new method for determining the time of recording ENF based on the rolling shutter effect in CMOS sensors.

Within the forensic field, video evidence becomes more and more relevant due to the wide availability of recording devices everyone carries with them in the form of a smart phone. Different types of crimes are filmed with a variety of camera devices, such as mobile phones. Within video forensics, it is of great importance to verify the authenticity of the videos made with such devices.

Next to the authenticity, the time of recording is important. The time of the video can give a large amount of information, such as proof of someone's whereabouts at a certain point in time. It is crucial that this information is correct and has not been tampered with. A method of time verification is using hidden information (such as metadata) present in videos. One of these types of hidden information is the ENF, which is a fluctuating signal within the power grid. This time-unique signal can be used to determine the time if it can be matched with data.

In this research, the possibility of performing an estimation of the time of recording for videos is explored for different light sources in different circumstances using the ENF. This research focuses on videos made with mobile phones. The mobile phone cameras make use of integrated CMOS sensors. The filmed videos are analyzed using software, which uses an ENF database to determine the time of recording of a video made in experimental circumstances.

This research shows that in ideal circumstances, it is possible to determine the time of recording with a video made with a mobile phone. However, it becomes clear that different light sources greatly influence the results. The best results are achieved with halogen and incandescent light sources, both of which also seem promising in less ideal circumstances. LED light sources do work in ideal circumstances; however, they do not show much success in less ideal situations. This research shows there is potential in using ENF to determine a time of recording of a video. It proves currently usable in ideal circumstances with the presence of a clear light source on a white wall. With more research, it may become a feasible method to use in circumstances that are less ideal.

ENF, CMOS, Time Estimation

C9 A Review of Axon Citizen™ From a Forensic Perspective as a Tool for Law Enforcement Investigations

Jesus Valenzuela, BSc, Seattle Police Department, Seattle, WA; Gretchel Lomboy, MSc, Seattle Police Department, Seattle, WA; Catalin Grigoras, PhD, National Center for Media Forensics, Denver, CO; Jason Latham, BA, National Center for Media Forensics, Denver, CO*

Learning Overview: Attendees of this presentation will gain insight on Axon Citizen™ public portal features as an asset to law enforcement agencies and be able to understand the known limitations of the software as well as the challenges that software developers face with changing operating systems and third-party updates. This presentation will inform members of the digital multimedia scientific community of the pros and cons of implementing this feature as an investigative tool as well as a discussion on the level of forensic preparedness an organization should consider when exploring this type of digital multimedia evidence collection. After attending this presentation, attendees will better understand the benefits and limitations of using the Axon Citizen™ software as an investigative and digital multimedia collection tool for law enforcement organizations across the nation.

Impact Statement: This presentation will provide awareness to a new technology developed for the collection of digital and multimedia evidence and the impetus for the Seattle Police Department (SPD) to use the Axon Citizen™ feature as well as sharing the experimental design, validation results, and insights from a forensic perspective about the emerging technology.

In 2020, the city of Seattle, WA, experienced ongoing protests over the murder of George Floyd. These demonstrations devolved into violent riots that resulted in widespread city property damage and the looting of many local businesses. The SPD was overwhelmed with attempting to identify the instigators and the suspects involved with the destruction of city property, which included several police vehicle units. SPD made the decision to open an evidence submission portal to solicit digital multimedia from the public using a trusted third-party vendor: Axon Enterprise, Inc. The Axon Citizen™ for Communities feature allowed SPD to create a URL and share the submission link through social media. The agency collected thousands of images and videos submitted by the public.

Since then, the SPD has been continuously working on expanding its use of Axon Citizen™ and is currently leveraging the mobile app version that allows officers and detectives to send individual digital evidence upload links to members of the public via Short Message Service (SMS) text or email. The testing and evaluation of Axon Citizen™ for Officers mobile application feature included validation tests of the Axon file transfer protocol performed by SPD in partnership with the University of Colorado National Center for Media Forensics. The purpose of the software test was to verify accurate acquisition and submission of digital multimedia to the Axon Evidence.com platform without alterations.

To further examine the capabilities of Axon Citizen™, a known dataset was created to compare the source files against the files uploaded to and received from the portal. The data analysis was performed between the original source file and the file received on the department's end to gain insights on data integrity, provenance, and authenticity. The mobile features were tested on both Apple® and Android® systems.

Axon, File Transfer, Digital Evidence

C10 Constructing Digital Video Recorder (DVR) Datasets for Multimedia Forensics Validation

Rayna Mock, BS*, Marshall University, Huntington, WV; Josh Brunty, MS, Marshall University, Huntington, WV

Learning Overview: Attendees of this presentation will understand the importance of validation in digital and multimedia forensics, and how test images for validation are lacking in the area and need to be created, especially for DVRs.

Impact Statement: Validation plays a vital role in the field of forensics. International Organization for Standardization (ISO) 17020/17025 require that forensic laboratory disciplines validate instruments to achieve consistent and reproducible results.^{1,2} In addition, organizations such as the Scientific Working Group on Digital Evidence (SWGDE), National Institute of Standards and Technology Organization of Scientific Area Committees (NIST OSAC), and American Society for Testing and Materials (ASTM) have all published best practice guides on the validation of digital and multimedia forensics tools. Validation not only ensures that software is working as intended, but also provides reliability and reproducibility in court.¹ While digital forensics has developed formalized validation processes, the subdiscipline of multimedia forensics is lacking in that area. Furthermore, multimedia forensics lacks a formal regulating body, has limited test images to use for validation, and has restricted access to answer keys for many test images that are publicly available.³

Test images are key products needed for validation and are created by both formal entities and various individuals for examiners to use when testing a new software or forensic tool. Formal entities such as NIST's Computer Forensics Reference Datasets (CFREDs), The Computer Forensic Tool Testing Project (CFTT), and Digital Corpora host various iOS®, Android®, Universal Serial Bus (USB), and computer-based images available for public download, however, very little exists for multimedia forensics tools. The only available images that exist come from the specific tool vendors themselves, such as DVR Examiner.⁴ Lack of access to multimedia forensic test images results in laboratories creating their own, which increases backlog, or requires them to buy from a specific vendor. For example, a request was made by Video/Imaging Technology and Analysis (VITAL) to OSAC, asking that a test image repository be created, since this is lacking in the field.⁵

This research focuses on creating a vendor-neutral multimedia forensic DVR test image that can be publicly available for forensic examiners. A 24-hour loop was recorded on a HeimVision DVR, then forensically imaged in three different formats: E01, raw, and Advanced Forensic Format (AFF). Based off SWGDE's three types of testing, a comparison test was completed by running the information across multiple multimedia forensic software tools.⁶ The information gathered from each software tool was noted and compared to one another to determine the accuracy of data produced. The purpose of the project is to create a publicly available and vendor-neutral forensic test image that digital forensic laboratories and examiners can use to validate multimedia forensic tools.

C11 Likelihood Ratios for Categorical Evidence with Applications in Digital Evidence

Rachel Longjohn, MS*, University of California-Irvine, Irvine, CA; Padhraic Smyth, PhD, University of California-Irvine, Irvine, CA; Hal Stern, PhD, University of California-Irvine, Irvine, CA

Learning Overview: The goal of this presentation is to introduce a likelihood ratio approach for the statistical analysis of cases where the evidence can be broadly described as counts for different categories of interest. In particular, this presentation will focus on applications in digital forensics involving counts of different types of user-generated events on a digital device.

Impact Statement: This presentation will introduce to the forensic science community a statistical method for quantifying the strength of categorical evidence in the form of count data and demonstrate how this approach could be used to support digital forensics investigations.

With the widespread use of smart phones and other devices, there exists a growing need for quantitative methods of analyzing digital evidence. Counts of user-generated activities are a common form of data that occurs in digital evidence (e.g., counts of websites browsed, texts/calls/emails sent, apps used, or locations visited). A common defense in cases involving digital forensics is that the recovered device was stolen or otherwise not in the possession of the suspect during the period of criminal activity. However, suppose that investigators can extract from the device historical counts of its user-generated activities, both (1) for the time period the suspect claims to have had the device, and (2) during the time period of the crime. Using this data, one would like to be able to answer questions such as how likely it is that these kinds of activities would be observed if the suspect actually had possession of their device during the period of criminal activity. Being able to answer such questions through robust, quantitative methods has the potential to greatly support investigative efforts in digital forensics.

In this study, a statistical modeling framework is introduced to address such questions when counts of user-generated activities on a digital device are available as evidence. The count data can be split into two time periods, one during which the suspect is known to have had the device and one in which the owner is unknown. The problem can then be formulated using a same-source versus different-source hypothesis framework. Under the same-source hypothesis, it is assumed that the activity counts in both periods were generated by the suspect; while under the different-source hypothesis, it is assumed that the suspect did not generate the counts during the unknown time.

The proposed model utilizes simple, parametric distributional assumptions that have been used across many other non-forensic applications in Bayesian statistics.^{1,2} These parametric assumptions lead to a straightforward formula for the likelihood ratio, which measures the relative probability of obtaining the evidence under the same-source and different-source hypotheses and is a widely accepted way to quantify the strength of evidence in forensics.^{3,4}

The potential efficacy of the model is demonstrated through an analysis of its theoretical properties and its performance in experiments on real-world datasets involving email communications and device location pings. While the presented framework is motivated by applications in digital forensics, the probability model is intuitive and flexible enough to support its application to a broad variety of forensic evidence types.

Likelihood Ratio, Statistical Analysis, Digital Evidence

C12 Skills for Success: Advancing Pattern of Life Analysis in Cyber Forensics Using a Multidimensional Approach

Mohammad Meraj Mirza, MS*, Purdue University, West Lafayette, IN and Taif University, Taif, Makkah, Saudi Arabia; Umit Karabiyik, PhD, Purdue University, West Lafayette, IN

Learning Overview: After attending this presentation, attendees will better understand the required skills needed in performing Pattern of Life (PoL) analysis for a user using a smart phone such as an iPhone® linked with other smart devices (e.g., Apple® smart watch). From there, this presentation will demonstrate advanced analytical skills using a multidimensional intelligence approach, which aids in investigating and conducting cyber forensics investigations when the required evidence/data are available.

Impact Statement: This presentation will impact the forensic science community by providing insights into a set of skills and advanced analysis techniques needed when investigating iPhone® devices containing geolocation data and vital human data such as heart rate gathered from smart watches. In addition, this presentation will show how to transform information and the available data into knowledge to aid investigations.

Everyone nowadays relies on their smart phones to keep up with the digital world and stay in touch with other sophisticated and smart objects such as Internet of Things (IoT) devices in their everyday lives. One example of these advanced devices is the Apple® Watch®, a computationally powerful device despite its diminutive size. It packs a punch when it comes to functionality, and with each new model, it gets more intelligent and versatile. Depending on which model/series, it can do everything from viewing incoming notifications, tracking activities and location, checking and monitoring heart rate, measuring blood oxygen level, and even taking an Electrocardiogram (ECG), which is only available on newer models.¹ Aside from that, as smart watches and other smart objects become more capable; smart phones that are connected to these smart devices receive an enormous amount of data. Therefore, these data can help highlight Personal Identifiable Information (PII), which is considered valuable to digital forensics investigations.² Yet, the PII needs to be complemented with different analytical skills and techniques to unlock their full potential.

The PoL is an analysis that evaluates behaviors, and this study focuses on the temporal and spatial dimensions.³ As a result, this type of analysis can assist in transforming information into knowledge and a storyboard that can explain the user's actions and activities that are not visible in standard analytical approaches (e.g., timeline analysis). It is one type of intelligence technique that aims to aid investigation to uncover the story and quickly identify critical actions considered valuable in investigations. Moreover, PoL analysis can help increase the value of information by giving it a meaningful context and creating a rationale to aid in answering the 6 Ws (i.e., who, what, when, where, why, and how).

In addition, this research uses PoL as a supportive analysis approach complemented by other types of intelligence domains (e.g., activity-based intelligence and location intelligence) to improve geo-mapping of collected information gathered from different systems and applications artifacts to help build a mapped storyboard. This digital storyboard is intended to aid in creating a representational geo-map that provides a significant contextual meaning of the collected evidence. As a result, digital forensic analysts and practitioners may construct models of scenarios and highlight critical events that can help predict what has possibly happened by using this multidimensional approach.

This presentation will demonstrate the skills and techniques discussed using a digital forensic case study, illustrating the aforementioned analytical techniques to highlight the benefits and challenges of the multidimensional approach and the intelligence-related knowledge demonstrated generated by linking what is known with what could enhance and improve digital forensic practitioners' decision-making processes.

Cyber Forensics, Multidimensional Intelligence Approach, Pattern of Life Analysis

C13 Virtualization, Self-Hosting, and File/Storage Systems—Recent Technological Advances and the Search for Digital Evidence

Jason Paroff, JD, Epiq, New York, NY*

Learning Overview: Technology is ever-changing, and today's technology requires an investigator or attorney to understand where essential digital evidence may be located. This presentation will expose attendees to open source and or free-to-use software that allows for easy virtualization of computers and the creation of networked attached storage systems with different types of drive arrays and structures. Items attendees will be exposed to will include: virtualization using Proxmox; different storage types within Proxmox; Virtual Machines and Linux Containers (LXC) within Proxmox; Open Media Vault Network Attached Storage (NAS); physical drives on Proxmox "passed through" to Open Media Vault; different storage types (including Redundant Array of Inexpensive Disks [RAID] arrays) supported by Open Media Vault; and, time permitting, the Union File System (UnionFS) and what it does.

Impact Statement: Yesterday's examiner was 80% detective and 20% IT person. Today's examiner probably needs to be the reverse—80% IT person and 20% detective. With new advents in technology, yesterday's investigator, and the litigators they gather evidence for, has had to gain more and more IT skills to remain in the hunt for today's evidence. Today's data isn't where it used to be, and the search for evidence may involve machines that don't even physically exist (e.g., virtual machines), so today's investigator needs to learn about these technologies so he/she can locate relevant evidence that simply would not have existed in this form only a few short years ago.

The concept of virtualization—the creating of entire computers and their storage disks within the physical hardware of a larger and more powerful computer—complicates matters today. In essence, what once was a physical laptop, desktop, or server can now be mimicked by software, sharing the hardware of a larger computer in the process. In this way, one physical machine can contain many virtual machines, so the number of "computers" a person can have and control can be significantly greater than it used to be. Through virtualization, you can now click on an icon and spin up an entire virtual computer that acts in every way like its bare metal counterpart, but you can now locate that computer in any part of the world. Finished using one of those machines for the day? Simply shutdown Windows® (or Mac® or Linux®) just like any other computer and the computer disappears from the network and returns to nothing more than a set of software instructions concerning how it uses the larger machine once you decide to use it again. Want to destroy all of the data/evidence on one of those virtual machines? Simply delete it, and it is gone forever, but don't worry, you can create a new one in about five minutes if you want to.

Now that broadband is readily accessible to many consumers across the globe, the ability to self-host applications is likewise growing quickly. Through self-hosting, it is now possible for average consumers to run applications and services like a website, blog, media server, DropBox alternative, Google® Drive, and OneDrive® alternatives and make all of their files accessible to themselves from anywhere in the world.

Today's attorneys, investigators, and analysts need to consider virtualized computers as potential sources of relevant data, and due to the ease with which they can be switched off or deleted, may need to move quickly to preserve that data if it may be relevant to an investigation or litigation. This presentation will expose attendees to many of these concepts and options so they can be better informed as to where to look for potentially relevant and important evidence during their next investigation or litigation.

Virtualization, Self-Hosting, Data Storage

C14 Keeping Forensic Tools Sharp: A Case Study of Updating Bulk_Extractor 1.6 to 2.0

Simson Garfinkel, PhD, George Washington University, Washington, DC*

Learning Overview: After attending this presentation, attendees will understand the need to keep digital forensics tools up-to-date, the resources available for doing so, and the amount of effort required. In particular, attendees will understand developments in the C++ and Python® programming languages over the past decade, and the opportunities to combine digital forensics reference data sets with modern software development practices to improve reliability and reproducibility of digital forensics tools while decreasing error rates.

Impact Statement: This presentation will motivate those in the digital forensics community to re-evaluate tools that have long been in use but have not been subjected to rigorous software development practices.

Digital forensics practitioners make extensive use of both proprietary and open-source software for extracting digital evidence from devices under study, for transforming evidence into a form that is readily understandable by examiners, and for organizing and correlating the vast quantities of digital evidence into a form that can be summarized and presented to investigators and juries. Like all software, digital forensics software must be maintained after it is created or it will eventually cease to function. Unlike traditional forensics, where reagents expire unless they are refreshed, forensic software aging happens because of changes in the underlying operating system on which the software executes and because the data under analysis increasingly comes from applications and systems that did not exist when the analysis software was written.

Maintaining digital forensics software is especially expensive, because forensics software must be able to analyze not just data created by all systems being sold in the market today, but data created by any system to which the subject may have had access.¹ Fortunately, advances in software development over the past decade have the potential to significantly decrease the cost, keeping digital forensics tools up-to-date while improving their overall quality. This includes the increased sophistication of underlying programming languages such as C++17 and Python® 3.9, the widespread availability of Continuous Testing and Continuous Integration platforms, wider use of unit testing and code coverage tools, and the increased sophistication of fuzzing technology.² Separately, the development of reliable digital forensics tools is aided by the increasing availability of complex reference data sets that can be used for both tool testing and training.³ Nevertheless, migrating digital forensics software developed over the past two decades to use these new technologies is a significant undertaking.

Presented here are the results of migrating the bulk_extractor forensic tool from the decades old C++98 standard, to the modern C++17 standard and documenting the increase in both performance and reliability that resulted from the move to modern software development techniques.⁴

C15 A Case Study of Virtual Programmable Logic Controllers (PLC) Forensic Framework on Investigating Control Logic Attacks in a Belt Conveyor System

Syed Qasim, BS, Virginia Commonwealth University, Richmond, VA; Irfan Ahmed, PhD, Virginia Commonwealth University, Richmond, VA*

Learning Overview: After attending this presentation, attendees will understand control logic attacks on a belt conveyor system and their network forensic investigation using a virtual PLC forensic framework. This presentation will cover a general architecture of PLCs, control logic attacks, and the challenges to investigate them in an industrial control system environment. It will further discuss a scalable virtual PLC forensic framework to recover and analyze a (malicious) control logic. The framework is tested on a heterogeneous Industrial Control System (ICS) environment for a belt conveyor system containing PLCs of different vendors, including Allen-Bradley MicroLogix™ 1400, 1100, and Micro 820 and 850, AutomationDirect CLICK, and Schneider Electric Modicon M221.

Impact Statement: This presentation will impact the forensic community by discussing an automated, scalable virtual PLC forensic framework to investigate control logic attacks on a belt conveyor system.

In ICS, PLCs use control logic to control physical, industrial, and infrastructure processes, such as nuclear plants. Attackers target control logic in a PLC to sabotage a physical process. For instance, Stuxnet demonstrates a control logic attack by infecting the control logic of a Siemens S7-300 PLC to manipulate the motor speed of centrifuges periodically to damage them permanently. Often, the control logic attacks compromise the control center and further transfer a (malicious) control logic over the network from the control center to a target PLC remotely. Suppose the network traffic of the control center is captured. In that case, it will contain the attacker's malicious control logic (forensic artifact) in the network stream. The challenge for a forensic investigator is to identify and recover the binary control logic from the network traffic streams and further transform it into a high-level control language such as ladder logic.

Recently, this study has developed a virtual PLC forensics framework to recover control logic from a network traffic dump.¹ This presentation will present a case study of the framework on a belt conveyor system. The framework consists of a virtual PLC that engages with the engineering software using a previously captured network traffic (forensic artifact). Mainly, it utilizes a commonly available upload function in engineering software to retrieve the control logic from a PLC.

The case study was performed on a working model of an industrial conveyor belt used to sort different types of objects. The model consists of capacitive and inductive sensors to differentiate between metals and plastic objects. When a metal object on the conveyor belt passes under the inductive sensor, the sensor senses it and sends a signal to the PLC. After processing the signal, the PLC opens the air solenoid valve to push the object out of the conveyor belt into the sorting storage. Similarly, the capacitive sensor sorts the non-metal objects.

Two attack scenarios were created for the conveyor belt. In the first scenario, the attacker penetrates the ICS network and conducts reconnaissance. The attacker steals the control logic running on the PLC to gather information about the industrial environment. This is done using the upload function of a PLC: the attacker sends the upload request to the PLC, and the PLC, in return, sends the control logic to the attacker in a series of messages. After successful reconnaissance, in the second scenario, the attacker develops a malicious control logic targeting different components, such as input, output, timer statement, etc., and downloads it to the PLC to disrupt the physical operation of the conveyor belt. The attacker inverts the output to air solenoid valves (actuator), which disrupts the sorting process.

To replicate the heterogeneous industrial environment, the belt conveyor system is connected with different PLCs controlling different belt sections. The case study utilizes Modicon M221 and MicroLogix™ 1400 PLCs of leading ICS vendors (i.e., Allen-Bradley and Schneider Electric [a 30% share of the PLC market]).^{2,3}

C16 Exploiting the Post-Attendee URL Feature in Zoom Webinar to Distribute Malware: Implications for Digital Forensics

Austin Cauley, BS, University of Central Oklahoma, Edmond, OK; Mark McCoy, EdD, University of Central Oklahoma, Edmond, OK*

Learning Overview: After attending this presentation, attendees will have a better understanding of the methods used by malicious actors to spread malware via Zoom® Webinar and the types of digital artifacts left by these attacks.

Impact Statement: This presentation will impact the digital forensics community by illustrating how the post-attendee URL feature within Zoom® Webinar can be exploited by sending webinar attendees to a compromised website.

The ability to force a Zoom® Webinar attendee to visit a compromised website without permission of the attendee is a security flaw that could be leveraged by someone hosting a Zoom® Webinar. These compromised websites, when accessed, can contain malicious code that negatively impacts the attendee.

With the current pandemic causing many businesses to operate virtually to maintain public health guidelines, the video conferencing application known as Zoom® has skyrocketed in popularity. Unfortunately, due to Zoom's® rapid rise in popularity, it has also become infamous for its security vulnerabilities, such as Zoom® bombings that involve projecting illicit material in a Zoom® meeting.¹ As a result, both security researchers and bad actors alike have entered an arms race to see who can discover vulnerabilities within Zoom®. While different methods have been discovered by both sides, there is one feature that is often overlooked: the post-attendee URL within Zoom® Webinar.

This study tested the post-attendee URL feature within the Zoom® desktop application by creating a purposefully compromised website that contained a keylogger that sent data to a third-party web server. Once created, a Zoom® Webinar event was created with the post-attendee URL set to the URL of the purposefully compromised website.

Four computers with new installations of Windows® 10 version 2004 were used as participants in the Zoom® Webinar event with each assigned one of the roles as defined by Zoom®: host, co-host, panelist, and attendee.² Each computer used the Zoom® desktop application version 5.7.5 and a baseline image was completed.

Each computer, aside from the computer designated as the host for the webinar, joined the webinar in one of two methods in order to determine what conditions cause the post-attendee URL to trigger. First, each desktop joined the webinar by launching the Zoom® desktop application and manually entering the webinar ID and passcode. After waiting for five minutes once the co-host, panelist, and attendee joined the webinar, it was determined that this joining method does not trigger the post-attendee URL to launch. However, when the co-host and attendee desktops joined via the email link that was sent to their email account after registering for the webinar, the post-attendee URL was successfully launched five minutes after joining the webinar. The keylogger that was embedded into the compromised website functioned as intended and successfully transmitted the user keystrokes on the compromised website to the third-party webserver. After the post-attendee URL was successfully opened on the attendee machines, FTK® Imager was used to capture RAM, then all the computers were imaged again. Once imaged, the Windows® Registry and web browser history were analyzed to discover potential digital artifacts that were created due to the malicious webinar.

The goal of this research is to not only determine the possibility of distributing malware to unsuspecting users, but to also discover and analyze the types of digital artifacts that are left behind from this type of attack. This will assist digital forensic examiners in the future by providing the information they need in order to create a more comprehensive timeline of events for cases that involve this type of attack.

Digital and Multimedia Forensics, Malware, Zoom®

C17 Revealing the Invisible: Investigating Evidence of Automated and Behind-the-Scenes Computer Activity

Josiah Dykstra, PhD*, National Security Agency, Fort George G. Meade, MD

Learning Overview: After attending this presentation, attendees will be able to describe the forensic implications of automated and behind-the-scenes cybersecurity now in practice on modern computers and networks and effective techniques to detect and explain such activity in forensic timelines.

Impact Statement: This presentation will impact the forensic science community by illuminating the forensic evidence of increasingly automated cybersecurity mechanisms that take place without overt end-user interaction and considerations for legal prosecution.

The field of usable security is a domain of human-computer interaction that attempts to create and evaluate cybersecurity solutions through the lens of user experience. Many users continue to struggle using cybersecurity tools, making decisions, or matching their intentions for security with the reality of their actions.¹ Expanding usability further, this study describes invisible security as an approach where cyber defenses occur automatically and transparently without end-user intervention. For example, automatic software updates and protective Domain Name System (DNS) are examples of this approach.² Invisible security helps average users and small businesses who lack the time, expertise, or funding for proper security. While this evolution is valuable to some, usable security impacts digital forensics because users may be unaware if or how their experience is being manipulated to protect them.

Invisible security may pose an impediment to the investigative process by obscuring or manipulating the environment, including the crime scene. For example, protective DNS is a defense against malware whereby a service provider filters domain name lookups. A byproduct is that users or attackers behind protective DNS may be unwittingly redirected or experience an unexpected interruption with internet services. Forensic investigators must understand if and how automatic updates are present and how to identify, preserve, collect, examine, analyze, and present the additional evidence. In some cases, the relevant data exist on other systems that may be controlled by third parties such as internet service providers. Automatic software updates similarly offer the opportunity for software to change with the user's awareness. To forensic investigators, invisible security may introduce new evidence in the timeline of events and introduce uncertainty about the source of observed activity.

This presentation describes common examples of invisible security today, including automatic updates, and changes on the horizon, including invisible user authentication. This presentation presents indicators and recovery techniques to aid forensic investigators in identifying and documenting invisible defenses in the crime scene. Finally, this presentation offers perspectives about the technical and legal implications of automated security to forensic evidence and prosecution. These results may inform future digital forensics of other automated and artificial intelligence systems.³

C18 The Decontamination of Drug-Contaminated Mobile Devices Using VTO Labs' Decontamination Kits

Arcelia Cohen, Marshall University, Huntington, WV; Joshua Brunty, MS, Marshall University, Huntington, WV; Lauren Richards-Waugh, PhD, Marshall University, Huntington, WV*

Learning Overview: After attending this presentation, attendees will have a better understanding of the importance of needing an applicable decontamination protocol to safely handle and analyze drug-contaminated digital evidence.

Impact Statement: This presentation will impact the forensic science community by presenting evidence that the decontamination protocol established by VTO Labs is a method that can be applied in the field.

There is a problem in digital forensics in which evidence seizure and data extraction cannot be completed due to possible health risks to seizure and examiner personnel. With rising drug use, more drug-contaminated devices are being seized. Previously, these devices were kept in storage because analysts could not safely handle the devices.¹

Understanding this issue, VTO Labs developed a decontamination protocol that not only protects the forensic analysts but also the personnel collecting the devices. After decontamination, analysts can safely retrieve the vital information kept on the devices.¹ The process is known to clean fentanyl, carfentanil, and methamphetamine residues from the devices.¹ Given the potential contact for additional substances, heroin, cocaine, and cocaine with suspected fentanyl were tested on various devices.^{2,3}

Nine different devices were contaminated with a drug sample from a Huntington Police Department case. These samples were scheduled for disposal and had previously been analyzed by the West Virginia State Police Forensic Laboratory. The contaminated devices were swabbed in three different locations using Kimwipes®, and the samples were extracted using methanol and a vortex.⁴ After the VTO Labs' decontamination process was completed, the surfaces were swabbed, and the samples extracted in a similar manner. The extracted samples were analyzed by Gas Chromatography/Mass Spectrometry (GC/MS), and the data was compared to determine if the decontamination process removed all traces of the controlled substances.

The contaminated samples showed that the different locations provided varying levels of drugs detected. VTO Labs' decontamination process produced a variety of observable damage to each of the devices; however, the decontamination process seemed to be an effective tool that can be utilized in the field.

Decontamination Process, Digital Devices, Cocaine

C19 Crowdsourcing Forensics: The Digital Artifact Catalog

Lam Nguyen, MS, Department of Defense, DC3, Linthicum, MD; Eoghan Casey, PhD, Department of Defense, DC3, Linthicum, MD*

Learning Overview: The aim of this presentation is to propose a framework for modeling digital forensic artifacts in order to overcome challenges associated with collating and curating investigative findings. This presentation will provide a prototype of the proposed model and discuss distribution options. Attendees will understand how artifacts can be structured in a manner that supports crowdsourcing and standardization.

Impact Statement: It is infeasible for an individual, or even a single organization, to keep pace with the growing number of applications on a variety of computing devices. As a result, there is an increasing risk that forensic practitioners will miss or misinterpret digital artifacts.

Prior work demonstrated the value and difficulties of designing a repository of digital artifacts.¹ On the one hand, the complexity of an ontology-based approach makes implementation more difficult. On the other hand, the oversimplification of treating digital artifacts as Files with tagging lacks precision and leaves it to individual users to infer what piece of data within the File is relevant and what the data represents. To strike a balance between these two extremes, the Digital Artifact Catalog has been conceived and populated by practitioners based on observations and insights from actual forensic examinations.

The Digital Artifact Catalog provides the forensic community with a robust framework for organizing and sharing knowledge about digital artifacts. Each entry in the Digital Artifact Catalog contains the details necessary to pinpoint the associated unit of interpretable data that is useful for addressing a specific question and cites supporting documentation and/or research results. References to external resources provide additional information for practitioners to learn more about specific item of data. This information is useful for tool development purposes and explaining digital evidence in court.

This initiative reduces wasted time and effort of each individual or organization studying digital artifacts independently, and it allows the relevant scientific community to establish general acceptance for specific digital artifacts. In addition, community curation of knowledge about digital artifacts helps increase thoroughness, consistency, and repeatability of digital forensic results. A longer-term ambition of the Digital Artifact Catalog is to aggregate statistics about digital artifacts to shed light on which are most useful for answering source-level and activity-level questions. More than ever, forensic practitioners need to have intimate knowledge of a wide array of digital devices, data structures, and network inter-operability. The process of interrogating a device for evidential data has become more art than science, making it increasingly hard for automated tools to keep pace. It can take weeks to research, experiment, and develop a novel approach to a single problem.

Yet examiners are expected to recognize the evidentiary significance of every possible data item on a device. They must be able to identify how the data is stored, physically locate it, and have the expertise to extract that data into human readable format. Theoretically, this process must be completed not just for every app, but every permutation of the app, its version, the hardware device version as well as the Operating System that runs it. The data structure of a banking app may be completely different from one version to the next. Or the same version may store data differently on Android® devices versus an Apple®-based iOS® device.

A data artifact, then, is a singular unit of interpretable data that can be extracted from a digital device. To be useful, it must be associated with the device and its specific operating system, the precise program that created the data, the location it was found, and the specific method used to extract the data.

Unfortunately, not all examiners can identify all possible data artifacts and interpret them. This isn't a weakness in the examiner. Digital forensics is unique in that every examination may involve never-before-seen data. It would be virtually impossible for an individual to know how to extract every single piece of data from every device they may encounter. In a world where technology is consumable and devices can be refreshed in less than a year, the problem is seemingly insurmountable. Across the country, digital forensic labs grapple with this issue. The problem is exacerbated within the context of law enforcement where reports are subject to an in-depth examination by prosecutors, defense attorneys, judges, and jury. Because of the complexity of litigation, the method of digital data extraction must be predicated on the principles of forensic science. It must be validated, documented, and determined to be forensically sound, all while still maintaining evidential integrity.

By using a common platform shared across public, private, and academic environments, practitioners can leverage and contribute to a crowdsourced knowledge repository that benefits the entire community. Rather than duplicate effort, participants would pool resources to tackle what would otherwise be an impossible problem for a single lab. The collaborative nature of a crowdsourced project is entirely dependent on the ability to organize and seamlessly share data across multiple users. It must be easy to use, readily available, and provide reciprocal benefit to its users. The proposed standards will allow practitioners to not only share artifacts as they are found, but to share the method used to extract and interpret them. As these artifacts and their respective data extraction methods are shared, a community of users are available to test, validate, and provide widespread acceptance and support.

What would otherwise take days, if not weeks, could be reduced to a simple database lookup. Labs would be able to validate and cross-reference materials produced by practitioners not only in their own lab; but with other labs across the entire forensic community. Smaller labs that do not have the resources to experiment or test methods would have access to a plethora of data that they may not have even realized was available.

C20 Standards Development Activities in Digital and Multimedia Forensic Science

Tracy Walraven, MFS, DC Department of Forensic Sciences, Washington, DC*

Learning Overview: After attending this presentation, attendees will have a better understanding of the status of discipline-specific standards pertinent to the field of digital and multimedia forensic science.

Impact Statement: This presentation will impact the forensic science community by creating greater awareness of standards development activities pertinent to digital and multimedia issues. It will also increase awareness regarding training, tools, and resources that support implementation, compliance monitoring, and broader understanding.

The Organization of Scientific Area Committees (OSAC) for Forensic Science was created to strengthen the nation's use of forensic science by promoting the use of discipline-specific forensic science standards. To this end, the OSAC drafts standards that are forwarded to Standards Developing Organizations (SDOs) that further develop and publish them. The OSAC also reviews standards and recognizes them on the OSAC Registry, which serves as a central repository of high-quality, consensus-based, technically sound standards.

During this presentation, updates related to digital and multimedia standards development will be discussed. These include: (1) recent standards that have been added to the OSAC Registry; (2) OSAC proposed standards; (3) published standards from the American Society for Testing and Materials (ASTM) and other authoritative bodies that have yet to go through the Registry approval process or are currently undergoing the approval process; (4) priorities for new documents or work products, and other highlights; and (5) projects undertaken by working groups within the digital evidence subcommittee, specifically the Quality Study Working Group's project entitled Quality Management in Digital Evidence Examination that interviews various members of the Digital & Multimedia Evidence (DME) and legal community to determine which elements of a quality system are most effective in digital forensics. Opportunities for supplemental training related to discipline-specific standards will be presented, as well as additional resources and tools designed to facilitate gap analysis, compliance monitoring, and outreach efforts.

Digital/Multimedia, Standards, OSAC

C21 Key Takeaways from a National Institute of Standards and Technology (NIST) Digital Forensic Scientific Foundations Study

James Lyle, PhD, National Institute of Standards and Technology, Gaithersburg, MD; Barbara Guttman, BA, National Institute of Standards and Technology, Gaithersburg, MD*

Learning Overview: After attending this presentation, attendees will be aware of some of the key takeaways from the National Institute of Standards and Technology (NIST) Digital Forensics Foundation Study.

Impact Statement: This presentation will impact the forensic community by increasing awareness in the community of available resources used to establish the reliability of digital forensic techniques and tools. This presentation will aid forensic practitioners in developing their own methods and materials for describing the reliability and fitness for purpose of digital forensic tools and techniques used in their investigations or locating materials that can be used to support statements about the reliability of the techniques and tools they have used.

In recent years, several scientific advisory bodies have expressed the need for scientific foundation reviews of forensic disciplines and identified NIST as an appropriate agency for conducting them. The purpose of a scientific foundation review is to document and consolidate information supporting the methods used in forensic analysis and to identify knowledge gaps where they exist. In addition to digital evidence, NIST is conducting scientific foundation reviews in DNA mixtures, bitemarks, and other areas.

One of the first key takeaways is that the details of digital tools and techniques evolves rapidly as the digital technology changes. Other key takeaways include:

- Digital techniques are a vast array of techniques as numerous as all the non-digital investigation techniques.
- The digital landscape evolves rapidly and in unexpected directions.

Validation of a technique is not the same as tool testing. Validation of a technique is demonstration of “fitness for purpose.” For example, testing a hashing tool to demonstrate that the tool computes the hash correctly is not sufficient to show that the right tool has been selected. It must also be shown that the hash algorithm has the desired set of properties such as collision resistance, etc.

Verification of tool implementations needs to be better supported. Only a tiny fraction of available tools receives any independent testing.

Software tools will never be perfect, they will always have flaws and quirks. The investigator needs to be aware of any flaws in the lab’s toolkit so that steps can be taken to mitigate the tool’s shortcomings.

Software tools that have been tested have not exhibited flaws that are likely to change the outcome of an investigation. The usual flaws observed would cause random things to be missed and therefore not considered.

Some identified gaps and needs include:

- There needs to be a central repository of digital artifacts that describes the artifact, the significance of the artifact, and what situations the artifact occurs in. There have been several attempts to create such a repository, but there needs to be more work.
- There is not a consensus in the community that establishes the requirements to demonstrate “fitness for purpose” for all the techniques in use.
- There need to be more validation studies to show “fitness for purpose” and to identify weaknesses in digital methods. There have been a few studies, but the diversity of case work needs to be considered.

In summary, while many digital tools have been shown to be effective and their use has been informed by known limitations, the field needs to evolve to test new tools and techniques more rapidly and comprehensively. As digital continues to evolve to analyze ever more devices, applications, and data collection, this will become even more important.

Digital, Verification, Validation

C22 What Is the Computer Forensic Tools and Techniques (CFTT) Catalog?

Jenise Reyes-Rodriguez, BS, National Institute of Standards and Technology, Gaithersburg, MD; Richard Ayers, MS, National Institute of Standards and Technology, Gaithersburg, MD*

Learning Overview: After attending this presentation, attendees will better understand the Computer Forensic Tools and Techniques catalog: what is it used for, how the forensic community would benefit from it, how to access it, and what it looks like.

Impact Statement: The content of this presentation will impact the forensic community by providing an overview of a Forensic Tools and Techniques catalog that the whole community has access to and can be beneficial not only to forensic examiners but to all forensic tool users in general.

As technology changes rapidly, the Computer Forensics Tool Testing (CFTT) program updates its documents to keep up and offer the forensic community current and relevant information. The Tools and Techniques catalog is an exception to the rule. In this case, instead of CFTT populating it and keeping it updated, it is populated and updated by the forensic tool vendors. The CFTT project maintains the website and makes sure the information is accurate and up to date.

The Computer Forensic Tools and Techniques catalog provides the ability to search by technical parameters based on specific digital forensic tool functions, such as disk imaging or deleted file recovery. All the information in the catalog is provided by the developer. All commercial or non-commercial products within the catalog are for information only and do not imply that the product has been tested. The catalog is still growing, and there is work on adding some forensic techniques soon.

In addition to the catalog offering a list of tools that the user can search based on the functionality of interest, the forensic community could also suggest changes to the catalog. Suggestions to changes may include changes to the catalog's taxonomy, adding search features, or suggesting new functionalities that may not be included within the catalog. This allows the forensic community to collaborate and engage with the catalog.

The primary goal of the Tool catalog is to provide a simple searchable catalog of forensic tools and techniques. This enables practitioners to find tools and techniques that meet their specific technical needs. A secondary goal of the Tool catalog is to provide a picture of the digital forensics tool landscape, showing where there are gaps (i.e., functions for which there are no tools or techniques).

Certain trade names and company products are mentioned in the text or identified. In no case does such identification imply recommendation or endorsement by the author or the author's employer, nor does it imply that the products are necessarily the best available for the purpose.

Computer Forensics, Tools and Techniques Catalog, Forensic Tools

C23 A Forensic Analysis of Microsoft® Teams

Herschel Bowling, MS, Purdue University, West Lafayette, IN; Kathryn Seigfried-Spellar, PhD, Purdue University, West Lafayette, IN; Umit Karabiyik, PhD, Purdue University, West Lafayette, IN; Marcus Rogers, PhD, Purdue University, West Lafayette, IN*

Learning Overview: After attending this presentation, attendees will understand what artifacts the Microsoft® Teams client stores on iOS®, Android®, and Windows® 10, as well as how they are stored.

Impact Statement: Microsoft® Teams is a largely undocumented platform from a forensic standpoint. This presentation will provide important information about how the platform stores user data across three different devices. How platforms handle data is useful not only to the forensic science community, but also the end users who use the platforms.

Digital forensic investigators have a duty to understand the relevant components of the cases they work. However, with the constant evolution of technologies, and the release of new platforms and programs, it is impossible for an investigator to be familiar with every application they encounter. It can also be difficult to know how forensic tools handle certain applications. This is why forensic researchers study and document new and emerging technologies, platforms, and applications, so that investigators have resources to utilize whenever they encounter an unfamiliar element in a case.

In 2017, Microsoft® released a new communication platform, Microsoft® Teams.¹ As of April 2021, Microsoft® Teams had 145 million daily active users—nearly double the number of daily users, at the same time, one year earlier.^{2,3} This rapid growth is attributed in part to the COVID-19 pandemic, as nearly all social, educational, and professional lives moved online.³ Given the size of its user base, it seems likely that forensic investigators will encounter cases in which Microsoft® Teams is a relevant component. However, due to the application's relatively young age, limited forensic research exists on Microsoft® Teams.

To address this gap, an analysis of data stored at rest by Microsoft® Teams was conducted, both on the Windows® 10 operating system as well as on mobile operating systems (iOS® and Android®). Basic functionality, such as messaging, sharing files, participating in video conferences, and other functionalities that Teams provides were performed in an isolated testing environment. The test devices were analyzed using both forensic tools' automated artifact finding capabilities, and non-automated investigation by investigating file system structures in details. Specifically, Cellebrite Universal Forensic Extraction Device (UFED) for the mobile devices, and Magnet AXIOM for the Windows® device were used. Manual or non-automated investigation recovered, at least partially, 77.6% of all artifacts across all three devices. For both mobile devices, at least 90% of populated artifacts were recovered with non-automated investigation, while 41.3% were discovered for the Windows® device. In this study, the forensic tools used automatically recovered and identified 13.7% of all artifacts across all three devices, recovering no more than 20% of populated artifacts for any device. These discovered artifacts, and the full results of this study, are documented in the hopes of aiding future digital forensic investigations involving Microsoft® Teams.

C24 The Correlation of Garbage Collection and Object Recovery in Userland Forensic Analysis

Sncha Sudhakaran, MTech, Louisiana State University, Baton Rouge, LA; Aisha Ali-Gombe, PhD, Louisiana State University, Baton Rouge, LA; Golden G. Richard III, PhD, Louisiana State University, Baton Rouge, LA*

Learning Overview: After attending this presentation, attendees will understand how Garbage Collection (GC) can affect object recovery in userland forensic analysis. The research highlights the impact of each type of GC on object recovery and how effectively the types of GC analyzed can impact object recovery for solving cyber cases.

Impact Statement: This presentation will impact the forensic community by illustrating how the type of GC that occurred before or during memory acquisition impacts the kind of evidence that may likely be recovered during a memory forensics investigation.

Userland memory forensics is a forensic technique to retrieve artifacts that provide sufficient information to recover application functionality by outlining the actions without prior knowledge of application logic. One of the major steps in most of the userland forensic analysis is process memory acquisition, which may be a dump acquisition instance when the runtime triggered a GC to occur, leading to the loss of few objects that may or may not serve as a piece of crucial evidence for investigation. Android® GC can impact the availability of evidence, as it is an automatic process that removes unused objects from memory. This research will demonstrate how different types of GC introduced by Android® Runtime (ART) can cause a change in objects recovered by forensic tools. The different types of GC include None, Partial, Sticky, Full, and Max.¹ First, none is a GC type when no GC is triggered. Then, Sticky is the type of GC that attempts to only free objects allocated since the last GC. The Partial GC is the GC type that marks the application heap but not the Zygote. The Full GC is the GC that marks and frees in both the application and Zygote heap. And finally, the Max GC identifies the different GC types that occurred.¹ This research primarily focuses on the thread running the GC iteration. The GC thread running on further examination identifies various parameters like the type of objects collected and the cause for GC from the dump acquired. This dump helps us determine what objects get collected in each GC type when analyzed with userland forensic tools. Finally, the research will develop an evaluation platform to enable forensic investigators to present the type of objects deleted from memory. The retrieved objects from userland forensic tools and the GC type identified with this approach can convince the jury that the objects deleted may or may not be critical in forensic investigation.

In newer Android® versions, ART allocates objects using RegionSpace and LargeObjectSpace allocators that trigger the GC for efficient memory utilization.^{2,3} The RegionSpace allocator allocates small objects like primitive objects, and the LargeObjectSpace allocator allocates large objects like multimedia in memory.^{2,3} If the application creates many objects, then the Android® Runtime environment triggers GC frequently.² As a result, the type and number of objects allocated and deleted during the runtime, the cause, and the type for GC to occur are unknown to forensics investigators. Thus, the impact of GC type triggered by the runtime is the primary focus of this research.

This presentation evaluates acquired memory dumps with tools like DroidScraper and AmpleDroid in recovering objects from RegionSpace and LargeObjectSpace, respectively.^{2,3} In this work, the memory dumps acquired from the same application are analyzed in-depth with the tools mentioned above to monitor the number of objects, the GC type, and the cause for GC to get triggered. The results demonstrated that different objects were collected and lost in different GC types; for example, dumps acquired when Full GC type occurred retrieved fewer objects than Sticky or Partial GC type. Hence, this study's hypothesis opens a new research dimension to explain the correlation between the GC and object recovery to identify which objects get removed during each GC type. The research illustrates how forensic investigators can convince the jury that the type of GC that occurred has or has not significantly impacted forensic analysis on a multi-app platform such as Android®.

Garbage Collection, Object, Recovery

C25 The Forensic Use of Sparse Files

Mark Guido, MS, MITRE, McLean, VA; Justin Grover, MS, MITRE, McLean, VA*

Learning Overview: The goal of this presentation is to introduce and describe a little-known method of representing a large file that has the potential to provide great benefits to the digital forensics community, allowing many existing forensic tools to operate normally on that large file.

Impact Statement: This presentation will impact the forensics community by providing the method and associated utilities that are now default in most modern operating systems that can help an organization save significant storage resources, leading to both time and money savings.

Linux® systems running kernel version 3.1 (released in October 2011) or later maintain near-universal support for sparse files. Sparse files are special files that have large amounts of space pre-allocated to them but do not use the full amount of space from a host's file system. Modern Linux® utilities handle these files; however, the use of sparse files in the field of digital forensics remains an underused and poorly understood concept. Common tools in a forensic examiner's toolkit, such as md5sum and dd, operate on sparse files like they would on a regular file with some counterintuitive results. Using md5sum, a regular file's MD5 hash matches that of its sparse counterpart. Similarly, the dd tool outputs the representative regular file when provided a sparse file as its input.

In a forensics laboratory with requirements for long-term storage, sparse files, if used correctly, may provide an organization with a potential for significant storage costs savings. So, if this is the case, why are sparse files not used more frequently in forensics? This presentation will attempt to answer questions concerning the use of sparse files: What are the advantages and disadvantages for using sparse files in forensics? Are there similarities and differences in the use of sparse files on Linux® EXT4, Windows® NTFS, and macOS® X APFS? Is it possible to transmit data in a sparse file format, limiting the amount of data sent from the sender to the receiver? Do mainstream forensics tools operate in the same manner on sparse files and their regular counterparts?

As an example of potential cost savings, this study conducted an experiment in 2013 at Purdue University, where over 1,100 forensic images of Samsung™ Galaxy S3 smart phones were collected.¹ Human test subjects used the smart phones normally for almost a semester and the smart phones attempted to deliver iterative forensic images each day. At the end of the experiment, the images were reconstituted, totaling more than 17TB of data collected. The analysis showed that over 40% of the data acquired were blocks of zero bits in unallocated space on these images. How much more storage costs and time savings could have been saved by properly utilizing sparse files to reconstitute the images?

Sparse, Preallocated, Representation

C26 Google® Chromebook™ and Takeout™ Forensics: A Comparative Analysis of Data Recovered from a Logical Acquisition of a Chromebook™ as Compared to Data from a Google® Takeout

Jessica Hyde, MS*, Magnet Forensics, Herndon, VA

Learning Overview: After attending this presentation, attendees will understand the importance of acquiring data from Chromebook™ and understand how the data available differs from the data available from a Google® Takeout™.

Impact Statement: This presentation will impact the forensic science community by showing the types of data available on Google® Chromebook™.

Chromebook™ sales have risen dramatically year-over-year with a 68.6% increase for the 2nd quarter of 2021.¹ The need to investigate Chromebook™ has recently been aided by the Chromebook™ Forensic Acquisition method released by Daniel Dickerman, making acquisitions of Chromebook™ accessible.²

Previous analysis looked at some of the data available on the Chrome OS™ by looking at data left behind on Chromium™ OS.³ This presentation will explore the data available from a Google® Takeout™ and a Google® Chromebook™ logical acquisition using the Daniel Dickerman method for the same account and compare the available data detailing the data locations for both sources.²

The goal of this research is to demonstrate that there are artifacts available from the Google® Chromebook™ that are not available from cloud-based acquisitions, such as a Google® Takeout™. It is hoped that this research will encourage digital forensic examiners to acquire data from Chromebook™ when conducting forensic examinations.

C27 The Examination of Questioned Digital Documents Customized From a Database

Oluwasola Mary Adedayo, PhD, The University of Winnipeg, Winnipeg, Manitoba, Canada; Martin S. Olivier, PhD, University of Pretoria, Pretoria, Gauteng, South Africa*

Learning Overview: The goal of this presentation is to describe novel approaches to examine digital documents that are customized and derived from a database.

Impact Statement: This presentation will impact the forensic science community by drawing attention to the examination of digital documents and describe approaches for examining customized digital documents derived from database systems.

The trend toward digitalization means that digital documents with intrinsic value are continually created. Whereas questioned document examination often relies on the examination of physical artifacts, approaches for examining questioned digital documents need to be improved.

Questioned digital documents may originate from different sources. A possible scenario is where a customized or personalized document derived from a database is questioned. Often an original document is created via a template that is populated with information in the database and is deemed to be the authoritative version of the document. The examiner is faced with the challenge of determining whether the document was derived from the template and the database instance at the time the document was created. Examination is based on comparing the document to the template, dependence of document fields on other database fields, and reconstruction of the database to the creation time of the document (if necessary).

The examination process may depend on the size and quantity of documents to be examined. Examination of isolated documents with minimal content may be performed manually by attempting to determine the values extracted from the database at the time of interest. Examination of multiple documents and/or documents with large amounts of data (e.g., account statements listing many transactions) will benefit from techniques to recreate the documents for comparison. This presentation discusses some approaches and challenges that apply to such a context.

The complexity of recreating the original document(s) from the database depends on the availability of the template from which the document was derived and the ability to determine the content of the database at the time the document was derived. Three possibilities were considered: (1) when the template previously used for the document creation exists, the original document(s) can be reconstructed if the database can be reverted to the same instance as when the document was created and the comparison process that can be automated; (2) when the document template has been modified, but still communicates the same information as before, the reconstructed document may differ from the questioned document, but the data extracted from the database should remain the same. Comparing the two documents may involve suppression of “constant” text and exploring differences in the remaining data, and (3) when the template is lost, the examiner may use the database schema and the questioned document to determine inferred values that may then be compared with those on the questioned document. It is important to note that when the database schema has changed or the database needs to be reverted, some information may be overlooked or not be available for comparison.

This presentation assumes that the database or schema can be reverted to the time that the questioned document was (purportedly) created. Although this research was not focused on reverting or reconstructing the database, approaches that have been described for this purpose can be used to obtain an earlier instance of the database for document examinations.^{1,2}

Questioned Digital Documents, Database Forensics, Reconstruction

C28 A Comparison of Apple® iPhone® Extraction Methods for Multimedia

Jeff Smith, MS, MITRE, McLean, VA*

Learning Overview: After attending this presentation, attendees will be informed regarding basic and advanced techniques for the analysis and comparison of images, video, and audio and the effects of various transfer methods on multimedia originating from Apple® devices with iOS® 13 and iOS® 14.

Impact Statement: This presentation will impact the forensic community by laying out the challenges in the extraction and comparison of multimedia files; demonstrating the effects of various seemingly innocuous transmission and sharing methods on multimedia; and justifying the need for continued study and documentation on the effects of transmission, sharing, and extraction methods on multimedia files.

In multimedia forensics, it is necessary to obtain test samples from known devices in order to conduct hypothesis testing on evidence. This can be necessary in various tasks, including authentication of media where one substantiates “that the data is an accurate representation of what it purports to be.”¹ This becomes important when testing a recording’s originality or evaluating its relationship with the device purported to have created it. It is up to the forensic scientist to obtain known samples from the specific device or devices for testing. Samples can be collected in various ways: from public datasets or other internet sources that have samples from the same make/model device, by obtaining the device and collecting the necessary material, or by request from the contributor of evidence who may be the victim, suspect, or other witness. In any case, collecting samples in their original form or the same manner that the evidence itself was obtained from the device is crucial. This task becomes complicated when analyzing material from mobile devices that can transmit and transfer multimedia files in a number of ways such as Bluetooth® connectivity, wired transfer to PC, Multimedia Messaging Service (MMS) native to the device, or by apps such as WhatsApp, email, file sharing apps like Dropbox, etc.

If the goal is to obtain test samples in their most original form, then collecting data from a forensic image or backup of the device is the best method. However, this is not always possible, practical, or necessary. Furthermore, when working with evidence in blind without knowledge of the originating device, an examiner relies on metadata such as EXIF data fields showing make/model or other unique entries. But in practice, while one field is consistent with what one would expect to see from a particular device, other fields may not be. While inconsistencies could arise from image or audio manipulation and attempted obfuscation, they could merely be the result of routine file sharing or transfer. Which transfer methods provide a bit-for-bit duplicate to what was created and stored on the device? Which methods modify or recompress data and how? As a baseline to further study and public documentation, the research presented here seeks to provide insight into these questions regarding Apple® iOS® 13-15 devices.

Multimedia, Digital, Comparison

C29 CoreDuet, KnowledgeC, and InteractionC: Just How Much Does My iPhone® Really Need to Know About Me?

Joseph Levi White, PhD, Defense Forensic Science Center, Forest Park, GA*

Learning Overview: After attending this presentation, attendees will understand the types of real-world user activities mobile devices track/log and how these activities may be used to generate a timeline for investigations. This presentation will present information through a case study from an investigation completed at the Defense Forensic Science Center's (DFSC) United States Army Criminal Investigation Laboratory (USACIL).

Impact Statement: This presentation will impact the forensic science community by providing insight into the application of data extracted from mobile devices, specifically the KnowledgeC and InteractionC databases on Apple® iPhones®, on determining a user's digital device interactions and real-world activities. This presentation will provide an example of how this information was used to provide critical information in a recent USACIL case.

One of the primary roles of a digital forensic examiner is using the data extracted/copied from submitted digital and multimedia evidence to outline a user's activities regarding an alleged incident under investigation. For analysis of mobile devices (cell phones, tablets, etc.), these activities have traditionally included text-based communication (text messages, email, third party messaging applications), call log entries, Global Positioning System (GPS) information, camera usage, and other types of data one would traditionally associate with the use of a mobile device. However, the past several years have seen great advancements in technology and hardware, along with a large expansion of the types of data that are logged on mobile devices. A few specific log files have proven to be a repository of a great amount of data useful to forensic analysts and investigators, including the KnowledgeC and InteractionC databases retained on Apple® mobile devices.

These databases are not exclusive to Apple® mobile devices but are also found on other Apple® devices, such as laptops and computers. No official explanation of the CoreDuet management system could be located. However, the understood intent of this tracking system is to allow for monitoring and management of internal components of mobile devices and computers and to allow for handoff between multiple Apple® devices utilized by the same user. The CoreDuet system maintains several databases containing data of potential forensic significance, including the KnowledgeC and InteractionC databases.

There is a multitude of data types that may be retained within the KnowledgeC and InteractionC databases on Apple® devices. This presentation will utilize a recent digital and multimedia evidence analysis completed at the USACIL as an outline for presenting data that may be retained within KnowledgeC and InteractionC database files. This case study provides an example of how something as simple as the battery percentage displayed on the device and whether or not the device was connected to a charger can provide enough detail to make or break a case of alleged sexual assault. This case will highlight the importance of examining system-managed database files when determining an exact timeline of events surrounding an alleged crime, or if it was even possible for the alleged crime to have happened at all.

Activity Tracking, Mobile Forensics, User Activity

C30 SQLite Data Recovery

Richard Ayers, MS, National Institute of Standards and Technology, Gaithersburg, MD; Jenise Reyes, BS, National Institute of Standards and Technology, Gaithersburg, MD*

Learning Overview: After attending the presentation, attendees will better understand the SQLite Data Recovery Specification, Test Assertions, and Test Cases document. The specification provides the forensic community with a documented set of test cases for basic methods of recovering and reporting evidence as contained within SQLite databases. The document defines SQLite forensic data recovery tool requirements. These requirements are used to derive test assertions, statements of conditions that are then checked after a test case is run. Each test assertion is covered by one or more test cases consisting of a test protocol and the expected test results. The test case protocol specifies detailed procedures for setting up the test, executing the test, and measuring the test results.

Impact Statement: This presentation will impact the forensic science community by informing attendees of the SQLite Data Recovery specification and associated requirements, test assertions, and test cases.

There is a critical need in the law enforcement community to ensure the reliability of computer forensic tools. A capability is required to ensure that forensic tools consistently produce accurate, repeatable, and objective test results. The goal of the Computer Forensic Tool Testing (CFTT) project at the National Institute of Standards and Technology (NIST) is to establish a methodology for testing computer forensic tools by the development of functional specifications, test procedures, test criteria, and test sets. The results provide the information necessary for toolmakers to improve tools, for users to make informed choices about acquiring and using computer forensics tools, and for interested parties to understand the tools' capabilities. This approach for testing computer forensic tools is based on well-recognized international methodologies for conformance testing and quality testing.

The scope of this specification is limited to software tools capable of presenting recovered data stored within SQLite databases. This also includes stand-alone SQLite forensic tools that provide additional functionality. This specification is general and capable of being adapted to other database formats should they become more widely used. The intended audience for this document is forensic examiners with an existing basic knowledge of SQLite. This document does not address every detail about how SQLite works. Rather, the scope of this material is at a higher level.

The goal of SQLite Data Recovery Specification is to provide the forensic community with Requirements, Test Assertions and Test Cases for testing a digital forensic tool tailored for reporting and recovering SQLite data artifacts.

The presentation gives an overview of the SQLite Data Recovery Specification, Test Assertions, and Test Cases document.

Digital Forensics, SQLite, Data Recovery

C31 A Forensic Analysis of the Viber Instant Messaging Application on iPhone® Devices

Akshata Thole, BTech, Purdue University, West Lafayette, IN; Nina Matulis, BS, Purdue University, West Lafayette, IN; Marcus Rogers, PhD, Purdue University, West Lafayette, IN*

Learning Overview: After attending this presentation, attendees will have a better understanding of the forensic artifacts of the Viber instant messaging application on iPhones® that are recovered from the iTunes® backup using various forensic tools and manual analysis. Attendees will also have a better understanding of the time frame of application installation to uninstallation on iPhone® devices.

Impact Statement: This presentation will impact the forensic science community by providing law enforcement officials with a guide to determine a time frame for the usage of the Viber application on iOS® devices. Additionally, law enforcement officials will gain a better understanding of the reliability of the forensic tools.

Among the various free messaging applications, the Viber application is one of the most widely used worldwide. Viber can be downloaded for free on Android®, iPhone®, iPad®, Windows® PC, Mac®, and Linux® devices, making it easily accessible. Analysis of the Viber application from a forensic standpoint is crucial as the app could be used as a method of communication for illegal actions as it can be easily uninstalled, therefore hiding any evidence of communication. Additionally, there are no current publications on recovering forensic artifacts from the Viber application on iOS® devices. There are also no publications related to determining the date and time when any application was deleted on iOS® devices. The inability to determine the exact date and time that an application was deleted from an iOS® device was the motivation for this research. If the date and time that the Viber application was deleted from iOS® can be determined, it is likely that the same information could be located for any application on an iOS® device.

The focus of this presentation is to provide the results of the analysis of the artifacts left behind by the Viber application in the iTunes® backup for iPhones® running iOS® 14 and determine if the date and time of uninstallation can be determined. The Viber application has three different installation states:

1. Installed and in use – The Viber app in frequent use by the user
2. Installed but removed from Home Screen – The Viber app is still in the user's App Library, however, not visible on the Home Screen
3. Uninstalled

The iTunes® backup from the different installation states will be analyzed using the following tools: (1) Magnet AXIOM®, (2) Cellebrite BlackLight®, and (3) reincubate iPhone® Backup Extractor®. Manual analysis will also be completed using (1) iBackup Viewer® and (2) DB Browser for SQLite®.

This study will analyze the forensic artifacts from the iTunes® backup for the Viber application that each of the forensic tools found and determine if the date and time that the app was fully uninstalled can be determined. Additionally, there will be a comparative analysis of each of the forensic tools to determine if there are any discrepancies between what artifacts each tool has found.¹ A comparative analysis between the artifacts that the forensic tools recovered versus the manual analysis will also be completed to determine the tools' reliability.

C32 Forensic Analysis on Cryptocurrency Wallet Apps

Chen, Shi, MS, Iowa State University, Ames, IA; Yong Guan, PhD, Iowa State University, Ames, IA*

Learning Overview: After attending this presentation, attendees will have learned the security issues discovered from cryptocurrency wallet apps as well as the type of digital evidence generated and associated location where the evidence is stored.

Impact Statement: This presentation will have an immediate impact on the forensic science community, in particular, digital forensic practitioners and prosecutors who have a casework investigation involving the use of cryptocurrency wallet apps or any other parties that have a general interest in the cryptocurrency wallet apps .

This project aims at conducting forensic analysis on a large scale of cryptocurrency wallet apps to discover all the digital evidence (i.e., Universally Unique Identifier [UUID], location) stored in the local file system or sent over to a remote server. Due to the influence of the COVID-19, cryptocurrency wallet apps are gaining increasing demand and accelerating the shift from cash to digital options. According to the statista, the ten most popular cryptocurrency wallets have been downloaded 2.2 million times in December 2020 and have grown to over 5.6 million one month later.¹

As with many investigations, location and timestamp information is vital to solving crimes, which could serve as crucial evidence to determine whether a suspect was at the scene when the crime was committed. Visited URLs, browser cookies, and bookmarks offer a wealth of information on user activities, where forensic practitioners could utilize them for investigations involving cryptocurrency transactions. In addition, usernames, passwords, and wallet addresses may be found in the browsing history as well. Additionally, user text inputs provide valuable information for forensic investigations. There may be keyword searches or searches for specific wallet addresses or crypto transactions (e.g., visits to blockchain.com [Bitcoin]). Therefore, we collect thousands of related source Application Programming Interfaces (APIs) targeting four groups of evidence types when conducting the analysis of cryptocurrency wallet apps .

This study's technique is based on the effective toolkits developed and published at the 12th Institute of Electrical and Electronics Engineers (IEEE) Systematic Approaches for Digital Forensic Engineering (SADFE 2018) and the Association for Computing Machinery (ACM) Conference on Computer and Communications Security (CCS 2018). This approach examines both system logs and file systems. This study collected 170 Android® cryptocurrency wallet apps from 57 different app markets worldwide. The analysis result demonstrates that, through this proposed approach, 157 of the 170 cryptocurrency wallet apps have been discovered to create various types of evidence and to store the information in local storage. This study identified 272 evidence records with evidence type and associated file path, which assisted forensic examiners with the digital investigation of Android® cryptocurrency wallet apps. This work demonstrates that 128 apps collect and store user private information, including location, timestamp, visited URL, etc.

According to the analysis result, 15 out of 170 cryptocurrency wallet apps (e.g., Bitcoin Wallet, Blockchain.com Wallet, Dogecoin Wallet) utilize BitcoinJ, a Bitcoin client library that is used to communicate with Bitcoin networks. However, this analysis experiment confirmed that Bitcoin wallet applications, which contain the BitcoinJ client library, store the user Bitcoin addresses in the app's internal storage. In addition, this study could retrieve Bitcoin transaction history from the system log for the apps mentioned above.

Mobile Forensics, Cryptocurrency Wallet, Digital Evidence

C33 Memory Forensic Analysis for Programmable Logic Controllers (PLCs)

Muhammad Rais, MS, Virginia Commonwealth University, Richmond, VA; Irfan Ahmed, PhD, Virginia Commonwealth University, Richmond, VA*

Learning Overview: After attending this presentation, attendees will understand the important forensic artifacts available in a PLC's memory dump and a process to extract them rapidly without involving tedious reverse engineering of proprietary firmware.

Impact Statement: This presentation will impact the forensic community by discussing a memory forensic methodology for PLCs referred to as DeepPLC. Instead of relying on firmware reverse engineering, DeepPLC generates the memory profile through planned test cases involving common application layer interaction with a test PLC. It then utilizes the profile to analyze the memory dump to extract forensic artifacts.

The PLCs, the nucleus of most Industrial Control Systems (ICS), directly monitor and control physical processes such as nuclear plants and power grid stations through a closed-loop control system involving sensors and actuators. Due to the central role of PLCs in ICS, they are often subject to a cyberattack to sabotage critical infrastructure. The memory forensic analysis of a suspect PLC can help answer questions about a cyberattack, such as the presence of malicious firmware, control logic injection, and manipulation of Input/Output (I/O) devices (e.g., sensor and actuators). In the current state, the PLC market is full of heterogeneous hardware architecture, proprietary firmware, and control software, making their memory forensics a challenging task. To address this research problem, this presentation proposes a memory forensic methodology for PLCs referred to as DeepPLC. Instead of relying on firmware reverse engineering, DeepPLC generates the memory profile through planned test cases involving common application layer interaction with a test PLC. It then utilizes the profile to analyze the memory dump to extract forensic artifacts. The profile is a formalized set of rules generated by discovering data structure definitions and connecting graphs identified throughout the process.

The aim of presenting DeepPLC methodology is to facilitate the community of interest (such as ICS owners, operators, forensic investigators, and vendors) to generate memory analysis tools for different PLCs. This presentation further discusses a case study of DeepPLC on a real-world PLC, Allen-Bradley 1756-L61 controller. The resultant profile successfully discovers the control logic (the control application running on the PLC), the state of sensors and actuators available in the physical process, PLC configuration data, and other forensically beneficial logs from the memory dump. The output of the case study, presented as a Python® library and shared with the community, can be readily used for the memory forensic analysis of the same model's controller.

PLC, Memory Forensics, CPS

C34 The Analysis of a Digital Diary to Aid in a Child Sexual Assault Investigation: A Case Study

Joseph Levi White, PhD, Defense Forensic Science Center, Forest Park, GA*

Learning Overview: After attending this presentation, attendees will understand the background functionality of Microsoft® (MS) Word® document recovery features and how these features allowed examiners at the Defense Forensic Science Center's (DFSC) United States Army Criminal Investigation Laboratory (USACIL) to provide investigators solid evidence in a case of alleged sexual assault of a minor.

Impact Statement: This presentation will impact the forensic science community by providing knowledge into the document recovery features of MS® Word®. This presentation will outline how analysis of a digital sexual diary maintained by the perpetrator was used in a child sexual assault investigation and provide insight into the sexual background and mindset of the document's author.

In 2012, several items of digital and multimedia evidence were submitted to the USACIL for analysis in an alleged sexual assault of a minor case. Items of evidence included a laptop computer, an external hard drive, and a mobile phone. The examiner was requested to recover all information related to the alleged sexual assault of a specific underage individual, but data located on the submitted external hard drive revealed much more than investigators originally understood about the case.

In addition to pictures and videos, contact information, messaging content, website profile information, and much more associated with the underage female, a very organized presentation of data regarding additional females were observed. This included an organized file structure, with folders named after individual females, each of which contained files such as documents regarding the individual, and pictures and/or videos detailing the sexual activities with the named female.

According to the submitter's information (interviews, etc.), the accused indicated a belief that the female who was the focus of this investigation was age 19 at the time of the incident. Copies of web pages from the submitted computer indeed showed how the underage female had apparently misrepresented her age as 19 online. The accused admitted to having sexual intercourse with the female, as proven through photographic and video evidence he maintained on the external hard drive, but did not admit to knowing her to be underage at the time.

One of the most important pieces of data recovered in this case was an MS® Word® document detailing the apparent sexual activities of the author, from childhood (13 years old) to 2011. This document detailed sexual encounters with over 350 females. Entries into the document were in chronological order and contained a name, age of the female, number of sexual encounters with that female, codes indicating specific sexual activities, ethnicity, height, weight, physical description, and a summary sentence regarding the female. It was noted that several females on the list were described as being under the legal age, but these were primarily listed as occurring in a timeframe of when the accused was also underage. However, at the time of the incidents under investigation, the accused was currently over 30 years of age and the victim was age 14.

MS® Word® maintains a recovery feature that allows users to not lose data in the case of a system/power failure. Two recovery copies of the aforementioned sexual diary were located by the examiner. A comparison of these documents showed a methodical change of information related to several females on the list, changing them from being underage to over the age of 18. Also modified between versions of the document was the actual name and age of the victim in this case. This information, coupled with the video evidence and additional case information, showed active knowledge of the victim's age at the time of the sexual acts.

Sexual Deviancy, Document Modification, Data Recovery

C35 Sextortion: Understanding Perpetrator Behavior and the Digital Evidence Available to Investigators

Martin Novak, MPA, National Institute of Justice, Washington, DC; Danielle Crimmins, MS, University of Baltimore, Baltimore, MD; Kathryn Seigfried-Spellar, PhD, Purdue University, West Lafayette, IN*

Learning Overview: After attending this presentation, attendees will understand: (1) types of sextortion; (2) the characteristics and psychology of individuals who engage in sextortion; and (3) the potential digital evidence involved in sextortion cases.

Impact Statement: This presentation will impact the forensic science community by: (1) addressing the types of digital evidence that can assist a sextortion case; and (2) providing an overview of the characteristics and psychology of individuals who engage in sextortion.

One devastating impact of COVID-19 reported around the world was the increase in child sexual exploitation offenses—including sextortion.¹⁻³ More than 86 million reports of suspected child sexual exploitation have been made to the CyberTipline between 1998 and 2020.⁴ However, of that 86 million, 21.7 million reports were made in 2020 alone—a 28% increase from 2019.⁴ The majority of these reports were for “apparent child sexual abuse material, online enticement (including sextortion), child sex trafficking, and child sexual molestation” (para 2).⁴ In addition, from 2017 to 2018, the Federal Bureau of Investigation (FBI) reported a 242% increase in extortion-related complaints, with the majority being sextortion.⁵

Sextortion is a form of “cyber extortion in which an offender demands that victims provide them with sexual images, sexual favors, or other things of value and threatens to harm or embarrass victims if they fail to comply.”⁶ Previous research has identified four types of sextortion offenders, which include: (1) Minor-focused; (2) Cyber; (3) Intimately Violent; and (4) Transnational.⁷

The goal of the current study is to examine three research questions: (1) What types of digital evidence is involved in sextortion cases?; (2) What are the characteristics and offender psychology of individuals engaging in sextortion?; and (3) Do any of the four types have commonalities between them? To answer these research questions, the current study examined the literature, relevant laws and court cases, and criminological and psychological theories.

In an effort to assist prosecutors and investigators, challenges associated with investigating and prosecuting sextortion cases are also addressed.

Digital Evidence, Sextortion, Offender Psychology

D1 The Characterization of Disperse Dyes in Polyester Fibers Via Direct Analysis in Real Time (DART®) Ionization Mass Spectrometry

Zoe Millbern, BS*, North Carolina State University, Raleigh, NC; Nelson Vinueza, PhD, North Carolina State University, Raleigh, NC

Learning Overview: Attendees can expect to learn a simple, straightforward method for analyzing polyester fibers via mass spectrometry without degradation or excessive sample preparation of potential evidence. Spectra and ion distributions for disperse dyes (one of the most widely applied colorant classes) will be explained and displayed, and the reasoning behind methodology decisions will be covered.

The methodology covered allows for rapid, sensitive analysis of evidence without damaging fibers, allowing for potential application to mobile instrumentation. A collection of spectra for 30 dyes presents a start for a potential database allowing for immediate/rapid identification of colorants.

Impact Statement: This presentation will inform attendees of an application for DART® ionization in trace fiber analysis by explaining how this methodology can be used to identify disperse dyes accurately and quickly in polyesters *in situ* via high-resolution mass spectrometry. A collection of disperse dye spectra and structures has been initiated as part of a proposed database allowing for rapid identification and comparisons between evidence and known contributors. The methodology presented highlights not only for DART® ionization as a non-destructive analysis for textiles, but also for its ability to analyze multiple colorants simultaneously.¹

Polyester and other synthetic fibers are found in clothing, carpets, upholstery, and several other everyday sources, so the chance of finding these fibers at the scene of crime are relatively high.² A good portion of these fibers likely contain some sort of colorant and, in the case of polyester and similar fibers, the most common colorants used are disperse dyes. Disperse dyes are generally inert molecules with a chromophore and structural resonance that promotes the excitation of light of a particular wavelength, and they can be separated into low-, medium-, and high-energy classes depending on their size. In trace evidence analysis, fiber samples may be small and need to be retained for additional testing, and a non-destructive methodology or one that minimally affects the evidence is advantageous.

DART® ionization involves a stream of heated, metastable gas that can provide instantaneous, real-time results, and with a relatively simple construction may translate well to a portable, hand-held device.³ The ionization mechanism employed by this methodology will be covered, specifically describing the process involved when ionizing the dyes, and informing attendees how the method works overall in a way that is applicable to other materials. Another significant advantage to DART® is the lack of sample preparation required, so an applicable fiber can be held in the ionization stream directly without further manipulation. Due to the fact these dyes (and in the case of Polyester Terephthalate [PET], the fibers) are inert, the fibers must be thermally swelled to open the structure and physically entrap the dye molecules. Therefore, analysis via a heated stream of gas, as with DART® ionization, works well for physically dislodging dye molecules. Acid and fiber reactive dyes are chemically bound to fiber, making them significantly more difficult to dislodge, and the optimum temperature for this methodology will consider the melting points of other fibers as well.

PET fabrics dyed with a known red, yellow, and blue dye with different chromophores and structural characteristics were generated, along with a trichromatic mixture generating a black fabric. Fiber and fabric samples of varying sizes were taken from each fabric and presented to the DART® gas stream in different manners (fiber and fabric via tweezers, mounting on an IonSense® mesh card, and extraction solutions) and at different temperatures and distances to generate a commonly applicable methodology. Once the mass spectrum for each color was confirmed, the black mixture was evaluated, and it was determined that each dye present was detectable. While these four samples will be presented as examples, the methodology was applicable and used to generate comparable high-resolution spectra for 30 disperse dyes.

DART®, Dyes, Fibers

D2 Portable Dynamic Vapor Microextraction (P-DVME) for Forensic and Environmental Field Studies

Adam Friss, PhD*, National Institute of Standards and Technology, Boulder, CO; Adam Broerman, BS, University of Colorado-Boulder, Boulder, CO; Megan Harries, PhD, National Institute of Standards and Technology, Boulder, CO; Tara Lovestead, PhD, National Institute of Standards and Technology, Boulder, CO

Learning Overview: After attending this presentation, attendees will better understand the concept design and development of a P-DVME sampling device for forensic studies and environmental monitoring. Attendees will also learn about the design process, including heat transfer considerations, power budgeting, and other crucial aspects required for a robust and functional device comparable to those used in a laboratory environment.

Impact Statement: This presentation will impact the forensic and environmental science community by exposing attendees to a novel field sampling approach using P-DVME. P-DVME has many advantages compared with other approaches (e.g., Solid-Phase Microextraction [SPME] fibers) owing to the ease of sample collection, sensitivity, and the ability to collect vapor without *a priori* knowledge of the species present.
