### ***PROCEEDINGS***

of the American Academy of Forensic Sciences 76<sup>th</sup> Annual Scientific Conference

The *Proceedings* of the American Academy of Forensic Sciences is an official publication of the American Academy of Forensic Sciences (AAFS). It is devoted to the publication of the abstracts of technical oral papers and posters presented at the AAFS Annual Scientific Conference. These include various branches of the forensic sciences such as anthropology, criminalistics, digital evidence, forensic nursing, engineering, jurisprudence, odontology, pathology, psychiatry, questioned documents, and toxicology. Similar submissions dealing with forensic-oriented aspects of the social sciences are also included.

Please note that some of the abstracts included in the *Proceedings* deal with topics, results, and/or conclusions that are controversial. The publication of abstracts does not imply that the AAFS, its sections, or the individual section program chairs/committee members have verified or agree with the studies, results, and/or conclusions of each abstract. During the process of planning a scientific program, it is impossible to “peer-review” each abstract and presentation to the degree that is accomplished during manuscript review. Abstracts and presentations are accepted, in part, so they can be critiqued and reviewed by other scientists. Thus, a forum is created to discuss controversial issues. The views expressed in this publication are not those of the AAFS. The data and opinions appearing in the published material were prepared by and are the responsibility of the contributor(s), not of the AAFS nor its respective employees, employers, officers, and agents. The AAFS does not supply copies of meeting papers. Please write directly to individual authors to obtain copies of specific papers. Presentation of some abstracts may have been scheduled or canceled after the publication of this document.

English is the official language of the AAFS and its meetings; neither oral nor written translations will be provided. Copyright 2024 by the AAFS. Unless stated otherwise, non-commercial photocopying of editorial material published in this periodical is permitted by the AAFS. Permission to reprint, publish, or otherwise reproduce such material in any form other than photocopying must be obtained from the AAFS.

## S1 Oh, the Places You'll Go! Exploring the Pathos to Justice for All

Dayla Rich, PhD, Union County Sheriff's Office, Monroe, NC; Claire Cartozzo, PhD, Worldwide Counter Threat Solutions, Louisa, VA; Cheryl Hunter, AAFS, Colorado Springs, CO; C. Ken Williams, MS, JD, NJSP Office of Forensic Sciences, Hamilton, NJ; Emily Rue, PhD, U.S. Army Criminal Investigation Division, Atlanta, GA; Christopher Thompson, MD, David Geffen School of Medicine at UCLA, Los Angeles, CA; Alex J. Krotulski, PhD, CFSRE, Abington, PA; M. Gabriela Roca, PhD, SERATEC mbH, Goettingen, Niedersachsen, Germany; Krystal R. Hans, PhD, Purdue University, West Lafayette, IN; Dirk M. Vastrick, BA, Dirk Vastrick Presents, Spokane Valley, WA; Anna S. Duggar, PhD, Loyola University, New Orleans, LA; Beth S. Goodspeed, MS, MA State Police Crime Laboratory, Bellingham, MA; Joe Adserias-Garriga, DDS, PhD, Department Applied Forensic Sciences, Mercyhurst University, Erie, PA; Deirdre Amaro, MD, Boone/Callaway County Medical Examiner's Office, Columbia, MO; Michelle R. Peace, PhD, Virginia Commonwealth University, Richmond, VA; Davette Gadison, MA, Tulane University, Bangkok, Krung Thep, Thailand; Katarzyna Michaud, MD, University of Lausanne/University Hospital in Lausanne, Vaud, Switzerland; Jeremy Boone, MS, Thermo Fisher Scientific, Moseley, VA; Marilyn Miller, EdD, Virginia Commonwealth University, Chesterfield, VA

**Program Description:** This full-day session will present the opportunity for attendees to learn about the many career paths one can take in the forensic science community and how each play a unique role in promoting justice for all and advancing the field.

**Educational Objectives:** The Young Forensic Scientists Forum (YFSF) offers students and young professionals the opportunity to interact with professionals in the forensic science community as they begin their careers. This session presents attendees with the chance to learn about the multitude of careers available in forensic science as well as develop professional skills that are essential for the job-hunting process. Our mission is to provide the education, mentorship, and resources necessary to champion students and young forensic scientists to promote interest, membership, and participation with AAFS and the forensic science community for years to come.

**Impact on the Forensic Science Community:** After attending this session, attendees will have a better understanding of the diversity of roles and career paths in the forensic science community and how each play an integral part in furthering the field on a national and international level. Additionally, attendees will have the opportunity to sharpen their professional skills in resume writing and making impactful introductions.

The overall theme of the 2024 AAFS Conference is *Justice for All*. As AAFS President C. Ken Williams has stated, justice for all is at the core of the AAFS Vision Statement, and this principle reminds us why we all must strive to perform at our best in this field. For this year's YFSF Special Session, the YFSF committee has chosen the theme *Oh, the Places You'll Go! Exploring the Paths to Justice for All* to showcase the various career paths young forensic scientists can choose in order to promote justice for all. A multidisciplinary approach only works to advance the field to achieve this mission.

The speakers for this year's session have a vast range of knowledge and experiences that will shed light on the innumerable ways forensic scientists work and collaborate to bring justice for all. Specifically, our presenters will showcase various disciplines in forensic science, speak about performing research in the field, offer professional development advice as well as offer international perspectives and practices. The YFSF offers this session in an effort to integrate young professionals and students into the field through presentations by professionals with significant experience in the field. Further, the session this year will offer a resume review workshop, so do not forget to bring your updated resume to the session! Also, new to the session this year, we will offer an end-of-the-day mixer for attendees to have an opportunity to meet and speak with the session's presenters as well as other distinguished professionals representing a multitude of forensic science disciplines and expertise. We are once again excited to announce that YFSF has collaborated with The Center for Forensic Science Research and Education to honor and award two outstanding scientists for their contributions to the forensic science community.

## **S2 Interdisciplinary Symposium: With Liberty and Justice for All: The Role of Forensic Science in Truth and Fairness**

*Claude Roux, PhD, University of Technology Sydney, Ultimo, New South Wales, Australia; Patrick Buzzini, PhD, Sam Houston State University, Huntsville, TX; Jessica Volz, DNP, Adventist HealthCare Shady Grove Medical Center, Rockville, MD; Michelle D. Miranda, PhD, The Center for Criminal Justice Studies-Farmingdale State College (SUNY), Farmingdale, NY; Antonel Olckers, PhD, African Forensic Sciences Academy, Pretoria, Gauteng, South Africa; Bernice B. Donald, JD, Resolute Systems LLC, Eads, TN; Keith Inman, MCrim, California State East Bay, Hayward, CA; Adam Freeman, DDS, Westport, CT; Iain Pretty, BDS, PhD, Manchester Science Park, Manchester, England, United Kingdom; Sarah P. Chu, PhD, Director of Policy and Reform, Perlmutter Center for Legal Justice at Cardozo Law, New York, NY*

**Program Description:** This half-day Interdisciplinary Symposium will discuss the influence of forensic science on the concept of *Justice for All*. Presentations on forensic science's foundational principles, ethics, and evolving definitions will be explored through an in-depth discussion of the Sydney Declaration. The importance of scientific rigor and the role of transparent utilization of knowledge grounded in proper forensic science principles in ensuring the preservation of fair and just judicial and humanitarian outcomes will be highlighted by presenters discussing forensic science policy and context-specific challenges impacting innocence work and wrongful convictions. The last half of the symposium will be focused on understanding similarities and differences in the past and current real-world application and role of forensic sciences to the justice system in the United States, the United Kingdom, and South Africa/Africa. The aspiration of working toward a world where there is *Justice for All* is in the hearts of many forensic scientists. This presentation will discuss the application of forensic science to the basic human right of access to justice and open discussion about the future of the intersection of societal needs, science, and law.

**Educational Objectives:** Upon completion of this workshop, attendees will: (1) articulate the basic principles outlined in the Sydney Declaration and describe its significance; (2) discuss reasons why scientific rigor and transparent application of science grounded in proper forensic science principles is critical to ensuring justice; and (3) explain some of the similarities and differences in the application of forensic sciences to justice in the United States, United Kingdom, Australia, and South Africa/Africa.

**Impact on the Forensic Science Community:** This symposium will impact the forensic science community by providing novice and expert forensic scientists the opportunity to gather, learn, and discuss the role and significance of their practices on the concept of *Justice for All*. Sharing and highlighting knowledge on the foundational principles outlined in the Sydney Declaration, the acknowledgment of forensic science's role in seeking truth, and examination of forensic science application in areas across the globe will lay the foundational knowledge to inspire conversation about the history, current state, and future of forensic science's role in justice in the world. This presentation will underline why it is a critical duty and ethical obligation of forensic scientists to understand the intersection of the principles, limitations, and rigor of science in supporting justice for victims of crime and the accused.

The concept of truth is fundamentally tied to the concept of justice, "the ethical, philosophical idea that people are to be treated impartially, fairly, properly, and reasonably by the law . . .<sup>1,2</sup> Regardless of their discipline, forensic scientists play a critical role in the integrity of criminal justice systems across the world. Historical examples (e.g., the Salem Witch Trials) of accused persons receiving baseless or unjust legal outcomes that result in imprisonment and death are limitless.<sup>3-5</sup> Likewise, the number of victims who have been unbelievably, blamed, and have been ignored or denied justice is countless.<sup>6</sup> Rumors, unchecked political authority, flawed forensic science, and hysteria are some examples of historical reasons for miscarriages of justice.<sup>3,4,7</sup> For millennia, mankind has faced challenges with understanding forensic sciences' role in safeguarding justice regardless of culture, race, age, and form of the justice system.

Today, some of these underlying threats to justice continue to exist. Organizations focused on wrongful convictions and exonerations, including the Innocence Project, cite eyewitness misidentification, misapplication of forensic science, false confessions, official misconduct, and coerced pleas as threats to the accused.<sup>8</sup> Threats to a victim's ability to seek and obtain just outcomes in the world often include disbelief, policies that restrict access to help, and criminal justice systems that are not designed to account for the nuances of interpersonal crimes, with Gender-Based Violence and Femicide (GBVF) as one example of non-optimal systems globally.<sup>9,10</sup> Forensic scientists should understand how science applies to understanding truth and ensuring *Justice for All*.

This Interdisciplinary Symposium will explore the challenges, limitations, advances, and successes of forensic science in supporting justice today. The foundational principles of forensic science will be discussed by experts on the Sydney Declaration and describe why every forensic practitioner and researcher must be familiar with how its principles impact their work.<sup>11</sup> The topic of unjust outcomes and wrongful convictions in historical and modern times will be focused on by discussing innocence work and forensic science policy. This discussion will also explore the impact delays in justice and wrongful convictions have on victims who already face many challenges in receiving justice.

The final section of the symposium will consist of a panel of forensic experts from four countries and an expert in ethics. This interview-style panel will provide a forum for these experts to discuss the similarities and differences of forensic science application to justice systems across the world. The future of forensic science's role in ensuring impartial, fair, and proper application of justice will round out the discussion, followed by time for questions from the audience.

## Justice; Ethics; Forensic Science

## **CBI The Boundaries of Judicial Discretion in Admitting Forensic Scientific and Technical Evidence**

*Stephanie Domitrovich, JD, PhD\*, Administrative Office of PA Courts, Erie, PA; Milton Nuzum III, JD\*, Vincent, OH*

---

**Program Description:** In this presentation, Judge Stephanie Domitrovich and former Judge Milt Nuzum will facilitate an interactive dialog with the session attendees as they examine a series of cases and scenarios that test the limits of a trial judge's judicial discretion in admitting scientific and technical forensic evidence. Attendees will analyze a series of scenarios based on actual cases and place themselves in the role of a trial judge in making decisions on admissibility of the evidence in each scenario.

**Educational Objectives:** The goals of this presentation are: (1) to examine a series of cases and scenarios that test the limits of a trial judge's judicial discretion in admitting scientific and technical forensic evidence; and (2) to help attendees understand the Rules of Evidence and relevant case law that establish the guidelines a trial judge must follow in making critical decisions on the admissibility of scientific and technical forensic evidence.

**Impact Statement:** Attendees will analyze a series of scenarios based on actual cases and place themselves in the role of a trial judge in making decisions on the admissibility of the evidence in each scenario. This dynamic presentation will impact the forensic science community by enabling prosecutors, defense attorneys, judges, and expert witnesses to be prepared to successfully face the scrutiny of the court when seeking admissibility of scientific and technical forensic evidence in cases where the outcome likely hinges on the testimony of an expert witness.

The presenters will review the Rules of Evidence and relevant case law that establishes the guidelines a trial judge must follow in making critical decisions on the admissibility of scientific and technical evidence. Attendees will analyze a series of scenarios based on actual cases and place themselves in the role of the judge in making decisions on admissibility of the evidence in each scenario. This dynamic presentation will enable prosecutors, defense attorneys, civil litigators, and expert witnesses to be better prepared to successfully face the scrutiny of the court when seeking admissibility of forensic scientific and technical evidence in cases where the outcome likely hinges on the reliability of the testimony of an expert witness. Trial judges have wide discretion in *Daubert* jurisdictions versus how trial judges admit scientific and technical evidence in *Frye* jurisdictions. The differences between the admissibility of scientific and technical evidence in both types of jurisdictions will be discussed. Trial judges are considered to have more active roles as gatekeepers of expert testimony rather than trial judges in *Frye* jurisdictions. Under Federal Rule of Evidence 702, the trial judge must determine that the expert's opinion, as well as the basis and methods used by the expert to reach that opinion, are both relevant and reliable.<sup>1</sup> Federal Rule of Evidence 702 was recently amended to clarify the application of the preponderance of the evidence standard for admissibility of evidence as required by Federal Rule of Evidence 104(a). Moreover, the new language in Federal Rule of Evidence 702 clarifies the trial judge's role in determining the conclusions reached by the expert and the methodology applied to reach those conclusions. Previously, a significant number of courts had taken a liberal view of the admissibility standard and determined expert testimony was presumed to be admissible and hence improperly had the jury make these determinations. Indeed, the trial judge's gatekeeping role in *Daubert* jurisdictions means the trial judge must more closely scrutinize an expert's proffered testimony before said expert's testimony is presented to the jury. Court-appointed experts under Federal Rule of Evidence 706 can be very helpful to the court for their gatekeeping role.

### **Discretion; Judicial; Boundaries**

## CB2 Xylazine—An Emerging Cause of Death in Correctional Institutions

Marie E. Lasater, MD\*, Texas County Coroner's Office, Licking, MO

**Program Description:** The unregulated veterinary drug xylazine is emerging as a cause of death in state correctional facilities. Unlike the drug fentanyl, there is no antidote. The origins and toxicity of the drug are discussed and illustrated with a case study of an offender death due to xylazine mixed with fentanyl.

**Educational Objectives:** The goals of this presentation are to: (1) identify physical symptoms of xylazine use, (2) identify treatment for xylazine overdose, and (3) obtain proper toxicology samples in case of fatal overdose.

**Impact Statement:** This presentation will impact the forensic science community by informing attendees that the importance of recognizing signs/symptoms of xylazine use cannot be overstated. As an emerging drug, xylazine is not always included in basic forensic panels, so expanded testing is recommended. Xylazine has no approved antidote for humans. It is NOT a federally controlled substance, so has the propensity to be easily obtained.

Xylazine, known on the street as “tranq,” is making its mark on a rural Missouri county, showing up in the local maximum security prison resulting in two offender deaths within six months. Unlike fentanyl, which is identified and treated emergently with narcan, xylazine has no approved antidote for humans. It is NOT a federally controlled substance.

Xylazine is an analog of the common drug clonidine, used to treat hypertension, but is only authorized for veterinary use due to its potentially lethal side effects that include bradycardia and profound hypotension. It is an  $\alpha_2$ -adrenergic agonist that acts via stimulation of central  $\alpha_2$ - receptors. Xylazine was discovered in 1962 by Farbenfabriken Bayer after Bayer and Farben reconsolidated in 1951 after the earlier IG Farber was dissolved by the allies following World War II. Early clinical studies confirmed its effects on the central nervous system, and today it is only approved in the United States for use as a sedative, analgesic, and muscle relaxer in dogs, cats, horses, and various deer species.

Human use of xylazine first became apparent in Puerto Rico in the year 2000. Philadelphia has been extremely hard hit by the drug, with the first detection in that city in 2006. The number of fatal overdoses in Philly involving xylazine have increased every year since its introduction. Despite being a medication approved only for use in certain animals, xylazine is relatively easy to purchase and is available online on several veterinary medicine sites (current price: \$26.95 for 100mg), requiring a prescription from a veterinarian. In most cases, xylazine is mixed with another drug, frequently fentanyl. While narcan reverses the effects of fentanyl, death can still occur with fatal overdose cases seen with xylazine levels from trace to 16ml/L. There is no “safe” dose of xylazine in humans.

Effects are usually seen within 15 minutes after administration, with sedative effect lasting 1–4 hours. The drug diffuses readily throughout the body, penetrating the blood-brain barrier; 70% of the dose is eliminated in the urine, making it useful in detecting xylazine intoxication. Due to rapid metabolism, xylazine decreases fairly rapidly to undetectable levels, so procurement of toxicological specimens as soon as possible is recommended. Although there is no approved antidote to xylazine in humans, the drug has been effectively counteracted in veterinary practice. The natural herb yohimbine, a  $\alpha_2$  adrenergic antagonist, has been shown to reverse the antihypertensive effects of xylazine in dogs and elephants.

The drug atipamezole is another  $\alpha_2$ -antagonist used to reverse the effects of xylazine, and while tested in humans in Phase I trials, it is not an approved medical treatment for xylazine overdose. As xylazine is commonly injected and mixed with other drugs, particularly fentanyl, the symptoms of pinpoint pupils, physical deterioration, dependence, and track marks will be evident. In addition, chronic xylazine users develop serious non-healing infected skin ulcers due to skin oxygen deficit following hypotension, bradycardia, and respiratory depression secondary to use of the drug. The ulcers may ooze pus and have a characteristic odor. In severe cases, amputations must be performed on the affected extremities.

As an emerging drug contributing to fatalities in correctional institutions with no antidote approved for human use, personnel in correctional medical facilities should be aware of the presence of xylazine. Markers of xylazine use include very distinct odorous pustular lesions that can be found anywhere on the body due to the ability of the drug to rob the skin of oxygen. Currently, there is no field test for xylazine, but it is readily detected in blood or urine in expanded testing completed by forensic laboratories.<sup>1-9</sup>

## CB3    Vacuous Accreditation: The Illusion of Quality in Forensic Science

*Tiffany A. Roy, MFSF\*, ForensicAid, LLC, West Palm Beach, FL; Kimberly S. Kunkler, PhD, Marshall University, Huntington, WV*

---

**Program Description:** This presentation will call attention to gaps in the quality oversight structure by questioning the current perceptions of forensic laboratory accreditation, highlighting its strengths and limitations, providing specific examples of where failures have occurred, and discussing potential opportunities for improvement.

**Educational Objectives:** This presentation is intended to highlight common misconceptions regarding accreditation and quality assurance in United States forensic laboratories. Accreditation is often misdescribed by practitioners and misunderstood by judges and juries. As a result of participation in this presentation, attendees will gain a clearer understanding of the role of forensic laboratory accreditation in the United States, including its strengths and limitations.

**Impact Statement:** This presentation will impact the forensic science community by fostering discussion about what meaningful and effective forensic science oversight would look like in the United States and why current accreditation frameworks are insufficient to ensure production of accurate and reliable forensic results. This presentation will draw the attention of justice partners to the need for statutory oversight of forensic science on the state and federal level in the image of the Texas Commission on Forensic Science.

Following nearly 15 years of calls for standardization and meaningful oversight in the forensic sciences by numerous independent bodies, significant efforts (including the investment of millions of dollars and thousands of volunteer hours) have been dedicated to the development of consensus standards to aid forensic science service providers on the path toward strengthening forensics in the United States. However, the United States still does not have a regulating body or other mechanism for meaningful oversight in place at the national level, or in most states. Forensic laboratory accreditation is often perceived by the community and stakeholders as a means of oversight through its role in ensuring that service providers are properly adopting and implementing the new and improved standards, and that service providers are producing accurate and reliable results. Unfortunately, such perceptions of forensic laboratory accreditation often far exceed its realistic abilities, making accreditation a poor substitute for oversight by a regulating body.

It is true that forensic laboratory accreditation can be effective at checking that a management system addressing concepts related to quality and reliability is in place, as well as checking that the laboratory is following the rules it sets for itself within its management system. However, forensic laboratory accreditation is currently not effective at ensuring that best practices are being utilized or that the reported results are complete and technically accurate. Furthermore, accrediting bodies often lack transparency in their operations, do not respond to stakeholder concerns or formal complaints in a timely manner, and actively perpetuate false claims of their function that are misleading to customers, stakeholders, and the public.

---

### **Accreditation; Accuracy; Quality Assurance**

## CB4 2023 State Legislative Encroachments Against Forensic Pathology Professionalism and Independence: Harbingers of Future Threats and the Opportunity for Strategic Planning and Action

*M.J. Menendez, JD\*, Willow Grove, PA; Joyce L. deJong, DO, Department of Pathology, Western Michigan University, Homer Stryker M.D. School of Medicine, Kalamazoo, MI*

**Program Description:** In 2023, the independence of forensic pathology in the context of Medicolegal Death Investigations (MDIs) was directly attacked by the introduction of various state legislative proposals and bills passed into law. These legislative proposals and laws erode the ability of forensic pathologists to maintain impartiality and objectivity, mandate particular findings on death certificates, and allow non-physicians to perform autopsies. The cause for alarm is heightened by the apparent lack of scientific and medical underpinnings in the bills and laws. This program will address threats to the independence and neutrality of MDI and the medical practice of forensic pathology.

**Educational Objectives:** After attending this presentation, attendees will understand the importance of monitoring and evaluating state legislative proposals through a prioritized, anticipatory process. Vigilance in monitoring is warranted due to the recent uptick in legislative proposals and passed bills that dictate processes and outcomes in MDIs. The information obtained by attendees will enable proactive and informed responses to proposed legislation that encroaches on the independence of forensic pathology and MDIs.

**Impact Statement:** This presentation impacts the forensic science community by exposing threats to the independence and neutrality of MDIs and the medical practice of forensic pathology and by encouraging forward-leaning responses to ward off such threats.

MDIs are performed by coroner or medical examiner offices to explain the occurrence of unexpected, suspicious, and violent deaths, and to diagnose threats and offer preventative guidance for avoidance of premature death in the living. Forensic pathologists are essential to MDIs, as they employ specialized medical training to reach medical diagnosis relating to cause and manner of death. Forensic pathologists use external examination, medical records, pathology, histology, toxicology, and a surgical procedure known as the autopsy to determine presence or absence of diseases, poisons, or external factors that caused death. The Centers for Disease Control and Prevention Vital Statistics System, which provides foundational, baseline data for innumerable federal, state, and local entities, relies universally on accurate and objective autopsy, toxicology, and related findings as to cause and manner of death.

In 2023, the independence of forensic pathology in the context of MDIs was directly attacked by the introduction of various state legislative proposals and bills passed into law. These legislative proposals and laws erode the ability of forensic pathologists to maintain impartiality and objectivity, mandate particular findings on death certificates, and allow non-physicians to perform autopsies. The cause for alarm is heightened by the apparent lack of scientific and medical underpinnings in the bills and laws.

In Texas, HB 6 and companion SB 645 mandated that death certificates include the term “Fentanyl Poisoning” if toxicology examination reveals fentanyl or fentanyl-related substances in previously identified lethal amounts and autopsy results are consistent with opioid overdose as the cause of death. Illinois SB 1086 mandated the inclusion of “Fentanyl Poisoning” on death certificates under similar circumstances. These bills undermine the independence of forensic pathologists to consider all the facts and circumstances in a case, and additionally assume there is a universally agreed upon lethal concentration of fentanyl, which there is not. On June 14, 2023, Texas HB 6 was signed into law.

Indiana’s HB 1286, another bill relating to the fentanyl crisis, mandated testing body fluids for any amount of xylazine, including trace amounts, if the coroner reasonably believes that the cause of death was due to overdose. Legislative proposals such as HB 1286 would increase the workload and costs for state health departments and toxicology laboratories, as well as compromising forensic pathologist independence. HB 1286 was signed into law on April 20, 2023.

In Oregon, SB 953 was engrossed by the Senate on April 17, 2023, after a March introduction, with a heading that reads, in pertinent part: “Provides that a physician assistant or nurse practitioner may be appointed as county medical examiner or assistant county medical examiner and may perform autopsies in deaths requiring investigation. Directs Chief Medical Examiner to provide training and supervision to physician assistants and nurse practitioners in performance of their duties.” While the language of the bill was softened slightly in the amendment process, the bill was recommended for passage in committee and went to fiscal review and public comment before dying at adjournment of legislature.

Vigilant monitoring of state-specific legislation is essential to remaining in front of changes so that temporally effective, scientifically informed responses can be formulated. Attendees will be provided with governmental and open-source electronic resources that can be utilized to track bills and legislative movement in their respective states.

**Conclusion:** Laws and regulations that intrude into the independence of the medical diagnosis of death threatens the independence of medicine writ large. Heightened vigilance is called for among all those working in forensic science, and particularly in MDI systems, to monitor, challenge, and resist evolving legislative activity that threatens to encroach and erode the independence of forensic pathology diagnosis and conclusions.

---

### Legislation; Fentanyl Toxicity; Xylazine

## CB5 Protecting the Innocent: The Urgent Need to Research When, and Under What Circumstances, DNA Evidence Can Lead to Wrongful Convictions

*J.D. Schmid, JD\*, Sixth District Public Defender's Office, Duluth, MN*

**Program Description:** This presentation will address how two recent trends in forensic DNA analysis require stakeholders to re-evaluate the power of DNA evidence to accurately distinguish the guilty from the innocent. First, courts must learn to account for the increased sensitivity of current DNA testing methods and the ensuing risk that DNA recovered from a crime-scene is unrelated to the crime. Second, courts must learn to account for the increased use of probabilistic genotyping software programs and common misunderstandings about the meaning and limitations of the subsample likelihood ratios generated by such programs. Research exploring how each of these trends impacts stakeholders' abilities to distinguish the guilty from the innocent is urgently needed to prevent wrongful convictions.

**Educational Objectives:** The goal of this presentation is to explore the urgent need to further research how recent technological advancements in forensic DNA analysis are impacting the administration of justice in the American criminal court system.

**Impact Statement:** Several members of the forensic science community have either: (1) identified common misunderstandings about likelihood ratios among lay people, or (2) recognized the impact of highly sensitive testing methods on the detection of irrelevant DNA at a crime scene. The materials discussed in this presentation will impact the forensic science community by hopefully providing empirical guidance to practitioners and decision makers in cases where the presentation of subsample likelihood ratio could lead to a wrongful conviction. This presentation will also hopefully encourage researchers with technical expertise and resources to study whether existing procedural safeguards are sufficient to protect innocent defendants faced with incriminating DNA evidence.

The primary goal of criminal courts is to distinguish the guilty from the innocent. Forensic DNA analysis has historically provided the court system with a powerful tool to make this distinction. DNA evidence has allowed courts to hold perpetrators of previously unsolvable crimes accountable for their conduct. Hundreds of exonerees also owe their freedom to the power of DNA evidence.

Two recent trends, however, require careful consideration of the potential for DNA evidence to mistake the innocent for the guilty. First, current DNA testing methods have become incredibly sensitive. The risk that an innocent person's DNA will be detected in crime-scene stain is greater now than at any other time. This risk will continue to grow as technological advances allow laboratories to generate full profiles from increasingly small amounts of DNA. Courts must therefore learn how to account for the irrelevance of some DNA associations. Knowing when, and under what circumstances, irrelevant DNA poses an intolerable risk of wrongful conviction must be understood.

Second, courts must learn how to account for common misunderstandings about the meaning and limitations of subsample likelihood ratios. Most laboratories have implemented, or are in the process of implementing, probabilistic genotyping software programs. The laboratory reports and analyst testimony derived from these programs generally express weight of evidence in the form of a subsample likelihood ratio. Subsample likelihood ratios are often misunderstood and/or misrepresented by stakeholders in the criminal justice community. Research has identified a tendency among laypersons to misinterpret likelihood ratios by "transposing the conditional" or by using a subsample likelihood ratio to draw inferences about source or activity level propositions. Little is known about whether such misunderstandings persist in the face of properly limited testimony and, more importantly, how misunderstanding the meaning and limitations of a subsample likelihood ratio impacts a stakeholder's ability to distinguish a guilty defendant from one who is innocent.

Several procedural safeguards exist that may allow courts to account for the risks outlined above. Tools such as cross-examination and evidentiary rules are frequently used to mitigate the impact of potentially misleading evidence. Confidence in the ability of such safeguards to prevent wrongful convictions should not, however, be assumed. Empirical data is necessary to determine when, and under what circumstances, DNA evidence may lead to wrongful convictions, and whether any of the procedural mechanisms available to courts are sufficient to prevent such injustices.

Upon completion of this program, attendees should be able to recognize how recent trends in forensic DNA analyses could lead to wrongful convictions if not properly addressed. Attendees should also be able to recognize the urgent need to research whether, and to what extent, existing procedural safeguards are sufficient to prevent wrongful convictions.

---

### Activity Level; Score Likelihood Ratios; Wrongful Conviction

---

## CB6 New Jersey's Top 10 Most Wanted: Anthony Mota Apprehended

*Anna W. Delaney, MA\*, New Jersey State Police, Hamilton, NJ*

---

**Program Description:** This presentation will cover how the New Jersey State Police Fugitive Unit, New Jersey State Police Office of Forensic Sciences Forensic Anthropology Unit, and the United States Marshal's Office were able to locate and close one of New Jersey's Top 10 Most Wanted cases—the case of Anthony Mota. Even in death, we strive to resolve and provide closure and justice to our victims and their families.

**Educational Objectives:** After attending this presentation, attendees will understand how to execute an international exhumation, gain knowledge of the valuable resources that the United States Marshal's Office can provide for assistance in cases, learn what samples provide the best DNA results, and the importance of documentation throughout a complex case.

**Impact Statement:** This presentation will impact the forensic science community by bridging the gap between international agencies working to achieve the same goals, demonstrating how to work collaboratively with multiple agencies across domestic and international jurisdictions, and informing attendees of the resources available from federal agencies.

Anthony Mota committed several heinous crimes, including a brutal murder in 1997 that occurred in New Jersey. Mr. Mota was federally indicted in 1998 for charges including murder, kidnapping, racketeering, arson, possession of a weapon for unlawful purposes and theft by extortion; however, he evaded apprehension by fleeing to his native Dominican Republic after the murder was committed.

This presentation will discuss how the New Jersey State Police Fugitive Unit and United States Marshals were able to locate Mr. Mota in the Dominican Republic, where he lived a double life under an alias until his death in June 2021. Due to his death, authorities were unable to extradite him alive back to the United States. Through investigative interviews in the United States and Dominican Republic, the true identity of his alias became apparent, showing that Mr. Mota had finally been found after all these years. The New Jersey State Police Office of Forensic Sciences Forensic Anthropology Unit helped develop and implement an international exhumation and retrieved his remains for anthropological examinations and DNA analysis in the United States. Through the assistance of multiple state and federal agencies, the identity of one of New Jersey's most wanted was confirmed.

This presentation will demonstrate how, after 25 years on the run, the collaboration of multiple agencies led to justice for all through the identification of one of New Jersey's Top 10 Most Wanted Individuals and the closure provided for the family of the victim. A plethora of technologies were employed to not only locate Mr. Mota, but also to scientifically confirm his identity. No matter the length of time or how a cold case seems impossible to resolve, the dedication of the men and women in law enforcement continue to provide justice for the citizens of New Jersey.

---

**Anthropology; Exhumation; Homicide**

---

### CB7 Operation Death Harvester: How the FBI Is Dismembering the Illegal Trade in Human Body Parts

*Paul Micah Johnson, PhD\*, Federal Bureau of Investigation, Detroit, MI*

---

**Program Description:** This presentation is a case review of the largest human body parts industry investigation in the Federal Bureau of Investigation's (FBI's) history. Death Harvester was opened by the author as an organized crime case in the Detroit Field Office in 2011. Its purpose was to investigate the illegal sale of human remains for research and education that was taking place through a network of anatomical supply companies. What started with the finding of severed heads in a rusty van ultimately resulted in the seizing of thousands of human remains across the country, the closure of four body donation programs, the arrest and conviction of seven individuals, and the identification, cremation, and return of human remains to hundreds of victim families.

**Educational Objectives:** This presentation will help the attendee to better understand the global trade in human remains for research and education, the common crimes associated with the trade, what has been, and can still be, done to stop the illegal activity, and the roles that forensic science professionals can play.

**Impact Statement:** The expertise of forensic pathologists and forensic anthropologists is regularly needed in criminal investigations of the human body parts trade, as are the skills of fingerprint examiners and a range of DNA specialists. Having a broad understanding of this industry and its common crimes will better prepare these forensic science professionals to assist with ongoing efforts to stem some of the rampant illegality. Additionally, this presentation will impact the forensic science community by helping all attendees better understand the risks associated with donating one's body to science.

On the night of October 23, 2011, the driver of a rusty navy-blue Ford® Econoline® van attempted to cross the international border between Canada and the United States. In the back of the van were several picnic coolers and in them, something the United States Customs and Border Protection agent did not expect. Each cooler contained five standard kitchen trash bags and each trash bag contained a wet object about the size of a large bowling ball. What the agent saw when he opened the bags was "the most cruel and inhumane thing that I have ever encountered on the job." He followed up with "I want to see everyone associated with this brought to justice."

Death Harvester is the name of the FBI case that was initially opened to investigate the illegal activity of Arthur Rathburn, former University of Michigan Willed-Body Program Coordinator, owner of International Biological, Inc. (IBI) and the driver of that navy-blue van. Death Harvester was the first criminal enterprise case of its kind in the FBI, investigating the international market in human body parts. The case centered on a network of so-called "body brokers" and willed-body-to-science businesses with extensive interstate and international connections. These entities fraudulently obtained, then dismembered, packaged, and sold or leased human body parts to a vast network of medical researchers, medical equipment developers, pharmaceutical companies, and individual domestic and foreign buyers. Many of the body part donors had tested positive for serious infectious diseases—a fact that sellers went to great pains to hide from buyers. This presentation will discuss the details of the Death Harvester case and will include the roles played by forensic professionals in its successful outcome.

Death Harvester was worked with direct assistance from the Centers for Disease Control and Prevention (CDC), the Arizona Office of the Attorney General, and the United States Department of Transportation, Office of Inspector General. Additionally, the Office of the Wayne County Medical Examiner, the FBI Technical Hazards Response Unit, the FBI Evidence Response Team Unit, and the FBI Laboratory were critical to the safe handling and analysis of thousands of seized human remains. Much of the case was prosecuted by the United States Attorney's Office for the Eastern District of Michigan.

---

#### Cadaver; Human Remains; Unidentified Persons

## CB8 Online Child Exploitation: Proactive Law Enforcement Strategies

*Paul C. Graf, MS\*, Independent Consultant of Child Abuse Legal Matters, Sr. Special Agent, NCIS (Retired), Castle Rock, CO*

**Program Description:** Under any other circumstances, a child sex offender would have to approach a child and converse, which is a much more difficult hurdle in terms of circumstance, intellectual capability, and social functioning. Online communication has dispensed with much of the social skills and verbal communication required to seduce a child, which may have deterred some offenders, and given them direct access to children, many of whom are online with little or no adult/parental supervision. In response to this crisis, law enforcement has adopted a number of proactive strategies to enforce child-protective criminal statutes. Those statutes, the communication elements of the internet, and the development of law enforcement efforts in this field will be discussed.

**Educational Objectives:** After attending this presentation, attendees will: (1) learn what conduct on the part of individuals expressing a sexual interest in children is illegal, and what conduct, though possibly objectionable, is protected by United States Constitutionally guaranteed freedoms; (2) learn to identify the various communication elements of the internet; (3) be able to understand how persons expressing a sexual interest in children make use of the various communication components of the internet to contact both persons who share similar interests and potential child victims; and (4) be introduced to several proactive techniques used by law enforcement, and the technology that makes them possible, to target and investigate criminal child sex offenders online.

**Impact Statement:** Federal statutes prohibit the possession of graphic Child Sexual Abuse Materials (CSAM), the distribution of CSAM images by any means, including computer, the buying and selling of children for the purpose of producing CSAM images, and interstate or foreign travel with the intent to engage in a sexual act with a child. Law enforcement's proactive investigations often involve undercover communication with individuals who display a sexual interest in children; they document exchanges of illegal CSAM and rely heavily on face-to-face undercover meetings. This presentation will impact the forensic science community by delineating what conduct is and is not prohibited by federal and various state laws. A discussion of proactive law enforcement methods will be presented, as well as an explanation of the internet and its communication media components, such as the World Wide Web (WWW), the Dark Web, online gaming platforms, Internet Relay Chat (IRC), chat rooms, newsgroups, and file servers, all with case examples.

Due to the incredible popularity and utility of the global linking of computer systems known as the internet, the incidence of child pornography possession and distribution has exploded. The internet is the ideal medium for such criminal activity, as it affords individuals with a sexual interest in children a degree of anonymity and ease of communication—both with others who share their interest in children and thus, help validate their behavior, and with actual (potential) child victims. Under any other circumstance, a child sex offender would have to approach a child and converse, a much more difficult hurdle in circumstance, intellectual capability, and social functioning. Online communication has dispensed with much of the social skills and verbal communication required to seduce a child, which may have deterred some offenders, and given them direct access to children, many of whom are online with little or no adult/parent supervision. In response to this crisis, law enforcement has adopted a number of proactive strategies to enforce child-protective criminal statutes. Those statutes, the communication elements of the internet, and the development of law enforcement efforts in this field will be discussed. Federal statutes prohibit the *possession* of graphic Child Sexual Abuse Materials (CSAM) images, the *distribution* of CSAM images by any means including computer, the *buying and selling* of children for the purpose of producing CSAM images, and *interstate or foreign travel* with the intent to engage in a sexual act with a child. Law enforcement's proactive investigations often involve undercover communication with individuals who display a sexual interest in children, they document exchanges of illegal CSAM and rely heavily on face-to-face undercover meetings. This training seminar will delineate what conduct is and is not prohibited by federal and various state laws. A discussion of proactive law enforcement methods will be presented, as well as an explanation of the internet and its communication media components, such as the World Wide Web (WWW), the Dark Web, online gaming platforms, Internet Relay Chat (IRC), Chat Rooms, Newsgroups, and File Servers, all with case examples.

---

### Child Abuse; Law Enforcement; Sexual Crimes

### LS1 W.W.G.D. (What Would Gibbs Do?): The Real Work of NCIS Special Agents

*Paul C. Graf, MS\*, Independent Consultant of Child Abuse Legal Matters, Sr. Special Agent, NCIS (Retired), Castle Rock, CO*

---

**Program Description:** The duties and responsibilities of a Naval Criminal Investigative Service (NCIS) Special Agent, along with real case examples, will be discussed through the lens of the real-life Jethro Gibbs.

**Educational Objectives:** After attending this presentation, attendees will be familiar with the duties and responsibilities of NCIS Special Agents and understand the similarities, and the many differences, between the *NCIS* television shows and “real life” NCIS work.

**Impact Statement:** This presentation will impact the forensic science community by developing awareness of the critical missions of NCIS Special Agents and their roles in federal law enforcement.

When the presenter, Paul C. Graf, began his career with the United States Naval Investigative Service (NIS), he often said it took well over 20 minutes to tell someone who he worked for and why he was asking so many questions. Now, and since the advent of the wildly popular CBS Television series *NCIS* and its offshoot programs (*NCIS Los Angeles*, *NCIS New Orleans*, *NCIS Hawaii*) the re-named Naval Criminal Investigative Service (NCIS) has become a household word. That said, many viewers still believe it to be a fictional agency and are surprised to hear the presenter spent 33 years conducting criminal, counter-intelligence, counter-terrorism, and espionage as a Senior Special Agent of NCIS (a.k.a.: The Real Gibbs). Mr. Graf was assigned to offices in Long Beach, CA, Naples, Italy, Newport, RI, Brunswick, ME, and Guantanamo Bay, Cuba. His duties included narcotics investigation, grand larceny, sabotage, espionage, Double Agent Operations, homicide, arson, rape, procurement fraud, cold case homicide, and child abuse investigations, his specialty. In his role as an Executive Protection Supervisor, he led teams of armed Agents who protected military and civilian VIP’s and world leaders, worldwide. Mr. Graf conducted NCIS investigations and operations in 26 countries of the world. Therefore, the duties and responsibilities of an NCIS Special Agent, as seen through the lens of his extensive career, along with real case examples, will be discussed. The forensic science community will, thus, develop an awareness of the critical missions of NCIS Special Agents and their role in federal law enforcement.

---

**Crime Scene Investigation; Death Investigation; Law Enforcement**

## LS2 Getting Things Started With a Bang: Interpreting Gunshot Sounds in Audio Forensic Analysis

*Robert C. Maher, PhD, PEng\*, Montana State University, Bozeman, MT*

**Program Description:** This presentation begins with the historical background of gunshot audio interpretation, then provides several fascinating case studies of the current state-of-the art, demonstrating how gunfire sounds can provide essential forensic information. Attendees will learn the essential physical principles of how firearms make sounds and how those sounds are affected by the recording location and the recording system. At the conclusion of the seminar, attendees will understand how to interpret audio waveforms and spectrograms from gunshot audio recordings and how to apply their new knowledge to examples and case studies.

**Educational Objectives:** After attending this presentation, attendees will: (1) understand the basic physical principles of how firearms make sound and how gunshot sounds propagate through the air to the microphone; (2) have viewed waveforms and spectrograms of gunshot sounds, identifying the key features and important details; (3) understand how to interpret and knowledgeably discuss the strengths and weaknesses of various sources of gunshot audio recordings; (4) understand the basic features of contemporary gunshot detection and location systems, such as ShotSpotter™ from SoundThinking, Inc.; and (5) recognize the proper steps in handling user-generated audio evidence in forensic investigations.

**Impact Statement:** This presentation will impact the forensic science community by introducing the attendees to gunshot audio forensic examination.

More and more criminal forensic cases involve audio forensic evidence in general, and gunshot audio recordings in particular, due to the millions of newly installed residential security and doorbell camera systems, the growing use of body-worn cameras by law enforcement officers, and the significant number of communities with gunshot detection systems such as ShotSpotter™. The sounds of gunfire—although generally familiar to most people—actually may contain many details about the circumstances of the shooting incident and the type(s) of firearm(s) involved.<sup>1</sup> Audio recording devices have become omnipresent, so gunshot acoustic evidence is more common than ever before. Gunshot sounds can play a unique role in forensic investigations. Gunshots recorded near a crime scene help answer key questions about the timeline of a shooting event and the circumstances of the incident.<sup>2</sup> Forensic recordings nowadays can come from numerous possible sources, including law enforcement body-worn cameras, residential doorbell cameras and commercial surveillance systems, bystanders with mobile phones, and emergency call center recordings.

The presentation will cover the historical background of gunshot audio interpretation and provide fascinating case studies of the current state-of-the art, demonstrating how gunfire sounds can provide essential forensic information.<sup>3</sup> Audio forensic examiners are commonly asked to determine the location of gunfire, the type of firearm(s) involved, and the time sequence of successive shots (“who shot first?”). Recent research studies have revealed how the relative orientation between the firearm and the microphone affects the recorded sound. Examiners also must understand the role of acoustic reflection, diffraction, and reverberation when interpreting gunshot recordings.<sup>4</sup>

Time will be provided during the session for attendees to ask questions and interact with other participants interested in expanding their knowledge of audio forensic analysis of gunshot acoustics.

**Audio; Forensic Analysis; Crime Scene Investigation**

---

## LS3 Human Spaceflight Medicolegal Death Investigations

*Edward Mazuchowski, MD, PhD\*, Forensic Pathology Associates, Division of HNL Lab Medicine, Allentown, PA*

---

**Program Description:** This presentation will give an overview of the phases of human spaceflight and the unique challenges each phase presents. Past fatal mishaps will be reviewed. The current applicable protocols in regard to human spaceflight medicolegal death investigations, current knowledge gaps, and future challenges to these investigations will be discussed.

**Educational Objectives:** Upon completion of this workshop, attendees should be able to describe the phases of spaceflight and the unique challenges these phases present during a spaceflight death investigation.

**Impact Statement:** This presentation will impact the forensic science community by providing a historical overview of human spaceflight medicolegal death investigations and an overview of current knowledge gaps and challenges for these investigations.

Since Cosmonaut Yuri Gagarin orbited the earth on April 12, 1961, over 600 individuals have traveled past the Karman line (altitude of 100km)—the boundary of Earth's atmosphere and space. As part of the National Aeronautics and Space Administration (NASA) Apollo program, 24 astronauts flew to the moon and 12 astronauts walked on the lunar surface. Over the past two decades, astronauts have continuously occupied and operated the International Space Station in low Earth orbit. Historically, human spaceflight has been conducted by government-sponsored space agencies. Recently, commercial spaceflight companies have been successful in achieving human spaceflight, including travel to the International Space Station and low Earth Orbit. Future programs include travel to the lunar surface, Mars, and deep space.

The phases of spaceflight include ground/launch, ascent, earth orbit, entry, and landing phase for missions orbiting Earth. Outbound, lunar orbit, lunar surface, and earth return are additional phases of spaceflight for lunar missions. Each phase of flight poses unique hazards to the astronaut, and those supporting them, that may result in death. Understanding these hazardous and the changes the human body undergoes during various phases of flight is critical for comprehensive human spaceflight death investigations.

Although there have been human spaceflight mishaps, there have been relatively few incidents resulting in loss of crew. Loss of crew incidents have occurred during the launch/ground, ascent, entry, or landing phases of the flight. There have been no fatalities during the earth orbit, outbound, lunar orbit, lunar surface, or earth return phases of flight. Deaths during these phases present unique challenges for declaration of death, preservation of evidence, examination of the remains, and containment of the remains to prevent injury to the remaining crew.

This presentation will review the various phases of human spaceflight and highlight the loss of crew incidents that have occurred over the past six decades. The current applicable protocols and documents regarding human spaceflight death investigations will be presented. The challenges and knowledge gaps of human spaceflight, including return to the lunar surface, mission to Mars, and future deep spaceflight, as they relate to death investigations will be discussed.

---

### Human Spaceflight; Medicolegal Death Investigation; Phases of Spaceflight

## LS4 There Is No I in TEAM: The Importance of Leadership, Personal Accountability, and Personality Type in High Stress Work Environments

Charla Skinner Perdue, MFS\*, Florida State University, Panama City Campus, Panama City, FL

**Program Description:** This presentation's goal is to show the importance of the role each person plays in high stress, collaborative work groups that make up many of the various positions in the fields of forensic science. High stress work environments are where the substance of the work is difficult, there is increased pressure to be right, and heavy caseloads and rapid pace take a toll on both mental and physical health. Reducing the stress on the team improves the work culture for everyone. There is no I in TEAM, but the argument can be made that there should be. The only person whose decisions and actions we can control is ourselves. We will take a quick 11-question multiple choice quiz to determine personality color and then explore how understanding ourselves and just as importantly, how others perceive us, can lead to better workplace interactions, reduce errors, and improve the overall quality of our work and our agency culture.

**Educational Objectives:** At the completion of this luncheon presentation, attendees will be able to: (1) identify their personality color by completing a short 11-question multiple choice quiz; (2) recognize the characteristics of their personality color and how they may be perceived by others; (3) discuss the importance of using personality color to improve communication; (4) examine studies related to secondary trauma in high stress work environments; (5) relate the concept of stress in the workplace to noise and errors; (6) describe the physical and mental effects of the high stress workplace, both primary and secondary; (7) discern the role one plays in challenging work situations; (8) evaluate the importance of leadership; and (9) explore ways to leverage the team's talents.

**Impact Statement:** This presentation will impact the forensic science community by highlighting the benefits of knowing the individual's personality color and the color of those they work with. It will include a brief 11-question multiple choice quiz to identify their personality color, to better understand how others perceive them, and consider studies and techniques from the field of sociology to improve how they interact with others. We will examine the importance of leadership as a tool to enhance the workplace culture and how a positive work environment may even reduce errors. By understanding that the only person whose decisions and actions we can control is ourselves, we can endeavor to improve our high stress work environment for ourselves and everyone on the team.

Sociologists approach personality in terms of an individual's status in a group.<sup>1</sup> Since crimes are not solved by any one person but by everyone working together, it is imperative that the group members can cooperate. Personality determines how we interact with colleagues, management, and those we are serving in the community. Even more critical is how we are perceived by our peers. Using the research of sociologists to find one's personality type and that of those we work with can improve communication and reduce error.

The work of solving crime by its nature creates trauma. Studies have shown vicarious trauma in those working in these roles can compound the harm caused.<sup>2</sup> High stress work environments where the substance of the work is difficult, the increased pressure to be right, heavy caseloads and rapid pace take a toll on both mental and physical health. Reducing the stress on the team can decrease the secondary traumas of working in this type of environment.

Recent studies on the concept of noise have increased awareness of how error rates can be affected by these types of distractions. Examples of noise include emotional reactions, mood, fatigue, and group dynamics and are areas where the workplace can be a factor.<sup>3</sup> A positive work environment can reduce noise and in turn may reduce errors in casework.

One of the best indicators of ethics in any agency is the culture. Leadership perpetuates the culture of an agency, and the culture sustains behavior.<sup>4</sup> In difficult workplace situations, each of us plays one of four roles: victim, bystander, perpetrator, or leader.<sup>5</sup> Frequently, those in forensics tend to be more introverted and the role of leader can be self-contradictory.<sup>6</sup> Understanding the importance of leading even when difficult gives one confidence to speak up when ethical issues arise. As individuals working in the criminal justice system, we promote public trust and must be able to make sound decisions based on ethical principles.

Understanding one's personality type and how we are regarded by others leads to better interactions at work. It allows self-reflection of one's potential blind spots, weaknesses, and strengths.<sup>7</sup> Knowing how to find one's voice can allow us to be part of workplace solutions, preserving peace and allowing for better team dynamics.

### Ethics; Mental Health; Workplace

## W1 Recommendations From the NIST/NIJ Expert Working Group on Human Factors in Forensic DNA Interpretation

*Jarrah Kennedy, MSFS, Kansas City Police Crime Lab, Kansas City, MO; Angela Spessard, Maryland State Police, Pikesville, MD; Tiffany A. Roy, ForensicAid, LLC, West Palm Beach, FL; Melissa Taylor, National Institute of Standards and Technology, Gaithersburg, MD; Mikalaa M. Martin, RTI International, Greenville, SC; Britton Morin, Union County Prosecutor's Office Forensic Laboratory, Westfield, NJ; Nikola Osborne, National Institute of Standards and Technology, Auckland, New Zealand; Hope Zagaria, RTI International, Alexandria, VA*

**Learning Overview:** Upon completion of this workshop, participants will be familiar with the recommendations in the National Institute of Standards and Technology (NIST)/National Institute of Justice (NIJ) Expert Working Group on Human Factors in Forensic DNA Interpretation report. They will know the implications of these recommendations for their own practice and how the recommendations serve to improve the practice of DNA examination. Participants will be invited to discuss how relevant and feasible the recommendations are to their own practice and to the wider forensic DNA community.

**Impact Statement:** The study of human factors in forensic science is an essential element to inform our understanding of the interaction between humans and the systems they use. In understanding human factor issues, we can identify and address the potential for error and bias. Furthermore, we can develop ways to shape positive laboratory culture, improve staff morale, and increase work productivity. This workshop presents three years' worth of effort to understand human factors as they apply to forensic DNA interpretation. This effort provides guidance to DNA analysts, laboratory management, and legal practitioners on how to improve practice for safer justice outcomes.

Studying human factors is essential to inform our understanding of humans' interactions with the systems they use. This is especially important in forensic science, where the outcomes of these interactions can have a direct impact on an individual's life or liberty. Human factors are often associated with cognitive bias, an issue that continues to receive significant attention in forensic science. Human factors extend far beyond bias, however, and include any activity in which a human is involved. For example, human factors study can also assist in developing effective ways to shape positive laboratory culture, improve staff morale, increase work productivity and quality, inform training standards, enhance communication of results, inform research gaps, and much more.

In recognizing the importance of human factor issues in forensic science, the NIST and NIJ collaborated to develop an Expert Working Group Series on Human Factors in Forensic Sciences. To date, the series has produced two successful reports: one in latent print examination and another in handwriting examination.

In February 2020, the NIST/NIJ Expert Working Group (EWG) on Human Factors in Forensic DNA Interpretation first convened and was charged with conducting a scientific assessment on the effects of human factors in forensic DNA analysis and interpretation with the goal of recommending approaches to improve its practice and reduce the likelihood of errors and bias. The EWG has since evaluated relevant scientific literature and technical knowledge to develop a report and recommendations. This evaluation serves to educate members of forensic DNA laboratories and allied criminal justice system partners (e.g., attorneys, investigators, parent organization leadership).

In this workshop, we will walk participants through the EWG's process to develop the report, highlight key findings, discuss some of the more controversial topics, and provide steps to implement the resulting recommendations. Topics and recommendations will relate to DNA interpretation and:

- Education, Training, and Professional Credentialing
- Quality Assurance/Quality Control
- Cognitive Bias and Error Reduction
- Reporting and Testimony
- Management
- Work Environment
- Expressing Evidence Strength (e.g., likelihood ratios)
- Research
- Emerging Technology

This full-day workshop will comprise a mixture of lectures, discussions, and interactive activities. Workshop participants will be expected to engage with the material and provide feedback on the relevance and feasibility of implementing the recommendations in their own practice (i.e., on the individual-, team-, and organization-level). This workshop is relevant to forensic DNA professionals and other forensic science professionals, laboratory leadership, forensic science and human factors researchers, educators, legal practitioners, and anyone interested in understanding and improving decision-making in forensic science.

---

### Forensic DNA; Bias; Reliability

## W2 Get Fired Up for Improvements to Fire Debris Standards! (Overview, Use, and Implementation of the Major Revisions to ASTM E1618)

*Brenda B. Christy, Virginia Department of Forensic Science, Norfolk, VA; Kimberly S. Kunkler, Marshall University, Huntington, WV; Laura J. Hernandez, Verity Labs Inc., Las Cruces, NM*

**Learning Overview:** Attendees of this workshop will receive information and training on major revisions to the American Society for Testing and Materials (ASTM) E1618.<sup>1</sup> Presenters will discuss why the revisions are needed, explain the new specifications for the ignitable liquid classification system, provide an overview of the performance-driven instrumental analysis requirements, and facilitate implementation of the new interpretation and reporting requirements through practical exercises. Intended as an introductory workshop, attendees will gain experience using these new specifications for classification of ignitable liquids and a practical understanding of how the updated requirements can reduce misattribution or misidentification of ignitable liquids in complex matrix samples.

After completing this workshop, attendees will: (1) be familiar with the major revisions currently being made to ASTM E1618-19 Standard Test Method for Ignitable Liquid Residues in Extracts from Fire Debris Samples by Gas Chromatography-Mass Spectrometry; (2) understand the potential impact of the revisions on their laboratory's standard operating procedures; and (3) have basic experience in utilization of some of the revisions through completion of practical, hands-on exercises.<sup>1-4</sup>

**Impact Statement:** The major revisions to ASTM E1618-19 provide additional information that is designed to clarify its requirements and improve consistency of its use in fire debris analysis. This workshop will impact the forensic science community's practice by providing orientation and training related to implementation of the major revisions to ASTM E1618.

The Organization of Scientific Area Committees for Forensic Science (OSAC) Subcommittee on Fire Debris, Explosives, and Gunshot Residue (SC), responsible for reviewing fire debris related standards, initially assessed ASTM E1618 to determine if it provided sufficient information to be considered a best practice and if it was suitable for placement on the OSAC Registry. The SC members identified several key areas where additional information was needed to strengthen the standard, clarify intended requirements, and improve the consistency of its use.

Since then, the SC has compiled and carefully reviewed existing literature and data resources to provide this additional information through major revisions of ASTM E1618 with the intent of guiding labs to current best practices in validation, instrumental analysis, classification, interpretation, and reporting of results. These revisions resulted in the creation of two new, separate standards (one detailing the classification system, one providing requirements for reporting of results) and an intensive revision to E1618 detailing the interpretation process. These three documents are currently progressing through the ASTM balloting process as a prerequisite to placement on the OSAC Registry. In addition, guidance for validation and verification of methods used in fire debris analysis is slated to become an annex to an overarching standard focused on validation in the various forensic chemistry subdisciplines.

### References:

1. ASTM E1618-19 Standard Test Method for Ignitable Liquid Residues in Extracts from Fire Debris Samples by Gas Chromatography-Mass Spectrometry (under revision as OSAC 2022-S-0004 & OSAC 2022-S-0005).
2. ASTM WK73482 Standard Practice for Reporting Results and Opinions of Ignitable Liquids Analysis.
3. ASTM WK81720 E1618 Standard Test Method for Ignitable Liquid Residues in Extracts from Fire Debris Samples by Gas Chromatography-Mass Spectrometry.
4. ASTM WK81724 Standard Classification for Ignitable Liquids Encountered in Fire Debris Analysis.

### Fire Investigation; Standards; Interpretation

## W3 Machine Learning-Powered SpectrApp: An Open-Source Tool for Analyzing Forensic Spectroscopic Data

*Eugenio Alladio, Department of Chemistry, University of Torino, Torino, Piemonte, Italy; Paolo Garofano, Centro Regionale Antidoping "A. Bertinaria," Roma, Lazio, Italy*

**Learning Overview:** Upon completion of this workshop, attendees will gain a comprehensive understanding of SpectrApp, an open-source tool developed by the Department of Chemistry at the University of Turin, its capabilities in forensic spectroscopic data analysis, and utilize multivariate data analysis. This user-friendly tool combines advanced machine learning techniques with a seamless interface, catering to both experts and non-experts in the field. Participants will delve into the power of SpectrApp's multivariate data analysis and chemometric strategies, facilitated by the R Shiny environment, explore a vast array of graphical approaches, including univariate, bivariate, and multivariate visualizations, and uncover intricate patterns within complex datasets. They will learn about SpectrApp's support for cluster analysis, Principal Component Analysis (PCA), and other advanced methodologies, such as PLS-Discriminant Analysis (PLS-DA) and PLS-Regression (PLS-R), and witness how SpectrApp enables the prediction of new samples, empowering forensic analysis like never before. Don't miss this enlightening workshop that showcases the potential of SpectrApp to revolutionize the future of forensic science through machine learning and data analysis.

**Impact Statement:** This session on SpectrApp will have a profound impact on the forensic science community by introducing a transformative tool that leverages machine learning for spectroscopic data analysis. Participants will gain invaluable insights and practical skills to navigate the complexities of forensic data, propelling them towards more accurate and efficient analyses. The workshop's educational objectives emphasize the integration of cutting-edge techniques, such as multivariate data analysis and chemometric strategies, enabling forensic experts to extract meaningful information from intricate datasets.

By empowering both experts and non-experts with the user-friendly interface of SpectrApp, this workshop aims to democratize advanced data analysis in forensic science. This accessibility will promote broader adoption and foster a culture of collaboration and knowledge-sharing within the community. The practical application of PLS-DA and PLS-R will enable participants to make informed decisions and enhance the efficacy of forensic investigations. The ability to predict new samples using SpectrApp further strengthens the community's capacity for real-world applications, fostering more accurate and reliable results. Furthermore, SpectrApp's role as an open-source tool encourages transparency and reproducibility in forensic data analysis. Researchers can verify and build upon existing work, ensuring the reliability and credibility of scientific findings.

By showcasing SpectrApp's potential to revolutionize forensic spectroscopic data analysis, this workshop encourages innovation and drives advancements in the field. This newfound integration of machine learning methodologies in forensic science will undoubtedly influence research directions and encourage further exploration of data-driven approaches.

A hallmark of SpectrApp lies in its exceptional user-friendliness, making it accessible to both seasoned experts and non-experts in the fields of machine learning and forensic science. Its intuitive interface empowers users to seamlessly evaluate spectroscopic data through sophisticated multivariate data analysis and chemometric strategies. Powered by the versatile R Shiny environment, SpectrApp elevates the data analysis experience, streamlining visualization, preprocessing, and analysis tasks.

During this immersive session, participants will embark on a captivating journey into SpectrApp's expansive repertoire of graphical approaches, granting them unprecedented insights into the complex relationships and patterns within the datasets. Through an array of univariate, bivariate, and multivariate visualizations, attendees will glean valuable understanding from the data, revealing crucial information that transcends traditional data representations.

The workshop will delve deep into SpectrApp's impressive support for Cluster Analysis and PCA, showcasing its efficacy in uncovering hidden structures and dependencies within the data. Additionally, participants will have the privilege of exploring a diverse selection of advanced multivariate modeling methodologies, including the powerful PLS-DA for classification and PLS-R for quantification.

The true power of SpectrApp lies in its capacity to enable the prediction of new samples, an essential feature that has transformative implications for forensic analysis. Armed with SpectrApp's predictive capabilities, attendees will be able to assess the origin, classification, and quantity of new samples with precision and accuracy, bolstering the efficacy of forensic investigations.

## W5 Forensic Postmortem Radiology and Medicolegal Death Investigations

*Summer J. Decker, Department of Radiology, University of South Florida, Tampa, FL; Edward Mazuchowski, Forensic Pathology Associates, Division of HNL Lab Medicine, Allentown, PA; Natalie L. Adolphi, New Mexico Office of the Medical Investigator, Albuquerque, NM; Fabrice Dedouit, Hopital Rangueil, Toulouse, Midi-Pyrenees, France; Lars Ebert, 3D Center, Institute for Forensic Medicine, University of Zürich, Zürich, Switzerland; Jamie Elifritz, Office of the Medical Investigator, Affiliate, Albuquerque, NM; Michael J. Thali, Institute of Forensic Medicine, University of Zurich, Zurich, Switzerland; Jonathan M. Ford, Department of Radiology, University of South Florida, Tampa, FL*

---

**Learning Overview:** This workshop is an update on current practices in forensic postmortem radiology and medicolegal death investigations. National and international forensic pathology and radiology practitioners will provide an introduction to and update on best practices in the field. After attending this workshop, attendees will: (1) be informed of the different modalities for postmortem radiology, (2) understand the strengths and weaknesses of the different current modalities, (3) learn about the interpretation of the postmortem radiology scans and levels of forensic evidence, and (4) be aware of current advances, collaboration, and potential resources available to interested practitioners.

**Impact Statement:** This presentation will impact the forensic science community by providing attendees with expertise on best practices, interpretation of radiology imaging, and incorporation of forensic postmortem radiology into medicolegal death investigations.

It has been over a decade since the publication of the National Academy of Sciences Report calling for the strengthening of the forensic sciences. In this seminal report, the critical role that imaging, specifically radiologic imaging, plays in the documentation of findings sufficient for courts, for providing the opportunity for review by outside experts, as well as for allowing for reevaluation of evidence as medical knowledge advances was noted. Since then, forensic radiology has grown significantly as a field to incorporate advanced radiology techniques into medicolegal death investigations. However, the type of modality and incorporation into the daily medicolegal death investigation varies widely across medicolegal jurisdictions.

Currently, there are four main radiologic imaging modalities that are used in medicolegal death investigations: fluoroscopy, digital radiography (X-ray), including whole-body radiography, Computed Tomography (CT), and Magnetic Resonance Imaging (MRI). There are strengths and weaknesses of each modality. Location/infrastructure, equipment cost, personal cost, time to scan, interpretation and incorporation of findings, presentation at medicolegal proceedings, and storage of results must all be evaluated.

This workshop will provide an overview of how the different radiologic imaging modalities have been incorporated into specific medicolegal death investigations. Through directed lectures and case presentations, the advantages and limitations of the modalities will be presented. How postmortem radiology enhances the medicolegal death investigation will be discussed. Topics will include natural disease, trauma, overdose, postmortem changes, and artifacts. Representative digital radiographs, CT images and Three-Dimensional (3D) reconstructions will be presented. Techniques that overcome some of the limitations of different modalities, such as postmortem angiography for the evaluation of vascular/soft tissue injury, will be presented. The incorporation of these findings into legal proceedings will also be discussed. Participants will have the opportunity to discuss with the presenters through a panel discussion implementation of forensic radiology imaging into their medicolegal system.

Similar workshops have been presented at AAFS by the same team over the past few years, and they have been highly attended by members from different sections. This workshop represents new and updated content to present new advances in the field.

---

### Forensic Pathology; Forensic Radiology; Postmortem Imaging

## W6 Don't Know Much About Standards: Incorporating Forensic Science Standards Into University Curricula

*Heidi Eldridge, The George Washington University, Washington, DC; Julie A. Howe, Saint Louis University, Saint Louis, MO; Teresa L. Ambrosius, AAFS Standards Board, Colorado Springs, CO; Sarah Seashols Williams, Virginia Commonwealth University, Richmond, VA; Jennifer Limoges, New York State Police Forensic Investigation Center, Albany, NY; A. Karl Larsen, Jr., University of Illinois at Chicago, Chicago, IL; McKenzie Weyh, Michigan State Police, Lansing, MI; Arely J. Parra López, The George Washington University, Eaton, CO; Britni Skillman, Sam Houston State University, Huntsville, TX; Peter Stout, President and CEO, Houston Forensic Science Center, Houston, TX*

**Learning Overview:** During this presentation, representatives from universities and the Forensic Science Education Programs Commission (FEPAC) will present on ways they have incorporated standards into their university programs, examples of specific courses where students' knowledge has been enhanced by such standards, and how to overcome obstacles of changing curriculum to include private sector standards. Representatives from forensic laboratories will present on how hiring practitioners with a knowledge of standards affects their practices, as well as how they are implementing standards into lab training and standard operating procedures. The latter portion of the workshop will be comprised of a panel, including educators, lab managers, young forensic professionals, and recent university graduates, to discuss how forensic standards are changing, and will continue to change, the landscape of forensic education and training.

After attending this presentation, attendees will have a better understanding of how incorporating standards in an educational curriculum affects students' understanding of the discipline and forensic sciences when they enter post-graduate employment.

**Impact Statement:** This presentation will impact the forensic science community by creating greater awareness of how standards are currently being implemented in university level educational programs, and how lab managers have both incorporated standards into their training and how they use standards for minimum qualifications and education of practitioners.<sup>1</sup>

Multiple forensic and standards organizations are working with members, partners, and constituents across the standards community to develop education initiatives that highlight the economic, societal, and environmental benefits of standards to students, emerging professionals, and the general public. These responsive programs and activities are designed to engage students of all ages in the world of standards and conformity assessment and ensure the strength and efficacy of the next generation of United States standardization leaders.

Avenues exist for professional development and training of practitioners at workshops, conferences, and webinars, but little opportunity currently exists for students in higher education to learn about forensic science standards. Expanding training at this level presents an opportunity to fill a gap by introducing private sector standards and better prepares students for entry into the workforce, while also aligning with recent national strategies that support fostering development in the forensic sciences through "enriching undergraduate experiences."<sup>2</sup>

Implementation begins with awareness. Some agencies are not aware of the standards that are available, why they are needed, how they are developed, or how they can be implemented. Still others recognize the value of standards but fight an uphill battle in garnering the enthusiasm and cooperation of their employees. An incoming workforce of forensic science students who have already learned the ins and outs of forensic science standards and expect their use in the workplace could go a long way toward closing this gap. However, some universities also struggle with the best way to incorporate standards into a curriculum that is already packed with university general education requirements, accreditation science, and discipline-specific requirements, while leaving some space for electives.

### Education; Standards; Forensic Science

## W7 Emerging Semi-Synthetic Cannabinoids: THC Isomers and Analogs

*Ayako Chan-Hosokawa, NMS Labs, Horsham, PA; Sarah A. Shuda, Center for Forensic Science Research and Education, Willow Grove, PA; Barry K. Logan, Center for Forensic Science Research and Education, Horsham, PA; Nicole Lattanzio, NMS Labs, Willow Grove, PA; Joanna De Morais, European Monitoring Centre for Drugs and Drug Addiction, Lisbon, Portugal; Erin Karschner, Armed Forces Medical Examiner System, Dover Air Force Base, DE*

**Learning Overview:** This workshop will address the growing semi-synthetic cannabinoid market from both a toxicological and a seized drug chemistry perspective. It will provide an overview of the legislation and scheduling of Tetrahydrocannabinol (THC) -related compounds in the United States, discuss drug trends in semi-synthetic cannabinoids in both Europe and the United States, and review analytical methods for the separation of THC isomers in seized drug material. This workshop will also focus on the known pharmacological activity and potency of currently available semi-synthetic cannabinoids, provide reviews of cross-reactivity of the cannabinoid isomers and analogs on the commercially available immunoassay platform, and describe analytical methods for isomer separation in toxicological samples. Finally, delta-8-THC blood concentrations and trends in the Driving Under the Influence of Drugs (DUID) cohort will be presented.<sup>1,2</sup>

After attending this presentation, attendees will be familiar with semi-synthetic cannabinoids such as delta-8-THC, THC-P, HHC, etc., their appearance in various cannabis-containing products, their potency, and their legality. Additionally, attendees will understand analytical challenges associated with these newly emerging THC isomers and analogs and how to resolve chromatographic interferences.

**Impact Statement:** This presentation will impact the forensic science community by providing a legal, pharmacological, and analytical overview of emerging semi-synthetic cannabinoid products.

The 2018 Farm Bill legalized industrial hemp production in the United States, making cannabis and cannabis-derived products containing less than 0.3% delta-9-THC more commercially accessible. This also led to overproduction of Cannabidiol (CBD), which can serve as a precursor for synthesis of psychoactive isomers and analogs of THC. Cannabis manufacturers have exploited legislative loopholes since the Farm Bill's introduction and successfully promoted products containing THC isomers and analogs whose legal status is unclear, or variable, state to state, as an attractive alternative to the clearly federal Schedule I drug, THC. Products are often advertised to contain THC isomers or analog such as delta-8-THC, delta-10-THC, delta-6a,10a-THC, exo-THC, THC acetate (THC-O), THC-P, and HHC, among many others; however, upon analysis, these products could contain not only delta-9-THC but also a combination of compounds. This leads to analytical challenges as well as interpretation challenges.

Edibles, candies, baked goods, personal care products, beverages, dietary supplements, e-cigarette liquids, and other cannabis-derived products containing <0.3% THC and other semi-synthetic THC derivatives manufactured from CBD have proliferated and are sold not only at smoke shops, but also at gas stations, in malls, and in boardwalk storefronts, providing consumers with ample options for purchasing products containing psychoactive THC isomers.

### Cannabinoids; Isomer; Analogs

## W8 Non-Fatal Strangulation: An Update on Practice and Current Literature

Stacey A. Mitchell, Texas A&M University School of Nursing, Magnolia, TX; Kathy Bell, Oklahoma State University Center for Health Sciences, Tulsa, OK; Jessica Volz, Adventist HealthCare Shady Grove Medical Center, Rockville, MD; Patricia M. Speck, University of Alabama at Birmingham School of Nursing, Hoover, AL; Diana A. Faugno, AFN, Escondido CA; Sean P. Dugan, Shasta Community Forensic Care Team, Shasta Community Health Center, Redding, CA; Diana A. Faugno, AFN, Escondido CA

**Learning Overview:** “He only choked me . . .” Anoxic brain injury can occur in minutes. Non-fatal strangulation and its associated effects are not well understood by responding providers. This potential lethal act is present in more cases than one thinks. The workshop presenters plan discussions around how the current evidence impacts the investigation, documentation, care, and prosecution of strangulation cases. Long-term effects such as traumatic brain injury are now being studied, with current information to be discussed. Key concepts will be illustrated through the use of case studies and group discussion. We will: (1) discuss the prevalence of non-fatal strangulation; (2) appraise current literature related to addressing non-fatal strangulation in the clinical arena; (3) associate linkages between non-fatal strangulation and traumatic brain injury; and (4) evaluate assessment and documentation of non-fatal strangulation through the use of case studies.

**Impact Statement:** Many disciplines that investigate, provide care, or prosecute cases where non-fatal strangulation is a component will benefit from understanding this topic. Investigators and crime scene personnel will be able to better recognize and investigate this potentially lethal act. Health care providers must properly assess and treat those who have experienced strangulation. Finally, prosecutors must develop knowledge about how to charge and prosecute for this action and to effectively use the expert witness to convey the significance that strangulation has on the victim.

Strangulation is a lethal form of violence and occurs in intimate partner violence, sexual assault, and other types of physical assault. Since the early 2000s, non-fatal strangulation has been recognized as a method of control, harm, and even death. Victims often do not disclose that strangulation has occurred unless asked by the health care provider or first responder. It is critical that first responders, law enforcement, and crime scene analysts understand injury mechanisms and the health outcomes that may affect a criminal investigation. Health care must recognize the signs and symptoms to determine an appropriate plan of care for both the short- and long-term effects.

Non-fatal strangulation has two primary mechanisms of action. One prevents inflow and the other prevents outflow of either blood or oxygen. The presentation and symptoms are different. Some symptoms of non-fatal strangulation are memory loss, confusion, difficulty breathing, and trouble talking. Non-fatal strangulation may result in anoxic brain injury where consequences include seizures and loss of bowel and bladder function, to name a few. Understanding the strangulation event is the first step in the response. This workshop plans to take participants step by step through what occurs in a non-fatal strangulation case and the response necessary to discover what actually happened.

“Audrey” reports her boyfriend pushes her against the wall and puts his arm around her throat. “Sandra” says her husband puts both of his hands around her throat, shaking her when they argue. She reports she has passed out. Marcus” says that the neighbor bully knocks him to the ground and puts him in a choke hold where he cannot breathe. These are all forms of non-fatal strangulation.

In developing the skills to assess and document strangulation events, health care delivery and investigations will become more robust. As prosecutors understand the magnitude of the long-term effects of non-fatal strangulation and associated traumatic brain injury, charges may be better determined. Expert witnesses are better utilized to describe the physical and psychological effects. Workshop presenters will provide information that will assist professionals who encounter cases of non-fatal strangulation to better be prepared to respond to the unique needs of this population.<sup>1-9</sup>

### Non-Fatal Strangulation; Traumatic Brain Injury; Violent Behavior

---

## **W9     The Requirements and Implementation of ANSI/ASB Standard 123—Standard for Routine Internal Evaluation of a Laboratory’s DNA Interpretation and Comparison Protocol: Laboratory and Legal Perspectives**

*Charlotte Word, Richmond, VA; Virginia Barron, Law Office, Westbrook, MN; Terri Rosenblatt, Post Conviction Justice Unit, New York County District Attorney’s Office, New York, NY; Brian Higgins, USACIL, Forest Park, GA; Ashley Luther, Indiana State Police Laboratory, Indianapolis, Indianapolis, IN*

---

**Learning Overview:** After attending this workshop, attendees will have a heightened understanding of: (1) the need to monitor the efficacy and consistency of use of the laboratory DNA interpretation and comparison protocols; (2) the specific requirements of Standard 123 and how to implement the standard in a DNA testing laboratory effectively in conjunction with other relevant DNA standards; (3) how to assess the results of the internal evaluation process with appropriate corrective actions; and (4) the legal perspective regarding the consistent use of high-quality interpretation and comparison protocols prior to and post-conviction and how that may help to provide “Justice for All.” The attendees will have the opportunity to network with the speakers and other attendees while discussing implementation options.

**Impact Statement:** This workshop will impact the forensic science community and the “Justice for All” initiative by providing information to laboratory staff, attorneys, and judges regarding the value of performing an annual review of the forensic science service provider’s interpretation and comparison protocols. Guidance for monitoring and evaluating the consistency of use and suitability of the protocol within a DNA laboratory via implementation of the American National Standards Institute/Academy Standards Board (ANSI/ASB) Standard 123, Standard for Routine Internal Evaluation of the Laboratory’s DNA Interpretation and Comparison Protocol, and its possible effect on the judicial system will be the main focus of this workshop.

Several studies conducted over the past 20 years have demonstrated the inconsistent use of the interpretation and comparison protocols within some DNA testing laboratories as well as variability in the reporting of results and conclusions, especially when complex DNA profiles were evaluated that fell outside of the types of profiles routinely evaluated during mandatory proficiency testing. A standard, drafted by the Organization of Scientific Area Committees (OSAC) and developed by the ASB, provides for the continued monitoring of the efficacy and consistent use of the laboratory’s protocol. This workshop will focus on the specific requirements of Standard 123 and provide effective mechanisms for implementation of the standard, including the evaluation of the resulting data to ensure quality interpretation and comparison of DNA data. DNA analysts and attorneys will provide insights regarding the importance of and value added through the implementation of this standard.

---

### **DNA; Interpretation; Quality Assurance**

---

## W10 Evolving Approaches and Technologies to Address Existing Challenges in Seized Drug Analysis

*J. Tyler Davidson, Sam Houston State University, Conroe, TX; Edward Sisco, National Institute of Standards and Technology, Gaithersburg, MD; Ira Lurie, The George Washington University, Washington, DC; Frances Scott, National Institute of Justice, Washington, DC; Amber K. Burns, Maryland State Police Forensic Sciences Division, Pikesville, MD; Sherri L. Tupik, Drug Enforcement Administration, Dulles, VA*

---

**Learning Overview:** After attending this workshop, attendees will have learned about readily implementable evolving approaches and technologies to address existing challenges in seized drug analysis. The attendees will learn about emerging technologies, such as Direct Analysis in Real Time-Mass Spectrometry (DART®-MS), Gas Chromatography-Vapor-Phase Infrared spectroscopy (GC-VIR), Gas Chromatography-Vacuum Ultraviolet spectroscopy (GC-VUV), and Ultra-High Performance Liquid Chromatography-Photo Diode Array Ultraviolet single quadrupole Mass Spectrometry (UHPLC-PDA UV-MS). In addition, attendees will also learn about evolving approaches, such as microcrystal tests and the analysis of marijuana and marijuana products.

**Impact Statement:** This workshop will impact the forensic science community by providing chemists, section leaders, and laboratory managers with the necessary information to determine which evolving approach or technology may be most appropriate to address their specific laboratory needs. Aspects such as the approximate cost, analysis time, capabilities, limitations, and specific challenges that each approach or technology can help address will be provided. Informing the seized drug community about the strengths and limitations of the identified evolving approaches and technologies will better prepare forensic laboratories to make informed decisions about how to combat their specific challenges in seized drug analysis.

Challenges with the analysis of seized drugs have necessitated research into alternative approaches and technologies to assist forensic laboratories with the identification and quantification of unknown seized drugs. These challenges include the rapidly evolving nature of the seized drug landscape, with the continued emergence of Novel Psychoactive Substances (NPS), the identification of closely related chemical substances, the detection of minor components in mixtures, the differentiation of hemp and marijuana, screening of multiple subunits, and growing backlogs. However, there is a considerable divide between the research community developing these alternative approaches and technologies and actual implementation by practicing forensic laboratories. The Evolving Approaches and Technologies for Seized Drug Analysis subcommittee was established to specifically address this divide by the Forensic Laboratory Needs Technology Working Group (FLN-TWG), which is housed at the National Institute of Justice (NIJ) and supported by the Forensic Technology Center of Excellence (FTCOE) through a cooperative agreement with RTI International.

This workshop provides a summary of the subcommittee's developed technical notes and overarching white paper designed to help address the divide between the research community and practicing forensic laboratories. During this workshop, attendees will learn about readily implementable evolving approaches and technologies that are either not widely known or are currently underutilized. These approaches and technologies have been identified by the subcommittee as potential solutions to address existing challenges with the analysis of seized drugs. Each approach and technology will be introduced, including the principles of operation or analysis, approximate cost and analysis time, and specific capabilities and limitations as they pertain to seized drug analysis. In addition, this workshop will help address implementation needs, including a discussion about installation requirements, user training, and the availability of validated methods and searchable libraries.

---

### Drug Analysis; Novel Psychoactive Substances; Education

## W11 Police Officers Injured in the Line of Duty: The Role of Peer Support in Recovery

Gregory I. Mack, Psychological Evaluation Section, Medical Division New York City Police Department, Shrub Oak, NY; Daniel A. Martell, UCLA School of Medicine, Irvine, CA; Learie C. Johnston, Westchester B.L.U.E. Foundation/Mount Vernon Police Department, Mount Vernon, NY; Matthew Frank, Westchester B.L.U.E. Foundation, Port Chester, NY; Paul Puccini, Westchester B.L.U.E. Foundation, New Rochelle, NY; Jamie M. Elifritz, Forensic Radiology Group/Department of Radiology, University of New Mexico, Albuquerque, NM

**Learning Overview:** After attending this workshop, attendees will: (1) better understand the experiences of police officers who have been severely injured in the line of duty; (2) build skills to identify the many challenges one can face while recovering from a Traumatic Brain Injury (TBI) caused by a gunshot wound to the head; (3) be made aware of the physical damaged caused by a Gunshot Wound (GSW) to the head; (4) appreciate the effects of TBI on cognitive and psychological assessment protocols; (5) be informed about the current empirical research and literature on peer-assistance programs, peer support, and peer-facilitated interventions for police officers; and (6) have a better understanding of the role social support, gratitude, resilience, and satisfaction with life have on recovery.<sup>1-4</sup>

**Impact Statement:** Presentations in this workshop will impact the forensic science community through detailed accounts of police officers who were injured in the line of duty. Through their first-hand accounts, these officers will discuss their road to recovery and associated psychological sequela and its impact on their families. The forensic science community was previously introduced to one of the officers (LCJ) through a presentation at the 75<sup>th</sup> Annual AAFS conference. This workshop will also impact the forensic science community by providing the most up-to-date information on the role, responsibilities, and best practices associated with a Peer Support Program.

This presentation will provide an overview of the of circumstances that led up to the wounding of New York police officers and the challenges that they faced and still endure. We will engage in an interactive discussion with these officers and learn how they faced aspects of their physical and psychological recovery and the role other factors played in their seeking help such as individual characteristics, the availability of peer support, stigma, family, and social support, gratitude, resilience, and satisfaction with life. Special focus will be given to a traumatic brain injury caused by firearm. This workshop will discuss topics requiring basic knowledge pertaining to brain anatomy, brain function, and cognitive and psychological effects of TBI.

In their July 2023 “Law Enforcement Officers Shot in the Line of Duty” report, the National Fraternal Order of Police reported that there have been 226 officers shot in the line of duty, of which 31 were killed. Sixty-seven of these officers were shot and wounded and 14 were killed in 69 separate ambush-style attacks.<sup>5</sup> Officers who survive these devastating injuries face many long hours of rehabilitation and recovery. If an officer survives a deadly encounter such as a gunshot wound to the head, the road to recovery is unimaginable.

Ninety percent of victims of a gunshot wound to the head die. Many die before they make it to the hospital. Fifty percent of those victims who do survive the initial trauma end up dying in the emergency room. Gunshot wounds to the head account for 12% of all TBI and are the cause of death in an estimated 35% of all deaths attributed to TBI.<sup>6</sup>

On October 30, 1993, 23-year-old Mt. Vernon, NY, police officer LCJ was shot with a .380 caliber handgun. He was struck by a single round that entered the left frontal side of his head without exiting. The officer was in a coma for several weeks. LCJ sustained severe neurological damage. During his initial recovery and rehabilitation, he had to relearn how to speak and ambulate and was left with partial paralysis of the right side of his body. He was subsequently retired at the rank of detective.

On April 20, 2006, a Mount Vernon, NY, detective was walking out of the police interview room after questioning a 33-year-old Bronx man in connection with the April 14 killing of a local businessman when the man jumped out of his chair and grabbed the detective’s gun. A life-and-death struggled ensued, and the man was able to get his hands on the trigger and fired a shot that penetrated the detective’s left foot.

## W12 Reading the Blueprint to Construct the Framework: Demystifying Forensic Accreditation

*Nicole S. Jones, RTI International, Research Triangle Park, NC; Erin P. Forry, RTI International, Research Triangle Park, NC; Allison Getz, National Institute of Standards and Technology, Monrovia, MD; John H. Grassel, RTI International, Apex, NC*

**Learning Overview:** After attending this workshop, attendees will understand some principles of International Organization for Standardization (ISO) accreditation programs and quality management, necessary elements of the requirements in each standard (ISO/IEC 17020 and ISO/IEC 17025), and guidance on how to meet the requirements. Attendees will be provided with resources to help them develop an effective quality management system and become an accredited Forensic Service Provider (FSP).

**Impact Statement:** This presentation will impact those in forensic science who are considering accreditation, or who are beginning the process of obtaining accreditation, by explaining the pieces needed to build a framework of accreditation. It has been over a decade since the National Academy of Sciences (NAS) published recommendations to the forensic science community about how forensic science can be strengthened in the United States, which includes accreditation of FSPs.<sup>1</sup> Since then, accreditation of Forensic Science Service Providers (FSSPs) (e.g., Crime Scene Investigator [CSI] units, crime labs, latent print units, etc.) has been endorsed by the National Commission on Forensic Science (Recommendation to the Attorney General Universal Accreditation 2015), forensic science professional organizations (e.g., the American Academy of Forensic Sciences [AAFS], the American Society of Crime Laboratory Directors [ASCLD], the Association of Forensic Quality Assurance Managers [AFQAM], the International Association for Identification [IAI]), and even mandated by organizations such as the United States Department of Justice and state forensics oversight boards (e.g., New York, Texas). Many conference presentations and webinars have been given and reports written that advocate for accreditation in FSPs, giving explanations for why it is beneficial to an organization, but what comes next? Where do they start? What do these standards mean? How are they supposed to meet them? This workshop will provide attendees with answers to these questions as well as practical guidance and considerations when building the quality assurance framework to obtain accreditation.

This workshop will provide an overview of the Framework for Accreditation of Forensic Units developed as part of cooperative agreement 70NANB21H098 with the National Institute of Standards and Technology (NIST) that can be used by FSPs through the accreditation process.

The workshop will review the benefits, and the drawbacks, to accreditation for an organization, particularly with respect to CSI and latent print units. It will also discuss why accreditation of FSSPs is important to the criminal justice system, using practical examples in forensics as well as other industries. Attendees will learn what a forensic accreditation program consists of and the structure of the International Organization for Standardization/International Electrotechnical Commission (ISO/IEC) 17020 and ISO/IEC 17025 standards used to build a framework, along with the similarities and differences between the two. Attendees will learn how to approach building a quality management system and the overall accreditation process as well as tips for reading and interpreting standards.

Case studies about CSI units and small labs, some with only one or two employees, obtaining accreditation will be presented and discussed. Resources and ideas to help the attendee design and build their quality management systems to become accredited will be shared. Chances are their organization currently meets many of the requirements, and they may just need to document them. Participants should leave with a better understanding of quality management and accreditation in forensic science and their importance and feel more confident in the possibility of incorporating both into operations in their units and labs.

Accreditation of CSI units is important because the scene investigation is the main gateway for the recognizing, recording, collecting, transporting, and storage of forensic evidence, which can have lasting impact on the analysis, interpretation, reporting of results, and ultimately the outcome of the investigation. Accreditation also gives the criminal justice system and the public confidence in the agency's results and ensures that the agency maintains impartiality. Accreditation is a formal recognition that an agency has implemented internationally recognized standards and best practices and demonstrates and maintains competency with a commitment to continuous process improvement. The 2009 National Academy of Sciences (NAS) Report documented the need for mandatory accreditation for forensic disciplines, including many that police agencies and identification units engage in.<sup>1</sup> This is particularly important in the practice of CSI and forensic science as, unlike other industries, there is no mandatory regulatory approach to ensuring quality. Therefore, a voluntary standardization approach is important for maintaining public trust and transparency.

### Standards; Forensic Accreditation; Forensic Service Provider (FSP)

## W13 Beyond the “Who Done It . . .” DNA Interpretation Given Activity Level Propositions

*Tim Kalafut, Sam Houston State University, Department of Forensic Science, Huntsville, TX; Simone Gittelsohn, District of Columbia Department of Forensic Sciences, Washington, DC*

**Learning Overview:** After attending this workshop, attendees will be able to communicate expert knowledge on the evaluation of DNA evidence given activity level propositions using a scientifically sound framework and published practices. Participants will understand how to apply the Case Assessment and Interpretation (CAI) framework to perform case pre-assessments, formulate activity level propositions, and assign likelihood ratios for biological evidence given activity level propositions. This knowledge provides attendees with tools to handle hypothetical questions commonly asked in court, how to recognize poorly worded questions, and provide answers to these hypotheticals in a scientifically correct manner.

**Impact Statement:** This presentation will impact the forensic science community by providing guidance for real-world testimony on how to handle DNA testimony when the court’s interest is beyond that of an “inclusion” and its associated sub-source likelihood ratio.

This workshop will demonstrate peer reviewed, published methods for evaluating DNA evidence given activity level propositions as well as related testimony at court. DNA testimony has moved past the “Who?” questions related to the source of the DNA and it is now common for questions to be asked about “How?” the DNA ended up on the evidence item. While this is often done using hypothetical questions designed to elicit vague answers about “possible” or “could have” or “consistent with”, there are published frameworks and reporting and testimony guidelines available to assist both experts and the court. This workshop will cover the theory and application of Case Assessment and Interpretation (CAI) and Bayesian networks (BN) to evaluate DNA evidence profiles given activity level propositions and the communication of these results via report writing and testimony. A combination of lectures, demonstrations, and hands-on group activities will be used in this workshop. Challenges in both the evaluation of the evidence and testimony in an adversarial court system will be addressed as well.

There are numerous misconceptions and misunderstandings regarding the interpretation of DNA evidence given activity level propositions. Questions in court often focus on hypothetical DNA transfers (e.g., “Is it possible that DNA transferred during such-and-such activity?”), though many people don’t realize that by answering, they are testifying about activity level propositions. This workshop will demonstrate how to interpret DNA evidence and share expert knowledge using a scientifically sound framework and published practices when questions about the evidence relate to what may have happened.

In the morning session, participants will learn (1) how to formulate activity level propositions in accordance with the 2020 recommendations of the DNA Commission of the ISFG [1], (2) conduct a case pre-assessment using the Case Assessment and Interpretation (CAI) framework [2,3], and (3) assign likelihood ratios for DNA evidence given activity level propositions. After these lectures, the participants will understand the difference between Transfer-Persistence-Prevalence-Recovery (TPPR) and an activity level proposition. In addition, an introduction to Bayesian networks will provide the participants with an understanding of what Bayesian networks are, and how this approach may be used to assign the probabilities in the numerator and denominator of a likelihood ratio.

In the afternoon sessions, participants will first explore a hands-on exercise to apply this newly acquired knowledge and skill set on a mock case. Strategies for how to read forensic DNA literature to inform probabilities will be discussed. In the second half of the afternoon, the workshop will cover court testimony of biological evidence. In this part of the workshop, the participants will learn to handle the hypothetical questions that are commonly asked in court, and importantly, learn how to model responses to hypothetical questions.

After attending this workshop, participants will be able to recognize poorly worded questions and how to answer them in a scientifically correct manner by testifying on the evidence rather than on what happened (i.e., avoid the transposed conditional). The workshop will conclude with a discussion and a question and answer session. This workshop will provide attendees with examples of the scientific framework, knowledge, and skills to effectively evaluate DNA evidence given activity level propositions and to correctly present this information in court testimony.

### Forensic DNA; Evaluation; Activity Level

## W14 Applications of Digital Forensic Audio/Video for Real Life Challenges With DeepFake Video, Audio, and Artificial Intelligence

*Catalin Grigoras, National Center for Media Forensics, Denver, CO; Zeno J. Geradts, NFI/University of Amsterdam, Den Haag, Zuid-Holland, Netherlands; Cole Whitecotton, National Center for Media Forensics, Denver, CO*

**Learning Overview:** After attending this workshop, attendees will: (1) be familiar with the latest developments in forensic audio analysis and authentication; (2) understand criteria used for media authentication; and (3) understand how to conduct analysis within a forensic framework, and (4) multiple frameworks to use for DeepFake video detection.

**Impact Statement:** This workshop will impact the forensic community by: (1) explaining the scientific approach in forensic audio authentication; (2) demonstrating an authentication investigation framework; (3) discussing tools used to combat multimedia forgery; (4) showing multiple frameworks to use for DeepFake video detection.

Digital multimedia authentication seeks to determine the validity of digital multimedia containers and contents by investigating their format, structure, time, frequency, pixel, and/or sample level features. This workshop will discuss the digital audio and video analysis process providing the user with methods of detecting and authenticating audio, including DeepVoice and DeepFake videos. It will also demonstrate the incorporation of multiple tools and techniques into unified frameworks appropriate in forensic examinations where reducing examiner bias and error is crucial.

**Section 1—Audio:** We propose a one-hour workshop covering audio analyses and authentication. The goal of this workshop is to provide an overall view of conducting comprehensive examinations that rely on the results of multiple analyses to inform an ultimate finding or opinion.

The workshop will focus on real-life audio challenges and solutions. The proposed audio authentication frameworks combine both container and content analysis to determine authenticity of the recording as well as the purported source.<sup>1,2</sup> Audio container analysis will exploit characteristics of the multimedia file format and structure while content analysis will cover time and frequency domain techniques including quantization level, power, direct current offset, butt splice, spectral, and Multidetector Computed Tomography (MDCT) analysis.

**Section 2—Video:** We will discuss the use of Artificial Intelligence (AI) to detect deepfakes with explainable methods. We will also cover other methods for analyzing deepfakes, including:

- Blood flow analysis can be used to detect deepfakes by looking for inconsistencies in the blood flow of the face. Deepfakes often have unnatural blood flow patterns, which can be identified by AI-powered software.
- Lip sync analysis can be used to detect deepfakes by looking for inconsistencies between the movement of the lips and the audio track. Deepfakes often have lip movements that are not synchronized with the audio, which can be identified by AI-powered software.
- Electric network frequency analysis can be used to detect deepfakes by looking for inconsistencies in the electric network frequency of the video. Deepfakes often have a different electric network frequency than the original video, which can be identified by AI-powered software.
- Photo Response Non-Uniformity (PRNU) analysis can be used to detect deepfakes by looking for inconsistencies in the PRNU pattern of the image. PRNU is a unique pattern of noise present in all cameras. Deepfakes often have a different PRNU pattern than the original image.
- Visual analysis can be used to detect deepfakes by looking for inconsistencies in the appearance of the face. Deepfakes often have unnatural skin texture, lighting, or shadows. Visual analysis can be done by humans or by AI-powered software.

We will also discuss the limitations of each of these methods and how they can be used together to improve the detection of deepfakes. We hope this workshop will provide you with a comprehensive overview of the methods available for detecting deepfakes.

### DeepFake; Digital Forensics; Audio Video

## W15 To Tell the Truth: Perspectives on the Practice of Courtroom Testimony

*J.C.U. Downs, ForensX, LLC, Johns Island, SC; Gina Londino-Smolar, Department of Chemistry & Chemical Biology, Indiana University–Purdue University Indianapolis, Indianapolis, IN; Marc A. LeBeau, FBI Laboratory, Quantico, VA; Ken E. Melson, The George Washington University, Kinsale, VA; Tamela Adkins, Superior Court, Gwinnett County Georgia, Lawrenceville, GA; Michelle Medina, The Baez Law Firm., Miami, FL; James L. Caruso, Office of the Medical Examiner, Denver, CO; Craig Ackley, Compendia, Inc./Forensic Case Solutions, Inc., Nashville, TN*

**Learning Overview:** Upon completion of this workshop, attendees will be better able to understand and perform one of the most challenging parts of any forensic practice—courtroom testimony in its many forms, be it civil or criminal; federal, military, or state; and deposition or trial.

**Impact Statement:** This workshop will impact the forensic science community by providing a multidisciplinary look at the why and how of the practice of courtroom testimony, including recognizing potential challenges and pitfalls.

This session is a multidisciplinary workshop focused on courtroom testimony. The sessions are geared for all levels of experience from novice to seasoned professionals. While the speakers will focus on subjects that include training, preparation, cognitive bias, courtroom technology, and “high-profile” cases, the sessions will explore criminal versus civil, deposition versus trial, state versus federal versus military, etc. Various perspectives from the different stakeholders involved are addressed—judge, prosecutor, defense, professional, and consultant.

Regardless of the particular section, all the forensic sciences converge in the courtroom with testimony regarding the findings. While there are expected customs and duties assigned to the various parties involved, there is not—nor can there actually be—any single “standard” for a witness and how they tell their story. While the basics are generally well-known, the court officials have various interests in their individual takes of “the truth, the whole truth, and nothing but the truth.” Certain topics can affect that sworn duty: training, preparation, cognitive bias, courtroom technology, and “high-profile” cases.

In our adversarial justice system, the judge – as the gatekeeper – is the arbiter of what is allowed. In the criminal courts, the jurisdiction sets the rules, with an overall movement toward the Federal Rules of Evidence. The prosecution has specific duties to provide information to the defense. Generally, the government has as its witnesses those government personnel already assigned to the task as day-to-day forensic scientists employed by the venue’s forensic laboratory. On occasion, consulting experts are called in to assist with the case, but this can prove expensive and be a “difficult sell” to those in control of finances, since the work has already been done and paid for by a regular employee. The defense generally can seek out an expert, but there are various constraints they potentially face, two significant ones being funding and availability. In civil proceedings, attorneys for the plaintiff and respondent are both reliant on those same government employees, but both sides are free to and do routinely engage consulting forensics practitioners.

Regardless of the venue, information is elicited from witnesses by means of a series of questions intended to provide the desired information *in a specific way* and *in a specific order*. How information is elicited varies widely, depending on the attorney’s strategy. The witness is limited in how they are allowed to respond, with the judge serving as final authority as to what is responsive to the question asked. A witness cannot volunteer information but should only respond to the question asked. Attorneys for both sides should be fully cognizant of the facts and should follow up as needed to fully provide the information sought from the witness. Prosecutors additionally have a duty to provide any information they believe to be potentially helpful to the defense. The witness, unlike counsel, is not an advocate but should be an objective—a neutral analyst who looks at the data in a specific case and then provides a reasoned interpretation of the information with their ultimate conclusion. Although the mechanics are similar across all jurisdictions and in all courts, human personalities come into place to make the whole process even more interesting.

This workshop will focus on the many factors that make up court testimony. Various perspectives from the different stakeholders involved are addressed, with special focus on training, preparation, cognitive bias, courtroom technology, and “high profile” cases. The purpose is to better understand and perform one of the most challenging parts of any forensic practice—courtroom testimony.

---

### Evidence; Lawyer; Court

## W16 Statistics and Forensic Science: From Probability to Black Box Studies to Likelihood Ratios

*Linton Mohammed, Forensic Science Consultants, Inc., Poway, CA; James Green, Eugene, OR; Michael J. Salyards, Compass Scientific Consulting LLC, Tucson, AZ; Hal S. Stern, University of California, Irvine, Irvine, CA*

**Learning Overview:** After attending this workshop, attendees will: (1) be familiar with the language and key concepts of probability, including the role of populations and sample, laws of probability, dependence/independence of events, conditional probability and Bayes' rule, and the Likelihood Ratio (LR); (2) be familiar with the language and key concepts of statistical inference, including the role of data collection, measurement, error rates, reliability and validity; (3) understand issues associated with the design, execution, and interpretation of black box studies; (4) understand statistical hypothesis testing and its relevance for the two-stage approach for analyzing forensic evidence; and (5) understand the likelihood ratio/Bayes factor approach to assessing forensic evidence along with its strengths and weaknesses.

**Impact Statement:** Understanding the applications of statistics by the forensic science community will assist practitioners, attorneys, and jurists in evaluating evidence and opinions. This workshop will impact the forensic science community by leaving attendees in a position to better understand and engage in ongoing discussions (in the Organization of Scientific Area Committees [OSAC] and other places) about appropriate approaches to assessing forensic evidence and reporting forensic conclusions.

This workshop introduces key concepts in probability and statistics for forensic practitioners by linking them to key topics that are currently impacting the forensic community. The target audience is anyone from the forensic science community (practitioners, lawyers, judges, advocates) with a desire to better understand ongoing conversations about error rates, black box studies, inconclusive findings, and LRs.

The analysis of many types of forensic evidence, including handwriting, firearms (bullets and cartridge cases), latent prints, and glass fragments, requires the comparison of items, usually one of questioned origin and one or more from a known source, to assess their similarity and probative value. Tools from probability and statistics play a critical role in the logical assessment of forensic evidence.

The workshop is organized into four sections. The first section reviews the definition of probability and key concepts, including conditional probability, independence, and Bayes Rule that are relevant to forensic scientists. The concepts are illustrated through court cases where they arise naturally.

The second session addresses data collection (statistical sampling), design of experiments and studies, and statistical measurement. Important measurement concepts like bias, variance, reliability, and validity are discussed. This leads naturally to a discussion of the strengths and weaknesses of black box studies. Results from some of the published black box studies are reviewed.

The third section reviews more formal statistical concepts like estimation and hypothesis testing. These are discussed primarily in the context of a two-stage approach to the analysis of forensic evidence; the two-stage approach first makes a determination as to whether a questioned and known sample can be distinguished, then attempts to assess the probative value of the resulting conclusion.

The final part of the workshop addresses the LR framework for assessing forensic evidence. The LR has been used in the analysis of DNA evidence for many years. This section of the workshop reviews the motivation for the LR, the way it works in DNA, the challenges associated with using the LR for pattern evidence, and the relationship of the LR with other approaches. Newer approaches that rely on scores (e.g., FRSTATS) are also discussed.

The workshop is intended to leave participants in a position to better understand and engage in ongoing discussions (in Academy Standards Board [ASB], OSAC, and other places) about appropriate approaches to assessing forensic evidence and reporting conclusions.

---

### Statistics; Forensic Science; Evaluation

## W17 Crime Scene Reconstruction: Using Critical Thinking, Logic, and Reflection

David Pauly, Methodist University, New London, NC; Steve Downs, Methodist University, Fayetteville, NC; Bryan W. Brendley, Methodist University, Greensboro, NC; Douglas Young, Thornton Police Department, Broomfield, CO

**Learning Overview:** The goal of this workshop is to assist attendees in understanding and implementing the scientific method of inquiry to criminal investigations and forensic science problems by the use of physical evidence, objective data/information, artifacts of affect, and methods/processes of reasoning, logic, and cognitive learning within the contextual bounds of where this data/information is located, to derive knowledge regarding a particular incident and, when possible, to provide a chronological sequence to the incident.

**Impact Statement:** This workshop is critical to all forensic scientists, crime scene investigative personnel, detectives, pathologists, and attorneys charged with investigating violations of law. By understanding logic, critical thinking, and reasoning, the law enforcement and forensic professional will better understand how their own biases and/or lack of knowledge and understanding can impact this forensic science community's decision-making process that could lead to a flawed outcome or conclusion.

This workshop is applicable to all forensic science disciplines and will begin with an overview of forensic reconstruction in a broad sense, followed by detailed information on how people process information to come to a conclusion, and culminating with a hands-on practical exercise involving all attendees who will implement the concepts studied and presented. During this presentation, attendees will be instructed on the background of reconstruction and how, by using a multidisciplinary systematic method of inquiry to problem-solving, they will be more likely to come to a logical and factual outcome.

Since the mid-1950s, the United States population has nearly doubled to an estimated 330 million citizens. Crime of all types remains a significant problem, with most metropolitan centers having a higher concentration. Estimates place law enforcement solve rates of most crimes below 20%, with homicide hovering around 60% nationally.

Technology has exploded in law enforcement with the use of aerial drones, 2D panoramic and 3D scanners, along with portable alternate light sources being more available and utilized than ever before. Despite all the advances in technology, there remains a need for law enforcement and forensic science professionals to understand *Reconstruction*. Reconstruction is most thought of as the physical reconstruction of a motor vehicle collision, bloodstain pattern, fire scene investigation, aviation disaster, or bullet trajectory.

This workshop will begin by introducing attendees to the fundamentals of how a person thinks, how they process information, and some of the pitfalls of drawing a conclusion without sufficient knowledge. Evaluating a crime scene, damage to a vehicle, or injury to a body remains a crucial part of crime solving, including the process of refuting that a crime occurred as alleged, or at all. This workshop will provide attendees with a better approach to all investigations by providing a better foundation to problem solving that directly impacts the physical reconstruction process.

Attendees will receive instruction on the implementation of the scientific method of inquiry to criminal investigations and forensic science problems by use of physical evidence, objective data/information, artifacts of affect, and methods/processes of reasoning, logic, and cognitive learning within the contextual bounds of where this data/information is located, to derive knowledge regarding a particular incident and, when possible, to provide a chronological sequence to the incident.<sup>1-11</sup>

### Decision Making; Shootings; Bloodstains

## W18 Campus Shootings in America: Is There More We Can Do?

*Betsy Adelizzi, Missouri Southern State University, Joplin, MO; Patricia Smith, Harris County District Attorney's Office, Houston, TX; Timothy Wilson, Missouri Southern State University, Joplin, MO; Travis Walthall, Missouri Southern State University, Joplin, MO; Patricia Williams, Franklin, TN*

**Learning Overview:** The goal of this presentation is to provide an overview of campus shootings in America and continue with legislative and legal updates through case analyses. This workshop will explore gender, mental illness, behavior, victimology, and weaponry. Attendees will be able to assess their role in making positive and effective changes to policy, practice, and research within and among multiple disciplines. Attendees will have the opportunity to discuss their existing practices and brainstorm alternates throughout the presentation.

**Impact Statement:** This presentation will impact the forensic science community by reminding all attendees of their role in making positive and effective changes to eliminate campus shootings by focusing on our historical, at the time of, and post-incident responses and by using case analyses to encourage accountability and promote real-time collaborative research and practices within multiple disciplines.

The goal of this presentation is to create an open and honest dialog about shootings on campuses across the United States. "Violence . . . crosses racial and gender boundaries, as these horrific acts affect every racial group, social class, ethnicity, gender, and any time other category one can image."<sup>1</sup> The forensic science community and the criminal justice system as a whole has the responsibility of ensuring public safety through meaningful and structured analyses, collaboration, and behavior-based changes to prevention and responding to incidents.

The United States has seen staggering numbers of mass shootings since the 1960s and increasing incidents at educational institutions.<sup>1</sup> Mass shootings are statistically rare, accounting for less than 1% of all firearm homicides in the United States.<sup>2</sup> However, mass shootings on campuses are growing and leaving behind a trail of gross destruction that emotionally outweighs the number of incidents.

According to The Violence Project, most mass shooters experienced childhood trauma; were exposed to violence at a young age; had an identifiable grievance or crisis point; have studied the actions of past shooters and sought validation for their methods and motives; and had the means to carry out an attack.<sup>2</sup> A mass shooter profile is unique to their targeted location and often includes some level of mental illness. A one-size-fits-all profile does not exist.

Gender does play a minor role in the type of shooter, although most are male. According to a November 2011 United States Department of Justice Report, women committed just 6% of all murders with multiple victims, four studied under the Violence Project, and two of those cases involved a male partnership.<sup>3</sup>

There are signs of shooter crises. There are specific changes in behavior that are noticeable to others. There are frequent incidents where concerns about a shooter's behavior was identified and reported but not taken seriously or connected until after an incident.

Weaponry and access to firearms brings up much concern and debate. Handguns were present in over three-fourths of all mass shootings. However, at least one semiautomatic assault weapon, rifle, and/or shotgun were included.<sup>2</sup> Background checks are required, but sharing background check information has demonstrated inconsistency and, in some cases, failed completely.

This presentation will include an overview with case analyses. We will discuss law enforcement responses and what improvements can be made at all phases of an incident. Further, we will discuss the type of weaponry and how mental illness plays a role in the incidents and what practical implications can be derived from our case analyses through open dialog with the audience, hoping to reduce violence on campuses and improve related policy and practice through inclusive and diverse research and analyses.

### School Shootings; Weapon Analysis; Mental Health

## W19 Forensic Scientists on the Front Lines

*Agnes D. Winokur, Laboratory Director, DEA, Miami, FL; Barry K. Logan, PhD, Executive Director, CFSRE, Horshan, PA; Alex J. Krotulski, Associate Director, CFSRE, Abington, PA; Larry D. Fluty, Assistant Commissioner, U.S Customs & Border Protection, Montgomery, TX; Scott R. Oulton, Deputy Assistant Administrator, Drug Enforcement Administration, Springfield, VA; Jonathan McGrath, Principal Technical Advisor, U.S. Customs and Border Protection, Houston, TX; Sarah A. Shuda, Senior Scientist, CFSRE, Willow Grove, PA;*

**Learning Overview:** After attending this workshop, attendees will be able to discuss examples of teamwork approaches that place forensic scientists on the front lines, addressing the challenges associated with the growing number of emerging drug substances and precursors, the complexity of the analysis, and the impact on enforcement and intelligence investigations. Attendees will be able to: (1) describe how forensic techniques can be used beyond simply reporting the presence of controlled substances to provide insights into changes in drug manufacturing and distribution practices; (2) evaluate the differences in analytical capabilities and workflow strategies provided in central laboratories versus front line laboratories; and (3) explain how forensic analysis impacts intelligence gathering to support investigations, health, and safety.

**Impact Statement** This workshop will benefit the forensic science community by highlighting the impacts of forensic science collaborations on investigations, epidemiology, drug intelligence, public health, and canine training and operations. It will also highlight how deployment of laboratories on the front lines strengthens the efficiency of these operations, utility of the results, and timeliness of testing.

Forensic science is typically practiced in the controlled environment of a laboratory. The laboratory setting can house high-tech instrumentation, offer a more stable environment for standardization and contamination control, and provide optimal conditions for peer review and quality systems implementation.

The needs, role, and impact of forensic science have been transformative, increasing its use by the investigative sciences, law enforcement, medical examiners and coroners, crime and death scene response, border agencies, and national security agencies, and even extending to other professional domains like canine detection teams, public health agencies, drug intelligence agencies, and others.

These initiatives require scientists to leave the laboratory setting and employ best practices to support these investigative efforts, explore new field-friendly technologies, develop creative ways to expand laboratory services to the field environment, rely on reach-back approaches to support what is feasible in the field, and make the best of difficult environments without sacrificing the quality and standards expected by the public and the courts for both investigative and forensic work.

This workshop will provide insights into various examples of forensic scientists working on the front lines supporting investigations or collection of intelligence that supports public health and public safety agencies. Examples include satellite laboratories from the Canada Border Services Agency, known as Designated Safe Sampling Areas, within Ports of Entry with high interdictions of illicit drugs, equipped with advanced real-time drug identification technology. Similarly, the United States Customs and Border Protection (CBP) established Forward Operating Laboratories, which utilize Fourier-transform infrared spectroscopy, Gas Chromatography/Mass Spectrometry (GC/MS), and colorimetric technologies to perform preliminary drug screening at United States border inspection sites, including international mail facilities. These compact, chemist-led labs are designed to provide border and law enforcement officers along with crime and intelligence analysts the advanced real-time drug identification needed to improve their ability to seize narcotics, collect intelligence information, decrease response-time of informing law enforcement partners, and support border security.

A key component of border security and drug interdiction is the use of specially trained canines to aid with screening and searches. CBP will present on their laboratory program to test, develop, and maintain narcotics and pseudo-narcotics training aids. The CBP program is developing science-based strategies to strengthen canine training and operations, using solid phase microextraction GC/MS to characterize the chemical odor profiles of target materials. This CBP canine program provides a model for how forensic laboratories can strengthen drug interdiction strategies.

Working in collaboration with customs officers to obtain authentic current drug seizures and test them for potency, purity, the presence of adulterants, and evidence of unreacted precursors and reaction byproducts, in addition to supporting the development of drug canine training aids, helps investigators identify changes in the methods of drug synthesis, packaging, and tableting. This workshop will feature data from a CBP collaboration with the Center for Forensic Science Research and Education (CFSRE) on fentanyl profiling to determine insights into changing drug manufacturing and smuggling practices. This will include a review of current synthetic methods for fentanyl and related compounds and the identification of analytical markers for different synthetic routes as well as data analytics on fentanyl signatures from various points of seizure. The CFSRE will also present data from collaboration with public health agencies, which provides a real-time look at what drugs and drug combinations are circulating at the street level. Scientists from the Drug Enforcement Administration (DEA) will also discuss their collaboration with CBP and Food and Drug Administration (FDA), bringing scientists to the front lines and expanding scientific expertise to supplement intelligence and investigative information, providing a more comprehensive and holistic picture of the illicit fentanyl supply.

## W20 Moving Toward High Reliability in Forensic Science

*Brian J. Gestring, 4n6services, Guilderland, NY; Laura C. Fulginiti, Maricopa County Office of the Medical Examiner, Phoenix, AZ; K. Scott Griffith, SG Collaborative Solutions, Roanoke, TX*

---

**Learning Overview:** After attending this workshop, attendees will have learned to see, understand, and manage risk within their operations.

**Impact Statement:** The work product of forensic providers is critical to the criminal justice system. While there have been advances in overall quality over the years, forensic providers still find themselves reacting to adverse incidents as they become front-page headlines. This presentation will impact the forensic science community by informing attendees of proactive approaches that will prevent adverse events from occurring and mechanisms that can be put in place to quickly recover from these incidents if they do occur.

Socio-technical systems are made up of humans interacting with technology within the confines of an organizational culture. Forensic practice is socio-technical because it involves all these elements. Attendees will learn to see, understand, and manage risk in each of these elements to increase their overall organizational reliability and will be informed as to how to take steps to make their operations resilient.

In recent years, there have been significant advances in the quality associated with forensic practice. Systems are being put in place to manage quality assurance and quality control, but forensic practitioners are still inexperienced in managing risk.

In layman's terms, risk is the potential of something going wrong. As individuals, we manage risk every day, and our judgments differ based on the severity of the potential negative outcome. Our risk tolerance is higher when we rummage through the refrigerator evaluating expiration dates than when we evaluate getting an elective surgery.

For organizations to become reliable, they must learn how to evaluate the risk in each element of the socio-technical system. The first step in this process is seeing the risk. While there are many cognitive biases that can interfere with seeing risk, the most pernicious is outcome bias. If a specific behavior is "risky," it must be changed, regardless of the outcome. Unfortunately, the outcome of an adverse event will dramatically change an organization's response. We even see this in our society. The penalty for being caught driving under the influence is significantly different for drivers that are apprehended after a routine traffic stop than for those involved in fatal accidents.

Even if we see a risk, we don't always fully understand it. After the outbreak of the novel coronavirus (COVID-19), authorities were aware of the disease, but they did not fully understand how COVID-19 was different from a previous outbreak of respiratory disease that occurred in 2003.

Once risk is seen and understood, it then has to be managed. Risk avoidance is not always possible, so high-risk processes must have recoveries in place should an adverse event occur. In the medical field, administering certain medications can be a high-risk process and it can't be eliminated. Both technological and human processes can be put in place to try and prevent the wrong medication from being administered. Technologically, a system can be put in place to only dispense the medication and doses prescribed. Humans can also be used to double-check that the proper medication is being dispensed.

While these barriers and redundancies will make the system reliable, if the improper medicine or dose is inadvertently administered, having an antidote on hand will make the system resilient because it will allow the reliable system to quickly recover from an adverse event.

There is a pattern to how bad things happen and a science for preventing them. Moving toward high reliability and resiliency in forensic practice should include learning how to see, understand, and manage the risks associated with our work.

---

### High Reliability; Risk; Resiliency

## W21 Investigation and Certification of Intoxication Deaths for the Non-Pathologist

*James R. Gill, Office of the Chief Medical Examiner, Farmington, CT; Laura Labay, NMS Labs, Langhorne, PA; Kelly Keyes, RTI, International, Yorba Linda, CA; Candace H. Schoppe, San Diego County Medical Examiner's Office, San Diego, CA*

**Learning Overview:** The goal of this presentation is to introduce attendees to the essential components necessary for competent medicolegal death investigation and proper certification of suspected substance-related deaths. Experts from their respective fields will discuss death investigation, autopsy, and forensic toxicology. This program focuses on practical information that can be used by the non-pathologist and the pathologist-in-training to understand the necessary task of investigating and certifying these deaths. The importance of proper death certification for public health and safety purposes will be stressed. Upon completion of this educational activity, attendees should be able to: (1) recognize relevant investigative information and where to obtain it; (2) understand the role of the autopsy in these investigations; (3) critically interpret toxicology testing in the context of the entire case investigation; (4) understand the role of the forensic toxicologist; and (5) understand how drug intoxication deaths are certified and how they affect the public health and criminal justice systems.

**Impact Statement:** This presentation will impact the forensic science community by providing non-pathologists with practical information to help them understand the medicolegal investigative process, toxicological testing, and result interpretations to facilitate the recognition, investigation, and certification of drug intoxication deaths. Attendees will learn what investigative findings raise suspicion for an intoxication death, the importance of interpreting postmortem toxicology results in light of the investigative and autopsy findings, and the critical roles of the forensic toxicologist and forensic pathologist. Ultimately, this will lead to an appreciation of how accurate death certification impacts public health and the criminal justice system.

This workshop brings together experts in medicolegal death investigation, forensic pathology, and forensic toxicology to discuss the investigation and toxicological analysis when substance use is suspected, focusing on identifying and certifying these deaths. Common problems faced during the investigation, confounding or competing findings at autopsy, and pitfalls in postmortem toxicological testing and interpretation will be explored. To properly certify these deaths, experts will discuss the impact of information gained from the investigation of the circumstances, autopsy, and appropriate postmortem toxicological testing.

Over the past ten years, the number of accidental, substance-related deaths has increased to epidemic levels and constitutes a public health crisis. Annually, over 100,000 people have died from accidental drug intoxications in the United States in 2021 and 2022. This, combined with a workforce shortage of forensic pathologists, has further strained medicolegal death investigation systems and forensic toxicology laboratories. Despite these hindrances, the joint efforts of the medicolegal death investigator, forensic toxicologist, and forensic pathologist are still needed to investigate and certify deaths due to drug intoxications.<sup>1</sup>

Attendees will be introduced to the essential components necessary for competent medicolegal death investigation and proper certification of suspected substance-related deaths. This program focuses on practical information that can be used by the non-pathologist and the pathologist-in-training to understand the necessary task of investigating and certifying these deaths. This workshop brings together experts to illustrate their specialized roles in investigating accidental substance use deaths.

The medicolegal death investigator considers the circumstances and looks for clues at the scene and on the body to assess the likelihood that a particular death requires further investigation (e.g., a postmortem examination). The initial triage of the report of any death is a critical step. Once jurisdiction is declined, it is rare to get a second opportunity to reconsider. Numerous investigative signs and autopsy findings associated with drug use, some subtle, are presented.

The forensic pathologist is at the center of the investigation of the cause of death and, in addition to performing the autopsy, correlates the death investigator's and toxicologist's findings.<sup>2</sup> Not performing an autopsy may lead to missing other possible causes of death, such as disease or trauma, that supersede the drug intoxication as the cause of death. The benefits of the autopsy in excluding other or contributing causes of death are highlighted.

The forensic toxicology laboratory analyzes biological samples using the context of the case history to help direct testing so that drugs of forensic relevance are detected and quantified. Analytical scopes and methodologies will be discussed, particularly in the context of novel psychoactive substances.<sup>3</sup>

Common pitfalls encountered during each stage of the investigation and death certification process also will be demonstrated through practical case examples, as they can affect proper scene investigation, triage, toxicology testing, result interpretation, and certification.<sup>4</sup> The important professional relationships and interactions among the medicolegal death investigator, toxicologist, and pathologist are elucidated.

Overall, this presentation will impact the forensic science community by providing non-pathologists and pathologists-in-training with an understanding of how toxicology testing factors into death investigations and how the pathologist determines if a person died *of* drug intoxication or simply died *with* a drug intoxication so that the death is correctly certified. The importance of proper death certification for public health and safety purposes will be stressed.

## W22 How Should Forensic Genetic Genealogy (FGG) Navigate the Court System? A Mock Cross Examination

*Colleen M. Fitzpatrick, Identifinders International LLC, Fountain Valley, CA; Karra Porter, Intermountain Forensics, Salt Lake City, UT; Michael Coble, Center for Human Identification, University of North Texas Health Science Center, Ft. Worth, TX; Mitch Morrissey, United Data Connect, Lakewood, CO*

---

**Learning Overview:** By attending this workshop, attendees will gain a perspective on important issues related to the introduction of FGG in court, from both the prosecution and defense points of view. The mock trial and subsequent discussion will also provide FGG practitioners with insight into how to present expert testimony.

**Impact Statement:** This presentation will impact the forensic science community through a demonstration of the cross examination of a qualified, competent FGG expert witness, to show in real time various technical and legal challenges that may arise in court as FGG moves further into the judicial system.

This workshop provides insight into the technical and legal challenges that may arise during cross examination, in the context of challenges the community faces if FGG should move further into the court system.

FGG was recently introduced into court as an investigative lead in the trial of Patrick Leon Nicholas for the 1991 murder of high school senior Sarah Yarborough in Federal Way, WA, as a way to address privacy concerns that the defense raised related to the state constitution. This landmark case has brought to the forefront important issues concerning the relevance of introducing FGG in court. FGG can only produce investigative leads; ultimately, legal identification depends on a Short Tandem Repeat (STR) match to crime scene DNA.

As FGG has helped solve many hundreds of cold cases, it is inevitable that it will move further into the criminal justice system. The Yarborough case is only one of a very few examples to date of expert witness testimony on the subject; as more occur, it is critical to develop an understanding of the role that FGG plays in solving a case in relation to issues that may arise with its introduction at trial. At present, the FGG community offers few courses in professional development in a larger sense and very few, if any, covering expert witness testimony.

An expert witness must meet ANSI National Accreditation Board (ANAB) and Organization of American Studies (OAS) standards, which brings up concerns over the lack of training and professional background of FGG practitioners. An expert is viewed not as a subject matter expert in a narrow sense, but as a person qualified by knowledge, skill, experience, training, or education; that is, a practitioner broadly defined as an expert by his education and relevant work experience. Without further training, practitioners called to testify in the near future will have little experience preparing for trial testimony, with insufficient knowledge of what to expect.

By observing a mock FGG cross examination in real time involving a case where FGG provided investigative leads resulting in an arrest, attendees will learn how a qualified, competent expert witness can respond to issues that may arise at trial, such as credentialing of FGG practitioners, ongoing communication with an agency, apparent biases for or against law enforcement, and the use of unaccredited laboratories for producing FGG Single Nucleotide Polymorphism (SNP) data.

---

### Cold Case; Genealogy; Court

## W23 The Impact of Burning on Skeletal and DNA Evidence

*Jane E. Buikstra, Arizona State University, Tempe, AZ; Katelyn L. Bolhofner, Forensic Anthropology, Arizona State University, Glendale, AZ; Joanne Devlin, University of Tennessee, Knoxville, TN; Giovanna Vidoli, Forensic Anthropology Center, University of Tennessee, Knoxville, TN; Anne Stone, Arizona State University, Tempe, AZ; Laura C. Fulginiti, Maricopa County Office of the Medical Examiner, Phoenix, AZ; Cody E. Parker, School of Human Evolution and Social Change, Arizona State University, Gilbert, AZ; Erin M. Rawls, Arizona State University, Tempe, AZ*

**Learning Overview:** After attending this workshop, attendees will have learned how fire affects bodies and the ability of researchers and forensic practitioners to obtain skeletal and DNA evidence. Attendees should be able to: (1) describe methods used to characterize the extent of burning in bone; (2) understand the effects of burning on bodies, (3) appreciate the different extraction methods applied to burned and highly degraded skeletal tissues, and (4) evaluate which downstream analyses are likely to produce useful data for case identification.

**Impact Statement:** The recovery and analysis of skeletal evidence and DNA from burned human remains represent some of the most challenging cases in medicolegal investigations. This workshop will impact the forensic science community by increasing attendees' understanding of how burning affects the body and DNA preservation. Specifically, attendees will understand the characteristics used to score the level of burning in bones and the protocols used for optimal recovery of DNA from burned bone and tissue.

The presenters will provide an overview of how bodies burn from case examples as well as experimental burning of complete human bodies and will discuss the classifications used to describe the extent of burning (i.e., the temperatures reached) in bone by previous researchers. Attendees will also learn about DNA extraction methods that have been applied to burned tissue and bone. The presenters will discuss the success of these methods based on data from research projects examining the effects of burning on skeletal remains and on the recovery of DNA from those remains. Attendees will learn how the DNA recovered from these burned remains performs in subsequent Combined DNA Index System (CODIS) Short Tandem Repeat (STR) and Next Generation Sequencing (NGS) analyses that aim to test the limits of DNA recovery from fire-death victims. This workshop probes the methods (and challenges) for obtaining DNA using novel ancient genomic technologies optimized for maximum ultra-short molecular recovery as well as for obtaining skeletal evidence, including evidence for trauma, from burned human remains.

Thermal alteration of the human skeleton reduces the amount of DNA available for STR genotyping and downstream NGS analyses. As a consequence, the identity of many who died as the result of fire, such as some victims recovered from wildfires, house fires, or other medicolegal contexts, remain unknown. In this workshop, the presenters will discuss how fire affects bodies and the ability of researchers and forensic practitioners to obtain skeletal and DNA evidence. Attendees will first hear an overview of how bodies burn from case examples as well as experimental burning of complete human bodies. This discussion will include how burning affects evidence of trauma as well as the classifications that have been used by previous researchers to describe the extent of burning (i.e., the temperatures reached) in bone based on coloration and other tissue characteristics. The presenters will also provide details about DNA extraction methods that have been applied to burned tissue and bone, and we will discuss the success of these methods based on data from research projects conducted by researchers from Arizona State University with the Maricopa County Office of the Medical Examiner (MCOME) and the Forensic Anthropology Center (FAC) at the University of Tennessee, Knoxville. Attendees will learn how the DNA recovered from these burned remains performs in subsequent CODIS STR and NGS analyses. The NGS data enable comparisons of the success rates of DNA libraries generated using both single- and double-stranded methods for mitochondrial genome and genome-wide single nucleotide polymorphism (SNP) capture. These analyses aim to test the limits of DNA recovery from fire-death victims using a suite of these cutting-edge genomic technologies.

**A1 Increasing Access and Engagement at Academic Conferences: Comparing Modalities and Facilitating Interactions**

*Lisa Monetti\*, Drew University, Madison, NJ*

---

**Learning Overview:** After attending this presentation, attendees will understand barriers to access to academic conferences in the fields of forensic and biological anthropology. Attendees will also understand possible new directions for conference and session structure that will be more accessible and increase diversity of presenters.

**Impact Statement:** This presentation will impact the forensic science community as it will address barriers to access to academic conferences. It will highlight the value of diversity of presenters at academic conferences and show ways to make conferences within the forensic sciences more accessible. Developing more accessible spaces for sharing knowledge within forensic science propels the field toward greater inclusivity and diversity of scientific thought.

Changes implemented within higher education in response to the COVID-19 pandemic are innumerable. For one, international academic conferences shifted from in-person to virtual and hybrid modalities. By now, many have returned to in-person formats while others retain hybrid options.

Prior to the COVID-19 pandemic, hybrid conference modalities were rare, but it had been suggested that their implementation could increase accessibility, particularly for early career researchers and folks with other barriers to access, including geographic location. The pandemic posed an opportunity to interrogate whether this was, in fact, the case. Of course, geographic location of the author and the conference itself are not the only barriers to access, though many of the challenges are related to location, including travel costs, visa considerations, as well as perceived safety during travel and when sharing accommodation or staying alone. The author analyzed conference proceedings from the fields of forensic anthropology and biological anthropology to identify the proportion of first-author presenters who were from countries and continents other than those of the host institution, following the methodology of Hirst et al.<sup>1</sup> Findings suggest that these proportions remained largely unchanged regardless of the modality of the conference. Twenty-two percent of first authors were from out of the host country for in-person years, and 24% for hybrid and virtual modalities when considering the American Academy of Forensic Sciences (AAFS) and American Association of Biological Anthropologists (AABA) conferences from 2016–2022. Because we understand that diversity and accessibility are essential for progressing scientific thought, what can be done to increase access and international engagement at academic conferences?

An often-mentioned challenge within the discourse on virtual and hybrid conference modality is that of networking, which is seen as more difficult when attendees are not physically in the same space as one another. The author developed and employed an adapted conference session format during a virtual conference in 2021 that aimed to increase engagement, networking, and international collaboration in the virtual space. This included organizer engagement with authors ahead of the conference, leading to the authors writing open-ended questions focused on topics adjacent to their research but which they could not answer without increasing their collaboration with others. An increased number of discussion blocks were added to the session and these questions were discussed in groups to identify areas of future collaboration and increase interaction between speakers and attendees.

**Conference; Anthropology; Diversity**

## A2 Assessing Opportunities for Forensic Casework Experience for Students Through Educational Programs and Internships

*Katherine M. Lane\*, University of Central Florida, Winter Park, FL; Stephanie Fuehr, University of Central Florida, Orlando, FL; John J. Schultz, University of Central Florida, Orlando, FL; Kelly C. McGehee, University of Central Florida, DeLand, FL*

**Learning Overview:** This presentation utilizes survey data from forensic anthropology students to explore their opportunities and experiences with casework through academic programs and/or internships. After attending this presentation, attendees will have a better understanding of the opportunities available for forensic anthropology students and the gaps in accessibility for students to attain this crucial training.

**Impact Statement:** This presentation will impact the forensic science community by demonstrating that forensic anthropology students regard applied casework experience as essential to their professional growth in the field. Adequate forensic casework experience is crucial to prepare them to become forensic anthropology practitioners.

The American Board of Forensic Anthropology (ABFA) provides certifications for forensic anthropology practitioners who have demonstrated expertise in their field. However, currently no qualifications and competencies have been defined for forensic anthropology students, who are poised to become the next generation of practitioners. In order for students to become qualified forensic anthropology practitioners, there needs to be access to applied training in forensic anthropology while attaining undergraduate/graduate education. While other core competencies are required of forensic anthropology students, perhaps the most crucial is that of obtaining sufficient knowledge for practice and receiving practical experience. Therefore, students interested in pursuing forensic anthropology, and especially ABFA certification, must primarily master these skills and have the casework background necessary for practice while completing their degree(s).

This study investigates the opportunities for and experiences with forensic anthropology casework through degree programs and internships from the perspective of students. An Institutional Review Board (IRB)-approved electronic survey was distributed on July 12, 2023, and remained open through October 31, 2023. The survey is advertised to both student and practitioner participants, and the survey questions are generated based on which category defines a respondent. Both undergraduate and graduate students are able eligible to participate, and students are asked questions regarding basic demographics and relating to their personal experiences with forensic casework.

Descriptive statistics were generated for participant responses. Currently, 32 current forensic anthropology students (or recent graduates) have participated in the survey. Most respondents (56%) have completed a master's degree, followed by a bachelor's (36%). Of the 32 initial respondents, only 23 participants answered, "Have you assisted with/conducted forensic casework?"; of these, approximately 82% of respondents had casework experience. Students reported contributing to anywhere from 1 to 150 forensic cases, though only four respondents indicated analyzing more than 30 cases. Many students attained casework experience through degree programs (undergraduate [9%], master's [30%], and doctoral [21%]), while others (26%) received casework experience through an internship and/or visiting scientist program; 7% had not assisted with forensic casework. Of those students who had casework experience, they were able to contribute roughly equally to search and recovery, maceration, photography, skeletal analysis, and case report writing. Of those who assisted with writing case reports, the majority (36%) did not sign as author/co-author while 28% did. Through free-form questions, students shared similar sentiments about the importance of gaining casework experience while in school. For example, respondents noted that assisting with casework provides them with the opportunity to determine if forensic anthropology is the appropriate career path for them, apply the methods they have learned through coursework, learn how to write case reports, learn how to navigate the larger death investigation system in which forensic anthropologists operate, and become qualified to be a practicing forensic anthropologist.

These preliminary results indicate that, of the surveyed students, many forensic anthropology students have had experience with at least one forensic case through academic programs and/or internships. These findings demonstrate most forensic anthropology students are receiving some applied training, either in their educational programs or through internships. These results will be useful for students who do not receive hands-on learning to advocate for themselves or to provide emphasis for searching for external learning opportunities, such as internships. This study aims to stress the importance of obtaining practical forensic anthropology experience as a student.

---

### Casework; Survey; Anthropology

---

**A3      How Contextual Information and Consideration of the Type of Bones Present Influence Interpretations of Identifiability**

*Andrea Palmiotto\*, Indiana University of Pennsylvania, Indiana, PA; Allysha P. Winburn, University of West Florida, Pensacola, Florida; Christine M. Pink, Western Michigan University Homer Stryker M.D. School of Medicine, Kalamazoo, MI*

---

**Learning Overview:** After attending this presentation, attendees will better appreciate the impacts of human decision-making when assessing the identification potential of human skeletal remains.

**Impact Statement:** This presentation will impact the forensic science community by demonstrating that interpretations of the potential for skeletal remains to lead to individual identifications are minimally influenced by biasing contextual information. However, interpretations of identifiability may be swayed by the type of bones present in an assemblage.

Previous studies have demonstrated that forensic scientists are susceptible to the biasing effects of contextual information. In forensic anthropology, for example, indicators of cognitive bias have been identified in interpretations of both metric and morphological estimates of sex.<sup>1,2</sup> However, forensic anthropologists have also emphasized the capacity for quality-assurance protocols like blind analysis, peer review, and linear sequential unmasking to mitigate such contextual effects.<sup>1-3</sup>

The potential relationship between biasing contextual information and perceptions of identifiability is as-yet uninvestigated and formed the focus of this study. An online, anonymous, Institutional Review Board (IRB) -approved survey was sent to forensic anthropologists (n=155) and other individuals (including other forensic practitioners [n=121] and members of the public [n=48]). Participants examined a series of photographs of incomplete human skeletal remains and were asked to interpret the potential for the remains to be identified. Possible responses were limited to “Unlikely,” “Possible,” “Probable,” and “Very Likely.” One-third of participants viewed these photos with no accompanying contextual information, one-third were exposed to limited biasing context (e.g., “The following set of remains was recovered from a forensic context with several personal artifacts and other material evidence.”), and the remainder were exposed to extensive biasing context (e.g., “The following set of remains was recovered in association with panties, a bra, and breast implants.”). Two hypotheses were examined: (1) contextual information and (2) the type of bones present will impact perceptions of identifiability among other forensic practitioners and the public—but forensic anthropologists will not be biased by either context or type of bones present.

These hypotheses were based on the assumptions that forensic anthropologists, with their expertise in skeletal analyses and their familiarity with methods of skeletal identification based on multiple bodily regions, would recognize that biological inferences can be made from nearly any bone in the human skeleton. We assumed that other individuals, who may be less familiar with anthropological analytical capabilities, would be influenced by the contextual information and type of bones present. Therefore, we anticipated that forensic anthropologists would indicate that each set of remains had a “Very Likely” chance of being identified, while other respondents would vary in their responses.

Chi-square contingency tables were used to examine differences in responses based on type of participant (“forensic anthropologists” and “others”) and exposure to contextual bias (“none,” “limited,” or “extensive”). Responses indicated that participants generally were not swayed by biasing information. Regardless of contextual details or anthropological experience, participants reported similar interpretations of identifiability for two of the three photographs ( $p > 0.05$ ). However, all participants, including forensic anthropologists, were influenced by the type of bones present in the photographs. No matter the type of contextual details provided, each group (“forensic anthropologists,” “others”) reported “Very Likely” identifiability statistically significantly more frequently when the skull was present in an image compared to images with no skull present. Moreover, for the image of predominantly long bones (no skull, ribs, vertebrae, or bones of the hands and feet), interpretations varied significantly among all groups.

These outcomes indicate that estimates of identifiability are relatively resistant to the biasing effects of contextual information, regardless of who is making the estimate. This also suggests a greater awareness of forensic science analytical capabilities among the public. However, additional underlying assumptions—specifically about the analytical value of the human skull and other elements—may be affecting interpretations of skeletal assemblages and their identification potential. This study highlights an additional area that forensic anthropologists should consider when assessing human skeletal assemblages.

**A4 Mapping Barriers to Entry of Spanish-Speaking Students of Forensic Anthropology: Diversity in Academic Opportunities at United States Hispanic-Serving Institutions**

*Patricia N. Morales Lorenzo\**, Idaho State University, Pocatello, ID; *Samantha H. Blatt*, Idaho State University, Pocatello, ID; *Trace Miles*, Idaho State University, Pocatello, ID; *Bailey Bates*, Idaho State University, Pocatello, ID; *Juliette Bedard*, Idaho State University, Pocatello, ID

---

**Learning Overview:** After attending this presentation, attendees will be informed about barriers to entry in forensic anthropology for Spanish speakers within the United States and understand the need for increased availability and resources of forensic anthropological programs/degrees and opportunities available in Hispanic-Serving Institutions (HSI).

**Impact Statement:** This presentation will impact the forensic science community by demonstrating the need for recruitment and retention strategies for Spanish-speaking students in forensic anthropology by analyzing the availability and resources of forensic anthropology programs within United States HSI. This presentation further benefits the forensic science community by offering new strategies for improving educational opportunities for Spanish-speaking and other diverse students in forensic anthropology.

Diverse research groups have been shown to produce more novel findings, introduce more technological innovations, and research cited more often and by a wider audience.<sup>1</sup> Yet, the lack of diversity within forensic anthropology is well documented, with 87% reporting as non-Hispanic, White, forensic anthropology lacks diversity among its practitioners.<sup>1,2</sup> This lack of diversity of practitioners likely produces blind spots in regard to the needs, challenges, and culturally specific solutions of those the field serves. Even though 84.3% of forensic anthropologists believe that it is fundamental to recruit and retain diverse practitioners in the field, no equitable outreach strategies have been put into place. In fact, the homogeneity of the field increases from undergraduate to graduate to professional ranks, sifting-out diversity at each level.<sup>2</sup> While scholars have begun to examine the history of inequity in the field (e.g., race and gender, primarily) and call for strategies necessary to increase and support diversity (e.g., Goliath et al. 2023), language barriers have not been explored.<sup>3</sup> Numerous factors affect the enrollment and retention of minority students, but without interrogating the data, the forensic sciences cannot self-examine the barriers to diversity within the field or enact changes to attract and retain minority practitioners.

The lack of Spanish-language scholarship in forensic anthropology appears to reflect the lack of the field's diversity.<sup>4</sup> As part of a larger study exploring the experiences of Spanish-speaking forensic anthropology students and practitioners and the gaps in Spanish-language scholarship in the field, this study will present a Global Information System (GIS) map using the HSI database of the: (1) locations, (2) availability of biological and forensic anthropology courses, (3) degrees and certificates, (4) faculty mentors, and (5) enrollment costs, and other resources of United States HSI. As defined by the United States Department of Education, an HSI is an institution that has an enrollment of at least 25% full-time undergraduate students making them eligible for funding to provide expanded opportunities and resources for these students.<sup>5</sup> As of Fall 2020, 451 universities/colleges were classified as HSIs with 2,044,533 enrolled Hispanic students within 25 states and Puerto Rico. This data is compared to results from a random selection of non-HSI institutions within the United States that are listed as having forensic anthropology programs on the bioanth.org and AAFS.org websites. The map is intended for use as a resource for prospective students, committees on diversity, and demonstrates one aspect of gatekeeping for minorities in our discipline.

**A5 Using Cause of Death and Skeletal Indicators of Health and Stress to Understand Structural Inequality**

*Allyson M. Simon\**, The Ohio State University, Westlake, OH; *Tempest D. Mellendorf*, University of Tennessee, Knoxville, Rapid City, SD; *Colleen M. Cheverko*, Rush University Medical Center, Chicago, IL; *Melissa A. Clark*, Cleveland State University, Cleveland, OH; *Mark Hubbe*, The Ohio State University, Columbus, OH

---

**Learning Overview:** This presentation will demonstrate how Cause Of Death (COD) is related to different skeletal markers of physiological stress and health, namely linear enamel hypoplasia, stature, and antemortem tooth loss. After attending this presentation, attendees will understand how COD and skeletal markers of stress and health can provide useful information in medicolegal investigations when considered together. Both measures contribute contextual information about the deceased's lived experiences.

**Impact Statement:** This presentation will impact the forensic science community by showing that COD and skeletal markers of physiological stress and health are tools to uncover context about people's lived experiences. Combining information from COD and skeletal markers of stress and health can advance forensic investigations by reducing the number of possible identities and identifying events or factors that contributed to an individual's death.

The cumulative burden of physiological stress during an individual's life is reflected in a complex interplay of disease vulnerability, morbidity, and mortality. Stress responses are often related to COD, both of which can be used as a measure of population health.<sup>1</sup> Here, we investigate the association between COD and markers of physiological stress in a sample of 297 individuals from the Hamann-Todd Osteological Collection (HTOC), comprised of individuals from predominantly low socioeconomic statuses from the late 19<sup>th</sup>- to early 20<sup>th</sup>-century Cleveland. Those in the HTOC were largely employed as laborers or in unskilled trades and would have lived in areas of overcrowded housing causing high disease spread. Thus, the background of the HTOC is comparable to forensic samples that often include victims of multifaceted structural inequality.<sup>2</sup> Linear Enamel Hypoplasia (LEH) incidence and stature were used as indicators of physiological stress during growth and development, while Antemortem Tooth Loss (AMTL) was used as an indicator of health during adulthood. LEH were scored as present/absent for each individual. Stature was available through medical and autopsy records. AMTL was calculated as the proportion of teeth missing antemortem.

Documented CODs were available for most individuals in the sample from death certificates. CODs varied by socially ascribed race and sex within the sample. Black Americans were twice as likely to die from tuberculosis than White Americans ( $\chi^2=4.793$ ,  $p=0.029$ ). Individuals that died from degenerative diseases, such as cardiovascular disease, had a significantly more AMTL ( $H=18.53$ ,  $p=0.002$ ). Differences in AMTL among COD categories were still significant when controlling for age at death ( $F=2.388$ ,  $p=0.038$ ). Females that died from degenerative diseases had significantly shorter statures compared to those that died of infectious disease ( $t=2.903$ ,  $p=0.004$ ). There were no significant differences in LEH prevalence among the different CODs represented ( $\chi^2=4.449$ ,  $p=0.487$ ), although a previous study found an association between stature and LEH presence for females in the HTOC.<sup>3</sup>

These trends show that several skeletal markers of stress are related to degenerative disease in this sample. These results demonstrate how combining information from COD and skeletal markers of physiological stress and health may provide additional context about an individual's lived experiences, which can aid forensic investigations by narrowing the pool of possible identities and understanding the events that led to an individual's death.

**A6 The Development of a Migrant Profile for Unidentified Human Remains Found Across Three Medicolegal Offices in Greece**

*Sophia Mavroudas\*, Forensic Anthropology Center at Texas State, Texas State University, San Marcos, TX; Despoina E. Flouri, Forensic Medicine Unit, University Hospital of Heraklion, Heraklion, Iraklion, Greece; Konstantinos Moraitis, National and Kapodistrian University of Athens, School of Medicine, Athens, Attiki, Greece; Christina Karydi, National and Kapodistrian University of Athens, Alimos, Attiki, Greece; Pavlos Pavlidis, Laboratory of Forensic Sciences, Democritus University of Thrace, Alexandroupolis, Evros, Greece; Valeria M. Karakasi, University Department of Psychiatry, Laboratory of Forensic Sciences, Democritus University of Thrace, Alexandroupolis, Evros, Greece; Elena F. Kranioti, University of Crete, Heraklion, Iraklion, Greece*

---

**Learning Overview:** This presentation will utilize demographic data from unidentified human remains cases originating from three offices within Greece to demonstrate documented demographic trends between individuals considered migrants and individuals considered non-migrants. The goal of this presentation is to contribute to ongoing research that is working toward building a migrant profile for remains discovered in border regions globally.

**Impact Statement:** This presentation will impact the forensic community by highlighting the potential for anthropological analysis to assist in the determination and identification of migrant remains. This presentation will also inform the forensic community about the diversity of migrant remains within the Greek medicolegal system and the similarities between the Greek and United States migrant humanitarian crises to foster collaboration in identification efforts.

For this study, the demographic and Global Positioning System (GPS) data from 770 cases between the years 1995 and 2022 were gathered from three offices in Greece in which unidentified human remains were recovered. The offices were located across a diversity of landscapes, including the Forensic Medicine Unit of the University of Crete in Heraklion on the island of Crete (n=99), the Forensic Anthropology Unit of the Department of Forensic Medicine and Toxicology at National and Kapodistrian University of Athens located in the city of Athens (n=317), and the Department of Forensic Medicine of the Democritus University of Thrace located in the city of Alexandroupoli (n=354). From the combined dataset, a total of 367 individuals were considered migrants, while 403 individuals were considered non-migrants. For the individuals considered migrants with a known country of origin, the majority of the individuals originated from Pakistan (n=35), followed by Syria (n=33) and Afghanistan (n=19), but in total 18 countries were represented in the data from both the western and eastern hemispheres. The migrant cases consisted of primarily males (n=322, 87%) with an average age of 27.1 years. The female migrant cases had an average age of 28.9 years. The primary cause of death for the migrant cases was drowning, followed by traffic/train accidents. This migrant demographic profile differs from the non-migrant profile of unidentified individuals from among these offices in that the non-migrant cases consisted of 49% males (n=201) with an average age of 59.4 years, while the females in this group had an average age of 66.4 years. The primary cause of death for the non-migrant cases was undetermined.

The identification rate for the migrant group was 47%, while the identification rate for the non-migrant group was 34%. The identified non-migrant cases included individuals of both Greek and non-Greek ancestry. For both groups, the means of identification included combinations of visual identifications, personal effects, fingerprints, and genetic methods. The GPS data for each case was used in hotspot analysis to qualitatively examine any differences in concentrations across the Greek landscape between the migrant and non-migrant groups. The hotspot analysis shows a higher concentration of migrant remains in the northeastern/Thracian region of Greece. While the data presented in this study indicate a specific demographic and geographic trend of migrant remains, the study is limited by the inclusion of only three offices, an absence of data from major shipwrecks containing migrants which are handled by other jurisdictions, and the data mining from a combination of pathology and anthropology reports. This presentation will also discuss these limitations and directions for future research to build stronger migrant profiles and increase identification rates for both migrant and non-migrant unidentified human remains in Greece.

**A7 The Development of a Multidisciplinary, Minimally Invasive Approach for the Forensic Examination of Skulls**

*Ayusha Dahal\**, University of Technology Sydney, Campbelltown, New South Wales, Australia; *Dennis McNevin*, University of Technology Sydney, Ultimo, New South Wales, Australia; *Denise Donlon*, University of Sydney, Sydney, New South Wales, Australia; *Stewart Fallon*, ANU Radiocarbon Laboratory, The Australian National University, Canberra, Australian Capital Territory, Australia; *Jodie Ward*, Australian Facility for Taphonomic Experimental Research, University of Technology Sydney, Broadway, New South Wales, Australia

---

**Learning Overview:** After attending this presentation, attendees will have a greater understanding of the accuracy and consistency of the age at death, sex, and ancestry estimations through anthropological, odontological, radiological, isotope analysis, proteomic, and genetic methods. Through the discussion of the findings, attendees will ultimately appreciate the recommended multidisciplinary approach to forensic human identification for skeletal remains.

**Impact Statement:** This presentation will impact the forensic science community by assessing various forensic profiling methods for human remains identification to showcase the strengths and limitations of each when applied to skull-only remains. The presented findings will help guide investigators to choose optimal methods and samples for age at death, sex, and ancestry estimations to aid missing persons investigations and disaster victim identification.

Forensic examination of human skeletal remains is important to establish the unknown deceased person's identity using an accepted scientific method such as dental or DNA analysis or to estimate the individual's age at death, sex, ancestry, lineage, externally visible characteristics, and other information such as geographical region of origin.<sup>1-3</sup> Such approaches to human remains identification typically involve one or more anthropological, radiological, isotopic, and genetic methods.<sup>4</sup>

This research focuses on cranial remains to evaluate a multidisciplinary, minimally invasive approach for the forensic examination of skulls. The absence of a post-cranial skeleton often presents challenges for identification by limiting the skeletal elements available to generate investigative leads when traditional dental and/or DNA matches fail. Therefore, this research aims to recommend an accurate, comprehensive, and least-destructive sampling and examination workflow for skull-only cases to maximize identifying information.

Eight human cadavers donated to the Australian Facility for Taphonomic Experimental Research (AFTER) and subjected to different environmental conditions were examined by various forensic experts applying different forensic examination approaches, starting with an anthropological assessment, using both non-metric and metric approaches. The non-metric approach utilized a visual assessment of the skull for age, sex, and ancestry estimation, while the metric approach included 30 cranial measurements analyzed through CRANID, FORDISC®, and AncesTrees programs for sex and ancestry estimation. Different skeletal and dental elements were then sampled and submitted for DNA-based sex, phenotype, ancestry, and paternal and maternal lineage estimations. These samples were also submitted for expert radiocarbon dating and stable isotope analysis.

The examination results obtained from each forensic technique/expert were reviewed to determine the accuracy of the age at death, sex, and ancestry estimations by comparing them to documented and self-reported donor data.

The expert non-metric anthropological assessments provided accurate results for all age, sex, and ancestry estimation of the donors, showing a more conservative result for age and ancestry predictions (e.g., "adult Caucasian male" instead of a specific age range or ancestral group). The metric evaluation produced accurate sex estimation but showed only moderate success with ancestry prediction, showing a broad range of possible ancestries, and proving to be more useful for accurate elimination of ancestral groups not corresponding with the donors' measurements. Both nuclear and mitochondrial DNA were successfully recovered from the petrous bone with the phenotype, ancestry, maternal lineage, and paternal lineage results agreeing with the reported donor phenotype, ancestral, and sex information. The radiocarbon dating results for date of birth and death provide a comparable age estimation with higher precision than the non-metric anthropological age assessment. The oxygen isotope results for region of origin information are currently under progress.

The findings of this research highlight the need for forensic experts from different disciplines to work together for a holistic investigation to ensure accurate and comprehensive human remains identification in skull only cases.

## A8 An Investigation Into the Facial Dimensions of a North Indian Population: Implications in Facial Identification

Ankita Guleria\*, Panjab University, Chandigarh, India; Kewal Krishan, Panjab University, Chandigarh, India; Vishal Sharma, Panjab University, Institute of Forensic Science, Chandigarh, India

**Learning Overview:** After attending this presentation, attendees will understand the importance of facial morphometrics, the dominant and rare facial features present in a north Indian population, and the usefulness of facial dimensions and their prediction in forensic examinations.

**Impact Statement:** This presentation will impact the forensic science community by providing in-depth knowledge of facial features and the classification of faces for personal identification. The knowledge will be helpful for anatomists, plastic surgeons, and forensic experts to identify and isolate the common and rare characteristics in the population.

Personal identification is a distinctive approach that distinguishes people from each other and makes them unique. The human face is the most common approach that represents the uniqueness of a person.<sup>1</sup> Facial features are the results of environment and genetics that represent the specific characteristics of the population in specific regions. Moreover, facial identification from video surveillance systems is becoming a common approach in the current era.

The present study was conducted in the Mandi district of Himachal Pradesh, India, after obtaining ethical approval from the institution and written informed consent of the participants. This study incorporated 228 participants (158 males and 70 females) who were healthy and young with an age range of 18–35 years. A total of 19 facial measurements were taken in a Frankfurt horizontal plane using a sliding and spreading caliper following the standard procedure. Statistical analysis was done using the IBM® SPSS Statistics Version 20. Sexual dimorphism in the mean values of the measured parameters was analyzed by using an independent sample t-test.

The present study evaluated three facial indices (i.e., facial index, nose index, and lip index) among the participants following the classification by Williams et al., Martin and Saller, and Sarkodie et al.<sup>2-4</sup> In males, the mean facial index, nasal index, and lip index were found to be 81.139, 71.18, and 39.73, respectively, whereas mean facial index, nasal index, and lip index of 78.78, 69.83, and 36.72 were observed in females, respectively.

By calculating the facial index, the most common and rare facial types present in the target population were studied. The most dominant face was found to be hypereuryprosopic (very broad face) and the least was hyperleptopsopic (very long face). The most common nose type was the mesorrhine, whereas platyrrhine and hyperplatyrrhine types of noses were the least commonly present. In most of the target population, intermediate types of lips were observed, whereas the least commonly found lips were of a thick type. Sexual dimorphism was also observed in the facial dimensions. Furthermore, a low to strong correlation was observed among the various facial dimensions considered in the study. Afterward, the regression models were formulated, which will be helpful for forensic anthropologists and law enforcement agencies for facial reconstruction and identification. This study provided data for facial phenotype among the North Indian population, which will be helpful for plastic and oral surgery, biometric purposes as well as facial identification in forensic science, etc.

## **A9 The Identification of Fragmented Cranial Remains Exhumed From a Site Adjoining the Ajnala Site: A Forensic Anthropological Case Report**

*Jagmahender Singh Sehrawat\*, Panjab University, Department of Anthropology, Chandigarh, India; Niraj Rai, Birbal Sahni Institute of Palaeosciences, Lucknow, Uttar Pradesh, India*

**Learning Overview:** After attending this presentation, attendees will be sensitized about the importance of the application of advanced forensic anthropological techniques for forensic identification of badly damaged skeletal remains.

**Impact Statement:** This presentation will impact the forensic science community by informing attendees that the multidisciplinary approach of the anthropological, molecular, and chemical examinations of the isolated and badly damaged or commingled human remains can be very helpful in the identification of such remains retrieved from forensic or bioarchaeological contexts.

Mankind have suffered several unexpected disasters, heinous crimes, and brutalities, resulting in a large number of unknown skeletal remains to be identified and repatriated to their relatives. Forensic anthropological identification of badly damaged and commingled human remains is a very difficult task owing to poor preservation, severe fragmentation, missing elements, and the inadequate records about the conflicts or disasters that produced such human remains. Establishing identity to such remains is the ultimate purpose of almost all forensic anthropological examination.<sup>1</sup> Integrated inputs from archaeology, modern genetics, ancient DNA, and proteomics and stable isotope analysis has made such identifications possible.<sup>2</sup>

In one such incident of mass killings, 282 Indian-origin soldiers were killed by the colonial rulers, and the remains were dumped in an abandoned well at Ajnala, India in 1857; forensic anthropological examinations of these remains found them belonging to different Indian states as mentioned in the written accounts. However, the damaged cranial fragments belonging to two individuals were retrieved from the area adjoining to Ajnala mass-burial site during a construction activity carried out later in 2014.

The present study was conducted to ascertain whether the recovered cranial fragments were synchronous to Ajnala skeletal remains or if they belonged to a different traumatic situation, with the objective of estimating the identity and population affinity of these cranial fragments. The morphological examination of jaw fragments and teeth was used for their forensic anthropological examination. The ancient DNA from the second molar and temporal auditory meatus of both the specimens was extracted and analyzed using standardized protocol, and library preparation was performed.<sup>4-6</sup>

The morphoscopy, osteological, molecular, and stable isotope results supported the versions that cranial fragments of two individuals excavated from an adjoining site to Ajnala well belong to the same group of individuals who were captured and killed at Ajnala and whose cadavers were dumped into an ancient abandoned well. It may be possible that cadavers of these individuals may have been buried after the main mass burial site (the Ajnala well) was filled with sand. The general robusticity of the skull, and the size and shape of the gonial angle, mental eminence, and the mastoid process, showed that fragments supposedly belonged to a male. The eruption of third molars with relatively minimal wear of the teeth, and the apparent degree of cranial suture fusion (although this may be affected through taphonomic damage/distortion), indicated they were young-mature adults, though other skeletal indicators may put these specimens in an older age category. The occlusal surface wear analysis shows that the teeth belong to a pretty youthful individual, but the possibility of using a soft diet by these individuals cannot be ruled out. The pubic symphysis or auricular surfaces were not available among the Ajnala skeletal assemblage for ascertaining the age of the specimen. The ancient DNA results were in accordance with the observations reported in the previously published article where the geographical affiliation of the remains have been found to be non-local to the site, potentially belonging to Eastern Uttar Pradesh, Bihar, and some Northeastern Indian.<sup>3,6</sup>

**Learning Overview:** After attending this presentation, attendees will be able to describe the management protocol in the case of human remains discovery.

**Impact Statement:** This presentation will impact the forensic science community by showing the usefulness of protocol-based procedures in the context of human remains discovery.

In this case report, we describe a case of a skull discovery in Diamante, Italy, near a Roman archeological site. We carried out: a skull external examination with photographic surveys before and after washing of internal surface of the skull; a radiological evaluation by performing a computer tomography scan before and after washing of the internal surface; after skull sampling, a chronological evaluation was performed by determining the radiocarbon concentration and comparing it with values of current  $^{12}\text{C}$  and  $^{13}\text{C}$ , and the calculation of  $^{14}\text{C}$  with  $\text{C}_6$  Sucrose standard samples. An anthropological analysis was performed to estimate age at death by an examination of the degree of suture closure (the “Mindle Lovejoy” method) and an ancestry evaluation was conducted by application of the Hefner method. For taphonomy evaluation, the soil was sampled.

From anthropological and forensic examinations that were conducted, the skull was estimated to be a male subject. Age-at-death estimation was performed both with a mean age of  $51.5 (\pm 12.6)$  years and with the latero-anterior system with a mean age of  $56.2 (\pm 8.5)$  years. Human ancestry was comparable at 60.63% with Europoid one (Caucasoid). Radiocarbon dating collocates the skull to between 1877 and 1916 with a 29.5% interval of confidence. The skull examination revealed multiple alterations on the cortical surface of the bone consisting of postmortem fractures, discolorations, cracking, exfoliations, and erosions. Postmortem fracture can happen due to the soil weight acting on the bone surface or due to other pressure/mechanical factors. Some areas of ethmoidal bone and zygomatic processes were presenting postmortem fractures. Discoloration phenomenon was observed mainly in the right side of the skull, with the presence of yellow/orange spots, most likely determined by the position of the skull in contact with the soil.

In the posterior-superior portion of the left parietal bone, an irregular oval area was present with a brownish mark in the center, referable to a combustion sign that occurred after death. At morphological and radiological examinations, the presence of suspicious perimortem cut-marks, traumatic cut lesions, caused by a blade with a thin section inflicted just before death were detected.

The investigations performed showed that the suspicious skull injuries described before were not compatible with perimortem lesions but to a postmortem disarticulation. Moreover, from the anthropological and forensic analyses, it was possible to determine that the skull belonged to a male subject who underwent a postmortem disarticulation, attributable to funeral rituals, which were conducted during prehistoric ages in Europe.<sup>1,2</sup> In order to reach those conclusions, we employed this protocol: external examination with photographic survey; radiological imaging with evaluation of the results; anthropological analysis; radiocarbon dating; cataloging of circumstantial data present inside the skull (in order to perform future analysis).

**A11 Skeletal Indicators of Down Syndrome: A Case Study in Forensic Anthropology**

*Theresa M. De Cree, Texas State University, San Marcos, TX; Ivanna Robledo\*, Texas State University, San Marcos, TX; Emily Brooks, Arizona State University, Tempe, AZ*

---

**Learning Overview:** After attending this presentation, attendees will understand the importance of studying the skeletal manifestations of Down syndrome and how the condition was represented in the remains included in this study.

**Impact Statement:** It is estimated that over 200,000 people are living with Down syndrome today.<sup>1</sup> However, current forensic anthropological literature does not comprehensively address recognizing this condition in skeletal remains. The impact of this research will hopefully be the beginning of establishing methods for recognizing Down syndrome in remains.

Estimated to affect 1 in 800 births, Down syndrome is a chromosomal condition caused by a mutation referred to as trisomy 21.<sup>1</sup> There are between 200 and 300 genes on chromosome 21; the main characteristics of this condition include hypotonia, respiratory issues, delayed development, intellectual impairments, and a higher risk for infections.<sup>2</sup>

According to clinical and dental literature, skeletal phenotypes with varying rates of presence include: short stature, shortening of hand and foot bones, unstable atlanto-axial joint, 12<sup>th</sup> rib absence or poor formation, shortened long bones, low nasal bridge, a narrow and short and deep and high palate, changes in dental eruption timing, brachycephaly, malocclusion underdevelopment of osseous tissues, and mid-facial hypoplasia.<sup>13</sup>

In addition to the listed skeletal abnormalities, delayed skeletal and dental growth could affect established age estimation methods in forensic anthropology. Earlier onset of osteoporosis and increased rates of obesity could skew degradation-based age methods higher. The overall small size of people with Down syndrome and hypotonia likely results in more gracile muscle attachment sites and therefore sex estimations could skew toward female. Abnormal long bone ratios could cause errors in stature estimates which are primarily based on long bone measurements. Population affinity is often assessed qualitatively by examining facial features, with cranial facial alterations such as a low nasal bridge and palate shape changes; therefore, these methods could be affected.

In this case study, an individual with Down syndrome from the Texas State Donated Skeletal Collection was examined for non-metric variation, and the biological profile was assessed utilizing common current methodologies. A complete biological profile was assessed, age was determined utilizing ADBOU 2.1, sex was determined using MorphoPASSE, and FORDISC® 3.1; FORDISC® 3.1 was also used for stature and population affinity. Two authors assessed each aspect of the biological profile with strong agreement between observers. Sex estimation incorrectly classified the individual as female with high probabilities for all utilized methods. Population affinity was correctly estimated to be White with both cranial and post-cranial methods with high probabilities. Stature estimation was calculated utilizing FORDISC® 3.1 and the estimated stature with a 90% confidence interval; most resultant estimations contained the living stature; however, it was often the low point of the estimates. The individual's age was contained in the age estimate. The individual was also examined for any skeletal phenotypes listed in clinical literature, and the majority of traits listed above were observed with the exception of a low nasal bridge, absence of the 12<sup>th</sup> rib, and brachycephaly. Due to edentulism, palate and dental differences could not be observed.

This research demonstrates the importance of recognizing Down syndrome is skeletal remains, as doing so can aid in identification of individuals and prevent the use of methodologies that are not appropriate for estimating the biological profiles of people with Down syndrome. Further research is needed with an expanded sample size to better determine a set of skeletal characteristics that forensic anthropologists can utilize to potentially recognize Down syndrome.

**A12 The Characteristics of a Vertebroplasty in Human Skeletal Remains**

*Nicholas V. Passalacqua\*, Western Carolina University, Sylva, NC; Rebecca L. George, Western Carolina University, Cullowhee, NC; Erin Chapman, Erie County Medical Examiner's Office, Buffalo, NY; Emma F. Taylor, Western Carolina University, Cullowhee, NC; Nuwan Perara, Western Carolina University, Cullowhee, NC*

---

**Learning Overview:** The goal of this presentation is to explain the surgical procedure of a vertebroplasty and demonstrate its dry bone characteristics.

**Impact Statement:** This presentation will impact the forensic community by providing explanations of the physical modifications associated with a vertebroplasty procedure, which may be confounding to forensic anthropologists and other medicolegal death investigation experts.

Vertebroplasties are safe and effective medical procedures where bone cement is injected into a vertebral body in order to reduce pain and increase stability of the area. Vertebroplasties are typically performed to correct or stabilize a Vertebral body Compression Fracture (VCF), usually resulting from osteoporosis. However, vertebroplasties may also be used to reinforce vertebral bodies in cases of Schmorl nodes or other pathological conditions that weaken a vertebral body.<sup>1</sup>

Riggs and Melton report that there are over 700,000 VCFs diagnosed every year in the United States, resulting in ~115,000 hospital admissions.<sup>2</sup> VCFs are three times more likely to occur in females compared to males and may result in chronic pain, immobilization, kyphosis, pulmonary deterioration, and depression.<sup>1,2</sup> Clinically, VCFs are often treated with analgesics, bed rest, and external bracing; however, approximately one-third of patients require the invasive treatment of a vertebroplasty.<sup>1</sup> Vertebroplasties are typically performed using fluoroscopy; a needle is inserted through the pedicle of vertebra into the vertebral body, where the bone cement is injected. The volume of bone cement for a vertebroplasty will vary but is typically between 3.5–5.0mL depending on the size of the vertebra.<sup>1</sup> The most widely used bone cement for VCFs is Polymethyl Methacrylate (PMMA), which has a curing time of approximately nine minutes.<sup>1</sup>

Here we present the dry bone characteristics of an individual with a vertebroplasty from Western Carolina University's (WCU) willied body donation program. WCU's willied body donation program operates in support of its human decomposition facility, the Forensic Osteology Research Station (FOREST). In this case, the individual had consented to taphonomic research and was used in a controlled burn as part of a continuing education course. After the thermal alterations, the individual decomposed in the FOREST and was subsequently cleaned and curated in WCU's John A. Williams Donated Skeletal Collection. During processing for curation, abnormal characteristics were observed on the first lumbar vertebra. This vertebra presented as abnormally heavy with a compressed vertebral body, where portions of the superior vertebral body's cortical bone were absent and a hard, off-white substance was protruding in some areas. Upon donation, this individual did not record previous medical procedures in their optional donation paperwork, so the cause of the abnormality was unclear with multiple possible origins initially hypothesized (e.g., antemortem neoplasm, antemortem surgical intervention, postmortem fungal growth).

Laboratory analyses were performed to investigate the abnormal vertebra. Gross observation of the vertebra did not locate any obvious areas of antemortem needle insertion; however, the cortical bone of the vertebra was porous, which may have obscured surgical defects. The cortical bone on the superior vertebral body was thin and fragile, suggesting that the absent portions of bone in this area likely occurred postmortem. Radiography of the vertebra demonstrated the unknown substance was present throughout the inside of the vertebral body. The unknown substance was analyzed using Fourier Transform Infrared Spectrometry (FTIR). The resulting spectrum showed the presence of PMMA and barium sulphate, consistent with bone cement. Based on these results, the compressed vertebral body and presence of bone cement are indicative of a vertebroplasty. Due to a lack of medical history for this donor, the age of the vertebroplasty and cause of the VCF is unknown.

With almost 20,000 vertebroplasties performed in the United States every year, forensic anthropologists are likely to encounter them occasionally in their casework.<sup>3</sup> Understanding this medical procedure as well as its characteristics in dry bone will assist forensic anthropologists in correctly identifying these vertebral abnormalities and potentially assist in the identification process of unknown individuals expressing these characteristics.

**A13 An Unusual Case of Human Remains Found in an Urban Aqueduct**

*Stephanie Torres\*, Los Angeles Medical Examiner-Coroner, Pomona, CA; Ellen Fricano, Western University of Health Sciences, Pomona, CA*

---

**Learning Overview:** This presentation will outline the unique taphonomic effects observed on remains discovered in an urban aqueduct. After attending the presentation, attendees will better understand taphonomic changes that can occur in a man-made water system and how it could impede trauma identification.

**Impact Statement:** This presentation will impact the forensic science community by sharing how taphonomic changes in an urban water system differs from a naturally occurring water system. Temperature, currents, fauna, flora, and water chemistry are among factors that can affect human remains during decomposition. All these variables are drastically different in a man-made water system where the water is chemically treated and filtered to remove contaminants, microorganisms, and debris. Distinguishing perimortem trauma from postmortem changes in forensic anthropology relies on whether the bone was wet or dry when the damage occurred. In the case presented, the chemically treated water likely prolonged decomposition and the highly pressurized water pipe created ample opportunity for postmortem damage on bone that retained its moisture content.

The skeletal remains of a single 30-year-old decedent were discovered in an urban aqueduct and water feeder pipe. Based on the timeline from investigators, the decedent was likely in the pipe from 2015 to 2022. The remains were mostly skeletonized with remnant wet soft tissue surrounding the vertebrae. No evidence of animal or insect activity was observed. The water was treated, clean water, which would reduce the presence of biological agents normally found in natural bodies of water such as invertebrates and microorganisms.

The water pressure of the pipe caused significant damage to the skeleton, which occurred in the perimortem period, as defined by the period in which the bone retains enough collagen and moisture to resist fracturing.<sup>1</sup> Several ribs and the scapula exhibited significant plastic deformation, with some ribs bent as much as 90 degrees with little or no external or internal fracturing. Longitudinal fractures were observed on the superior and inferior margins of the bent ribs. Rib fractures can be particularly challenging to assess given the shape of the bone, dynamic responses to loading specific to ribs, and the scarcity of forensic anthropological literature on the subject.<sup>2-5</sup> Abrasion consistent with the remains being in a turbulent aquatic environment for some time was observed but it was much more localized than would be expected in a natural water context, taking on the appearance of incised defects and even saw marks to the untrained eye.

This case emphasizes the need for decomposition equations for different types of aquatic environments as well as more trauma and taphonomy studies in urban aquatic environments. By sharing the details of this unique case, anthropologists can better understand the taphonomic changes caused by water movement in the context of the specific biological and chemical environment of an urban aqueduct.

---

**Learning Overview:** This presentation will provide a deep understanding of the challenges forensic anthropologists face when analyzing burned human remains due to heat-induced changes. After attending this presentation, attendees will understand how vibrational spectroscopy techniques like Fourier Transform Infrared FTIR and MicroRaman can help assess the structural and chemical degradation of burned skeletons, focusing on key spectral markers and their correlation with exposure temperature. In fact, it demonstrates the potential for using vibrational spectra to distinguish burned remains, especially in complex scenarios, shedding light on the role of exposure duration in degradation. This knowledge equips attendees to apply vibrational spectroscopy effectively in forensic anthropology, advancing the field's capabilities.

**Impact Statement:** This presentation will impact the forensic science community by introducing innovative methods using vibrational spectroscopy for assessing the structural and chemical degradation of burned human remains, significantly advancing the field of forensic anthropology. By providing forensic anthropologists with precise tools to determine bone exposure temperatures and identify key spectral markers, this study enhances the accuracy of forensic analysis, particularly in complex scenarios involving commingled or scattered remains, while also contributing to broader interdisciplinary research.

Burned human remains pose challenging analytical problems to forensic anthropologists due to heat-induced changes. The determination of the maximum temperature of exposure through bone has been frequently addressed in the past but still requires additional investigation. This research explores the potential of vibrational spectroscopy in determining the structural and chemical degradation based on spectra from the organic and inorganic composition of burned human skeletons.

To explore this, an assemblage of 560 samples from 40 skeletons of the 21<sup>st</sup>-Century Identified Skeletal Collection (University of Coimbra) experimentally burned at different maximum temperatures (from 500°C to 1,050°C) and durations (from 45 to 240 minutes) were analyzed through vibrational spectroscopy, namely FTIR and MicroRaman.<sup>1</sup> The relationship between the spectra of individual bones (long bones and hip bones) and the variation of the intensity of the bands assigned to either organic or inorganic components such as amide I and II vibrational modes of proteins, CH<sub>2</sub> bending and stretching vibrational modes of lipids, carbonate, hydroxyapatite, phosphate, hydroxylation patterns were investigated. The correlation of the spectra of the organic and inorganic components with the maximum temperature of exposure is clear. Transition from polymorphic hexagonal to monoclinic hydroxyapatite occurs at a temperature higher than 800°C. The band (Ca-OH) (*ca.* 345 cm<sup>-1</sup>) is detected only for burning temperatures equal to or above 700°C, being absent for lower temperatures.

However, the chemical degradation of the burning experiment is still a variable that needs to be further investigated since it could reveal discriminatory “fingerprinting” in cases of commingled or scattered contexts. Therefore, duration of the exposure plays an important role in the structural and chemical degradation of burned human remains. This study obtained promising results regarding the potential of analyzing vibrational spectra from burned human remains to assess the structural and chemical degradation correlated with the maximum temperature to which they have been exposed.

**A15 Is It Scientifically Impossible to Burn Human Bodies to Ashes? Revisiting the 2014 Case of the 43 Missing Students from the Ayotzinapa Rural Teachers College in Guerrero, Mexico**

*Elayne J. Pope\**, *Fatal Fire Forensics, Knoxville, TN*; *Alison Galloway, University of California–Santa Cruz, Volcano, CA*; *Chelsey A. Juarez, California State University Fresno, Fresno, CA*; *James G. Quintiere, University of Maryland, Margate, NJ*; *Riccardo Torres, Forensic Investigations Group Global, Pharr, TX*

---

**Learning Overview:** This presentation reexamines some of the older forensic and fire science that was used to investigate a 2014 case involving the disappearances and incineration of 43 students in an outdoor dumpsite in Guerrero, Mexico. In 2015, an investigation by the Inter-American Commission of Human Rights (IACHR) had appointed the Interdisciplinary Group of Independent Experts (GIEI) to independently investigate the case. Portions of the GIEI's report were based on research findings from burning large wood cribs (pyre) with pig bodies to model the incineration of humans.<sup>1</sup> The GIEI final report concluded that the 43 students were not incinerated in the dumpsite. In 2015, the IACHR had rejected the claim that 43 victims were incinerated to "ash" at that site and concluded that the official account of events was scientifically impossible. Some of the decade-old forensic and fire science that were used to investigate this case were compared to current findings from experimental fatal fire research involving n=10 outdoor incendiary fire tests that demonstrated the multiple variables and processes associated with intentional cremation into fragmentary burned bones as ashes. After this presentation, the attendees will understand the process of how human cadaver bodies are cremated based on current fatal fire research.

**Impact Statement:** This presentation will impact the forensic science community by demonstrating the importance of reevaluating older forensic casework with updated scientific research findings, which can offer newer information into the case.

Over the past decade, there have been advances in the analysis of burned human remains from fatal fire research and the analysis of fire victims by forensic anthropologists. Current research from forensic anthropology and fire science were applied to a 2014 case in Guerrero, Mexico, involving the disappearances and incineration of 43 male victims. We revisited some of the original case findings and compared them with current research models to test the hypothesis that it is scientifically impossible to burn 43 bodies to ashes.

We analyzed the results from n=10 experimental outdoor incendiary fire experiments using non-embalmed human cadaver bodies (donated with family consent), different types and amounts of fuels, and burned for varying durations for forensic training and research during the Fatal Fire Death Investigation Course by the San Luis Obispo Fire Investigation Strike Team (SLO FIST) in California<sup>2</sup>. Data collection from these tests documented different fuel types and amounts, durations, passive and active involvement (refueling), the processes of cremation into burned tissues, bones, and teeth, and how much time, fuels, and efforts are needed to intentionally cremate a human body to ashes. These results were compared to the research tests and findings by fire scientist Dr. Torero in 2015 who burned pigs on wood cribs (pyre) to replicate human cremation.<sup>3</sup>

A comparative analysis of the research methods, materials, and findings from our current tests and those from the original investigation was conducted to examine how much time, fuels, and efforts are needed to intentionally cremate a body. Torero's research had estimated that to cremate one pig body would require ~700kg of wood to burn for 12 hours to ash. Our research results demonstrated that full cremation resulted from significantly less fuels of ~150kg–200+kg of wood for ~2 hours. We observed that the most extensive damage resulted from activities of refueling and intentionally stoking, crushing, and pulverizing fragile burned bodies and burned bones into smaller fragments, which significantly reduced the time and materials needed for cremation. In 2014, the site was excavated by the Equipo Argentino de Antropología Forense (EAAF) forensic anthropologists who recovered multiple darker charred fragments of burned human bones and teeth that had remained camouflaged within the black fire debris and overlooked until site excavation. White calcined bones would be easier to identify and remove from black fire debris, which could explain their absence and why so few bone fragments were recovered.

Our research results demonstrated that it is scientifically possible to intentionally cremate bodies to ashes as charred and calcined fragmented bones and teeth burned in a large outdoor incendiary fire event with the intent to destroy evidence and that these newer scientific findings should be considered to revisit the case. Three of the missing victims have been identified through DNA testing and newer technologies (i.e., Rapid DNA) that provide better results for thermally degraded bone, especially for the charred remains. For almost a decade, the families and communities of the 43 missing victims have been given false hope and are still searching for their loved ones after the Mexican government's investigation concluded that it was scientifically impossible that a mass cremation had occurred at the dump site and to keep looking elsewhere.

**A16 An Evaluation of Commingled Remains Using Computational Methods to Reconstruct Dental MNI Based on Dental Wear**

Melanie Need\*, Leiden University, Amsterdam, Noord-Holland, Netherlands; Xenia Paula Kyriakou, University of West London, Fort Myers, FL; Tim Eckhardt, University of Groningen, Groningen, Netherlands

---

**Learning Overview:** This presentation will utilize computational methods to reconstruct dental Minimum Number of Individuals (MNI) based on dental wear. After attending this presentation, attendees will have a better understanding of this pilot study that shows a different approach to estimating the MNI and the importance of improving method efficiency and accuracy.

**Impact Statement:** This presentation will impact the forensic scientific community by highlighting the use of age-related dental wear to re-associate commingled teeth and reconstruct MNI using Python®. Attendees will grasp a better understanding of the use of Python® for purposes of re-associating commingled teeth and the potential use of this particular method to a wide range of commingled osteological datasets.

A high recovery of commingled osteological human remains at an archaeological site is quite difficult due to a wide range of factors.<sup>1</sup> Existing methods used in the estimation of MNI are time-consuming and present with accuracy challenges and embedded bias.<sup>2</sup> Osteo-sorting methods are limited to reconstructing MNI based on the most frequent recurrence of a diagnostic skeletal or dental element. Commingled and disarticulated dentition is exceptionally problematic in the absence of associating alveoli. An experimental approach using computational methods was developed to reconstruct MNI using age-related dental wear scores following Lovejoy (1985) in a commingled dental assemblage (1,278 adult teeth; 22 cist graves) from the Kourion Amathus Gate Cemetery (KAGC) in Cyprus.<sup>3</sup>

For the purposes of this study, a script was written in Python® that automatically calculated the MNI per tomb based on the amount of repetitive teeth and dental wear score in order to reconstruct individuals. The code looped over every tooth per tomb and created new individuals based on dental wear and tooth type. When the tooth did not fit any of the requirements to be placed within an already existing individual, a new individual was created. The dental wear scores per individual varied only +/- 1 phase – as described in the Lovejoy method – from the first tooth listed in the individual. These results were compared to the already determined MNI based on repetitiveness. It showed that a higher MNI was found in almost all the tombs when taking dental wear into account. The total MNI before the Python® method was used was 66. After applying the method, the MNI was calculated as 111. The Wilcoxon test found that this difference was statistically significant with a p-value of 0.000599.

It is, however, suggested that caution is applied in using this method because at this pilot stage, it is recognized that more research on this topic is required by testing the method on different datasets, preferably of known demographics and established dental MNI based on the level of wear present. This will allow us to exploit weaknesses in the method and prevent these by tackling them in advance. In addition, the possibility of uneven dental wear in an individual should be researched further to include that as a bias in the method to make it more reliable. The results of this pilot study show promising potential and should be explored further in the future.

**A17 MNI, NIDS, Centroids: Additional Considerations for Individuating Commingled Remains Using Stable Isotope Ratios**

Stephanie B. Hartley\*, SNA International Contractor, Defense Prisoners of War/Missing in Action Accounting Agency, Joint Base Pearl Harbor-Hickam, HI; Lesley A. Chesson, Laboratory, Defense POW/MIA Accounting Agency, Joint Base Pearl Harbor-Hickam, HI; Gregory E. Berg, Defense POW/MIA Accounting Agency, Joint Base Pearl Harbor-Hickam, HI

---

**Learning Overview:** After attending this presentation, attendees will have a better understanding of the intraperson variation seen in the stable isotope ratios of human bone collagen (carbon and nitrogen), and how this can and cannot be used in the segregation of commingled human remains.

**Impact Statement:** This presentation will impact the forensic science community by providing a more complete understanding of intraperson isotopic variation seen in human bone collagen, as well as a novel approach to the segregation of commingled human remains assemblages using stable isotope delta ( $\delta$ ) values.

Fragmentary and/or highly commingled assemblages can make the anthropological segregation of skeletal elements into discrete individuals more difficult. Stable isotope ratios ( $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  values) measured for bone collagen have been shown to reliably sort modern commingled human remains by creating an isotopic Minimum Number of Individuals (MNI) for an assemblage.<sup>1,2</sup> Similar to morphological MNI in biological anthropology, the application of isotopic MNI has limitations for large-scale commingled assemblages from similar backgrounds (e.g., individuals consuming similar diets), often underestimating the number of individuals represented in an assemblage.

Isotope  $\delta$  values have also been shown to reliably segregate faunal remains into a Number of Isotopically Distinct Specimens (NIDS). In the NIDS approach, Euclidean distances using a combination of  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  values in tandem rather than independently are applied to an assemblage for individuation.<sup>3</sup> Currently, there is no comprehensive understanding of skeletal turnover rates within the literature. We hypothesized that bone turnover could affect the isotopic profile of an individual, possibly leading to one element, or grouping of elements (e.g., lower body, upper body), to be consistently “average” compared to the individual’s “overall” combined isotopic profile. In other words: Is there an element that consistently represents the average isotopic signature of the entire human body? Additionally, we hypothesized that a NIDS metric calculated for a human assemblage would be smaller than that previously calculated for faunal assemblages, based on the relative isotopic homogeneity of the modern human diet.

Collagen isotope ratios from 21 modern adult male individuals were examined. Each individual had a minimum of five long bones (at least two upper and two lower body elements); in total, 118 elements were included. The individuals originated from Northeast Asia, Southeast Asia, and the United States, and is a subset of the dataset previously used to determine human isotopic MNI.<sup>1</sup>

Chi-square tests were used to determine that there was no statistically significant difference between the mean or median elements when comparing all long bones (statistically assuming all elements had an equal likelihood of being the centroid). Chi-square tests were also used to determine that there were no statistically significant differences between various groupings (e.g., upper versus lower body, also assuming equal likelihood). Lastly, the mean intraindividual Euclidean distance was calculated as 0.29‰ ( $\sigma = 0.16$ ), compared to the 0.52‰ ( $\sigma = 0.45$ ) seen in faunal remains.<sup>2</sup> This supports the assumption that modern human diets are overall isotopically simple.

We found that there is no one element, nor grouping of elements within the long bones, that can be reliably used as a centroid for intraperson isotopic variation in the segregation of large-scale commingled assemblages. While bone turnover rates are still scarcely understood, our results suggest that intraskeletal variation in bone collagen  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  values is not statistically affected by typical turnover processes. Additionally, the NIDS metric calculated in this study is smaller than what was seen previously in faunal remains, which suggests that a NIDS metric built from a human model could also be used for individuation, although further examination is required. This should be tested in real-world applications using other commingled remains.

**A18 The Accuracy and Reliability of Visual Pair Matching Lower Limb Bones in a Commingled Skeletal Assemblage**

*Abigail K. Kindler\*, SNA International, Supporting the Defense POW/MIA Accounting Agency, Honolulu, HI; Courtney N. Hulse, SNA International, Joint Base Pearl Harbor-Hickam, HI; Carrie LeGarde, Defense POW/MIA Accounting Agency, Omaha, NE*

---

**Learning Overview:** After attending this presentation, attendees will have a better understanding of the accuracy and reliability of visual pair matching of lower limb bones within a commingled skeletal assemblage as well as the effect of unconscious bias during evaluation.

**Impact Statement:** This presentation will impact the forensic science community by bringing awareness to the strengths and limitations of visual pair matching as an association and segregation tool within commingled skeletal assemblages.

In cases of commingled human remains, visual pair matching is a commonly utilized method for sorting remains due to its efficiency and ease of use. However, the success of this method is largely based on observer experience, and few studies have tested its accuracy. As such, this study aims to address questions regarding the accuracy and reliability of visual pair matching of lower limb bones, as well as whether being aware of case context creates unconscious bias.

The sample consists of remains from individuals who were killed in the Battle of Tarawa during World War II. After recovery and identification efforts in the mid-1900s, unknown individuals were subsequently buried in the National Memorial Cemetery of the Pacific in Honolulu, HI. When these individuals were later disinterred by the Defense POW/MIA Accounting Agency (DPAA) for continued identification efforts, it was discovered that, in some cases, a moderate amount of commingling had occurred during both the recovery and early identification efforts.

For this study, pairs of femora, tibiae, and fibulae from ten unknown individuals, as received by DPAA, were analyzed. True pairs were based on the results of peer-reviewed analyses conducted at the DPAA laboratory by trained anthropologists. A total of 17 observers of varying experience and educational levels were given the 30 long bone pairs without any context and were asked to record: (1) if the antimeres pair match, (2) their confidence in their determination, and (3) a ranking of the top five skeletal features used in their determination. After at least one month, the observers were then asked to complete another evaluation of the remains. However, during the second analysis, the observers were provided basic information regarding the history of commingling for each pair of bones.

Results from both rounds of analysis yielded average pair-matching accuracies over 85%, with observer accuracy ranging from 64% to 100%. Intra-observer agreement between the first and second round of analysis, evaluated through kappa scores, showed moderate-to-good agreement overall; however, the variation in kappa scores for individual observers ranged from slight agreement to almost perfect agreement. Interestingly, intra-observer agreement does not seem to reflect years of experience or education.

This research highlights the overall accuracy and reliability of visual pair matching when given previously paired antimeres from commingled contexts. Furthermore, it discusses the influence of experience and context. While generally accurate and reliable, this research still demonstrates the potential benefit of more standardized visual pair matching methodologies in commingled contexts. Future research will explore the role of analyst confidence and observed skeletal traits in visual pair matching.

**A19 Assessing the Impact of Opioid Use on Human Clavicles Through Clinical Computed Tomography (CT): A Pilot Study**

Randi M. Depp\*, *The University of Akron, Akron, OH*; Reed A. Davis, *Baldwin Wallace University, Berea, OH*; Evin Hessel, *Northeast Ohio Medical University, Rootstown, OH*

---

**Learning Overview:** This presentation will utilize clinical CT data from human decedents to investigate and illustrate potential morphological changes to the clavicles of young opioid users. After attending this presentation, attendees will understand the different classes of gross presentations of the costal tuberosity of the clavicle, the prevalence of each type found in opioid users versus non-opioid users, and that forensic anthropologists should consider opioid-induced morphological changes when assessing skeletal remains.

**Impact Statement:** This presentation will impact the forensic science community by providing the first known assessment of gross morphological changes to the clavicles in opioid users. This is especially important in a forensic anthropological context, as opioid users make up an increasing proportion of the decedents encountered, and the morphological impact of opioids on bone are currently unknown.

Opioid use and overdose deaths have been rapidly increasing in recent years.<sup>1</sup> Opioids are known in clinical settings to cause changes to bone quality and can present as osteoporosis-like pathologies.<sup>2</sup> In forensic anthropology, these pathologies may interfere with the assessment of skeletal remains (e.g., age estimation); however, evidence of any drug-related pathologies is not well documented and typically is only found in anecdotal form. Previous case studies described resorptive-like changes to the costal tuberosity along the inferior surface of the medial clavicles of known opioid users.<sup>3</sup> Prior research has described a variety of gross presentations of the costal tuberosity, also known as the rhomboid fossa or costal pit, ranging from smooth to elevated, depressed, or pitted.<sup>4,5</sup> In this pilot study, we utilized decedent CT scans to identify the pattern of these morphologies in the clavicles of documented opioid users to help inform forensic anthropological practices.

Clinical CT scans of 20 decedents (10 males, 10 females) ages 17–37 years were obtained from the New Mexico Decedent Image Database. Of those 20 decedents, 5 males and 5 females were known opioid users. The remaining decedents were age- and sex-matched controls with no history of opioid use. The right and left clavicles were segmented through manual thresholding and selection tools. Surface meshes were generated to create 3D models for visual scoring of the costal tuberosity for each clavicle using five classes: smooth, flat, elevated, depressed, and pitted. Cross-sections orthogonal to the bone surface were extracted for review of any internal changes. The clavicles of both the male and female opioid users presented with a mixture of classifications: smooth (two bilateral, three unilateral), flat (four unilateral), elevated (one unilateral), depressed (one bilateral, four unilateral), and pitted (two unilateral). The male controls presented with only depressed (four bilateral) and pitted (one bilateral), while the female controls presented with only smooth (one bilateral) and flat (four bilateral). In nearly all individuals, the cortex of the costal tuberosity region was visualized as more radiolucent when viewed in cross-section, indicating a potential region of ongoing bone remodeling.

While the sample size of this study is small, the results indicate opioid users, especially females, may display different classes of costal tuberosity morphologies than non-opioid users. This work also lays the foundation for future research into opioid-induced gross morphological changes to the human skeleton and their impacts on forensic anthropological casework.

**A20 An Evaluation and Integration of Disparate Classification Schemes for Interparietal Bones in the Human Crania**

*Rhian R. Dunn\*, Michigan State University, Lansing, MI; Holly Long, Michigan State University, Bath, MI; Melissa Clarkson, University of Kentucky, Lexington, KY; Joe T. Hefner, Michigan State University, East Lansing, M*

---

**Learning Overview:** After attending this presentation, attendees will be familiarized with scoring strategies for interparietal bones and newly developed, standardized composable diagrams capturing various expressions of interparietal bones in a single system for use by forensic anthropologists, skeletal biologists, and clinicians.

**Impact Statement:** This presentation will impact the forensic science community by addressing a significant gap in current understanding of the growth and development, distribution, and classification of interparietal bones.

Supernumerary (wormian, extrasutural) bones in the skull are some of the most recognizable cranial non-metric traits in the human skeleton. The study of supernumerary bones has extended well beyond anthropology to other disciplines, likely due to their abundance, variation in form, and association with various clinical conditions (e.g., pyknodysostosis, rickets).<sup>1,2</sup> However, disciplines interpret supernumerary bones differently due to divergent points of interest and focus, leading to disparate scoring strategies and limiting interdisciplinary research. Standardization is needed for better collaboration and communication but should not erase or alter existing systems. A compromise is the creation of a unifying model using an evidence-based approach, incorporating data from currently available systems into a single data collection/data sharing protocol.

To demonstrate the utility of standardization through evidence-based composable schematics, the authors focus on research into interparietal bones in the human occipital. Interparietal bones are of particular interest due to their various manifestations and because their documentation is essential for forensic anthropologists differentiating between supernumerary bones and perimortem trauma. Through a comprehensive review of the available literature, we identified research articles and chapters focusing on the appearance and classification of interparietal bones. Specifically, the authors examined trends in the study of interparietal bones over time, as well as differences in foci and the various approaches to classification of these manifestations. In addition to this literature review, the authors examined physical evidence of interparietal bone variations on crania, including those in research article figures and those available in nearby university skeletal collections.

Much of the research focused specifically on the growth and development of interparietal bones through examination of fetal occipital squamae and the identification of ossification centers. We found large discrepancies in the reported number (ranging anywhere from 1–10) and positioning of ossification centers. In terms of classification, we identified a number of disparate methods. Some of these use a dichotomous (absence/presence) system, often based on the presence of a complete transverse occipital suture, while others use the overall morphology of the interparietal bone, where any additional bone in the occipital squama is included and the structure emphasized (e.g., bipartite, quadripartite). Although some overlap between systems exists, the variations in foci are often too disparate for direct comparisons.

Therefore, the next step in our research was the development and deployment of composable schematic illustrations incorporating all of these methodological descriptors into one unifying system. These diagrams, digitally created and stored as Scalable Vector Graphics (SVGs), account for the location of all occipital ossification centers and variations in the expression of interparietal bones observed in adult crania or identified in the literature. The inclusion of all variations seen in our unifying model allows for comparison between systems not previously possible, without the erasure or modification of previous work.

Standardization is an important component of science. Our research captures multiple systems in one outlet and permits data collection, data sharing, and data management using evidence-based illustrations. In addition, the flexibility of our approach permits the inclusion of new morphologies without the need to change an old system. We present this research and argue similar standardization is needed for other supernumerary bones on the human cranium.

**A21 Is Bone Speed of Sound Affected by the Molecular Composition of Infant Bone?**

*Miriam E. Soto Martinez\*, Harris County Institute of Forensic Sciences, Houston, TX; Jason M. Wiersema, Harris County Institute of Forensic Sciences, Houston, TX; Christian Crowder, Tarrant County Medical Examiner's Office, Fort Worth, TX; Angela Bachim, Baylor College of Medicine, Houston, TX*

---

**Learning Overview:** The goal of this presentation is to investigate whether the molecular composition of infant bone affects bone Speed of Sound (SOS) values and, if so, evaluate which components are influential.

**Impact Statement:** This presentation will impact the forensic science community by contributing to the research evaluating the relationship between the components of bone quality and SOS values in infants.

Forensic anthropologists, either explicitly or implicitly, assess bone quality as part of a blunt force trauma analysis. In association with pediatric trauma cases, forensic pathologists and attorneys may ask the consulting forensic anthropologists for their expert opinion regarding a child's bone quality as this may have important bearing on the death investigation and legal proceedings. Yet, there is currently no non-invasive quantitative method to measure general bone quality in infants. Such a method could inform diagnoses of infant skeletal trauma in both the clinical and/or medicolegal settings. Studies of the adult population indicate that bone SOS values, as measured by quantitative ultrasound, are significantly correlated with Bone Mineral Density (BMD), mechanical properties associated with bone strength, and fracture susceptibility. As such, SOS values are reported to measure bone quality in the adult population. It is unclear whether the same is true for infants.

This is the third phase of a larger study investigating the relationship between SOS and bone quality in infants. Previous phases identified significant correlations between SOS and: (1) the volumetric BMD (vBMD) of infant bone as measured by micro-Computed Tomography (microCT), and (2) the ultimate bone strength and elastic toughness of infant bone as measured by mechanical testing.

The current phase evaluates the relationship between the molecular composition of infant bone, as measured by Raman spectroscopy, and SOS. The study sample consists of 47 infants between the ages of 30 weeks gestation and 10 months at the time of death that were autopsied at the Harris County Institute of Forensic Sciences. Post autopsy, SOS (m/s) was measured on the anteromedial aspect of the left tibial midshaft using a quantitative ultrasound device. Planks of the tibial midshafts coinciding with the SOS measurement site were subjected to Raman spectroscopic analysis to quantify bone composition. Univariate statistics were used to investigate the relationship between SOS and bone composition.

Results indicate that SOS is positively correlated with mineral-to-matrix ratio, explaining 10% of the variance in SOS ( $r = .309, p = .029$ ). SOS was not correlated with any other bone composition parameters, including mineral-to-collagen ratio. These findings suggest that SOS increases as bone mineral content increases. A linear regression predicting SOS using mineral-to-matrix ratio values and vBMD with stepwise variable selection was performed to further explore the relationship between SOS, bone mineral content, and bone mineral quantity. Mineral-to-matrix ratio was excluded from the model, indicating that bone mineral content on the molecular scale did not significantly contribute to the variance in the SOS data beyond bone mineral quantity. This may suggest that bone quantity is more influential on SOS than bone mineral content. However, these results may also reflect the difference in scale in which SOS and bone composition were measured. Translated for medicolegal use, ultimate material strength and elastic toughness, as measured by mechanical testing, vBMD as measured by microCT, and bone mineral content as measured by Raman spectroscopy are positively correlated with SOS, indicating SOS is influenced by multiple components of bone quality in infants. There is still variance in the SOS measurements that remains unexplained by any of the tested methods. Future phases will investigate the source(s) of this unexplained variance, including possible effects of the presence and distribution of subperiosteal new bone on the methods used to quantify the components of infant bone quality.

**A22 Laser Me This: Using Laser-Induced Breakdown Spectroscopy to Detect Formalin in Human Remains**

Morghan Montana Hogg\*, Florida Gulf Coast University Human Identity and Trauma Analysis Laboratory, Fort Myers, FL; Micki Besse, Florida Gulf Coast University Human Identity and Trauma Analysis Laboratory, Fort Myers, FL; Heather A. Walsh-Haney, Florida Gulf Coast University Human Identity and Trauma Analysis Laboratory, Fort Myers, FL; Savanna Agilar, Florida Gulf Coast University Human Identity and Trauma Analysis Laboratory, Fort Myers, FL; Jay Radtke, District 14 Office of the Medical Examiner, Panama City, FL

---

**Learning Overview:** After attending this presentation, attendees will have learned a new approach to evaluating taphonomic changes to human remains.

**Impact Statement:** This presentation will impact the forensic science community by introducing attendees to the detection of formalin within preserved remains using Laser-Induced Breakdown Spectroscopy (LIBS).

Forensic anthropologists are tasked with evaluating taphonomic change as it informs death investigations. The use of LIBS in forensic anthropological casework has matched skeletal elements to the individual in mass fatality or commingled assemblages. However, the LIBS is both an analytical instrument and a technique increasing in popularity and utility in research laboratories as the spectrometer applies a high-powered, minimally destructive pulsed laser to a sample surface area and creates vaporized plasma for spectral analysis at various wavelengths (nm).<sup>1,2</sup> Despite these advances, researchers have not addressed the utility of the LIBS in the detection of human remains exposed to embalming fluids. Formalin is a fixative chemical (containing 40% aqueous formaldehyde) that can be used during embalming funerary practices.<sup>3</sup>

In this case study of fetal remains presumed to be associated with a defunct funeral home, the LIBS (System 150 Nano Series Pulsed Nd: YAG laser—RMA 0346-00) was used to analyze the intensity of formalin (10% neutral buffer) on human bone and soft tissue. A standard control was established by soaking a sterile cotton swab in formalin until saturation. This standard was compared to spectra of soft tissue, left temporal, right scapula, right femur, and soil (e.g., fill dirt) associated with these remains. The LIBS was sampled on the midpoint surface of each element and produced spectral analyses evaluated from 528nm to 716nm. The formalin control had 14 peaks that were used for comparison. The soft tissue spectrum yielded 100% peak similarities and suggested that the formalin was completely absorbed in the sample. In descending order, the temporal (64.3%), soil (21.4%), and scapula (7.1%) revealed spectral peaks consistent to the control (Fisher's Exact Test,  $N = 6$ ,  $p > 0.05$ ). The femur (0%) produced no similar peaks to the control but was previously encased in the soft tissue. This case study revealed that the LIBS can detect formalin (10% neutral buffer) with most of the similarities produced in the soft tissue, skeletal elements, and soil containing the remains.

**A23 An Application of Dietary Isotopes to Estimate Temporal Context of Unidentified Human Remains in British Columbia, Canada**

*Damon C. Tarrant\*, Simon Fraser University, Burnaby, BC, Canada; Laura Yazedjian, British Columbia Coroners Service, Burnaby, BC, Canada; Michael Richards, Simon Fraser University, Burnaby, BC, Canada*

---

**Learning Overview:** The goal of this presentation is to demonstrate the basics of dietary isotopic analysis and how it can be employed as an investigative tool in determining the medicolegal significance of unidentified human remains. Using carbon and nitrogen isotopes, we demonstrate how an individual's diet can be an initial indicator of temporality.

**Impact Statement:** This presentation will impact the forensic science community by demonstrating one of many potential uses for human isotopic analysis in forensic investigation. Isotopic analysis provides a cost-effective initial strategy for investigations involving skeletal unidentified human remains. Dietary isotopes indicated that 15 of 33 individuals were of an archaeological context. These interpretations were validated using radiocarbon dating.

Isotopic analysis has been used in archaeological and forensic contexts to examine diet, migration, trace evidence, and the origin of individuals.<sup>1</sup> On behalf of, and in collaboration with, the British Columbia (Canada) Coroners Service, this project sought to estimate the medicolegal significance of 33 cases of unidentified human remains using isotopes to indicate the subsistence pattern of these individuals. Carbon and nitrogen isotopes were analyzed as they are strong indicators of diet and could potentially differentiate an archaeological or contemporary population. As bulk isotopic analysis is more affordable than radiocarbon dating, this method may be a cost-effective initial strategy to estimate the medicolegal significance of unidentified human remains.

Archaeological populations in British Columbia typically maintained a marine diet resulting in higher  $\delta^{15}\text{N}$  and  $\delta^{13}\text{C}$  isotopic values, while contemporary populations typically maintain a terrestrial-based diet, resulting in lower  $\delta^{15}\text{N}$  and  $\delta^{13}\text{C}$  isotopic values.<sup>1</sup>

We extracted collagen from the 33 individuals and measured the carbon and nitrogen isotopes in the Archaeology Isotope Laboratory at the Department of Archaeology, Simon Fraser University, Canada. Using K-means cluster analysis, the sample was clustered into two archaeological or contemporary groups. Cases considered archaeological would be returned to local communities for reburial, while those determined to be contemporary indicate possible medicolegal significance. These results were validated using radiocarbon dating to determine the accuracy of the authors' interpretations.

Fifteen individuals were classified as archaeological context due based on their increased  $\delta^{15}\text{N}$  and  $\delta^{13}\text{C}$  values, while the remaining 18 individuals were classified as contemporary due to their lower  $\delta^{15}\text{N}$  and  $\delta^{13}\text{C}$  values. Radiocarbon dating confirmed that all individuals classified as archaeological were not of forensic interest.

The significance of this research is the demonstration that bulk isotopic analysis can provide a cost-effective initial strategy to the investigation of unidentified human remains when it is unclear whether they are from forensic or archaeological contexts.

**A24 How Low Can You Go? A Lower Bound Limit for  $\delta^{15}\text{N}$  Values From Human Bone Collagen**

Amanda N. Friend\*, SNA International in Support of DPAA Hawaii, Joint Base Pearl Harbor-Hickam, HI; Claire Maass, Defense POW/MIA Accounting Agency, Joint Base Pearl Harbor-Hickam, HI; Gregory E. Berg, Defense POW/MIA Accounting Agency, Joint Base Pearl Harbor-Hickam, HI; Lesley A. Chesson, Defense POW/MIA Accounting Agency, Joint Base Pearl Harbor-Hickam, HI

**Learning Overview:** After attending this presentation, attendees will understand a potential new tool for determining if osseous material is non-human animal based on nitrogen isotope delta values.

**Impact Statement:** This presentation will impact the forensic science community by demonstrating a lower bound limit for nitrogen isotope delta ( $\delta$ ) values for human bone collagen that can assist in determining if osseous material originated from a non-human animal.

One of the foundational questions in forensic investigations is identifying the material being examined and determining its probative value. For laboratories that routinely deal with small, non-diagnostic osseous material, this process often entails asking: is it human or non-human? The answer to this question has major implications within laboratory and medicolegal systems, as a non-human result will often remove the item from an evidentiary tract.

For non-diagnostic remains, multiple approaches for answering human vs. non-human questions are available in a large interdisciplinary laboratory setting. Histological analysis and DNA analysis (12S protocols) are often used. However, these analyses may not be feasible or appropriate due to resource limitations and/or available sample materials. Stable isotope ratio analysis has previously been used for assessing the origin of unidentified human remains, assisting with individuation, and supporting identifications in large, commingled assemblages.<sup>1</sup> The integration of isotope testing into the laboratory framework provides an opportunity to investigate its potential as an additional tool for determining if osseous material is human or non-human.

The present study investigates the use of nitrogen isotope  $\delta$  values ( $\delta^{15}\text{N}$ ) to determine if a lower limit exists for human bone collagen. The examined data were generated from an accredited laboratory that prepares, analyzes, and interprets bone collagen  $\delta^{15}\text{N}$  values as a routine part of casework. In total, approximately 4,068 samples had measured  $\delta^{15}\text{N}$  values available for the study. This dataset was scrubbed to remove samples with unacceptable atomic C:N ratios ( $<3.1$  or  $>3.5$ ); second preparations/analyses of samples completed solely for research purposes; and known non-humans, resulting in a final dataset of 3,613 test results. Individuation of the final dataset was not performed to mimic real casework circumstances in which an individual may be sampled multiple times for testing.

The mean  $\delta^{15}\text{N}$  value for the 3,613 samples was 11.38‰ with a standard deviation ( $\sigma$ ) of 1.17‰. The range was 5.16‰ to 19.33‰. Using these statistics, we propose a lower limit of  $3\sigma$  from the mean for “are probably” non-human and a limit of  $4\sigma$  from the mean for “are” non-human. After accounting for measurement uncertainty (0.34‰) and rounding to the nearest 0.05‰, these proposed limits are 7.50‰ and 6.35‰, respectively. From the dataset, 43 samples fell below the “are probably” non-human limit of 7.50‰ for an error rate of 1.19% and only 5 samples fell below the “are” non-human limit of 6.35‰ for an error rate of 0.14%.

An initial test of these limits using 12 non-human elements and standards available in the laboratory found that 67% ( $n = 8$ ) fell below the “are probably” limit, and 50% ( $n = 6$ ) fell below the “are” limit. The limits will be further tested using all routine casework samples prepared in the laboratory between August 2023 and January 2024. Additionally, no modern human bone collagen  $\delta^{15}\text{N}$  value found in the published literature to date has fallen below these limits. Future work will use more published data (e.g., a large dataset of non-human samples) to test the lower bound limits for  $\delta^{15}\text{N}$  values of 7.50‰ for “are probably” and 6.35‰ for “are” non-human to refine their use and application.<sup>2-4</sup>

**A25 Taphonomic Effects on the C:N Ratio and  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  Isotopes in Bone Collagen**

Nicole Long\*, North Carolina State University, Cary, NC; Ann H. Ross, North Carolina State University, Raleigh, NC; Ethan Hyland, North Carolina State University, Raleigh, NC

**Learning Overview:** After attending this presentation, attendees will understand the taphonomic effects of season and deposition type on stable isotope values in bone collagen using fetal and juvenile domestic pig bone samples.

**Impact Statement:** This presentation will impact the forensic science community by providing data on the preservation quality of collagen in bone using the C:N value, as well as identifying variation in the  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  values in bone deposited in different seasons and in deposition types.

Bone provides mechanical and functional properties to the skeletal elements within the human body. Structurally, the organic, proteinaceous part of bone creates a protective framework around the inorganic, mineral part of bone. This structure gives bone resistance against diagenetic processes such as bacterial invasion. The C:N ratio in bone has been used to measure the quality of the organic material in bone, which is almost entirely made up of the protein collagen.<sup>1</sup> In addition, the  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  values from bone collagen have been used to reconstruct past diets and determine suitability of collagen for radiocarbon dating.<sup>2</sup> In various conditions, microbial processes affect the rate of bioerosion depending on length of time and the conditions of the environment.<sup>3</sup> In turn, stable carbon and nitrogen isotope values in bone collagen may be influenced by the environment in which the bone is buried or deposited. In a forensic context, observing the conditions in which the C:N ratio may be affected by taphonomic factors is important to understand not only taphonomic effects of varying burial conditions, but also the reliability of  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  values.

The purpose of this study is twofold: (1) to explore collagen preservation in bone using the C:N ratio and its variation according to depositional and seasonal environments in a temperate zone; and (2) to examine individual  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  variation within these different seasonal and depositional environments. The current research draws on samples of *Sus scrofa domesticus* (fetal n=16 and juvenile n=13) deposited seasonally over the course of two years in Raleigh, NC. Raleigh, NC, is in the Piedmont region, which is defined by the Köppen-Geiger climate classification system as a Cfa climate: temperate, without a dry season, and with a hot summer.<sup>4</sup> Isotopic values were measured using an elemental analyzer isotope ratio mass spectrometer. A one-way Analysis Of Variance (ANOVA) was performed to compare the effect of season and deposition on C:N,  $\delta^{13}\text{C}$ , and  $\delta^{15}\text{N}$ . A paired sample t-test was performed on all results to compare each pair of seasons (summer and winter, summer and fall, summer and spring, spring and winter, fall and winter, spring and fall) and each pair of depositions (bag and control, blank and control, bag and blanket fetal remains, and buried and surface juvenile remains).

The ANOVA and paired sample t-test results from this study indicate that conditions of burial associated with seasonality, such as moisture and temperature, affect the stable isotope values obtained from bone. Season was a significant factor in the  $\delta^{13}\text{C}$  value in juvenile bone (p-value=0.011), the C:N ratio between summer and winter (p-value=0.023), and in fetal bone between summer and fall (p-value=0.029), and fall and spring (p-value=0.017).

Season was not a significant factor in the  $\delta^{15}\text{N}$  value for fetal (p-value=0.557) and juvenile (p-value=0.228) bone, and deposition was not a significant factor in C:N ratio (p-value=0.405) or the  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  values for both fetal (p-value=0.727; p-value=0.386, respectively) and juvenile (p-value=0.753; p-value=0.689, respectively) bone. Conditions of seasonality affect stable isotope analyses on bone collagen, and taphonomic alteration should be considered when conducting these analyses. Further research is needed to consider if the variation observed in this study is applicable in other settings and how to control for this variation.

## A26 Using Forensic Anthropological Landmarks to Optimize DNA Extractions From Post-Cranial Remains

Keith Biddle\*, University of Wisconsin,-Parkside, Kenosha, WI

**Learning Overview:** After attending this presentation, attendees will understand how the various bone cell types (osteoblasts, osteoclasts, and osteocytes) that contribute to the formation, maintenance, and changes that forensic anthropologists rely on relate directly to forensic DNA analyses. Additionally, there will be discussion of the bone tissue types (cortical, trabecular, and lamellar) and how these also relate to mitochondrial, autosomal, and Y-chromosomal DNA analyses. There will be a brief discussion of the specific sampling method, which was designed to limit the amount of destruction to bone tissue while maintaining the integrity of DNA extraction, quantitation, and analysis.

**Impact Statement:** This presentation will impact the forensic science community by providing an effective method for human bone sampling that reduces destruction to bone tissue, cost, and turn-around time associated with low DNA levels while increasing efficiency and accuracy. The method is effective for mitochondrial DNA (mtDNA) analysis, Short Tandem Repeat (STR) profile construction, and Y-chromosomal analysis and is currently being investigated for use in Single Nucleotide Polymorphism (SNP) panel construction for use in Forensic Genetic Genealogy (FGG).

It is well known in the fields surrounding forensic human identification that not all bones are ideal sources of postmortem DNA. To date, studies have focused on the primacy of postmortem (taphonomic) factors such as soil pH or exposure to water or sunlight, in an attempt to explain differences in DNA preservation. No current studies of human skeletal remains exist that incorporate deep understanding of the cellular components of bone as a potential reason for differential DNA preservation between or within post-cranial elements.<sup>1-12</sup> This research seeks to fill that void. By testing nearly 400 extraction sites representing all bone groups and three bone tissue types, this study seeks to find an explanation for differential DNA preservation that spans all demographic and taphonomic factors and uses far less bone tissue than in previous studies. Here, we show that knowledge of the cellular processes and populations specific to skeletal development and maintenance leads to far more targeted and accurate DNA extractions. By combining this novel sampling strategy with well-established DNA analytical methods, we can avoid excessive destruction of human skeletal material, reduce associated costs and turnaround time, and increase reliability of forensic DNA testing.<sup>13-17</sup>

Unlike previous studies, this project began from a targeted cellular and microstructure-based approach. Combining knowledge of bone cell and tissue types with traditional forensic anthropological methods of human identification, this project sought a new explanation for differential DNA preservation in intra-and inter-elemental extraction sites. The project began with a very targeted and strategic approach to sampling, followed by traditional chemical DNA extraction, amplification and quantitation of both autosomal DNA and mtDNA, and concluded with forensic STR profile construction.

This study provided a rare opportunity to investigate the role of the different osteological cell types: osteoblasts (including their differentiation into bone lining cells), multinucleated osteoclasts in the process of bone matrix resorption at the time of death, and fully encapsulated osteocytes, as a potential reason for differential DNA preservation and extraction quantity and quality in modern forensic cases.<sup>19-29</sup> From this launching point, detailed analysis was performed of the variance in DNA preservation and accessibility across a single, recently deceased individual's skeletal remains. This analysis into the number of starting molecules for mitochondrial, autosomal, and Y-chromosomal DNA, as well as the ability to obtain a complete Combined DNA Index System (CODIS) profile, allows us to understand how differential DNA presence, and therefore accessibility, can be predicted and measured across the post-crania. Finally, the results clearly showed that this sampling method is more accurate, significantly less destructive, and thus more cost and time efficient than methods used previously. The method can be used by forensic practitioners as well as biological anthropologists involved with genetic and genomic research of ancient humans and hominins.

By starting from a cellular and biochemical launching point, this research attempts to bridge the knowledge gap between forensic anthropology, forensic DNA analysis, and biomedical understanding of human skeletal biology and to make that knowledge accessible and applicable to those professionals on the front lines of the real-world problem of identifying unknown human skeletal remains.

## A27 Validation and Quality Control of 3D Coordinate Data From Human Crania for Forensic Casework

Amanda R. Hale\*, DPAA Laboratory/SNA International, Kaneohe, HI; Rebecca J. Taylor, Defense POW/MIA Accounting Agency, Kapolei, HI

**Learning Overview:** After attending this presentation, attendees will have a new approach to performance check digitizers according to laboratory accreditation standards for the purpose of obtaining 3D coordinate data from human crania.

**Impact Statement:** This presentation will impact the forensic science community by demonstrating how to compute the measurement uncertainty and repeatability for Interlandmark Distances (ILDs) obtained from 3D coordinate data in accordance with laboratory accreditation standards.

Direct digitization of anatomical landmarks more accurately captures geometrical information than traditional linear approaches. Other studies have demonstrated high repeatability with relatively low intra- and inter-observer error in locating most anatomical landmarks on crania with direct digitization as well as between other 3D modalities.<sup>1-5</sup> Laboratory accreditation, however, requires annual performance checks for measurement devices, including 3D coordinate machines.<sup>6</sup> Further, 3D coordinate data obtained for forensic casework are often transformed to ILDs to be used in discriminant analysis function software to interpret population affinity. Therefore, the purpose of this study was to design a quality control, performance check procedure that ensures ILDs extracted from 3D coordinate data are below the threshold of measurement uncertainty required by laboratory accreditation standards.

Eleven traditional craniometric measurements and their corresponding 18 anatomical landmarks were collected from 25 complete crania at the Defense POW/MIA Accounting Agency (DPAA).<sup>7</sup> To assess the full range of measurement uncertainty, Type I, II, and III landmarks were included.<sup>8</sup> Crania were measured twice at one-week intervals and digitized with a Microscribe® G2X digitizer a total of six times between two sessions (three times per session) at one-week intervals.<sup>9</sup> Landmarks were identified using small dot stickers when obtaining traditional measurements and were removed between the two one-week intervals. Measurement uncertainty has two components: random and systematic. The systematic uncertainty of the digitizer is reported by the manufacturer as 0.23mm and the measurement variance is 0.0529mm. The random measurement uncertainty was calculated as the combined standard uncertainty, or the square root of the variance of all measurements, and then expanded to encompass a 95% confidence interval. If the expanded uncertainty across the repeated measures was less than 2mm, it was within the acceptable margin of error for traditional craniometric measurements. A mixed effects Analysis of Variance (ANOVA) model for repeated measures was employed to assess the repeatability of the measurements between the two modalities. Finally, a repeated measures Multivariate Analysis of Variance (MANOVA) test was used to assess within-group differences across all measurements collectively.

The expanded measurement uncertainty of all 11 ILDs was below 2mm, with a range of 1.18 (frontal chord) to 1.72mm (asterionic breadth), and within a 95% confidence interval. Frontal chord distance also showed the most consistent values of uncertainty for each cranium digitized. In general, the measurements showing the greatest variation in uncertainty were parietal chord, maximum cranial length, and asterionic breadth. None of the craniometric measurements were significant for the univariate repeated measure random effects demonstrating good repeatability across 11 measurements collected. The MANOVA procedure also showed no significant differences between repeated measures across all craniometric ILDs ( $p=0.3528$ ). These results demonstrate: (1) good repeatability across the measurements collected, and (2) the digitizer used has relatively low measurement uncertainty within acceptable standards. Finally, this procedure provides consistent measures that demonstrate its efficacy for collecting 3D coordinate data within performance check standards.

### Validation; 3D Coordinate Data; Measurement Uncertainty

## A28 A Multivariate Analysis and Evaluation of Classification of Human Skeletal Vertebrae for an Applied Context

*Jolen Anya Minetz\*, University of Illinois, Paxton, IL; Stephen Ousley (posthumously), Erie, PA*

**Learning Overview:** This presentation explains a new osteometric method for classifying vertebrae and will demonstrate how multivariate analyses and quantitative classification of individual vertebrae within a vertebral column can be applied in a Forensic anthropology context.

**Impact Statement:** This presentation will impact the forensic science community by demonstrating the utility of a multivariate analysis of vertebrae in an applied context.

The purpose of this osteometric vertebral classification method is to assist with the sorting and analysis of fragmentary or commingled skeletal remains. The human vertebral column is a morphologically complex group of elements. Current methods rely on morphological characteristics to classify isolated vertebrae qualitatively. This research provides a bridge between morphological assumptions for vertebral designations and quantitative classification. These osteometric methods and statistical analyses provide quantifiable information relating to the accuracy of classifying individual vertebrae.

The sample used for this analysis consists of osteometric vertebral measurements from intact vertebral columns from 59 individuals. To assess the overall potential for these vertebral measurements to classify vertebrae, regional grouping models based on vertebral column segments (cervical 3-7, thoracic, and lumbar models) were developed and analyzed. The data was tested for multivariate normality and homogeneity of Variance-Covariance Matrices (VCMs) to comply with the assumptions required by the statistical analyses used for classification. This analysis utilized Linear Discriminant function Analysis (LDA) and K-Nearest Neighbors (KNN) classification methods. LDA requires homogenous VCMs, so when the VCMs were not homogenous, KNN was used for classification. LDA classification analyses for two cervical models (C3-C7 and C3-C5) were conducted using all available variables. The C3-C7 model has a prediction accuracy of 0.7366, and the C3-C5 model has a prediction accuracy of 0.7108. The full models for the thoracic and lumbar vertebral segments could not use LDA for classification since the VCMs for these full models were not homogenous, so KNN was used. The KNN algorithm is a supervised machine learning classification technique; the optimal number of k neighbors for each model was determined by proportionally splitting the data into training (70%) and testing (30%) samples. The classification for the full thoracic model (T1-T12) using the KNN algorithm (k=28) results in a prediction accuracy of 0.5103. The classification for the full lumbar model (L1-L5) using the KNN algorithm (k=9) results in a prediction accuracy of 0.5672. The sensitivity and specificity of each vertebral group prediction within each model was evaluated.

This method has been developed to assist with the sorting and analysis of commingled and fragmentary skeletal remains, which have a variable number of potential measurements. The results in this abstract illustrate the potential applicability of these methods in a broad and passive way; however, in an applied situation, the LDA and KNN methods should be used more dynamically (i.e., create the most appropriate models, using the most appropriate methods, for each situation) in order to accommodate the process of eliminating groups of vertebrae to reduce the model to the most relevant groups of vertebrae for the final analysis. For example, an unsorted mid-thoracic vertebra might start with a broad T1-12 model, but through an iterative deductive process, it may end with a T5-T7 model with probabilities associated with each potential vertebral group classification. This research demonstrates that by using osteometric methods and statistical analyses, the accuracy of individual vertebra classification is quantifiable.

**A29 Investigating Applications of Forensic Fractography of Bone Over the Postmortem Interval**

*Carter A. Unger\*, Texas Tech University, Lubbock, TX; Mariyam I. Isa, Lubbock, TX*

---

**Learning Overview:** After attending this presentation, attendees will be informed about fractographic features observed in bones exposed to outdoor conditions in the semi-arid climate of West Texas.

**Impact Statement:** This presentation will impact the forensic science community by contributing regionally and seasonally relevant data on the utility of forensic fractography of bone throughout the Postmortem Interval (PMI).

Fracture surfaces may provide important information about bone failure.<sup>1</sup> Fracture surfaces of brittle materials exhibit features relating to the origin, speed, stability, and direction of the propagating crack.<sup>1</sup> Research shows fractographic surface features can reliably indicate crack initiation and propagation in fresh bone, however there is limited data on their utility throughout the PMI.<sup>1-3</sup>

The objectives of this study were to: (1) investigate whether fractographic surface features are observed in bone throughout the PMI, (2) evaluate whether their frequency varies with PMI length, and (3) investigate their utility for reconstructing crack propagation throughout the PMI.

Forty partially de-fleshed deer femora were acquired from a local wild game processor. Five bones were never exposed to outdoor conditions (trial 0). The remaining 35 bones were placed within caging in a designated outdoor research area in Lubbock, TX, in January 2023. Five bones were removed every 2 weeks for 14 weeks (trials 1-7). A drop tower apparatus was used to deliver blunt force impacts to the anterior midshafts of each femur.

After impact, bones were macerated and fragments >10mm were examined for fractographic features, including bone mirror, bone hackle, arrest ridges, wake features, and cantilever curl. Fragments were examined using the unaided eye, a magnifying lens (3x magnification), and a stereomicroscope (0.7x–4.5x magnification). Fractographic features were then used to determine crack propagation direction and nucleation.<sup>2</sup>

Environmental data was obtained from the West Texas Mesonet weather network. During experiments, the average daily minimum temperature was 2.22°C, maximum temperature was 19.44°C, minimum relative humidity was 21%, maximum relative humidity was 71%, precipitation was 0.032cm, and solar radiation was 5.43kWh/m. Accumulated degree days following outdoor placement were as follows: trial 1 (537), trial 2 (1,164.5), trial 3 (1,892), trial 4 (2,618), trial 5 (3,379.5), trial 6 (4,243.5), and trial 7 (5,075).

The number of fragments produced per bone ranged from 0 to 31 (average = 9.3). Fractographic surface features were present in all trials. Cantilever curl was most frequently observed (90% of experiments), followed by arrest ridges (62.5%), bone hackle (52.5%), wake features (40%), and bone mirror (30%). In one bone (trial 0), no fractographic surface features could be identified. While most features were present in similar frequencies from trial 0 to 7, bone mirror was identified less frequently in later trials.

Orientation of fractographic features aligned with biomechanical expectations for anterior loading of the femoral midshaft. When present, bone mirror was always located posteriorly, consistent with crack initiation on the posterior tensile surface. Cantilever curl was located anteriorly 90% of the time, consistent with termination on the anterior compression surface.

This study contributes data on fractographic features in bone exposed to outdoor conditions during the mild winter and spring months in West Texas. The results show fractographic features are present and can be used to reconstruct crack propagation and nucleation throughout the recent PMI. The similar frequencies of fractographic features across different PMIs suggest that their presence alone is not indicative of PMI. These results are consistent with results obtained in human bones subjected to simulated warm weather conditions up to 40,600 accumulated degree hours.<sup>3</sup> The next phase of research will repeat experiments during the hot summer to fall months to investigate potential seasonal effects on expression of fractographic features.

**Learning Overview:** After attending this presentation, attendees will understand the different decomposition research conducted and its shortcomings due to different taphonomic agents. This presentation highlights the need for a controlled environment to account for as many variables as possible and proposes a new way of conducting this research in a controlled laboratory environment as opposed to an outdoor setting using whole bodies on body farms. This presentation also discusses the relationship between microbes and their off gases (VOCs).

**Impact Statement:** This presentation will benefit the forensic science community by focusing on a new experimental design with a proof of concept that can be replicated in a laboratory setting. Body farms are not in abundance and whole-body research has many limitations. This method can be used to test and control all variables known to impact human decomposition and was still tested on humans instead of on animal proxies; this will allow for more research to be conducted on human decomposition and will allow for better Postmortem Interval (PMI) estimation.

Accurate estimation of the PMI is a key element of forensic investigations, influencing aspects as diverse as victim identification, event reconstruction, and alibi corroboration. Current forensic pathology methods, based on a variety of short-lived physiological and biochemical markers, are effective at low PMI ranges of a few days. However, after the onset of more advanced decomposition stages, current PMI estimation methods must rely on the degree of decomposition of soft tissues, or entomological data. Most PMI research focusing on soft tissue decomposition utilizes designs based on the deposition of whole bodies at outdoor body farms, usually grouping decomposition into five broad macroscopic stages (fresh, bloat, active, advanced, and skeletonized). However, these designs do not allow the control of many relevant taphonomic variables (e.g., experimentally fix their values), their results are difficult to extrapolate to other geographic and environmental contexts, and make it difficult to reliably standardize the collection of some decomposition outputs, such as VOCs, which are gas byproducts produced as microbes break down organic macromolecules during decomposition.

This study proposes a more accessible design for collecting and analyzing VOCs, including at outdoor settings, utilizing isolated muscle tissue samples to be later safely stored, maintained, and analyzed in a controlled, hypoxic laboratory environment. One-gram samples of human muscle tissue were placed into 52 hermetic headspace vials filled with either sterilized or non-sterile natural soil, which were then maintained in an incubator at 25°C for 60 days. This design allowed us to sample and analyze the produced gases without opening the vials. Two sample vials from each treatment were extracted every five days, and their VOCs analyzed through Solid-Phase Microextraction (SPME) Gas Chromatography/Mass Spectrometry (GC/MS) to examine their evolution with time in each one of the soil treatments.

Preliminary findings indicate significant differences in VOC off-gassing between sterilized and non-sterile soil samples, serving to outline differences in the relative contributions of the soil and tissue microbiomes to the decomposition process. VOC composition was also observed to change over time, likely reflecting the evolution of the microbial community.

This tightly controlled experimental approach is a proof of concept and initial attempt to sample and characterize the VOCs emitted by decomposing human tissue. The results of this line of research show great promise to contribute to PMI estimation and areas such as buried body detection, soil chemistry, and the evolution of microbial communities during human decomposition.

**A31 Tracing PMI Through Bone Metabolomics With GC/MS and LC/MS/MS**

Elisa Roggia\*, University of Central Lancashire, Piemonte, Italy; Luke William Gent, University of Central Lancashire, Preston, England; Andrea Bonicelli, University of Central Lancashire, Preston, England; Noemi Procopio, University of Central Lancashire, Preston, England; Eugenio Alladio, Department of Chemistry, University of Torino, Piemonte, Italy

**Learning Overview:** The goal of this presentation is to show how metabolomic approaches can be used for Postmortem Interval (PMI) estimation on skeletonized tissues and will highlight the accuracy in the estimation that can be achieved by conducting such studies and how parameters such as burial depth affect the estimations.

**Impact Statement:** This presentation will impact the forensic science community by offering a new approach for PMI estimation of skeletal remains buried for up to six months. Attendees will learn about the effect that the burial environment plays on the metabolomic signature and about the accuracy that this method offers.

The estimation of the PMI has a key role in forensic investigations.<sup>1</sup> The postmortem modifications affecting the human body are complex and known to be affected by various intrinsic and extrinsic factors, making the PMI estimation challenging and debated. Recent studies have shown the potential of metabolomics for estimating PMI starting from skeletal remains.<sup>2,3</sup> This study aims to investigate the correlations between bone metabolites and PMI in a six-month time window, as well as to investigate the influence of depth on the metabolomic signature.

The experiment was conducted at the Taphonomic Research in Anthropology: Centre for Experimental Studies (TRACES), the animal taphonomy facility of the University of Central Lancashire, United Kingdom. Overall, 12 pig mandibles purchased from a local butcher were divided into four quadrants. All the fragments obtained were considered to be biological replicates, as preliminary analyses on the fresh bones showed that their metabolomic profile was comparable. A total of 48 bone replicates were buried at four different depths (0, 10, 30, and 50cm); for each depth, two replicates were deposited approximately 70cm from each other. Every month (up to six), a couple of replicates for each depth were recovered and frozen until further processing. Subsamples were obtained using a drill by cutting a wedge shape fragment, which was then powdered using SPEX® Sample Prep 6775 Freezer Mill. Samples were then prepared for the metabolite extraction weighing 40±1mg of bone powder in 2ml Pre-Filled Bead Mill Tubes. The extraction was performed by adding methanol/water solvent (8:2) to each tube, then homogenized and centrifuged. The extraction just described was run two times and the extracted liquid was then transferred in two sets of Eppendorf® tubes (one set for Gas Chromatography/Mass Spectrometry [GC/MS], one for Liquid Chromatography/Tandem Mass Spectrometry [LC/MS/MS] analysis). Samples were then dried using the Sample Concentrator and stored at -20 degrees. For the reconstitution MOX and BSTFA solvents were used in equal volume; each addition was followed by a 15-minute run on the ThermoMixer® at 60 degrees/400rpm. Finally, all the samples were transferred into glass vials with an insert and secured with their cap. For the analysis, samples were run in Agilent® 8879 GC (MSD 30m x 250µm x 0.25µm column), with autosampler, combined with 5977C GC-MSD, paired with Mass Hunter™ software. Untargeted metabolomics was then carried out also using a Thermo™ Orbitrap™ instrument.

Identified compounds with both GC/MS and LC/MS/MS revealed the lack of significant correlations between the metabolomic profile and the burial depth, showing that depth does not have a relevant influence on PMI estimation when using bone metabolomics. Regarding the PMI estimation, Partial Least Squares Regression (PLS-R) was performed on the data acquired with the GC/MS and showed a Mean Absolute Error (MAE) value of 0.47 months, highlighting the potential that this method may offer for PMI estimation of skeletal remains with relatively short PMIs. In addition to the GC/MS data, LC/MS/MS results will be also presented to the attendees, and the difference between the two platforms and relative results will be discussed at the conference. By comparing these two techniques, we expect to obtain wider metabolomic coverage.

Overall, it can be concluded that the bone metabolomics approach is a valid resource for relatively short PMI investigation from skeletal remains in a cheap and reliable manner, and further studies may elucidate its applicability to real forensic scenarios.

**A32 Using Evidence of Microbial Modifications on Postmortem Bone Surfaces to Narrow Down Time Since Death Estimations**

Caroline Rowe\*, University of Minnesota Twin Cities, Minneapolis, MN

---

**Learning Overview:** After attending this presentation, attendees will understand how to differentiate bacterial from fungal bone surface modifications on the cortical surfaces and the internal microstructure of postmortem bone. Attendees will also learn how these modifications, in conjunction with microbial sequencing patterns, may assist in narrowing down the Postmortem Interval (PMI).

**Impact Statement:** This presentation will impact the forensic science community by increasing the methods available that are useful for assisting forensic investigators with the determination of the PMI.

Determining the PMI during a forensic investigation is critical for numerous reasons, including predictions regarding cause of death, validating alibis, and the identification of victims.<sup>1</sup> However, resources for assisting investigators with this task are limited, thus the development of additional tools that forensic investigators have for predicting PMI is critical. One such tool that has recently been exploited is the sequencing of microbial communities during the stages of decomposition. Because human decomposition is sustained by shifts in ever-present microbial communities, the knowledge of microbial succession can provide a reliable postmortem clock.<sup>2</sup> One class of microbes found consistently throughout the stages of decomposition are those that are capable of lysing collagen, which may result in the bioerosion of bone.<sup>3</sup> These collagenolytic bacteria are thought to be released from the enteric and thoracic cavities as decomposition progresses.<sup>4</sup> While previous research has isolated morphology unique to modifications created by collagenolytic microbes, including fungi and bacteria, on the internal microstructure of postmortem bone, there is no existing research that documents microbial modifications on the cortical surface of postmortem bone.<sup>5</sup>

This study will document the morphology of modifications made by collagenolytic microbes on the cortical surface of bone. This study will then use those data, along with previous reported data identifying microbial bioerosion on the internal microstructure of bone, to determine the timing between the first appearance of collagenolytic microbes on a carcass and evidence of bioerosion on the cortical surface and the internal microstructure of postmortem bone.

This study first isolated, established, and confirmed morphology consistent with that of microbial modifications on the cortical surfaces of bone by inoculating bones with either collagenolytic bacteria or allowing them to naturally accumulate fungus in a shallow burial environment. Bones were examined for modifications periodically over four weeks. The second part of this study determines the stage of decomposition when collagenolytic microbes first appear relative to the time it takes for these microbes to create modifications on both the cortical surface and within the microstructure of the bone. Sixty rat carcasses were left to decompose in a shallow burial environment with long bone elements removed from two rats per day for 30 days and until skeletonization occurred. Bones were cleaned and examined for bone surface modifications using scanning electron microscopy. The same bones were then prepared for examination under light microscopy for evidence of bioerosion within the microstructure of the bones. As long bones were initially removed, the enteric and thoracic cavities of the rats were cultured on skim milk agar plates to identify the presence of collagenolytic bacteria.

Preliminary results show that it is possible to differentiate between modifications created by bacteria and fungi on the cortical surface of postmortem bone. Bacterial modifications presented as areas of staining around nutrient foramina as well as the formation of bone sequestra during the transition to skeletonization. Fungal modifications presented as staining in the shape of hyphae, which intensified throughout decomposition. Tunneling of the fungi into the bone, which has been previously documented on the internal microstructure of bone, did not appear within the first 30 days, but was present on random bone samples that had been buried for three months.<sup>5</sup>

Results show that the timing between the appearance of collagenolytic microbes and the appearance of modifications on the internal microstructure was approximately two days, versus four days on the cortical surface of the bone. These preliminary results suggest that the presence of microbial modifications may be used, along with information regarding the timing of first appearance of collagenolytic microbes during decomposition, to assist in narrowing the PMI of a corpse.

**Microbial; Postmortem Interval; Decomposition**

**A33 The Megyesi Total Body Score Method: Inter-Observer Agreement and Sources of Bias**

Tempest D. Mellendorf\*, University of Tennessee, Knoxville, Rapid City, SD; Madeline R. Leggiero, Mercyhurst University, Gouldsboro, PA; Luis L. Cabo, Mercyhurst University, Erie, PA; Allyson M. Simon, The Ohio State University, Westlake, OH; Varun V. Tewari, Mercyhurst University, Seneca Falls, NY

**Learning Overview:** After attending this presentation, attendees will learn how the accuracy of the Total Body Score (TBS) method by Megyesi et al. and its recommended modifications by Moffatt et al. is affected by scoring using only photographs versus scoring using photographs with the addition of case-related written documentation.<sup>1,2</sup> Attendees will learn about inter-observer agreement and possible origins of scoring bias in this sample.

**Impact Statement:** After attending this presentation, attendees will be aware that the findings of this study strongly suggest that the flaws of macroscopic Postmortem Interval (PMI) estimation methods cannot be explained by subjectivity factors, such as lack of clarity, or levels of detail in the scoring methodology and documentation. The flaws of these methods are more likely caused by fundamental factors, such as the inability of the TBS scale to represent decomposition progression in sufficient detail, or the inability to represent the relationships between TBS and Accumulated Degree Days (ADD) through mathematical models.

The PMI is an important part of forensic investigations. The first PMI estimation method from macroscopic decomposition stages was proposed by Megyesi et al.<sup>1</sup> This method is based on TBS and ADD. TBS is determined by combining the numerical scores assigned to decomposition stages of three anatomical regions (Head/Neck, Trunk, Limbs) from photographs. The TBS is converted to ADD, which is then compared with weather-station temperature data to obtain the PMI estimate, similar to the use of physiological times in forensic entomology. This study's objective is to test the accuracy of the Megyesi et al. method, and its recommended modifications by Moffatt et al., in an American Northeast sample, when TBS is estimated from photographs alone or when they are supplemented with case-derived written documentation.<sup>1,2</sup>

The study sample consists of 44 forensic cases from the Mercyhurst University Department of Applied Forensic Sciences Database (MU-DAFS DB). All selected cases were surface deposits of adult individuals, with appropriate photographs and preserved body regions. The first observer scored each case back-to-back, once only from photographs, then with both photographs and case notes. A second observer scored a subsample of 25 cases to test inter-observer agreement. All scores were then plugged into the respective equations provided by the Megyesi and Moffatt methods to obtain ADD and PMI estimates. The different types of estimates from both methods and observers were compared through Wilcoxon tests. Spearman correlations and percent agreement were utilized to quantify agreement between methods and between observers. The addition of notes did not result in any significant differences either in the resulting ADD (Megyesi,  $p = 0.765$ ; Moffatt,  $p > 0.999$ ) or PMI estimates (Megyesi,  $p = 0.762$ ; Moffatt,  $p > 0.999$ ) in any of the methods. Indeed, the estimates obtained with and without the addition of extra documentation showed extremely strong correlations with one another (Megyesi: ADD:  $r = 0.98$ , PMI:  $r = 0.99$ ; Moffatt: ADD:  $r = 0.98$ , PMI:  $r = 0.98$ ). Moderate to high agreement rates were also found between observers, with variations depending on the anatomical area. From only photographs, the anatomical section with the highest inter-observer agreement was the Head/Neck region (80%), followed by Limbs (68%), and Trunk (64%). Although utilizing photographs and the addition of notes did not influence the final ADD and PMI estimates, it appeared to decrease inter-observer agreement. When observers incorporated case documentation during scoring, inter-observer agreement was 72% for Head/Neck, 64% for Limbs, and 56% for Trunk. Overall, supplementing the use of photographs with additional information, in the shape of detailed case notes and documentation, did not improve the PMI estimates obtained from either of the methods. However, the addition of the supplementary information appears to increase observer bias, decreasing inter-observer agreement. This strongly suggests that the shortcomings of these methods are not explained by subjectivity factors, or deficits in the clarity or level of detail of their scoring methods and documentation, but likely by more fundamental factors, such as the ability of the TBS scale to represent decomposition progression in sufficient detail or of their mathematical models to represent the relationships between TBS and ADD.

**A34 Using Artificial Intelligence: Deep Learning for Human Decomposition Staging**

*Anna-Maria Nau\*, University of Tennessee, Knoxville, TN; Phillip Ditto\*, University of Tennessee, Lenoir City, TN; Dawnie W. Steadman, Forensic Anthropology Center, University of Tennessee, Knoxville, TN; Audris Mockus, University of Tennessee, Knoxville, TN*

---

**Learning Overview:** After attending this presentation, attendees will have a better understanding of how deep learning vision methods can be used to automatically assign the stage of human decay from digital photos.

**Impact Statement:** This presentation will impact the forensic science community by demonstrating an approach that utilizes deep learning to automate identification of the stage of human decomposition from a digital photograph.

Knowing the Stage Of Decomposition (SOD) based on morphological features can inform the potential Postmortem Interval (PMI) of the decedent and aid in identification of the remains. Presently, establishing the SOD is commonly done manually by trained experts via an existing evaluative method, such as Megyesi et al., which stages human decomposition by assigning a point value by body region and giving a total body score in an effort to estimate objectively the SOD and PMI.<sup>1</sup> This study aims to automate Megyesi et al.'s method for determining the SOD by building a deep learning model from photos of approximately 800 human donors undergoing decomposition at the Anthropology Research Facility, located at the University of Tennessee, Knoxville.

The described approach employed the Xception Convolutional Neural Network (CNN) model architecture trained on the human decomposition image dataset.<sup>2</sup> To align with Megyesi et al.'s staging method, which divides staging into three body segments (i.e., head, torso, and limbs), three Xception models, trained on head images (head-CNN), torso images (torso-CNN), and limbs images (limbs-CNN) were developed and evaluated. Specifically, each model classifies an image into one of the following four stages of decay used by Megyesi et al: (1) fresh or SOD1, (2) early decomposition or SOD2, (3) advanced decomposition or SOD3, and (4) skeletonization or SOD4.

To evaluate the performance of each CNN model, the macro-averaged F1 score (maF1), which is an unweighted mean of the F1 scores calculated per class (i.e., SOD) commonly used for multi-class classification problems, was calculated. The maF1 scores for each CNN model were as follows: 0.89 for head-CNN, 0.88 for torso-CNN, and 0.7 limbs-CNN. Similar SOD prediction performance was achieved by the head-CNN and torso-CNN as indicated by their maF1 scores. However, the limbs-CNN maF1 score was notably lower than the maF1 scores of the head-CNN and torso-CNN, which could be due to the decay variability present in limbs (e.g., part of a leg was fresh or SOD1, while the remaining part was showing advanced decomposition or SOD3) as well as the photography itself. This variability can confuse the Artificial Intelligence (AI) and hence lower its classification performance. Early results of the maF1 scores have indicated model ability to predict the SOD from images, but future work will build upon this foundation to further improve model performances.

This proof-of-concept study suggests that contemporary AI methods may be successfully applied in forensic anthropology. Specifically, it may be possible to automate the manually intensive task of determining the SOD and applying it to existing and ongoing investigations and examinations by law enforcement and medical examiner offices. Additionally, it may also support research on PMI estimation and other downstream forensic tasks. The current deep learning model would only apply for human remains in temperate conditions. Further work of training the model on other forensic collections representing varied climatic conditions may be needed.

**A35 Testing Decomposition Scoring Methods at FOREST in Cullowhee, North Carolina**

*Leilah Melerine\*, Western Carolina University, Cullowhee, NC; Rebecca L. George, Western Carolina University, Cullowhee, NC; Nicholas V. Passalacqua, Western Carolina University, Sylva, NC*

---

**Learning Overview:** After attending this presentation, attendees will have a better understanding of how published decomposition scoring methods to estimate the postmortem interval do not sufficiently model the patterns of decompositional changes observed at a human decomposition facility in Cullowhee, NC. Difficulties with two published methods versus the morphological changes observed will be discussed.

**Impact Statement:** This presentation will impact the forensic science community by adding to the ongoing discussion of regional differences demonstrated at human decomposition facilities.

The purpose of this study was to examine the performance of two of the primary decomposition scoring methods, Megyesi et al. and Connor et al., using decomposition data generated from the human decomposition facility at Western Carolina University, the Forensic Osteology Research Station (FOREST).<sup>1,2</sup> FOREST is on WCU's campus in Cullowhee, NC. Cullowhee is within an area classified through Köppen-Geiger as a warm-temperate, fully humid, warm summer (Cfb) region.<sup>3</sup> The average temperature is 12.97°C (55.35°F), and the area receives approximately 130.23cm (51.27 inches) of rain annually.<sup>4</sup> Donors often undergo periods of extensive moisture changes due to the rain and temperature shifts at FOREST, and scavenging often leads to differential skeletonization between individuals and across single sets of remains.<sup>5,6</sup>

For this project, 20 donors from the 2022 calendar year were chosen: winter donors were placed in February, spring donors were placed between April and May, summer donors were placed between late June and August, and fall donors were placed between September and November. Donors that were included had not been enrolled in any other skeletal modification studies nor had they arrived beyond the earliest stages of decomposition; autopsied donors were included, though, as FOREST often receives individuals who were organ donors or autopsied. Donor remains were scored for both the Megyesi et al. and Connor et al. methods from daily and weekly photographs taken for six months or until the donor was recovered from FOREST, whichever happened first.<sup>1,2</sup> Total Body Score (TBS) and Total Body Desiccation Score (TBDS) were calculated, respectively, for the given photograph ranges, and Accumulated Degree Days (ADD) were also tallied per donor for the given range utilizing temperature data from the nearby NOAA station at the Jackson County Airport, which is approximately 3.54km (2.2 miles) from FOREST. ADD estimates were calculated for the Megyesi et al.<sup>1</sup> method to examine the accuracy and precision of actual ADD; as no equations are provided in Connor et al.<sup>2</sup> to calculate the predicted ADD from this method, qualitative data were utilized to examine the fit to the decompositional processes at FOREST.<sup>1,2</sup>

Results found that only 1 of the 20 scored donors had an actual ADD within the 95% confidence interval for predicted ADD from the Megyesi et al. method, making it neither accurate nor precise for scoring decomposition at FOREST. The conciseness of this method was helpful for quickly scoring donors, but the broadness of each category was insufficient to capture the variation in decomposition. In particular, the combination of scoring upper and lower limbs together complicated scoring as donors at FOREST often retain mummified tissue on the lower limbs for several months beyond that of the upper limbs, likely due to differential scavenging patterns. For the same reason that the Megyesi et al. method was not fitting the decompositional pattern at FOREST, the Connor et al. method was more helpful.<sup>1,2</sup> The division of scoring for upper and lower limbs, as well as the expanded categories, provided more options. However, the dearth of variety in the color category and the lack of qualifiers for the moisture category often left questions about how to score the unique colorations and tissue moisture observed at FOREST. For example, donors at FOREST often have orange patches on their skin in the early stages of decomposition that are not captured in the provided color category. Additionally, portions of the donor's faces, mainly eyes and mid-face, are targeted by scavengers, while the rest of the face may still have fresh tissue. These complicating factors make neither of these methods a good fit for regular use in the decompositional environment of the FOREST.

**Decomposition; Human Remains; Postmortem Interval**

**A36 It's a Dry Heat: Testing Existing Postmortem Interval (PMI) Equations in Clark County, Nevada**

Dayanira Lopez\*, University of Nevada Las Vegas, Las Vegas, NV; Clairra Ralston, University of Nevada, Las Vegas, Henderson, NV; Jennifer F. Byrnes, University of Nevada, Las Vegas, Las Vegas, NV

**Learning Overview:** After attending this presentation, attendees will have a better understanding of how existing equations used to estimate the PMI for human remains perform in the hot desert environment of Clark County, NV. Specifically, the accuracy of three different methods used to estimate PMI for decomposing human remains encountered in outdoor and aqueous environments are discussed, with recommendations for continued practice.

**Impact Statement:** This presentation will impact the forensic science community by demonstrating the need for environment- and region-specific methods for estimating the PMI. These improvements will aid stakeholders of the medicolegal community in their investigations by providing more accurate estimates of time since death, improving chances of positive identification, and promoting collaboration between practitioners seeking justice for all decedents.

The state of Nevada is divided into two very different environments: in the north are “cool mountain forests” and in the south, where Clark County is located, a “scorching lowland desert.”<sup>1</sup> With the possibility of reaching extreme temperatures well over 100°F, estimations of PMI for decedents found in advanced stages of decomposition can be challenging for forensic anthropologists.<sup>1</sup> Furthermore, the commonly used equations for estimating PMI in forensic anthropology were not designed to estimate decomposition rates in desert environments, like that of Clark County, posing additional challenges.

Previous research has evaluated the Megyesi et al. equation, comparing its accuracy between three different decomposition facilities in Texas and Tennessee.<sup>2,3</sup> Results of their comparative study found that the estimated and actual accumulated degree days did not correlate well, overestimating for remains directly in the sun and underestimating those in the shade.<sup>3</sup> However, their study was conducted using the original equation, not the improved equation proposed by Moffatt et al.<sup>4</sup>

This study, modeled after previous research, compares the accuracy of three PMI equations in the desert environment of Clark County, NV.<sup>3</sup> With permission from the Clark County Office of the Coroner/Medical Examiner, their existing database was used to identify cases for inclusion. For this study, the following parameters were used: (1) positive identification of the decedent; (2) decedent/remains found outdoors; (3) listed date found; (4) listed date last known alive or reported missing; and (5) photographs of all body regions to be scored (i.e., head and neck, trunk, and limbs). Out of 688 cases reviewed, 52 met the parameters for inclusion. Photographs for each case were scored following the guidelines published by Megyesi et al. with the improvements recommended by Moffatt et al.<sup>3,4</sup> For skeletonized cases, Behrensmeyer was also used to estimate PMI (n = 6).<sup>5</sup> Finally, cases found submerged in Lake Mead (n = 3) were evaluated following Heaton et al.<sup>6</sup> Spearman's Rank Correlation was calculated for the estimated PMI produced using the Moffatt et al. equation and the actual PMI in days.<sup>4</sup> There was a positive correlation between the two groups,  $r(50) = 0.76$ ,  $p < 0.001$ . However, due to the small sample size, as well as over half of the cases scoring in the “Early Decomposition” phase, a two-sample, two-tailed t-test was also performed. There was a statistically significant difference between the two means ( $t[102] = 2.52$ ,  $p = 0.01$ ). All cases evaluated following Behrensmeyer fell within the estimated PMI range, except for one that was underestimated.<sup>5</sup> Finally, all aqueous cases evaluated following Heaton et al. grossly underestimated the PMI.<sup>6</sup> These results suggest that the PMI estimates produced using Moffatt et al.'s equation may not be the most accurate for cases in advanced stages of decomposition in southern Nevada. For cases where a PMI estimate by a forensic anthropologist in Clark County, NV, is requested, results suggest that Behrensmeyer should be used for the most accurate results.<sup>5</sup>

These data evaluate existing methods of estimating PMI in forensic anthropology for quality assurance, highlighting areas for improvement within the field. Though a preliminary study, demonstrating the underperformance of these methods for the hot and dry desert environment of Clark County supports the development of region-specific equations, which will improve our accuracy in PMI estimations. By continuing to improve our methods, we increase our chances of accurately estimating time since death, aiding investigators in the positive identification of decedents. Importantly, this supports the ultimate goal of seeking justice for all.

**A37 Postmortem Interval in the Pacific Northwest—King County, Washington**

*Kiana C. Miller\*, King County Medical Examiner's Office, Seattle, WA; Andrew C. Seidel, King County Medical Examiner's Office, Seattle, WA*

**Learning Overview:** After attending this presentation, attendees will be familiar with the general timeline of the decomposition process in King County, WA, and its applications for estimating the Postmortem Interval (PMI).

**Impact Statement:** This presentation will impact the forensic science community by addressing the scarcity of research concerning PMI estimation in the Pacific Northwest. The anthropology department at the King County Medical Examiner's Office (KCMEO) conducted a retrospective case review to establish broad-scale timeframes for the decomposition process within its jurisdiction—a region extending from the Cascade Mountains to the Puget Sound and including settings ranging from urban to rural.

This case review examined 102 cases involving anthropology consultations at KCMEO between 2001 to 2022. Only cases in which the decedent was positively identified were included, and PMI was approximated by comparing the date of recovery to the date the individual was last known alive. Cases that were thermally altered, unidentified, or exhumed were not reviewed. Of the 102 cases reviewed, three fell into the “fresh” category and were excluded from further analysis. Investigation, autopsy, and anthropology reports as well as scene photographs were used to classify each case into decomposition stages and calculate a Total Body Score (TBS).<sup>1,2</sup> Additional information recorded includes the location (latitude and longitude), an inventory of remains, the presence of clothing/covering, depositional environment (including indoor versus outdoor contexts), and observable taphonomic changes. Box plots were used to explore the rate at which decomposition occurred across different settings.

Results of this research indicate that, relative to published data from other regions of the United States, decomposition rates in King County are delayed.<sup>1-4</sup> Observed rates of decomposition in King County are comparable to those reported from a study in British Columbia, however, likely reflecting the influence of a shared moderate oceanic climate that is distinct from regions where the bulk of decomposition studies have occurred.<sup>5</sup> Although the total ranges of PMI for each stage of decomposition overlap, their interquartile ranges exhibit greater separation. Within this dataset, early-stage individuals (corresponding to TBS scores of 8–18) are typically seen from a few days to three weeks but may persist for upward of one month. Of note, no early-stage individuals were recovered outside in the cases reviewed for this study. Individuals exhibiting advanced decomposition (associated with a TBS of 18–26) had PMIs that generally fell between one and two months but could occur as early as two weeks or persist for more than six months. Skeletonization (TBS of 24–35) can be seen as early as three weeks but is more common after a period of approximately three months. Although possibly the result of sampling error, the available data indicate that advanced decomposition is attained more quickly in indoor settings, but that skeletonization occurs more rapidly outside. Bleaching and exfoliation of the bone in the extreme stage (TBS >31) are only seen in cases recovered from outdoor settings. Bleaching typically occurs after one year of exposure, while exfoliation and/or cortical cracking is not observed until approximately 18–24 months.

It is a truism that decomposition rates exhibit regional variability, yet the majority of human decomposition facilities in the United States have been established in areas with similar Köppen climate classifications.<sup>6</sup> This research not only provides baseline data for decomposition rates in the climatically distinct Pacific Northwest, but also illustrates the utility of retrospective studies for the study of PMI in the absence of formal human decomposition facilities.

**A38 A Drop in the Bucket: An Analysis of Southwest Florida Weather Station Variables to Inform Postmortem Interval**

*Savanna Agilar\*, Florida Gulf Coast University Human Identity and Trauma Analysis Laboratory, Fort Myers, FL; Micki Besse, Florida Gulf Coast University Human Identity and Trauma Analysis Laboratory, Fort Myers, FL; Heather A. Walsh-Haney, Florida Gulf Coast University Human Identity and Trauma Analysis Laboratory, Fort Myers, FL*

---

**Learning Overview:** After attending this presentation, attendees will have learned the importance of site-specific soil data collection and weather station instrumentation placement in the estimation of anaerobic Postmortem Interval (PMI).

**Impact Statement:** This presentation will impact the forensic science community by identifying the need to obtain crime scene soil data due to the variability of data extracted from open-source weather stations. These findings influence the calculation of the PMI estimated by forensic anthropologists and entomologists.

Existing PMI estimation methods recommend the use of weather data obtained from National Weather Service (NWS) stations closest to the crime scene.<sup>1-3</sup> However, recent research suggested that selecting NWS stations based on closest proximity may not provide climate data effective for accurate PMI estimations.<sup>4</sup> Specifically, Dabbs found that NWS stations up to 9km away from the scene were more effective at establishing an accurate PMI than those stations nearest in proximity by comparing the NWS temperature data to site ambient weather loggers (60cm above ground) that captured the microclimatic differences.<sup>4,5</sup>

The NWS' instrumentation standards (e.g., temperature sensors should be 5 feet above ground and 100 feet from a paved or concrete surface) are more defined than alternative weather stations. A relatively new weather station platform, WeatherSTEM™ (WS), provides both ambient weather and soil data but its applicability in PMI estimation has not been tested. In this study, we investigated the utility of WS stations and the effect that station installation variables have on PMI estimation. Further, we supplement existing NWS PMI studies by examining ambient humidity and temperature relative to Site-Specific Soil (SSS) data (i.e., temperature and moisture) within Florida Gulf Coast University's Buckingham Environmental Forensics Facility (BEFF).

We compared data from the BEFF WS to the five closest stations that yielded ambient weather and soil data. Then, as an alternative to the microclimate data loggers used in previous studies, we collected the SSS data using Vernier® LabQuest® 3 temperature and moisture probes during an exhumation at BEFF and tested the efficacy of these data as applied to Vass' anaerobic equation. The data revealed a difference between average BEFF WS and SSS temperature and moisture, where SSS temperature was 3°C higher and soil moisture was 59.5% less saturated than BEFF WS. Among the other WS stations, three of the five (60%) stations were situated within two yards of dense vegetation or fixed structures (e.g., a building). Two stations (40%) were situated within irrigated orange groves or gardens. The altitude among stations varied significantly ( $p < 0.05$ ) with the lowest and highest altitudes being 7 feet and 161 feet above sea level, respectively. One of the five (20%) WS stations had a soil sensor at the same depth (50cm) as the BEFF and the burial we used to test Vass' equation while the other WS units captured soil data at depths ranging from 30cm to 58cm ( $p < 0.05$ ). Despite these variations in station factors, only the SSS data produced an accurate PMI range for the exhumed decedent. This study shed light on the utility of the WS and emphasized the need for forensic practitioners to collect SSS data from the scene to accurately estimate PMI in subaerial contexts.

**Postmortem Interval; Burial; Accuracy**

## A39 Under the Weather: A Report of Faunal Scavenger Activity During Major Weather Systems Within a Taphonomic Facility in Southwest Florida

Micki Besse\*, Florida Gulf Coast University Human Identity and Trauma Analysis Laboratory, Fort Myers, FL; Savanna Agilar, Florida Gulf Coast University Human Identity and Trauma Analysis Laboratory, Fort Myers, FL; Heather A. Walsh-Haney, Florida Gulf Coast University Human Identity and Trauma Analysis Laboratory, Fort Myers, FL

**Learning Overview:** After attending this presentation, attendees will better understand the influence of major climatic events on faunal activity at an outdoor taphonomic facility.

**Impact Statement:** This presentation will impact the forensic science community by introducing attendees to faunal presence and activity related to major weather systems at a taphonomic facility in Southwest Florida. This research has potential implications on Postmortem Interval (PMI) estimation as these faunae have been identified as scavengers at similar taphonomic facilities.

Faunal presence and activity at taphonomic facilities is well-documented with wild boar (*Sus scrofa*), bobcat (*Lynx rufus*), squirrel (*Sciuridae*), raccoon (*Procyon lotor*), rat (*Rattus*), mouse (*Mus*), and dogs (*Canidae*) identified as common scavengers within these facilities.<sup>1-3</sup> However, the presence of these faunae at the Florida Gulf Coast University (FGCU) Buckingham Environmental Forensics Facility (BEFF) and faunal activity changes during major climatic events within taphonomic facilities, in general, is less understood. Major climatic events, such as Hurricane Irma (Category 5) in 2017, produced extreme atmospheric changes (e.g., barometric pressure, temperature, and relative humidity) that influenced faunal scavenger activity.<sup>3</sup> For example, Hurricane Irma reduced deer (*Odocoileus virginianus*) populations and altered migration patterns, with deer leaving marshes and shrub habitats in favor of pine forests in the aftermath of the storm.

In this study, we documented the impact of two hurricanes (Category 1 Hurricane Nicole = indirect hit; Category 5 Hurricane Ian = direct hit) on the presence and frequency of faunal scavengers within the BEFF. These data were collected via FGCU's Human Identity and Trauma Analysis (HITA) WeatherSTEM™ unit and 11 Xtellar trail cameras (with motion-triggered infrared sensors). We visually inspected the weather station video feed and trail camera photographs that were time and date delineated, recorded the presence of the faunal scavengers within the facility, and controlled for overlapping data (i.e., animal movement on multiple cameras). We used the six-month interval prior to the storms' impact as our control.

Through our analysis of the weather station videos and trail camera photographs, we identified four common faunal scavengers: wild boar (*Sus scrofa*), bobcat (*Lynx rufus*), squirrel (*Sciuridae*), and raccoon (*Procyon lotor*). *Sus scrofa* was the most abundant faunal scavenger recorded, with the greatest abundance occurring during Hurricane Nicole and the least abundance recorded the week prior to Hurricane Ian. This activity was positively correlated (0.217) with the timing of the storm systems ( $p < 0.05$ ). We observed no change in bobcat, squirrel, or raccoon abundance within BEFF in this study. The temperature, barometric pressure, and relative humidity changed significantly ( $p < 0.005$ ) from the control. These findings can inform PMIs estimated by forensic anthropologists, especially in Florida, as *Sus scrofa* abundance is estimated to be 500,000 to 1 million (in Florida) and is considered the most widely distributed invasive ungulate across the United States.<sup>4</sup> As observed in this study, *Sus scrofa* was the most prolific faunal scavenger observed at the BEFF.

### Postmortem Interval; Hurricane; Scavenging

---

**A40 Exploring the Scavenging Behavior of Bobcats, *Lynx Rufus*, in the Middle Tennessee Area and Its Forensic Implications**

*Yangseung Jeong, University of Tennessee, Knoxville, Murfreesboro, Tennessee; Aaron Gatewood\*, Middle Tennessee State University, Murfreesboro, TN*

---

**Learning Overview:** After attending this presentation, attendees will have learned about the scavenging patterns of bobcats, *Lynx rufus*, and their taphonomic effects on a carcass in the Middle Tennessee area. Additionally, there will be an overview of the decomposition research facility of the Middle Tennessee State University (MTSU) Outdoor Forensic Facility (MOFF) provided to the attendees.

**Impact Statement:** This presentation will impact the forensic science community by highlighting the scavenging activities of bobcats, which have generally been known as hunters. A deeper understanding of bobcats' scavenging effects will allow forensic investigators to identify their activities and will furthermore help reconstruct the context of crimes more accurately when bobcat-associated trauma is found on a victim.

Knowledge about local scavengers and their scavenging activities is required to determine if any trauma/damage observed on a victim was inflicted by animals or humans.<sup>1</sup> Although bobcats are generally known as hunters, their scavenging activities have recently been reported.<sup>2</sup> Fain and Jeong also confirm that bobcats are among the primary scavengers active in the Middle Tennessee area.<sup>3</sup> The goal of this study is to examine the scavenging patterns of bobcats and their taphonomic effects on carcasses.

Experiments took place at the MTSU Outdoor Forensic Facility (MOFF) in Murfreesboro, TN, an outdoor decomposition research facility administered by the MTSU Forensic Science Program. Seven deer carcasses were placed into plots across 15 months (January 2022–April 2023). Each plot was surrounded by 3-foot-high metal fences and monitored by two motion detection cameras. Bobcats' activities were examined with the following factors considered: the time of day/year, weather conditions, and type of activities.<sup>1</sup> The types of activities fell into five categories: Feeding, Covering/Scent marking, Resting, Appearing with no activity, and Unknown. The peak hours of bobcat activity reported by Rippley and colleagues (04:00 a.m.–10:00 a.m. and 6:00 p.m.–12:00 a.m.) were tested.<sup>2</sup>

The results showed that bobcats are readily willing to scavenge in this area. There were 71 occurrences of bobcats recorded by the cameras, with 38 instances being of them feeding on the carcasses. There were 27 occurrences where bobcats appeared with no activity, and the other three categories had fewer than five occurrences each. Two of the seven carcasses had no bobcat recordings at all, and one carcass received visits from a bobcat with no feeding involved. Out of the remaining four carcasses, three were fed on by a bobcat within eight days of placement. The duration of bobcat scavenging ranged from 4 days to 46 days. Limbs appeared to be the initial target of scavenging; however, no distinct preference between the forelimbs and hindlimbs was noticed. Regarding weather conditions, bobcats did not seem to display a strong aversion to colder seasons/temperatures, precipitation, or carrion insects. This study suggests revised peak hours of 5:00 p.m.–7:00 a.m. during which 64 out of the total 71 occurrences happened (90.1%).

This is one of the few studies examining bobcat scavenging from a forensic perspective. The results will provide forensic investigators with practical knowledge about bobcat scavenging activities in this area, helping them to: (1) distinguish bobcat-associated evidence from human-induced trauma, (2) reconstruct the context of peri- and postmortem events more accurately, and ultimately (3) resolve forensic cases on a more informed basis.

---

**A41 A Longitudinal Observation of Pattern and Trajectory of Packrat Scavenging Among a Cohort of Human Donors**

Christiane I. Baigent\*, Southern Illinois University Carbondale, Fairplay, CO

---

**Learning Overview:** After attending this presentation, attendees will understand the longitudinal pattern and trajectory of packrat scavenging among a cohort of human donors.

**Impact Statement:** This presentation will impact the forensic science community by supplementing the case study-based body of knowledge with controlled, longitudinal observation of the pattern and trajectory of packrat scavenging among a cohort of human donors.

The destructive nature of packrat (*Neotoma cinerea*) progenerated scavenging of human remains has received considerable attention in archaeological literature, but specificity is less understood in forensic ecological context.<sup>1,2</sup> Data pertaining to packrat scavenging in both contexts is limited to retrospective point observation derived from midden dissection and forensic case study.<sup>1-3</sup> While specific reference can be found in forensic taphonomy literature, data are more typically nested within a greater discussion of “rodent” behavior.<sup>3</sup> While rodent scavenging of both soft and osseous tissue has been described in the literature, absent are data derived from longitudinal observation of the pattern and trajectory of packrat scavenging within a cohort of human donors.<sup>4,5</sup> A higher resolution model of packrat scavenging is reported, with an emphasis placed on synchronous longitudinal patterns of hard and soft tissue removal, with the goal of describing the distinct trajectory of intragroup scavenging behavior.

The impact of packrat scavenging was investigated at Colorado Mesa University’s Forensic Investigation Research Station high-altitude satellite facility (FIRS-TB40). FIRS-TB40 is in the Rocky Mountain Region of Colorado 9,500 feet (2,896m) Above Mean Sea Level (AMSL). The local environment is characterized by steep slopes, alpine forests, open moraine grasslands, hypoxia, precipitate weather fluctuation, punctuated precipitation patterns, a high Ultraviolet (UV) index, wildfires, and heavy annual snowfall with persistent overburden. Distinct environments foster distinct adaptive radiation, manifest in competitive and cooperative models for resource procurement, and environmentally mediated behavioral patterns and motivating factors in resource exploitation. Summarily these variables are expected to yield a polyvalent outcome on local scavenger behavior.

Packrat scavenging behavior was observed within a cohort of 12 human donors opportunistically placed between March 2020 and October 2021. Field observation persisted through November 2022. Human donors were placed unclothed, supine, on a 45° slope in 10'x10' steel cages. Donors were monitored by game cameras programmed to collect both time-lapse and motion-activated photographs. The presence of packrats was established through game camera capture, midden construction, game trails, scat, and tracks.

Temporal specificity was not observed in packrat scavenging. While scavenging was observed throughout the year, voracity increased markedly in late fall and persisted throughout overwintering. Scavenging began in early decomposition, temporally preceded avian scavenging, and presented on a smaller anato-spatial scale. Scavenging accelerated as postmortem interval increased. Primary modes of packrat scavenging included: (1) opportunistic exploitation of unique resources and lipid dense diet; (2) resource-centric shelter (i.e., intracorpore nesting); (3) superficial tissue removal and skeletal gnawing; and (4) territorial resource defense. Superficial tissue removal was the predominant mode of scavenging and was characterized by: (1) layered peeling of the epidermis from the dermis, followed by separation of the dermis from the hypodermis, where tissue removal terminated; (2) peeling of tissue layers from superficial bone; (3) peeling of dense ceraceous layers of superficial tissue from the hands, feet, face, and abdomen; and (4) consumption of deep tissue throughout intracorpore overwintering. Osseous involvement was limited to ridge gnawing and cortical destruction of the manual and pedal phalanges. The introduction of incisal striae—an expected byproduct of packrat scavenging—was not observed within the sample.

Longitudinal observation serves to inform the pattern and trajectory of packrat scavenging inherently absent from archaeological and case study derived data. This higher-resolution model serves to establish temporal markers associated with modes of tissue destruction and establish an environment specific trajectory from which regional variation and continuity may be derived.

**A42 Multiple Scavenging Agents: The Effect of Termite and Canine Scavenging on Forensic Cases in Northern Thailand**

*Sittiporn Ruengdit\**, Department of Forensic Medicine, Faculty of Medicine, Chiang Mai University, Chiang Mai, Thailand; *Sangob Sanit*, Department of Parasitology, Faculty of Medicine, Chiang Mai University, Chiang Mai, Thailand; *Kwankamol Limsopatham*, Department of Parasitology, Faculty of Medicine, Chiang Mai University, Chiang Mai, Thailand

---

**Learning Overview:** After attending this presentation, attendees will have a better understanding of how to differentiate between termite activity, canine scavenging, bone weathering, perimortem trauma, and anatomical variants.

**Impact Statement:** This presentation will impact the forensic science community by providing examples of multiple taphonomic effects resulting from living and non-living agents that could complicate the determination of animal scavenging, perimortem trauma, and anatomical variants. Better understanding of these defects could enhance the efficacy of death investigation.

Forensic taphonomy is application of taphonomic analysis in forensic perspectives to estimate elapsed time since death, reconstruct the events happening to the remains, and distinguish between defects caused from human behavior and biological, physical, chemical, or geological agents. The latter aspect is one of the most important foci of forensic taphonomy in forensic anthropology circumstances. It could aid in differentiating between perimortem trauma to the bones and breakage that occurred after death. Therefore, the purpose of this study was to thoroughly describe and interpret the effect of termite and canine scavenging on human skeletons as the first report of multi-scavenging agents, especially termites, in the northern region of Thailand in order to provide better understanding of bone defects affected by different taphonomic agents.

Remnants and traces of tunnels and nests created by termites was observed on the cranium, mandible, and part of the right scapula that were found in the wooden area of Northern Thailand. Tunnel remnants were built on the surface and through cavities of the cranium. Skeletal macro- and microscopic modifications were examined. Obliteration of bone and boreholes were found on the left parietal bone macroscopically and could possibly be misunderstood as parietal foramina. The largest borehole was measured at 3.71mm in its maximum diameter, while the maximum diameter of the smallest one was measured at 2.52mm. Examination utilizing stereomicroscope revealed osteophagic activity of termites, including edge gnawing, star-shaped features, and clusters of subparallel striations on the surface of the cranium. In addition to termite activity, defects resulting from canine scavenging on bones were also noted. Bone destruction on the tip of left and right mastoid processes demonstrated signs of canine chewing. Tooth pit, which could be measured 6.42mm for its maximum diameter, was also observed on the lateral surface of the left mastoid process. Pupal cases of *Chrysomya nigripes* were also found endocranially with the mass of a termite's nest. It was evident that canine and *Chrysomya nigripes* scavenging occurred before that of termites since the tunnels were obviously built on top of the damaged tip of the right mastoid process and the pupal cases were found underneath the termite's nest inside the cranium. Careful microscopic examination could aid in distinguishing between boreholes (termite activity), tooth pit (canine scavenging), parietal foramen (anatomical variant), and penetrating wound (sharp force trauma). Bone weathering, such as sun bleaching and cracking were also found.

This study provides examples of taphonomic effects resulting from the living, emphasizing termite and canine scavenging as first reported in Thailand, and non-living agents that could aid in reconstructing events that happened to the skeletons. Additionally, these features could obscure or mimic perimortem trauma characteristics; therefore, correct determination of these defects could maximize the efficiency of death investigations.

**Anthropology; Taphonomy; Scavenging**

---

**A43 Soft Tissue Scavenging Patterns of Mice on Human Remains**

*Alexander J. Smith\*, Forensic Investigation Research Station, Colorado Mesa University, Grand Junction, CO*

---

**Learning Overview:** After attending this presentation, attendees will better understand the soft tissue scavenging patterns of mice on human remains.

**Impact Statement:** This presentation will impact the forensic science community by building on the existing knowledge of a common scavenger and the potential impact of that scavenger on both human remains and a death scene overall.

While rodent scavenging on human remains has been documented repeatedly through recent forensic literature, most of this documentation covers individual cases, not patterns observed in multiple cases. Within this, there is limited documentation of mouse scavenging, and again this comes in the form of case studies.<sup>1-3</sup> From existing documentation, mice generally consume soft tissue rather than gnawing on bone. They generally prefer tissue from the hands, feet, face, and areas where other defects are present.<sup>1-3</sup> Scavenging is initiated throughout the decomposition process from fresh to skeletonized, though activity generally targets soft tissue with little to no impact to bone. Common features include scalloped edges and serrated tissue.<sup>1-3</sup>

Mice are frequently observed on motion-activated game cameras at the Forensic Investigation Research Station (FIRS) in Whitewater, CO. At the facility, donated human remains are placed on the surface, exposed to the environment, and allowed to decompose naturally. The mice documented at the facility are frequently observed on, in, and around human remains, both to scavenge soft tissue and nest within desiccated torsos. While most donors frequented by mice showed no signs of scavenging activity, 11 individuals were confirmed to be scavenged by mice. Almost all game cameras deployed within the facility in the past ten years have documented mouse activity, and most remains recovered from the facility for cleaning and curation have evidence of mouse nesting within the torso.

Scavenging at the FIRS presented most often in the limbs and was confined to the soft tissue. While the initial scavenging of some donors began in areas where the tissue was already opened (autopsy, insect activity, etc.), mice often opened new defects. Tissue consumption was layered, showing some preference for the adipose tissue over muscle tissue. While some muscle tissue was consumed, generally the mice did not eat all the way to the bone.

Mouse scavenging was most common in the spring (March–May), with more than 70% of confirmed cases at the FIRS beginning within this time frame. Generally, scavenging began on the limbs, then moved proximally. This sometimes left a trail pattern of impacted tissue along the limbs and torso. The defect margins showed fraying and scalloping. Scavenging was rarely deep enough to reach bone and no bone gnawing was observed. Mice were predominately observed at night and spent more time around the remains than they spent scavenging. Generally, mice scavenged in groups of two or more. Mice were also observed scavenging during the window of other active scavengers, though not simultaneously.

While some elements of the scavenging observed at the FIRS were consistent with documented mouse scavenging, there were some inconsistencies. There were no defects observed on the face and while distal limbs were scavenged, hands and feet were not impacted, contrasting previous documentation. Mice scavenged everything from fresh remains to mummified remains, which is consistent with documented cases. While there are a couple existing examples of mice consuming large amounts of tissue, most cases elsewhere document far less tissue consumed than was observed in most cases at the FIRS.<sup>1</sup> In the most extensive case at the FIRS, mice consumed tissue from nearly the full length of all four limbs.

Mouse activity can interfere with the state of human remains on a scene and even confuse cause of death in some cases. There is not a lot of information available about mice as scavengers despite the prevalence of omnivorous mice in a variety of environments. Detailed documentation of their scavenging patterns and behaviors can help increase understanding of these scavengers as it pertains to death investigations.

---

**Learning Overview:** In cases of homicide, the absence of the victim's body can present a formidable obstacle for forensic pathologists, particularly when tasked with determining the potential use of non-traditional methods, like melting the body. This presentation will illustrate how a judicial experiment can help substantiate an investigative theory in a homicide trial when scientific literature lacks conclusive data. This way, even when it appears unlikely to secure definitive evidence, a judicial experiment can help bring justice to missing bodies.

**Impact Statement:** This presentation will have a significant impact on the forensic science community by demonstrating the effects of melting metal on a carcass until its complete destruction. This presentation will cover various aspects, including the duration of the process, characteristics of the remains, odor perception, and smoke production, all within the context of a single case study. Furthermore, this presentation can serve as a resource for the forensic community, contributing to the advancement of knowledge in this field based on the data presented.

The authors conducted a study to assess the feasibility of concealing a corpse in a brass furnace during a homicide trial and to investigate the effects of melted metal on a deceased body. Due to the lack of existing literature on this topic, an experimental study was performed using a swine carcass in the presence of the court. A preliminary study indicated that, with certain precautions, there was no risk of an explosion.

The experiment was conducted at a scale of 1:6 using a roughly oval melting furnace measuring 84x42cm in dimensions and 35cm in depth, containing 400kg of brass, and maintaining a stable temperature between 960–990°C. Above the furnace, a movable aspiration hood connected to a collection tank was installed. A young female specimen of *Sus scrofa domestica* weighing 13.2kg, which had died of suspected bacterial septicemia, was selected. To simulate human clothing, the sample was wrapped in towels.

No explosions occurred during the entire experiment. Upon placing the carcass inside the furnace, intense flames were generated from the body and towels; however, they gradually diminished after five minutes. Throughout the experiment, the entire carcass floated on the surface of the molten metal. Initially, almost transparent smoke emanated from the furnace, which progressively darkened over time, although it never reached an intense level within the building. After ten minutes, a distinct burnt keratin smell was detectable, but it dissipated after a few minutes. The side of the carcass not in direct contact with the brass gradually burned and carbonized, resulting in a reduction in volume and a diffuse muscle contraction affecting its position. Conversely, the side of the body in direct contact with the brass did not generate flames and merely underwent gradual consumption. The complete combustion and consumption process took approximately 2.5 hours. To determine the maximum time of combustion without external handling, the carcass remained untouched. At the conclusion of the experiment, the combustion remnants were separated from the brass. After an hour, they had cooled down sufficiently to be handled and weighed 4.6kg, consisting of ashes, dust, and larger debris. Some fragments of the bone structure could still be recognized within the debris, but they could be easily destroyed by applying light finger pressure. Samples of dust and debris were collected; however, considering the high temperatures involved, the authors did not seek DNA traces on them based on forensic literature.<sup>1</sup>

The experiment demonstrated the possibility of concealing a corpse in a foundry furnace and provided insights into the effects of direct contact between melted brass and an organic body, comparable to a human organism. The process involved a combination of combustion effects similar to carbonization (for the side of the body not in direct contact with the melted brass) and accelerated combustion (for the side in direct contact).<sup>2</sup> The consumption of the body occurred more rapidly in the areas in contact with the melted metal. Therefore, it is hypothesized that the more the body is moved within the furnace, the faster carbonization and body destruction occur. This hypothesis was later confirmed: the remains were mixed four times, and after each mixture, they became progressively less recognizable. Studies on cremation suggest that the total weight of remains should have been approximately 0.5kg.<sup>3</sup> However, the measured total of 4.6kg of remains was not surprising as it consisted of a mixture of heavy melting brass debris and swine ashes. Further studies could enhance the understanding of the effects of melted metal on human bodies and provide more in-depth insights into them.

**A45 Determining Forensic Significance: Pilot Observations of the Taphonomic Patterning of Greek-Orthodox Cemetery Inhumations in Cyprus**

*Samantha Cohen\**, University of Glyndwr-Wrexham, Wales, United Kingdom; *Xenia Paula Kyriakou*, University of West London, London, United Kingdom

---

**Learning Overview:** This presentation will review the taphonomic changes observed in skeletal remains buried in a Greek-Orthodox cemetery, reflect upon the funerary rites practiced within this religious framework, and discuss how these contribute to the postmortem modification of the human body after burial in a way that informs the forensic significance of unknown remains found in Cyprus.

**Impact Statement:** This presentation will impact the forensic scientific community by providing information on the taphonomic state of human remains found within the specific burial environment of Greek-Orthodox funerary practice. Attendees will learn about those traits that can help distinguish between remains buried in cemeteries and those found in clandestine graves, thus providing a framework for determining forensic significance.

Research on burial taphonomy allows for the differentiation between cemetery remains and remains from clandestine graves. The ability to make this distinction is very important in determining the forensic significance of unknown and uncontextualized human remains, a task that is one of the most challenging in forensic anthropology. The current literature is, however, limited in terms of geographical variations that may also reflect socio-cultural and religious differences in the treatment of the dead. Existing literature on this topic has been primarily based on material from North America.<sup>1</sup> This significantly limits the direct application of these methods elsewhere, outside of North America, where the dead are treated under a different suite of funerary rites and burial practices. The current Greek-Orthodox mortuary framework observed on the island of Cyprus today has been consistent for more than 100 years.

Following the method by Pokines, the taphonomic state of 62 adult (skeletonized only) cemetery inhumations was evaluated to determine the type and distribution of skeletal modifications related to Greek-Orthodox funerary rites and burial practices.<sup>2</sup> The results varied and the prevalence of some traits were both similar and differed from those observed by Pokines.<sup>2</sup> For example, whereas evidence of embalming is typical in remains from cemeteries in North America, only one (1.6%) individual exhibited this trait in the Greek-Orthodox sample. On the other hand, like North American samples, the Greek-Orthodox sample also exhibited a high prevalence of adhering sediment (n=60; 97%), followed by brain preservation (n=53; 85.5%) and coffin wear at pressure points (n=52; 83.9%). Similarly, staining from water minerals was absent in the Greek-Orthodox sample; however, evidence of wine staining was found in 85.5% (n=53) of the inhumations instead. Additionally, the presence of adhering roots (n=42; 67.7%) and hair (n=30; 48.4%) was also noted.

The results suggest that cultural variation in mortuary behavior may be a determining factor in accurately distinguishing between cemetery-buried and clandestine grave remains. However, more research is still required in order to map out these variations across time and space on a global scale. In conclusion, research conducted in cemetery environments of different socio-cultural and religious settings has the potential of further informing forensic significance and allowing for the identification of unknown remains found not only in clandestine graves but also in those remains that may have been displaced from their original burial place following a natural catastrophe. The global prospects of this research are high, and thus more research outside of North America is highly recommended.

**A46 The Resilience of Cut Mark Characteristics: An Experimental Study on the Effect of Corrosive Chemicals**

*Maisy Jordan\*, Liverpool John Moores University, Liverpool, England; Matteo Borrini\*, Liverpool John Moores University, Liverpool, England*

---

**Learning Overview:** After attending this presentation, attendees will understand the impact of corrosive chemicals on bones and how they can negatively impact the analyses of cut marks.

**Impact Statement:** This presentation will impact the forensic science community by illustrating how some traits used for cut marks examinations to differentiate serrated and non-serrated knives could be altered by corrosive chemicals, affecting the reliability of the analysis.

In the United Kingdom, the prevalence of knife crime is at an all-time high, with sharp instruments being the most frequent cause of homicidal death in England and Wales as of March 2022.<sup>1</sup> Knife marks classification systems have become more standardized in recent years; however, analyzing how the selected traits are resilient to different taphonomic factors is important to develop reliable methodologies.

As the United Kingdom is also the country with the highest reported number of acid attacks per capita, more research regarding the effect of chemical exposure on trauma lesions is particularly relevant.<sup>2</sup> Several studies regarding the morphological effect of acid/alkali substances on hard tissues have been conducted, although the aim was predominantly on restorative dentistry or medicine. In addition, most knowledge regarding chemicals for body disposal is based on case reports; therefore, there remains a lack of forensic experimental research on how chemicals can affect the reliability of trauma analysis.

The authors present a study whereby cut-mark characteristics were exposed to several chemical substances to determine whether there were significant alterations and if these could affect the classification of the implements used (serrated/non-serrated knives).<sup>3</sup> The traits examined were: (1) shape of the cut mark; (2) shape of the cross profile; (3) rising profile; (4) feathering; (5) bone shards; and (6) mounding.

One single-edged, micro-serrated knife was used to create 180 cut marks on 18 defleshed porcine ribs (*Sus scrofa domestica*). According to previous analysis, the implement was selected as the most recognizable due to the distinctive traits left behind.<sup>3</sup> The samples were divided equally across six experimental conditions, including five laboratory-grade chemicals: hydrochloric acid, sulfuric acid (96–98% and 32%), sodium hydroxide, sodium hypochlorite, and a tap water control. A stereomicroscope with a total magnification range of 4.73–7.5x was used to observe the cut marks and categorize their traits prior to and post-chemical exposure. The samples were submerged and controlled at intervals: 4, 8, 12, 24, 48, and 72 hours. Macroscopic observation of bone morphology was also recorded at each observational stage.

The study demonstrated that hydrochloric acid caused the most morphological destruction to the samples, destroying any evidence of cut marks and their associated characteristics at 48 hours. The second most destructive chemical was 32% sulfuric acid, followed by 96–98% sulfuric acid and sodium hydroxide. Sodium hypochlorite and tap water had minimal effect on the bone and the visibility of cut marks. Evidence of sharp force lesions remained detectable for up to 72 hours in all conditions except hydrochloric acid.

The most variation was seen to elliptical-shaped cut marks ( $SD=10.799$ ) and V-shaped cross profiles ( $SD=7.480$ ) in 96–98% sulfuric acid. However, no statistically significant association could be made between the cut marks' shape and cross profile shape at the end of the study ( $p>0.05$ ), meaning that it was impossible to recognize that cuts were created by a serrated knife.

To improve the real-life application of the study, the authors suggest future research on non-defleshed ribs to evaluate the impact of muscle and fat on cut mark preservation. Testing a more extensive range of knives is also recommended to improve the reliability of the results.

**A47 The Resilience of Cut Mark Characteristics: An Experimental Study on the Effect of Fire Exposure**

*Katie Griffiths, Liverpool John Moores University, Liverpool, England; Matteo Borrini\*, Liverpool John Moores University, Liverpool, England*

---

**Learning Overview:** After attending this presentation, attendees will understand the impact of fire on bones and how it can negatively impact the analyses of cut marks.

**Impact Statement:** This presentation will impact the forensic science community by illustrating how some traits used for cut mark examinations to differentiate serrated and non-serrated knives could be altered by burning and cremation, affecting the reliability of the analysis.

In murder investigations, the analysis of cut marks left on human bones can play a crucial role in forensic investigation. The examination can be particularly challenging when the remains have been altered by taphonomic factors, especially in arson cases or when the bones have been cremated.<sup>1</sup>

This study aimed to identify the resilience of cut mark characteristics after exposure to direct fire for different time intervals. The effects of temperature on soft tissue and bone have been forensically evaluated, considering that cremation and fire are noted to be one of the oldest disposal methods for human remains in both cultural and criminal.

Fifteen defleshed porcine ribs (*Sus scrofa domesticus*) have been used in place of human bones, and ten cut marks per bone were created using a standard serrated kitchen knife in one back and forward motion, mimicking a stabbing action. One single-edged, micro-serrated knife was used to create the cuts on the ribs; the implement was selected as the most distinguishable due to the typical traits left behind. The marks were then examined under a low-powered stereomicroscope using a total magnification of 4.73–7.5x, and the traits were recorded. For the present study, the authors used six characteristics previously identified as indicative of the correct classification between serrated and non-serrated knives.<sup>2</sup> The traits examined were: (1) shape of the cut mark; (2) shape of the cross profile; (3) rising profile; (4) feathering; (5) bone shards; and (6) mounding.

After the initial observations, groups of three ribs were burned on an outdoor pyre for different times: 5, 10, 20, and 40 minutes. In addition, a group had been burned for 20 minutes, then rapidly cooled in water, recreating a scenario where firefighters extinguish flames. After the exposure to the fire, the bones were again examined with the stereomicroscope, and the traits were recorded to be compared with the original observations.

Results showed that the resilience of the traits did not notably change with the duration of the exposure to the flame. Four out of six traits exhibited a definitive survival rate: the overall shape demonstrated a 100% survival rate with all samples remaining unchanged, whereas feathering, rising, and mounding demonstrated 0% resilience after exposure to the fire. The traits that do not follow this trend are shards and cross-profile shape. Shards' survival varied from 0% to 33.33%, and unlike what would be expected, the resilience did not decrease with the duration of the burning process, suggesting that the way the flames reached the bones may have played a significant role in the experiment. Another recorded anomaly is the cross-profile shape: following the classification used, the cross-profile shape was initially identified as Y or V; however, after the burning, a new category (U shape) was identified.<sup>1</sup> As the introduction of this category may have impacted the results in identifying the resilience of the original cross-profile shapes, the authors recommend further investigation in order to evaluate this new type and its significance.

In conclusion, the authors demonstrate that even if using a standard methodology for classifying cut marks on human remains is important, it is vital to understand how often they survive a fire exposure and if they can be correctly recognized after thermal alterations.

**Forensic Anthropology; Taphonomy; Thermal Damage**

## A48 In Full or in Part: The Effect of Incomplete Remains on Trauma Analysis

Hailey Scacciaferro\*, Florida Gulf Coast University Human Identity and Trauma Analysis Laboratory, Fort Myers, FL; Savanna Agilar, Florida Gulf Coast University Human Identity and Trauma Analysis Laboratory, Fort Myers, FL; Heather A. Walsh-Haney, Florida Gulf Coast University Human Identity and Trauma Analysis Laboratory, Fort Myers, FL; Micki Besse, Florida Gulf Coast University Human Identity and Trauma Analysis Laboratory, Fort Myers, FL

**Learning Overview:** After attending this presentation, attendees will better understand how completeness of skeletal remains can affect forensic anthropological trauma analysis.

**Impact Statement:** This research impacts the forensic science community by presenting the relationship between skeletal completeness and forensic anthropological trauma findings.

Forensic anthropologists may conduct trauma analyses on human remains months to decades after the original autopsy. Their skeletal analysis of trauma may be further constrained by: (1) the incompleteness of the skeletal remains related to cases that are unsolved, unidentified, and/or a victim of domestic violence; or (2) the medical examiner/coroner requested the analysis of specific skeletal elements to the exclusion of the rest of the skeleton. While the utility of forensic anthropological trauma analysis is well documented, there is a gap in the research concerning whether the quantity of skeletal elements (completeness) impacts identification of trauma type (blunt, sharp, ballistic, or strangulation) relative to the state of decomposition.<sup>1-3</sup>

We evaluated closed, adjudicated forensic anthropology trauma analysis reports (n = 97) in Florida from 2018–2020. Of the cases from 2018 (n = 30), 2019 (n = 28), and 2020 (n = 39), 26 females and 71 males were represented in a unimodal age distribution where the sample mean age range was 41–50-years-old. On average, these remains were in a fresh state of decomposition (45%), followed by active decomposition (29%), and skeletonization (26%), though a majority of these decedents were complete with greater than 90% of elements present for analysis.

Overall, an average of 86 elements (42%) were evaluated by the forensic anthropologist. Interestingly, trauma was identified more commonly in cases with fewer elements present ( $r = -0.326$ ,  $p < 0.01$ ) for males, with age not significantly correlated for males ( $p = 0.088$ ) or females ( $p = 0.202$ ). These data revealed that males received a more detailed analysis because their skeletons were more complete (47%) than females (26%) within the sample. Yet, the frequency of trauma type was the same for both sexes, with the absence of trauma being most often observed followed in descending order by blunt, sharp, and ballistic trauma ( $p < 0.001$ ). Of those individuals without trauma (n = 13 females, n = 47 males), an average of 108 bones (or 52%) were evaluated. In contrast, when trauma was identified, the forensic anthropologist was asked to evaluate only 24% of the skeletal remains. Importantly, 42% of female cases and 24% of male cases involved a focused analysis of the neck organ block (i.e., hyoid, thyroid, cricoid cartilage, tracheal rings). This study revealed that the forensic anthropologist's detection of trauma was not impacted by the state of decomposition, trauma type, or quantity of elements evaluated.

**A49 A Case Presentation of Fractures to the Wrists and Hands in a Suicide and Homicide**

*Tuesday M. Frasier\*, Florida Institute of Forensic Anthropology and Applied Science, Tampa, FL; Erin H. Kimmerle, Florida Institute for Forensic Anthropology & Applied Science, Tampa, FL*

---

**Learning Overview:** This presentation will compare two case studies of wrist injuries to demonstrate the importance of careful consideration of trauma when it comes to the interpretation of fracture patterns. It further demonstrates fractures from gun recoil, beyond the site of impact. Following this presentation, attendees will be able to identify the overall similarity in fractures between the cases and the need for further investigation into patterns in wrist injuries.

**Impact Statement:** This case comparison emphasizes the similarities in injury between those sustained during a homicide and those from a suicide. This presentation will impact the forensic science community by highlighting the need for thorough trauma analysis to identify other injuries that better represent the cause and manner of death.

Equivocal death investigations are challenging and often remain unresolved. In cases involving fractures of the forearms, wrists, and hands, the etiology may not always be clear. In states like Florida that have the death penalty option, the number of injuries is often critical evidence for demonstrating an aggravating factor. Under Florida law, the jury must find at least one aggravating factor, such as the crime being “especially heinous, atrocious, or cruel” to consider the death penalty.

While published literature supports finding injuries to the wrists and hands from gun recoil and from professional fighting in a sports setting, not much exists regarding these injuries in a forensic context.<sup>1-4</sup> The purpose of this study is to explore two case studies with similar patterns of injury resulting from homicide and suicide.

The cases come from the University of South Florida (USF) Donated Skeletal Collection, a well-documented collection with extensive data regarding donor life history, autopsy reports, and the official cause and manner of death. Both donors selected for study exhibit fractures to the wrists and hands, which highlights the similarity between fractures caused due to the recoil of a gun and those sustained through brawling.

In the first case study, the donor’s manner of death was homicide, and the cause of death was multiple gunshot wounds to the chest. In addition to ballistic trauma, he exhibited several fractures consistent with a physical assault that occurred just prior to being shot. This decedent presented fractures to the cranial vault, craniofacial region, and the right fourth metacarpal. The second case study was that of a donor whose manner of death was suicide, and the cause of death was a gunshot wound to the right side of the head. In addition to extensive fracturing of the cranium from the ballistic trauma, he exhibited fractures to the right second metacarpal and the right radius. Donor records indicate that the individual was right-handed, which is consistent with both the position of the entrance wound, as well as the fracturing to the hand and wrist following the gunshot. The perimortem wrist injuries were the result of gun recoil. The second metacarpal would have been used to pull the trigger, which could explain why it fractured instead of the other surrounding metacarpals.

The similarities in injury between the two cases show that these injuries could possibly confuse the manner of death. In cases of gunfire injuries to the head, most postmortem autopsies do not X-ray the hands and arms. While an external exam of the tissues should note injury to this region, documentation in this area is frequently lacking, especially in decomposing cases. The wrist injuries in the case of the suicide could easily be misinterpreted as injuries sustained while trying to fight off an attacker. Other evidence of skeletal trauma is necessary to determine manner of death, which highlights the need for thorough recovery at scenes involving advanced decomposition or skeletal remains and the utility of direct skeletal observations in all cases.

**A50 Tibia Size and the Contribution to Variance in Fracture Outcomes**

Angela L. Harden\*, Injury Biomechanics Research Center, The Ohio State University, Grove City, OH; Kyra Stull, University of Nevada, Reno, Reno, NV; Amanda M. Agnew, The Ohio State University, Columbus, OH; Yun-Seok Kang, The Ohio State University, Columbus, OH

---

**Learning Overview:** After attending this presentation, attendees will understand the relationship between global tibia size and fracture characteristics through an examination of fracture outcomes in human tibiae experimentally loaded in the same blunt force bending mechanism.

**Impact Statement:** This presentation will impact the forensic science community by providing data and analyses that explore why fracture outcomes vary in the same skeletal element impacted under matching loading conditions and whether tibia morphology explains the variance in fracture characteristics.

Understanding individual-specific variables that contribute to variation in fracture outcomes is critical to forensic skeletal trauma analysis. Fracture characteristics (e.g., number and type of fractures) have been shown to demonstrate variation under the same loading conditions.<sup>1</sup> Identifying which variables contribute to and explain the variance in fracture characteristics is critical to support analyses of skeletal trauma and prevent potentially inaccurate interpretations. Previous research has demonstrated that in human tibiae, age had a significant, but weak, relationship with both number and type of fractures, while sex had no relationship with either when considered independent of age.<sup>2</sup> However, the role of bone-specific variables and their contribution to fracture characteristics has yet to be explored. Therefore, the objective of this research is to examine relationships between global bone morphology and fracture characteristics in human tibiae.

Sixty human tibiae (females, n=31 [29–102 years old, M=68]; males, n=29 [24–96 years old, M=59]) were experimentally loaded at 6m/s in a lateral-medial direction in a 4-point bending scenario. Prior to testing, the following measurements were obtained for each tibia: Length (excluding medial malleolus), Maximum Proximal Epiphyseal Breadth, Distal Epiphyseal Breadth, and Maximum and Minimum Diameters at the nutrient foramen. After testing, each tibia underwent fracture analysis, consisting of identification of fracture type, group, and qualifiers, and number of fracture types per tibia, following the methods outlined in the AO/OTA Fracture and Dislocation Classification Compendium.<sup>3</sup> The number of fractures reflects the count of identified fracture types and not each individual fracture. For example, a single transverse fracture and an intact wedge fracture would both be documented as one fracture. Additionally, while longitudinal fractures are not currently represented in the AO/OTA classification system, they were documented as their own fracture type and included in the number of fractures per tibia when present.<sup>3</sup> The analyses included Random Forest (RF) models to explore the relationship between tibia size variables and their ability to predict type, group, or location of fracture. A Principal Component Analysis (PCA) was implemented to discover if the multivariate relationship of the quantitative tibia variables can be linked to any of the fracture morphology variables. Lastly, a Multiple Correspondence Analysis (MCA) was conducted to explore the relationships between the fracture type, group, location, and categorical demographic variables.

The RF models revealed no predictive power in the tibia size variables to predict the type or group of fracture. Even with demographic variables included, the predictive power did not meaningfully increase. The PCA results show complete overlap for the type, group, and location of fractures. In contrast, the MCA analyses revealed clusters when categorical demographic variables were used; longitudinal fractures grouped together, multifragmentary fractures grouped together, and simple and wedge fractures grouped together. However, there were no obvious patterns within Body Mass Index (BMI), sex, and age categories. In consideration of these and previous findings, future work will incorporate tibia cross-sectional variables and evaluate their predictability of fracture outcomes in both univariate and multivariate analyses.

**A51 An Analysis of Lower Extremity Fracture Patterning in Fatal Motor Vehicle Collisions**

*Lillian S. Antonelli\*, California State University, Chico, Chico, CA; Jered B. Cornelison, Western Michigan University Homer Stryker M.D. School of Medicine, Kalamazoo, MI; Christine M. Pink, Western Michigan University Homer Stryker M.D. School of Medicine, Kalamazoo, MI*

---

**Learning Overview:** After attending this presentation, attendees will recognize fracture patterning of the lower extremities in fatal Motor Vehicle Collisions (MVCs), as well as the role that select intrinsic and extrinsic factors play in initiating lower extremity fractures in this context.

**Impact Statement:** This presentation will impact the forensic science community by providing attendees with a better understanding of a suite of Lower Extremity Long Bone (LELB) fracture patterns resulting from fatal motor vehicle collisions. Further, it will contribute toward improving interpretations of fracture patterns for forensic anthropology case work related to motor vehicle accidents.

LELBs are the second-most common injury resulting from MVCs, though forensic investigations most often focus on more fatal injuries of the head, neck, spine, and pelvic regions.<sup>1</sup> LELB fractures are well documented in engineering and automotive safety research and accompany clinical investigations of LELB injuries in MVC survivors. These studies assist forensic anthropologists in interpreting blunt force trauma and fracture patterning, while a gap in the forensic literature exists on this topic. Aiming to fill this gap in forensic science, the present study focuses on investigating the frequency and patterning of femur, tibia, and fibula fractures in fatal front and side impact MVCs.

This retrospective study examined patterning in the presence, type, and location of LELB fractures, the relationship between fracture frequency, morphology, impact direction, and the influence of intrinsic and extrinsic variables to fracture frequency and patterning. Cases were selected from the Office of the Medical Examiner's database at the Western Michigan University Homer Stryker M.D. School of Medicine, Department of Pathology that matched inclusion parameters. These parameters included: that the death investigation occurred between 12/31/2016 and 11/16/2020, at least one fracture is present in the LE, that the decedent was located in a car, SUV, van, or truck, the collision occurred with a front or side impact, and that the decedent was 15 years old.<sup>2</sup> Cases where decedents were ejected or the vehicle rolled over were excluded. In total, 67 decedents of front (n=51) and side (n=16) impact collisions were included. For each case, fracture data were collected from radiographs, and demographic and extrinsic collision variables were collected from available medicolegal records.

Fracture patterning was predicted for each impact type through a thorough review of the available literature on LELB fracture in MVCs. In the study sample, fracture patterning demonstrated some agreement with the predicted patterning of ankle, knee, and femur fractures.<sup>3</sup> Side impact fracture patterning coincided less with the predicted pattern of primarily tibial fractures. In both impact directions, no statistically significant relationship was found between intrinsic (decedent) and extrinsic (vehicle and collision) factors and fracture presence and location in Pearson's Chi-squared tests.

Front and side impact collisions differed in the most-often fractured LELB. Femoral fractures accounted for the majority (41%) of front impact fractures, while the majority of side impact fractures were of fibulae (48%). Utilizing a Pearson's Chi-squared test, a statistically significant ( $p=0.05$ ) relationship between anatomical location of fracture and LELB was found in front impact collisions—indicating that there are common mechanisms causing LELB fracture between individuals and incidents. The same was not found in side impact collisions. With respect to fracture type, comminuted fractures were most common in front impact collisions, while oblique fractures were most common in side impacts.

The present research demonstrates that there is variable fracture patterning in fatal MVCs based on impact direction and other factors. This conclusion is supported by the common understanding that impact direction influences fracture propagation and patterning. This work compliments recent forensic anthropological interest in fracture patterning due to motor vehicle collisions (i.e., Hulse, Stull, and Weaver 2018), and contributes to forensic literature on this subject.<sup>2</sup>

## A52 Establishing a Skeletal Atlas of Elder Abuse: An Examination of the Relationship Between Bone Density and Skeletal Fractures in Accidental Falls and Suspected Abuse

*Emelia Jensen, Arizona State University, Gilbert, AZ; Kaitlyn J. Fulp, Arizona State University, Scottsdale, AZ; Katelyn L. Bolhofner\*, Forensic Anthropology, Arizona State University, Glendale, AZ; Laura C. Fulginiti, Maricopa County Office of the Medical Examiner, Phoenix, AZ; Jane E. Buikstra, Arizona State University, Tempe, AZ; Jacob A. Harris, Arizona State University, Phoenix, AZ*

**Learning Overview:** After attending this presentation, attendees will be aware of the relationship between bone density and skeletal fracture occurrence associated with the abuse/neglect of elderly individuals as distinguished from those commonly found in accidental ground-level falls.

**Impact Statement:** This presentation will impact the forensic science community by examining the contribution of osteoporosis to differential skeletal fracture occurrence in cases of suspected abuse and in documented accidental falls, contributing data to the ongoing effort to unmask elder abuse more broadly.

Ten percent of adults aged 65+ will experience some form of abuse annually.<sup>1</sup> Physical abuse and caregiver neglect account for most cases, yet remain difficult to prove.<sup>2</sup> Skeletal expressions of abuse offer key indications of inflicted and untreated injuries but are masked by assignment to accidental falls. Funded by the National Institute of Justice, our research aims to produce a standard for the diagnosis of elder abuse in the skeletal system.<sup>3</sup> We previously identified differences in the skeletal patterns of injury between accidental falls and cases of abuse/neglect.<sup>4,5</sup> To further refine a standard of expected skeletal injury associated with abuse in elders, we must consider the degree to which aging affects the structure and density of the bone in relation to fracturing. Osteopenia, the early loss of bone density, and osteoporosis, a condition of progressive deterioration of bone tissue, affect approximately 54 million individuals in the United States and are associated with increased fracture risk.<sup>6-9</sup> Radiographic standards have been established for the measurement of bone density and assessment of osteoporosis.<sup>10-14</sup> To explore the relationship between bone density and skeletal fractures in abuse/neglect vs accidental falls, cases from the Maricopa County Office of the Medical Examiner were reviewed.

Digital radiographs of 175 individuals over the age of 60 who had sustained skeletal trauma were examined and scored by three observers with varying levels of experience according to Barnett and Nordin 1960.<sup>11</sup> This method was chosen as an investigatory starting point based on low rates of reported inter-observer error and ease of implementation by a range of professionals, of particular interest for the future application of our criteria. Bone density measurements were estimated from the hands, femora, and vertebrae, and osteoporosis was diagnosed where the threshold for minimum bone loss was met. Of those examined, 66 were cases of abuse/neglect based on previously established criteria and 109 were cases of witnessed falls.<sup>4,5</sup>

To assess potential differences in bone density between those individuals manifesting skeletal fractures from an accidental fall and those for whom abuse/neglect is suspected, we performed independent t-tests to compare the average bone density scores for left and right metacarpals and femora, respectively. The results suggest no significant differences in metacarpal density (hand:  $t=1.1$ ,  $df=85$ ,  $p=0.28$ ), but a significant difference in femoral bone density between abuse and accidental cases (femora:  $t=2.53$ ,  $df=109$ ,  $p=0.01$ ). The World Health Organization defines osteoporosis as a bone mineral density value more than 2.5 standard deviations below the mean.<sup>15</sup> We examined differences in osteoporosis between accidental and abuse groups and found a disproportionately high frequency of osteoporosis among individuals sustaining fractures in accidental falls ( $X^2=8$ ,  $df=1$ ,  $p=0.005$ ).

To better understand the potential for implementation of this simplistic measurement of bone density in a forensic context, we performed a paired t-test of inter-analyst correspondence using a sample of the data ( $n=129$  pairs). The results of the paired t test suggest no significant differences between analysts (hand:  $t=-0.096$ ,  $df=65$ ,  $p=0.92$ ; femora:  $t=-0.096$ ,  $df=105$ ,  $p=0.06$ ; alpha =0.05).

Fractures remain the most common musculoskeletal condition requiring hospitalization among individuals aged 65 and older in the United States, and rigorous diagnostic criteria must be developed to differentiate accidental injury from abuse.<sup>6</sup> Radiographic assessment of skeletal fragility and injury is the standard initial approach to fractures in both living and deceased individuals.<sup>16</sup> To develop a standard of expected skeletal injury associated with accidents and/or abuse, we must first be able to provide a baseline of bone health against which we may evaluate noted fractures. Results from this ongoing study represent an extensive effort to develop and improve diagnostic criteria for a skeletal atlas of elder abuse.

**A53 Assessing Variability in Kerf Floor Shape Utilizing a Revised Set of Shape Categories**

*Meghan M. Gast\*, Des Moines University, West Des Moines, IA; Alexis L. VanBaarle, Michigan State University, East Lansing, MI; Heather M. Garvin, Des Moines University, Des Moines, IA; Ann L. Braverman, Des Moines University, West Des Moines, IA*

---

**Learning Overview:** This research utilizes a modified classification system to assess saw kerf floor shapes in bone. After attending this presentation, attendees will better understand challenges in assigning kerf floor shape categories, as illustrated with inter-observer assessments, and patterns between kerf floor shapes and saw characteristics.

**Impact Statement:** This presentation will impact the forensic science community by highlighting some of the limitations and utility in kerf floor shape analysis to predict saw class characteristics in dismemberment cases.

In cases of dismemberments, forensic anthropologists are asked to assess bony kerf variables to provide information about the tool used. Kerf floor shape has been proposed to reflect specific saw class characteristics. In this study, we created a set of 12 kerf shape categories based on previous studies and observations. We aimed to test inter-observer agreement in kerf floor assignments and to evaluate the relationship between kerf shapes and saw characteristics.

This research utilized a subsample of incomplete saw cuts in human bone made available by Mercyhurst University and originally collected as part of a National Institute of Justice grant project (2005-IJ-CX-K016).<sup>1</sup> The cuts were made on fully macerated long bones using a controlled sawing method. A subsample of 90 specimens, created by 19 saws, were semi-randomly chosen, ensuring approximately equal representation of each saw. Stereomicroscopic photos were taken of the kerf profiles and three observers scored the 90 kerf floors. Percent agreement between observers and patterns in kerf floor shape were assessed to investigate the utility of floor shape in classifying saw characteristics.

Agreement between the two inexperienced observers and the experienced observer was 60.0% and 75.6% for the 12-shape scoring system. Kerfs with a “W” or truncated “W” shape had 100% agreement across all observers, illustrating the ease of differentiating this shape from flat or curved kerfs. Collapsing the kerfs with flat or slightly rounded floors increased agreement to 90.0% and 88.8%. Patterns between kerf floor shape and saw class characteristics were limited. All W-shaped kerfs were created by hand saws with alternating crosscut teeth, with one exception: a mechanical circular rip saw produced two W-shaped kerfs, but the peaks of the “W” were shallow and easily differentiated from the other W-shaped kerfs. Similarly, all hand-alternating crosscut saws produced W-shaped kerfs except for four kerfs produced by two saws (a dovetail and general carpenter saw). Beyond being created by rip saws, no patterns were discerned between the various flat and rounded kerf floors and saw characteristics; they were created by hand and mechanically powered saws of various sets and teeth-per-inch. A new category developed, relatively flat kerfs with a midline divot, was only observed in mechanical reciprocating rip saws with a raker set, although not all mechanical reciprocating raker rip saws created this divot feature.

This preliminary research expands upon our understanding of kerf floor shape and saw characteristics. Saws are highly variable, however, with various combinations of power, set, tooth shape, teeth-per-inch, blade width and length, and intended cutting material. As such, it is important to further assess kerf shape patterns in a diverse array of saws if forensic interpretations are to be drawn from kerf floor shape in casework.

## A54 A Comparison of Fatal and Non-Fatal Postcranial Gunshot Wounds

*Sam W. Coberly\*, SNA International, Honolulu, HI*

**Learning Overview:** The goal of this presentation is to focus on the skeletal differences between postcranial fatal and non-fatal Gunshot Wounds (GSWs).

**Impact Statement:** This presentation will impact the forensic science community by allowing for better recognition of fatal vs. non-fatal skeletal GSWs in the postcranial region.

Gun violence has a devastating effect on the United States with over 48,000 firearm deaths in 2021.<sup>1</sup> In addition, there have been over 385,000 injuries between 2006 and 2010.<sup>2</sup> Approximately \$734.6 million is spent each year on treating GSWs.<sup>2</sup> The difference between a fatal GSW and a non-fatal GSW is complex and varied.

C.A. Pound Human Identification Laboratory case folders from 1974 to 2020 were examined for trauma. There were 268 total GSW cases: 93 had postcranial trauma; thorax = 48, neck = 20, abdomen = two, pelvis = zero, and limbs = three. Seventeen had trauma to more than one region, two were unknown, and two were antemortem. The majority (31%) of cases had trauma to five+ elements, with the greatest frequency to the ribs (45%) followed by thoracic vertebrae (18%). In 63%, one shot occurred.

Radiographs of living trauma victims located in Florida were pulled (with Institutional Review Board [IRB] approval) from the University of Florida's Clinical and Transitional Science Institutes Integrated Data Repository. Cases came with radiographs and doctors' notes. One hundred and five cases were pulled: thorax = 54, neck = one, abdomen = 19, pelvis = 15 (including three to the penis), limbs = three, multiple regions = six, and seven unknowns. Fifty-six percent had trauma to no elements. In 81% of cases, the individual was shot once. The non-fatal GSWs had a higher chance of no skeletal trauma, with fatal GSWs involving more elements per case. The non-fatal had more trauma to the pelvis and abdomen. The fatal population had a higher frequency of comminution. The non-fatal population had less catastrophic trauma. The scapula had the most similar types of fracturing between all the elements.

The majority of GSWs are non-fatal within the literature, with the exception of one study from Finland.<sup>3,4</sup> Several studies conclude that the cranium and thorax are the most common sites of fatal GSWs.<sup>4-7</sup> This can be seen in the fatal sample where the majority are cranial followed by thorax. Non-fatal GSWs are often found in the limbs, abdomen, and pelvic region.<sup>8-11</sup> The non-fatal sample had few cases with limb GSWs, but this may have been due to the random nature of the selection. The sample did have several cases involving the pelvis and abdomen, but the majority were from the thorax, specifically rib fractures. One study found that approximately 36% of cases had only one shot per individual and 61% had trauma only in one region, which is keeping with both the fatal and non-fatal sample.<sup>3</sup> Single GSWs and GSWs to single elements are commonly found in fatal GSWs with one study finding 41% having trauma to one element.<sup>12</sup> One study found a correlation between multiple GSWs and requiring a hospital stay or death.<sup>3</sup> However, another study found no correlation between multiple GSWs and greater morbidity.<sup>13</sup> Both sample populations had more males than females, which is fairly universal with over 90% of non-fatal GSWs and 81% of fatal GSWs being male. 1,8,9,11 Males tend to have riskier behavior.<sup>14</sup>

Further study could be done to expand on the results here such as adding the skull to see how different survivability is compared to other regions. In addition, most of the doctors' notes were from initial review of the trauma. It would be interesting to see if additional trauma was found during surgery versus radiographs. Overall, fatal GSWs tend to involve more elements with more severe trauma, and abdomen and pelvic GSWs are seen more often in non-fatal GSWs than fatal.

**Gunshot; Trauma; Non-Fatal****A55 The Patterning of Fracture Characteristics in Gunshot Wounds in Long Bones**

*Alexandra Semma Tamayo\*, MSc, Binghamton University, Binghamton, NY; Laure Spake, Binghamton University, Binghamton, NY*

---

**Learning Overview:** After attending this presentation, attendees will have a better understanding of the fracture characteristics that are typically associated with gunshot wounds in long bones.

**Impact Statement:** This presentation will impact the forensic community by contributing data on gunshot wound fracture patterning in the long bones. Gunshot wounds in tubular bones are understudied relative to those of the cranial vault, though they are increasingly common in medicolegal contexts.

Gunshot wound analysis remains a challenge in forensic anthropology. The potential utility of skeletal gunshot wounds in medicolegal contexts is limited by the fact that descriptive characterization of fracture patterns in ballistic trauma has focused on the skull, with few studies dedicated to long bone injuries.<sup>1,2</sup> Publications on long bone gunshot wounds are derived from medical research and orthopedic interventions, where descriptions of fracture patterns of forensic interest are somewhat limited. A more comprehensive characterization of fracture initiation and propagation in gunshot wounds to tubular bones is still needed.

In recent years, Computed Tomography (CT) scans have been considered a complement to traditional autopsy, enhancing reconstruction of gunshot wounds and fracture patterns.<sup>3</sup> With the increasing availability of CT scans, they now represent an important source of high-quality data for the study of gunshot wounds with broader applications in forensic research.

In this study, postmortem CT scans were used to characterize gunshot wounds in long bones and to explore patterning of lesion characteristics that could be indicative of projectile trajectory. CT scans from 33 individuals (mean age=37; SD=15) with gunshot wounds in long bones were selected from the New Mexico Decedent Image Database (NMDID). Scans were processed with automated thresholding segmentation protocols to visualize the skeletal tissue using 3D Slicer 5.3.0 and InVesalius 3.0. Fragment realignment for fracture reconstructions was completed using Blender 3.6 LTS. Qualitative characteristics of the wounds were recorded, such as the shape and size of bone defects, and the presence or absence of radiating, concentric, spiral, and butterfly fractures. Patterning of characteristics were explored using hierarchical cluster analysis.

Three types of fractures were observed in the data: indirect fractures (bullet did not impact the bone); entrance wounds of direct impacts; and exit wounds of direct impacts. Indirect fractures without penetrating injuries were characterized by the absence of bone defects and the presence of transverse, butterfly, and spiral fractures. Direct impacts to long bones were characterized by oblong-shaped bone defects with radiating and concentric fractures forming a butterfly pattern. Differentiating between entrance and exit wounds was complicated by challenges with fracture reconstruction and the presence of image noise as a result of metallic artifacts from projectile fragments. This led to difficulty observing important features detailed in other studies, including irregular defects, beveling, delamination, and edge sharpness.

Results demonstrate clusters of characteristics that could be associated with indirect, entrance, and exit wounds. However, conclusions about the characterization of entrance and exit wounds associated with the fracture category groups could not be drawn since the confirmed projectile trajectory information from the autopsy records was not available for this sample. If these clusters can be reliably associated with entrance and exit wounds, these results can be used for reconstructing projectile trajectory and potentially circumstances of death in cases of gunshot wounds to the postcranium.

**A56 An Analysis of Bevel Angle in Gunshot Trauma to Long Bones**

*Devin L. Adcox\*, University of Tennessee Knoxville, Dickson, TN; Ashley Kendell, California State University, Chico, Chico, CA; Eric J. Bartelink, California State University, Chico, Chico, CA*

---

**Learning Overview:** After attending this presentation, attendees will understand that bevel angle in gunshot entrance wounds to long bones has a degree of variance that likely cannot be attributed to impact angle or caliber alone. This suggests that entrance beveling is influenced by bone morphology, as well as microstructure, indicating a need for more studies that investigate how bevel angle forms.

**Impact Statement:** This presentation will impact the forensic science community by providing information on bevel angle variance and formation. While bevel angle is an important indicator of directionality in gunshot trauma, information on how it forms and potential variability in bevel angle is limited. There are few actualistic studies concerned with variability in bevel angle formation. The data here suggest that bevel angle can be highly variable and is likely influenced by bone morphology.

Bevel morphology has consistently been used to indicate directionality in gunshot trauma; however, few studies have examined how the bevel angle is created. Previous research on gunshot trauma to the cranium suggests that bevel angle morphology is variable. This study directly examined bevel angle formation and variability through actualistic research on porcine femora. We hypothesized that handgun caliber would influence the bevel angle, and there would be variability in the angle of the bevel around the circumference of the entrance wound.

Bevel angle was measured in 32 porcine femora, 15 of which were shot with a 45-caliber handgun and 17 of which were shot with a 9mm handgun. The soft tissue was removed from all but two limbs, which were held as controls for the mm sample. After tissue removal, the limbs were shot by a trained marksman at a distance of 15 feet. The femora were suspended within a plexiglass container to assist in the retention of all bone fragments.

When possible, measurements were taken in three locations to assess the degree of variance in bevel angle. To obtain these measurements, the fragments were pressed into a contour gauge while keeping the fragment perpendicular to the gauge. The resulting contour was transferred to paper. A digital angle finder was then used to measure the apex of the bevel—where the outer surface of the bone transitions to the entrance bevel. Additional comparisons were made between the caliber type to assess if caliber type altered bevel angle. The results indicate that there is a high degree of variance within each gunshot wound. For example, the mean range for all 30 of the test impacts was 18.87 degrees (median value = 18.3). In addition, no significant differences were found in bevel angle between caliber types ( $p=.355$ ;  $\alpha=.05$ ). The degree of variance in each entrance wound bevel angle suggests that the morphology of the bone in the area—its thickness, density, and shape—likely plays a larger role in the formation of bevel morphology than caliber or impact angle. Thus, the lack of difference between the two caliber types suggests caliber size and speed in this case do not play key roles in bevel angle formation.

This research suggests that morphology, in particular bone thickness and shape, play a significant role in the formation of bevel angle. Additionally, it shows that caution should be used when trying to interpret angle of impact solely from the bevel morphology of an entrance wound.

---

**A57 A Comparison Between Full Metal Jacket and Hollow Point Projectile Effects on Bone**

*Joe Adserias-Garriga\*, Mercyhurst University, Erie, PA; Roberto Escudero-Izquierdo, Servicio Nacional de Medicina Legal y Ciencias Forenses, Ecuador, Bolivar, Ecuador*

---

**Learning Overview:** Attendees to this presentation will acquire a higher understanding of how bone reacts to different types of projectiles by the analysis of the entrance and exit defects morphology, which may assist in the reconstruction of the events.

**Impact Statement:** This presentation will impact the forensic science community by providing morphological traits that may be consistent with different types of ammunition in gunshot trauma defects in the bone.

The location, size, and shape of the gunshot defects in a body depend on the amount of kinetic energy lost by the bullet in its path through the tissue, the loss of energy, and the characteristics of the tissue.<sup>1</sup> However, the type of projectile and its behavior when impacting the tissues plays an important role in the effects in the tissue.

The bullet is the part of the cartridge that hits the target. Jacketed bullets contain a core covered by a thin layer of some other material, referred to as the jacket. If the entire bullet is fully enclosed, and the jacket is crimped shut at the base of the bullet, that's referred to as a Full Metal-Jacketed Bullet (FMJ). The jacket covering the tip prevents its deformation upon impact. If the jacket leaves part of the tip uncovered and hollowed out, the bullet is referred to as a semi-jacketed Hollow-Point (HP) bullet and expands to double the bullet diameter on impact.<sup>2,3</sup>

Different projectiles can produce different defects depending on the interaction of the bullet with the tissues. Bullet deformation and fragmentation are significant contributors to permanent cavity formation.<sup>4,5</sup> Additionally, radiating, concentric, delamination, and avulsion fractures may be associated with gunshot defects.<sup>6</sup>

The aim of the present study is to evaluate the entrance and exit defects morphology in bone caused by two types of ammunition: FMJ and HP bullets.

FMJ and HP projectiles were impacted at different distances and angulations on 32 specimens of swine (*Sus scrofa*) skulls with soft tissue present and skeletonized.

The results showed that HP defects in dry bone didn't present as many associated fractures as specimens with soft tissue present. Entrance wounds on skeletonized samples caused by FMJ ammunition created radiating fractures. On the contrary, HP caused defects presented as several radiating fractures. Concentric fractures appear only in entrance defects with soft tissue present. These fractures are caused by intracranial pressure created by the bullet as it passes through the skull and compresses the soft tissue.

This study confirmed some of classical statements about the features of gunshot defects such as size and shape and opened up new perspectives on the analysis of fracture patterns that may assist in the reconstruction of the events.

**A58 Antemortem Trauma and Trauma Reporting in the Texas State Donated Skeletal Collection**

Theresa M. De Cree\*, Texas State University, San Marcos, TX; Emma M. Giacomello, Texas State University, Huntsville, TX; Michelle D. Hamilton, Texas State University, San Marcos, TX; Elizabeth Moore, Texas State University, Fort Cavazos, TX; Katie Gerstner, Texas State University, San Marcos, TX

---

**Learning Overview:** After attending this presentation, attendees will understand trends in antemortem trauma in a modern United States population. In addition, attendees will understand the importance of trauma reporting for the recognition and interpretation of antemortem trauma in forensic case work.

**Impact Statement:** This research will impact the forensic science community by illuminating trends in antemortem trauma through the statistical analysis of observed skeletal lesions. This presentation will improve interpretation of antemortem trauma by providing instances of trauma with known and documented explanations.

Trauma analysis is an important component of forensic anthropological investigation. It has the potential to provide information about perimortem events that can inform the determination of cause and/or manner of death.<sup>1</sup> When compared to perimortem trauma, antemortem trauma analysis is underreported in forensic anthropological literature. Understanding the patterning of antemortem trauma can assist with the interpretation of health and injury along the life course, as well as provide individualizing information to assist with positive identification efforts.<sup>1,2</sup>

This research project assessed the presence, absence, and accumulation of antemortem trauma in the Texas State Donated Skeletal Collection.<sup>3</sup> This sample examines 62 individuals for trauma patterns assessed based on body location, sex, age group, and socioeconomic status. In addition, the accuracy of antemortem record keeping by donors and their families was assessed to determine the amount of skeletal trauma that goes unreported.

Eight of the 62 (13%) individuals had no instances of antemortem trauma observed on the present skeletal elements. The body was divided into regions and assessed for percentage of trauma by fracture count. The head and neck contained 8.36% of trauma, the trunk had the highest rate of trauma at 65.07%, the upper extremities had 8.06%, and the lower extremities had 18.51%. When fracture counts were analyzed by element, it was found that rib fractures were highly underreported and made up 38.97% of all fractures. Both thoracic and lumbar vertebrae made up 6.54% of fractures each, with the third-highest rate of fractures (4.9%) seen in the tibiae. When trends in the number of fractures within demographic groups were analyzed for significance with unpaired T-tests, the difference between middle and older adult approaches significance ( $P=0.0656$ ). Because the sample only contained two young adults, they were removed in statistical analysis. No other grouping (sex, occupation, or socioeconomic status) showed significance when examining number of fractures per person.

In the assessment of accuracy of antemortem donor paperwork, it is noted that one individual could not be assessed for matching records due to the incompleteness of remains. Out of the 61 individuals assessed, 13 were self-reported (~21%) and 48 (~79%) were Next-of-Kin reported. Records were assessed as complete, partial, or not a match to what was observed on the remains. The difference between reporting type accuracy was not statistically significant ( $P=0.7721$ ). However, self-reported records had fewer instances of no match at 46% when compared to the Next-of-Kin reported records at ~75%.

The ability to characterize the embodiment of antemortem trauma in a contemporary documented skeletal collection has applications in bioarchaeology, medicolegal death investigation, and the medical field. This research indicates there could be correlation between amount of antemortem trauma and age and provides evidence for the underreporting of rib fractures. Further research is required to determine patterns in rib fractures as well as fracture frequency by age group.

## A59 Standards Development in Forensic Anthropology: Updates from the OSAC and ASB

*Julie M. Fleischman, Harris County Institute of Forensic Sciences, Houston, TX; Eric J. Bartelink\*, California State University, Chico, Chico, CA; Wendy E.P. McQuade, Center for Human Identification, University of North Texas Health Science Center at Fort Worth, Fort Worth, TX*

**Learning Overview:** After attending this presentation, attendees will be updated on the status of standards and best practices drafted by the Organization of Scientific Area Committees (OSAC) Forensic Anthropology Subcommittee and those published by the American Academy of Forensic Sciences' Standards Board (ASB) Anthropology Consensus Body.

**Impact Statement:** This presentation will impact the forensic science community by increasing awareness of forthcoming and existing standards and best practices in forensic anthropology, including publication by the ASB and placement on the OSAC Registry. This presentation will further highlight the need for participation and engagement by the forensic anthropology community in the development of consensus standards.

The OSAC was established in 2014 to facilitate the development of national standards for all areas of forensic science, including forensic anthropology. Each OSAC subcommittee is tasked with drafting standards documents, which are then submitted to a Standards Developing Organization (SDO) for further development and eventual publication. The Forensic Anthropology Subcommittee submits draft standards to the ASB, which was established in 2015 as an SDO accredited by the American National Standards Institute to publish forensic science standards; once a standard is published, the Forensic Anthropology Subcommittee reviews it for technical merit, makes a recommendation for its placement on the OSAC Registry, and submits it to the Forensic Science Standards Board for final approval.

This presentation will describe the differences between standards and best practice documents; summarize recent standards development activities by the OSAC Forensic Anthropology Subcommittee and the Anthropology Consensus Body of the ASB, including ASB standards currently on the OSAC Registry; list ASB standards eligible for the OSAC Registry; inform attendees of proposed forensic anthropology standards that are currently open for public comment or in comment adjudication at the OSAC or ASB; and briefly summarize the topic areas addressed by drafts of standards and best practice recommendations that are currently in progress at the OSAC and/or ASB. As of August 1, 2023, one Forensic Anthropology document is currently listed on the OSAC Registry, and eight other published ASB standards are eligible for the Registry. Three standards are undergoing further development at the ASB and are anticipated to be published in the next nine months. Additionally, the ASB is drafting four best-practice recommendations, and six standards are currently under development by the OSAC Forensic Anthropology Subcommittee, including one that is a collaborative effort with Task Group members representing the OSAC, ASB, and the American Board of Forensic Anthropology (ABFA).

### Standards; ASB; OSAC

## A60 Assessing the Place and Feasibility of Activism and Advocacy in Forensic Anthropology

*Sadie R. Friend\*, California State University, Chico, Chico, CA*

**Learning Overview:** After attending this presentation, attendees will have a better understanding of the field's consensus on activism and advocacy. Attendees will have an idea of the variation in the conceptualization of attitudes about activism and advocacy held by their peers in the field.

**Impact Statement:** This presentation will impact the forensic science community by spurring discourse and intellectual engagement with activism and advocacy within forensic anthropology. This is especially important during the current climate where these topics are sometime perceived as divisive. This presentation will elucidate the nuances and the similarities in the opinions that forensic anthropologists share regarding these topics.

This research explores the attitudes surrounding the place, practicality, and feasibility of activism within the field of forensic anthropology. It examines the comfort of forensic anthropologists in performing activist and advocacy work and evaluates how these are conceptualized within the field. For this ongoing study, data were collected through a combination of surveys (n=38), questionnaires (n=11), and interviews (n=9). Only surveys that were at least 75% complete were included in the current study. This research will provide insights into the conceptualizations of advocacy and activism and their trajectory within forensic anthropology and present the shared and diverse opinions of the field. This will further assess relationships between attitudes toward activism and multiple variables such as a practitioner's level of experience, pedagogical era, and the context in which one practices. These data will be used to answer three research questions: (1) Is the conceptualization of activism and advocacy consistent across the field? (2) Is the conceptualization of activism and advocacy influenced by the context in which the forensic anthropologist practices? And (3) How comfortable are forensic anthropologists with integrating activism and advocacy into their practice?

Out of the 38 surveys, 31.6% are students, 36.8% are primarily practicing in academia, 15.8% are primarily practicing within the government, and 3.2% are practicing within the medicolegal context (in medical examiners or coroners' offices). In response to the questions regarding the conceptualization of activism where respondents were asked to identify whether a given scenario qualifies as activism or not, the most common of the five response options was "Not Activism" (26.6%). However, when comparing responses of "Not Activism" to those that indicate that the given scenarios represented some level of activism, responses that indicated any activism were more popular (71.8%). When rating how comfortable the practitioner would be in performing the same scenarios, the most common answer was "Very Comfortable" (46.1%). There are slight differences in the frequency and type of responses by practice context and many responses to scaled survey questions included supplemental context to the answer. These results may indicate a general consensus in the conceptualization of activism in the extremist connotation across the field, which is supported by the responses from the interviews and questionnaires. Also reflected by the survey data and supported by interviews and questionnaires is the breadth of opinions, attitudes, and comfortability with advocacy and activism in forensic anthropological practice.

### Anthropology; Activism; Advocacy

**A61 Forensicanthrotok: The Depiction of Forensic Anthropology on TikTok**

Donovan M. Adams\*, University of Central Florida, Orlando, FL; C.M. Trent, University of Central Florida, Orlando, FL; Jasper K. Sharpless, University of Central Florida, Barboursville, WV

---

**Learning Overview:** After attending this presentation, attendees will understand the public perception of forensic anthropology on TikTok, the discipline's use of the social media platform, and the interconnections of forensic anthropology with various TikTok subcommunities.

**Impact Statement:** This presentation will impact the forensic science community by providing information regarding the presence of forensic anthropology on TikTok and discussion regarding effective use, ethical issues, and public interaction with the discipline via the platform. This research presents initial findings from a mixed method, digital ethnographic investigation of TikTok videos to understand how anthropological concepts are discussed on social media, particularly by extremist communities.

Social media platforms like TikTok have dramatically increased in popularity in recent years, particularly due to restrictions associated with COVID-19. Much like other platforms, an algorithm provides content to users based on their prior activity (e.g., videos watched, liked, and shared). Sometimes seemingly unrelated videos are shown to users despite a lack of prior interaction with the topic. As such, a broad audience may view and interact with forensic anthropological content. Additionally, different ways to engage in material (e.g., duets, shares, comments) allows users to not only share anthropological information but to utilize this information for different purposes, whether educational, ideological, or entertainment.

The present research seeks to understand the ways in which forensic anthropological content is produced and interacted with on TikTok. Hashtags directly related to some aspect of forensic anthropology (e.g., #forensicanthropology, #cranium, #biologicalanthropology, #dentalmorphology) were selected from a database of TikToks collected as part of a larger investigation of the relationship between anthropology and extremism on social media. TikTok metadata and videos were collected using the Python® package TikTokAPI where the 500 most “popular” TikToks were downloaded for each hashtag over a one-month period.<sup>1</sup> TikTok comments were downloaded using the Python®-based code TikTokCommentScraper.<sup>2</sup> The analyzed sample for this presentation included 5,117 TikToks drawn from 22 hashtags.

Due to the heavily skewed nature of the data, non-parametric descriptive statistics were calculated. The median value for the number of likes is 8,540 (Quartile 1: 142; Quartile 3: 77,550). The median value for the number of shares is 45 (Quartile 1: 1; Quartile 3: 505.5). Last, the median value for the number of comments is 87 (Quartile 1: 5; Quartile 3: 1,017.8). This compares to median values of 16,700 likes (Quartile 1: 828; Quartile 3: 156,600), 184 shares (Quartile 1: 8; Quartile 3: 8,864), and 204 comments (Quartile 1: 20; Quartile 3: 1,359) from the broader sample of 543,798 TikToks. These results indicate that those TikToks related to forensic anthropological concepts have a generally smaller engagement compared to other TikToks in the database; however, TikToks still receive thousands of likes and views and, therefore, have a broad reach. Some of the topics discussed included the television show *Bones*; educational material; day-in-the-life vlogs of anthropology students; “aesthetic” depictions of forensic anthropology; and comedic jokes regarding forensic practice and education. Additionally, many TikToks either: (1) address issues of biological essentialism of gender, or (2) utilize forensic practice to invalidate trans identity or the distinction between sex and gender.

A network analysis using the R package *quanteda* was conducted to understand the 100 most commonly associated hashtags and, by extension, communities of the sampled TikToks.<sup>3</sup> Notably, the most associated communities included Anthro TikTok, Academic TikTok, ConspiracyTikTok, ArtistsofTikTok, and FurryTikTok. Many of these communities' hashtags were within the 50 most popularly associated hashtags. These results highlight the significant overlap of forensic anthropology with seemingly disparate digital communities and the discipline's possible far-reaching influence.

With the constant expansion of social media platforms and the quick turnover of trends in digital space, it is important to understand how digital communities engage with forensic anthropology and how the discipline ethically and effectively engages with these platforms and audiences. By introducing ways in which forensic anthropology exists on TikTok, this presentation will discuss issues including curriculum for responsible presentation of the discipline and imagery of human remains, ethical public engagement (e.g., discussion of bioprofile estimation; avoiding images containing intact, skeletal, and decomposing human remains), and combating weaponization of forensic anthropology in prejudicial rhetoric.

**Anthropology; Social Media; Ethics**

## A62 Forensic Anthropology and Structural Vulnerability in Casework

Jaymelee Kim\*, Wayne State University, Detroit, MI; Allysha P. Winburn, University of West Florida, Pensacola, FL

**Learning Overview:** After attending this presentation, attendees will gain insight into the burgeoning literature that analyzes the expansion of forensic anthropology practice, specifically in the realm of public health and social vulnerability reporting. This presentation will critically examine the idea of applying archaeological and social anthropology lenses to interpreting crime scenes, material evidence, skeletal trauma, and skeletal pathology to extrapolate information about the victim's lived experiences. To promote further discussion of this emerging topic at our primary conference, this presentation will address ethical obligations of forensic anthropologists as last responders, practical challenges, and the current strengths and challenges that have surfaced in recent professional discussions and related scholarship.

**Impact Statement:** This presentation will impact the forensic science community by laying the groundwork for further discussions within the field on how forensic anthropology data drawn from cases could be used to inform other sectors related to the medicolegal system.

Forensic anthropologists within the United States have traditionally been expected to extrapolate information regarding biological profile, trauma, pathology, or postmortem interval to assist in victim identification, crime reconstruction, and cause and manner of death. However, as anthropologists, those in the forensic subfield can still choose to pursue archaeological and sociocultural training that may inform forensic anthropology.<sup>1,2</sup> Recent scholarship has emphasized the unique potential of these skills for expanding forensic anthropological practice.

Specifically, recent publications have underscored the potential for forensic anthropologists to contribute to policymaking and data reporting for social vulnerability determinants. This application of anthropological analysis exists in other subfields but not within standard forensic anthropology practice. Through exploring the ability, limitations, and potential of forensic anthropological analysis to infer information about access to resources and health status, practitioners may find the role of forensic anthropology changing to provide data that is evidentiary of human rights law (e.g., access to housing) or serves public health initiatives.

Longstanding studies in structural violence discuss social inequity in terms of access to resources such as housing and health care.<sup>3,4</sup> These same principles are seen in international human rights law (e.g., Universal Declaration of Human Rights, International Covenant on Economic, Social, and Cultural Rights) that is framed in similar language and also has a deep interdisciplinary scholarship base. In the United States, accessibility and access to resources remains a fundamental concern for policymaking and community response, with organizations such as the Centers for Disease Control and Prevention (CDC) using a social vulnerability index to identify communities that need additional support. Medical anthropologists, bioarchaeologists, and other bioculturally focused practitioners are often familiar with some of these literatures (we suggest forensic anthropology also engage with broader public health and human rights law issues).<sup>5,6</sup>

In essence, the United States approach to forensic anthropology has largely focused on the individual—enabling their identification and case resolution. While these goals remain important, we wish to highlight the potential for the discipline to refocus on population-level trends among the decedents we analyze. In this presentation, we ask: What patterns emerge among their causes of death, circumstances of death, and the lived experiences they may embody? What social structures are implicated in those patterns? How might forensic anthropological reporting inform public health and policy to effect change, improve quality of life, and seek to prevent future deaths?

Recent forensic anthropological research and casework explores forensic anthropologists' ability to extrapolate information from individual cases or bodies of casework regarding a population's access to resources and health status—particularly when contextualized for a specific geographic region.<sup>7-</sup>

<sup>9</sup> Here, we synthesize and critically evaluate literature related to Winburn, Wolf, and Marten's proposed Structural Vulnerability Profile (SVP).<sup>10</sup> Some scholarship calls attention to the relationship between SVP reporting and human rights/humanitarian anthropology, while other literature highlights concerns that should be addressed before pursuing an SVP.<sup>11,12</sup> This presentation reviews the literature to summarize main arguments, clarifies the original intent of an SVP proposal, and encourages further discussion among practitioners.

Forensic Anthropology; Structural Vulnerability; Ethics

## A63 Justice for All Missing: The Mississippi Repository for Missing and Unidentified Persons

Jesse R. Goliath\*, Mississippi State University, Mississippi State, MS; Jordan Lynton Cox, Mississippi State University, Mississippi State, MS; Elise J. Adams, Mississippi State University, Starkville, MS

**Learning Overview:** After attending this presentation, attendees will have a better understanding of who goes missing in the state of Mississippi and how the Mississippi Repository incorporates socioeconomic data to help resolve missing persons cases.

**Impact Statement:** This presentation will impact the forensic science community by highlighting the need to develop region- and state-specific databases that rely on multiple sources, including missing persons data, health data, and socioeconomic factors for missing persons work.

In the United States, a lack of missing and unidentified persons repository data at both the state and national level continues to impact the identification of missing and unidentified people, particularly from historically marginalized communities.<sup>1-3</sup> As of July 2023, the National Missing and Unidentified Persons System (NamUs) reported 23,446 open missing persons cases, only 24% of the open cases in the FBI's National Crime Information Center database.<sup>4,5</sup> These statistics highlight a discrepancy in missing persons data, and such inconsistencies are compounded for marginalized groups, who are less likely to be reported missing, less represented in media coverage, and have fewer resources allocated to their cases.<sup>6-8</sup> However, state data collection and analysis can help rectify these inequities by providing more accurate data that can be shared nationally. The Mississippi Repository for Missing and Unidentified Persons was developed to help identify, resolve, and archive Mississippi's cases of missing and unidentified persons. The Mississippi Repository is a statewide database and collaborative tool that seeks to increase public access to missing persons information, partner with neighboring states to facilitate data sharing of missing and unidentified persons information, and visualize socioeconomic and medicolegal disparities affecting missing persons using geospatial analysis.

The Mississippi Repository comprises over 800 current and resolved missing persons profiles gathered from local law enforcement agencies, non-profit missing persons advocacy groups, and social media platforms. Preliminary analyses have shown that Black, Native American, and Multiracial individuals were overrepresented in the Repository compared to their general population percentage in Mississippi. Of all the missing persons resolved, 62% of those found deceased were Black. Moreover, Black men and women were twice as likely to be found deceased compared to their White counterparts. These disparities are also present in looking at health outcomes. Compared to White Mississippians, Black Mississippians have the highest mortality rate from cancer, diabetes, heart disease, homicide, hypertension, renal disease, and stroke.<sup>9</sup> These stark Black-White disparities in Mississippi are geographically structured as well. The Mississippi Delta and other counties with high Black populations have the worst rankings on premature death, self-reported health, and percentage of low-birth-weight newborns in the state.<sup>10</sup> Combining missing persons data with socioeconomic factors will provide a greater understanding of who goes missing and how we can help identify and resolve these cases in Mississippi and across the Southeastern United States.

### Missing Persons; Social Justice; Rural Communities

## A64 The Cold Case Initiative: Bringing Cases up to Current Investigative Standards

*Erin H. Kimmerle\*, Florida Institute for Forensic Anthropology & Applied Science, Tampa, FL*

**Learning Overview:** The goal of this presentation is to present an inclusive investigative model for Unidentified Human Remains (UHR) and missing persons at the state level, including field, lab, and archival methods.

**Impact Statement:** The National Institute of Justice (NIJ) guidelines for establishing cold case units calls for inclusive models combining homicide, missing person, and unidentified human remains investigations. The research presented here was a state-wide initiative that serves as a template for other agencies and programs seeking to establish similar units. This presentation will impact the forensic science community by providing best practices for locating and identifying lost investigative materials, with a focus on including traditionally underserved demographic groups and minority populations.

Throughout Pennsylvania, thousands of unresolved homicides dating back to the 1960s represent families and victims who have been denied justice. Among the most difficult to solve are the hundreds of Missing Persons (MP) presumed dead and the 500+ individuals who are victims of homicide or died alone, resulting in unknown identities. Such cases pose significant prosecution challenges with thousands of hours spent searching for human remains and clandestine burials.

The Institute for Forensic Anthropology and Applied Science at the University of South Florida (IFAAS) began a collaboration with the Pennsylvania State Police (PSP); numerous district coroners and district attorney offices; the Philadelphia Police Department, the Philadelphia District Attorney and Medical Examiner Offices; the Pennsylvania Attorney General's Office, and several other Eastern District police departments. The purpose of the Cold Case Initiative was to bring select UHR cases from open homicide investigations up to current investigative standards, facilitating they meet protocol standards and methods required to solve long-term open cases. This initiative led to numerous positive outcomes, positive identifications, and was successful in laying the groundwork for a statewide effort. The methods, results, and policy recommendations are discussed in this presentation.

In 2016, Philadelphia had a total of 41 UHR cases listed in NamUs, and all other counties throughout Pennsylvania had a combined total of 62 UHR cases. As a result of this initiative, an additional 178 UHR cases from Philadelphia and 29 from surrounding counties for a total of 207 UHR were added to the existing lists into NamUs and National Crime Information Center (NCIC). Still, these impressive results represent only a portion of the total number of unresolved cases.

This investigation found significant bias among minority communities in terms of missing person investigations. A consistent gap in records shows that cases involving females and minorities have not been investigated (e.g., there is no documented female missing person investigation in the city of Philadelphia from 1985-1992, and only one missing Black female is listed prior to 1980). The majority of listed missing persons cases since that time are females from minority communities; yet the majority of UHR listed by coroners and medical examiners are male, illustrating the disconnect between reported MP and UHR cases. Two of the UHR cases we attempted to exhume in 2016 were unknown Black children. Neither were in the reported graves upon exhumation and currently their skeletal remains are "lost." It was further discovered that one female child had never been in the missing persons system despite police reports about her disappearance in 1984.

The results of this project also establish areas for further investigation that will be addressed in the presentation such as locating John/Jane Doe graves in unmarked cemeteries; the need for vital statistics to provide death certificate data on burial locations, the use of facial reconstructions to engage the public for generating investigative leads, and the occurrence of undocumented UHR located in university research and teaching collections.

**A65 The East Marshall Street Well Project: Community-Driven Research to Restore Identity and Dignity**

*Tal Simmons\*, Virginia Commonwealth University, Richmond, VA*

---

**Learning Overview:** After attending this presentation, attendees will understand the role of descendant communities in providing direction, guidance, and oversight to humanitarian forensic research concerning recent historical remains. Community engagement objectives and preliminary results of the project will also be discussed.

**Impact Statement:** This presentation will impact the forensic science community by raising awareness of the need not only to consult and engage with but also be guided by descendant communities when conducting research with humanitarian objectives.

During construction of a new building on the Virginia Commonwealth University (VCU) medical campus in 1994, a brick-lined well, or anatomical sink, was discovered containing human remains. The university president gave archaeologists a single weekend to remove the deposits with a backhoe and retrieve the remains. Archival research indicates that these individuals most likely were grave-robbled from local cemeteries of enslaved Africans and paupers (ca.1840-1860) by resurrectionists, used at the medical school for anatomical dissection and amputation practice, and subsequently discarded in the Well. In 1994 when the Well was rediscovered during construction, VCU did not comply with the law and had the remains hurriedly removed with a backhoe over a weekend, never filed the appropriate paperwork with the Virginia Department of Historical Resources, and shipped the remains to the Smithsonian for analysis—all without the knowledge of the local community. The community only became aware of what had occurred in 2011, with the screening of a film (*Until the Well Runs Dry: Medicine and the Exploitation of Black Bodies*) by Dr. Shawn Utsey, of VCU's African American Studies department.<sup>1</sup> VCU then began a program of community consultation concerning what should be done with the Ancestral remains.

Published analyses (2012) by anthropologists from the Smithsonian Institution's Museum of Natural History determined that there were a minimum of 54 individuals, including nine children under the age of 16 years, primarily of African ancestry.<sup>2</sup> As awareness in the community grew, the Family Representative Council (FRC) was established in 2015 to stand in for the descendant community and set research, memorialization, and interment goals for the Ancestral Remains.<sup>3</sup> After some seven years of ongoing community consultations, the skeletal remains of the Ancestors from the East Marshall Street Well (EMSW) were returned to Richmond in 2019 and VCU's Forensic Anthropology Laboratory in 2022; DNA analysis to re-associate the bones into individuals and to establish their ancestry, phenotype, and relationship to people living in the community today is ongoing. This presentation will explore the ethical treatment of human remains, the agency of the community in determining the fate of the Ancestral remains, and the community's oversight of the research and involvement of scientists. The session will also present the results of the research thus far and the continuing goals of the project. Additional community engagement has occurred in the form of an "Ethical Treatment of Human Remains" curriculum for high school students, which was piloted to two Richmond Public Schools in the spring of 2023.

Over 1,000 commingled bones were recovered from the EMSW, of which approximately half are being sampled and analyzed for DNA in order to re-associate them to form as complete individuals as possible; ribs, vertebrae, and patellae were excluded from sampling, as well as clavicles that were previously subjected to unauthorized isotopic sampling. Method development enabled the DNA sampling to be restricted to a 40mg bone powder sample obtained using a Dremel® tool with a diamond bit. Although the work is still ongoing, results from comparisons of (1) anthropological pair matching with bone-to-bone DNA matching and (2) anthropologically determined population affinity and genetically determined ancestry will be discussed. In addition, phenotype estimates from the genotypes obtained will be discussed. Current work involves using mitochondrial DNA (mtDNA) to both understand the diverse ancestry of the current community and attempt to relate individuals living today to those ancestors recovered from the EMSW.

**A66 Mapping Medicolegal Disparities and Indigenizing Harm Reduction Strategies for Missing and Murdered Indigenous Persons in Idaho**

*Juliette Bedard\**, Idaho State University, Pocatello, ID; *Samantha H. Blatt*, Idaho State University, Pocatello, ID; *Patricia N. Morales Lorenzo*, Idaho State University, Pocatello, ID; *Trace Miles*, Idaho State University, Pocatello, ID; *Bailey Bates*, Idaho State University, Pocatello, ID; *Jake R. Shields*, Idaho State University Department of Anthropology, Meridian, ID

---

**Learning Overview:** After attending this presentation, attendees will better understand the intersectional factors of the Missing and Murdered Indigenous Persons (MMIP) crisis in North America. Attendees will be able to incorporate factors such as social services and health care support via Geographic Information Systems (GIS) mapping in order to assess the vulnerabilities, resource needs, and cultural knowledge fundamental to finding solutions in MMIP cases.

**Impact Statement:** This presentation will impact the forensic science community by offering strategies for collating and contextualizing MMIP cases through the incorporation of Indigenous cultural knowledge, public health theory, and culturally informed harm-reduction strategies.

Indigenous persons are disproportionately reported as missing or unidentified, necessitating a specialized response. In Idaho, Indigenous peoples account for 3.38% of the total missing persons entries, compared to 1.76% of total entries nationwide, and in proportion to their population, are 2.1–10 times more likely to go missing.<sup>1</sup> These numbers likely misrepresent the true nature of the crisis due to the unknown number of cases that go unreported or unentered into databases.<sup>1</sup> Inconsistencies in reporting and lack of collaborative efforts among law enforcement and forensic practitioners with tribal leaders precludes culturally specific strategies and preventative measures.<sup>2-3</sup>

Since there is no national unified system for the reporting of missing/unidentified persons, nor a federal mandate for law enforcement to compile their data centrally, databases are often incomplete, decentralized, inconsistent, challenging to access, and understaffed. None have standards to collect tribal data and lack the inclusion of relevant socioeconomic data that could allow a contextualized analysis. Jurisdiction also impacts reporting and resources for MMIP cases, as tribal police may engage in their own data collection (often with few resources). Further, in regard to Indigenous stakeholders, there is consensus that policy or law enforcement definitions of “missing persons” lack cultural/communal understanding, leading to mistrust, inter/multi-agency miscommunication, under-resourced tribal dispatches, and a lack of culturally appropriate services to Indigenous victims and families.<sup>1-5</sup> All of these factors fail to support the data collection needed for longitudinal/trend analysis necessary for guiding community-specific action.<sup>2,3,5</sup>

To illustrate the potential of contextualizing MMIP data, this study presents a GIS database and map of MMIP in Idaho. Data are compiled from open-source databases such as Idaho Missing Persons Clearinghouse, the National Missing and Unidentified Persons System (NamUs), National Center for Missing and Exploited Children (NCMEC), the Charley Project, LGBTQ+ Accountability for Missing and Murdered Persons (LAMMP), and the DNA Doe Project. These repositories include demographic and individualizing information, city of origin, and last known location. A map is developed using MMIP geographic markers (last known location, location of unidentified remains) and overlaying polygonal census/health data.

This presentation demonstrates spatial patterning of missing persons and correlates that to three different factors of vulnerability; specifically, the visibility of the area, population size, and law enforcement presence all factor into the rate of missing persons. The rate of missing persons is contextual depending on county resources: counties with the highest presence of law enforcement also hold the most missing person cases, while other counties are among the lowest for population and have some of the highest rates of missing persons. These results show the correlation between social services and social vulnerability in that certain factors predispose individuals of marginalized groups to experience colonial violence, racism, and discrimination, which are the foundation of the MMIP crisis. Finally, Indigenized harm reduction strategies are proposed by combining these multi-layered data with Indigenous ways of knowing.<sup>2-3,5</sup>

Herbert, Texas State University, Kyle, TX;*

**Learning Overview:** By attending this presentation, attendees will learn which anatomical regions are more challenging to use for radiographic comparisons based on the preliminary results of an experimental study. Attendees will also learn how many concordant points are more predictive of positive identification by anatomical region and the effects of specific categories on the probability of positive identification.

**Impact Statement:** This presentation will impact the forensic science community by addressing a substantial gap in best practices in positive identification via radiographic comparisons. We will present preliminary predictive statistical models used to assess the validity of identifications from radiographic comparisons.

Forensic anthropologists are often called upon to assist with personal identification, many times using antemortem radiographs of a decedent as a reference. Radiographic comparisons are quick, easy, inexpensive, have broad utility, and are therefore commonly employed for positive identification. Moreover, radiographic comparison is considered a basic competency, expected of forensic anthropologists who are certified by the American Board of Forensic Anthropology. However, relatively little empirical research has been conducted on the reliability and validity of such analyses. This research gap creates a problem of objectivity for radiographic identification, particularly when it needs to be defended in court. Radiographic comparisons can be performed on any region of the body that contains mineralized tissue or bone and that has an antemortem image from the suspected decedent. The accuracy of radiographic comparisons is critical because they are used to make positive identifications in forensic cases and may be the only evidentiary means by which to make such an identification. However, the validity and reliability of these common methods have yet to meet the Daubert guidelines and National Academy of Sciences (NAS) report recommendations. Validity has only been demonstrated for specific regions of the body (e.g., AP chest). A more standardized, objective protocol and robust methodological approach to radiographic comparisons are required. In this presentation, we present preliminary results of the validity of radiographic comparisons as they pertain to predictive accuracy based on anatomical location and number of features using an experimental approach.

We generated a large dataset from a contemporary sample of radiographic data via partnership of the University of Nevada, Las Vegas (UNLV); Clark County Office of the Coroner/Medical Examiner (CCOCME); and Forensic Anthropology Center at Texas State University (FACTS). We used two means to collect radiographs: (1) archived case files from CCOCME from individuals identified using radiographs, and (2) whole-body donations at FACTS. We hypothesized that unique human skeletal morphological variation is sufficient to produce valid personal identifications and the identification probability can be calculated, regardless of the anatomical location being used. Over two years, ten participants of varying levels of experience and education each conducted nearly 500 radiographic comparisons of sex-matched image sets grouped by seven anatomical locations (AP skull, AP chest, AP elbow, AP hand/wrist, AP lumbar and pelvis, AP knee, and lateral foot) to identify correct matches. Participants were given basic introductions to radiographic comparisons and the comparison interface. They were instructed to identify as many concordant points as they deemed sufficient to make a confident match. The concordant points were divided into four categories: (1) normal anatomy, (2) developmental anomaly, (3) pathological, and (4) surgical. Ten percent of the sets presented to the participants were non-match sets.

Preliminary data were analyzed using a generalized logistic mixed-effects model to identify the factors that were most likely to predict an accurate identification. Results indicate that the minimum number of concordant points necessary to increase the probability of a positive identification is statistically significantly moderated by minimum education attained and anatomical region. Across participants and regardless of education level, the AP chest was statistically significantly the most difficult region for comparisons. In addition, participants who used more than one identificatory category (e.g., normal anatomy) statistically increased the probability of a match, as were those who used a minimum of ten points of concordance. The effect of specific identificatory categories on comparison predictive success will be discussed. Finally, these preliminary results indicate that continued exposure to radiographic comparisons improved mean accuracy rates over time for all body regions except for AP chest. These results will be used to highlight recommendations for radiograph best practices, minimum education, and training.

**A68 A Part-to-Part Comparative Analysis to Assess Intra-Individual Similarity and Inter-Level Distinctions for Personal Identification**

*Summer J. Decker\*, Department of Radiology, University of South Florida, Tampa, FL; Daniel W. Martin, Department of Radiology, University of South Florida, Tampa, FL; Jonathan M. Ford, Department of Radiology, University of South Florida, Tampa, FL; Guy Ruttly, East Midlands Forensic Pathology Unit, Leicester, England; Zackery Beauchamp, Department of Radiology, University of South Florida, St. Petersburg, FL*

---

**Learning Overview:** After attending this presentation, attendees will have gained a deeper understanding of the utilization of the lumbar vertebrae from Antemortem and Postmortem Computed Tomographic (AMCT and PMCT) scans for personal identification and the limitations of using cross lumbar level comparisons.

**Impact Statement:** This presentation will impact the forensic science community by providing a cross-level lumbar vertebral comparison for personal identification. Our previous work has shown the reliability of part-to-part comparison on accurately identifying individuals based on their L1-L5 lumbar vertebrae with promising results showing no false positives and no false negatives.<sup>1</sup> The current study examines the cross-level reliability of comparing the different lumbar levels.

In the field of forensic anthropology and medicolegal death investigations, the accurate identification of human remains is of paramount importance. As part of a personal identification project sponsored by the National Institute of Justice (NIJ 2019-DU-BX-0031), the authors examined the utilization of lumbar vertebral models from AMCT scans and the comparison of those models to PMCT scans. That study strictly compared vertebrae from the same lumbar levels, with all lumbar level 1 (L1) vertebrae compared to only other L1s continuing through the L5s. However, in the event of mass disasters or discovered remains, it is common for bones to be found *ex situ* or even individually scattered about the scene. In this comparative analysis, we delve into the utilization of AMCT and PMCT scans to discern if individual variations across lumbar levels can be leveraged to aid in the identification of human remains in forensic scenarios.

Thirty-seven paired AM and PM de-identified thoraco-abdominal CT scans were imported into the Mimics® Innovation Suite v. 24. The L1-L5 vertebrae of each subject were isolated and modeled via hand-segmentation and thresholding. The AM L1 of all subjects were compared against all the L2-L5 vertebra of all the PM scans using part-to-part comparison. A threshold of +/- 1mm was set for the analysis. This process was conducted for every lumbar level where every AM vertebra was compared against every PM L1-L5 vertebrae. A match-ratio was recorded for each analysis, which resulted in over 27,000 unique data points.

A Receiver Operator Curve (ROC) was calculated for every comparison. The Area Under the Curve (AUC) for AM L1 against PM L2, L3, L4 and L5 was 0.928, 0.775, 0.643 and 0.608, respectively. The AUC for AM L2 against PM L1, L3, L4 and L5 was 0.927, 0.923, 0.716 and 0.612, respectively. The AUC for AM L3 against PM L1, L2, L4 and L5 was 0.88, 0.974, 0.909 and 0.714, respectively. The AUC for AM L4 against PM L1, L2, L3 and L5 was 0.751, 0.753, 0.895 and 0.814, respectively. The AUC for AM L5 against PM L1, L2, L3 and L5 was 0.696, 0.637, 0.665 and 0.79, respectively.

The study's findings, measured through the AUC values, demonstrated the potential of cross-level lumbar vertebrae comparison for personal identification. Notably, the AUC values for different vertebrae comparisons indicated varying degrees of accuracy, with some pairs showing high discriminatory power (e.g., AM L3 against PM L2, L4, and L5), while others exhibited lower discriminative ability (e.g., AM L1 against PM L4 and L5). Overall, the results highlight the potential of lumbar vertebrae in forensic human identification, with the highest accuracy observed in the comparisons between AM L3 and PM L2, L4, and L5. Notably, lumbar levels were most similar to their adjacent neighbors. With L3 being the most "central" vertebrae, it had an overall higher match to L2, L4 and L5. L1/L2 matches strongest with each other with L1 and L5 matching the least. However, as each comparison had an AUC higher than 0.5, which signifies that even at the worst values, the match is still greater than chance and significant.

In conclusion, the study's findings demonstrate the accuracy of cross-level lumbar vertebrae comparisons for personal identification. The highest discriminatory power was seen in the comparisons between AM L3 and PM L2, L4, and L5, highlighting the significance of the central vertebrae (L3) in matching with its adjacent neighbors. Moreover, the results demonstrated that even at their lowest values, the matches still surpassed chance, reinforcing the robustness of using lumbar vertebrae for identification purposes.

---

**Learning Overview:** After attending this presentation, attendees will be familiar with machine learning techniques based on deep neural networks applied to the task of comparing chest radiographs (N=2,753) for identification purposes.

**Impact Statement:** This presentation will impact the forensic science community by addressing a significant gap in current methodological approaches to positive identification, particularly levels of subjectivity encountered when performing comparative medical radiography.

When assisting in decedent identification, forensic anthropologists use several approaches, including passive approaches leading to identification (e.g., bioprofile) and more active efforts linking an antemortem record from a tentative identity to the postmortem record of the decedent. Many “active” methods lack quantification, automation, or standardization. In most cases, analysts identify features of concordance (or discordance) in a point-by-point comparison between antemortem and postmortem records to support or refute the identification decision. While such comparisons have withstood the test of time, advancing methods to increase the accuracy, effectiveness, and efficiency of decedent identification is essential to the goals of medicolegal death investigation. One facet of innovation is quantifying how human examiners recognize radiographs from the same individual; another equally important facet is assessing the uniqueness of radiographic features and the specific areas of focus used by human examiners when making an identification.

To investigate this, 2,753 anonymized chest radiographs representing 680 individuals were compiled from the National Institutes of Health (NIH) Chest X-Ray Database and casefiles from the Michigan State University Forensic Anthropology Laboratory. This dataset will advance comparative medical radiographic identifications by providing probabilistic estimates for the confidence of matches and automate the comparison process. To that end, the dataset was divided into training (N = 1,498) and testing (N = 1,255) samples. Images were temporally organized, with earlier radiographs used for training and radiographs taken at a later date reserved for testing. This approach ensures effective learning and accurate assessment by the models.

To prepare the dataset, four Regions Of Interest (ROIs) were digitally annotated in each radiograph: (1) thoracic vertebrae one through five; (2) complete vertebral column; (3) clavicles; and (4) the entire radiograph. Deep learning classification models were developed using three Convolutional Neural Networks (CNNs): ResNet, DenseNet, and EfficientNet architectures with different hyperparameters.<sup>1-3</sup> A closed-set identification protocol was employed (i.e., for each test image [single radiograph], other images corresponding to the same identity were present in the training set). The models were trained using images in the training set. During the evaluation stage, each test image was input to a model, and the output consisted of a ranked list of matching identities with corresponding confidence scores. The results of the initial models are promising. Using only a single ROI, the DenseNet-169 model had the best performance, correctly identifying 74.42% of the test samples using the T1-T5 region. When using the complete vertebral column, EfficientNet-B3 outperformed other models, with an identification accuracy of 73.71%. DenseNet-201 had an identification accuracy of 69.72% when using the clavicles only, and DenseNet-169 had an identification accuracy of 69.72% using the entire chest radiograph. When the confidence scores of multiple ROIs (using multiple regions of a radiograph) were fused, the identification accuracy of both DenseNet-169 and DenseNet-201 reached 80.00%. Interestingly, most models relied more heavily on the T1–T5 and vertebral column regions than the clavicles. The DenseNet-201 model was able to identify 1,255 radiographs in 17 seconds with 74.42% accuracy, whereas trained human examiners need 30 to 60 hours to find a match from 1,000 radiographs but with 100% accuracy.<sup>4</sup>

Most of the current comparative medical radiographic techniques do not quantify the strength of evidence concerning a positive match. In this study, two aspects were evaluated: (1) computed identification accuracies of multiple deep learning models tasked with reconciling potential matches in a large sample of radiographs, and (2) areas in the chest radiographs utilized by these models to achieve those accuracies. Answering questions like these requires considerable collaboration and a multidisciplinary approach. Our research team comprises experts in biometrics, skeletal morphology, machine learning, and computer engineering, demonstrating the effectiveness of a multidisciplinary approach.

**A70 Visual Comparisons of Frontal Sinus Radiographs: Documenting Accuracy and Exploring the Effects of Experience**

*Heather M. Garvin\*, Des Moines University, Des Moines, IA; Jessica L. Campbell, Campbell Forensic Anthropology, LLC, Winona, MN; Lauren Butaric, Des Moines University, Des Moines, IA*

---

**Learning Overview:** This presentation will provide results from a recent study in which forensic and medical practitioners were asked to evaluate pairs of radiographic sinuses for matches. After attending this presentation, attendees will better understand the accuracy rate of radiographic frontal sinus visual comparisons and the effects of training and experience on results.

**Impact Statement:** This presentation will impact the forensic science community by providing accuracy rates and a better understanding of factors involved in radiographic frontal sinus comparisons. These data may be used to support forensic testimonies and develop future training sessions.

The use of frontal sinus radiographic comparisons for forensic identification is well known in medicolegal fields. Visual assessments are the most commonly employed method, although several quantitative methods of sinus matching have been proposed in an attempt to decrease potential subjectivity. In this study, we aimed to assess accuracy rates in visual comparisons of frontal sinus radiographs and to explore the effects of training and experience on accuracy and confidence rates.

An electronic questionnaire was distributed asking participants questions about their education level, certifications, training, profession, and experience in radiographic comparisons. This was followed by 25 pairs of frontal sinus radiographs of which participants were asked whether they believed the two sinuses came from the same individual and to rate their confidence level (1–10). The radiographs were obtained from the American Association of Orthodontists Foundation (AAOF) Craniofacial Growth Legacy Collection. Of the 25 pairs, observers were presented with 18 in which both radiographs were from the same adult individual but taken a year or more apart. Radiographs were cropped to only display the frontal sinus so other craniofacial information would not play into observer decisions. Seven pairs had sinuses from two different individuals. These “mismatched” pairs were selected based on results from another on-going study, in which Elliptical Fourier Analysis (EFA) was used to quantitatively match sinuses of 128 individuals; the mismatched sinuses used in this study were ones EFA incorrectly assigned as a match. Consequently, the mismatched pairs presented to observers should represent challenging mismatches. All radiographs presented were antemortem and taken in the mid-to-late 20<sup>th</sup> century, meaning the presence of soft tissue and radiographic quality also made the comparisons challenging.

In total, 145 complete responses were received. Respondents included professionals and students in forensic and medical disciplines. Even with 65% reporting zero previous experience conducting radiographic comparisons, 89.9% (94.5% median) of the total comparisons (n=3,625) were scored correctly. Eighty-three respondents (57%) scored 92% or better (of those 29 scored 100%). Experience, training, and specialties were shown to affect results. The highest percent-correct scores were found among forensic odontologists (n=3; 98.7% accuracy) and forensic pathologists (n=3; 96% accuracy). Among forensic anthropologists, board-certified individuals scored significantly higher (95.8%; n=20) than those not certified (91.4%; n=28) ( $p=0.031$ ). A significant positive Spearman correlation was found between an observer’s accuracy and their average confidence level ( $p<0.001$ ;  $r=0.754$ ). Incorrectly scored radiographs were biased toward wrongly excluding a match (12.6% of matches erroneously reported as mismatches; 3.6% of mismatches erroneously reported as matches). It appears that slight differences in orientation played a role in the two lowest-performing radiographic pairs. Visual assessment of frontal sinus pairs also outperformed preliminary results from the quantitative outline analyses, given that practitioners can better evaluate explainable differences and internal features such as septa. These results confirm that visual comparisons of frontal sinus radiographs are highly accurate, even considering varied experience levels and less-than-ideal radiographic parameters. Training and experience are recommended to obtain the highest accuracy rates given forensic implications of erroneous personal identifications.

## A71 Investigating Variation in Trabecular and Cortical Bone Structure Due to Mobility Impairment: A Natural Experiment in Reduced Loading

*Devora S. Gleiber\*, Harris County Institute of Forensic Sciences, Houston, TX*

**Learning Overview:** The goal of this presentation is to discuss how mobility impairment is reflected in the trabecular and cortical bone of the upper and lower limb bones. Attendees will come away with an in-depth view of how bone responds to disuse due to reduced mobility, the utility of micro-Computed Tomography (micro-CT) imaging in such a context, and the implications this research has for identifying mobility impairment in the forensic context.

**Impact Statement:** This presentation will impact the forensic science community by demonstrating the utility of micro-CT imaging and bone microstructure analyses in assessing individualizing conditions such as mobility impairment. Since vulnerable populations, such as persons with physical disabilities, are often those most subject to violent crimes and thus more likely to show up in the forensic context, being able to recognize and diagnose mobility impairment can contribute toward identification of human remains.

Bone is a dynamic tissue that responds to changes in loading regime by increasing or decreasing in mass and adjusting the architecture. Since mechanical usage influences trabecular architecture and cortical density, reduced ambulatory ability should be reflected in the trabecular structure and cortical area of the limb bones. This research examines the effects of reduced loading on human bone by quantifying long bone trabecular and cortical bone structural variation associated with mobility impairment. Both left and right femora and humeri of 69 mobility-impaired individuals and one side of the sex- and age-matched fully mobile individuals were imaged using high-resolution computed tomography. Image stacks were processed to produce binary images and trabecular thickness and spacing maps. Trabecular architecture was quantified using multiple geometrically homologous spherical Volumes Of Interest (VOIs) positioned within each joint head for which Bone Volume fraction (BV/TV), Trabecular Thickness (Tb.Th), and Trabecular Spacing (Tb.Sp) were extracted. In addition, these VOIs were used to create maps of average Tb.Th and BV/TV values across the joint surface to view consistent patterns. Single spherical central VOIs were also extracted from each joint head for assessment of variation level captured within a single, more easily reproducible region. Results demonstrate that mobility-impaired individuals have significantly less Tb.Th and BV/TV and greater Tb.Sp. than the fully mobile individuals. Amount of time of impairment and impairment types were investigated with varied results, indicating an individualized response to bone loss due to impairment. Cortical bone area and geometry were quantified using BoneJ with results indicating that mobility-impaired individuals have less cortical area in all directions.

The results of this study demonstrate that the lack of biomechanical burden on mobility-impaired individual femora is reflected in their trabecular structure and cortical bone with more varied results in the humeri, depending on the impairment type. This research helps to improve our understanding of bone functional adaptation, especially as associated with disuse. Furthermore, the results of this research have implications for identifying and diagnosing mobility impairment in the forensic context for purposes of identification.

**A72 Facial Photo-Anthropometry for the Exclusion of Candidates Under Non-Restrictive Photographic Conditions**

*Pilar Navarro, Panacea Cooperative Research, Granada, Spain; Valentino Lugli, Panacea Cooperative Research, Granada, Spain; Andrea Valsecchi, Panacea Cooperative Research, Capoterra, Italy; María A. Guativonza, Panacea Cooperative Research, Granada, Spain; Verónica Martínez, Panacea Cooperative Research, Granada, Spain; Guillermo Ramírez, Panacea Cooperative Research, Granada, Spain; Oscar Ibáñez Panizo\*, Faculty of Computer Science, CITIC, University of A Coruña, La Coruña, Spain; Rosario Guerra Martí, Panacea Cooperative Research, Granada, Spain; Inmaculada Alemán, Physical and Forensic Anthropology, University of Granada, Granada, Spain;*

---

**Learning Overview:** After attending this presentation, attendees will be informed about the real potential of photo-anthropometry in forensic facial comparison. This presentation shows that a sophisticated comparison method can reliably exclude a large number of candidates under realistic photographic scenarios, and even more so when augmented using artificial intelligence.

**Impact Statement:** This presentation will impact the forensic science community by changing the status of photo-anthropometry in the field of forensic facial comparison, turning a technique that was considered hardly applicable into a reliable and effective approach to the filtering of multiple candidates.

Photo-anthropometry is a facial image comparison technique where measurements of the face are taken from an image using facial landmarks. Both measurements and ratios between them, called “Dimensions and Proportionality Indices” (DPIs), are compared against DPIs from another facial image. Multiple studies concluded that simple photo-anthropometric facial comparison is suitable for elimination only in the unlikely circumstance that both images are acquired under the very same facial pose, expression, and camera parameters.<sup>1,2</sup> However, a recent study by Martos et al. demonstrated the usefulness of DPIs when using a more sophisticated approach.<sup>3</sup> The authors developed a series of formulas that, using the DPIs from a photo, allowed them to predict the corresponding DPIs of the 3D face of the subject of the picture. These predicted DPIs can then be compared against those of a candidate to determine compatibility. In their experimental study, the method was able to exclude 57% of the negative candidates while, critically, retaining all positive ones.

The study by Martos et al. provides proof of concept of their novel approach but suffers from important limitations. The number of subjects involved was only 30. With respect to the prediction of DPIs, the authors tested only one simple linear approach. This study is meant to address these limitations. We employed facial 3D scans from 122 subjects, from which we simulated 500 photographs each, for a total of 61,000 images. In addition to linear regression, we compared several modern regression techniques from the field of Machine Learning and Artificial Intelligence. Also, we studied the effect of several factors that were not included in the original study, such as the different photographic setup, availability of information about the image (e.g., metadata), and lack of visibility of certain landmarks due to occlusion.

Our experimental study validates the approach and measures its effectiveness in a variety of realistic scenarios. Positive cases are always retained as required, while the filtering of negative cases varies between 45% and 69%. This shows the technique is viable and leads to a substantial reduction of the number of candidates in the comparison.

**A73 Correlations of Facial Soft Tissue Thicknesses with Craniometric Dimensions to Improve Craniofacial Identification Estimates: Fact or Fiction?**

*Te Wai Pounamu Telena Hona\**, Laboratory for Human Craniofacial and Skeletal Identification (HuCS-ID Lab), School of Biomedical Sciences, The University of Queensland, Brisbane, Queensland, Australia; *Carl Stephan*, Laboratory for Human Craniofacial and Skeletal Identification (HuCS-ID Lab), School of Biomedical Sciences, The University of Queensland, Brisbane, Queensland, Australia

---

**Learning Overview:** After attending this presentation, attendees will understand that craniometric dimensions are only weakly correlated with Facial Soft Tissue Thicknesses (FSTTs) and not strongly enough for practically useful improvements in estimates of soft tissue thicknesses above arithmetic means in craniofacial identification casework.

**Impact Statement:** This presentation will impact the forensic science community by debunking the popularly held (but erroneous) notion that linear regression and craniometrics can be used to produce superior facial soft tissue estimates that outperform arithmetic means in casework.

Regression approaches that estimate the FSTTs from an individual's craniometric dimensions have been posited to boost the accuracy of craniofacial identification methods.<sup>1</sup> While alluring in principle, the method ultimately depends on strong correlations between craniometrics and FSTTs—but these have not been robustly observed or elucidated in prior research.<sup>1,2</sup> For example, Simpson and Henneberg's original concept paper employs approximations of craniometric values (rather than direct measurements) and uses statistical corrections in attempt to remove substantial noise from the data (and boost strength of associations).<sup>1</sup> Subsequently, the practical utility of a regression approach is presently unconfirmed and would benefit from a decisive test using medical imaging methods where craniometric and FSTT values can both be directly measured and assessed without statistical corrections.

This study uses Magnetic Resonance Imaging (MRI) to directly measure craniometrics and FSTT in 38 adult Australian cadavers (24 males and 14 females, aged 66 to 99 years) to examine their correlations and utility for regression. The measurement of cadavers was strategic to enable Simpson and Henneberg's protocols to be repeated in the very same heads for comparison to the MRI data.<sup>1</sup> Seven craniometric dimensions and 13 FSTT measurements (8 median and 5 bilateral) were taken for each individual using each method. MR measurements were taken using Osirix® v4.1.2 from T1-weighted MRIs taken at 0.8mm slice thickness, 256mm FoV, 6.2ms Repetition Time (TR), 2.3ms Echo Time (TE) with a 3T MRI (Magnetom Prisma<sup>fit</sup>, Siemens). After MRI scanning, the very same heads were measured by the needle puncture method and craniometric dimensions approximated per Simpson and Henneberg's protocol whereby soft tissue over the craniometric landmarks was compressed by manual pressure exerted by spreading GPM® calipers.<sup>1</sup> Pearson Product Moment Correlation Coefficients (*r*) between FSTTs and craniometric dimensions were calculated for both approaches and standard errors of the estimates calculated. Simpson and Henneberg's linear regression models were applied to both MRI and manually acquired data.<sup>1</sup> Standard errors of the regression estimates were additionally compared to those obtained using data means for both this sample and the 2023 T-Table. All data analysis was performed in Statistical Program for Social Sciences (SPSS, version 28) and Microsoft® Excel® 2013.

Across both MRI and manually acquired data, craniometric dimensions exhibited weak correlations with FSTTs with *r* ranges from -0.41 to +0.31 (mean *r* across landmarks was  $-0.1 < r < +0.1$ ). The application of Simpson and Henneberg's regression models to the MRI and manually acquired data of this study yielded higher FSTT estimation errors than those originally reported by Simpson and Henneberg's (Sest increased by a grand mean value of 3mm).<sup>1</sup> This study's means for MRI and manually acquired data, when used as FSTT estimators, consistently outperformed Simpson and Henneberg's linear regression models (MRI mean Sest = 3.3mm vs. regression model = 3.8mm and manual mean Sest = 3.5mm vs. regression model = 5.5mm). These findings contrast the common belief that craniometric-based regression models provide superior FSTT estimates, especially in comparison to arithmetic means. Craniometric measurements acquired by MRI were different to caliper compression methods (per Simpson and Henneberg's protocol) at statistically significant levels (Bonferroni adjusted, paired Student's *t*-test,  $p < 0.005$ ).

This MRI study demonstrates that FSTTs are only weakly correlated with craniometric dimensions. The small *r* values observed in this study do not justify the calculation of regression models from craniometrics for FSTT estimation, not even when the craniometrics are directly measured from the MRI scans to remove any residual soft tissue components.

**Learning Overview:** After attending this presentation, attendees will have learned about our newly developed semi-automated methodology for extraction of facial soft tissue depth and direction values. Using Computed Tomography (CT) medical images, we have trained algorithms to extract both facial and cranial 3D models through segmentation. Next, we have automated the placement of both cephalometric and craniometric landmarks, which results in a series of x, y, and z coordinates for each of the cephalometric and craniometric landmarks. We computed the statistical distribution of the depth and direction vector for each pair of cephalometric-craniometric landmarks. This semiautomated approach allows us to deal with unprecedented amounts of data.

**Impact Statement:** This presentation will impact the forensic science community by presenting research that changes the field of craniofacial identification by adding a new dimension: the study of the spatial relationship between bony and facial structures and its variability according to population, sex, Body Mass Index (BMI), and potentially other biological profile characteristics. Preliminary research results within our research group show radical improvement in the potential of positive identification using techniques such as craniofacial superimposition when incorporating this information.

In this work, we present a novel methodology developed to study the spatial relationship between cranial landmarks and their facial homologues. Most facial soft tissue depth studies have not addressed this spatial relationship between landmarks and its variability in different populations, sex, age, and BMI groups. However, prior research in the area seems to indicate that this information could potentially improve the results in the application of different craniofacial identification techniques, such as Facial Approximation and Craniofacial Superimposition.<sup>1,2</sup>

Our data consists of 800 anonymized Computed Tomography (CT) scans from the New Mexico Decedent Image Database, with an even distribution among male and female individuals and with an age ranging from 20 to 60 years old.<sup>3</sup> From the CTs, we extract two 3D models using a segmentation algorithm: one of the face using a given threshold of Hounsfield Units; another one of the skull with a higher threshold. At the same time, the algorithm developed performs a clipping of the area of interest. Afterward, a different algorithm, trained with the input of several anthropologists, automatically provides a number of cephalometric and craniometric landmarks for each model.<sup>4</sup> This results in a series of x, y, and z coordinates for each of the landmarks, allowing the assessment of their relationships and variation. With all the 3D models aligned using the Frankfurt plane, we computed the statistical distribution of the depth and direction vector for each pair of landmarks. Using this approach, we can observe how the thickness and positional relationship of soft tissue in relation to the underlying bone varies with different factors such as BMI, age, or sex.

This methodological approach allows us to deal with unprecedented amounts of data and can ultimately be used to develop regression models capable of estimating an individual set of 3D cephalometric landmarks for a given set of 3D craniometric ones.

**Learning Overview:** After attending this presentation, attendees will better understand Craniofacial Superimposition (CFS), the challenges involved in its application, and the latest developments in the creation of accurate and robust automatic methods.

**Impact Statement:** This presentation will impact the forensic science community by detailing the design and validation of a novel skull-face overlay method that is a significant improvement over the current state of the art. This means performing CFS can be performed automatically, with increased precision and less subjectivity.

CFS is probably the most challenging skeleton-based identification method.<sup>1,2</sup> It requires superimposing a Postmortem (PM) skull onto facial Antemortem (AM) photographs, projecting the former onto the latter, in order to assess their anatomical consistency. Three stages can be distinguished in the CFS process: (1) acquisition and processing of the skull and facial images, together with the localization of anatomical landmarks that usually guide CFS; (2) Skull-Face Overlay (SFO), which focuses on achieving the best possible projection of the skull onto the AM facial image(s) of the subject; and (3) decision-making to determine whether the skull belongs to the person in the photograph(s) or not.

In the past decade, researchers developed several computer algorithms to carry out the skull-face overlay process automatically by leveraging advances in Computer Vision and Artificial Intelligence.<sup>3</sup> However, subjectivity over the position of the anatomical landmarks and lack of specific knowledge on the amount of the facial soft-tissue of the subject can lead to low-quality results. In this study, we aim to improve the SFO process by widening the information employed by the automatic method beyond the location of the landmarks. This includes a statistical model of the facial soft-tissue as well as information about the photograph, namely the focal distance, the subject-to-camera distance, and the overall facial pose. Moreover, the algorithm uses the shape and positional relationship of the chin profile, while the overall profile of the skull is matched to that of the face.

Our experimental study involved a sample of computed tomography scans of 27 subjects. From each scan, we obtained a 3D model of the skull, and we also simulated 10 frontal photographs and 10 lateral photographs, for a total of 540 images. Each photograph has been superimposed with all 27 skulls, for a grand total of 14,580 skull-face overlays. The results show a clear improvement over the current state of the art in terms of accuracy and robustness due to the additional information involved in the process.

**A76 Sex Estimation Methods in Forensic Anthropology: Current Practice and Trends**

*Alexandra R. Klares\*, Washburn University, Topeka, KS; Kate M. Lesciotto, University of North Texas Health Science Center, Fort Worth, TX*

**Learning Overview:** The goal of this presentation is to inform attendees about the current state of skeletal sex estimation in forensic anthropology, including practitioner preferences, reporting practices, and trends across time.

**Impact Statement:** This presentation will impact the forensic science community by reporting on the variation within the field for sex estimation from the human skeleton.

Estimation of sex is generally the first step when constructing the biological profile of an unidentified individual, primarily because many of the other biological profile parameter methods are sex-specific. However, method selection and reporting vary considerably across practitioners. An electronic research survey was distributed to forensic anthropology educators, practitioners, and students to understand more about the methods used by forensic anthropologists to estimate biological sex, as well as the factors that influence decisions regarding method selection. This survey (IRB# 2022-105) asked demographic questions about each participant's level of education and forensic anthropology casework experience and questions about sex estimation methods. A total of 150 survey responses were collected, with 119 participants completing some or all of the questions analyzed in this study.

Most respondents (93.3%) held a graduate degree in anthropology (MA, MS, or PhD), and 39.5% were American Board of Forensic Anthropology (ABFA) diplomates. Nearly all respondents preferred to combine metric and morphological methods to estimate sex. A rank system was used (1=most informative to 4=least informative) to rank skeletal regions by preference for sex estimation based on data type. For morphological methods, the pelvis was overwhelmingly preferred as the best indicator of sex (average rank 1.1), followed by the skull (2.1), long bones (2.9), and other regions (4.0). For metric methods, long bones were the most preferred skeletal region (1.7), followed by the skull (2.1), pelvis (2.2), and other regions (4.0). Participants were also provided with ~25 methods and were asked to indicate the likeliness of using those methods (1=extremely unlikely to 5=extremely likely). The most preferred sex estimation methods in order of average rating were FORDISC® (4.6), Klares et al. 2012 (4.4), MorphoPASSE (4.3), Walker 2008 (4.2), and Spradley and Jantz 2011(4.0).<sup>1-5</sup> Respondents' decision-making process for selecting a particular method for estimating sex is frequently influenced by: (1) whether the method has been subjected to independent validation and error studies, (2) personal experience with the method, and (3) the type of equipment needed. When using multiple methods to estimate biological sex and the methods do not agree, most respondents indicated that they present the results from all methods utilized, but their final estimate is based upon their personal experience and general impression of the remains (37.1%) or they give preference to methods using pelvic traits or measurements (35.1%).

The results from this survey were compared to a previous survey on sex estimation conducted by Klares 2013, with surprisingly similar results.<sup>6</sup> FORDISC® and the three pubis traits (ventral arc, subpubic contour/concavity, and medial aspect of the ischio-pubic ramus) remained the most preferred methods/traits; however, the Klares et al. 2012 and MorphoPASSE revisions have replaced Phenice 1969 as the more commonly preferred method since the 2013 survey.<sup>2,3,7</sup> Since the 2013 survey, more respondents have indicated that they prefer to use *both* metric and morphological methods, rather than a preference being given to morphological methods when only one data type was used to estimate sex. Respondents also showed a high likelihood of using a method that combined data from multiple skeletal regions. The current paucity of methods that combine both metric and morphological data from multiple regions suggests opportunities for future method development.

**A77 A Test of the Applicability of Decision Trees for Sex Estimation Utilizing an Expanded Suite of Morphological Traits**

*Morgan J. Ferrell\*, University of Central Florida, Orlando, FL; John J. Schultz, University of Central Florida, Orlando, FL; Donovan M. Adams, University of Central Florida, Orlando, FL*

---

**Learning Overview:** This presentation will discuss the utility of decision tree models for estimating sex from an expanded suite of morphological traits of the skull. After attending this presentation, attendees will have a better understanding of the strengths and limitations of utilizing decision tree models for sex classification of the skull.

**Impact Statement:** This presentation will impact the forensic science community by building upon current research in forensic anthropology exploring the application of machine learning to improve sex estimation classifications for the skull.

Forensic anthropological casework incorporates morphological and metric assessment of the os coxae, skull, and long bones for sex estimation in cases of unknown individuals. Morphological sex assessment of the skull commonly utilizes the glabella, supraorbital margins, mastoid processes, nuchal crest, and mental eminence. However, morphological methods for the skull suffer from lower classification rates compared to the pelvis as well as an overreliance on the aforementioned traits. Recent studies have attempted to address these issues through the application of machine learning to produce sex classifications from morphological traits of the skull.<sup>1</sup> The present study builds on this research by exploring whether higher sex classification rates for the skull could be achieved utilizing decision trees and an expanded suite of traits. This research seeks to: (1) select an expanded suite of morphological traits and assess intra-observer error for each trait, (2) generate multiple decision trees, and (3) compare the classification performance of the generated trees to the performance of the tree developed by Langley and colleagues.<sup>1</sup>

Twenty-two morphological traits of the skull were chosen from frequently referenced sex estimation methods. A total of 215 individuals were sampled from the Hamann-Todd Osteological Collection and 147 individuals from the University of Tennessee Knoxville (UTK) Donated Skeletal Collection. Intra-observer error was assessed from 43 individuals from the UTK Collection. Statistical analyses were conducted utilizing R Statistical Software. Intra-observer error was assessed utilizing Krippendorff's Alpha to assess which traits to include when generating the decision trees. All analyses were conducted on the pooled sample (n = 362), European Americans (EA) (n = 209), and African Americans (AA) (n = 153). Each dataset was split into a training sample (80% of the data) and a testing sample (20%). The following decision trees were generated utilizing the training samples and the *party* package trees with traits from the entire skull, trees for cranial traits only, and trees for mandibular traits only.<sup>2</sup> The error of each tree was assessed using the testing sample. Finally, the performance of the Langley et al. tree for estimating sex from the present study's sample was tested.

Of the assessed traits, 12 achieved an acceptable level of intra-observer error. Overall, the highest performing trees identified incorporated traits from the cranium and mandible, with classification rates of 92.5% (pooled), 93.5% (EA), and 94.9% (AA). Trees that included cranial traits produced classification rates of 91.0% (pooled), 91.3% (EA), and 89.7% (AA), while trees that included mandibular traits produced the lowest rates of 79.1% (pooled), 84.8% (EA), and 84.6% (AA). When individuals from the present study were classified utilizing the Langley et al. tree, 76% of the pooled sample, 80% of the European American sample, and 70% of the African American sample were correctly sexed compared to their reported accuracy of 96%. The Langley et al. tree was built utilizing only European individuals, thus partially explaining why their tree resulted in an increased classification rate for the European American sample.

Overall, most decision trees achieved classification rates over 80%, with several over 90%. The population-specific trees often outperformed the pooled sample trees. Thus, it is recommended that future sex estimation research involving decision trees should develop and test methods for individual populations. However, trees that perform well for multiple groups would be beneficial for forensic cases in which an individual's population affinity is not estimated or unknown. Further, the comparison with the tree developed by Langley and colleagues indicates that tree classification performance decreases when applied to different skeletal samples. This research demonstrates the need for further testing of these methods and the importance of expanding beyond decision trees to more robust methods such as random forest modeling.

**A78 An Exploration of the Subadult Pelvic Sex Estimation Method Using Pelvic Metrics and Geometric Morphometrics**

*Leah E. Auchter\*, University of Nevada, Reno, Reno, NV; Kyra Stull, University of Nevada, Reno, Reno, NV; Heather M. Garvin, Des Moines University, Des Moines, IA*

---

**Learning Overview:** This presentation will provide attendees with a better understanding of the relationship between subadult pelvic size and shape and biological sex estimations, as well as a more complete ontogenetic analysis of skeletal growth.

**Impact Statement:** This presentation will impact the forensic science community by exploring two approaches to estimate the biological sex of subadult individuals. The current project will increase confidence in applying pelvic metrics and shape analyses for sex estimation in immature individuals, which substantiates previous subadult research using morphological pelvic traits.

The forensic anthropological field has posited that there should be a better understanding of the biological foundations that enable biological profile estimations of skeletal human remains. In alignment with this is a better understanding of the ontogenetic processes that influence variations in growth and subsequent trait expressions. Biological sex estimation represents a main component of the biological profile estimated by forensic anthropologists. Adult sex estimation methods using morphological and metric analyses of the pelvis consistently yield high classification accuracies. Subadult sex estimation methods have been less successful primarily because of a lack of large skeletal samples representing all of ontogeny. However, approaches can be reevaluated now that larger samples are available through virtual anthropology. Pelvic metrics have not been fully explored regarding their utility in sex estimation of subadults even though the innominate has potential at a young age because of its early age of fusion and mediation by hormones early in puberty.

A subset of 369 individuals aged between 8 and 20 years from the United States subset of the Subadult Virtual Anthropology Database (SVAD) were included in this study. The criterion of an actively fusing or completely fused ilio-ischial union at the triradiate cartilage was employed to limit the sample to individuals with complete innominates. A total of 34 pelvic landmarks were recorded for each individual; 16 landmarks were used to calculate 11 Interlandmark Distances (ILD) defined in the *Data Collection Procedures for Skeletal Material 2.0* with some minor definition modifications.<sup>1</sup> Seventeen landmarks were used in the geometric morphometric analyses. A General Procrustes Alignment (GPA) and Principal Components Analysis (PCA) was performed, and a Multivariate Analysis of Variance (MANOVA) was performed on all the Principal Components (PCs) as a multivariate test of significant shape differences between males and females. ANOVAs were then performed to test which specific PCs demonstrated significant sex differences. Linear Discriminant function Analyses (LDA) were used on a training sample for both the ILDs and on the PC scores to generate sex estimation models; a test set was used to evaluate the models.

The LDA using 11 ILDs was applied to a hold-out sample and correctly classified 97.14% of females and 92.73% of males for an overall classification accuracy of 94.44%. The LDA using PCs 1 through 5, which included all PCs with greater than 5% variance, correctly classified 80.00% of females and 90.57% of males. When all PCs with greater than 1% variance were included (PCs 1–22), 85.71% of females were correctly classified while 92.45% of males were correctly classified. The inclusion of centroid size in the LDA with PCs 1 through 5 improved the classification accuracies and reversed the sex bias; 91.43% of females and 90.57% of males correctly classified, resulting in an overall classification accuracy of 90.91%.

Results of this study suggest that both metric analyses and geometric morphometrics can correctly estimate sex of individuals with fusing or completely fused innominates with high accuracies. The current study relies on the biological age, or skeletal maturation of the individual, to inform the practitioner, which removes the need to estimate age prior to estimating sex. The geometric morphometric analyses highlight the importance of pelvic size as a meaningful component to accurate subadult sex estimation, which was seen with the sex bias when centroid size was not included. The success of this study expands the anthropological toolkit when faced with subadult remains and supports the use of pelvic metrics to improve biological profile estimations, including sex estimation, of subadult individuals.

---

**Learning Overview:** After attending this presentation, attendees will be able to appreciate the role of mandibular measurements taken from Computer Tomography (CT) scans for estimating the sex in a defined ethnic population.

**Impact Statement:** This presentation will impact the forensic science community because the importance of CT scan measurements of the mandible for estimating the sex in a defined ethnic population will be discussed, which may further be studied in other populations.

Partial identification of an individual can be established by criteria like age, sex, race, stature, etc. Sexual dimorphism is expressed in most human bones. However, at times only some body parts of the deceased may be available for forensic interpretation. The mandible is the largest and strongest bone of the face. Therefore, in comparison to other facial bones, it remains for a longer time and has a slower degradation rate. Sex dimorphic characteristics of the mandible have been reported from studies using either bone or CT scan images of the mandible.<sup>1-3</sup>

The sample size was estimated based on sample size estimation for area under the Receiver Operating Characteristic (ROC) curve. Under the alternative hypothesis, it was anticipated that the discriminatory ability of the discriminant function is 0.6 in estimating the sex with the CT measurements against the null hypothesis at 0.5 as the Area Under the Curve (AUC) value. Therefore, at a 5% level of significance and 90% power, accounting for the proportion of males and females in the sampling frame, the total sample size was estimated to be 280. The following parameters were measured: Bi-Condylar Breadth (BCB), Bi-Gonial Breadth (BGB), Bi-Antegonial Notch Breadth (BANB), Bi-Mental Foramina Breadth (BMFB), Maximum Ramus Height (MxRH), Maximum Ramus Breadth (MxRB), Maximum Mandibular Length (MML), Maximum Mandibular Body Length (MMBL), Minimum Ramus Breadth (MnRB), Coronoid Height (CrH), Condylar Height (CnH) using inbuilt measuring scale present in Syngo Via Software. Mandibular Angle (MA) was measured using an inbuilt angle detector present in Syngo Via Software.

In our study cohort, we had a total of 150 (53.6%) males and 130 (46.4%) females. It was found that all the parameters except MA differed significantly between the two genders. We observed that among all the discriminant function that was built, function 2 (BGB) showed the least Wilk's lambda value ( $\lambda = 0.343$ ), which indicated the best discriminatory ability of the model among all. MA gave the maximum Wilk's lambda value, suggesting it has the least value among all the discriminant functions for the discriminatory ability. The area under the ROC curve was plotted for each of the discriminant functions. Function 13 (combination of all parameters) had the best AUC (0.951; 95% CI = 0.920, 0.982) whereas Function 9 (MA) had the least AUC (0.498; 95% CI = 0.422, 0.573).

This CT scan-based observational study showed that all the measured mandibular parameters, except MA, were significantly able to estimate the sex of the individual with high accuracy.

**A80 Increasing Transparency in Sex Estimation From the Skull by Monitoring Variation in Decision-Making Patterns**

Nicole Mantl\*, University College London, London, England; Sherry Nakhaeizadeh, Sherry Nakhaeizadeh, University College London, London, England; Ruth M. Morgan, University College London, London, England

---

**Learning Overview:** After attending this presentation, attendees will have a clear understanding of decision-making strategies and the impact of experience used in sex estimation of the skull.

**Impact Statement:** This presentation will impact the forensic science community by providing greater insight into decision-making strategies and how forensic anthropologists set about making inferences when estimating sex from the skull.

An increased focus on decision-making in forensic anthropology follows the growing demand for increased transparency in forensic reporting.<sup>1,2</sup> This has been particularly prominent in visual non-metric methods, such as sex estimation where the methods are inherently more subjective and appear to be more dependent on the experience of the observer.<sup>3,4</sup>

This presentation will show results from a study investigating intuitive and reflective decisions made in sex estimations from the skull. Students as well as academics and professionals participating in this study were asked to apply non-metric sex estimation to a sample of skulls.

At the initial stage of the study six archaeological crania (United Kingdom) were utilized. Participants were asked to provide an intuitive first impression based on a visual assessment of each skull under time-pressure (five seconds) followed by a full assessment scoring sexual traits on a five-point scale. Initial results showed that consistency, between first impressions and estimations drawn from method application, and confidence were lowest when the traits were most ambiguous.

Subsequently, the methodology was further developed where participants are instead asked to estimate sex from ten digitally rendered 3D skulls modelled on CT scans from a modern population from New Mexico.<sup>5</sup> Preliminary results show that participants are equally likely to correctly identify the sex of an unknown skull without contextual information. It is suggested that there is only a marginally significant difference between the consistency of intuitive and methodical sex estimations reported across the different experience groups. Overall, the results suggest that even when prompted to report a first impression, the more experienced participants based their intuitive estimation on overall appearance, three times more frequently than the less-experienced participants, followed by the recognition of multiple features of the skull. Furthermore, academics and/or practicing forensic anthropologists reported a moderate increase in confidence level compared to student participants.

Three key findings from these studies will be discussed: the impact of experience on decision-making; the significance of trait perception in intuitive first impressions; and the importance of characteristics affecting trait perception, such as population affinity, on the confidence levels reported by participants when it comes to self-perception of correctly estimating of sex from skulls.

**Sex Assessment; Skull; Psychological Behavior**

**A81 Combining Metric and Morphological Traits for Sex Estimation: A Pilot Study Using the Innominate**

Kate M. Lesciotto\*, University of North Texas Health Science Center, Fort Worth, TX; Alexandra R. Klales, Washburn University, Topeka, KS; Michael Price, Channel Cognition, Somewhere, AL

**Learning Overview:** The goal of this presentation is to inform attendees about the potential impact of combining metric and morphological data types into a single statistical model for sex estimation using pilot data from the innominate.

**Impact Statement:** This presentation will impact the forensic science community by presenting a new statistical model that combines metric and morphological data for sex estimation using the innominate and comparing this model to commonly used metric-only and morphological-only methods.

The estimation of osteological sex is a crucial component in the construction of the “biological profile” from a set of unidentified skeletal remains. Traditionally, sex estimation methods have focused exclusively on the use of either metric (e.g., FORDISC®, DSP2) or morphological (e.g., MorphoPASSE) data.<sup>1-3</sup> Surveys of forensic anthropologists have shown that the majority of practitioners use multiple sex estimation methods based on both metric and morphological data. However, there is significant divergence in how the results from different methods are combined into a final estimation of sex and expression of statistical confidence. If results of the methods do not agree, forensic anthropologists may give preference to one method over another, provide a final estimation based on personal experience, or take an average of all methods.<sup>4</sup>

While the long-term goal of this research is to develop a novel method for sex estimation that can accommodate metric and morphological data from multiple skeletal elements, this pilot study focuses on the integration of these data types using the innominate. The innominate is the most sexually dimorphic bone in the human skeleton; however, the most commonly used morphological features (e.g., ventral arc, subpubic concavity, etc.) are not captured by the most commonly used measurements (innominate height and breadth) and vice versa. Two experienced observers collected metric and morphological data from the innominate in a sample of 19 females and 16 males ( $n = 35$ ) from the Southeast Texas Applied Forensic Science Facility Skeletal Collection. Metric data included the measurements defined by Brůžek et al. for DSP2, excluding greater sciatic notch height (IIMT).<sup>2</sup> Morphological data included the Ventral Arc (VA), Subpubic Concavity (SPC), and Medial aspect of the Ischiopubic Ramus (MIPR) from the MorphoPASSE program, as well as the shape of the greater sciatic notch, presence of a composite arc, pubis shape, and subpubic angle.<sup>3,5-7</sup>

Sex estimation was tested using four statistical models: DSP2 (using only metric data), MorphoPASSE (using only morphological data for the VA, SPC, MIPR), a Random Forest (RF) model (using all metric and morphological data), and a Feed-Forward Neural Network (FFNN) model (using all metric and morphological data). Using a decision threshold of  $PP > 0.95$ , the FFNN model had the optimal performance, combining high accuracy and low sex-bias, while remaining highly inclusive of the sample. MorphoPASSE and the RF model achieved perfect accuracy for both observers, while one female was misclassified by DSP for both observers. However, while these three models produced high accuracy levels, the implementation of a decision threshold reduced the sample from the initial full set of 35 individuals to as low as 23 individuals. Using the FFNN, Observer 1 achieved perfect accuracy for 32 individuals meeting the decision threshold (18F/14M), and Observer 2 achieved 97.2% accuracy with all 35 individuals meeting the decision threshold, with one female being misclassified as male.

While existing sex estimation methods using the innominate are highly accurate, this pilot study demonstrates the potential for achieving nearly perfect accuracy with high statistical confidence by combining metric and morphological traits using a FFNN model. This model will continue to be tested using larger samples and data collected from multiple skeletal elements with the long-term goal of creating a freely available program for sex estimation that can integrate metric and morphological data, incorporate traits from the entire skeleton, and accommodate missing data.

**Sex Estimation; Metric and Morphological Data; Neural Network Model**

**A82 The Impact of Chemical Maceration on Elemental Concentrations and  $^{87}\text{Sr}/^{86}\text{Sr}$  Values in Bone**

*Julianne J. Sarancha\*, Arizona State University, Phoenix, AZ; Gwyneth Gordon, Arizona State University, Tempe, AZ*

**Learning Overview:** After attending this presentation, attendees will be aware of how chemical maceration, the removal of soft tissue from bones, may affect elemental concentrations and strontium isotope ratios ( $^{87}\text{Sr}/^{86}\text{Sr}$ ) in bone samples. Attendees will also learn which chemical elements are either contaminated in or removed from bone samples during maceration.

**Impact Statement:** This presentation will impact the forensic science community by demonstrating how chemical elements and  $^{87}\text{Sr}/^{86}\text{Sr}$  values are altered by maceration. Additionally, this presentation will suggest caution toward some maceration methods when  $^{87}\text{Sr}/^{86}\text{Sr}$  analysis may be used in both research and casework situations.

Chemical maceration is a common process to remove any remaining soft tissues from bone. This process is done both in anthropology research facilities and medical examiner labs. Previous research has evaluated chemical maceration for efficacy and preservation of DNA.<sup>1,2</sup> However, no previous studies have examined the preservation of elemental concentrations (used in determining postmortem alteration) or  $^{87}\text{Sr}/^{86}\text{Sr}$  (used in creating a geographic profile to assist with identification).

This study evaluated concentrations for major and trace elements as well as  $^{87}\text{Sr}/^{86}\text{Sr}$  values for five different maceration protocols. Five racks of pig ribs were obtained from a butcher. The pigs originated from a single farm and were raised and butchered in Oregon. The ribs of each rack were separated, and the bulk of soft tissues was mechanically removed. From each rack, two samples were set aside as controls and seven experimental samples were chemically macerated using modified parameters from published methods. All experimental ribs from a single rack underwent one maceration method and were compared to the controls from the same rack ensuring intra-individual comparison. A total of five maceration treatments were used: (1) Alconox® at 100°C for 24 hours, (2) Biz® laundry detergent with sodium carbonate at 90°C for four hours,<sup>2</sup> (3) Greased Lightning® at 100°C for 24 hours, (4) Adolph's® unseasoned meat tenderizer with Palmolive® dish soap at 90°C for 10 hours, and (5) Tergazyme® at 88°C for 24 hours.<sup>1-4</sup> Each reagent was dissolved in local tap water from Tempe, AZ.

Results indicate shifts in concentration for various elements. For sodium (Na), the Alconox®, Biz® with sodium carbonate, and Tergazyme® methods saw the largest increases in concentration (percent increase: 114%, 42 %, and 68 %, respectively), while the Adolph's® with Palmolive® method saw a more moderate shift (percent increase: 14%), and the Greased Lightning® method saw relatively no shift (percent increase: 2 %). These increases indicate treatments are inducing varying levels of Na contamination. For potassium (K), rubidium (Rb), and cesium (Cs), all maceration methods saw a decrease in concentrations (percent decrease in K: 70%, 42%, 75%, 43%, and 71%; Rb: 75%, 49%, 80%, 49%, and 76%; and Cs: 67%, 48%, 76%, 50%, and 71%). These decreases indicate all methods removed K, Rb, and Cs from bone. Commonly used elemental ratios such as Ca/P, Sr/Pb, and U/Ca were relatively unaltered by each maceration method.

For  $^{87}\text{Sr}/^{86}\text{Sr}$ , the Biz® with sodium carbonate and Adolph's® with Palmolive® methods had relatively small shifts (average shift for both methods: + 0.000006), while the Alconox®, Greased Lightning®, and Tergazyme® methods displayed shifts that are analytically significant (analytical error: 2SD for  $^{87}\text{Sr}/^{86}\text{Sr}$  = 0.000019) but not inferentially significant (average shifts: + 0.000032, + 0.000064, and + 0.000079, respectively). However, these average shifts are all enriched in  $^{87}\text{Sr}$  compared to the control values and are trending toward the  $^{87}\text{Sr}/^{86}\text{Sr}$  value of the local tap water. Although the  $^{87}\text{Sr}/^{86}\text{Sr}$  values were shifted for some maceration methods, the Sr concentrations remained relatively consistent across all treated samples (largest average percent change in concentration was a decrease of 5% for the Tergazyme® method). Hence, the most likely factor in  $^{87}\text{Sr}/^{86}\text{Sr}$  value alteration is isotopic exchange with the maceration solution.

The elemental concentration data demonstrates that some elements are altered and should not be analyzed in macerated bone while the isotopic data suggest  $^{87}\text{Sr}/^{86}\text{Sr}$  analysis is acceptable for bones macerated within the parameters studied. However, variations of maceration methods should be evaluated independently since systematic shifts, although not inferentially significant, were measured.

## A83 The Use of Multi-Isotopes for Geoprofiling Unidentified Decedents to Assist Law Enforcement Agencies in the United States

Liotta N. Dowdy\*, University of South Florida-FL. Institute of Forensic Anthropology and Applied Science Tampa, FL; Gennifer M. Goad, University of South Florida, Tampa, FL; Erin H. Kimmerle, Florida Institute for Forensic Anthropology & Applied Science, Tampa, FL; Anthony Menicucci, University of South Florida Stable Isotope Lab, Tampa, FL; George Kamenov, University of Florida, Gainesville FL., Gainesville, FL

**Learning Overview:** After attending this presentation, attendees will better understand how multi-isotopic analyses can improve human identification efforts. Isotope analysis of human teeth or skeletal material can illuminate the birth location, early childhood residence, and migration patterns based on specific elements embedded in the skeletal tissue of the individual.

**Impact Statement:** This presentation will impact the forensic science community by providing multi-isotopic reference data from a collection of skeletal materials with known origin.

Anthropologists continue to play a prominent role in the process of human identification, particularly in decomposing and skeletonized cases, as the parameters they provide about age, sex, and ancestry may provide investigative leads for unidentified decedent cases.<sup>1</sup> Forensic anthropologists have recently collaborated with geochemists to perform isotopic analyses of human tissues to estimate the geographic birthplace or migration patterns of unidentified decedents.<sup>2-7</sup>

Coupled with high domestic and international migration into Florida, the comparison of local missing persons and local unidentified persons cases is often insufficient for positive identifications.<sup>8</sup> Consequently, academic collaborations among the University of South Florida (USF) -Florida Institute of Forensic Anthropology and Applied Science (IFAAS), USF-Stable Isotope Lab, and the University of Florida Geological Sciences (UFGS) have utilized specific radiogenic isotopes that include strontium (<sup>87/86</sup>Sr) and lead isotopes (<sup>206/204</sup>Pb, <sup>207/204</sup>Pb, <sup>208/204</sup>Pb), along with stable isotopes oxygen (<sup>18</sup>O) and carbon (<sup>13</sup>C) for current and cold casework in the Tampa Bay area.

One of the major aims of these collaborations is to generate multi-isotopic data on modern human skeletal material with known origin to improve isotopic reference data.<sup>[9]</sup> To do this, donated teeth were collected from a local dentist (Dr. Amy Rotham, DDS) clinic in Tampa, FL, and by Dr. Caitlyn Menicucci DMD, (CPT, United States Army) from volunteers. Along with the donated teeth, very basic demographic information was collected from participants, and the identity of the participants was kept anonymous to the researchers. Stable isotopes (<sup>18</sup>O, <sup>13</sup>C) and radiogenic isotopes (<sup>87/86</sup>Sr, <sup>206/204</sup>Pb, <sup>207/204</sup>Pb, <sup>208/204</sup>Pb) were analyzed.

Results for enamel and/or tooth root (n=81) from donated teeth from individuals born in Florida and/or who lived in Florida through their early childhood, along with other individuals born in the United States and Central and South America as comparison samples. Individuals from Florida exhibit an average strontium isotope ratio of  $0.70894 \pm 0.00205$ . Lead isotope values fall into the expected United States ratios: <sup>206/204</sup>Pb ~ (18.4 to 19.1), <sup>207/204</sup>Pb ~ (15.6 to 15.7), and <sup>208/204</sup>Pb ~ (38.1 to 38.8). Oxygen isotope (<sup>18</sup>O) values are more positive compared to other regions of the United States. The <sup>13</sup>C values measured consistently indicate a typical diet in the United States. However, there were carbon values for individuals that were more positive than expected, possibly reflecting cultural practices and dietary choices. Overall, this data will be utilized to establish an isotopic reference data set for Florida and assist with local investigations of unidentified decedent cases. Additional research in this region and other geographic regions of the United States is critical for successful georeferencing of unidentified decedents and to improve the solvability of cold cases.

**A84 Origins and Isoscapes: A Reassessment of Oxygen and Strontium Isotopic Data for Human Identifications in North America**

*Kirsten A. Verostick\*, University of Utah, Salt Lake City, UT; Chris Stantis, University of Utah, Salt Lake City, UT; Alejandro Serna, University of Utah, Salt Lake City, UT; Gabriel Bowen, University of Utah, Salt Lake City, UT*

---

**Learning Overview:** After attending this presentation, attendees will have an improved understanding of how the current oxygen and strontium isotope data available for geolocation and provenancing of unidentified persons in North America can be used, along with understanding areas of these isotopic studies that needs improvement.

**Impact Statement:** This presentation will impact the forensic science community by using data compiled from known and assumed origin human tissues throughout North America, reviewing how the data have been collected and types of data, analyzing spatial variation based on multiple variables, and offering suggestions for improvements for future isotopic research and applications to forensic identification efforts.

Isotopic geolocation methods rely on reference data documenting spatial isotopic variation in human tissues. Many studies report such data, and the use of isotopes for forensic applications and identification is becoming more frequent. The value and use of these data depend strongly on several factors such standardization of metadata, variation in analytical protocols, and the geographic coverage of data from any given tissue and isotope system.

After a large-scale review of oxygen and strontium isotopic literature on human tissues, a dataset of >3,000 isotopic data points were compiled from 25 studies. The broadest coverage in North America is for keratin. Tooth enamel isotopic values have the second broadest coverage, with isotopic values from 12 studies comprising >800 data points. We focus here on tooth enamel carbonate  $\delta^{18}\text{O}$  data due to its excellent preservation and frequent use in human identification.

We compared the tooth  $\delta^{18}\text{O}$  with isotopic maps (isoscapes) of precipitation  $\delta^{18}\text{O}$  values, which are expected to provide a first-order estimate of the geographic pattern in tooth isotope values driven by variation in drinking water isotope values. Although there was a strong relationship ( $R^2 = 0.4$ ), a substantial amount of variance in the tooth dataset was not explained by the water isoscape (residual standard error = 1.7‰). We investigate three sources of potential variability in the compiled data that may contribute to this residual variance. (1) While all enamel samples are reported as being of “known” origin, some studies have incomplete or unspecific data on residential life history or which teeth were sampled, which may compromise comparisons with the isoscape. (2) Each study reporting oxygen isotopic values used different sample pretreatment protocols and reaction times, which have been shown to affect resulting isotopic values.<sup>1</sup> (3) A variety of tooth types, representing different ages of mineralization, were analyzed.

We found that the variance of residuals for samples with and without high-quality life history information was similar, suggesting that incomplete information did not significantly degrade the comparison with the precipitation isoscapes. For the other two factors, we found substantial bias between studies using different lab methods and between teeth formed at different ages, suggesting that lack of standardization added noise to the comparison.

We further investigated these factors using the Quality Analysis (QA) tool in the assignR package to evaluate the expected improvement in the precision of isotope-based geographic assignments if we corrected for the mean residuals. For both factors (lab methodology and tooth mineralization age), we found that correcting for the regression offsets gave a 20% improvement in geographic specificity when assignments were conducted using confidence thresholds up to ~80%.

The gestalt of this dataset fits the expected patterns and expectations. As noted, several issues that were considered limitations have proven to not be problematic, such as assuming data origin. However, other issues confound or degrade the quality of the dataset, such as the use of different pretreatment protocols (affecting oxygen tooth enamel values specifically), analytical methods, and calibrations. The currently available data can still be used to generate models but requires certain variables and analytical aspects be taken into consideration. A large-scale collection of teeth from donors of known origin with controlled methods would benefit forensic anthropology and human identification efforts.

**A85 Isotopic Taphonomy: A Critical Review of the Effects of Diagenesis on Human Tissues Used for Stable Isotope Analysis**

*Shelby Hard\*, California State University, Chico, Colorado Springs, CO*

---

**Learning Overview:** This presentation will provide a critical review of the taphonomic literature relating to the application of stable isotope analysis of human scalp hair and nail keratin for reconstructing the diet and provenance history of unidentified decedents. After attending this presentation, attendees will better understand the importance of taphonomic processes in altering stable isotope ratios of scalp hair and nail keratin, which is critical to proper interpretation of geolocation and diet from unidentified remains cases.

**Impact Statement:** This presentation will impact the forensic science community by providing a critical review of the literature surrounding the effects of taphonomic processes on scalp hair and nail keratin ratios. Further, the value of isotopic ratios present in scalp hair and nails in forensic investigations will be demonstrated through case examples.

The study of the influence of taphonomic processes on stable isotope ratios of unidentified individuals has become increasingly utilized in forensic investigations, as they affect whether accurate information can be provided about an individual's life history. Isotopic ratios reflect aspects of an individual's life such as diet and geolocation information. This analysis is especially pertinent to forensic investigations of unidentified individuals because it has the potential to narrow the pool of matching identifications as well as provide new leads where other methods have proven ineffective. Human scalp hair and nails provide snapshots in time that document the months leading up to an individual's death. Hair grows at an average rate of about 1cm per month and fingernails about 2-3mm per month, providing the potential for sequential sampling and the isolation of dietary and geolocation information from specific months prior to an individual's death.<sup>1</sup> This presentation will examine the literature documenting how the postmortem environment may influence reliable applications of stable isotope analyses of human scalp-hair and nail keratin.

Many studies have examined the interchangeability of isotopic ratios in human scalp-hair and nails, the provenancing of unidentified remains based on isotopic ratios in hair samples, the documentation of diet and geolocation in the isotopic composition of nails, the general reliability of isotopic ratios present in hair and nail samples, as well as many others to better understand the application of isotopic analyses to forensic investigations.<sup>2,3</sup> Many of these studies utilize samples taken from living individuals or recently deceased individuals, where isotopic ratios are expected to accurately represent aspects of the individual's life. However, there have been few studies that examine the effects of the taphonomic process on isotopic ratios of human hair and nails.

Saul's 2017 novel research examined the isotopic ratios of human hair from donated individuals at the Anthropological Research Facility (ARF) at the University of Tennessee, Knoxville, and the Forensic Anthropology Research Facility (FARF) at Texas State University.<sup>4</sup> Samples in this study were collected from individuals placed on the surface and placed in shallow burials at both facilities at various stages throughout the taphonomic process over a period of one year.<sup>4</sup> By examining buried and surface-placed individuals, Saul was able to examine two different placement scenarios within the same local environments.<sup>4</sup> The results of isotopic analysis showed that isotopic values in these environments retain accurate enough information to be considered reliable predictors of dietary and geolocation information.<sup>4</sup> Gordon et al. and Saul et al. further examined the preservation of hair samples during packaging in forensic contexts as well as summarized several considerations when examining the isotopic ratios of hair samples in the Tennessee postmortem environment.<sup>5,6</sup> This information is incredibly valuable to forensic investigations within Tennessee and Texas environments but is not representative of the taphonomic histories of other regions like high elevation and mountainous regions.

In forensic cases where individuals are not able to be identified, whether due to advanced decomposition, mutilation, or other taphonomic influences, isotopic analyses of scalp hair and nails have proven useful to provide information about geolocation and dietary information that can potentially narrow the focus of investigations.<sup>7</sup> Future applications of stable isotope analysis in forensic contexts should examine more geographic regions with more variable environments. The better we understand how the environment impacts isotopic values present in human scalp hair and nail tissues, the more applicable these results are to forensic contexts and investigations. Further, studies should also be held over a longer time period to continue to verify the reliability of the isotopic information provided by scalp hair and nail samples as the taphonomic and decomposition processes ensue.

## A86 The Impacts of Chronic Opioid Exposure on Bone Biomechanical Parameters

*Sydney Q. Chizmeshya\*, Newmarket, ON, Canada; Janna M. Andronowski, Memorial University of Newfoundland, St. John's, Newfoundland, Canada*

**Learning Overview:** The goal of this presentation is to describe the impacts of chronic opioid exposure on bone fracture risk and patterns. Attendees will learn how Synchrotron Radiation-based micro-Computed Tomography (SRμCT) and biomechanical bend testing techniques allow for a novel multi-modal examination of the effects of opioid exposure on bone quality, cross-sectional geometric parameters, and fracture type.

**Impact Statement:** This presentation will impact the forensic science community by: (1) further elucidating the indirect effects of opioid use on the products of bone remodeling (e.g., resorption spaces, Haversian canals, secondary osteons) used in histological age-at-death estimation methods; and (2) describing the associated impacts on bone fracture risk, interpretation, and patterns relevant to trauma interpretation.

Prolonged opioid exposure has been demonstrated to disrupt bone remodeling by inhibiting osteoblast activity and decreasing trabecular bone connectivity, thus inevitably predisposing individuals to osteoporosis and increased bone fracture risk.<sup>1-4</sup>

Our study builds upon proof-of-principle data from a pre-clinical rabbit-opioid model system to explore the: (1) biomechanical impact of opioid exposure on bone fracture risk, (2) relationship between cross-sectional geometric values and fracture patterns, and (3) relevant microstructural parameters (e.g., cortical porosity and osteocyte lacunar density) that inform bone fracture risk as observed via high-resolution SRμCT. We hypothesized that: (1) a decrease in bone's cortical area and lacunar density, an increase in cortical porosity, and enlarged medullary cross-sectional area will be observed in opioid animals compared to controls, and (2) fracture risk will be increased in opioid animals, and less force will be required for bone failure.

New Zealand White (NZW) rabbits were selected for our work given their shortened remodeling period and recommendations from the Food and Drug Administration for bone research.<sup>5-8</sup> Male rabbits were divided into three groups of seven animals each: morphine sulphate, fentanyl, and controls for eight weeks of experimental treatment.<sup>5</sup>

High-resolution bone imaging data of left tibiae were collected using SRμCT at the Canadian Light Source Synchrotron Facility in Saskatoon, SK. Reconstructed images (1.5μm resolution) were segmented using a novel Deep Learning Model created in Dragonfly v.2020.2. Microstructural parameters of interest (e.g., pore morphometric variables including pore density, volume, connectivity, etc.) were extracted using a custom model in CTAnalyzer v1.18.8.0.

Three-point bend tests were performed on the right tibiae from the same animals using an Instron® E3000 at a strain rate of 1mm/min until failure. Structural properties (e.g., flexural modulus and flexural strength) were collected from normalized biomechanical data and correlated with bone architectural properties (e.g., cortical area, orientation, moments of inertia, etc.) to associate structure with function.

Preliminary vascular pore morphometric data revealed that morphine animals have significantly greater (\* =  $P < 0.05$ ) porosity compared to the fentanyl group (morphine: 0.00004318 objects/voxel > fentanyl: 0.00001806 objects/voxel). Morphine animal pores are larger in size compared to the fentanyl group (Morphine: 16.67 pixels > Fentanyl: 11.16 pixels).

Preliminary biomechanical data demonstrated that all mean load (kN), displacement (mm), and test time (s) were significantly different between groups (\*\*\*\* =  $P < 0.0001$ ). The morphine group demonstrated the greatest mean load (Fentanyl: 0.1105 kN < Control: 0.1193 kN < Morphine: 0.1233 kN). The fentanyl group demonstrated the greatest displacement (Morphine: 4.897mm < Control: 4.984 mm < Fentanyl: 5.89mm) and longest test duration (Control: 227s < Morphine: 227.4s < Fentanyl: 277.1s). Tissue distribution may help explain these findings, as distribution further from the neutral axis can increase strength and resistance to bending forces.<sup>9</sup> Additionally, opioids may have a dehydrating effect that increase sample stiffness, tensile strength, and hardness.<sup>10-12</sup>

The proposed work is culturally relevant as the misuse and addiction to prescription opioids (and illicit synthetic opioids) continues to be a serious public health crisis nationwide. Our work offers insight relating to: (1) the long-term impacts of opioid exposure on the products of bone remodeling used in histological age-at-death estimation, and (2) fracture pattern interpretation following drug exposure. Findings from our work further offer support to forensic practitioners by expanding understandings of bone biological parameters relevant to creating more precise biological profiles, especially in the case of age-at-death estimation.

Certain work included here is supported by the National Institute of Justice, Award 2018-DU-BX-0188. The opinions, findings, and conclusions expressed are those of the authors and do not necessarily reflect those of the Department of Justice.

**A87 The Right to the Truth: A Multimodal Investigation of Mass Graves and an Analysis of Commingled Remains for Conflict Resolution in Humanitarian Forensics**

*Xenia Paula Kyriakou\**, University of West London, Fort Myers, FL; *Nicholas V. Passalacqua*, Western Carolina University, Sylva, NC; *Matthieu Baudelet*, University of Central Florida, Orlando, FL

---

**Learning Overview:** This presentation will review the current state of scientific and professional aspects in the investigation of mass graves and the analysis of commingled remains, and it will introduce the new multidisciplinary research consortium, CONFORM. During this presentation, professions, policies, processes, and technologies utilized in the investigation of mass graves and de-commingling will be highlighted; as well as the need for the operationalization of standards to ensure method efficiency, accuracy, and reproducibility as well as best practices for quality assurance.

**Impact Statement:** This presentation will impact the forensic scientific community by providing a review of the current methodological approaches to the investigation of mass graves and analysis of commingled remains. Attendees will learn about the different methodological approaches in locating and excavating mass graves, resolve commingling, and will be provided with a framework for future scientific developments that could enhance and support these processes.

Humanitarian forensics plays a central role in conflict resolution and peacebuilding. Forensic archaeology and forensic anthropology are key disciplines that support community transitions in post-conflict territories. Mass graves are a global phenomenon of humanitarian significance. They are characterized by diversity in the way they have been created and modified by human and environmental agents.<sup>1</sup> Commingled mass graves pose the highest level of challenge for archaeologists and anthropologists alike because the causes of commingling vary from one mass grave to another, whether primary, secondary, or tertiary burial contexts.<sup>2</sup> Therefore, from discovery to repatriation, archaeological and anthropological methods used in the investigation of mass graves differ depending on the context of their application and guiding mandates. Yet, the relationship between field processes and methods of anthropological analysis for de-commingling and identification is significant in ensuring efficiency in pair-matching, skeletal re-association, and the reconstruction of the Minimum Number of Individuals (MNI).

The aim of the symposium is to present original research and case studies pertaining to the search, recovery, and excavation of mass graves, and forensic methods for the analysis and evaluation of commingled, disarticulated, and fragmentary human remains. The symposium encourages the presentation of work that showcases multidisciplinary approaches, whether field-based, lab-based, or combined. The symposium presentations will discuss advantages/prospects, disadvantages/limitations, problems/solution, and most importantly highlight the role of forensic science in accounting for missing persons in a way that contributes to conflict resolution and peacebuilding.

The symposium presenters will also provide recommendations and suggestions stemming from their work experience as it pertains to the investigation of mass graves and processes of de-commingling. The objective of the symposium is to identify grounds for international and interdisciplinary research collaboration for the development of a standardized and operationalized set of guidelines for the investigation of mass graves that adhere to best practices, streamline the processes involved, but also provide flexibility to allow adaptation for different transitional justice mandates.

---

**A88 The Use of Computational Methods in Assessing Legacy Databases of Commingled Remains and Reconstructing Stratigraphic Relationships**

*Chris Mavromatis\*, Dickson City, PA; Xenia Paula Kyriakou, University of West London, Fort Myers, FL*

---

**Learning Overview:** This presentation will utilize archaeological stratigraphy, artifact, and human skeletal assemblages from a commingled context to demonstrate how these dataset types can provide valuable contextual information for reconstructing archaeological relationships with the use of computational methods. After attending this presentation, attendees will better grasp how engaging with stratigraphic, artifact, and human bone datasets can contribute to, and augment, their existing approaches to analyzing multiple commingled interments, using Python® and R-suite statistical applications.

**Impact Statement:** This presentation will impact the forensic anthropology community by showcasing how to create a flexible framework for extracting data from legacy and contemporary stratigraphic and assemblage datasets, using computational methods, to help contextualize commingled human remains recovered from forensic archaeological contexts. Attendees will gain insights into the project's techniques for cleaning datasets with the Python® programming language, combining stratigraphic layers into aggregated units, and analyzing these aggregated units and their assemblages with the Python® and R programming languages.

Commingled contexts present with complex stratigraphy must be excavated systematically and in detail. Archaeological data collected during excavation are by default legacy datasets in the sense that field recording methods, although universal in concept, their application varies significantly between agencies, companies, or country systems, but also between terrains, landscapes, and environments. This is especially the case for the excavation of commingled contexts that may combine highly fragmentary skeletal remains and intermixing of bone with other material (e.g., artifacts, animal bones).

Field records are a valuable tool for reconstructing context, artifacts, and skeletal associations. Most archaeologists would agree that analyzing legacy archaeological datasets can provide new insights.<sup>1,2</sup> However, the evaluation and reanalysis of stratigraphic data for reconstructing stratigraphic sequences in relation to biological material (e.g., human remains) and artifacts can be problematic, and it presents various technical and methodological problems. The use of advanced computational approaches can be a useful tool in the assessment of legacy databases comprising of complex stratigraphic relationships, such as those encountered in commingled contexts.

Field records collected during the excavation of cist graves found at the archaeological cemetery of Kourion Gate Amathus (KAGC), in Cyprus, combined with an osteological inventory of 16,000 skeletal fragments, were evaluated using the Python® and R programming languages. The objective of the study was to establish new deposit profiles using a data-driven approach to consolidate recording discrepancies and assess the relationship between stratigraphy, artifacts, and skeletal remains. Data remediation (i.e., cleaning the project's datasets) was a critical first step in this process. The data-driven component relied heavily on the methods of the Python® class we developed specifically for stratigraphic analysis. A class provides the framework for defining and organizing an object's attributes and methods.<sup>3</sup> Objects in Python® (and other similar programming languages) provide a concise way to model complex systems by combining attributes (i.e., descriptive information) and methods (i.e., behaviors and actions) with data. Because each class instance contains the same methods and attributes, it provides a consistent way to compare multiple stratigraphic units and their assemblage profiles quickly. The combination of data-driven and descriptive information provided rich contextual information that helped explain the stratigraphic record and evaluate relationships between human skeletal remains and artifacts.

The analysis indicated that most cist tomb deposits exhibited a disturbance profile resulting from human and environmental agents, consistent with multiple uses of the grave over time, post-cemetery disturbance from salvage and reclamation activities, and hydroturbation and root action. Additionally, except for tombs that only contained Depositional Unit B501, the distribution of bone preservation suggested that higher levels consisted mainly of small fragments resulting from context intermixing over time, consistent with tertiary burial conditions. Despite in-depth analysis, artifacts could not be securely matched with skeletal remains.

In conclusion, the combination of Python® and R programming languages has shown great promise in cleaning, sorting, organizing, classifying, quantifying, and modeling excavation data statistically, as well as visually using Geographic Information Systems (GIS). Python® allowed for combining different sets of data quickly and when paired with R programming language, it aided in the efficient evaluation of complex statistical relationships. Python's® computational capabilities have remarkable potential for streamlining data in forensic archaeology and therefore can be beneficial in a range of ways during post-excavation assessment of field records.

**A89 A Case from “EL TUBO”: An Analysis of Commingled and Highly Fragmented Skeletal Remains Recovered From an Abandoned Water Exploration Well in Northeastern Mexico**

Nicole Lambacher\*, *International Commission on Missing Persons (ICMP), Ubide, Pais Vasco, Spain*; Caterina Raffone, *BIOMICs Research Group, Vitoria-Gasteiz, Pais Vasco, Spain*; Sandra Sostaric, *International Commission on Missing Persons (ICMP), Sarajevo, Federation of Bosnia and Herzegovina, Bosnia and Herzegovina*; Benito Ramos-González, *Instituto de Criminalística y Servicios Periciales, Fiscalía General de Justicia del Estado de Nuevo León, Monterrey, Nuevo Leon, Mexico*; Francisco Etxeberria Gabilondo, *University of the Basque Country, San Sebastian, Pais Vasco, Spain*

---

**Learning Overview:** After attending this presentation, attendees will have an understanding of two new protocols for inventorying and describing commingled human remains and appreciate both the advantages and the limitations of using these standardized procedures when dealing with commingled human remains in forensic contexts.

**Impact Statement:** This presentation will impact the forensic science community by showing that a systematic and standardized approach to recording commingled human remains provides a wealth of information to the analysis. Furthermore, using such an approach results in additional statistical data for use in anthropological reports that allows for comparative studies and for the recording of skeletal completeness in a standardized and objective manner.

The complexities associated with recording and analyzing commingled remains have been particularly highlighted in the forensic field following the investigations of mass graves and investigations of human rights violations. Mass graves in the former Yugoslavia found in secondary contexts, commingled cases in Chile, and in the Republic of Kiribati (Tarawa Project), etc., are just a few examples of complex cases of commingling.<sup>1-4</sup> While DNA is often cited as the most reliable method for resolving commingling, for challenging cases where preservation is poor and identification hypotheses are limited (i.e., open context assemblages), its use is not fail-safe, and primarily anthropological techniques are being recommended.<sup>3,5</sup>

In light of this premise, this presentation shares findings from a case in Nuevo Leon, Mexico, known as “EL TUBO.” The human remains from EL TUBO were recovered in a highly commingled and fragmented state from an abandoned water well, over several months. This presentation describes the process from the recovery of the remains to the anthropological-anthropometric analysis including the assessment of relationship between disarticulated and commingled body parts. The implementation of a standardized protocol for the inventory of the fragmented commingled material provided a systematic and time-efficient recording process. This resulted in the inventory of a total of 23,828 bones and bone fragments, from which it was possible to individualize 17 distinct individuals. Not surprisingly, the state of preservation influenced the success rate of the DNA analysis and the attribution of bones to specific individuals. However, the detailed recording and analysis resulted in the positive human identification of 13 of the 17 individuals. Furthermore, the application of this methodology has allowed for the recording of a quantitative description of the individualized human remains in a standardized and objective manner based on well-established formulas in physical anthropology to calculate the percentage completeness, bone representation index, and fragmentation analysis for each set of remains.

The complexity of commingled cases is challenging, but nonetheless, the management of such collections needs to be discussed and standardized given the difficulties they present. In summary, this case study is an attempt to outline and present a specific standardized methodology within the framework of forensic protocols for the anthropological management of commingled remains.

---

**A90 The Reassociation of Disparate Elements at a Human Decomposition Facility**

Rebecca L. George\*, Western Carolina University, Cullowhee, NC; Reagan Baechle, UCL, Charlotte, NC; Autumn J. Hall, Western Carolina University, Sylva, NC

---

**Learning Overview:** After attending this presentation, attendees will have a better understanding of the difficulties of reassociating disparate skeletal elements from a human decomposition facility. The various organizational systems undertaken to manage this process will be reviewed.

**Impact Statement:** This presentation will impact the forensic science community by demonstrating the real-world impacts of skeletal commingling, pair matching, and inventories from observing how an organizational system was developed for reassociation at a human decomposition facility.

The Forensic Osteology Research Station (FOREST) and associated Western Carolina Human Identification Laboratory (WCHIL) at Western Carolina University in Cullowhee, NC, are home to an active willied body donation program that creates the foundation for the John A. Williams Human Skeletal (JAW) Collection. Since FOREST's opening in 2008, most donors have been placed on the surface to decompose naturally; this allows for scavengers, mainly turkey vultures (*Cathartes aura*), black vultures (*Coragyps atratus*), and opossums (*Didelphis virginiana*), to interact with the donor remains.<sup>1</sup> Prior to PVC cages being regularly used in the summer of 2023, donors were either left uncovered or were covered with black plastic tarping at various points throughout their decomposition process at FOREST. This led to skeletal elements being scattered throughout the facility and not always immediately reassociated with the correct donor, creating commingling situations. Elements that could not be reassociated out at FOREST had been brought into WCHIL. Often, though not always, notes were taken as to where these disparate elements were located at FOREST, what donors they were found by, and what date they were located, as well as any other pertinent information; the elements were not always processed of any remaining dirt or tissue.

During the fall 2021 semester, a concerted effort was undertaken to begin systematically inventorying and organizing the disparate elements. At this point, there were at least three boxes with notes of varying quality on sheets of paper identifying the elements within each box and which bags they were in; it was discovered that these notes were not often accurate. Senior undergraduate students had been assigned that semester to create a digital inventory in Excel® of what bones were present. Following completion of the master inventory sheet, students worked to reassociate elements with their donor. As many bags of elements lacked appropriate notes, this effort was not overly successful; less than 20 disparate elements were reassociated that semester.

For the following year, this method continued, though with more advanced students who had stronger osteology skills, making them more adept at identifying pair matches and recognizing the degrees of human variation within the JAW Collection. It became apparent that the lack of consistent skeletal inventories was also an issue for this project, so students were directed to create skeletal inventories whenever they encountered a donor without one. This step was critical to realizing what was present or absent for each donor and often revealed other problems with the collection, such as the commingling of elements that was not caught in the initial curatorial process. The presenting author overhauled the master inventory sheet and overall collection of the disparate elements in December 2022. Elements were inventoried by bodily region, with boxes being numbered and bags within those boxes being labeled to match these regions. Notes were also added to the sheet that included sex and age indicators, as well as which donors could be missing these elements based on when they were found. Additionally, sex and age for donors within the JAW Collection were added to the master inventory sheet so students working on this project could use that contextual information to better pair the elements to the appropriate donor. With this new organizational system, the authors were able to reassociate at least 55 elements in just three and a half months. This mode of reassociation will be augmented by the addition of a searchable database for all donor inventories, while the use of PVC cages at FOREST has thus far limited the amount of scavenging and commingling of donor remains from occurring.

**A91 De-Commingling the Past—When an Attempt to Resolve Misidentifications Results in Setbacks:  
The Tihovici Case**

*Sandra Sostaric\*, International Commission on Missing Persons (ICMP), Sarajevo, Federation of Bosnia and Herzegovina, Bosnia and Herzegovina; Bojana Tomasevic, International Commission on Missing Persons (ICMP), Sarajevo, Federation of Bosnia and Herzegovina, Bosnia and Herzegovina; Samra Terzic, International Commission on Missing Persons (ICMP), Sarajevo, Federation of Bosnia and Herzegovina, Bosnia and Herzegovina; Almir Olovic, KU Leuven, Heverlee, Vlaams-Brabant, Belgium; Beisa Talic, International Commission on Missing Persons (ICMP), Sarajevo, Federation of Bosnia and Herzegovina, Bosnia and Herzegovina*

---

**Learning Overview:** The goal of this presentation is to outline an ongoing attempt to resolve individual presumptive misidentifications of human remains from one commingled mass grave, exhumed in 1996 following the 1992–1995 Bosnian war. This case study will show how coordination and due diligence should never be discounted in governmental intra-institutional efforts to address complex, non-routine cases such as decades-old misidentifications.

**Impact Statement:** This presentation will impact the forensic science community by providing a vivid narrative of tackling presumptive misidentifications as a complex project with intertwined actors and stakeholders and by offering a lesson on ethics: on unintended, avoidable, and serious consequences.

Following the 1992–1995 Bosnian war, the mass post-war identification process in Bosnia and Herzegovina (BiH) has had two phases: the presumptive identification phase of around 8,000 missing, starting even during the war with war-time exchanges, and the DNA-based identification phase, starting in 2001, when the International Commission on Missing Persons (ICMP) established a human identification laboratory in Sarajevo, tasked with high-throughput matching of postmortem samples from skeletal remains with blood reference samples of surviving relatives.<sup>1,2</sup>

A significant number of human remains that were presumptively identified originated from mass grave and mass deposition contexts, such as caves and pits; however, there were cases of human remains from the same contexts which remained unidentified, even after the advent of DNA analysis, indicating that their existence was a consequence of previous non-systematic presumptive misidentifications.<sup>3</sup> Subsequent DNA analysis of a limited number of presumptive identifications indicated an error rate of 30-38%, but for specific commingled contexts that were excavated by inexperienced personnel, and which saw no adherence to scientific standards of forensic archaeology and anthropology, the error rate may be much higher.<sup>4</sup>

Misidentifications can impact at least two, if not more families: if the previous presumptive misidentification is not uncovered with DNA testing, then the family of the victim buried under the wrong name will never find their missing family member. On the other hand, addressing a potential misidentification can have serious negative consequences for the family that already had closure—psychological and socioeconomic—on the matter decades ago.

We will outline a case study of a mass grave exhumed in 1996 in Tihovici, near Sarajevo, from which all but two sets of human remains were identified presumptively and repatriated to their families. Decades later, DNA analysis of the remaining unidentified human remains and a targeted blood reference sample collection project exposed a current error rate of 100% for the previous presumptive identifications from this mass grave and triggered a domino effect of reexhumations. We will discuss the right and wrong ways to approach such a situation through the lenses of ethics, rule-of-law mechanisms, and psychosocial impact.

## **A92 Matching Antimeres: Prospects and Limitations of Statistical Methods for the Reassociation of Commingled Left and Right Humeri**

*Erica Baer\*, Kean University, Union, NJ; Xenia Paula Kyriakou, University of West London, Fort Myers, FL*

**Learning Overview:** This presentation will provide support for the use of statistical methods when reassociating commingled remains. After attending this presentation, attendees will better understand the prospects of employing statistical analysis in conjunction with visual techniques valid for sorting commingled remains.

**Impact Statement:** This presentation will impact the forensic science community by informing attendees that traditional methods of reassociation related to commingled remains rely on subjective analyses, such as visual matching of traits (for example, texture, coloration, and density).<sup>1</sup> The addition of statistical metrics in this process provides a framework for the quantification of pair-matching and, thus, a more objective approach that can add validity to pairing determinations.

For this study, the sample included humerus measurements from 119 individuals of Greek-Cypriot ancestry from the Cyprus Research Reference Collection (CRCC) (1975–2015). These measurements were used to evaluate the use of two statistical techniques to pair antimeres: m-statistic and linear regression. Recent research has shown the benefits of discriminant function analysis in pairing antimeres and of linear regression in pairing bones in the lower and upper limbs.<sup>1–3</sup> Additional research has suggested the use of m-statistics to aid in the exclusion of non-matching pairs.<sup>4</sup>

M-statistics compare the difference between two measurements by creating a proportion of the average value. M-statistics were calculated for all individuals in the sample and the distributions for each measurement location were found to be non-normal for males, females, and the total sample. Given this result, previous metrics were not optimal for use as an exclusionary method.<sup>4</sup> Therefore, a log transformation of the data was conducted, and one-tail 95% confidence intervals were created using a modified Cox method.<sup>5</sup> This method did not achieve the desired results, with 167 of the 899 total measurements (18.59%) falling outside the confidence interval. For females, 73 of 467 measurements fell outside the confidence interval (15.63%), and for males 81 of 432 measurements fell outside the confidence interval (18.75%). However, counting the number of matched measurement pairs that are excluded per individual, only 8 of 115 (6.96%) had five or more measurement pairs excluded. For females, only 4 of 60 (6.67%) had five or more measurement pairs excluded. For males, only 3 of 55 (5.45%) had five or more measurement pairs excluded.

Two linear regression equations were developed for each measurement location. The first equation was a simple linear regression predicting the left-side measurement from the right-side measurement. For the second equation, sex was added as a potential predictor and was found to be a significant predictor for half of the measurement locations. The resulting linear regression equations showed strong coefficients of determination ( $r^2 = 0.583–0.910$ ) and low residual standard error ( $RSE = 0.787–6.528$ ). All analyses were evaluated using R Studio 4.2.1.

The results indicated that linear regression outperformed m-statistic in this case, as it provided excellent predictions with high levels of accuracy. In comparison, m-statistics do not provide as much predictive power, as by definition, they are measures of exclusion, rather than inclusion. Still, m-statistics may add some benefit in aggregate, as approximately 95% of individuals had fewer than half of the measurement locations excluded based on 95% confidence intervals. Therefore, evaluating m-statistics for the entire bone, rather than per measurement location, may prove useful as a method of exclusion. In sum, statistical techniques, especially linear regression, will provide added benefit to researchers already using visual or other techniques when reassociating commingled remains.

**A93 The Chemical Reassociation of Commingled Remains Via Laser-Induced Breakdown Spectroscopy**

Kristen Livingston\*, University of Central Florida, Orlando, FL; Katie Zejdlik, Western Carolina University, Cullowhee, NC; Jonathan Bethard, University of South Florida, Tampa, FL; Matthieu Baudelet, University of Central Florida, Orlando, FL

---

**Learning Overview:** This presentation describes the utility of Laser-Induced Breakdown Spectroscopy (LIBS) in the sorting of commingled remains. After attending this presentation, attendees will understand how chemical profiles obtained via LIBS provide valuable information for differentiating individuals' remains.

**Impact Statement:** This presentation will impact the forensic science community by explaining the feasibility of reassociating skeletal assemblages based on chemical information. This study shows how chemical analysis may supplement existing physical methods for sorting commingled remains and thus promotes interdisciplinary collaboration.

A major challenge in forensic anthropology is the development of efficient and effective methodologies for sorting skeletal remains in mixed assemblages.<sup>1</sup> Reassociating bones to their respective individual using physical and morphological traits is a tedious process, especially if the bones are fragmented or have undergone taphonomic changes. Examining the chemical composition of bone may provide valuable information to support the sorting process. Several studies have shown that chemical variation exists between individuals' bones as a result of various factors, such as diet, health, and living environment.<sup>2,3</sup> This study explores how the chemical profile of bones may be incorporated into a method for classifying commingled remains. The chemical information from bones is acquired using LIBS. LIBS is a visually non-destructive analytical technique used to obtain chemical information from the surface of a sample in seconds. Furthermore, the commercial availability of field-deployable, portable LIBS instruments contributes to efficient analysis of skeletal samples in the field.

In this study, LIBS profiles were collected from 1,284 bones across 45 individuals from the John A. Williams documented skeletal collection. In total, over 8,000 chemical signatures from the skeletal remains were acquired for statistical testing. A newly developed feature selection algorithm based on principal component analysis was combined with machine learning models such as linear discriminant analysis. The approach revealed which chemical elements varied most between individuals and classified bones to their corresponding individuals with an accuracy ranging from 85% to 100%. These findings demonstrate how chemical information of bone may be key for expediting reassociation of large skeletal assemblages recovered in a forensic context. Ultimately, this research study provides evidence that LIBS is a promising technique to complement the reassociation methods currently available to forensic anthropologists.

Note: This project is supported by NIH Award #15PNIJ-21-GG-04151-SLFO, "Pre-grouping of commingled skeletal remains by elemental analysis."

## A94 Don't Forget About ME: How Material Evidence Can Inform (or Complicate) Commingling From the Battle of Tarawa

*Allison M. Campo\*, US Department of Defense POW/MIA Accounting Agency, Joint Base Pearl Harbor-Hickam, HI; Rylan Tegtmeier Hawke, SNA International Supporting the Defense POW/MIA Accounting Agency, Waipahu, HI*

**Learning Overview:** This presentation will combine historical records, modern archaeological excavation, and modern-day forensic identification and accounting practices to demonstrate the complications that can arise from both the use, and misuse, of incorporating Material Evidence (ME) or recovered personal effects into the resolution of commingled skeletal assemblages. After attending this presentation, attendees will better understand the nuances and potential pitfalls associated with historic and modern archaeological recovery as they relate to the use of material evidence in positive identification.

**Impact Statement:** This presentation will impact the forensic science community by showing the contributions that material evidence and personal effects can make to the resolution of commingled skeletal assemblages and the identification of skeletal remains, but also highlight where caution should be applied when associating such items with a single individual within a commingled assemblage.

During World War II, from November 20–23, 1943, United States forces invaded and fought for control of the Japanese-occupied Betio Island as part of an island-hopping campaign in the Pacific. The battle (known as the Battle of Tarawa) resulted in the loss of over 1,000 United States service members with approximately 375 individuals still unaccounted-for. The Defense POW/MIA Accounting Agency (DPAA) is responsible for the location, recovery, identification, and repatriation of the remains of unaccounted-for service members and, since 1979, the DPAA (and its predecessor organizations) along with History Flight, Inc., a DPAA strategic partner, have conducted excavations to recover the remains from the Battle of Tarawa. Complications such as battlefield burial practices, the relocation of grave markers, and repeated disinterment and reinterment of remains have affected modern-day accounting practices and contribute to struggles surrounding the resolution of the commingled remains. Many of the individuals who were buried following the battle were buried with associated personal effects, which, historically, were used to aid in identification. These items can also assist in the resolution of commingled assemblages during present-day analysis and can provide a unique insight into battle history and the prioritization of equipment and personal effects during military campaigns.

However, the inaccurate association of material evidence in the past due to the inexperienced and incomplete recovery of remains can contribute to pitfalls with modern-day accounting practices. The value placed on material evidence in the historic record, and how we approach the presence of personal effects within commingled assemblages in forensic investigations today, has far-reaching implications for identification within these contexts. While the presence of material evidence can reconstruct both past events and the relationship an individual may have had with the people and places around them, its association and utilization in positive identification of skeletal remains should be done carefully and with a strong understanding of the environment and context in which both the remains and evidence was found.

**A96 The Dirt on DNA: Utilizing Soil as Evidence of Clandestine Burials and Mass Graves**

*Meradeth H. Snow\**, University of Montana, Missoula, MT; *Kaylee Hinds, MA*, University of Montana, Missoula, MT; *Atlantis Baron, BA*, University of Montana, Missoula, MT

---

**Learning Overview:** The use of DNA in mass grave scenarios is often limited to the testing of individuals and the attempt to reassociate comingled remains. However, as attendees at this presentation will learn, there are several ways in which DNA from the surrounding soil can be applicable toward mass grave scenarios. These include: aiding with identifying primary, secondary, and tertiary mass grave location; managing non-destructive analysis of the remains themselves; and the use of the microbiome for identification purposes.

**Impact Statement:** This presentation will impact the forensic science community by addressing ways in which soil DNA can be obtained and analyzed, allowing for a larger toolkit for identification and management of mass graves. The operationalization of these methods into a practical set of guidelines or best practices can serve those working in humanitarian forensics and help facilitate the extraction and analysis of DNA from soil.

DNA evidence from soil is typically not the first choice of forensic professionals working at any kind of crime scene, especially that of mass graves. Soil is often seen as the material that must be removed to facilitate identifications. However, the soil within a burial context houses a great deal of information regarding the individuals interned within it or on its surface. Through analyses completed, as well as work within the ancient DNA field, DNA from individuals will leach into the surrounding soil, thus creating a potentially rich microbiome that contains human DNA and differs from the surrounding soil.<sup>1-3</sup> This DNA can be detectable at the surface level (influenced primarily by the soil type and environment), allowing for soil DNA testing to facilitate unknown burial location detection with a relatively low-cost and low-labor method.

Soil also has the benefit of being tested for DNA from individuals without requiring destruction of the remains. As there are many cultures who prefer to retain their relation's remains as intact as possible, the ability to sample soil surrounding the remains affords the ability to avoid drilling or hazardous chemical exposure of the remains—as well as potentially avoiding disruption of the burials at all. An example of where this would be a key addition to the best practices would be the boarding school burials of Native American children that are scattered across North America.<sup>4</sup>

The development of this process whereby we create standard methods that can be implemented toward the sampling, transportation, DNA analysis, and then individual identification is ongoing. Preliminary analysis utilizing pig limbs to test the movement of DNA in the soil in the Montana forests throughout the summer and fall has demonstrated that DNA lingers in the soil both below the surface and on the surface above the burial, even after the removal of the limbs, for an extended length of time.<sup>1</sup> Additionally, contaminants in the soil (arsenic, cadmium, etc. from mining activities) influence the movement and longevity of pig DNA within the soil, ostensibly as they also influence microbial activity.<sup>5</sup> Additional work in this area will continue to aid in the ability to identify and restore individuals to their families, which in turn promotes justice for the victims.

Friend, SNA International in Support of DPAA Hawaii, JBPHH, HI; Reshma Satish, SNA International in Support of the Defense POW/MIA Accounting Agency, Honolulu, HI; Melissa Menschel, SNA International in Support of the Defense POW/MIA Accounting Agency, Honolulu, HI*

---

**Learning Overview:** This presentation will demonstrate the multidisciplinary, complex, and systematic analytical process used in the identification of deceased United States military personnel from the Korean War through multiple case studies. After attending this presentation, attendees will have a better understanding of the complexity involved in the processing of commingled remains, including the triage, segregation, and name association workflows that support recommendations for identification.

**Impact Statement:** This presentation will impact the forensic science community by sharing the successful, multifaceted approach utilized by the Defense POW/MIA Accounting Agency (DPAA) to process, analyze, and identify commingled remains from the Korean War. This promotes and highlights the necessary collaboration from multiple disciplines to achieve the identification of individuals from commingled contexts.

The DPAA's mission is to provide the fullest possible accounting of missing United States service members from past conflicts to their families and the nation. The DPAA's Scientific Analysis (SA) directorate is the largest forensic skeletal identification laboratory in the world, employing a multidisciplinary team of anthropologists, odontologists, DNA and stable isotope scientists, and war historians, among other specialists.<sup>1</sup> One of the many conflicts investigated by the DPAA is the Korean War, which claimed the lives of approximately 36,500 United States service members in its three years, of which nearly 7,500 are still unaccounted for.

The Korean War Identification Project (KWIP) was established in 2011 to support the analysis and identification of United States casualties recovered from the Korean War. The impetus for the project's formation was the recognition that the remains being received and recovered were often highly commingled. For example, many boxes from unilateral turnovers were initially thought to contain single individuals, but DNA analysis produced multiple mitochondrial DNA (mtDNA) sequences per accession. The high degree and complexity of commingling observed in the Korean War remains necessitated the development of a systematic workflow that focuses on the segregation of remains into individuals by aggregating data from multiple lines of evidence. As such, KWIP's mandate is primarily the segregation and name association of these commingled remains. KWIP cases are approached in two ways: (1) mtDNA sequence-based or (2) accession-based. Case examples of each approach and the challenges they involve will be presented. This process has been formalized within DPAA-SA by the Commingled Human Remains analysis (CHR) standard operating procedure. The CHR process originally developed by KWIP has now been adopted by all other special projects involving commingled remains within the DPAA. The marked success of using a multidisciplinary approach to resolving commingling is highlighted by several complex case studies. These cases will demonstrate the synthesis of DNA, stable isotope, historical, archaeological, anthropological, odontological, and radiological evidence that is used to resolve commingling and support identification while also working with family members towards resolution. Overall, KWIP represents a unique assemblage involving highly commingled human remains associated with thousands of unresolved service members with multiple proveniences. As of July 2023, KWIP has identified a total of 664 United States service members and repatriated more than 300 foreign allies to their home countries, illustrating the strength of this approach.

**DPAA; Commingling; Humanitarian**

## A98 The Role of Starvation in the Underestimation of Living Stature from Skeletal Remains

Maryann Hobbs\*, *SNA International in Support of the Defense POW/MIA Accounting Agency, Honolulu, HI*; Rylan Tegtmeyer Hawke, *SNA International in Support of the Defense POW/MIA Accounting Agency, Waipahu, HI*

**Learning Overview:** After attending this presentation, attendees will understand the potential role that severe dietary deficiency plays in the underestimation of living stature from human skeletal remains.

**Impact Statement:** This presentation will impact the forensic science community by bringing awareness to the potential impact that severe dietary deficiency has on stature and living stature estimation and how to mitigate the risk of underestimating stature in affected populations.

The estimation of stature is a key component in the forensic identification of unknowns. In commingled assemblages, stature is often used as one line of evidence, capable of assisting in the segregation of remains, as well as helping to strengthen or rule out potential identification matches. Previous research has shown that changes to stature are not only a function of developmental stage, but that bone growth and stature are particularly sensitive to nutrition and dietary wellness. Despite this, dietary deficiencies and other nutritional considerations are rarely incorporated into stature analyses or interpretations, leaving the potential for an underestimation of living stature based on skeletal measurements.

This study compares the recorded living statures to the forensically estimated postmortem statures of two temporally consistent populations to determine if known dietary deficiency impacted stature estimations during the identification process. The first sample population consists of individuals who died during internment in the Cabanatuan Prisoner of War Camp during World War II; the second sample population consists of individuals who were killed during the World War II Battle of Tarawa. The individual records from Cabanatuan had documented a pattern of extensive dietary deficiencies preceding burial at the Camp.

The study consisted of 141 individuals from Tarawa and 24 individuals from Cabanatuan (n=165). All individuals were between the ages of 18–48, with an average age of 23 years. While the correct stature was captured within the 95% Confidence Interval (CI) for all individuals identified and living stature was consistently underestimated from the Probability of Identity (PI) across the board, the degree to which stature was underestimated for those individuals from Cabanatuan was demonstrably more significant than those individuals from Tarawa (mean difference Cabanatuan 1.26 inches, mean difference Tarawa 0.40 inches;  $p=0.003$ ). The extent to which the forensically ascribed stature and living stature vary between those individuals who had documented cases of severe nutritional arrest and dietary deficiency and those who do not reaffirms that stature is sensitive to outside pressures and that health status at time of death may affect stature estimation.

This research highlights the role that nutrition and diet, particularly around the time of death, play in forensic and living stature estimation. While it is widely accepted that nutritional stress may interrupt skeletal development in the skeletally immature, correction factors for stature decrease are rarely employed for adults under 45 years of age. It is proposed that in order to mitigate the risk of underestimating stature and preemptively or falsely excluding a potential identification match, researchers take into consideration additional contributing factors—such as severe dietary deficiencies—when making exclusions based on stature, regardless of age.

---

### Stature; Diet; Mass Graves

## A99 Mass Graves: An Analysis of Injuries and Causes of Death

*Nermin Sarajlic\*, University of Sarajevo, Sarajevo, Federation of Bosnia and Herzegovina, Bosnia and Herzegovina*

**Learning Overview:** The goal of this presentation is to focus on the determination of cause and manner of death for human remains exhumed from mass graves in Bosnia and Herzegovina and the distinction between antemortem and perimortem trauma, as well as postmortem breakage in these. This presentation will discuss the challenges encountered in the identification of trauma on human remains in different degrees of decomposition and how these challenges are mitigated.

**Impact Statement:** This presentation will impact the forensic scientific community by showcasing the application of forensic science in overcoming challenges in the identification of trauma on human remains and present examples from casework conducted in a humanitarian setting. Attendees will learn how the work of the local forensic team supports the Transitional Justice framework in Bosnia and Herzegovina.

The modern history of the Balkans is painted in blood. The Yugoslav wars, a series of conflicts between different Balkan nations in part of what is today former Yugoslavia, had devastating consequences for the people of the region, and mass atrocities are seen in the discovery of mass graves. Bosnia and Herzegovina were affected by a war that lasted four years between 1992 and 1995, which has left more than 30,000 missing persons. Mass graves in Bosnia and Herzegovina are characterized by varied burial conditions. To this day, a total of 23,000 sets of human remains have been exhumed from numerous mass graves ranging from burials in the ground, pits, wells, septic tanks, and caverns. Human remains were occasionally also found exposed and unburied above ground, placed in open fields, meadows, and forests. While the majority of the remains were found completely skeletonized, occasionally, in some instances, individuals were found saponified or mummified depending on the burial conditions they were found in.

During forensic postmortem autopsy of remains exhumed from these mass graves, it has been noted that these remains often exhibit morphologies and defects associated with postmortem modification to the bones, especially postmortem breakage. Similarly, injury to preserved internal organs under postmortem conditions may also pose a problem. It is deduced that this is in part due to the variable burial conditions and mode of deposition of the remains in primary mass contexts; the transfer of the remains from primary to secondary, or even tertiary, mass graves while undergoing decomposition and/or have been skeletonized; processes of decomposition themselves such as the effect of saponification; and also in part due to the different forensic archaeological techniques used during the exhumation process.

The Transitional Justice model established for Bosnia and Herzegovina revolves around the accounting and repatriation of these missing persons and has justice for the victims at its core. As a result, the identification and interpretation of trauma, as it relates to cause and manner of death, is central to forensic analysis as it is paramount in securing the conviction of perpetrators. Similarly, the assessment of antemortem injuries is not only important in the legal process in order to determine the cause of death, but it is also helpful in the identification process when considering antemortem information obtained from family members or witnesses about injuries sustained. Therefore, the assessment of antemortem injuries for individuals retrieved from such mass grave, commingled, contexts in Bosnia and Herzegovina is a challenging task. It requires a multidisciplinary approach and a good understanding of the interplay between the everchanging field conditions, forensic taphonomy, and how these may affect skeletal structures and subsequent determination of the cause of death.

---

**A100 Substance Misuse, Stress, and Sternal Rib End Morphology: Implications for Forensic Age Estimation**

*Christine M. Pink\*, Western Michigan University Homer Stryker M.D. School of Medicine, Kalamazoo, MI*

---

**Learning Overview:** This presentation demonstrates the effects of chronic drug misuse on age-at-death estimation using the morphology of the fourth sternal rib end. Attendees of this presentation will have a better understanding of how chronic environmental stress affects morphological indicators of age in the skeleton.

**Impact Statement:** This presentation will impact the forensic science community by informing attendees that in the context of a drug overdose epidemic, forensic anthropologists should consider the potential effects of chronic substance misuse on morphological, or phenotypic, indicators of biological age in the skeleton. These data indicate that secular change is occurring in the morphology of the fourth sternal rib end.

One of the basic tenants of method development and application in forensic anthropology is that the reference sample should be an accurate and unbiased representation of the subject under analysis. Since 2014, drug-related mortality has risen precipitously, and synthetic opioids have been the primary driver of this trend. Synthetic and non-synthetic opioids are known to have variable effects on bone metabolism and healing.<sup>1</sup> In a more global sense, substance misuse is accompanied by a variety of environmental stressors, including housing insecurity, food insecurity, risk of infectious disease, and risk of accidental injury. This study investigates whether an individual experiencing significant prolonged stress due to drug misuse behaviors will exhibit premature skeletal aging. This preliminary study compares phase scores of the fourth sternal rib end in decedents with a reported history of substance misuse and those with no drug-misuse history. Bone Marrow Adipose Tissue (BMAT) volume is presented as a potential biomarker of stress.

From December 2022 through June 2023, the fourth sternal rib end was sampled from decedents receiving a full autopsy at the Western Michigan University Homer Stryker M.D. School of Medicine (WMed). The Department of Pathology and Office of the Medical Examiner are co-located at WMed. Over seven months, 202 ribs (n=135 substance users; n=67 no substance misuse) were sampled. The ribs were scored following Hartnett's system.<sup>2</sup> Males scored Phase 4, 5, 6, and 7 have a sufficient balanced sample to evaluate differences of mean age for a given phase by drug misuse history. In all four phases, the mean age of decedents with a drug misuse history is younger than the decedents with no history of drug misuse. The difference in mean age was tested using a Wilcoxon Rank Sum test with significant differences in Phase 6 and Phase 7 males (p=0.0500 and p=0.0166, respectively). All four phases exhibited significant differences in mean age at  $\alpha \leq 0.10$ . These preliminary data suggest that forensic anthropologists will systematically over-age males with a history of drug misuse.

Although the synthetic opioid fentanyl is detected in the postmortem toxicology of most drug overdose deaths, the norm is for individuals to use multiple substances that include both Central Nervous System (CNS) depressants and stimulants. This study does not consider decedents' preference for CNS depressant versus stimulant drugs. Different substances undoubtedly affect bone metabolism diversely; however, this study argues that the overall stressful environment of people with substance use disorders is more important in the expression of fourth sternal rib end morphology than the specific substances used.

BMAT was recently identified as a unique type of adipose tissue with osteoclastogenic and insulin resistance properties. The relative volume of BMAT is an indicator of stress where individuals under higher stress tend to have more BMAT.<sup>3</sup> All the decedents at WMed are imaged by Computed Tomography (CT) upon intake. The relative volume of BMAT to bone marrow in the manubrium, sternum, and xiphoid process was measured from CT data. Initial results from a small subset (n=9; n=5 substance misuse, n=4 no substance misuse) indicate that regardless of sex, decedents with a drug misuse history have more BMAT relative to bone marrow. The pattern suggests that BMAT is a sensitive biomarker of stress, and that decedents with a drug misuse history are subject to more stress than those with no drug misuse history.

These study findings demonstrate significant secular change occurring in the United States population with respect to skeletal age indicators. Reference samples that are the basis for rib aging methods are in need of updating in an environment of increased drug-related morbidity and mortality.

**A101 Aging Increases Regional Variation in the Pore Morphometry of Human Ribs**

Mary E. Cole\*, The Ohio State University, Columbus, OH; Yun-Seok Kang, The Ohio State University, Columbus, OH; Amanda M. Agnew, The Ohio State University, Columbus, OH

---

**Learning Overview:** After attending this presentation, attendees will understand the importance of accounting for cross-sectional variation, age, and sex in quantifying porosity.

**Impact Statement:** This presentation will impact the forensic science community by improving understanding of sources of intraskeletal variation in porosity, a key determinant of bone quality and fragility.

Porosity is an independent predictor of fracture risk, particularly at common sites of osteoporotic fracture. Pores concentrate mechanical stress, allowing microcracks to initiate and propagate into fracture even under low nominal stress. Localized mechanical strain also regulates the frequency and extent of bone remodeling, influencing how pore systems are shaped and modified over the lifespan. Defining relationships between this strain patterning and the resulting pore structure should improve predictions about pore morphometry in a tissue region, strengthening inferences about fragility. In the human midthoracic rib, simplified bending places the cutaneous and pleural cortices into opposing tension and compression. Histological studies have identified a significant elevation of percent porosity in the cutaneous cortex, compared to the pleural cortex. Porosity also increases with age, especially as pores expand and coalesce from small, rounded “cortical” pores into large, irregular “trabecularized” pores. The objective of this research was to investigate whether pore morphometry also displays regional patterning, and whether these patterns are altered by pore type, age, and sex.

Human midthoracic ribs ( $n = 124$ , [males = 76, females = 48], 22–97 years old, mean = 57.4 years) were cross-sectioned at the midshaft, histologically prepared, and imaged at 100X magnification. Pore morphometry was quantified with a custom ImageJ macro, Pore Extractor 2D for each pore type (all pores, cortical pores only, trabecularized pores only) within each rib region (cutaneous cortex, pleural cortex).<sup>1</sup> For each pore type, linear mixed models compared pore morphometry between the cutaneous cortex and pleural cortex, co-varying and interacting with age and sex.

Percent porosity was significantly higher in the cutaneous cortex for all pores, without age interaction ( $p < 0.001$ ). Cortical percent porosity was initially also higher in the cutaneous cortex, but the pleural cortex increased more with age, and surpassed the cutaneous cortex around the sixth decade ( $p = 0.002$ ). Trabecularized percent porosity remained significantly higher over the lifespan and increased more with age in the cutaneous cortex ( $p = 0.022$ ).

Pore density was initially higher in the cutaneous cortex for all pores ( $p < 0.001$ ) and cortical pores ( $p < 0.001$ ) but was surpassed by a steep increase in the pleural cortex in middle age. Trabecularized pore density was significantly higher in the cutaneous cortex, without age interaction ( $p < 0.001$ ).

Pore size (mean pore maximum diameter) and pore elongation (mean pore aspect ratio) were both significantly higher in the cutaneous cortex for cortical pores ( $p < 0.001$ ). Males maintained larger, more elongated trabecularized pores in the cutaneous cortex over the lifespan. Females initially formed especially large, elongated trabecularized pores in the pleural cortex, which decreased with age. Increases in cutaneous cortex size and elongation overtook the pleural cortex around the sixth decade ( $p = 0.002$ ).

Regional differences in pore morphometry accelerated with age, shifting the cutaneous cortex toward trabecularized porosity and the pleural cortex towards cortical porosity. Trabecularized porosity, trabecularized pore density, and overall pore size remained highest in the cutaneous cortex across the lifespan. Cortical porosity and cortical pore density were initially also highest in the cutaneous cortex but were overtaken by the pleural cortex in middle to older adulthood. Regional strain mode appears to influence not only the extent of porous bone loss, but also the preferred mechanism of either trabecularization or cortical pore formation.

**A102 Testing a Novel Method for Estimating Adult Age at Death From the First Rib in Forensic Casework**

*Amy Joy Spies\*, Department of Basic Medical Sciences, University of Arizona College of Medicine-Phoenix and Department of Interdisciplinary Health Sciences, A.T. Still University - Arizona School of Health Sciences, Mesa, AZ; Kaitlyn J. Fulp, Arizona State University, Scottsdale, AZ; Laura C. Fulginiti, Maricopa County Office of the Medical Examiner, Phoenix, AZ*

---

**Learning Overview:** This presentation utilizes characteristics of the first rib to test a novel method of estimating the ages at death of unknown decedents in forensic casework. After attending this presentation, attendees will better understand that scoring the ribs using the current descriptions and photographic references is difficult, yielding age-at-death estimates with extended ranges.

**Impact Statement:** This presentation will impact the forensic science community by demonstrating that novel methods of estimating adult age at death need to be tested to be validated. The proposed method of estimating age at death using the first rib is difficult to use but may be improved with further modifications.

Age at death is one of the first traits estimated when developing a biological profile of an unknown decedent. The first rib, which is more robust than the traditionally assessed fourth rib, more commonly recovered in skeletal cases, and more easily identifiable, has been proposed to yield reliable age-at-death estimates using a probabilistic approach.<sup>1</sup> However, *Daubert* criteria requires that the applicability of this method in forensic casework be validated.

The aim of this study is to test the method proposed by Luna and Aranda for estimating adult age-at-death from the first rib.<sup>1</sup> The sample consists of 32 first ribs from decedents at the Maricopa County Office of the Medical Examiner and the Forensic Anthropology and Bioarchaeology Laboratory at Arizona State University. The articular surfaces and periarticular margins of the costal surfaces and heads of these ribs were scored following guidelines by Luna and Aranda.<sup>1</sup> Twenty ribs were scored independently by each author to determine inter-observer repeatability, and ten ribs were scored twice by the same author two months apart to calculate intra-observer error. Rib scores were used to estimate the age at death of each decedent, and these estimated ages were compared to actual ages or mean estimated ages using the pubic symphyses and fourth ribs.<sup>2,3</sup> The Tau B coefficient ( $\tau$ ) showed that inter-observer repeatability was moderate to good ( $\tau = 0.53-0.92$ ), and intra-observer repeatability was good ( $\tau = 0.81-1.00$ ). Age estimation accuracies were 9.4% for within 1 year of the actual age at death, 12.5% for within 2.5 years, 31.3% for within 5 years, and 43.8% for within 10 years. These accuracies are much lower than those reported by the original authors (43.5%–94.7%), and the method, at present, does not improve on current methods for use in forensic casework. Each author found the ribs difficult to score by using the current category descriptions and photographs as a guideline. As a result, ribs may have been scored incorrectly, resulting in inaccurate age-at-death estimates. More detailed descriptions and clearer photographs of each category may aid in increasing the accuracy and inter-observer repeatability of this method, and thus its applicability in forensic casework. This method may be used with caution if traditional elements are unavailable to assess.

---

**A103 The Utility of Deciduous Dental Microstructures in Forensic Anthropology**

*Marin Pilloud\*, University of Nevada, Reno, Reno, NV; Christopher Aris, Keele University, Staffordshire, England; Emily Smith, University of Nevada, Reno, Reno, NV*

---

**Learning Overview:** After attending this presentation, attendees will better understand how the Neonatal Line (NNL) can be used in forensic anthropological analysis to estimate age and identify a live birth.

**Impact Statement:** This presentation will impact the forensic community by demonstrating the utility of the NNL in medicolegal death investigations and will aid in the development of more precise and statistically accurate age estimates within a forensic context. It also serves to identify the utility of accentuated striae as indicators of general stress events.

The dental enamel serves as a record of growth and development *in utero* through to late adolescence. Enamel cross striations (i.e., daily secretions of enamel) can be used to count days of enamel deposition to create age estimation methods and to understand dental development. The enamel can also record episodes of non-specific stress in the form of accentuated striae. These striae can be identified in histological cross-section of the enamel under low magnification. The first identifiable accentuated stria in the enamel is considered to be the NNL, an artifact found in the enamel microstructure of teeth associated with an individual leaving the intrauterine space. As such, the NNL can be used to identify a live birth, is a means to calculate age since birth, and can be used as a marker of events pre- and post-birth visualized in the dental structure. However, not much is known about the NNL, including how often it occurs, why it occurs, which teeth best illustrate the NNL, nor how long a tooth needs to develop before and after the development of the NNL for it to be visualized. This preliminary study aims to fill this gap through an investigation of microanatomy of the NNL (and accentuated enamel striae) of deciduous teeth and associated structures.

Dental histological slide preparation was undertaken on a sample of two individuals with known prenatal and postnatal health, gestational age, and sex (with permission of both parents and children in the United States). All available naturally exfoliated deciduous teeth were sectioned for analysis (n=22), which included each tooth type in the dental arcade for the upper and lower jaws. The NNL was recorded, and its width documented. Data were recorded on the number of cross-striations visible prior to and after birth. Accentuated striae in the enamel were also recorded and correlated to known health events of the two individuals.

Preliminary results indicate that the NNL could be visualized in deciduous teeth that had completely formed. Further, accentuated striae did not always correspond to known times of stress in these deciduous teeth. Future research will continue to count cross-striations of dental development to understand how long teeth develop and to create robust age estimation methods for infants and children. Additional developed teeth will be included as well as the dentition of fetal and infant remains of developing teeth to test and validate age estimation methods. This pilot study demonstrates the potential utility of the NNL in deciduous teeth and how dental microstructure can be used to understand life events and aid in forensic anthropological analysis.

**A104 Dental Age Estimator Performance Relative to Weighted Kappa: A Simulation Study**

*Valerie Sgheiza\*, SNA International, Joint Base Pearl Harbor-Hickam, HI; Helen M. Liversidge, Queen Mary University of London, London, England*

**Learning Overview:** After attending this presentation, attendees will understand how weighted kappa measures of observer agreement correspond to dental age estimation precision, accuracy, and bias. This presentation will demonstrate potential consequences of reduced agreement in scoring.

**Impact Statement:** This presentation will impact the forensic science community by highlighting the importance of observer agreement in controlling downstream estimation error.

Cohen's weighted kappa is a common measure of observer agreement for ordinal data such as dental development scores, with values above 0.8 generally considered good. How weighted kappa values correspond to downstream error in age estimates is not known. Here we test the relationship between weighted kappa values and dental age estimation error by estimating ages from a single sample with additional simulated observers, each scoring at a fixed weighted kappa value relative to the original observer.

The dataset consisted of Moorrees et al. scores of left permanent mandibular molars from 1,040 London children 5–18 years old, distributed uniformly by year of age.<sup>1</sup> Multivariate cumulative probit models were fit to the original observer data with age on a log scale. Ages were estimated with simulated observers of validation data and ten-fold cross-validation. To simulate observer error, the original scores were jittered via a normal distribution, then rounded to whole number scores. Error was balanced, over scored, and under scored, each with kappa values of 0.80, 0.90, and 0.95. Ages were also estimated from the original scores (kappa = 1.0) for a total of ten combinations of error direction and weighted kappa. Performance metrics were age interval width relative to true age, the success rate of the age interval at capturing the true age, and residual error.

Within each type of scoring error (balanced, over, under), lower kappa values were consistently associated with worse performance across all metrics. Notably, the overall success rate from the original scores was 0.93 (expected value 0.95). The next highest was 0.85 from over scoring at kappa = 0.95, and the lowest was 0.55 from under scoring at kappa = 0.80. Over scoring produced positive residuals and under scoring negative residuals. Success rates were better from over scoring than under scoring or balanced scoring at equal kappa values. This is potentially related to larger age intervals from over scoring, particularly at younger ages. Age interval width was narrower and less variable across the age range from under scoring than from over scoring or balanced scoring at equal kappa values.

In conclusion, age estimation performance testing on live multi-observer dental development data is warranted. A cutoff for weighted kappa of 0.80 may be insufficient to control estimation error introduced through observer discrepancies.

**A105 Estimating Age in Adults Using Measurements of Dental Radiographs: A Validation of the Kvaal Method**

*Katherine Skorpinski\*, Defense POW/MIA Accounting Agency, Omaha, NE; Laura E. Cirillo, SNA International in Support of the Defense POW/MIA Accounting Agency, San Francisco, CA*

---

**Learning Overview:** After attending this presentation, attendees will better understand the potential use of dental radiographs for estimating age in adults.

**Impact Statement:** This presentation will impact the forensic community by providing a performance assessment of a non-invasive method of adult age estimation, discussing current limitations and challenges of this method, and proposing future directions to improve method performance.

Age estimation in adult remains is limited by several factors. Specifically, adult skeletal age estimation involves few reliable indicators and focuses on markers of degeneration. These challenges are further complicated by damaged or absent elements in forensic and historical contexts. However, the durability of enamel results in greater tooth preservation and retention in a variety of taphonomic conditions. Although dental age estimation methods primarily focus on development, secondary dentin deposits throughout adulthood have been used to estimate age beyond young adults.

The Kvaal et al. method of measuring pulp cavity size to estimate age was developed on a small clinical sample ranging in ages from 20 to 87 years, and measurements on three maxillary teeth (central and lateral incisors, and second premolars), and three mandibular teeth (lateral incisor, canine, and first premolar).<sup>1</sup> In order to examine the applicability of this method to other forensic contexts, a sample of dental radiographs of identified male United States servicemembers from World War II and the Korean War (n = 107, ages ranging from 17 to 52 years) was tested.

Inter-observer error was first tested on a subsample of ten cases with complete dentition for all measurements and ratios used in the Kvaal et al. method. Although some individual measurements demonstrated a significant difference between observers, the mean difference in measurement was consistently under 0.5mm and did not significantly alter the age estimate. T-test results indicated that there was no significant difference in the ages estimated between observers for all teeth.

The method was applied to a total of 272 teeth with an overall accuracy of 83.5% within one Standard Error of Estimate (SEE). Accuracy by tooth type ranged from 78.6% (mandibular first premolars) to 93.1% (maxillary central incisors). Individuals with a known age that fell outside of the 1 SEE interval were underestimated in 65.9% of cases. Results using the three maxillary or mandibular teeth equations were accurate in the majority of cases but did not achieve as high of a percent accuracy as the single tooth equations. The method performed with a higher percent accuracy for ages under 30 years, including those younger than the original sample (i.e., under 20 years of age).

Despite the high accuracy overall in this application, several limitations excluded a large portion of the test sample, including dental restorations and pathological conditions. The method also relies on measurements of single-rooted teeth, but the high frequency of multiple roots in teeth used in the method significantly impacted the ability to test the multi-tooth equations. Further complications, including root morphology, observer error, and radiograph quality and orientation, were identified and adjustments and future considerations are proposed.

**A106 Innominate Weight Over the Lifespan: A Method for Estimating Age From the Pelvis**

*Andrea M. Zurek-Ost\*, University of North Carolina at Chapel Hill, Durham, NC; Mark Sorensen, University of North Carolina at Chapel Hill, Chapel Hill, NC*

---

**Learning Overview:** After attending this presentation, attendees will gain a better understanding of how innominate bone weight changes throughout the lifespan.

**Impact Statement:** This presentation will impact the forensic science community by demonstrating the utility of innominate dry bone weight as a trait that can be employed in age-at-death estimations.

The innominate is frequently used to estimate age at death in both forensic and paleodemographic contexts. Age changes in bone can be difficult to quantify and score consistently, particularly between males and females, due to changes in bone mineral density, calcium intake and absorption, endocrine status, nutrition, hormones, and biological sex.

This research investigated the relationships between bone weight, chronological age, and biological sex. This study examined 383 innominates from the Hamann-Todd Collection from individuals aged 16-93 years to investigate how bone weight (here a proxy for bone mineral density) was patterned throughout the lifespan. Standard osteology laboratory equipment as well as a scale were used to measure innominate height and dry bone weight. While dry bone weight is an imperfect proxy for bone mineral density, the phenomenon of decreases in bone weight with age was observed and quantified in this dry bone sample. While both males and females are affected by a slow reduction in bone mineral density over the course of their lifespans, this effect is exaggerated in women and was reflected in the study results.

To quantify these changes, the authors created a predictive Bayesian linear model to estimate age at death from dry bone weight and height. Both sex-specific and sex-unknown tests were conducted using JASP 0.17.1.<sup>1</sup> In Bayesian linear regressions, parameter estimates are drawn from the posterior probability distribution of the observed data, which is proportional to the product of the likelihood of the data and the prior probability of the parameters. In this study, the posterior predictive distribution was drawn with Markov Chain Monte Carlo sampling using the Beetle Antennae Search (BAS) algorithm. A model was then fitted to the simulated data, and these new parameter estimates were compared to the final model. A 95% credible interval was estimated on the final model to predict age given known innominate weight and length. The model  $R^2$  was 0.32, with an average inaccuracy of 14.02 years. Estimated age was within  $\pm 10$  years of known age for 42.7% of the sample, and 75.2% of estimated ages at death were within  $\pm 20$  years of known age.

In conclusion, when used alongside other age-at-death estimation methods, this pilot study demonstrates that dry bone weights may be used to support estimations of chronological age. These analyses should be utilized in concert with well-validated age-at-death estimation methods.

**A107 An Age-at-Death Estimation From Pubic Bone Mineral Density on Postmortem CTs**

Eulalie Pefferkorn\*, Medico-Legal Institute of Tours University Hospital, Chambray-lès-Tours, Centre, France; Fabrice Dedouit, Hospital Rangueil, Toulouse, Midi-Pyrenees, France; Agathe Bascou, CHU Toulouse, Midi-Pyrenees, France; Frederic Savall, CHU Toulouse-Rangueil, Toulouse, Midi-Pyrenees, France; Norbert Telmon, CHU Toulouse-Rangueil, Toulouse, Midi-Pyrenees, France; Pauline Saint Martin, Medico-Legal Institute of Tours University Hospital, Chambray-lès-Tours, Centre, France

**Learning Overview:** The objective of our study is to estimate age at death through a simple measurement of the pubic Bone Mineral Density (BMD) on Postmortem Computed Tomography (PMCT). PMCT cannot be analyzed in the same way as clinical CTs; it is crucial to consider the structural changes in tissue caused by putrefaction.

**Impact Statement:** This study will have a significant impact on the forensic community by enabling quick and straightforward estimates of age at death through a simple measurement of pubic bone mineral density on PMCTs. Our results are particularly accurate when accounting for the degree of putrefaction

Age-at-death determination is an important issue in forensic medicine and anthropology. The use of imaging in the forensic field has facilitated the development of new techniques that provide age estimation while preserving remains. These techniques include morphological studies using 3D scanographic reconstructions as well as methods using bone mineral density. However, most of these studies primarily focus on CT scans of living individuals.<sup>1-7</sup> In this study, the authors investigated the correlation between pubic bone mineral density and age at death on PMCTs.

We conducted a study on postmortem CTs of cadavers autopsied in the Forensic Institute of Tours (France) to determine whether there was a correlation between the BMD of the pubic symphysis measured on PMCT and age at death. We excluded individuals under the age of 15 years, unidentified bodies, or those with trauma that hindered the measurement of Radiological Alteration Index (RAI) or BMD. Postmortem delay was not a determining factor for inclusion, as our study specifically sought bodies with varying degrees of decomposition.

CT measurements of BMD are an estimation (in Hounsfield units) and are potentially modified because of putrefactive gases into the cancellous bone tissue. This phenomenon could falsely decrease bone density and thus overestimate age at death. In the specific postmortem context, we therefore used a radiological degradation score (RAD) to quantify the degree of putrefaction and establish whether putrefaction interferes with the determination of age at death according to our method.<sup>8</sup>

**Results:** Our sample consisted of 402 PMCTs, comprising 148 females and 254 males. The average RAI was approximately 25, indicating that the majority of bodies were only slightly decomposed. Our study showed a correlation between pubic BMD and age at death. To use this method, it is necessary to quantify the degree of putrefaction by calculating the RAI index. Indeed, in order to increase the accuracy of the results, the equations used to calculate age at death are different according to RAI subgroups (0, 1 to 24, 25 to 49, 50 to 74, 75 to 100). However, our technique cannot be used for highly putrefied bodies (RAI >75) as there is no correlation between age at death and pubic BMD in this group due to significant structural changes associated with the putrefactive gas infiltration of the cancellous bone.

**A108 Decoding Age-at-Death With DNA Methyloomics: A Cutting-Edge Approach for Forensic Analysis of Skeletal Remains**

Luke William Gent\*, University of Central Lancashire, Preston, England; Noemi Procopio, University of Central Lancashire, Preston, England; Edward Schwalbe, Northumbria University, Newcastle upon Tyne, England

---

**Learning Overview:** After attending this presentation, attendees will be aware of a novel application of genome-wide DNA methylomics to forensic anthropology. The learning objectives here are to gain an appreciation of how advances in whole-genome sequencing offer potential to increase precision in Age-At-Death (AAD) estimation in medicolegal investigations.

**Impact Statement:** This presentation will impact the forensic community by providing an innovative tool for the estimation of the AAD of human skeletal remains using a genome-wide approach. The DNA methylation-based epigenetic age prediction model presented here leverages a large *in silico* dataset focused specifically on bone material and will allow for the future development of targeted forensically relevant epigenetic approaches for improved AAD estimations.

The estimation of AAD from skeletal remains using routine anatomical approaches lacks precision and may be hampered by missing skeletal elements or environmental weathering. Many reports have described forensically applicable assays that use DNA methylation patterns at specific CpG loci to predict biological age; however, these approaches were developed using readily obtainable DNA sources such as blood, saliva, and teeth.<sup>1,2</sup> The use of biomolecular markers to estimate AAD from skeletal remains offers potential for greater precision, but their application has been hampered by poor DNA quality and quantity.

CpG locus signatures applicable to bone samples have been identified using the standard molecular clocks; these signatures were developed in both skeletal and non-skeletal tissue as age-associated markers.<sup>3,4</sup> However, robust, bone-specific CpG loci of aging that are compatible with DNA derivatives from decomposed skeletal remains are yet to be described.

In order to address this question, two approaches were conducted. First, an *in silico* study focused on identifying a forensically applicable CpG aging signature for bone was developed. An ideal forensic assay to predict age would use a small number of loci (i.e.,  $\leq 20$  loci), enabling its assessment with Polymerase Chain Reaction (PCR) -based approaches. We gathered six publicly available genome-wide bone methylation datasets with reported donor age (total  $n=173$ ; average age 65 years [range 0.25-92, spanning the whole human lifespan]). This dataset assayed CpG methylation at  $>450,000$  loci. We tested previously published biological age-prediction signatures and, using cross-validation, employed six different machine learning algorithms to develop age-prediction signatures. The best performing algorithm was GLMNet, where a 20 CpG signature for predicting AAD had a Root-Mean-Square Error of 6.2 years, Mean Absolute Error of 4.7 years, and  $R^2$  coefficient of 0.89.

The second investigation addresses the difficulty of obtaining DNA of sufficient quantity and quality from skeletal remains. We employed an optimized ancient DNA extraction protocol to maximize DNA recovery. To detect methylation using sequencing or hybridization, sodium bisulfite conversion is typically used to induce a methylation-dependent change to the primary DNA sequence. Bisulfite conversion is a destructive process ( $>90\%$  of DNA is lost). In order to preserve DNA, we used a gentler enzymatic methylation conversion kit that is suitable for low DNA inputs. These methods were tested on a pilot cohort of donor human skeletal tissue samples (28–93 years age; 0–2,236 days Postmortem Interval [PMI]) collected from Southeast Texas Applied Forensic Science (STAFS) facility and Forensic Anthropology Center at Texas State (FACTS).

The methylation conversion rate for five pilot samples was  $>99\%$  and all were run on the TWIST Biosciences Human Methylome Panel. The range of loci with  $>5$  reads ranged from  $\sim 470,000$  to 3,750,000 CpG loci;  $>90\%$  of the CpG aging signature loci were measurable using the TWIST panel, enabling cross-platform integration. Ongoing analysis of the rest of the bone DNA cohort ( $n > 45$ ) is proceeding and will be presented to the attendees at the conference, where we will address the accuracy of AAD estimation using the TWIST panel and the *in silico* cohort.

This study represents one of the largest collections of genome-wide methylation status in bone. Fundamentally, the TWIST assay offers potential for methylome capture from skeletal bones recovered from burial sites. The applicability of this methodology will be discussed for future applications on forensically relevant human skeletal remains.

**A109 Intra-Skeletal Variation in Lower Limb Microstructure for Histological Age Estimation**

Victoria M. Dominguez\*, Lehman College-CUNY, Astoria, NY; Bailey AG Colohan, CUNY Graduate Center, New York, NY

**Learning Overview:** After attending this presentation, attendees will understand the importance of bone microstructural variance and sampling location for developing and applying methods of histological age-at-death estimation.

**Impact Statement:** This presentation will impact the forensic science community by establishing the need for research on intra-skeletal variation in bone microstructure to inform method development and accuracy in histological aging.

Age-at-death estimation is a major and challenging component of the biological profile. The most commonly applied methods after macroscopic approaches are histological. Although various methods exist, almost all are exclusively based on one of two skeletal elements: the femur or rib. Furthermore, previous research demonstrates that sampling location and Region Of Interest (ROI) size also influence the reliability of age estimates, demonstrating that intra-skeletal variation plays a significant role in the success of these methods.<sup>1,2</sup> So long as this remains the case, the use of histological methods for estimating age at death will be limited.

One of the only papers to consider other bones in histological aging is Kerley's foundational work using remodeling events (i.e., secondary osteons) counted in the femur, tibia, and fibula to estimate age.<sup>3</sup> Kerley found that fragmentary counts of osteons in the fibula demonstrated the best relationship with age of the entire sample, but this finding has largely been overlooked in subsequent years. As such, the current paper analyzes remodeling and relative cortical area in the fibula and femur relative to each other and to age as a preliminary exploration of the fibula's potential for age estimation.

The sample consisted of right fibulae and femora from ten individuals of known age (15-105 years, sd=9.71 years) and sex (5F, 5M). Samples were ethically obtained via the body donation program at The Ohio State University and prepared following standard histological protocols. Images captured at 100x magnification were used to calculate Relative Cortical Area (Rel.Ct.Ar) for each cross-section in mm<sup>2</sup>. Live microscopy using a 20x objective was utilized to count intact and fragmentary osteons across the entire cross-section. These data were then used to calculate three variables: Osteon Population Density (OPD), intact OPD (iOPD), and fragmentary OPD (fOPD).

Paired samples *t*-tests found no significant differences in Rel.Ct.Ar between the fibulae and femora, though a strong correlation between the elements may reflect allometry. For combined OPD, there were no significant differences either, but when split, both iOPD ( $p=0.008$ ) and fOPD ( $p=0.002$ ) were significantly different. Summary data indicates fibulae have higher fragment counts, whereas femora possess more intact osteons. This may result from the femur's larger cortex requiring more vasculature, combined with earlier and/or increased remodeling of the more constrained number of intact osteons in the smaller fibula.

Rel.Ct.Ar showed no significant relationship with age. A negative trend observed in the femur, possibly resulting from cortical trabecularization, was not seen for the fibula. All OPD relationships demonstrated significant, positive relationships with age for both elements. In both elements, the strongest relationship with age was for OPD (Fib  $R^2=0.83$ , Fem  $R^2=0.84$ ), then fOPD (Fib  $R^2=0.81$ , Fem  $R^2=0.69$ ), and finally iOPD (Fib  $R^2=0.58$ , Fem  $R^2=0.58$ ). Again, fragments in the fibula appear to comprise a more substantial part of the microstructural variance than in the femur.

These findings suggest that other long bones, such as the fibula, merit development as sites for histological age-at-death estimation based on their similarities with the more commonly utilized femur and due to its own unique relationship between fragmentary and intact remodeling events.

**A110 Introducing OA-TA: A New Tool for Adult Age-at-Death Estimation Using Osteoarthritis of the Synovial Joints**

Michala K. Stock\*, Metropolitan State University of Denver, Denver, CO; Ariana N. Strasheim, Grouse Mountain Environmental Consultants, Sheridan, WY; Allysha P. Winburn, University of West Florida, Pensacola, Florida

---

**Learning Overview:** After attending this presentation, attendees will have a better understanding of how to evaluate Osteoarthritis (OA) and utilize its presence or absence in synovial joints to estimate age from human skeletal remains.

**Impact Statement:** This presentation will impact the forensic science community by introducing OA-TA, a new Graphical User Interface (GUI) for use by forensic anthropology practitioners, to generate an adult age-at-death estimation from osteoarthritis presence/absence scores.

Age-at-death estimation is a crucial facet of the biological profile that forensic anthropologists generate from human skeletal remains. Adult age estimation often relies on particular indicators, such as the pubic symphyses or sternal ends of the fourth ribs, which are regularly taphonomically damaged or altogether missing from incompletely recovered cases. To circumvent this reliance and bolster forensic anthropologists' adult age-estimation toolkit, recent research has demonstrated the correlation between age and osteoarthritis in multiple synovial joint complexes among diverse groups of modern United States individuals.<sup>1,2</sup>

Here we present OA-TA, a GUI for generating adult age estimates based on the presence or absence of OA in synovial joints. Users may select to utilize as few as one or as many as nine appendicular joint complexes and create an estimate based on pooled sex, female-, or male-sex-assigned-at-birth reference samples from the University of Tennessee Knoxville (UTK) Donated Skeletal Collection (database N=408 individuals). For each joint, all bones are examined for OA and scored on a binary presence/absence scale; this score is then entered into the respective joint's field. For example, when evaluating the elbow, the presence of OA anywhere on the distal humerus, radial head, or proximal ulna would yield a score of 1 (present) for this joint. Based on the work of Winburn and Stock, OA-TA uses transition analysis—binomial generalized linear models with the probit link function—to generate age estimates based on the age at which 90% or 95% of the population transitions from “no OA present” to “OA present” in the given joints.<sup>1</sup> An age estimate interval, or floor or ceiling age estimate, is then provided for this individual.

OA-TA Version 1 is available for download at <http://www.apwinburn.com/oata>. If peer feedback is received prior to presentation, this will be incorporated into OA-TA Version 2 and shared using the same link.

We performed a test of the OA-TA GUI using a sample of 100 unique UTK donors (distinct from those in the database sample) using all available joints as well as testing each of the nine joints independently (i.e., ten iterations per individual, where applicable [joints previously demonstrated to have weak age correlations, such as the ankle in female individuals, were not assessed]).<sup>1,2</sup> Each iteration was performed using the sex-specific and pooled-sex equations and assessed for accuracy at both the 90% and 95% thresholds, for a total of 3,400 test cases. The OA-TA age-estimation interval was correct in 68.4% of these cases (2327/3400). The most accurate joints (i.e., where the age interval included the individual's known age-at-death) were the hip and shoulder; the least accurate joints were the TMJ and male ankle, with accuracy rates generally decreasing distally along the limb. When all available joints were utilized, accuracy rates for the test sample ranged from 82% (at the 90% threshold) to 78.5% (at the 95% threshold). These results corroborate findings from a previous study noting the proximal-to-distal accuracy pattern in age estimation using OA, with the low accuracy of the ankle—even among males—also recommending against the ankle joint's use for OA-based aging.<sup>2</sup>

The intervals yielded by OA-TA are often broad, and we are not advocating that OA replace primary age estimation methods in forensic anthropological practice. However, since OA has demonstrated a significant and reliable relationship with age, its presence/absence provides a tenable method to estimate age in incomplete or fragmentary cases and enhance age estimation during complete skeletal analyses. The binary scoring of OA in the synovial joints is already a straightforward process; with the OA-TA GUI, we offer a free, easy-to-use, openly accessible tool that further streamlines and standardizes the process of interpreting OA for purposes of forensic anthropological age estimation.

**A111 Validating Population Affinity Method Platforms for Macromorphoscopic Traits in Specific 20<sup>th</sup>-Century Contexts**

Cortney N. Hulse\*, SNA International, Joint Base Pearl Harbor-Hickam, HI; Amanda N. Friend, SNA International in Support of the Defense POW/MIA Accounting Agency Hawaii, Joint Base Pearl Harbor-Hickam, HI; Rebecca J. Taylor, Defense POW/MIA Accounting Agency, Kapolei, HI; Amanda R. Hale, DPAA Laboratory/SNA International, Kaneohe, HI; Abigail K. Kindler, SNA International in Support of the Defense POW/MIA Accounting Agency, Honolulu, HI

---

**Learning Overview:** After attending this presentation, attendees will better understand the relative performance of Macromorphoscopic (MMS) method platforms for populations consistent with those from the Defense POW/MIA Accounting Agency (DPAA).

**Impact Statement:** This presentation will impact the forensic science community by validating multiple MMS method platforms for forensic casework and demonstrate their relative accuracy.

MMS traits are used in non-metric analysis for assessing population affinity. However, it is necessary to establish validity of the statistical platforms for MMS traits applied to specific contexts. This ensures their applicability to context-specific casework and adherence to laboratory accreditation requirements. One method platform more recently introduced for these methods, the Osteomics' hefneR GUI, also requires validation per laboratory accreditation for inclusion in DPAA laboratory casework.<sup>1</sup> Therefore, the purpose of this study was: (1) to validate the method platforms for MMS traits in accordance with laboratory accreditation, and (2) to understand the relative efficacy of each platform for DPAA casework.

Data was aggregated from 347 forensic anthropology case reports from the DPAA. Per these reports, traits were scored following Hefner and Linde.<sup>2,3</sup> Traits were then evaluated with four MMS method platforms, namely: Optimized Summed Score Attributes (OSSA); the Hefner and Ousley decision tree; the discriminant functions for 3-, 5-, and 7-traits; and the hefneR GUI for 3-, 5-, 7-, and 11-traits.<sup>1,4,5</sup> Sample sizes for each test are as follows: OSSA ( $n=219$ ), decision tree ( $n=309$ ), 3-traits ( $n=253$ ), 5-traits ( $n=83$ ), 7-traits ( $n=75$ ), and all traits ( $n=47$ ).

Trait scores were used to classify individuals into population groups for each statistical platform. The OSSA method results in White or Black classifications. The decision tree and Hefner methods can result in White, Black, or Hispanic classifications, while the hefneR GUI also includes Asian and Native American classifications.<sup>1,4,5</sup> The recorded perceived demographics from the antemortem records of the 347 identified individuals include: White ( $n=326$ ), Black ( $n=15$ ), Mexican ( $n=2$ ), Native American ( $n=1$ ), and Asian (e.g., Korean;  $n=3$ ).

For the OSSA and decision tree methods, the correct classification rates were 94.5% and 90.5%, respectively. Using the discriminant function equations from Hefner, the 3-trait equation had a correct classification rate of 93.6%, 91.5% for the 5-trait equation, and 0% for the 7-trait equation.<sup>5</sup> Using the hefneR GUI, there was a correct classification rate of 77.3% for 3-traits, 73.2% for 5-traits, 87.8% for 7-traits, and 85.1% for 11-traits.<sup>1</sup>

Both the OSSA and decision tree methods performed best based on correct classification rates, but neither of these methods could account for individuals with Asian or Hispanic population affinity. The 3-trait discriminant function performed better than the 5- and 7-trait equations overall, but the opposite pattern was observed for the hefneR GUI results, with the 7-trait performing better than all other trait suites.<sup>1</sup> Notably, the 7-trait discriminant function analysis had a correct classification rate of 0% for this sample compared to the reported cross-validated correct classification rate of 83.4% in Hefner.<sup>5</sup> While a Hispanic estimation does not preclude consistency with a White antemortem record, all cases but three resulted in a Hispanic classification. This suggests a potential bias within the reported formula as this pattern was not observed for the 3- and 5-trait equations. Excluding the 7-trait discriminant function analysis, accurate classifications were for individuals having White, or European, recorded in their antemortem records, while incorrect classifications tended to occur for individuals with "non-White" antemortem records. In conclusion, these results suggest that all platforms, excluding the 7-trait discriminant function, perform relatively well for this context.

Traits scores were aggregated from 347 forensic anthropology case reports and associated notes and do not reflect analyst interpretations. Reported perceived race refers to the category of race in Individual Deceased Personnel Files for all deceased servicemembers relevant to DPAA investigations. For more detail, see Hale and colleagues.<sup>6</sup>

**A112 A Comparison of Ancestry-Specific Versus Ancestry-Independent Stature Estimation**

Rylan Tegtmeier Hawke\*, SNA International Supporting the Defense POW/MIA Accounting Agency, Waipahu, HI; Laura E. Cirillo, SNA International Supporting the Defense POW/MIA Accounting Agency, San Francisco, CA; Abigail Kindler, SNA International Supporting the Defense POW/MIA Accounting Agency, Honolulu, HI; Lara E. McCormick, SNA International Supporting the Defense POW/MIA Accounting Agency, Omaha, NE; Emily S. Tarbet Hust, SNA International Supporting the Defense POW/MIA Accounting Agency, Mililani, HI; Katie Whitmore, SNA International Supporting the Defense POW/MIA Accounting Agency, Omaha, NE

---

**Learning Overview:** After attending this presentation, attendees will understand the differences in error between ancestry-specific and ancestry-independent stature calculations.

**Impact Statement:** This presentation will impact the forensic science community by identifying where there are areas of significant difference between ancestry-specific and ancestry-independent equations for stature estimation.

Ancestry assessment in a forensic context is a widely discussed topic as the field weighs the potential harms and benefits of its application.<sup>1,2</sup> One area that proponents of the continued use of ancestry assessment in the biological profile point to is its application in estimating other aspects of the biological profile such as sex and stature. The aim of this study is to evaluate the impact of a prior ancestry assessment in estimating stature through a comparison of error between the point estimates based on ancestry-specific and ancestry-independent calculations and known statures. For prior ancestry assessment to be considered impactful, the results of ancestry-specific calculations should significantly differ from ancestry-independent calculations, and individuals from a reported ancestry group should have the least error between their known stature and the stature estimate from the corresponding ancestry-specific equation.

The significance of ancestry-specific stature estimation was tested on a skeletal sample of 270 identified White male service members from the USS *Oklahoma* incident of World War II. Individuals were selected based on the following criteria: consistent reported height throughout their antemortem records (as defined by a deviation of  $\leq 0.5$  inches across all documents), known ancestry (reported as “race” in the antemortem military records), and a maximum length measurement of at least one applicable skeletal element (humerus, radius, ulna, femur, tibia, or fibula). In total, 158 left and right humeri, 80 left and right radii, 89 left and 77 right ulnae, 207 left and 200 right femora, 180 left and 172 right tibiae, and 111 left and 113 right fibulae were used to calculate point estimates across the three sets of regression equations available in FORDISC® 3 19<sup>th</sup>-Century FStats and Trotter MStats.<sup>3</sup> For all equations, the Black male (BM), White male (WM), and Any male comparative groups were used, with the addition of Hispanic male (HM) for 20<sup>th</sup>-Century FStats.

When the stature estimates from the 19<sup>th</sup>-Century CStats equations were compared, WM consistently produced a point estimate closest to known stature (error of 0.94 to 1.42 inches between elements). The Any male equation results were significantly different from the WM estimates ( $p < 0.01$ , overall error of 1.21–2.24 inches, average difference of 0.5 inches), but consistently performed better than BM equation.

When the stature estimates from the 20<sup>th</sup>-Century FStats equations were compared, WM produced a point estimate closest to the known stature in 6/12 of element (error of 0.89–1.32 inches). The Any male equation produced a point estimate closer to the known stature in 4/12 elements (error of 1.04–1.46 inches), but all results were not significantly different from the WM estimates ( $< 0.25$ -inch difference). HM produced the point estimate closest to the known stature in 4/12 elements.

When the stature estimates from the Trotter MStats equations were compared, WM consistently produced a point estimate closest to known stature (error of 0.90–1.31 inches between elements). The Any male equation results were not significantly different from the WM point estimates (error of 0.92–2.07 inches). The Any male equation consistently performed better than BM equation (error of 1.64–2.89 inches).

The Any male equations produced values that did not significantly differ from the WM point estimates for White males using the 20<sup>th</sup>-Century FStats and Trotter MStats equations. Further, the Any male values often matched the error of the WM estimates in the FStats and MStats samples, and even outperformed the WM estimates for multiple elements in the FStats sample.

Future directions should evaluate more diverse populations, as the current study’s impact is limited by the homogenous reported sex and ancestry of the test sample.

**A113 Evaluating the Prevalence of Torus Mandibularis and Torus Palatinus in Relation to Ancestry, Sex, and Age in a Modern Skeletal Sample**

Alex F. Wong\*, A.T. Still University, Gilbert, AZ; Amandine Eriksen, University of Indianapolis Department of Biology, Indianapolis, IN; Stephen Nawrocki, University of Indianapolis, Indianapolis, IN

---

**Learning Overview:** This presentation aims to inform attendees about the prevalence of Torus Mandibularis (TM) and Torus Palatinus (TP) in a modern skeletal sample and how such traits may covary to ancestry, sex, age at death, and their interactions. In addition, this study should fill some of the gaps in our current knowledge of TM and TP by examining a contemporary sample neglected in bioanthropological literature.

**Impact Statement:** This presentation will impact the forensic science community by helping attendees gain a better understanding of the prevalence of TP and TM and how such traits are linked to ancestry, sex, age at death, and their interactions. This quantitatively justifies the use of these skeletal traits in formulating biological profiles in forensic anthropological analysis.

Few features of the human skull have attracted the attention of anthropologists more than TP and TM. Historically, these distinctive oral bony outgrowths have been classified as useful “racial biological markers” because of their varying frequencies in specific populations and ethnic groups.<sup>1,2</sup> As a result, these traits have been adopted in forensic anthropology to estimate ancestry of unknown skeletal remains. When present, they are considered indicative of East Asian and American Indian ancestry.<sup>3,4</sup> However, their connection to sex and age at death remains unclear, and the effects of all independent demographic variables on their expression are weak.<sup>4,5</sup> Therefore, the validity of each trait in biological profile analysis must be carefully evaluated.

A contemporary sample of 307 individuals (148 females, 159 males), aged 21–107 years old, were analyzed from the osteological collection at the University of Hawai‘i. The donors were classified into one of four subgroups: (1) African, (2) Asian, (3) European, and (4) Pacific Islander. TP and TM were scored based on: (1) presence or absence, (2) shape, and (3) size. The following multivariate model was used to express the possible relationships between the variables:

$$\text{torus expression} = \text{sex} + \text{ancestry} + \text{sex*ancestry} + \text{age} + \text{error}$$

“Torus expression” is the dependent variable, “sex\*ancestry” is the interaction between those two categorical independent variables, and “age” is a continuous covariate. Ordinal and binary logistic regression were then employed to assess the effects of each independent variable.

A total of 65.1% (200 of 307 individuals) exhibited TP, while 34.2% (105 of 307 individuals) exhibited TM. TP was observed in 94 females (63.5%) and in 106 males (66.7%), while TM was identified in 50 females (33.7%) and 55 males (34.5%). However, statistical tests indicate that the effect of sex on the presence of TP or TM was not significant ( $p > 0.05$ ). With respect to ancestry, TP was recorded in 50% (7/14) of Africans, 80.5% (66/82) of Asians, 55.2% (101/183) of Europeans, and 92.9% (26/28) of Pacific Islanders. These differences indicate a significant effect of ancestry ( $p < 0.05$ ), with Europeans being far less likely to express TP than other subgroups. In contrast, TM was observed in 14.3% (2/14) of Africans, 32.9% (27/82) of Asians, 36.6% (67/183) of Europeans, and 32.1% (9/28) of Pacific Islanders. This indicates ancestry does not have the same impact on TM expression. Last, the two-way interaction between sex and ancestry was not significant for either torus, nor was the effect of age at death. Given these results, this study serves to contextualize the significance of these bony oral traits as indicators for ancestry, sex, and age at death of unknown skeletal remains in a forensic context.

**A114 How Do Agencies Use Biological Profile Data? A Pilot Study Investigating Stakeholder Engagement With Forensic Anthropological Estimates**

*Samantha M. McCrane\*, University of New Hampshire, Gainesville, FL; Allysha P. Winburn, University of West Florida, Pensacola, Florida; Amanda N. Friend, SNA International in Support of the Defense POW/MIA Accounting Agency Hawaii, Joint Base Pearl Harbor-Hickam, HI*

---

**Learning Overview:** After attending this presentation, attendees will understand how medicolegal personnel view the various aspects of the biological profile estimated by forensic anthropologists as well as where opportunities for miscommunication can arise.

**Impact Statement:** This presentation will impact the forensic science community by highlighting areas where forensic anthropologists' findings may be differentially interpreted by medicolegal personnel, indicating a need for more direct engagement between forensic anthropologists and client personnel as well as more clarity in communicating findings.

Over the past several years, the field of forensic anthropology has begun reevaluating how biological profile estimates are generated, reported, and potentially affect case outcomes. Special attention has been given to estimation of ancestry or population affinity and consideration of gender in addition to skeletal sex. Notable points of debate often center on the terminology used to report classifications as well as how terminology or a category of the biological profile itself could affect decedent identification.<sup>1,2</sup> Despite extensive engagement on what is considered best practice in anthropological casework, no research has directly engaged with the mode of communication between anthropology producers and their clients who act on the information.<sup>3-5</sup> In this research, we present preliminary data from a Qualtrics® survey aimed at understanding how forensic anthropological biological profile data are used by consulting agencies, and if differences arise in the identification process when a forensic anthropologist's reported findings are translated into missing persons profiles by non-anthropologist stakeholders.

Medicolegal personnel were recruited via the *AAFS Newsfeed*, listservs, and social media to participate in an online, anonymous, Institutional Review Board (IRB) -approved Qualtrics® survey. This survey asked participants to review three mock forensic anthropology case summaries involving an unknown individual with no Believed-To-Be (BTB) match and report the demographics for that decedent according to their typical protocols (i.e., by creating a NamUs profile or other standard procedure). Overall trends in reported demographics were analyzed across cases, as well as responses to questions about the value of particular biological profile aspects, and forensic anthropology consultations in general, to making identifications.

In total, 41 individuals answered at least a portion of the survey (17 individuals completed the survey). These individuals consisted of medical examiners or pathologists, operations directors, death investigators, forensic anthropologists, forensic artists, and other medicolegal personnel from the Midwest, Southeast, Southwest, and Northeast United States.

Most respondents (73.17%, or 30 individuals) utilized NamUs, but around a quarter (26.83%, or 11 individuals) did not. In general, sex, age ranges, and stature ranges were entered verbatim as stated in the forensic anthropology mock case summaries (regardless of whether NamUs or another standard operating procedure was utilized). However, discrepancies did arise when ancestry was entered, with respondents frequently utilizing different ethnic classifications (Hispanic/Latino, Hispanic/Latino and Black/African American, Uncertain, Other) based on the same description. Additionally, when a mock case reported both skeletal sex and indication of gender (i.e., pelvic morphology consistent with male individuals observed in a decedent wearing women's clothing and exhibiting indications of facial feminization surgery), respondents again listed different classifications (Male, Female, Unsure, Other, or combinations thereof) for screening missing persons' lists. When asked to rank the importance of the components of the biological profile in making identifications, sex was listed as the most important, followed by age, then stature, and finally ancestry/population affinity. Notably, just under half of respondents (46.15%) stated that they would exclude a missing person from consideration if one or more of the forensic anthropologist's biological profile estimates did not match a potential candidate.

While preliminary, this research contributes to a better understanding of how biological profile data are applied in processes of decedent identification and furthers a dialog aimed at bettering communication and facilitating the more accurate use of forensic anthropological reports. Furthermore, it elucidates areas where disjuncture can occur between forensic anthropologists' phrasing and medicolegal personnel's interpretations of their reports and highlights opportunities for collaboration to improve decedent identification processes on both ends.

**A115 Assessing the Reliability of the DSP2 Software for Skeletal Sex Assessment in a Modern Italian Reference Collection From Syracuse, Sicily**

*Henrietta Vita\*, Liverpool John Moores University, Liverpool, England; Constantine Eliopoulos, Liverpool John Moores University, Liverpool, England; Matteo Borrini\*, Liverpool John Moores University, Liverpool, England*

---

**Learning Overview:** After attending this presentation, attendees will understand the potential of the DSP2 sexing tool, as it is shown that it is highly accurate on a modern Italian skeletal collection.

**Impact Statement:** This presentation will impact the forensic science community by illustrating the applicability of the DSP2 sexing tool on a modern skeletal collection. This further validates DSP2 as an invaluable tool with universal application.

Sex assessment is an essential step in forensic as well as archaeological settings when examining human skeletal remains. The os coxae has been deemed the most reliable skeletal element to assess biological sex as it is sexually dimorphic. A variety of methods exist for attributing sex, some relying on the differential morphology between the male and female pelvis while others employing osteometry. DSP (Diagnose Sexuelle Probabiliste) is a free online software that relies on ten measurements of the os coxae that are then compared to an extensive database in order to statistically estimate sex. In the original publication, it is stated that the software can confidently be used on any anatomically modern human populations, thus making it suitable for forensic as well as archaeological applications. When building the reference dataset, 12 populations were included. The more recent version of the software (DSP2) utilized two additional collections. Both the original and second versions claim an accuracy rate of over 99%. Somewhat lower but highly significant results were obtained when the method was validated on different populations. DSP2 was tested on 133 individuals from Crete, Greece, showing an accuracy rate of 85.6%, while an 88.34% accuracy rate was shown on a mixed Brazilian population. The software has also been successfully validated in a virtual environment as well as on Pre-Colombian mummies.

The aim of the current study was to test the accuracy of the software on modern Italian remains as this population was not included in the original reference dataset nor has it ever been tested. A total of 51 individuals were included, 35 males and 16 females, with recorded sex, age at death, and cause of death. The remains were recovered from a cemetery in Syracuse, Sicily, in 1909 and are currently housed at the Museum of Anthropology and Ethnology in Florence, Italy. When employing DSP2, an overall accuracy of 88.2% was recorded with 100% accuracy for females and 85.71% for males. However, it is important to note that no individuals were misclassified, but not all males were classified due to the software's 0.95 posterior probability of correct group assessment. When taking into consideration only the individuals who were classified by DSP2, the accuracy rate reaches 100% for both sexes.

Further statistical analyses were conducted to calculate inter- and intra-observer error using the Technical Error of Measurement (TEM), relative Technical Error of Measurement (rTEM) as well as the coefficient of Reliability (R). All ten measurements were taken three times per individual, which served as the basis for the assessment of intra-observer reliability. Significant results were obtained with the highest rTEM being 1.72% and the lowest R being 0.97. To determine inter-observer reliability, eight ossa coxae were measured by a second observer using the same TEM, rTEM, and R. As expected, higher error rates were recorded than for intra-observer reliability, with the highest rTEM being 2.15%, but R was equal or higher to 0.94 in every case. For both inter- and intra-observer error, the measurement showing the highest error rates was SPU.

Overall, the study concludes that DSP2 is an excellent and reliable method for sex determination in an Italian population and its use is highly recommended. This further solidifies the software's claim to non-population specificity.

## A116 Sex Estimation of Modern Greek-Cypriots Utilizing Measurements of the Calcaneus and Talus

Anelis Diaz\*, University of Central Florida, Winter Park, FL; Georgia Hennessy\*, Plymouth Marjon University, Bristol, England; Erica Baer, Kean University, Union, NJ; Xenia Paula Kyriakou, University of West London, Fort Myers, FL

**Learning Overview:** This presentation utilizes a forensic approach to osteometrics from the calcaneus and talus to establish sex estimation models for modern Greek-Cypriots. After attending this presentation, attendees will better understand the applications of binary logistic regression in forensic anthropology for purposes of sex estimation and the benefit of considering a stepwise backwards approach to develop models for individual and combined skeletal elements.

**Impact Statement:** The research conducted will impact the forensic science community by showcasing the application of statistical methods in the development of population-specific standards for human identification. It will inform the forensic science community on the validity of sex estimation models for modern Greek-Cypriots.

Population-specific standards are very important in human identification due to the biological variation that characterizes human populations. In humanitarian forensics, the application of osteometry provides an objective level of validation for sex estimation. Proxy populations serve geographical regions where religious guidelines prevent access to human skeletal remains for research or war prevents research from being conducted. Metric sex estimation models on small bones such as those in the ankle are not as prominent as cranial and long bones studies. This research aimed to use measurements of the calcaneus and talus to estimate biological sex of modern Greek-Cypriot individuals to create population-specific reference data. Metric assessments were performed on a total of 270 calcanei (left = 134, right = 136) from 144 individuals (males = 70; females = 74) and on a total of 208 tali (left = 103, right = 105) from 118 individuals (males = 61; females = 57). A total of 27 measurements were taken, 13 for the calcaneus and 14 for the talus. The measurements were adopted from a combination of publications and names were adapted for database recording purposes.<sup>1-8</sup>

Binary logistic regression analysis using k-fold cross validation was utilized to determine if the measurements taken could predict biological sex. The independent-samples *t*-tests showed that all measurements conducted on the calcanei and tali are significantly smaller for females than males ( $p < 0.05$ ). Additionally, approximately half of the measurements for both the calcanei and tali were significantly different than their antimeres ( $p < 0.05$ ). The calcaneus showed classification accuracy of 75.83% and 79.97% for the right and left side, respectively. The talus showed a classification accuracy of 75.54% and 77.62% for the right and left side, respectively. Last, stepwise regression was utilized to exclude measurements not beneficial to the models. The reduced models showed increased accuracies for the calcaneus (right = 84.62%; left = 84.62%) and talus (right = 85.71%; left = 86.52%). Overall, the results indicate a good but not great validity for the classification of sex utilizing osteometric data, with the talus having higher classification accuracy than the calcaneus. Although sex estimation using these skeletal elements may be possible, results should be considered with caution and utilize reduced, more effective measurements.

**A117 Sexual Dimorphism in the Human Mandible: The Application of 3D Statistical Shape Modeling**

*Yu-Young Kim\*, MS, Yonsei University, College of Dentistry, Seoul, Republic of Korea; Kang-Woo Lee, PhD, School of Mechanical Engineering, Gwangju Institute of Science and Technology, Seoul, Republic of Korea; Kyung-Seok Hu, DDS, PhD, Yonsei University, College of Dentistry, Seoul, Republic of Korea*

---

**Learning Overview:** This presentation demonstrates the ability to distinguish sex through the human mandible using 3D statistical shape modeling. After attending this presentation, attendees will understand what 3D statistical shape modeling is and how it serves as a useful method in estimating sexes or age groups through bone morphology. Furthermore, attendees will gain insight into the morphological differences in the mandible between males and females in a 3D aspect, which is the main agenda of this presentation.

**Impact Statement:** This presentation will impact the forensic science community by illustrating that sex estimation through bone morphology could be made in quantitative method: the application of 3D statistical shape modeling. Moreover, this presentation fosters interdisciplinary collaboration between forensic anthropology and medical engineering in pursuit of accurate and precise identification methodologies.

Statistical shape modeling allows for the creation of an average 3D model specific to groups (such as by sex or age) and also produces various models through statistical shape analysis of a group. Therefore, the application of statistical shape modeling could facilitate a more quantitative and accurate method for sex or age estimation in forensic anthropological context. This presentation will illustrate sex-specific differences in the human mandible, based on statistical shape models, and evaluate their utility in sex classification.

The analysis utilized 3D mandible data, derived from Computed Tomography (CT) scans of 44 cadavers each from Korean adult male and female subjects. To concentrate on the morphology of the mandible, teeth and the alveolar bone were excised, followed by a necessary post-processing procedure. The processed mandible data was analyzed with *ShapeWorks*, an open-source software specialized in statistical shape analysis. Morphological differences between average mandible models of each sex were visualized using vector data and statistical significance was tested.

In comparison of the average shape models, there were no significant differences in the overall size between males and females. However, certain regions exhibited disparity. Notably, the mandibular condyle and coronoid process were more medially developed in males, resulting in a narrower overall width compared to females. In addition, males demonstrated lateral development at the gonial angle and superior development at the extramolar sulcus. The female mandible body itself appeared more anteriorly developed, suggesting a longer anterior-posterior length in females compared to males. Of these, the gonial angle region and extramolar sulcus demonstrated statistical significance ( $p < 0.05$ ). The classification learner in MATLAB® was trained based on the Principle Component Analysis (PCA) scores from the statistical shape analysis, and the Efficient Linear Support Vector Machine (SVM) yielded the highest classification accuracy of 76.1%. In this training scheme, Analysis of Variance (ANOVA) and Kruskal Wallis tests revealed that Principal Components (PC) 49 and 12 reflect important features in classifying sex. PC 49 represents morphological changes in the coronoid process, while PC 12 reflects changes in the mandibular condyle and gonial angle.

The present research suggests substantial insights of the sexual dimorphism in human mandible morphology and emphasizes the capability of statistical shape modeling in forensic anthropology. Moreover, this study could lay a groundwork for the development of a classification model based on mandible morphology.

The presenter gratefully acknowledges the human data support provided by Korea Institute of Science & Technology Information (KISTI) which produced these data with the Catholic University of Korea.

**A118 The Ontogenetic Development of the Preauricular Sulcus and Its Utility in Estimating Sex in Children and Young Adults With Considerations for Pregnancy and Parturition**

*Stephanie J. Cole\**, The Ohio State University, Columbus, OH; *Marin Pilloud*, University of Nevada, Reno, Reno, NV; *Kyra Stull*, University of Nevada, Reno, Reno, NV

---

**Learning Overview:** After attending this presentation, attendees will have increased knowledge regarding the ontogenetic development of the preauricular sulcus.

**Impact Statement:** This presentation will impact the forensic science community by providing information regarding the utility of the preauricular sulcus as a sex indicator in children and young adults and whether pregnancy or parturition are likely to impact trait expression.

The utility of the preauricular sulcus in sex estimation has long been debated, and it has been suggested that this trait may be indicative of pregnancy and parturition. Recent studies have investigated these questions using adult samples and have found that the preauricular sulcus is sexually dimorphic and parity status is not likely to significantly impact trait expression.<sup>1</sup> To better understand the applicability of the preauricular sulcus in estimating sex in children and young adults, the trait's ontogenetic trajectory was examined using a large sample of postmortem computed tomography scans of known individuals ( $n = 583$ ,  $m = 358$ ,  $f = 225$ ) aged 8 to 20 years from the Subadult Virtual Anthropology Database (SVAD). Eight years was chosen as the lower limit to match the age that females from the United States typically enter puberty, since hormone-mediated changes occurring in females at puberty lead to the differences in pelvic morphology that allow for differentiation between the sexes.<sup>2</sup> Trait expression was assessed following the three-stage scoring procedure outlined in *The Ontogenetic Subadult Sex Estimation System (OnSEt) Manual*, where a score of 1 represents pronounced expression, a score of 2 represents minor expression, and a score of 3 indicates the trait is absent.<sup>3</sup>

Two different approaches were used to explore the ontogenetic trajectory of the preauricular sulcus. The first was to determine when the sexes diverge in trait expression. Ridge plots of trait score frequencies for each sex and annual age cohort were generated to visualize when score frequencies first become disparate. Differences in trait score frequencies between subadult males and females were also evaluated using Chi-square or, for comparisons using small samples ( $n < 5$ ), Fisher's exact test of independence with Monte Carlo simulation. The second approach was to determine the age at which full expression was reached in each sex. Full expression was considered attained when there was no further change in score frequencies with advancing age. Kruskal-Wallis with a Dunn's test and Holm's stepwise adjustment were used to determine the age at which score frequencies stabilized for each sex. The SVAD is comprised of cross-sectional data; thus, the preauricular sulcus of each individual in the sample was only evaluated once, and the onset of sexual dimorphism between the sexes and the attainment of full expression within the sexes was inferred based on changes occurring across chronological age cohorts.

Significant sex differences in trait score frequencies were observed by 13 years of age. Females 13 years of age and older were most frequently assigned a score of 1 (48.7%), followed by scores of 2 (36.1%) and 3 (15.2%). Conversely, males 13 years of age and older were most often assigned a score of 3 (66.3%), followed by a score of 2 (33.0%), with scores of 1 being rare (0.7%). Full expression was attained between 17 and 19 years for females. No significant differences in trait score frequencies were observed for males across any age cohorts, meaning full expression was already attained by 8 years.

The results indicate the preauricular sulcus is a useful trait for estimating sex in the young, with a score of 1 being strongly suggestive of female classification, and a score of 3 being fairly suggestive of male classification after 13 years. Although pregnancy and parturition information are not available for the sample used in this research, the high frequency of scores of 1 for many adolescent females strongly suggests that pronounced expression of the preauricular sulcus cannot be associated with parity alone, which is in agreement with studies that have investigated this question using adult samples.

**Juvenile; Puberty; Sex Assessment**

**A119 The Utility of the Maxillary Sinus in Estimating Biological Sex in a Modern American Population**

Abigail Elaine Houkes\*, University of Illinois Urbana-Champaign, Savoy, IL

**Learning Overview:** After attending this presentation, attendees will: (1) be familiar with the maxillary sinus as a predictive element for estimating biological sex in forensic anthropology, and (2) be informed about automatic 3D model-based methods for measuring the maxillary sinus.

**Impact Statement:** This presentation will impact the forensic science community by: (1) providing recommendations on the potential of the maxillary sinus for predicting biological sex, and (2) addressing the current drawbacks and limitations in research on sexual dimorphism in the maxillary sinus.

Forensic anthropologists develop biological profile estimates (biological sex, ancestry, stature, and age) from skeletal remains to provide an investigative lead to law enforcement and, in turn, the public about the decedent. The maxillary sinus has recently been examined as a potential tool for estimating biological sex within forensic anthropology.<sup>1,2</sup> This current research examines biological sex variation of the maxillary sinus's volume and dimensions using a 3D model constructed from Computerized Tomography (CT) scans within a contemporary United States population. The research study aims to: (1) determine whether there are differences between the right and left maxillary sinuses, and (2) examine whether the maxillary sinus exhibits sexual dimorphism.

The reference sample ( $n=90$ ) used for this research study included 45 identified males and 45 identified females. The sample was drawn from the New Mexico Decedent Image Database.<sup>3</sup>

The dependent variables of this study (maximum height, length, width, volume, and surface area) were examined using 3D modeling of CT scans through 3D Slicer® and MeshLab® following Robles et al. protocol and measured automatically in a uniform manner in Meshmixer®.<sup>4</sup>

Data were analyzed using JMP Pro16.1.0. Univariate descriptive statistics for the male and female samples were calculated for the linear dimensions (maximum length, width, and height), volume, and surface area. A paired t-test was used to test for significant differences between the right and left sides of the maxillary sinus. To test for sexual dimorphism between males and females, paired two-tailed t-tests were conducted using the measurements of the left maxillary sinus (given that there was no significant difference between the sides of the maxillary sinus).

Results of these t-tests reveal no significant differences between the right and left sides of the maxillary sinus or between the biological sexes ( $p > 0.05$ ). The statistically insignificant results between biological sexes contradict international studies stating that the maxillary sinus is a tool that can be utilized for biological sex estimation.<sup>5-7</sup> However, these results could either indicate: (1) that sexual dimorphism within a United States population is lower than in international samples, (2) sample sizes need to be increased to account for more population variation and to better interpret results, and (3) automated measurements from 3D models differ from measurements taken from 2D measuring techniques.

The reliability of the Robles et al. method to construct and segment, and isolate the model, as well as the methods used to measure the maxillary sinus, were assessed through intra-observer error rates. Considering  $p > 0.05$  for intra-observer error, intra-observer error was insignificant, indicating high reliability.

These results indicate that the maxillary sinus does not exhibit significant sexual dimorphism and, as such, may not be applicable in forensic anthropological casework. However, further validation studies of previous research are recommended regarding the: (1) collection of 2D versus 3D maxillary sinus measurements, and (2) automation of maxillary sinus measurements versus manual measurements. Such studies will aid in determining the validity of using maxillary sinus as a sex estimation method for forensic anthropological casework.

**Anthropology; Sex Assessment; Sexual Dimorphism**

**A120 Translating Results: Accessing Accuracy Within Sex Estimation Methods From the Biological Profile**

McKenzie Macon\*, University of Illinois at Urbana-Champaign, Harvey, IL; Cris E. Hughes, University of Illinois at Urbana-Champaign, Urbana, IL

**Learning Overview:** This presentation will utilize the Forensic Anthropology Database for Assessing Method Accuracy (FADAMA), focusing specifically on sex estimation methods used within the United States to demonstrate the importance of assessing method accuracy utilizing a repository where the decedent-identified sex is known. After attending this presentation, attendees will better understand that individual sex estimation methods that are used in high frequency have high accuracy rates and are comparable to the case-report level accuracy found in earlier studies.

**Impact Statement:** This presentation will impact the forensic science community by indicating to forensic anthropologists that the most common sex estimation methods appear to have consistently high accuracy. However, when considering overall method validation, both reproducibility and reliability may vary for sex estimation methods. Although methods such as “generalized morphology” are consistently used in casework and provide high accuracy rates for the FADAMA study sample, forensic anthropologists should be cautious when utilizing this method due to its highly subjective approach. If generalized morphology continues to be used in casework, it should undergo reproducibility and reliability assessment using an appropriate study model (e.g., black box study) to establish its validity.

Forensic practitioners are able to utilize a variety of methods to draw conclusions for the estimation of the biological profile, with recent studies indicating accuracy for sex estimation to be around 98% at the *case report level*.<sup>1,2</sup> However, the accuracy for the sex estimation at the *method level* should also be assessed in order to compare to the collective outcomes as reported at the *case report level*. The present study explored method-level accuracy for some of the most frequently used sex estimation methods, based on a robust sample of United States forensic anthropology casework from FADAMA. FADAMA cases (n = 641; cases submitted to FADAMA at the time of download on July 9, 2023) were analyzed to infer the methods that had the highest frequency of application, and the top six methods were selected for further analysis. Accuracy (whether the practitioner’s sex estimation matched the decedent’s identified sex) was assessed for the six methods and yielded rates of accuracy between 97% to 100%, which is comparable to the 98% accuracy of case-report level sex estimation accuracy in a FADAMA sample.<sup>3</sup>

Generalized Morphology (GM) was one of the top six most frequently used sex estimation methods for the FADAMA dataset. GM is an approach where the forensic anthropologist chooses to focus on whatever aspect of the skeletal remains indicate sexual dimorphism to them, which may or may not incorporate non-metric traits associated with other methods and is not grounded in statistical analysis nor applies/considers the same features for each case. GM in particular stood out because, unlike other methods, it is not validated nor grounded in statistical inference, yet provided accuracy rates comparable to the other five studied methods, compelling further analysis to assess its validity. Thus, it was next assessed whether GM’s accuracy rate remained high when being used in isolation (i.e., only method used to estimate for sex for given case, n = 52) as compared to when it is being used in conjunction with other methods (n = 150). Out of the 150 cases, accuracy was 99% when GM was utilized in conjunction with other methods and 96% when utilized in isolation. While the GM’s accuracy appears to be consistently robust, accuracy is not the only component when establishing a method’s reliability. GM continues to be utilized in practice, given that over 50 cases use it as the sole method for estimating sex and its application remains consistent even within the past decade of casework. As such, GM should undergo reproducibility and repeatability testing comparable to the “black box study” approach recommended for subjective methods in the 2016 President’s Council of Advisors on Science and Technology Report.<sup>4</sup>

## A121 Creating Continuity: The Proper Handling of Unprovenanced, and Unidentified, Legacy Forensic Cases and Prevention of Future Mishandling

*Chelsey A. Juarez\*, California State University Fresno, Fresno, CA; Alison Galloway, University of California Santa Cruz, Volcano, CA*

**Learning Overview:** This presentation will provide a workflow for dealing with unprovenanced and unidentified forensic material encountered as a result of retirements, job vacancies, and mishandling. After attending this presentation, attendees will better understand how to deal with unprovenanced unidentified skeletal material of forensic significance in a laboratory or university setting.

**Impact Statement:** This presentation will impact the forensic community by highlighting the problem of mishandled forensic legacy skeletal materials, providing achievable solutions for handling such collections and preventing their existence in the first place.

Although increasingly more rare, human skeletal material from forensic cases may be retained in forensic anthropology laboratories when cases remain unidentified. In some instances, cases may remain unidentified, stored in labs for years while undergoing yearly reevaluations with new techniques. During periods of transition, such as retirements, changing of jobs, closing down, or consolidation of labs or departments, such “legacy” forensic cases can get lost, only to be found again by someone that has no knowledge of their existence. Currently, we are at an inflection point in the discipline, since for the first time in the disciplines’ history, we have large populations of forensic anthropologists of retirement age that are beginning to give up their labs and step away from their practice. When continuity is lost, provenance information, report data, and even general knowledge of the remains existence may be lost.

Recently the Fresno State Forensic Anthropology Laboratory encountered a large forensic legacy skeletal collection lacking in any documentation. In the section below, we discuss: (1) encountering a skeletal collection and what first steps should be taken, (2) how to ensure that there is continuity while on the job, and (3) what to do at the time one departs a position when a replacement is uncertain.

If you encounter undocumented human remains, the first step is to review all cases to assess whether it is: (1) forensic, (2) archaeological, or (3) anatomical. Forensic significance can be established by the presence of modern skeletal or dental alterations, possible connections to historic/prehistoric populations, associated grave goods, or remaining documentation. One should prepare new peer-reviewed case reports on all material. C<sup>14</sup> bomb testing is recommended for any remains in which the time of death is uncertain and samples for DNA testing should be submitted to the appropriate authority. Reestablish chain of custody by contacting all potential law enforcement entities and sharing an electronic drive containing an inventory, biological profiles, and photographs of the remains.

Creating continuity requires access to information by individuals outside of the laboratory space. Create a lab electronic repository (like Google® drive shared with others who are in a position to step in if needed). Make sure you have an accounting of all human skeletal material associated with your laboratory, both forensic and non-forensic, where it is located. This inventory should be placed in the electronic repository. Consider an outside audit to review standard operating procedures, handling and storage of material, equipment needs, etc.

When one leaves a position, whether by retirement or subsequent employment, this often means that both lab and secured storage is lost. If another qualified person or agency is assuming the responsibilities of casework, then the material can be transferred to their care. However, if that is not the case, the departing anthropologist must secure their cases so nothing is lost if needed in the future.

If the anthropologist is a consultant to a number of agencies, steps must be taken. (1) Skeletal material and other items, such as radiographs, should be returned to the consulting agency. (2) Case files should be digitized and copies sent to the consulting agency. Unless there is secured storage available, hard copies of the case files are often best returned to the agency as well. (3) Digitized copies of cases should be retained by the anthropologist in case their testimony is needed at a future date. (4) A “death plan” should be established so heirs know what should be done with any case material when the anthropologist dies.

**A122 Identification Trends in Forensic Anthropology Cases at the New Mexico Office of the Medical Investigator**

*Nicollette S. Appel\**, University of New Mexico, Glen Head, NY; *Cris E. Hughes*, University of Illinois at Urbana-Champaign, Urbana, IL; *Paige Lynch*, Environmental Archaeology Laboratory, Albuquerque, NM

---

**Learning Overview:** This presentation examines identification trends in forensic anthropology casework at the Office of the Medical Investigator (OMI) in New Mexico, building on recent analyses of United States forensic casework that examined how decedent demographics related to identification success by Hughes and colleagues.<sup>1</sup> After attending this presentation, attendees will understand that OMI decedent demographics and biological profile estimations do relate to identification rates and identification method for decedent race, but not sex and age.

**Impact Statement:** This presentation will impact the forensic science community by highlighting how agency-specific analyses provide insight into how decedent demographics and biological profile estimations are related to investigations. The identification trends presented also more broadly show how societal contexts may play a part in how identifications are made.

There are continuing dialogs among practicing forensic anthropologists as to whether decedent demographics and biological profile estimations, in particular population affinity, should be provided in formal reports to death investigators. Before broad changes are made to how forensic anthropologists contribute to the investigative process, extensive scientific analyses must be done to prove or disprove whether forensic anthropological estimates foster biased investigative outcomes.

Previous research examined forensic anthropology case data of more than 1,200 identified and unidentified persons broadly representing United States forensic anthropology casework.<sup>2</sup> The authors emphasized that trends are likely agency or region-specific, and thus more research should be performed at local agencies to compare the trends found in the broader United States study. The present study addressed this need by focusing on trends for the OMI. Based on the most recent annual report of OMI cases with known race/ethnicity information, 49% are a race/ethnicity other than White, Non-Hispanic. Within this group, 71% are Hispanic, 22% are Native American, 6% are Black, and 2% are Asian/Pacific Islander.<sup>3</sup> This large proportion of Black, Indigenous, and People Of Color (BIPOC) decedents provides an appropriate dataset to expand the questions of whether decedent demographics are related to identification success.

To infer whether differences in identification rate correspond with decedent demographics, comparisons using Fisher's Exact test were made between identification status and decedent race/ethnicity, sex, or age. The sample included individuals with a biological profile estimated by a forensic anthropologist from 2017–2023 at the New Mexico OMI (n=68). Further analysis with Fisher's Exact test examined the relationship between positive identification methods (i.e., DNA, dental records, fingerprint comparisons) and decedent race/ethnicity, sex, or age. This sample included all individuals that had a forensic anthropological analysis performed, regardless of whether a biological profile was estimated (n=182).

There is a significant relationship between identification status and decedent race/ethnicity (two-sided test, p value = 0.0055), with identification rates greatest for Native American (86% identified) and White (67% identified) decedents compared with lower rates for Black (28% identified) and Hispanic (25% identified) decedents. Identification methods also differed significantly among decedent races (two-sided test, p value = 0.003), with DNA identifications more common for Black and Hispanic decedents, and dental identification more common in Native American and White decedents. Fingerprint identifications were most common in Hispanic and Native American decedents. Decedent sex and age had no significant relationship with identification method or status. These findings indicate that decedent race has a significant relationship with both identification method and identification status for the OMI sample, further highlighting the agency-specific trends relating to investigative outcomes. Contextual factors potentially contributing to the observed trends will be addressed in this presentation.

**A123 Forensic Anthropology Casework and Outreach: 50 Years of Operational Trends for Chico State's Human Identification Laboratory**

*Colleen Milligan\*, California State University, Chico, Chico, CA; Eric J. Bartelink, California State University, Chico, Chico, CA; Cheyenne D. Collins, California State University Chico, Chico, CA; Taylor Lambrigger, Chico State University, Chico, CA; Ashley Kendell, California State University, Chico, Chico, CA; Shannon Clinkinbeard, California State University, Chico, Lincoln, CA; P Willey, Chico State University, Chico, CA*

---

**Learning Overview:** This presentation provides a historical perspective regarding Chico State's Human Identification Laboratory's (HIL) impact to California's medicolegal and first responder community through both casework and outreach. An emphasis on training, especially during the past two decades, has produced a substantial increase in cases submitted to the HIL. After attending this presentation, attendees will understand the pivotal role that outreach has on increasing casework and involvement in mass fatality responses.

**Impact Statement:** This presentation will impact the forensic anthropology community by demonstrating that outreach in the form of education and training has a dramatic effect on increasing casework and improving statewide disaster responses.

A recently published study finds several factors that affect forensic anthropologists' annual caseload.<sup>1</sup> Those most notable factors include the number of search and recovery reports produced annually, the publication record, and the institution where the doctoral degree was received. However, the study failed to identify one of the most important factors: outreach training and education.

Although beginning casework 50 years ago, Chico State's HIL initially received few cases. Some early years saw little to no casework. Over the decades, the annual caseload increased dramatically, especially in the past two decades. The first three decades of lab operations saw an average caseload of ten cases per year. The past two decades saw an average caseload of 70 cases per year. That rise in caseload is correlated with an expansion in outreach and training, especially since 2012. The past decade of lab operations has seen an increased average caseload of 112 cases annually. The largest single factor for the HIL's increasing caseload can be tied to medicolegal outreach and training. Between 1974 and 2011, the HIL worked with 52 agencies, steadily adding new partners over that period. By 2012, HIL faculty and staff significantly increased yearly training courses and workshops, most notably becoming instructors in homicide courses within California's Peace Officer Standards and Training system (POST). Between 2012 and 2022, the HIL added an additional 91 new agencies. Of the current agencies the HIL works with on cases and recoveries, 64% of the agencies were added after 2012.

California is currently seeing an increase in the frequency and size of mass fatality events. While wildfires are the largest disaster threat each year, flash floods, mudslides, and earthquakes have also contributed to California's mass fatality events. Chico State's increased partnership with agencies across the state is valuable for another reason: mass fatality response. The deadliest and most destructive wildfire on state record was the 2018 Camp Fire. Through California's mutual aid system, nearly every county in California sent resources to that event, including their search and rescue personnel. Local and state agencies' familiarity with the HIL allowed the lab to play a centralized role in victim recovery and identification from that event. That led to the HIL communicating with state officials on improving future disaster responses and again increased the resulting yearly trainings that the HIL provides. Since 2018, the HIL has trained more than 3,000 medicolegal professionals through annual continuing education courses and workshops and through "Just in Time" training on disaster sites. The HIL conducts annual outreach training for an array of medicolegal professionals and first responders, including: law enforcement agents (POST); death investigators and coroners (California State Coroners' Association); search and rescue personnel (Search and Rescue Workshops); state emergency managers (California Office of Emergency Services); cold case investigators (California Department of Justice's Missing and Unidentified Persons); and fire investigators. By regularly and frequently presenting to these groups, providing lectures, and conducting workshops, authorities remain aware of the laboratory's presence and expertise as well as its role as a statewide deployable resource.

---

**A124 The Evolution of Forensic Anthropological Casework: Exemplifying the Importance of Routine Reanalysis of Long-Term Unidentified Remains at the Forensic Anthropology Center at Texas State (FACTS)**

*Emilie Wiedenmeyer\*, Texas State University, Kyle, TX; Theresa M. De Cree, Texas State University, San Marcos, TX; Michelle D. Hamilton, Texas State University, San Marcos, TX*

---

**Learning Overview:** After attending this presentation, attendees will better understand the necessity of systematically reviewing long-term unidentified human remains cases with new methodologies through a summary of casework reanalysis conducted at the FACTS. The assessment of updates to biological profile estimations with the use of new methods will be illustrated via a quantitative analysis of past and present case work.

**Impact Statement:** This presentation will impact the forensic science community by highlighting the importance of continued commitment and advocacy for the long-term dead and the significance of reviewing open cases in forensic humanitarian casework.

Forensic anthropologists in academic settings will sometimes store and maintain unidentified human remains following analysis until positive identification is assessed by the proper jurisdictional authority, enabling return to the next-of-kin. When these individuals remain unidentified despite forensic analytic efforts, they can be relegated to curation for an extended period pending updates, sometimes spanning decades. In these situations, proper stewardship and continued commitment to identification is paramount to resolving these cases and continuing to advocate for the long-term dead.<sup>1</sup>

When requested by jurisdictional authorities, FACTS consults on forensic cases and often maintains custody at the request of authorities until identifications are made. As of this writing, 58 forensic cases have been held at FACTS for more than five years with no further updates, with original dates of analysis for 22% of those cases occurring prior to 2005 and the earliest dating back to 1967. Several punctuated efforts have been made since then to reanalyze these cases and update all case reports, resulting in the majority of cases being examined at least twice. A select few were also included in a third round of analysis as part of an initiative started at FACTS in 2021 to systematically review all casework. This presentation summarizes the changes in resultant biological profiles over the course of all documented analyses. All assessments used the most current and accepted forensic anthropological methods and statistical programs available at that time.

Of the 58 forensic cases still in FACTS custody, 32 have been reexamined thus far, resulting in updates to all 32 biological profiles and one count of Minimum Number of Individuals (MNI). Changes made to all biological profile components and MNI estimations following each round of analysis were recorded. Any increase or decrease from the original range for stature ( $\pm 1$  inch) and age ( $\pm 5$  years) were noted as changed from the original estimate, and any modification from indeterminate to more specific (or vice versa), as well as complete change to a different category, were noted for both sex and population affinity.

After the first round of reanalysis in the 32 cases, approximately 28% of sex estimations, 75% of age estimations, 44% of population affinity estimations, and 37.5% stature estimations changed from their original results, and one case required a change to MNI. Following the second round of FACTS analysis, which included only six cases, approximately 17% of sex estimations, 83% of age estimations, 33% of population affinity estimations, and 17% of stature estimations required adjustments.

These updates have resulted in 16 of the 19 cases currently entered in the National Missing and Unidentified Persons System (NamUs) requiring official changes to their entries. The cases with recorded methodologies showed diverse changes in cited literature over time, with certain methods trending in similar years. However, changes to biological profile estimations notably evolved with different versions of software applied, exemplifying the impact of more inclusive samples and robust statistics.

These results emphasize the importance of revisiting all long-term unidentified casework with updated methodologies at regularly spaced intervals. Renewed efforts can result in more specific and/or accurate estimations due to new or improved methodologies, updated reference data, and increased practitioner knowledge and experience over time. As stewards of individuals who are often marginalized in life and are still vulnerable in death, forensic anthropologists can serve as advocates for the unidentified by implementing regular reanalysis of open cases.<sup>2</sup> By highlighting this ongoing reanalysis from an academic forensic anthropology laboratory, our hope is to continue the conversation of how to hone our strategies in identification efforts to best serve unidentified individuals in these settings.

---

**A125 A Comparison of Forensic Anthropology Casework Across Two Urban, Midwest Medical Examiner Offices, 2013–2021**

*Erin B. Waxenbaum\*, Northwestern University, Evanston, IL; Lindsay H. Trammell, St. Louis County Office of the Medical Examiner, Berkeley, MO; Anne Grauer, Loyola University Chicago, Chicago, IL*

---

**Learning Overview:** After attending this session, attendees will have an appreciation for the similarities and differences in forensic anthropology casework between two urban, Midwest medical examiner jurisdictions: the Cook County Illinois Medical Examiner's Office and the St. Louis County Office of the Medical Examiner between 2013–2021.

**Impact Statement:** This presentation will impact the forensic science community by helping attendees appreciate comparative forensic anthropology casework between two geographically similar urban medical examiner offices and be able to more broadly compare data to better understand how forensic anthropology practitioners are utilized across jurisdictions.

Forensic anthropology has garnered greater attention in the academic and medicolegal community with more practitioners embedded in Medical Examiners and Coroners' (ME/C) offices and increased coursework and forensic-oriented graduate programs offered at colleges and universities across the country. However, practitioners situated within the medicolegal system often have varied roles and responsibilities, with few opportunities to compare the nature, breadth, and outcomes of their casework with others. Sharing data will provide foundations upon which resource distribution, planning, and needs assessment can be based, and provide essential information for training the next generation of professionals in the field.

The present analysis compares work conducted by three forensic anthropology practitioners across two jurisdictions: two working as part-time consultants and one employed full-time within a Medical Examiner's Office (MEO). In the Cook County MEO (CCMEO) of Illinois, two anthropologists (EBW and ALG) consult on a part time, case-by-case basis. The St. Louis County, Missouri MEO (SLMEO) employs one full-time forensic anthropologist (LHT) who worked concurrently as a medicolegal death investigator during the period under analysis.

With the objective of comparing the composition of forensic anthropology casework at the CCMEO and the SLMEO between 2013–2021, the following variables were recorded and compared: month of discovery, decedent depositional environment, condition of remains upon initial discovery, type of anthropology consult requested, time from discovery to consultation request, time from consultation request to analysis, and time from analysis to report submission.

Between 2013–2021, forensic anthropologists working at the CCMEO completed a total of 119 cases (13.2 cases per year) with SLMEO completing 339 cases (37.6 cases per year). The greatest number of cases occurred at the CCMEO in 2021 (n=19) and the fewest occurred in 2020 (n=8). For SLMEO, the greatest number of cases occurred in 2019 (n=61) and the fewest in 2013 (n=19). A majority of cases at the CCMEO were discovered in June (n=18) and the fewest in December (n=1), while at the SLMEO, the majority of cases occurred in April (n=35), with the fewest cases discovered in January (n=19). Most cases were outdoor, surface recoveries for both jurisdictions. Upon initial discovery, a majority of cases for the CCMEO were in a stage of decomposition (52.1%), while for SLMEO, a majority of cases were fully skeletonized (50.4%). While consult requests may include multiple components, for the CCMEO, 68.9% of requests included biological profile estimation, while for SLMEO, 32.7% included radiographic identification—a task assigned to full-time radiology technicians at the CCMEO. On average for the CCMEO, 77.8 days elapsed from discovery to anthropology consult, 60.8 days from consultation request to anthropology visit, and 13.2 days from anthropology analysis in person to report submission. For the SLMEO, 4.3 days elapsed from discovery to anthropology consult, 2.2 days from consultation request to anthropology analysis, and 7.6 days from anthropological analysis to report submission. This is a direct result of the difference between employment within vs. outside the MEO context and the type of consult request.

The role and breadth of forensic anthropology is expanding both academically and within the medicolegal community. Greater discussion and comparison of the range of services, support, and expertise that forensic anthropologists provide ME/C offices broadens the understanding of the field, allows for the formulation of best practices, and serves as data upon which decisions regarding protocol, funding, resources, and need can be based. With additional practitioners collecting and sharing their data, a clearer window into the scope and utility of the field will be appreciated by both our colleagues and the greater forensic scientific community.

---

**Anthropology; Casework; Consultation**

## A126 Introducing the Forensic Science Research and Training Laboratory (FSRTL), a New Forensic Anthropology Research Facility at George Mason University

*An-Di Yim\*, George Mason University, Fairfax, VA; Emily D. Rancourt, George Mason University, Fairfax, VA; Joseph A. DiZinno, DDS, George Mason University, Fairfax, VA; Brian Eckenrode, George Mason University, Manassas, VA; Kimberly Rule, George Mason University, Fairfax, VA; Christopher Durac, George Mason University, Fairfax, VA; Mary E. O'Toole, George Mason University, Fairfax, VA*

**Learning Overview:** After attending this presentation, attendees will have a better understanding of the history, ongoing research efforts, and expected results as well as opportunities for collaboration afforded by the FSRTL at George Mason University (GMU).

**Impact Statement:** This presentation will impact the forensic science community by highlighting the ongoing processes and research at the FSRTL at GMU and offering opportunities to collaborate and advance knowledge in forensic taphonomy.

This presentation introduces the FSRTL, a human decomposition research facility at GMU. The human decomposition facility was first proposed in 2018, in recognition of the need for a forensic anthropology research facility in the mid-Atlantic region that contributes to a deeper understanding of the geographic variation in human taphonomy as well as develops practical forensic applications that aid federal and local agencies in the Washington metropolitan area. Approval from GMU was granted in 2020 and the facility was opened in 2021 on the Science and Technology Campus of GMU in Manassas, VA. The five-acre facility is located in a flat, wooded area and divided into an inner one-acre area dedicated to human decomposition research and an outer four-acre area for training and animal decomposition projects. Research to establish baseline environmental data has been completed to date.

A survey of the literature showed gaps in research that the FSRTL will fulfill. Using “forensic taphonomy” as the search keyword, we identified 107 entries in the *Journal of Forensic Sciences* between 1981 and 2023 on the Web of Science database. Of these, 23 (21.5%) were research articles or case studies conducted in human decomposition research facilities in the United States. The majority of the studies (12 studies, 52.2%) focused on decomposition rates, progression, or estimation of postmortem interval, while 30.4% (seven) of the studies reported scavenging patterns. Ongoing research at FSRTL will focus on the location and identification of human remains while supplementing research efforts with baseline data on geographic variation in scavenger activities and decomposition rates and progression.

At present, donors at FSRTL are accepted through the Virginia State Anatomical Program (VSAP), an agency within the Virginia Department of Health specializing in processing and receiving donations of human bodies for scientific study. The VSAP processes and transports the donors to the facility to be placed and provides documentation such as informed consent of donation, basic demographic information (sex, age, self-identified race, self-reported height and body weight), basic life and medical histories, as well as results of additional serology exams to GMU. The first donor is expected to be placed in the second half of 2023, with a second donor following before the end of 2023.

Plans are in place to collect more information regarding lifestyle, life, and medical histories, all of which will be made available in the future for research. Biological samples from donors will also be collected and stored for further DNA analysis. Current ongoing research efforts include establishing regional data regarding decomposition rates, progression, and scavenger activity, methods to identify clandestine graves, and methods to improve DNA recovery.

Finally, this presentation also provides information regarding the infrastructure that is in place to facilitate collaboration requests from interested researchers and future plans to develop data-sharing mechanisms.

---

### Forensic Anthropology; Human Decomposition; Taphonomy

## A127 Stakeholder Perspectives and End of Life Planning: The Future for Body Farms, Donation Programs, and Student Development

*Natalie S. Wise\*, Florida Institute for Forensic Anthropology & Applied Science (IFAAS), Tampa, FL; Erin H. Kimmerle, Florida Institute for Forensic Anthropology & Applied Science (IFAAS), Tampa, FL*

**Learning Overview:** The University of South Florida (USF) Donated Skeletal Collection is a critical resource, ethically sourced, for the development and validation of methods, student research, and education. The aim of this presentation is to investigate why people pre-register, choosing a forensic program over other final resting options, to ensure the policies and practices positively impact research opportunities.

**Impact Statement:** This presentation will impact the medicolegal community who contribute to end-of-life care, illustrating the needs and concerns of families and donors while highlighting the positive role donated collections have on research opportunities and student development.

The USF Human Donation Program was created in 2016 and is among 12 such programs worldwide. The research facility consists of a living donor program in which people pre-register to become donors (n=300+); the outdoor training facility where individuals are buried or placed for decomposition (the Facility for Outdoor Research and Training [FORT], a.k.a. body farm); and the USF Donated Skeletal Collection, the permanent skeletal collection and repository of the remains available for research and classroom instruction (n=128). The objective of this research paper is to investigate why people pre-register, choosing a forensic program over other final resting options and how the policies and practices of the 12 forensic facilities compare to one another in terms of who is admitted into the program and the impact that has on the types of research opportunities available.

Data comes from two sources and was analyzed using quantitative summary statistics and qualitative method analysis based on participant responses. Life history data about economic status, occupation, and the reasoning for choosing a forensic donation program was collected from the USF donor packets (n=300). Many donors added written letters to the packet explaining their interest and motivation for choosing the program and these were included. Second, a questionnaire was completed by each of the program directors (n=12) regarding types of research, funding sources, access to collections, and applications of research to criminal investigations within their programs.

Interestingly, of the pre-donor packets that indicate a reason for choosing this program, the top three reasons (84%) include its high educational value, the opportunity for multiple family members to be part of the same collection, and the long-term commitment of the program. Further, most respondents self-identified as middle- to upper-class socioeconomic backgrounds (70%). Anatomical collections have been widely misinterpreted as consisting of individuals of only lower socioeconomic status with false assumptions made about their motivations (i.e., financial necessity). One of the first donors into the USF program was a local principal who dedicated his life to teaching. Upon his unexpected death, the wife donated his remains stating, “There’s so much bittersweet in all of this. [He] wanted to continue teaching after his death. It would be my last gift to education, he’d say. This couldn’t be more perfect.” Another pre-donor said, “Being a retired homicide detective, I’m still very much intrigued with forensic anthropology,” indicating an understanding of the direct value that donation programs and forensic anthropology have on homicide investigations.

Multiple members of numerous families are also opting into the program, showing that such donation programs are an integral part of the preparation that goes into end-of-life planning, with donors viewing the collection as their eternal family resting place. The growth of similar forensic donation and outdoor facility programs is shown to be imperative not only for the advancement of forensic research, but also for individuals who have made their wishes of donation clear in their end-of-life plans. One-hundred percent of the pre-donors who came into the program over the past year called us as they were entering hospice.

Similar trends are seen across most of the other forensic facilities surveyed. When policies of collections were compared, program variation was mostly around whether unclaimed human remains are accepted. Three facilities do accept unclaimed remains. This practice has been subject to ethical debates about research on individuals who have not granted consent and the limited potential of research applications without known life and medical histories. Programs also varied in terms of research practices, with only a few programs allowing destructive analysis such as experimental trauma research (33%) or collaborations with outside government labs for DNA research (50%).

---

### Skeletal Remains; Body Donation; Decision Making

---

**A128 The Forensic Taphonomy Education and Research Facility: An Interdisciplinary Educational and Professional Resource**

*Sophia I. Reck\*, Louisiana State University, Baton Rouge, LA; Ginesse A. Listi, Louisiana State University, Baton Rouge, LA*

---

**Learning Overview:** After attending this presentation, attendees will have a better understanding of how a local forensic taphonomy facility has impacted forensic anthropological casework and professional development.

**Impact Statement:** This presentation will impact the forensic community by demonstrating practical interdisciplinary uses for forensic taphonomy facilities and provide baseline decompositional data for southeastern Louisiana.

Forensic taphonomy facilities primarily have focused on observing variation in rates of human decomposition to establish more accurate Postmortem Interval (PMI) estimations. Through body donation programs, forensic taphonomy facilities have explicated the progression of human decomposition, augmented donated skeletal collections, and created spaces for medicolegal professional development and interdisciplinary research. In 2019, the Louisiana State University Forensic Anthropology and Computer Enhancement Services (LSU FACES) Laboratory broke ground on a human decomposition research facility, and the associated body donation program was fully developed by the fall of 2022. Both the FACES Laboratory and the Forensic Taphonomy Education and Research Facility (FTERF) operate within the Department of Geography and Anthropology at LSU.

As of July 2023, the Human Body Donation Program has resulted in 21 registered living donors and 16 next-of-kin donations. Of the remains placed at the FTERF, 11 are male and 5 are female, with ages spanning from 26 to 91 years ( $\bar{x}$  = 61 years). Individual weights ranged from 125 to 339lbs. ( $\bar{x}$  = 191 lbs.) and statures ranged from 5'2" to 6'2" ( $\bar{x}$  = 5'9"). Currently, the longest interval of placement at the FTERF is 167 days. Preliminary taphonomic observations include a color sequence with a high presence of orange and red discoloration, extended persistence of marbling into advanced decomposition, and cycling dehydration and rehydration of tissue from intermittent rainfall.

The FTERF is located in the Cfa climate zone (temperate climate with a hot summer and no dry season) according to the Köppen-Geiger climate classification system—similar to multiple other forensic taphonomy facilities.<sup>1</sup> However, climate zones do not account for all environmental variability (e.g., elevation or ecoregions). Uniquely, the FTERF is situated in eastern temperate forests (Level I ecoregion) on the Mississippi Alluvial Plain and Mississippi Valley Loess Plains (Level III ecoregions).<sup>2-4</sup> Additionally, being positioned on the Mississippi River floodplain, specifically the Hammond alloformation, soil texture at the FTERF extends from silty clay to medium sand.<sup>5</sup> Regional decompositional differences are likely present between forensic taphonomy facilities in the same climate zone; accordingly, local taphonomic data are a vital resource for PMI estimation in forensic anthropological casework.

While the FTERF does work toward the traditional goals of forensic taphonomy facilities, being situated in a dual-discipline department also directs the goals of the FTERF toward interdisciplinary education. Consequently, the FTERF provides instructional space for students in physical geography, paleoanthropology, archaeology, and forensic anthropology. Training is available for various geophysical methodologies, recognizing taphonomic agents for both paleoanthropological and forensic contexts, and human remains recovery techniques. The FTERF also produces data relevant to climatology, soil science, DNA and isotopic analysis, and forensic imaging.

Regarding professional development, 82 individuals received training at the FTERF (representing 17 undergraduates, 13 graduate students and undergraduate student workers, and 52 medicolegal professionals). Of the student workers, 10/13 subsequently found positions in graduate programs or employment in forensics or archaeology. By extending the resources of taphonomy facilities to other disciplines, students gained a more robust education that has resulted in diverse academic and professional opportunities.

**A130 Considerations for Age Estimation Accuracy: Method-Derived Outcomes and Practitioner Interpretations**

*Cris E. Hughes\**, University of Illinois at Urbana-Champaign, Urbana, IL; *Chelsey A. Juarez*, California State University Fresno, Fresno, CA; *An-Di Yim*, George Mason University, Fairfax, VA

---

**Learning Overview:** This presentation utilizes forensic anthropology case data to assess the performance (accuracy) of the most commonly applied age estimation methods in United States casework. After attending this presentation, attendees will better understand the accuracy of different aging methods and the importance of studying practitioner-based interpretations with the “black-box study” model.

**Impact Statement:** This presentation will impact the forensic science community by providing accuracy rates for methods and by highlighting the discrepancies between method-derived outcomes and the practitioner modifications/interpretations of these outcomes. Validation studies to date tend to focus on the explicit method outcomes, but practitioner adjustments can play a key role in improving the accuracy of the final age estimation outcomes on case reports and must be incorporated into validity studies.

Recently, Hughes and colleagues observed that case-report level accuracy for age-at-death estimations by United States forensic anthropologists was at 92%.<sup>1</sup> The present study compares this case report level accuracy to method level accuracy for the most commonly used methods in United States casework, based on the Forensic Anthropology Database for Assessing Methods Accuracy (FADAMA).<sup>2</sup> Method application frequency was analyzed for  $n = 641$  cases and found only 15 methods with an application rate greater than 45 cases (based on cases submitted to FADAMA at the time of data download on June 6, 2023). Accuracy (whether the known decedent age fell within the age range yielded by a given method) was assessed for each method. Of the 15 methods, only four yielded accuracies greater than or equal to the 92% documented for case-report level accuracy. The other 11 methods produced accuracy rates ranging from 54% to 91%, with six of these below 70% accuracy, indicating that caution should be used in the application of these methods’ specific outcomes to casework. In fact, this disconnect between highly accurate age estimations at the case report level compared to the poor performance at method level suggests that practitioner interpretation of the methods is a critical step for increasing the accuracy rates of the combined age estimations as reported on the final case report. Additional findings further support this hypothesis—the study next examined whether case report-level accuracy was positively correlated with the number of aging methods used in a case.

For the cases that used at least one of the most common 15 methods, the median number of methods used in a single case is three (100% range is one to seven methods). Cases using a single method as well as cases using up to six methods all have comparable rates of accuracy for age estimations at the *case report level* ( $n = 525$ , Fisher’s Exact 2-sided test  $p = 0.93$ ; 80-90% accuracy). The findings of the present study clearly suggest that practitioners are interpreting and modifying specific method outcomes in ways that improve the overall accuracy of age estimations on their final reports. The implications for these findings greatly alter how forensic anthropologists should proceed with validation studies of age estimation methods and should be evaluated using “black-box studies” comparable to those outlined in the 2016 President’s Council of Advisors on Science and Technology Report.<sup>3</sup> Such approaches will render a more representative picture of the validity of the methods that have substantial practitioner interpretation.

**A131 A Regression-Based Machine Learning Framework for Adult Skeletal Age Estimation**

*David Navega, University of Coimbra, Centre for Functional Ecology, Department of Life Sciences, Coimbra, Portugal; Eugenia Cunha\*, National Institute of Legal Medicine and Forensic Sciences and University of Coimbra, Coimbra, Portugal*

---

**Learning Overview:** After attending this presentation, attendees will understand and be aware of the potential of regression-based approaches for skeletal age estimation, both in the construction of point-estimate and predictive interval models.

**Impact Statement:** This presentation will impact the forensic science community by increasing awareness of novel computational approaches and open source tools.

Age-at-death estimation of adult human remains poses significant challenges in forensic anthropology and medicine, in particular for the elderly. The intricate nature of adult age estimation arises from the interplay of biological and methodological complexities. Current anthropological approaches to age estimation suffer from limitations, including sparse array of skeletal traits, overemphasis on specific traits like the pubic symphysis, and the absence of a formal procedure to combine information from multiple skeletal parts, thus failing to reflect individual variation.

To address these prevalent methodological issues in adult skeletal age-at-death estimation, a novel scoring protocol for age-related skeletal traits and a machine learning regression-based framework have been developed. The regression-based approach uses deep random neural networks for point estimates and conformal prediction theory to construct predictive intervals for age-at-death estimates. Deep random neural networks use randomization techniques and multiple layers to improve feature extraction while balancing generalization and computational efficiency. Conformal prediction is a machine learning technique that quantifies prediction uncertainty, aiding the assessment of confidence and predictive interval construction.

Through results based on a rigorous cross-validation analysis, this presentation will demonstrate that age estimation from skeletal remains can be accurately inferred across the entire adult age span, yielding a mean absolute error of approximately six years. Moreover, this approach facilitates the generation of informative estimates and prediction intervals specifically tailored for the elderly population. Attendees will have access to open-source software tools developed using R and C++ programming languages, which they can apply to their own datasets to produce accurate models based on machine learning techniques.

This report will also present the Deep Random Neural Networks for Adult Skeletal Age-At-Death Estimation (DRNNAGE) tool, a software that operationalizes the proposed regression-based framework and provides a graphical user interface to a computationally intensive approach to adult skeletal age estimation. The comprehensive inclusion of multiple skeletal traits and the consideration of individual variation through statistical modeling of uncertainty for predictive intervals provide a robust and reliable tool for forensic anthropologists and medical professionals. DRNNAGE serves as a pivotal advancement in accurately determining the age at death of adult human remains, thereby enhancing the accuracy and precision of biological profiling in forensic investigations.

**A132 Cranial Masculinization: How Age Progression Affects the Accuracy of Sex Estimations in Adults**

Lyndsey Hornagold\*, University of South Florida, Johnson City, NY; Samantha Shipley\*, Binghamton University, Binghamton, NY; Erin H. Kimmerle, Florida Institute for Forensic Anthropology & Applied Science, Tampa, FL

**Learning Overview:** This presentation will look at primary methodologies used for sex estimation in forensic anthropological casework by examining both metric and non-metric methods. After this presentation, attendees will better understand how various methods are impacted by cranial masculinization caused by aging processes and the ideal method to use depending on an individual's age. Additionally, this research will look at which specific cranial landmarks used for metric and non-metric sex estimation methods are significantly affected by cranial masculinization.

**Impact Statement:** This research will impact how forensic anthropologists estimate sex in future casework, especially for older individuals. These findings will aid in making biological profiles more accurate and increase positive identifications, promoting equal justice for victims of all ages.

While there have been studies on sexual dimorphism in human crania, there have been few studies that take post-puberty age-related changes into consideration. A majority of age-related studies conducted tend to focus on the physiological changes that occur from childhood to early adulthood. Thus, different sex estimation methods have been developed based on physical developmental milestones. Regardless of multiple studies showing there are also age-related changes that occur throughout adulthood, methods post-puberty are the same for the remainder of an individual's life. Some of these post-pubertal changes are referred to as cranial masculinization, an aging process caused by a variety of factors leading to increased thickness and robusticity of different parts of the cranium in both males and females that minimizes sexually dimorphic features.<sup>1</sup> This research aims to further evaluate the changes caused by cranial masculinization in adults and how these changes impact the accuracy of commonly used sex estimation methods in forensic anthropology.

The accuracy of metric and non-metric cranial sex estimation methods was tested using a portion of the Florida Institute for Forensic Anthropology & Applied Sciences' donor collection (n= 84) at the University of South Florida. Donors were divided into three age cohorts: 36–50, 51–70, and 71+. Metric measurements were taken following the Data Collection Procedures for Forensic Skeletal Material 2.0 guidelines before being input into FORDISC® 3.1 to estimate sex.<sup>2,3</sup> All measurements and non-metric scoring using the mandible were excluded due to the significant inter-observer error that has been previously reported.<sup>4</sup> The Walker and Langley et al. non-metric sex estimation methods were also tested.<sup>5,6</sup> Current literature regarding cranial masculinization suggests the accuracy of all three sex estimation methods were expected to be impacted, especially for older age cohorts. Research also suggests predicting sex will be more accurate when using metric compared to non-metric methodologies.<sup>7</sup>

The sex of each donor was unknown prior to testing each methodology. The accuracy of each method was then analyzed using McNemar's test, with a few statistically significant results. Lastly, each measurement and trait were analyzed using a Multivariate Analysis of Variance (MANOVA) to better understand the interactions between age and sex. The MANOVA test showed that multiple measurements were significantly impacted, especially when age was a factor. Landmarks located on the hard palate and cranial base were more affected by age than any other region. Both the Walker and Langley et al. methods were less accurate in the 51–70 and 71+ age cohorts as compared to the 36–0 cohort.<sup>5,6</sup> Overall, the Langley et al. method was far more accurate in estimating an individual's sex than the Walker and metric methods.<sup>5,6</sup> Based on this study's results, the methods and landmarks used when estimating sex should be altered to increase the accuracy of their biological profile, especially when an individual is assumed to be older than 50 years of age.

**A133 Unaccompanied Minors Automatic Forensic Age Estimation (UMAFAE): Applying Artificial Intelligence-Based Methods to Estimate Legal Age in Undocumented Minors**

*Stefano De Luca, Panacea Cooperative Research S. Coop., Madrid, Spain; Javier Venema Rodríguez, Panacea Cooperative Research S. Coop., Granada, Spain; Oscar Ibáñez Panizo\*, CITIC, University of A Coruña, La Coruña, Spain; Pablo Mesejo Santiago, Department of Computer Science and Artificial Intelligence, Granada, Spain*

---

**Learning Overview:** After attending this presentation, attendees will understand that Artificial Intelligence (AI) is a very useful complementary tool when estimating the age of minors without family references since it allows obtaining precise and accurate information in a very short time and with less effort on the part of the experts involved in the process of evaluating the subject's identity.

**Impact Statement:** This presentation will impact the forensic science community by informing attendees that although most age-estimation methods perform reasonably well and are widely used in the scientific community, all of them rely on manual measurements or classifications, which require much time and effort. There is also a high degree of subjectivity (both intra- and inter-observer) in the dental evaluations obtained from some classical methods. Deep learning methods can be used to automatically and accurately predict someone's chronological age, especially in those undocumented minors arriving in Europe without any valid proof of identity, and to efficiently classify between subjects younger and older than 18 years of age.

Legal age estimation is essential for the identification of undocumented minors seeking asylum. In the European Union context, recommendations have been developed by the interdisciplinary German Study Group on Forensic Age Diagnostics (AGFAD) and the European Asylum Support Office (EASO) in order to standardize the assessment procedure and to implement quality assurance. However, due to the absence of good practices, the process is often subjective and inaccurate.

The main aim of the European Union-funded UMAFAE project is to develop and validate methods for estimating legal age by applying AI techniques in order to increase accuracy while reducing estimation times and subjectivity. For this purpose, we are collecting and processing the largest-ever data set of radiographic images (dental and carpal radiographs, computer tomographies of the chest, and cone-beam computed tomographies of the maxillofacial region) to train and validate AI-based methods. The inclusion criteria are: an age range between 14 and 25 years; known biological sex and age; and good quality of the images obtained. In addition, images of subjects with diseases of endocrine or congenital origin, alterations in dental and bone development, subjects with orthodontic history, or with bone trauma in the joints of interest (sternoclavicular, and wrist joint complex) are included to determine the degree of influence of these variables on the accuracy of the algorithms.

In this preliminary work, a sample of 10,848 Orthopantomographies (OPGs) from several countries (Bosnia, Botswana, Chile, Dominican Republic, Kosovo, Lebanon, Malaysia, Italy, Turkey, Uganda, Japan, and Korea) was used to train, validate, and evaluate an AI model for age estimation. As a first step, all images were pre-processed to remove duplicates, inconsistencies, and background noise. We have also segmented the lower left third molar to compare the results using the full OPG (best option) and the third molar only. Several Convolutional Neural Networks (CNN) architectures were trained using those images and metadata (sex and ethnicity) in order to estimate age. Our results in the test set (for the best model in validation) showed a Mean Absolute Error (MAE) of 1.15 years and an accuracy of 88.94% for legal age estimation (an individual age is >18 or not). Our findings are in agreement with previous studies but with a significant difference: we are validating our model on a sample composed of 12 different populations, not only one. Additionally, we are trying to simulate a real scenario by estimating age in samples that have never been seen by the model; that is, the training data does not contain any image from that sample. More specifically, the model showed an MAE of 1.20, 1.49, 1.50, and 1.43 years and an accuracy of 89.77%, 80.32%, 84.81%, and 80.95% for four samples from Russia, Ethiopia, Australia, and Egypt, respectively. We have also developed a model that penalizes age overestimation so that a minor is never classified as a legal adult. This model gets an MAE of 1.77 years and an accuracy of 81.49% in validation, but has less tendency to wrongly classify a minor. Since further experiments are still being performed these results should be considered only preliminary.<sup>1-3</sup>

**A134 Macroscopic Differences in Adult Human Femora Are Linked to Body Mass Index**

Daniel Wescott\*, Texas State University, San Marcos, TX; Elaine Y. Chu, Texas State University, Austin, TX; Adam D. Sylvester, The Johns Hopkins University School of Medicine, Baltimore, MD; Gengxin Shi, The Johns Hopkins University School of Medicine, Baltimore, MD; Wojciech Zbijewski, The Johns Hopkins University, Baltimore, MD; Lauren A. Meckel, Louisiana State University Health Sciences Center, New Orleans, LA; Deborah L. Cunningham, Texas State University, San Marcos, TX

---

**Learning Overview:** This presentation will demonstrate the utility of whole-bone femoral shape in estimating the Body Mass Index (BMI) category for the adult biological profile.

**Impact Statement:** This presentation will impact the forensic science community by demonstrating a relationship between whole-bone external femur shape and the BMI category and obesity status.

Body mass is generally not included when constructing a biological profile from skeletonized human remains because of the lack of precise and accurate estimation methods.<sup>1,2</sup> This is especially true for obese or emaciated individuals. Bone functional adaptation theory argues that bone tissue responds to mechanical strain in order to maintain skeletal element strain within acceptable limits.<sup>3</sup> Increases in body mass result in relatively higher loading of lower limb skeletal elements, producing strain levels that elicit bone formation and potentially alter the external shape of skeletal elements. This project examines the feasibility of establishing BMI category from external femur shape.

Eighty human femora that are part of the Texas State University Donated Skeletal Collection (TXSTDSC) curated by the Forensic Anthropology Center at Texas State University were used in this study.<sup>4</sup> Forty femora are from female donors and 40 femora are from male donors of known body mass and stature at time of death. For the female sample, we selected 20 individuals with a BMI of 19–27 (“moderate”) and 20 individuals with a BMI greater than 29 (“high”). In the male sample, we selected 20 individuals with a BMI of 18–26 (“moderate”) and 20 individuals with a BMI greater than 29 (“high”). Femora were scanned on a Canon® Aquilion Precision CT scanner, housed in the Division of Cardiology, Department of Medicine, at the Johns Hopkins Hospital. Triangular mesh surface models were generated from image stacks and all surface models were resampled (~25,000 vertices) to improve triangulation. Variation in femoral shape was quantified using a 3D landmark analysis based on the coherent point drift algorithm.<sup>5</sup> Shape variation was summarized using principal components analysis and BMI groups were compared for component scores.

Statistically significant shape differences ( $p < 0.05$ ) were detected in the male sample between moderate and high BMI categories. In the male sample, the high BMI group femora were associated with greater proximal diaphyseal breadths as well as lower anteversion angles. These shape differences between BMI categories were also detected in the female sample, although they only approached statistical significance ( $p = 0.065$ ). These results demonstrate the potential for incorporating external shape of the femur in estimating BMI for the purposes of improving the biological profile.

**A135 A Critical Validation of Dental Morphology as a Method of Ancestry Estimation in a Historical Forensic Context**

*Laura E. Cirillo\*, SNA International Supporting the Defense POW/MIA Accounting Agency, San Francisco, CA; Rylan Tegtmeyer Hawke, SNA International Supporting the Defense POW/MIA Accounting Agency, Waipahu, HI; Rebecca J. Taylor, Defense POW/MIA Accounting Agency, Kapolei, HI*

---

**Learning Overview:** After attending this presentation, attendees will have a better understanding of the accuracy of dental morphology methods in forensic casework for ancestry estimation and the factors that influence the success of the methods in forensic application.

**Impact Statement:** This presentation will impact the forensic science community by validating two major dental morphology methods used to estimate ancestry when applied to a forensic context and will highlight both intrinsic and extrinsic factors that may influence the application of the method.

As the field of forensic anthropology weighs the potential benefits and harms of ancestry estimation on a more theoretical level, the shortcomings of existing methods are being reevaluated to assess their practical value with a more critical eye. The preference for craniometric and morphoscopic methods of ancestry estimation has left dental morphology applications relatively undiscussed. The advanced training necessary to score the traits the dental methods are based on may be contributing to their relative disfavor in case work application. When applied, there are two major methods used with distinct considerations. Edgar only classifies individuals into three groups, severely limiting its application in blind forensic casework.<sup>1</sup> Scott et al. was not developed with a modern sample, so it has unknown classification accuracy in forensic application.<sup>2</sup>

Because casework conducted at the Defense POW/MIA Accounting Agency includes a comparison of antemortem records that report ancestry, the application of dental morphology methods can be tracked and assessed with relative ease compared to casework in other forensic contexts. Although dental morphology is not commonly used in the agency overall, a sample of 78 resolved cases using the Edgar or Scott et al. methods was used to identify trends of method application and performance in a historic forensic context.<sup>1,2</sup> Classifications were compared to the reported ancestry of each identified individual based on antemortem records to determine method accuracy.

Edgar was used in 41 cases (3 Black, 1 Hispanic, 37 White males) with an 80.5% overall correct classification accuracy and 89.2% for White males specifically.<sup>1</sup> Scott et al. was used in 38 cases (1 Asian, 2 Black, 1 Hispanic, 1 Native American, 33 White males) with a 60.5% overall correct classification accuracy and 63.6% for White males.<sup>2</sup> Because so few of the cases involved reported ancestry groups other than White, the correct classification accuracy for other groups was not calculated.

Despite the overall accuracy of the Edgar method exceeding that of the Scott et al. method by 20%, a Fisher's Exact Test indicated that the performance of both methods was not significantly different ( $p=0.08$ ) in this sample.<sup>1,2</sup> The average number of traits used with both the Edgar and Scott et al. methods was 13 traits, with a range of 2–20 and 1–21 traits, respectively.<sup>1,2</sup> A comparison of the number of traits used and the accuracy of the application resulted in a Point-Biserial Correlation Coefficient of 0.230 ( $p=0.16$ ) for Edgar and 0.035 ( $p=0.83$ ) for Scott et al., indicating a weak relationship for Edgar and no relationship for Scott et al., but neither were statistically significant.<sup>1,2</sup> The results suggest the performance of the methods is more complicated than simply meeting a threshold value of traits. Analyst confidence in the methods and choices during application are possible factors affecting performance.

**Method Validation; Misclassification; Teeth**

## A136 . . . and There Were Only Teeth: Postmortem Interval Estimation Based on XRD and FTIR

*Sara C. C. Zapico\**, New Jersey Institute of Technology, Newark, NJ; *Juan Suárez*, Universidad de Malaga, Málaga, Spain; *Stella Martín de las Heras*, Universidad de Malaga, Málaga, Spain; *Leticia Rubio*, University of Malaga- Faculty of Medicine, Málaga, Spain

**Learning Overview:** After attending this presentation, attendees will consider the possibility of determining the Postmortem Interval (PMI) on teeth samples based on imaging, non-invasive techniques, X-Ray Diffraction (XRD) and Fourier Transform Infrared (FTIR) spectroscopy.

**Impact Statement:** This presentation will impact the forensic science community by presenting, for the first time, a new approach to determining the PMI of skeletonized remains on the hardest tissues in the body, teeth, leading to accurately distinguishing among remains in the latest stages of decomposition.

PMI is the time elapsed between the physiological death of an organism and its examination. This constitutes one of the most challenging parameters for estimating in forensic science. Early Postmortem Interval (EPMI) is easier to determine based on physicochemical changes in the body, like rigor mortis. In contrast, Late Postmortem Interval (LPMI) is more difficult to estimate, particularly in skeletonized remains. The study of PMI in the latest stages of decomposition, on skeletonized remains, has been focused on the application of proteomics and other physicochemical techniques, like XRD and FTIR. There are several studies assessing PMI on bones applying these techniques, since they are easy to perform, fast, inexpensive, non-destructive, and show good accuracy in estimating PMI. Despite the potential application of these techniques, there are no studies focused on teeth samples. Teeth are the hardest tissues in the human body and remain after everything else has decomposed. Thus, they could be the samples of election moreover when dealing with fragmentary remains and remains exposed to different environmental insults.

The aim of this work is to assess changes in the mineral composition of human teeth applying XRD and FTIR and correlate these changes with the PMI to improve the accuracy of this estimate in latest stages of decomposition.

Forty healthily erupted human adult teeth (molars and premolars) were obtained from dental clinics and stored at times 0, 10, 25, and 50 years. Teeth were cleaned and pulverized with liquid nitrogen using a 6770 Freezer Mill. Then, 100mg of tooth powder were subjected to XRD analysis to determine crystallographic indices (crystallinity and crystal size) and 100mg of tooth powder were used to perform FTIR Attenuated Total Reflectance (ATR) analysis and determine different indices: Mineral to organic Matrix ratio (M/M); Carbon to Phosphate ratio (C/P); mineral crystallinity; and collagen maturity.

According to the XRD results, there are differences among PMIs: both crystallinity and crystal size increased with the PMI. With respect to the FTIR analyses, M/M ratio increased with the PMI, and in contrast, the C/P ratio decreased with the PMI, not finding differences on the other two indices. Applying Pearson correlations, it was possible to demonstrate a positive correlation among crystallinity, crystal size, and M/M ratio with the PMI, and a negative correlation between C/P ratio with the PMI.

The prediction models developed from these variables indicated a high accuracy for the estimation of PMI, particularly at 10 years and 50 years, with success rates of 87% and 80%, respectively.

Overall, these results demonstrated for the first time the feasibility of using XRD and FTIR to determine the PMI on the hardest tissue in the human body, the teeth, and their accuracy to distinguish between long-term PMIs, allowing the application to severely decomposed bodies. Future research will be able to expand these findings, increasing the number of teeth and assessing the impact of environmental and inherent factors on the determination of PMI.

## A137 Geofor: A Forensic Taphonomy Database for PMI Estimation Using a Machine Learning Model

*Katherine E. Weisensee\*, Clemson University, Clemson, SC; Madeline Atwell, Clemson University, Columbia, SC; Cristina I. Tica, Eastern New Mexico University, Portales, NM; Dane Smith, Clemson University, Central, SC; Carl Ehrett, Clemson University, Clemson, SC; Patricia Carbajales-Dale, Geospatial Technologies, Clemson, Seneca, SC; Patrick J. Claflin, Jr., Clemson University, Clemson, SC; Noah A. Nisbet, Clemson University, Greenville, SC*

**Learning Overview:** After attending this presentation, attendees will understand the limitations of the current state of Postmortem Interval (PMI) estimation in forensic anthropology and how machine learning models provide a more accurate estimation for time since death. Attendees will also learn how to register and use the geoFOR application—a forensic taphonomic database designed to provide practitioners with a platform to enter cases and receive an automated PMI estimation.

**Impact Statement:** This presentation will impact the forensic community by demonstrating how the geoFOR application can be used to provide a PMI estimation using observations of human remains and associated weather data through a machine learning model.

Estimating the time since death, or the PMI, poses a significant challenge to forensic scientists when human remains are discovered because of limited reliable methodologies, particularly for cases in advanced decomposition. Current PMI estimation methods lack scientific rigor and are often inconsistent, which can impede the successful identification of unknown human remains and the reconstruction of events around the time of death. Despite decades of research, existing studies regarding PMI estimation are significantly hindered due to reliance on small sample sizes, environmental homogeneity, and inconsistent definitions of the stages of decomposition.

To transcend longstanding methodological issues, we developed an ongoing collaborative forensic taphonomy reference database that utilizes ArcGIS® and machine learning models to deliver improved PMI estimations. This tool offers forensic practitioners a platform to enter case information, including demographic data and uniform descriptions concerning characteristics of decomposition, insect, and scavenger activity. The app automates the collection of weather data from the location of discovery using the Global Historical Climatology Network (GHCN) through the National Oceanic and Atmospheric Administration (NOAA). The database currently contains over 2,600 cases derived from medicolegal death investigations and human decomposition research facilities across the United States. Data collection is ongoing as new and existing collaborators enter case information. The size and comprehensive nature of the geoFOR data allow for the application of machine learning methods for estimating PMI. After users submit the details of their case, the app delivers a PMI prediction using a statistically robust regression model. The advanced cross-validated machine learning PMI predictive model results in an  $R^2$  value of 0.8 and users receive a predicted PMI with an 80% confidence interval. Results will be presented as a decision tree from the machine learning model to illustrate how the characteristics of decomposition are used to predict PMI.

This novel method for PMI estimation can help successfully narrow the search parameters for unknown decedents, which can expedite identification and more accurately inform us about the circumstances surrounding their death. The geoFOR app complies with recommendations from the National Institute of Standards and Technology (NIST) for the Standard for Taphonomic Observations in Support of the Postmortem Interval (2022) through the use of a data-driven model that accounts for a wide variety of environmental factors and decomposition characteristics. GeoFOR also follows an Open Science Framework through data sharing that promotes methodological integrity and reproducibility. These principles encourage fairness, equity, and inclusion within the research community.

### Postmortem Interval; Machine Learning; Taphonomy

---

**A138 Skeletal Element Recovery Rates From Outdoor Surface Contexts in Louisiana**

*Ginesse A. Listi\*, Louisiana State University, Baton Rouge, LA*

---

**Learning Overview:** This presentation provides skeletal element recovery rates for outdoor rural and suburban residential contexts in Louisiana and examines variation in recovery rates according to environment, dispersal, who collected the remains, and estimated Postmortem Interval (PMI). After attending this presentation, attendees will better understand how variables of interest affect skeletal element recovery rates and will have empirical data to help guide future research in methodologies for bioprofile skeletal assessment.

**Impact Statement:** This presentation will impact the forensic science community by providing skeletal element recovery data for forensic anthropology casework from outdoor contexts in Louisiana and by addressing how environment, dispersal, estimated PMI, and who collects the remains affect recovery rates. Such information will provide empirical data to help guide future research in methodologies for bioprofile skeletal assessment.

Human remains subject to postmortem taphonomic processes are affected with regard to both survivability and recoverability. A recent publication discusses the distinction between the two notions and urges forensic anthropologists to make available skeletal element recovery rates for their casework, with a rationale that such documentation can provide an empirical basis to guide forensic anthropological research.<sup>1</sup>

Heeding this appeal, the current study: (1) provides skeletal element recovery rates for select casework from Louisiana, and (2) examines variation in recovery rates according to environment, dispersal, who collected the remains, and estimated PMI. Data were gathered from case files at the Louisiana State University Forensic Anthropology and Computer Enhancement Services (LSU FACES) Laboratory. Cases included in this study were recovered between 1980–2023 from outdoor surface contexts in rural or suburban residential areas. Skeletal element recovery data were collated from bone inventories. Other variables, such as the environment in which the remains were found, the minimum and maximum estimated PMIs (PMI<sub>e-min</sub>, PMI<sub>e-max</sub>), whether the remains were dispersed or non-dispersed, and whether the remains were recovered by forensic anthropologists or medicolegal personnel, were gleaned from case reports, bench notes, and scene photographs.

Most skeletal elements were recorded as present or absent, and if paired, separated by side; the cranium was considered a single unit. For ribs, vertebra type, carpals, Metacarpals (MC), manual and pedal Phalanges (Phal<sub>man</sub>, Phal<sub>ped</sub>), tarsals, and Metatarsals (MT), only the total number of bones collected was recorded. Descriptive statistics were computed for the collective sample and for dispersed and non-dispersed subsamples. Inferential statistics were also computed to assess variation in skeletal element recovery rates among the other variables of interest. Significant differences among categories were noted if *p* values were less than .05.

The research sample included 152 cases. The cranium was most frequently recovered (96%, *n*=146); the hyoid least recovered (26%, *n*=39). In general, skeletal elements from the torso, and the larger elements from the limbs, were recovered in higher frequencies (88, 63%); smaller skeletal elements were recovered in lower frequencies (57, 26%). Chi-square tests showed that recovery rates were significantly different between non-dispersed (*n*=47) and dispersed (*n*=105) cases for all elements except the cranium; therefore, other inferential results are reported only by subsample.

Unsurprisingly, recovery rates for non-dispersed cases were high (72–100% for 35/36 skeletal elements); only the hyoid had a relatively low recovery rate (43%). Chi-square tests revealed no significant differences in recovery rates based on who collected the remains or environment. Student's *t*-tests indicated significant relationships between recovery rates and PMI<sub>e-min</sub> and PMI<sub>e-max</sub> for only 5/36 and 4/36 skeletal elements, respectively; in these cases, an inverse relationship was noted between recovery rate and estimated PMI.

For the dispersed sample, recovery rates were lower than, but mirrored the pattern for, the complete sample. Chi-square tests showed significant differences in recovery rates for 15/36 skeletal elements based on who collected the remains, and for 6/36 elements based on environment. For the former, forensic anthropologists consistently recovered more elements than other medicolegal personnel; for the latter, wooded areas impeded recovery rates more than other environments. Student's *t*-tests indicated significant relationships between recovery rates and PMI<sub>e-min</sub> and PMI<sub>e-max</sub> in 32/36 and 33/36 skeletal elements, respectively; an inverse relationship also was noted between recovery rates and estimated PMI for these elements.

In conclusion, results from this assessment of skeletal element recovery rates corroborate those found in previous studies and provide empirical information that may help guide research into methodologies for bioprofile skeletal assessment. Moreover, these data suggest that environment, estimated PMI, and who collects the remains primarily affect recovery rates in cases where remains are dispersed in wooded environments.

---

**A139 Small but Mighty: A Controlled Observation of Magpie Scavenging Among a Cohort of Human Remains in the Rocky Mountain Region of Colorado**

Christiane I. Baigent\*, Southern Illinois University Carbondale, Fairplay, CO

---

**Learning Overview:** After attending this presentation, attendees will understand the longitudinal composite of environmental, skeletal, and soft tissue change catalyzed by scavenging magpies.

**Impact Statement:** This presentation will impact the forensic science community by describing a longitudinal, controlled observation of magpie scavenging, facilitating distinguishment of magpie behavior from the forensically relevant corvid groups with which their behavior is typically grouped.

Black-billed magpies (*Pica hudsonia*) are recognized for their diverse and voracious feeding habits.<sup>1</sup> True omnivores, the magpie diet ranges from fruit and grain to active hunting of small mammals and invertebrates. Carrion is a preferred food source, demonstrated by the adaptive behavior of tracking human and non-human game hunters and exploiting their discarded carrion.<sup>1,2</sup> Because many corvid species cooperatively scavenge, avian scavenging has typically and necessarily been documented in sum, as cooperation precludes species-specific description of scavenging pattern, and behavior.<sup>3,4</sup> Longitudinal controlled study of environment-specific rate and pattern of human decomposition affords the appended opportunity for controlled study of associated scavenger behavior. Toward that end, magpie scavenging among a group of human donors is reported, with an emphasis placed on intraspecies continuity in behavior, and the temporal, anato-spatial, and archetypical presentation of magpie-mediated osseous and soft tissue change, summarily yielding a higher resolution model of magpie scavenging as distinct from typically associated corvid groups.

The impact of magpie scavenging was investigated at Colorado Mesa University's Forensic Investigation Research Station high-altitude satellite facility (FIRS-TB40). FIRS-TB40 is 9,500 feet (2896m) above mean sea level, in the Rocky Mountain Region of Colorado. The local environment is characterized by a complex composite of environmental and meteorological variables that summarily produce a harsh hypoxic environment distinguished by long winters and persistent snow overburden. The structure of scavenger guilds and the behavior of individual species is largely dictated by local environmental variables, among the most prominent of which is protracted overwintering resulting in limited mobility with concomitant reduction in home range size, scarce and limited resources, and metabolism slowed by physiological stress and plasticity.

Magpie scavenging was observed within a cohort of 12 human donors opportunistically placed between March 2020 and October 2021. Field observation persisted through November 2022. Human donors were placed unclothed, supine, on a 45° slope in 10'x10' steel cages and monitored by game cameras programmed to collect both time lapse and motion-activated photographs. The presence of magpies was established through game camera capture, feather shed, scat, and tracks.

Baigent et al. described the succession and progression of scavenger guilds among a porcine cohort placed at FIRS-TB40 in the summer of 2018.<sup>5</sup> Cooperative and competitive behavior between avian groups was observed. While vultures and ravens scavenged cooperatively, magpies demonstrated inter- and intragroup aggression. Subsequent construction of scavenger cages acted as a deterrent to vultures and ravens, precluding access to human remains and affording magpie radiation into the role of apex scavenger. Temporal specificity was not observed in magpie scavenging, though voracity increased in late fall and persisted throughout overwintering. Both primary pattern and mode of tissue removal were distinct, as were the passive byproducts of their behavior. Primary patterns of magpie scavenging included: (1) boring; (2) muscle mining initiated via transdermal tissue plug removal; (3) longitudinal tissue peeling; (4) ribboning of connective tissue; (5) trabecular mining; and (6) both focal (active trabecular mining) and passive skeletal destruction. Additionally, a propensity for focal soft tissue scavenging was observed before progression to a novel intracorpore source was undertaken. Passive byproducts of magpie scavenging included: (1) peripheral soil excavation; (2) beak raking and superficial talon stamping; (3) pseudoburial; and (4) commingling and displacement of skeletal elements.

Due to their propensity for cooperative scavenging, the environmental, soft tissue, and osseous change catalyzed by "avian" scavenging has necessarily been understood in sum. Site infrastructure facilitated the establishment of magpies as the apex scavenger at FIRS-TB40, affording the opportunity for controlled observation of soft tissue and osseous scavenging, yielding a distinct pattern of categorical change.

**A141 The Fluvial Transport of Human Remains: Forensic Application of an HEC-RAS Model for Predicting Search Parameters for Human Remains Recovered From the Sacramento River, California**

*Eric J. Bartelink\*, California State University, Chico, Chico, CA; Colleen Milligan, California State University, Chico, Chico, CA; Steffen Mehl, California State University Chico, Chico, CA; Erik Fintel, Geographical Information Center, California State University, Chico, Chico, CA*

---

**Learning Overview:** After attending this presentation, attendees will understand how the relationship between river flow rates and the fluvial transport of human remains can be used to model search parameters for river victims.

**Impact Statement:** This presentation will impact the forensic community by discussing the use of actualistic research and a hydraulic engineering model to predict fluvial transport rates and search parameters for human bodies deposited in riverine systems. This research provides a tool for forensic practitioners and law enforcement to locate human remains more rapidly in the Sacramento River.

When a deceased person is introduced into a dynamic fluvial system, their remains can be transported a substantial distance from their original point of entry. Search efforts to locate bodies in fluvial systems often involve searches by divers near the point of entry, the use of side scan sonar and underwater cameras, and boats. For search teams, identifying search parameters for deceased persons in bodies of water is especially challenging and involves significant expenditures of time, money, equipment, and personnel.

To date, few studies have been conducted to model the movement of human bodies in riverine systems, such as the Sacramento River. The Sacramento River is California's largest fluvial system, with the highest flow rates in winter and the lowest in late fall. Every year, the river claims several victims due to drownings and boating accidents, with a small number being suicides and homicide body dumps. Our historical study of cases (1972–2012) found a moderate relationship between postmortem interval and transport distance among cases with known points of entry and exit (Pearson's  $r=.583$ ,  $p<.001$ ;  $r^2=.34$ ,  $n=66$ ).

In addition to the case data, this study used two types of rescue mannequins to simulate "sinker" and "floaters" body positions (between River Miles 199–80). For the sinker trials, data were collected manually on transport distance for submerged mannequins, and flow velocities and depth were recorded using an acoustic doppler velocimeter. The substrate was also photo-documented and described in field notes. The data indicated minimal transport distances for sinker mannequins, especially under low flow conditions and in shallower waters. The river substrate was also an important factor. For sand/gravel substrates, velocities over 2.0ft/sec were sufficient to move the mannequin whereas cobble substrates required velocities over 2.7ft/sec. For the floater trials, mannequins were released under low ( $< 6,000\text{cfs}$ ), medium (6,001–9,000cfs), and high ( $>9,000\text{cfs}$ ) flow rates. To maximize coverage, the study area was divided into 20 sub-reaches, with three independent trial runs conducted per location for each flow rate condition. For many of the trials, mannequin Global Positioning System (GPS) tracking devices provided real-time data.

The hydraulic simulations used the Army Corps of Engineers Hydraulic Engineering Center River Analysis System (HEC-RAS), which was originally designed for flood control management. The model was used to predict distance from the source given several parameters, such as flow rate conditions and river channel properties, and was calibrated using the mannequin transport data. The model was used to develop SacRiverSearch, a web-based application that can predict search areas for cases where entry location and approximate time of death are known parameters. The search box includes a 95% prediction interval beginning with the float stage of a deceased person. Although developed specifically for the study area, this model can be adapted to other rivers.

Research supported by NIJ Grant 2016-DN-BX-0159 "Fluvial Transport of Human Remains: Forensic Application of a HECRAS Model for Predicting Search Parameters for Human Remains Recovered from the Sacramento River, CA."

**A142 Standards for Analyzing Skeletal Trauma in Forensic Anthropology**

*Donna C. Boyd\**, Radford University, Radford, VA; *Julie M. Fleischman*, Harris County Institute of Forensic Sciences, Houston, TX; *Jade S. De La Paz*, University of Otago, Dunedin, Otago, New Zealand; *Carolyn V. Isaac*, Michigan State University, East Lansing, MI

---

**Learning Overview:** After attending this presentation, attendees will understand the importance of scientifically valid methods for skeletal trauma analysis, why many do not meet *Daubert* guidelines, and the importance of conducting skeletal trauma analyses that meet current published standards.

**Impact Statement:** This presentation will impact the forensic science community by reviewing the scientific validity of skeletal trauma research. It will discuss recommendations from the national Standard for Analyzing Skeletal Trauma in Forensic Anthropology, recently published by the American Academy of Forensic Sciences' Academy Standards Board (ASB).<sup>1</sup> Additionally, future research and initiatives in skeletal trauma analysis needed to meet the needs of the medicolegal community will be identified.

Skeletal trauma analysis is an integral part of a forensic anthropologist's requested examination of human remains in a medicolegal setting. However, the scientific foundation for trauma analysis, including its underlying theoretical and methodological approaches and the empirical data which support them, has undergone limited critical review. This has resulted in an absence of clarity and uniformity in method application, including an unknown degree of error associated with skeletal trauma analysis methodology. It has also led to subjective and over-interpretation of trauma evidence. For these reasons, skeletal trauma analyses often do not meet the *Daubert* guidelines for legal admissibility of scientific evidence, which can lead to uncertainties about the probative value of skeletal trauma evidence.

This study summarizes an evaluation of over 250 anthropological publications focused on skeletal trauma for their scientific validity and merit. This includes a systematic review of antemortem and acute/perimortem-focused skeletal trauma publications from the *Journal of Forensic Sciences* (1987 to 2023), *FSI International* (2010 to 2023), *FSI Synergy* (2019 to 2023), and *Forensic Anthropology* (2018 to 2023). Data collected from these publications focused on the use of a scientific approach, including defined terminology, clear and repeatable methodology, known error of methods used, and consideration of confounding variables affecting skeletal trauma presentation.

Results of this study indicate that, of the total (n=251) publications examined, the majority (70.5%) were classified as research articles, followed by technical notes (14.7%), case reports (7.6%) and literature reviews or retrospectives (7.2%). Research articles and technical reviews were scrutinized for their use of a scientific methodology; the following key deficiencies were identified: (1) misunderstanding, misuse, or absence of standardized skeletal trauma terminology or definitions (24.7%); (2) unclear, subjective, or inadequate methodology for trauma morphology observations and recording (32.3%); (3) unclear, subjective, or inadequate assessments of trauma mechanism (27.9%); (4) over-interpretation of skeletal trauma data beyond the supporting empirical evidence (58.4%); and (5) non-existent or inadequate inclusion of the limitations of the skeletal trauma study, including assessments of method error and validity as well as a consideration of the numerous intrinsic and extrinsic variables affecting skeletal injury and subsequent trauma interpretation (69.5%).

Standard 147 provides recommendations for skeletal trauma methodology, based on objective (empirically based) measures of fracture data observations, analyses, and interpretations. The use of macroscopic, microscopic (e.g., histology, light microscopy), imaging (e.g., CT, radiography) and other modalities for accurate trauma identification and interpretation are also recommended. The importance of meticulous distinctions between trauma description and interpretation is emphasized. Standardized trauma definitions are also provided.

In addition to these standard requirements, the authors recommend recognition and evaluation of error, bias, and limitations of methodological approaches in future skeletal trauma analyses, based on empirical data (such as that derived from controlled experimental design) in order to mitigate *Daubert* admissibility challenges. They also encourage the development of more formal training opportunities for forensic anthropology practitioners in skeletal trauma methodology, analysis, and interpretation, including an understanding of the legal restrictions and constraints associated with trauma interpretations. Finally, the importance of an interdisciplinary theoretical approach to understanding skeletal trauma, founded upon anthropological, anatomical, and biomechanical principles and functional perspectives, is also discussed.

**A143 The Use of Outline Analyses to Assess Kerf Floor Shape Patterns in Saw Marks**

*Alexis L. VanBaarle\*, Michigan State University, East Lansing, MI*

---

**Learning Overview:** After attending this presentation, attendees will have a better understanding of the relationship between kerf floor shape and saw class characteristics.

**Impact Statement:** This presentation will impact the forensic science community by providing an objective, quantitative analysis of kerf shape that can be referenced in dismemberment casework and future research.

In cases of dismemberment, forensic anthropologists assess the bony cut surfaces (i.e., kerfs) to estimate information (i.e., saw class characteristics) about the potential tool used, which can then aid in investigative and legal proceedings. One such variable, known as kerf floor shape, is defined as the incomplete kerf wall and floor profile. Previous research indicates that saw class characteristics such as tooth shape, saw set, and saw power can be deduced from the kerf floor shape. However, these studies are based on visual categorizations of kerf shapes, introducing subjectivity, and limiting statistical assessments. This study aimed to use Elliptical Fourier Analysis (EFA) to assess the relationship between kerf shape and saw class characteristics quantitatively and objectively.

The study sample consists of 133 incomplete kerf profiles made in 19 anatomically gifted, macerated human limbs using a diverse set of 19 saws. Entrance and exit profiles of the incomplete cuts were captured with a stereomicroscope and cropped at a depth of 3mm to produce a closed outline. The outline images were then imported into SHAPE ver.1.3 to perform an elliptical Fourier analysis to quantitatively represent the kerf shape, followed by Principal Component Analysis (PCA). Eighteen PCs (99% of variation) were exported and analyzed using IBM® SPSS. Multivariate Analyses of Variance (MANOVAs) were performed on all PCs to assess whether there was a significant difference between entrance and exit kerfs, and then to assess the effects of saw set, power, and tooth shape on overall kerf shape. When significant, Analyses of Variance (ANOVAs) were used to investigate which PCs were contributing to the differences and cross-validated stepwise Discriminant Function Analyses (DFA) were performed to evaluate classification accuracy.

There was no significant difference between entrance and exit defects ( $p=0.31$ ). Significant results ( $p<0.001$ ) were obtained for all saw class characteristics, indicating tooth shape, saw set, and power each affect kerf shape. PC 2, capturing “W-shaped,” flat, and rounded kerf floors, was significant for all three characteristics. PC1, capturing relative kerf width, contributed to power and set, but not tooth shape differences. DFA produced a model 88.0% accurate in assigning tooth shape. Rip saws tended to display relatively flat or stepped kerfs compared to crosscut saws that displayed W-shaped kerfs. DFA classified saw power with 89.5% accuracy. Mechanical saws displayed on average relatively wider kerfs that lacked W-shaped floors, while hand saws displayed narrower kerfs, with and without W-shaped floors. Classification of saw set, however, was relatively low, with only 59.4% correct overall.

The EFA results generally support anecdotal relationships presented in the literature and support the utility of kerf shape in forensic analyses. Results indicate that kerf floor shape (i.e., squared vs. W-shaped) can reliably estimate saw tooth shape and power with at least 88% accuracy. Estimations of saw set, however, are lower and this variable should not be estimated from kerf shape without further investigation. Kerf shape does not vary significantly between entrance and exit profiles. Note that kerf width is indirectly included in analyses given the standardized kerf depth, and PC1 (representing relative kerf width) did contribute to differences in power, but not tooth shape predictions. Overall, these results provide statistical support to kerf shape assessments and provide a foundation for future methodological approaches.

**A144 Deep Learning Models for Fracture Detection and Segmentation in Bone Histology**

*Carolyn V. Isaac\*, Michigan State University, East Lansing, MI; Redwan Sony, Michigan State University, East Lansing, MI; Alexis L. VanBaarle, Michigan State University, East Lansing, MI; Clara J. Devota, Michigan State University, East Lansing, MI; Arun Ross, Michigan State University, East Lansing, MI*

---

**Learning Overview:** This presentation will describe how deep neural networks can be used to automatically detect and segment fracture margins in whole slide images of decalcified cranial bone samples. After attending this presentation, attendees will understand how Artificial Intelligence (AI) can be applied to casework to enhance a practitioner's workflow.

**Impact Statement:** This presentation will impact the forensic science community as it is the first application of AI based on deep neural networks to histological fracture detection and segmentation, an integral first step in utilizing AI-enabled approaches for estimates of Post-Traumatic Survival Time (PTST).

As AI becomes more established and prominent in diverse fields, researchers should look toward utilizing this technology to benefit their respective fields. For example, digital pathology has implemented the AI subfield of deep learning to enhance diagnostic accuracy and efficiency, most notably in the oncologic application of identifying and quantifying cancerous cells and lesions. As researchers strive to establish methods to reliably estimate the PTST from fracture histomorphology, the capability of deep learning to detect patterns from a training dataset to interpret new data should be explored. This project is the first step in employing such models for histological fracture aging by developing deep learning approaches for the detection and segmentation of fracture margins in histological photomicrographs.

Several image analysis tasks are required in the analysis of a photomicrograph, including detection of the Region Of Interest (ROI), ROI segmentation, and ROI classification. In the context of analyzing a fracture photomicrograph for PTST, detection entails identifying the area of fracture, segmentation is demarcating that area, and classification is estimating the PTST. The study sample consisted of 120 photomicrographs of fractured cranial bone each annotated with a bounding box to demarcate the general fractured area and a precise contour outlining the fracture margins. The photomicrographs were divided into training (N=94) and testing (N=26) samples. Two approaches to automatic fracture detection and segmentation were developed and tested: a Faster R-CNN model and a Segment Anything Model (SAM). The Faster R-CNN uses two submodules: Region Proposal Network (RPN) and shared convolutional features. The RPN proposes the possible locations of the ROI with different aspect ratios to improve object localization, and the shared convolutional features allow reuse of the same set of features for different bounding boxes to enhance and streamline object detection. SAM is a versatile segmentation model pretrained on an extensive image dataset. Its architecture consists of three core components: the feature extractor, responsible for capturing essential features from the input; the prompt encoder, which converts the input bounding box into a meaningful embedding representation; and the mask decoder, which combines the extracted features of the object within the given bounding box to generate an output mask.

After training, the Faster R-CNN model was able to correctly detect the fracture bounding boxes with mean Average Precision (mAP) of 84.61% at Intersection over Union (IoU) threshold of 40%. To generate the precise contour of the fracture, the predicted bounding boxes from the Faster R-CNN model were used as input prompts in the generic SAM model to produce precise contours of the fracture defect. Initial qualitative observations of the SAM predictions show promise, with precise localization of the fracture in 7 of the 26 samples. As SAM has not been fine-tuned specifically for fracture photomicrographs, there is potential for substantial improvement with domain-specific training.

These results highlight the challenges of histological fracture PTST research broadly. The limited sample size makes it difficult to divide the sample for training and testing while maintaining an adequate training sample that represents the variety of fracture morphologies. Moreover, variations in bone samples due to the size, shape, composition, age of the individual, type of injury, and histological stain further make the task challenging.

As fracture detection and segmentation are the foundation of PTST estimates, future work will focus on refining deep learning models to improve accuracy, fine-tuning SAM for fracture photomicrographs, and data augmentation to provide a more robust training sample. This will allow for the second phase of study to commence: the development of the PTST estimation algorithm.

**A145 Unexpected Antemortem and Perimortem Rib Fractures in Infants Without Other Significant Injuries**

*Erin Chapman\**, Erie County Medical Examiner's Office, Buffalo, NY; *Katherine Maloney*, Erie County Medical Examiner's Office, Buffalo, NY; *Tara Mahar*, Erie County Medical Examiner's Office, Buffalo, NY

---

**Learning Overview:** The goal of this presentation is to describe five cases of infant death in unsafe sleep environments in which unexpected rib cage trauma was identified during postmortem examination.

**Impact Statement:** This presentation will impact the forensic science community by highlighting cases of unexpected trauma in infants and the need for gross and microscopic examination of osseous tissues, especially in the rib cage.

Studies have shown that the gross examination of osseous structures provides a better understanding of the timing and mechanism of injury, especially in juveniles.<sup>1</sup> Five cases of infant death were examined in which an anthropological analysis of the rib cage revealed numerous antemortem and perimortem rib fractures. Cases were selected based on the presence of healing and acute fractures in the absence of evidence of abuse or other significant traumatic injury to the deceased. In all five cases, unsafe sleep environments were confirmed. In all cases, there was no documented history of abuse or Child Protective Services reports. The infants ranged in age from 1 to 4 months old.

A total of 46 antemortem and 93 perimortem fractures were noted in the five infants. Antemortem fractures were predominately concentrated in the posterior rib cage. In all five cases, untrained and/or trained individuals administered manual Cardiopulmonary Resuscitation (CPR).

Although the current study includes antemortem and perimortem fractures, the authors were most interested in the potential cause(s) of the healing injuries. Studies have shown that anterior-posterior compression of the rib cage is necessary to create fractures in the posterior neck of the infant rib.<sup>2</sup> The mechanism of these injuries are consistent with the posterior migration of the rib shaft, which creates a Type II lever between the transverse process of the vertebra and the articulation with the vertebral body and rib head. The posterior migration of the rib shaft creates tensile force that acts upon the rib neck, causing initial failure on the visceral surface of the neck.<sup>2</sup> In other words, normal or appropriate manual CPR performed on an infant should not create posterior rib fractures. However, Love et al. have shown that unintentional anterior-posterior compression of the rib cage occurs in some cases during manual CPR administration in infants.<sup>3</sup>

In all cases, the administration of CPR does not account for antemortem healing fractures in the infant rib cage. The antemortem posterior fractures appeared to be consistent with anterior-posterior compression of the rib cage with initial failure in tension on the ventral neck or head of the rib at the terminus.<sup>2,4</sup> Posterior rib fractures of the neck have a high specificity for abuse; however, similar patterns may occur in accidental situations if the essential components exist.<sup>2</sup>

The cause of these antemortem injuries remains unknown. However, the cause was likely accidental in nature, given the information gathered during the investigation and postmortem examinations. The authors suspect that bed sharing and prior non-fatal rollovers on a soft surface may account for at least some of these healing injuries. The question remains whether or not the necessary posterior migration of the rib shaft happens when anterior compression of the rib cage occurs when the child is supine (in a rollover scenario) due to the soft surface beneath them.

**A146 Whole Body Fracture Patterns From Blunt Force Trauma Vary Within Similar Experimental Loading Events**

*Amanda M. Agnew\*, The Ohio State University, Columbus, OH; Angela L. Harden, Injury Biomechanics Research Center, The Ohio State University, Grove City, OH; John H. Bolte IV, The Ohio State University, Columbus, OH; Yun-Seok Kang, The Ohio State University, Columbus, OH*

---

**Learning Overview:** After attending this presentation, attendees will have an appreciation for interdisciplinary research in skeletal trauma analysis by learning how experimentally driven biomechanical validation of injury mechanisms can strengthen interpretations of observed trauma in forensic casework. Additionally, the importance of utilizing experimental data to explain differences in injury patterns will be emphasized.

**Impact Statement:** This presentation will impact the forensic community by demonstrating the need for caution in over-interpreting injury patterns. Further interdisciplinary analyses of skeletal trauma in experimental human specimens are needed to better understand fracture mechanisms and specific causes for differential injuries.

A 31% increase in deaths between 2010 and 2019 was identified for older occupants in car crashes in the United States.<sup>1</sup> In near-side impacts, specifically, small, elderly female occupants were identified as the most at-risk population for fatality from thoracic injury.<sup>2</sup>

Ten Postmortem Human Subjects (PMHS) were included in this study. All PMHS were elderly females over 60 years old (61–94 years), approximately 5<sup>th</sup> percentile in height (147–167cm) and weight (40–56kg), with osteopenic lumbar spine areal bone mineral Density (aBMD) in order to target a potentially frail demographic. Near-side impact sled tests were conducted that mimicked real-world motor vehicle crash boundary conditions. Boundary conditions for the series included an intruding driver's side door that was controlled using the Advanced Side Impact System (ASIS) on a HYGE™ sled. The sled acceleration matched the acceleration profile of the impacted vehicle with a delta-V of 50kph, while four pneumatic cylinders of the ASIS, covered by a door liner, produced realistic door intrusion. Each subject was seated on a mass-production driver seat, equipped with a side airbag and standard three-point restraint with a pretensioner. Subject seating and positioning were tightly controlled in a realistic driving posture to ensure highly repeatable tests.

Nine PMHS experienced rib fractures, particularly on the impact side, but the locations varied with most fractures occurring anteriorly, and some posteriorly. The upper ribs were most affected, and six PMHS had rib fractures on the non-impacted side. Injury severities ranged from *none* to *severe* according to the Abbreviated Injury Scale (AIS), and number of rib fractures per PMHS ranged from 0–20 rib fractures. Three PMHS had sternum fractures, five had upper extremity fractures, and seven had lower extremity fractures. One PMHS experienced no injuries at all.

The same loading conditions experienced by all ten PMHS resulted in extreme variability in fracture location and severity. This demonstrates that a great number of fractures throughout the body is not necessarily associated with a different or more severe traumatic event when interpreting fracture mechanisms. Common assumptions regarding loading direction, speed, or severity based on overall fracture patterns may not be reliable in trauma interpretations of blunt force trauma.

**Fracture; Blunt Force; Trauma**

## A147 Structural Violence in Orleans Parish, Louisiana: Implications for Forensic Anthropological Casework

Krista E. Bennett\*, Louisiana State University, Zachary, LA; Sophia I. Reck, Louisiana State University, Baton Rouge, LA; Ginesse A. Listi, Louisiana State University, Baton Rouge, LA; Teresa V. Wilson, Louisiana State University, Baton Rouge, LA; Emily F. Michon, Louisiana State University, Baton Rouge, LA

**Learning Overview:** After attending this presentation, attendees will have a better understanding of assessing forensic anthropological casework through the lens of structural violence in Orleans Parish, LA.

**Impact Statement:** This presentation will impact the forensic community by providing an examination of contemporary forensic anthropological case work for evidence of structural violence and how that may assist with the identification of unidentified remains.

In biological anthropology, structural violence refers to how the body, often the skeleton, is affected by systemic imbalances in access to health care, socioeconomic resources, and death care among different populations.<sup>1,2</sup> Osteological evidence often consists of skeletal pathology, antemortem injuries, and perimortem trauma. Since systemically engendered suffering in everyday life (i.e., structural violence) has accumulative effects on the body, anthropologists also consider injury recidivism, or the aggregate of traumatic lesions accumulated by an individual, in research that addresses structural violence.<sup>3,4</sup>

The current study explores the concept of structural violence in contemporary populations living in Orleans Parish (OP) using data culled from the forensic anthropology case files of the Louisiana State University Forensic Anthropology and Computer Enhancement Services (LSU FACES) Laboratory. Information on skeletal injury recidivism (considering both antemortem injuries and perimortem trauma) and recovery location were used to assess OP cases to identify patterns of structural violence that potentially could assist with generating leads for cases of unidentified human remains.

Case files from OP in which the decedent was identified, spanning 1991 to 2021, were selected for assessment (n=41). The sample consisted of 32 full anthropological analyses and nine trauma-only analyses. The sample included 31 males and 10 females; ages ranged from 18 to 89 years, with one individual of unknown age. Additionally, 26 individuals identified as Black, 10 as White, 2 as multiracial, 2 as Asian, and 1 as Hispanic. Assessment of case files involved examining reports for: (1) the number of antemortem skeletal injuries, (2) the presence of perimortem trauma, and (3) the type of perimortem trauma. Additionally, data from the United States Census Bureau (demographics and income) were collected for comparison with case file data to identify patterns regarding demographic and socioeconomic variables.

Skeletal evidence of one or more Antemortem Injuries (AMI) was observed in 66% (n=27) of the cases. Only three individuals had a single element with a healed injury. The remaining 24 individuals had two or more AMI involving multiple elements and various stages of healing. Additionally, 46% (n=19) exhibited Perimortem Trauma (PMT). High-velocity trauma and blunt force trauma had the highest rate of incidence at 31.6% each, versus sharp force and thermal trauma at 5.3% each. Of the 19 with PMT, 63% (n=12) also experienced AMI. The assessment of OP cases revealed a high percentage of individuals who experienced AMI and PMT that are consistent with injury recidivism.

Presence of AMI and/or PMT was also compared to sex (M:F), age, social race, Per Capita Income (PCI), and location of recovery. Of the 27 with AMI, 63% identified as Black (16M:1F), 26% White (5M:2F), the remaining 11% included Asian (1M), Hispanic (1M), and multiracial (1M) social races. When examining PMT (n=19), 68% identified as Black (10M:3F), 26% as White (2M:3F), and 5% as Hispanic (1M). From the 12 with AMI and PMT, 7 identified as Black males (68%), 2 each as White males and females (34%), and 1 as Hispanic male (8%). Regarding recovery location, two cases were found in areas with PCI > \$40,000, and 35 cases from neighborhoods with PCI < \$40,000; the recovery location for four cases was unknown.

Young to middle-aged males found in lower-income neighborhoods represented the largest group experiencing injury recidivism in this study. The assessment identified structural violence involving persons from historically marginalized communities, specifically Black males. The expansion of anthropological assessments to include data that can be socially and culturally contextualized as structural violence enables forensic anthropologists to provide information that will generate leads for unidentified remains and, thus, better serve medicolegal agencies, policymakers, and communities.

**A148 Skeletal Trauma in Suicide Cases (2017–2018) in Puerto Rico After Hurricane Maria**

Gabriela I. Rios Santiago\*, University of Coimbra, Coimbra, PR; Maria Teresa Ferreira, University of Coimbra, Coimbra, Portugal; Sofia N. Wasterlain, University of Coimbra, Coimbra, Portugal

---

**Learning Overview:** After attending this presentation, attendees will understand the importance of analyzing skeletal trauma-related deaths in suicide cases after a severe hurricane.

**Impact Statement:** The presentation will impact the forensic community by presenting skeletal trauma assessment in suicides after natural disasters.

Natural disasters (e.g., hurricanes) may increase suicide deaths.<sup>1</sup> In 2017, the category 5 Hurricane Maria caused massive destruction in Puerto Rico. The loss of basic living conditions (electricity, water, among others) led to an elevated suicidal ideation risk.<sup>2,3</sup> Within five months, the suicide rate increased 29% compared to previous years.<sup>3</sup> In forensic investigations, suicidal cases present unique challenges for skeletal trauma examination, depending on the mechanism of death. The three most prevalent methods of suicide after Hurricane Maria were hanging, gunshot wounds, and falls from heights.

In this study, the autopsy records from the medical examiner's office at the Institute of Forensic Sciences of Puerto Rico, namely 100 suicide cases that occurred between the years of 2017 and 2018, were analyzed. For that purpose, the cross-platform relational database FileMakerPro® version 14 was used. The inclusion criteria were individuals over 18 years of age, victims of suicide through hanging, gunshot wounds, and falls from heights. Skeletal trauma was recorded according to location in the skeleton.

The analyzed sample was composed mostly of males (89%). The average age of the analyzed individuals was 56 years (+/-16). Regarding the method of suicide, 44 were hangings (males: 41; females: 3), 34 were gunshot wounds (males: 33; females: 1), and 22 were falls from heights (males: 15; females: 7). All individuals who died from falls and from gunshot wounds presented skeletal trauma. In opposition, only 20.5% of the individuals whose mechanism of death was hanging presented skeletal trauma.

Falls from heights affected only the axial skeleton in 14% of the individuals and only the cranial skeleton in 4.5% of the individuals. The appendicular skeleton was never affected alone in this mechanism of death. Much more common was the combination of trauma in different parts of the skeleton (cranial and axial and appendicular: 27%; cranial and appendicular: 4.5%; axial and appendicular: 50%). Interestingly, the combination of trauma lesions in both cranial and axial skeleton was never observed in falls from heights. In deaths by gunshot wounds, 31 individuals (91.2%) presented cranial fractures, and 3 (8.8%) had fractures in the axial skeleton. Finally, in hangings, 77.8% of the individuals presenting skeletal trauma showed fractures in the thyroid cartilage, 33.3% in the hyoid, and 11.1% in the cervical vertebrae.

The results presented here, although preliminary, show the patterns of skeletal trauma more commonly observed in different methods of suicide and are in accordance with the described in forensic literature.<sup>4</sup> In a near future, the aim is to provide a baseline for the forensic sciences community to better understand the interrelationship between trauma-related deaths and their circumstances.

**A149 An Analysis and Reconstruction of Remains from a World War II Mass Grave in the Szpęgawski Forest, Poland**

*Joanna Wysocka\*, Polish Academy of Sciences, Wrocław, Dolnoslaskie, Poland; Dawid Kobińska, University of Łódź, Łódź, Lodzkie, Poland*

---

**Learning Overview:** This presentation examines human remains from a World War II mass grave located in Szpęgawski Forest in southeast Poland. After attending this presentation, attendees will understand the importance of conducting research on war crimes by highlighting the social impact on the public and the relatives of the war victims. Furthermore, the methodology used when working with cremains and case studies will be presented.

**Impact Statement:** This presentation will impact the forensic science community by highlighting the importance of humanitarian efforts in forensic archaeology, specifically in contexts surrounding war crimes.

The well-planned mass murder of Polish citizens by Nazi Germans was happening all around Poland during World War II in the autumn of 1939. Pomeranian voivodeship, where the Szpęgawski Forest is located, is one of the most affected areas. Educated, disabled, and mentally ill individuals were targeted and exterminated under the pretext of achieving the Nazis' vision of an ideal population, as prescribed by the Führer. No man, woman, or child was treated with condescension. Targeted educated people (e.g., teachers, politicians, policemen, and priests) were killed by gunshot to the head in the forest just prior to being buried. Additionally, disabled and mentally ill individuals who were perceived as "life not-worth-living" were often killed in hospitals by lethal injection, and their bodies were carried out to be buried with other victims. In 1944, when the war seemed to be lost for Nazi Germany, the exhumation and burning of those bodies were ordered to cover up the evidence of the war crimes.<sup>1</sup>

In the Szpęgawski Forest, there are approximately 5,000 people buried in multiple mass graves. They were marked as a single grave until after the war ended. In the summer of 2023, a team of forensic archaeologists and anthropologists excavated suspected regions in the forest to confirm the presence of the remains. Mass grave numbers 19 and 31 were excavated. Mass grave 31 was fully excavated and 19 was divided into four parts, of which only two were excavated.

The analysis of the human remains included assessment of fragmentation, taphonomic changes, degree of burning, sex, age at death, and pathological changes. One aim of the analysis was to estimate the Minimum Number of Individuals (MNI) buried.

Mass grave 31 was found empty and classified as a symbolic grave. Mass grave 19 had multiple layers of cremains and unburned human remains on the bottom of the grave pit. The postmortem changes of these remains (including bone warping, thumbnail fracture, and "sandwich effect") suggest that the bodies were partially covered with soft tissue during the exhumation in 1944, and then burned and reburied. The color of the remains indicated a low temperature of burning (around 200–550°C). The MNI was estimated to be 87 individuals, including six non-adults. Male features were observed more frequently, suggesting a predominance of men among the victims. Two individuals whose remains were not precisely exhumated and were not burned had evidence of gunshot wounds to the cranium, one reflected by a keyhole fracture. Reconstruction of one cranium was possible, and the trajectory of the projectile bullet was estimated.

The ongoing archaeological investigations and analyses conducted at the Szpęgawski Forest serve as a crucial endeavor to honor the memory of the victims and shed light on the atrocities perpetrated during this chapter of history, thereby facilitating the acknowledgment and understanding of the tragic events that transpired during the Second World War in Poland.

## A150 The Latin American Association of Forensic Anthropology (ALAF): 20 Years of Development

*Luis Fondebrider\*, Madrid, Spain*

---

**Learning Overview:** After attending this presentation, attendees will be aware of the developments that forensic anthropology has developed in various Latin American countries, its applications, and its challenges.

**Impact Statement:** The impact of this presentation will be reflected in the different processes that forensic anthropology has followed in the United States and in the development of the three branches of anthropology in Latin America, with a broader and more comprehensive perspective.

In 2003, the ALAF was created with a meeting of the main forensic anthropologists in Latin America and three independent teams (Argentine Forensic Anthropology Team, Forensic Anthropology Foundation of Guatemala, and Peruvian Team of Forensic Anthropology).

The ALAF brings together professionals from Latin America who work in the field of forensic anthropology and other forensic disciplines. ALAF currently brings together professionals from more than 20 countries and is the largest group of forensic anthropologists in Latin America.

The objectives of the ALAF are to establish professional and ethical criteria for the exercise and promotion of the use of Forensic Anthropology and Archeology in judicial investigations in the different countries of Latin America, as well as the creation of an independent directory that guarantees technical autonomy of forensic anthropological investigations and the development of studies and the quality of practice.

The initial objective in 2003 was to develop a model for the application of forensic anthropology following the specific needs of the region (violence of all kinds), with a perspective that contemplated the needs of victims of human rights violations. In 2012, a Forensic Anthropologist Certification process was created that has been on-going for ten years and has become a successful process in the world. In 2023, a similar certification process will be carried out for forensic archaeologists. To this day, ALAF holds a congress each year in a different Latin American country for five days and has about 120 members.

During this presentation, the different contexts of violence (political conflict, migrants, femicide, organized crime) to which forensic anthropology is applied today in Latin America and its growing role in the medicolegal systems of the continent will be discussed. Also, the achievements and challenges of these 20 years of work will be discussed, as well as the relationship with colleagues in the United States.<sup>1,2</sup>

### Latin America; Families; Certification

---

**A151 Missing Persons in Argentina: The Age Progression Technique to Support Non-Profit Organizations in the Search for the Lost**

*Laura Donato\*, Parma, Emilia-Romagna, Italy; Luigi Tonino Marsella, University of Tor Vergata, Rome, Lazio, Italy; Rossana Cecchi, Parma, Emilia-Romagna, Italy; Marcela Lerda, Lic. Relaciones industriales/ Voluntaria, Missing Children Argentina, Los Polvorines, Buenos Aires, Argentina; Michele Treglia, University of Tor Vergata, Rome, Lazio, Italy*

---

**Learning Overview:** This presentation will show how the age progression technique can be applied to the search for missing persons. After attending this presentation, attendees will understand the importance of involving age progression in the search for the long-lost in order to be able to disseminate updated mugshots according to the current age of the missing.

**Impact Statement:** This presentation will impact the scientific community by showing how age progression has been applied to the search for missing persons in Argentina. The example case examined will show how, thanks to the international collaboration of non-profit organizations, the process of age progression for the search for the missing is activated and implemented.

In every country in the world, the phenomenon of missing persons is present and focuses the attention of the authorities who have actions to monitor and contain the problem.

Argentina is one of the countries which, despite the difficulties associated with the political turmoil, has undertaken initiatives aimed at countering the increase in the number of missing persons. Among these, the Person Search Coordinated Action against Trafficking in Persons (ACCT) in 2013, the Nacional de Información de Información de Personas Menores Extraviadas, and Alerta Sofia monitor the number of missing persons in Argentina.

Some organizations have taken action to help spread the photos of the missing person in the area. Among these, the Missing Children Argentina (MCA) is a non-profit organization that supports the families of the disappeared. To increase the chances of finding those missing for many years, MCA makes use of the support of age progression, provided by the non-profit organization Italian Missing Children (IMC). MCA and IMC have activated their collaboration since 2020, processing eight cases of digital aging.

The case of a missing girl and her age progression is reported to document the collaborative work between these two organizations. Age progression technique is based on scientific standards of facial aging, developed for medical reasons, especially in cosmetic surgery and orthodontics. To obtain as accurate a result as possible, the IMC made use of photographic material of the relatives of the lost. Photos of parents and siblings were used to identify similar somatic traits and to study their evolution during growth. By using Adobe® Photoshop® graphic software, specific facial morphological features were searched for in the high-resolution reference photos and assembled until a new mugshot of the missing person was obtained as a result.

The photo of the missing individual's face, processed through digital aging, is inserted into a poster with information on the case and diffused by television and social media. The poster indicates the time and place of the disappearance, personal data of the missing person, contacts in case of sighting, photos closest to the moment of disappearance, and those obtained with age progression techniques.

It is important to also provide information to the population on the possibility of requesting the age progression of a person who has been missing for a long time, thus supporting research activities.

---

**Missing Persons; Forensic Anthropology; Age Progression**

---

**A152 The Role of Forensic Anthropology in Long-Term Missing Persons Cases in Scotland**

*Catriona M. Davies\*, Centre for Anatomy & Human Identification, Dundee, Scotland; Lucina Hackman, University of Dundee, Dundee, Scotland; Helen Langstaff, University of Dundee, Dundee, Scotland; Diana Swales, University of Dundee, Dundee, Scotland*

---

**Learning Overview:** After attending this presentation, attendees will have insight into the application and role of forensic anthropology in Long-Term Missing Persons (LTMP), “cold cases,” voluntary disappeared, and no body homicide cases as they relate to Scotland. Through examination of past cases, this presentation will discuss the benefits and limitations of anthropological involvement in such contexts and what lessons may be learned that can be applied to other body recovery and identification challenges, particularly in relation to vulnerable persons.

**Impact Statement:** LTMP cases, often termed “cold cases” by the general public, the media, and society at large, impact not only the immediate family and friends of the missing individual, but have the potential to affect whole communities for decades. In Scotland, forensic anthropologists are routinely involved in such cases from an early stage, either through planning, assisting in a ground search where bone fragments have been identified, or in the recovery and examination of human remains. This presentation will impact the forensic science community by sharing the experience of the forensic anthropology practitioners in Scotland in relation to these cases, enhancing the awareness of the benefits of the early involvement of anthropologists in such investigations.

Vulnerable persons, including the elderly, those with medical conditions such as dementia, poor mental health, or those who live at the fringe of society are more likely to be the subject of LTMP cases than other groups, and are also more likely to go missing without being reported to the police.<sup>1</sup> The expansive and rural nature of the majority of Scotland makes the task of investigating, and searching for LTMPs and those who have voluntarily disappeared particularly challenging, with discoveries of human remains often being the result of rural land-management activities or chance discoveries by outdoor enthusiasts. This presents challenges for the recovery of human remains, including effects of taphonomy, scavenging, and the lack of safe and easy access to the remains.

In recent years, forensic anthropologists based at the University of Dundee, Scotland, have been involved in various stages of investigations relating to individuals who have voluntarily disappeared and LTMPs, including those believed to be the victims of homicide. The early involvement of forensic anthropologists in such investigations has provided the opportunity for relevant information and advice to be provided during the planning of search activities and for appropriate attendance in the search, recovery, and postmortem examination of any recovered human remains. This presentation will, through the presentation of past cases, provide insight into the benefits of early involvement of forensic anthropologists in the search planning for LTMPs. Further case studies will illustrate the positive impact that the attendance of a forensic anthropologist during the subsequent search and recovery activities, including where fragmented and non-human remains are located; and finally, the benefit that the involvement of the forensic anthropologist in the postmortem examination of the remains can have on the success of the investigation. The particular context of voluntary disappearance and vulnerable persons will be considered in light of the specific challenges presented by these cases.

**Missing Persons; Unidentified Persons; Human Remains**

**A153 FORDISC® and AncesTrees: Limitations and Considerations for the Identification of Individuals From Central and South America**

Hannah G. Messersmith\*, University of Dundee, Kenosha, WI; Julieta Gómez García-Donas, University of Dundee, Dundee, Scotland

**Learning Overview:** The goal of this presentation is to present new data on population structure and population history from individuals from Central and South America through the interpretation of population-affinity estimations obtained by two online applications (FORDISC® and AncesTrees).

**Impact Statement:** This presentation will impact the forensic science community by providing forensic practitioners with a theoretical and practical background for the application of two popular online softwares, FORDISC® and AncesTrees, targeting issues for population-affinity estimations on human remains from Central and South American.

Extreme conditions leading to rapid skeletonization in some areas of the United States-Mexico border can make identification difficult.<sup>1</sup> From the demographics gathered for biological profile estimation, biogeographical origin can impact the choice of subsequent methods for sex or age-at-death assessment.<sup>2</sup> AncesTrees and FORDISC® are two computerized statistically based methods for estimating population affinity.<sup>3,4</sup> To determine the reliability of group allocation using these applications, different target samples should be tested. The aim of this study is to explore the reliability of these applications in estimating the origin of individuals from Central and South America, comprising population groups that likely form the migratory flow prevalent across the United States-Mexico border.

A total of 50 adult individuals (25 males and 25 females) identified as Mexican, Mexican American, Hispanic, New Mexican, or Latino were selected from the New Mexico Decedent Image Database.<sup>5</sup> Seventeen cranial measurements were collected from Computed Tomography (CT) scans. Compiled measurements followed protocols outlined by AncesTrees and FORDISC®. Parameter values were inserted into the online platforms, with the settings for the application determined as non-prior background information. For FORDISC®, both the Howells' and the Forensic Anthropology Data Bank (FDB) datasets were tested to explore any potential differences related to the chronology of the reference samples, as well as allowing for a comparison between AncesTrees and FORDISC® historical samples. All allocations are reported in the results, with Posterior Probability (PP) and Group Membership (GM) with values  $\geq 0.80$  being considered for further interpretation of the group allocation.

Results show that AncesTrees allocated individuals as European (48%) and East Asian (32%), with the remaining biogeographical population sample allocations representing less than 10%. For the FORDISC® FDB, 26% of the sample was estimated as White and 24% of the sample was allocated as Hispanic, with the third-highest number of individuals being associated to Japanese (16%), Guatemalan (12%) and Chinese (12%) samples. Regarding the FORDISC® historical dataset, 24% of the individuals were classified as European with the next highest allocation being for East Asian samples (40%). Very few individuals obtained a PP higher than the threshold for FORDISC® estimations while GM for AncesTrees was over 0.80 for around 62% of the sample

An accurate reconstruction of the biological profile is crucial for positive identification. Most of the population allocations obtained here using two commonly used online platforms present trends that suggest individuals from Central and South American origin would fall within Hispanic and European populations as well as East Asian samples. This research provides insights on population structure and population histories, as the patterns observed may be linked to social and political history.<sup>6,7</sup> Future research, including larger and more diverse samples, will confirm our results and provide further information on human variation and inter-population differences. A consensus on the terminology as well as a revision of the information used for grouping the samples is recommended to ensure consistency between forensic practitioners and researchers. Moreover, larger and more representative datasets are needed to increase the accuracy and reliability of identification of unknown individuals in a forensic context, especially for areas with high migration flows such as the United States-Mexico border.

**A154 The Forensic Border Coalition South Texas Cemetery Survey: Insights From a Forensic Science and Humanitarian Effort Addressing Unidentified Burials and Unidentified Remains**

*Kate Spradley\*, Forensic Anthropology Center at Texas State University, San Marcos, TX; Christine M. Kovic, University of Houston Clear Lake, Houston, TX; Robin C. Reineke, University of Arizona, Tucson, AZ; Molly A. Kaplan, Texas State University, San Marcos, TX; Molly Miranker, Texas State University San Marcos, Austin, TX; Mercedes Doretti, Argentine Forensic Anthropology Team, Brooklyn, NY; Rachel Daniell, Pratt School of Information, Pratt Institute, New York, NY*

---

**Learning Overview:** This presentation reviews the Forensic Border Coalition's (FBC) South Texas Cemetery Survey, 2015–2017. After attending this presentation, attendees will understand the challenges to finding, accounting, and conducting forensic and humanitarian interventions in Texas and the implications to missing and deceased migrant accounting in other fatal international border zones.

**Impact Statement:** This presentation will impact the forensic science community by informing attendees that the FBC conducted this South Texas Cemetery Survey in the Texas Rio Grande Valley region of the Central America-Mexico-United States migration corridor, assessing available death documentation of unidentified remains likely corresponding to migrants. The FBC consulted local cemetery and funeral home information and conducted physical surveys of multiple burial sites.

Through a review of the present research, its purpose, and its conclusions, the FBC shares: (1) a brief examination of the increase in deaths of persons in migration at the United States southwestern border, focusing on increased deaths in Texas; (2) background on the formation of the FBC in response to addressing missing migrants and migrant deaths; (3) the FBC's Texas Cemetery Survey Project development, methods, and outcomes; and (4) recommendations for actionable changes based on the experiences of this project.

**Field Work Summary:** Between July 22, 2015, through April 1, 2017, the FBC conducted site visits, cemetery surveys, and gathered public records (i.e., financial, death certificates, records of death, indigent burial records, NamUs Unidentified Person records, field surveys of cemeteries with unidentified burials likely to correspond to migrants, etc.) to examine challenges related to unidentified remains in Texas. Then, the FBC mapped 133 unidentified remains of probable migrants from seven South Texas counties (64 Hidalgo, 43 Cameron, 12 Starr, 14 Kenedy, 0 Willacy, 0 Jim Hogg; due to an existing collaborative relationship with the Brooks County Sheriff's Office and Operation Identification, the FBC did not survey cemeteries in Brooks County). This number is a conservative estimate because many migrants are never recovered. This is also a conservative estimate because of the limited and inconsistent documentation of where and how many unidentified burials exist in those counties.

The FBC's key findings point to severely lacking practices. There is a lack of data on migrant deaths, a lack of recordkeeping, and a lack of coordination of records among participating agencies. In some counties, the FBC found that if DNA had been collected on unidentified remains, it had not been entered into national databases, making it impossible to identify remains, even if relevant family reference samples exist and have been entered into these databases. In other cases, DNA samples were not collected before the remains were buried. The degree of fragmentation and failure to effectively manage the forensic cases of unidentified human remains in Texas need to be the core targets efforts for change.

The FBC initially planned that the seven counties would comprise only Phase I of several surveys. The findings, however, caused the FBC to pivot its efforts in Texas to address immediate needs indicated by the Survey (e.g., exhumations) and to adapt other southwestern border-wide activities to more effectively address the challenges related to migrant death. In the concluding discussion, the FBC shares five critical recommendations for supporting the processes around finding and investigating unidentified human remains of probable migrants that directly affect Texas counties and are relevant to the whole southwestern border and are informative to other fatal migration corridors such as the Mediterranean.

**A155 Shifting Routes: Expanding Migrant Decedent Identification Efforts in Texas**

*Molly A. Kaplan\*, Texas State University, San Marcos, TX; Courtney C. Siegert, Texas State University, Austin, TX; Ivanna Robledo, Texas State University, San Marcos, TX; Kate Spradley, Forensic Anthropology Center at Texas State University, San Marcos, TX; Chloe P. McDanel, Operation Identification, San Marcos, TX*

---

**Learning Overview:** After attending this presentation, attendees will better understand major shifts in migrant death investigation practices in Texas over the past ten years.

**Impact Statement:** This presentation impacts the forensic science community by exposing practitioners to the challenges, advancements, and changes in migrant decedent identification in Texas, which has implications for all jurisdictions handling transnational unidentified persons cases.

Migrant death along the United States-Mexico border persists at disastrous rates while many Texas border jurisdictions remain unable to access medicolegal services or feasibly manage decedent identification. In 2012, in response to an influx of migrant death in South Texas, Operation Identification (OpID) was founded as a humanitarian initiative of the Forensic Anthropology Center at Texas State (FACTS) to assist border counties with recovering, identifying, and repatriating migrant decedents. Specifically, OpID began as a project to assist with exhumations, forensic anthropology analysis, and DNA submission for the long-term unidentified buried in cemeteries throughout the Rio Grande Valley. As a member of the Forensic Border Coalition (FBC), OpID participated in the three-year South Texas Cemetery Survey to document the burial locations of migrant decedents and generate counts of unidentified human remains in the region. As a result of this survey, OpID and partners exhumed 230 long-term unidentified decedents from four counties between the years of 2013–2021, of which 31 have been identified.

However, shifting migration routes and increased death in under-resourced West Texas regions have created a new state of emergency necessitating additional responses. Throughout the past two years, OpID has adapted to include case management of more recently recovered individuals from counties that have little or no previous experience overseeing cases of unidentified migrants. Of the 225 cases OpID has received from direct agency transfers, 40 have come from 11 border counties not originally included in the South Texas Cemetery Survey. Additionally, at the request of county officials, throughout the fall and spring of 2023, OpID has focused efforts on exhuming and identifying 26 individuals who perished in Eagle Pass, Maverick County, in the summer of 2022. As a new epicenter of migrant death, Maverick County experienced an average of one death per day this past summer and began burying decedents without investigative efforts due to lacking storage—a situation mirroring Brooks County in 2012 that requires urgent intervention.

While increased identification hypotheses for these and other recently recovered individuals partially contribute to the sharp increase in identifications facilitated by OpID—from an average of five per year through 2021, to 26 in 2022, and 23 to-date in 2023—this also reflects the need for continued capacity building in border jurisdictions. Although extensive community outreach, training efforts, and stakeholder collaboration have improved case management in the Rio Grande Valley, particularly in Brooks County, the situation in West Texas and ongoing barriers to decedent identification call for the development of sustainable disaster management infrastructure.

The objective of this presentation is to discuss the challenges, advancements, and changes to migrant death investigation in Texas through the experiences of OpID. After recounting the trajectory of the OpID project over the past ten years, this presentation highlights trends in migrant death management along the Texas southern border through recent case examples. It is the goal of this discussion to promote the development of centralized agencies for migrant death investigation in Texas and to advance the integration of disaster victim identification approaches in jurisdictions managing high numbers of transnational unidentified deaths.

---

**Identification; Migrants; Medicolegal Death Investigation**

**A156 Necrosilence: GIS Visualizations of Migrant Mortality in South Texas, 2009–2020**

*Molly Miranker\*, Texas State University San Marcos, Austin, TX; Alberto Giordano, Texas State University San Marcos, San Marcos, TX*

**Learning Overview:** After attending this presentation, attendees will better understand geographic and temporal trends of reported migrant deaths in South Texas, as well as the implications of “empty map spaces” or necrosilences.

**Impact Statement:** This presentation will impact the forensic science community by addressing two persistent issues specific to the Texas-Mexico border migration context. First, it establishes a 12-year mortality profile. Second, it introduces the concept of necrosilences and their implications to both forensic and humanitarian work and usage of geospatial tools.

The study area, South Texas, is comprised of ten counties with some of the highest reported migrant mortality incidences, 2009–2020. A total of 1,412 records of migrant decedents were obtained from local sheriffs, justices of the peace, and Border Patrol. We applied Analyses Of Variance (ANOVA), spatial statistics, and cluster analysis to test the relationships of mortality point locations throughout South Texas. We used RStudio 3.5.3 ANOVA and independent t-tests to determine whether there were any differences in migrant mortality between counties and, in a separate set of tests, whether migrant mortality varied significantly by season. ANOVA is an aspatial type of analysis. To look at spatio-temporal patterns, we applied a suite of spatial analytical methods, starting with the Mean Center (MC), Standard Distance (SD), and Directional Distribution (DD) of mortality locations, which were calculated in ArcGIS® Pro 2.9.3. We used Getis-Ord Gi\* in ArcGIS® Pro to test for mortality clustering of migrant mortality locations in relation to neighboring features in the study area, specifically private land ownership, as well as by year the remains were found and in relation to distance to United States Border Patrol (USBP) structures (ports of entry, stations, checkpoints) and to roads. Finally, to examine patterns of spatial and temporal distribution together, we used SaTScan™ v10.0.

Two important aspects of the patterns of migrant mortality in South Texas emerge from spatial analysis and Geographic Information Systems (GIS) mapping. To start, the 12-year South Texas migrant mortality spatiotemporal profile illustrates a deathscape that approximates the “second border” of Border Patrol checkpoints.<sup>1,2</sup> Visually, this is illustrated by the majority of DD ellipses having a NW-to-SE orientation, as well as by county-level MCs falling near at least one USBP checkpoint (within 0.22–17.00km). Further, Getis-Ord Gi\* results showed that migrant decedents recovered farther away from or in between Border Patrol structures tended to be significantly more than expected, and decedents relatively closer to Border Patrol structures were fewer than expected.

The second important takeaway was that there were large swaths of South Texas that were devoid of migrant death. These “empty” areas are emblematic of necrosilences. That is, instances where there is a lack of access or accounting rather than absence of death. Necrosilences are the result of harmful inactivity, obfuscation of death, or failing to intervene in “letting die” situations. As pertains to the visualization and generation of spatiotemporal profiles of migrant mortality, necrosilences are informative. Smuggling of migrants is a highly coordinated process, and it is probable that once migrants are past the border itself, the process of being moved from stash house to stash house via vehicles creates the illusion of blank spaces, especially between the Mexican border and Border Patrol checkpoints.<sup>3</sup> Rather than being free of deaths, these areas likely are not searched regularly or are otherwise inaccessible due to lack of permission, personnel, or other resources. Key “empty” areas include all of Starr, Zapata, Willacy, and Cameron Counties, the northern portion of Hidalgo County, and the southern portions of Brooks and Kenedy Counties.

**B1 What's In It For Me (WIIFM)?: Streamlining Sexual Assault Evidence From Collection to Analysis to Achieve the Best Outcome for the Survivor**

*Fernanda Henry\*, Forensic Science Services, Saint Lucia Forensic Science Laboratory, Dennery, Saint Lucia; Joy Quinlan, Saint Lucia Forensic Science Laboratory, Castries, Saint Lucia; Valerie Mattimore Fuller, DNA Solutions, Inc., Oklahoma City, OK; Alier Compton, Saint Lucia Forensic Science Laboratory, Castries, Saint Lucia*

---

**Learning Overview:** This presentation will use result outcomes to demonstrate how the Saint Lucia Forensic Science Laboratory was able to streamline its sexual assault evidence collection kit to focus on DNA-based evidence collection in combination with a DNA-first approach to analysis. After attending this presentation, attendees will better understand the value of a shorter and more focused collection system for sexual assault evidence that allows for a faster turnaround time for analysis, while producing probative DNA results to assist the trier of fact in sexual assault cases.

**Impact Statement:** This presentation will impact the forensic science community by showing that a ten-step sexual assault evidence collection process is effective in collecting enough probative biological evidence for the effective investigation of sexual assault matters through a DNA-first approach. Forensic DNA analysts will also learn how to use the quantitation step and the Capillary Electrophoretic (CE) instrument to make decisions about stopping at quant or triaging cases for autosomal or Y-chromosomal Short Tandem Repeat (Y-STR) profiling.

Evidence collection after a report of a sexual assault is pivotal in proving or disproving the alleged events. In Saint Lucia, evidence collection is usually conducted in the Emergency Room (ER) of our two main hospitals on the island by on-duty medical doctors. It means that all “emergencies” are attended to ahead of a sexual assault survivor. This results in inordinate waiting times for the examination and re-traumatization of the survivor by the whole ER experience. Couple that with an almost 20-step evidence collection process as obtained previously, involving pubic/head hair combing, plucking or fingernail scraping, and drawing of blood.

The Saint Lucia Forensic Science Laboratory decided in 2011 to streamline the Sexual Assault Evidence Collection Kit (SAECK) to ten steps in keeping with the recommendations for standardized evidence collection by the National Protocol for Sexual Assault Medical Forensic Examinations by the United States Department of Justice.<sup>1,2</sup> The kit would be focused on biological evidence collection for subsequent DNA analysis, with considerable time savings for both the sexual assault survivor and the attending ER physician. Then in 2022, the DNA Unit transitioned to a new CE platform along with using new, more sensitive chemistries for extraction of sexual assault evidence such as the Casework Direct System by Promega® Corporation and the Erase Sperm Isolation Kit by PTC Laboratories.<sup>3-6</sup> We used the CE instrument to establish the DNA mass equivalent of our stochastic threshold Relative Fluorescence Units (RFU).<sup>7-9</sup> We are therefore able to identify the most probative samples for DNA profiling at the quantitation step. This approach not only improves the turnaround time for analysis in the DNA Unit and helps to reduce the backlog of cases, but also gives the laboratory the opportunity to provide feedback to the evidence collectors to improve on the quality of evidence collection at different steps in the process.

**B2 The Remains of the Crime: An Assessment of Body Fluid Identification Over Time**

*Francisco Medina Paz, New Jersey Institute of Technology, Newark, NJ; Brandon L. Kuba, New Jersey Institute of Technology, Oak Ridge, NJ; Emily Kryvorutsky, New Jersey Institute of Technology, Staten Island, NY; M. Gabriela Roca\*, SERATEC mbH, Goettingen, Niedersachsen, Germany; Sara C. Zapico, New Jersey Institute of Technology, Newark, NJ*

---

**Learning Overview:** After attending this presentation, attendees will consider the possibility of recovering body fluids, particularly blood and semen, up to three months old as rapid immunochromatographic tests were able to successfully identify them in different types of fabrics.

**Impact Statement:** This presentation will impact the forensic science community by presenting a validation study of blood and semen stability on different types of fabric over time and the sensitivity of rapid immunochromatographic tests and by assessing the possibility of recovering total DNA from the samples, thus leading to both the identification of body fluids and DNA isolation.

Among different methodologies to quickly identify body fluids at crime scenes, rapid immunochromatographic tests represent the simplest and quickest. They are based on antigen-antibody reaction against a specific human protein. Particularly, blood rapid immunochromatographic tests are based on the detection of hemoglobin, while semen tests are based on the detection of Prostate Specific Antigen (PSA). These are the most common body fluids encountered at the crime scene. One of the factors that could hamper the correct identification of these fluids is the substrate where they were deposited. Another factor could be the time. It must be considered that crime scene investigation could occur days or even months after the crime was committed. Currently, there are few studies analyzing the possibility of detecting body fluids over time and comparing among different substrates.

Based on these premises, the main aim of this work was to validate the detection of blood and semen samples from denim, cotton, and leather aged up to 3 months and analysis of nuclear DNA recovered from these samples.

Twenty microliters of blood and semen (three replicates per timepoint) were deposited in denim (black and white), cotton (black and white), and leather. The samples were recovered after 1 day, 2 days, 1 month, and 3 months. The fabrics were kept at room temperature under natural light conditions. Blood and semen were identified by SERATEC® HemDirect Hemoglobin Test and SERATEC® PSA Semiquant, respectively. The sample was swabbed for 30 seconds and the swab was diluted in 400ul of extraction buffer. This mixture was shaken for 10 minutes at room temperature. After this period, three drops of buffer were added in each cassette. DNA was extracted from the buffer applying silica-based columns, and later quantified by human-specific quantitation based on quantitative Polymerase Chain Reaction (qPCR). PowerPlex® Fusion 6C System was applied to generate the Short Tandem Repeat (STR) profiles.

The results showed that it was possible to detect blood and semen up to three months after deposition, although with different band intensities. Black denim and cotton showed stronger bands than white denim, cotton, and leather. Total DNA from all sample tubes was successfully recovered, obtaining full DNA profiles with different qualities. Leather, black denim, and cotton samples showed the highest qualities in DNA profiles up to three months. These findings indicate that it is possible to recover and identify blood and semen samples up to three months after deposition and also obtain DNA profiles.

Future research will be able to expand the results, assessing the detection of body fluids in other fabrics and different environmental conditions.

**Bodily Fluid; Fabric; LFI**

---

**B3 Dry Vacuum Recovery of DNA From Fabric**

*Emily Sam-Zee-Moi\*, John Jay College of Criminal Justice, New York, NY; Mechthild Prinz, John Jay College of Criminal Justice, New York, NY*

---

**Learning Overview:** After attending this presentation, attendees will be informed of an alternative non-destructive method of collecting touch DNA from fabric by using a dry vacuum and how it can be used for testing fabric evidence.

**Impact Statement:** This presentation will impact the forensic science community by presenting an optimized method that may be more efficient for DNA collection and may affect how different types of evidence are processed for DNA recovery. The success of the non-destructive dry vacuum method makes this process a valuable addition to the forensic science toolbox.

Touch DNA has proven to be a reliable forensic tool when investigating sexual assaults and other crimes. Current methods of DNA recovery from fabric include cutting, swabbing, scraping, and tape lifting. A Swedish tape lifting method was shown to be effective for DNA collection for plain woven fabric.<sup>1</sup> A new method using a dry vacuum technique has been successful in recovering touch DNA from written documents. This method uses suction to gather DNA onto a dry or moistened filter, which can then be processed to release the DNA and create a DNA profile.<sup>2</sup> The dry vacuum collection is an alternative non-destructive option for DNA collection from fabric.<sup>3</sup> Different filters and moistening agents may increase DNA yields for the dry vacuuming method. This experiment was designed to test the success of the dry vacuum technique on pieces of cotton fabric that had been briefly touched as well as the effectiveness of different moistening agents and filters.

Samples were gathered by having both female and male volunteers rub their faces, followed by rubbing their hands together and gripping DNA-free 15cmx15cm cotton fabric squares. A total of four fabric samples and one buccal swab were collected per donor. This method of collection was designed to simulate an assault with the suspect grabbing the clothing of their victim. The fabric was then vacuumed using either an irradiated glass pipette fit with a Puritan® cotton swab moistened with water, 10% Tween® 20, or an irradiated plastic pipette tip with the filter moistened with water or 10% Tween® 20. A vacuum hose was attached to the narrow end of the pipette or tip, allowing for the wide end to suction the fabric. DNA was then extracted using a QIAamp® DNA Investigator Kit on the QIAGEN® QIAcube® extraction robot. All samples were quantified in duplicate using Quantifiler® Trio.

Quantities from each donor varied; however, results show that the dry vacuum technique can collect a sufficient amount of touch DNA from fabric (>7pg/uL) to be used for DNA analysis from all donors. Water as a moistening agent allowed for a higher amount of DNA to be collected. There was no distinguishable difference when using a glass pipette versus a plastic pipette tip. The dry vacuum method is an efficient non-destructive method that can be implemented in any DNA laboratory that has a vacuum pump or a bench vacuum outlet.

**B4 An Initial Investigation of the Applied Biosystems® SeqStudio™ Genetic Analyzer for Human Identification Purposes**

*Brayleigh Keefe\*, Arcadia University, Southbury, CT; Megan Foley, The George Washington University, Washington, DC; Nicole Novroski, University of Toronto, Mississauga, ON, Canada; Fabio Oldoni, PhD, Arcadia University, Glenside, PA*

---

**Learning Overview:** This presentation will focus on educating attendees about the use of the innovative SeqStudio™ Genetic Analyzer with the GlobalFiler® Polymerase Chain Reaction (PCR) amplification kit for human identification purposes.

**Impact Statement:** This presentation will impact the forensic science community by sharing the determined limits and best practices for the fluorescence-based SeqStudio™ Genetic Analyzer system on mock casework samples.

Capillary Electrophoresis (CE) is the conventional method used to separate and detect DNA fragments for Human Identification (HID) purposes.<sup>1</sup> Over the years, multiple genetic analyzers have been developed; however, the platform of interest for this research is the latest Applied Biosystems SeqStudio™ Genetic Analyzer. The instrument includes an all-in-one reagent cartridge that contains four capillaries and can detect six different dyes.<sup>2</sup> When performing CE, many factors, including injection time, sensitivity and reproducibility, stutter, inhibition and degradation, and mixture performance must be considered.<sup>3</sup> Previous research has not yet fully established all capabilities and thresholds involved with the use of the SeqStudio™ coupled with the GlobalFiler® PCR amplification kit for HID purposes. This project aims at investigating these limitations and determining the best practices for this instrument.

This research requires performing different evaluation studies using a standard quantitative Polymerase Chain Reaction (qPCR)-to-CE workflow. DNA samples are quantified using Quantifiler® Trio DNA Quantification kit on the QuantStudio™ system, amplified with the 24-loci GlobalFiler® PCR kit on the ProFlex system, genotyped on the SeqStudio™, and profiles analyzed using the GeneMapper® ID-X v1.6. The first study to perform is the injection study that requires injecting samples at different injection times to determine the optimal injection time in order to generate reliable data. A reproducibility study is also conducted to determine the ability of the SeqStudio™ to reproduce genotypic results across multiple runs alongside a sensitivity study to determine the optimal range of target DNA (from 1ng/ul to 7pg/ul) to amplify when using the GlobalFiler® PCR kit. Furthermore, stutter and intra-locus and intra-/inter-color balance studies are performed to establish the amount of stutter produced at each Short Tandem Repeat (STR) locus and the overall balance among loci and dyes, respectively. A mixture study is conducted to define the detection of DNA donors in two-person (e.g., 1:1, 1:3, 1:5, 1:9, 1:19) and three-person (e.g., 1:1:1, 1:1:3, 1:1:5, 1:1:9) mixtures. Inhibition and degradation studies are also performed to assess the typing performance on inhibited and degraded mock samples stored at room temperature.

For the injection time study, one male and one female DNA sample were quantified and diluted to 0.5ng/ul and 1ng/ul and run on the SeqStudio™ at 1, 3, 5, 7, and 10s injection times in triplicate. Overall, a general decline in the max, med, and min Relative Fluorescence Units (RFU) values for alleles at all loci within each dye channel was observed as the injection time decreased. The injection times ranging from 1s to 5s provided optimal results at both concentrations, demonstrating the lowest values of standard deviation observed across all loci. The assessment of min and max peak height reproducibility was also completed for each injection time as well as heterozygous allele balance with no significant variation being reported. Moreover, full genotype reproducibility at all loci was observed across multiple runs at the concentrations tested. For the sensitivity study, no locus or allelic dropouts were observed from 1ng/ul down to 125pg/ul; further analysis is in progress to determine the overall locus/allelic dropout rates at lower concentration inputs.

In conclusion, our preliminary findings support the potential of the SeqStudio™ Genetic Analyzer in forensics, and the ongoing comprehensive evaluation will help elucidate further the best practices for this low-throughput platform.

**B5 A Morphological and Genetic Characterization of the Psychoactive Species *Psilocybe Cubensis* From Forensic Samples**

Ivana Horjan Zanki, Forensic Science Centre Forensic Science Centre “Ivan Vučetić,” Zagreb, Grad Zagreb, Croatia; Adela Makar, Ministry of the Interior, Forensic Science Centre “Ivan Vučetić,” Zagreb, Grad Zagreb, Croatia; Andrea Ledić\*, Ministry of the Interior, Forensic Science Centre “Ivan Vučetić,” Zagreb, Grad Zagreb, Croatia

**Learning Overview:** After attending this presentation, attendees will have insight on the applicability and usefulness of a different type of analyses regarding forensic fungal samples through results obtained from morphological and genetic research of casework samples conducted at the Croatian Forensic Science Centre, “Ivan Vučetić.”

**Impact Statement:** This presentation will impact the forensic science community by emphasizing the ongoing necessity of extending routine analyses of forensic fungal samples. Upgraded data deriving from complementary morphological and genetic analyses subsequently could lead to improvements of legal acts considering psychoactive fungi.

Consummation of psychoactive fungi containing Psilocybin (PY) and Psilocin (PI) causes less intensive LSD-like effects.<sup>1</sup> Although physically non-addictive, long-term use can lead to tolerance and psychical addiction, the reason why PY and PI are illegal in a majority of European Union countries, with fungi subsequently seized as forensic samples. Since PY/PI are not yet synthesized in spores, mycelia and sclerotia, routine toxicology methods on these kinds of samples are useless.<sup>2</sup> On the other hand, morphological (macroscopic and microscopic) analyses inevitable in research, taxonomic, and phylogenetic fungal studies are somewhat difficult or even impossible to proceed on forensic samples with too dry, too young, or scarce-fruited bodies, ground to powder, or lacking some of the macroscopic features. Applying molecular-based techniques can overcome some of the abovementioned limitations in identification process.

Hence, the main goal of this study was to present the usefulness of genetic analysis on fungal forensic samples to confirm their accurate species identification.

Within more than 200 described psychoactive species, *Psilocybe cubensis* (Earle) Singer and its varieties are most popular among users worldwide due to their proven potency, wide distribution, and ease of cultivation.<sup>3-5</sup> *P. cubensis* is classified in section *Cubensae* of the genus *Psilocybe* and distinguished from *Psilocybe subcubensis* only by one distinctive feature: the size of basidiospores.<sup>6,7</sup>

A total number of 63 forensic fungal samples seized in Croatia from 2010 to 2014 were morphologically analyzed and genotyped with genetic markers, including complete Internal Transcribed Spacer (ITS) of nuclear DNA and a large portion of 28S gene from 5' end (nuclear-encoded large subunit ribosomal RNA genes, nLSU-rDNA).<sup>8,9</sup> Macroscopic analysis using several taxonomic keys (6, 7, 10-13) resulted in five successfully identified species with *P. cubensis* as the most common (56/63), confirming its popularity. Microscopic analysis of a total 1,219 spores from *P. cubensis* samples, positioned 934 spores (76.62%) within range of basidiospores size for *P. cubensis* and 1,127 spores (92.45%) within *P. subcubensis* established range.<sup>6</sup> Obtained values well encompass both species without discrete grouping, rather showing overlapping and continuous transition from minor size values corresponding with *P. subcubensis* up to major values corresponding with *P. cubensis*.

These findings indicate that *P. cubensis* and *P. subcubensis* cannot be differentiated based only on size of basidiospores and are conspecific, (i.e., both belonging to the same species).

ITS and LSU sequences were successfully determined from 47/56 (83.92%) samples, each represented by only one haplotype. In addition, established haplotypes matched completely (100%) with *P. cubensis* haplotypes from the GenBank database. These results strongly confirm previously established results from morphological analyses. Eligible subsequent study should refer to the genetic analyses of *P. subcubensis* reference samples that served for initial species identification back in 1978.

Overall findings pointed out that molecular data can revise established fungal taxonomy classification based on genetic variations within species, inter- and intra-species phylogenetic relationships as well as the origin of shared morphological or phenotypic features among taxonomic groups.<sup>14-18</sup>

In summary, results imply that limited data obtained from toxicological analyses of forensic fungal samples are not adequate for species identification while morphological and genetic analyses represent actual necessity.

**B6 The Persistence of Wearer DNA on Clothing After Laundering**

*Rachel Rachel Breitenstein\*, San Diego Police Department Crime Laboratory, San Diego, CA; Shawn Montpetit, San Diego Police Department Crime Laboratory, San Diego, CA; Ismail M. Sebetan\*, Forensic Science, National University, San Diego, CA; Paul Stein\*, National University, Ramona, CA*

---

**Learning Overview:** This presentation will provide attendees with a better understanding of the evidentiary value of laundered clothing by showing the effects of three different wash conditions on the persistence of wearer DNA.

**Impact Statement:** DNA analysis is one of the most requested services provided by forensic laboratories. This presentation will impact the forensic science community by informing attendees that in order to make the best use of resources, laboratories need to recognize which evidence is most suitable for DNA testing. Laundered clothing may be considered unlikely to yield interpretable DNA results. Understanding the effect of different wash conditions on the persistence of wearer DNA will assist investigators and forensic examiners in deciding whether laundered clothing should be analyzed for DNA.

**Introduction:** Clothing is frequently recovered as evidence in criminal investigations. Processing these items for wearer DNA may provide relevant information for investigators to identify the perpetrator of the crime. However, if the clothing is laundered before it is recovered, the quantity of DNA that remains may be insufficient for Short Tandem Repeat (STR) profiling. This study was conducted to evaluate the persistence of wearer DNA after laundering and assess the quality of the resulting STR profiles.

**Methodology:** DNA was collected from 30 worn hats by swabbing half of the interior sweatband. The hats were divided into treatment groups and were laundered using one of three methods: machine-wash hot, machine-wash cold, or hand-wash lukewarm.

Post-wash samples were collected by swabbing the other half of the sweatband. All samples were extracted using the QIAamp® DNA Investigator Kit. DNA was quantified using a Rotor-Gene Q® real-time Polymerase Chain Reaction (PCR) cyclers and the QIAGEN® Investigator Quantiplex™ HYres Kit. If necessary, sample concentration was performed using Microcon® DNA Fast Flow Centrifugal Filter Devices. STR profiles were generated using the GlobalFiler® PCR Amplification Kit, SeqStudio™ Genetic Analyzer, and GeneMapper® ID-X Software. Persistence was evaluated by comparing: the proportion of pre- and post-wash samples meeting the validated amplification target, total peak heights across the profiles, locus dropout, and degradation curves.

**Results:** Statistical significance between pre- and post-wash sample values within each treatment group was measured using either a two-proportion *z*-test or a one-tailed, paired *t*-test. A one-way Analysis of Covariance (ANCOVA) test was used to compare peak height sums, locus dropout, and degradation slopes of the post-wash samples between the three treatment groups. The pre-wash values were used as the covariate in the statistical analysis. For all analyses, a *p*-value < 0.05 was needed to indicate significance.

The proportion of pre- versus post-wash samples to meet the amplification target was not significantly different in any treatment group. Peak heights were found to be significantly lower for post-wash samples than pre-wash samples in the machine-wash cold and hand-wash lukewarm treatment groups; however, the decrease in peak heights observed in the machine-wash hot treatment group was not statistically significant. Post-wash samples from all treatment groups displayed significantly greater locus dropout and steeper degradation slopes than pre-wash samples. Comparing post-wash samples from different treatment groups indicated no significant difference in persistence between wash conditions.

**Conclusion:** This study shows that wearer DNA does persist after laundering and should be considered a potential source of DNA evidence. Although post-wash samples were found to yield significantly less DNA and lower quality profiles, it was still possible to generate profiles suitable for comparison. Approximately 55% (*n*=29) of post-wash samples resulted in STR profiles with alleles detected at 6 or more of the 21 autosomal loci tested. Many of these samples were undetected by real-time PCR, indicating that low quantitation values should not preclude further testing if concentrating the samples is an option. This study found that neither water temperature nor laundering method had a significant effect on the persistence of wearer DNA.

**B7 A Multi-Species Reference Ladder Using Two PCR Multiplexes for the Rapid Identification of Most Domestic Animals for Forensic Purposes**

*Vallarie Ostenson, Florida International University, Miami, FL; Lindsey Kaufman, Signature Science, LLC, Miami, FL; DeEtta Mills\*, IFRI, Florida International University, Miami, FL*

---

**Learning Overview:** Following this presentation, attendees will be informed about a rapid method of identifying an unknown biological sample by comparing it to a reference ladder for ten domestic animals and one human reference as well. The multiplexes simultaneously amplify mitochondrial DNA (mtDNA) markers for a dog, cat, rabbit, chicken, goat, sheep, pig, cow, horse, and donkey and one human mtDNA marker that provides species identification based on length heterogeneity of the markers.

**Impact Statement:** This presentation will impact the forensic science community by providing a rapid screening method to identify unknown biological samples that can be found at a crime scene involving humans and pets or for cases involving crimes against animals.

Forensic identification techniques used in cases involving animals, animal abuse, or commingled at crime scenes often rely on blood or shed hair analysis to identify the species. While there are quantitative Polymerase Chain Reaction (qPCR) or Short Tandem Repeat (STR) commercial kits available for DNA testing of domestic animals, some only test for one animal species at a time. The qPCR kits are used in food fraud cases where, for example, a 100% beef hot dog, may actually contain dog, and these kits can quickly identify that adulteration.<sup>1,2</sup> However, if the food was adulterated with lamb, for example, those species-specific kits would not be able to confirm that mixture of meat products. In other examples, crime scenes often find hair, tissue, or blood at the scene. Common presumptive tests will test for human evidence. However, the scene can often be mixed with non-human DNA evidence—evidence that could provide additional leads in a case. To date, no presumptive method provides a rapid identification of multiple unknown species as the source of the evidence—critical to know before moving to STR analysis.

This project used mitochondrial DNA cytochrome B gene marker to create a reference ladder and design two multiplex kits that can *simultaneously* detect dog, cat, rabbit, donkey, goat, sheep, chicken, pig, cow, horse, and human DNA using a traditional forensic workflow. Labeled universal forward primers and species-specific reverse primers were used for simultaneous amplification of 11 species in two multiplexes.<sup>3,4</sup> The individual species' PCR products were column-cleaned, then mixed together to form a reference ladder with bin sets for precise identification of a sample. The validation of the ladder and kits was tested against mock crime scene samples, blinded to the analyst, of blood found in soil, on wood, carpeting, and clothing. The source species was able to be identified using the reference ladder and multiplex. In addition, the kits were tested on various dog food samples to verify ingredients on the labels did indeed match the meat products used in the production of the kibble. Ongoing research continues to expand the reference ladder and multiplexes by adding rat, mouse, guinea pig, and ferret species.

**B8 Advancing Semen Detection Techniques With Sperm Tracker STK® in Real Case Scenarios and Diverse Environments**

*Monica Omedei\*, Centro Regionale Antidoping "A. Bertinaria," Orbassano, Piemonte, Italy; Selena Cisana, Centro Regionale Antidoping "A. Bertinaria," Orbassano, Piemonte, Italy; Aurora Desogus, University of Turin, Villanovafranca, Sardegna, Italy; Giorgia Ferrero, University of Turin, Ceva, Piemonte, Italy; Florian Tharin, AXO Science, Villeurbanne, FL; Paolo Garofano, Centro Regionale Antidoping "A. Bertinaria," Roma, Lazio, Italy; Eugenio Alladio, Department of Chemistry, University of Torino, Torino, Piemonte, Italy*

---

**Learning Overview:** In this presentation, attendees will gain valuable insights into the cutting-edge field of semen detection at crime scenes. Attendees will learn about the innovative Sperm Tracker STK® and its role in forensic investigations. This presentation will delve into real case scenarios where STK® has been employed, showcasing its effectiveness in identifying semen traces and contributing to solving criminal cases. Attendees will also explore various conditions under which STK® has been tested, providing a comprehensive understanding of its reliability and versatility. By the end of the presentation, attendees will have a deeper appreciation of the importance of semen detection in forensic analysis and the significant impact that STK® can make in advancing investigative practices.

**Impact Statement:** This presentation on semen detection using Sperm Tracker STK® will have a significant impact on the forensic science community. By introducing this innovative tool, attendees will gain insights into advanced forensic techniques and how it significantly improves the accuracy and reliability of semen detection. Real case scenarios demonstrate the potential to solve cold cases through the analysis of, for instance, degraded samples. Moreover, the implementation of STK® will enhance crime scene investigations, allowing for more effective identification and preservation of semen traces. This presentation is expected to stimulate further research and collaboration within the community, driving continuous improvements in forensic science and its applications. Overall, our findings will empower investigators with a powerful tool in semen detection, leading to more efficient, accurate, and just outcomes in criminal investigations.

Forensic science plays a crucial role in criminal investigations, and the detection of bodily fluids at crime scenes is essential in establishing a link between suspects and victims. Among these fluids, semen is of particular importance due to its potential as a key piece of evidence in sexual assault cases and other crimes.<sup>1</sup> Traditional semen detection methods have limitations in sensitivity and specificity, requiring the exploration of innovative technologies to improve forensic practices. This work presents a comprehensive study on the utilization of the Sperm Tracker STK® for semen detection, with a focus on its effectiveness in real case scenarios and different environmental conditions.<sup>2</sup>

The objective of this study is to evaluate the impact of the Sperm Tracker STK® on forensic semen detection, elucidating its potential benefits for the forensic science community, by offering enhanced sensitivity and enabling the detection of trace amounts of semen that may have been missed using traditional techniques.

Through a series of controlled experiments and field tests, we assessed the performance of the Sperm Tracker STK® in various challenging conditions. These included scenarios with degraded semen samples on hair and skin specimens, varying environmental factors (i.e., humidity and temperature), and different storage conditions over time. The results demonstrate that the Sperm Tracker STK® consistently is a valuable alternative to traditional methods, with a higher rate of semen detection in the tested conditions, leading to more robust evidence collection and helping to ensure the integrity of the investigative process.

Moreover, the application of the Sperm Tracker STK® to real case scenarios has led to breakthroughs in investigations, including its use for casework related to suspected sexual assaults. The analysis of semen samples has proven crucial in establishing the identity of perpetrators and providing closure to victims' families.

In conclusion, Sperm Tracker STK® represents a groundbreaking advancement in forensic semen detection. By empowering investigators with this advanced technology, we aim to strengthen the foundations of forensic science and promote justice in criminal investigations.

**B9      Into the “Sexome”: Genital Microbiome Transfer and Applications**

*Julia Wang\**, Sam Houston State University, Huntsville, TX; *Rachel Houston*, Sam Houston State University, Huntsville, TX; *Sheree R. Hughes*, Sam Houston State University, Huntsville, TX; *Brendan Chapman*, Murdoch University, Murdoch, Western Australia, Australia; *Ruby Dixon*, Murdoch University, Baldivis, Western Australia, Australia

---

**Learning Overview:** After attending this presentation, attendees will have gained a better understanding of the genital microbiomes and its potential for forensic application.

**Impact Statement:** This presentation will impact the forensic science community by presenting support for genital microbiomes as potential evidence in sexual assault evidence in the absence of spermatozoa.

The preferential lysis-based differential extraction method is the conventional approach for sexual assault evidence processing. However, this workflow relies on the presence of spermatozoa to identify male perpetrators, making it limited in certain cases where spermatozoa may not be present. To address these shortcomings, there is a growing interest in using microbiome sequencing as a potential alternative, especially with the availability of next-generation sequencing technologies.

The purpose of this research was to investigate the potential post-coital transfer between vaginal and penile microbiomes in genuine samples. To achieve this goal, pre- and post-coital vaginal and penile swabs were collected from two donor couples. Microbiome libraries were prepared by targeting specific regions V3 and V4 of the 16S ribosomal RNA gene, commonly used in microbial community profiling.

The results of the study not only support previous literature findings, such as the primary genus found in vaginal microbiomes being *Lactobacillus*, but they also contribute to the relatively limited knowledge on penile microbiome communities.<sup>1</sup> Notably, post-coital vaginal and penile microbiomes displayed even greater diversity compared to their pre-coital state, suggesting potential changes or interactions resulting from sexual activity.

While further research with a broader range of samples will be conducted in the future, the observed differences in diversity between circumcised and uncircumcised penile microbiomes suggest potential variations in the persistence of coital transfer in different microenvironments. This finding aligns with previous studies that have shown that circumcision status can influence microbiome composition, which could have implications for the analysis of sexual assault evidence.<sup>2</sup>

Overall, this research contributes to the understanding of the dynamics of microbial communities in the context of sexual activity and has implications for forensic investigations. By utilizing microbial next-generation sequencing, this study highlights a promising avenue for gaining probative information, even in cases where conventional preferential lysis-based approaches may not be sufficient.

**B10 The Adaptation, Optimization, and Validation of a Semi-Automated DNase I-Based Differential Extraction Procedure on the Beckman Coulter Biomek NX<sup>P</sup> Automation Workstation**

*Susan A. Greenspoon\*, Virginia Department of Forensic Science, Richmond, VA; William Eggleston, Virginia Department of Forensic Science, Richmond, VA; Cathryn Shannon, Virginia Department of Forensic Science, Richmond, VA*

---

**Learning Overview:** The goal of this presentation is to describe the development of an automated separation of sperm from non-sperm cells for sexual assault samples using a DNase I-based method prior to DNA purification.

**Impact Statement:** This presentation will impact the forensic science community by providing a more automated and less hands-on, faster, more efficient and less labor-intensive method for processing sexual assault cases.

Processing of evidence in sexual assault cases is time consuming, which has led to high backlogs in many localities. A key challenge has been to separate DNA in sperm cells from DNA in epithelial cells prior to purification in order to simplify the mixture prior to DNA profiling. The Differential Extraction (DE) method developed by Gill et al. and still routinely used in forensic laboratories, is based on the higher density of sperm cells and their resistance to cell lysis in the absence of a reducing agent such as Dithiothreitol (DTT) relative to epithelial cells.<sup>1</sup>

Following lysis of epithelial but not sperm cells in buffers containing proteinase K and detergent, samples are centrifuged to pellet sperm cells (Sperm Fraction [SF]), leaving lysed epithelial cells in the supernatant (Non-Sperm Fraction [NSF]). Removal of the NSF and repeated washing of the SF prior to DNA extraction is used to develop separate fractions for DNA profiling.

While effective, the process is challenging to fully automate, and the repeated wash steps are slow, labor intensive, can lead to loss of sperm, and provide more opportunities for cross contamination. Multiple procedures to improve upon the differential lysis/centrifugation method have been developed, including laser-, acoustic-, pH-, pressure-, affinity- and enzyme-based approaches. Critical aspects of new methods are to demonstrate that they work as well or better than methods currently in use in the forensic laboratory and an ability to seamlessly integrate into existing workflows, which reduces the impact on casework output.

The Virginia Department of Forensic Science (VADFS) optimized and fully integrated an automated DNase I-based differential extraction method into the current automated DNA processing pipeline using the Promega<sup>®</sup> DNA IQ<sup>™</sup> DNA isolation system and the Beckman Coulter<sup>®</sup> Biomek NX<sup>P</sup> automation workstation. DNase I is a nuclease that degrades DNA to oligonucleotides and is used in this method to remove residual non-sperm DNA from the sperm cell pellets, thus removing the need for repetitive wash steps.

Starting from reports by Garvin et al. and Wong and Mihalovich and the VADFS's current DE procedure, DNase I digestion of SFs was performed using a new method developed for the Biomek NX<sup>P</sup>.<sup>2-4</sup> This was performed following manual epithelial cell lysis and pelleting of the sperm cells to remove the non-sperm cell lysate. We report the results of testing multiple enzyme concentrations, incubation times and temperatures, and semen dilutions using vaginal and buccal mock sexual assault samples from multiple donors. We also report the effects of commonly encountered vaginal contaminants and aging on results and tests to measure cross contamination rates in order to validate the optimized protocol on the Biomek NX<sup>P</sup>.

We found that multiple conditions worked comparably to the current VADFS standard DE protocol with respect to Y-DNA yields (measure of male DNA), ratios of autosomal-DNA to Y-DNA yields (A/Y ratios, which measure the relative quantity of female DNA), and the quality of sperm fraction DNA profiles (peak balance, profile completeness, etc.). No evidence for increased rates of cross contamination was observed due to the automated DNase I treatment. In less than one-half the time (e.g., ~80 minutes versus ~180 minutes for 13 samples, including epithelial cell lysis) needed by the current VADFS DE method, the automated DNase I DE method transfers DNase I-treated SFs into the deep well sample plate in which, along with other casework samples, the SFs will be purified for DNA using the existing automated extraction procedure.

**B11 From Tecan to Hamilton: Material Modification of Applied Biosystems™ PrepFiler™ Automated Extraction**

*Cristina L. Servidio\*, DNA Labs International, Boca Raton, FL; Rachel H. Oefelein, DNA Labs International, Deerfield Beach, FL; Brittany Stirmell, DNA Labs International, Deerfield Beach, FL*

---

**Learning Overview:** After attending this presentation, attendees will better understand the validation process that was undertaken by DNA Labs International to bring the HID NIMBUS® Presto System online.

**Impact Statement:** The presentation will impact the forensic science community by demonstrating how the HID NIMBUS® Presto System was brought online and could increase the processing capabilities at forensic laboratories around the world.

As advancements are made in the forensic science world, some of the most common questions revolve around how we make the process more efficient and accurate. The use of robotic systems to assist in laboratory processing has been used in the forensic community for decades to ensure reliability of results while also increasing efficiency. This allows forensic scientists to focus their efforts on more complex tasks like screening items of evidence, data interpretation, and mixture deconvolution.

Since 2013, the Tecan Freedom EVO® 150 Robotic Workstation has been dutifully extracting, quantifying, normalizing, and amplifying tens of thousands of samples every year. It has been a valuable tool with the capability of performing both extraction and quantification with minimal user intervention. However, as with all robotic platforms, at some point these years of glory must come to an end. Similar to the vehicles we drive every day, repeated use causes breakdown over time and at some point, it becomes time for a new instrument.

DNA Labs International began exploring alternative options for high throughput extraction for non-differential samples in 2022 and the HID NIMBUS® Presto System was taken into consideration. A large point to consider was that the same extraction chemistry currently in use on the Tecan could also be employed on this robotic platform consisting of the Hamilton™ Microlab™ NIMBUS® HD Liquid Handler in conjunction with the KingFisher™ Presto Purification System. Additionally, the processing time would be a fraction of the current processing time. Having dealt with the headaches of custom scripting in the past, the pre-made scripts offered on this system were also appealing. In 2023, the system was purchased, and training and testing went underway. This presentation will highlight the testing results, including sensitivity and modifications to the previous protocol as well as plans for the implementation of downstream quantification, normalization, and amplification platforms.

---

## B12 An Evaluation of the Effectiveness of Flow Cytometry in Sperm Testing in Mixed Semen Specimen

*Fang Chun Chung\*, Forensic Biology Division, Institute of Forensic Medicine, Ministry of Justice, New Taipei City, New Taipei, Taiwan (Republic of China); Chun-Yen Lin, Division of Forensic Biology Institute of Forensic Medicine, Ministry of Justice, New Taipei City, New Taipei, Taiwan (Republic of China); Kuan-Miao Yeh, Forensic Biology Division, Institute of Forensic Medicine, Ministry of Justice, Taiwan, New Taipei City, New Taipei, Taiwan (Republic of China); Yeh-Lin Lu, Core Facility Center, Office of Research and Development, Taipei Medical University, Taipei City, Taipei, Taiwan (Republic of China); Chun Changou, Core Facility Center, Office of Research and Development, Taipei Medical University, Taipei City, Taipei, Taiwan (Republic of China)*

**Learning Overview:** The goal of this presentation is to introduce attendees to a method with highly accurate and effective cell separation to identify sperm cells from samples mixed with sperm cells and female epithelial cells by flow cytometry.

**Impact Statement:** This presentation will impact the forensic science community by providing forensic personnel with an additional reference method for detecting cases involving mixed sperm cells in sexual assault cases.

The presence or absence of sperm cells is one of the key pieces of evidence in the detection and investigation of sexual assault crimes. Separating male sperm cells from female epithelial cells in mixed samples and obtaining a higher concentration of suspect sperm cells while reducing interference from female epithelial cells is one of the challenges forensic personnel faces. In practical criminal cases involving sexual assault, the conditions of mixed sperm cell samples from the female vagina are often less than ideal. Factors such as postmortem changes, decomposition, or a small number of male sperm cells within a background of a large amount of female epithelial cells further increase the difficulty of analysis. Therefore, developing techniques with highly accurate and effective cell separation is one of the challenges that forensic personnel must overcome to clarify the case. Flow cytometry, which possesses the characteristic of cell separation, can collect cells with high specificity, achieving the desired separation effect. These characteristics can be utilized in the identification of samples containing female cells and sperm cells in sexual assault cases.

In this study, a mixture of female oral epithelial cells and male sperm cells was prepared to simulate samples from sexual assault cases, and flow cytometry analysis was performed on the samples. The Forward Scatter ( FSC ) and Side Scatter ( SSC ) parameters of flow cytometry were used for analysis. The results showed that there were two cell populations in the mixed samples (located in regions R1 and R2), demonstrating that flow cytometry can indeed classify mixed samples into distinct groups. Furthermore, to achieve significant cell classification, this study evaluated several antibodies to enhance the cell classification effect. CD52, ACRV1, MOSPD3, JLP, DEFB126, PH20, and ADAM23 antibodies were selected to label male sperm cells, and the results showed that CD52 antibody labeling had the best effect (88.7% positive in region R2). CD324, CD326, and CD227 antibodies were selected to label female oral epithelial cells, and the results showed consistent effects for all three antibodies (positive rates in region R1 were 92.6%, 91.4%, and 92.2%, respectively). Additionally, mixtures containing different amounts of male sperm cells were examined to evaluate the limitations of the flow cytometry technique. It was found that when the sperm cell concentration was below  $10^3$ , the positive signal of sperm cells was too low, which could potentially affect subsequent DNA profiling analysis. Therefore, in addition to utilizing the differences in surface antigens between male and female cells, this study also used parameters such as differences in nucleic acid content and exclusion of the CD45 signal to improve the classification of sperm cells and female cells in mixed samples, providing forensic personnel with an additional reference method for detecting cases involving mixed sperm cells in sexual assault cases.

**B13 An Examination of Vaginal Swab Cross-Reactivity in Presumptive Saliva Testing**

*Emily Wiesen\*, Denver Crime Laboratory, Denver, CO*

---

**Learning Overview:** After attending this presentation, attendees will be informed about the use of presumptive saliva testing on vaginal swabs when investigating sexual assault kits. This examination involved comparing two presumptive saliva tests commonly used within the forensic science community and determining if menstrual cycle impacted the rates of cross-reactivity.

**Impact Statement:** This presentation will impact the forensic science community by providing an update to the collection of sexual assault evidence to include the collection of vaginal swabs prior to the collection of urine. Additionally, this research allows practitioners to be aware of the limitations of presumptive saliva testing.

**Background:** Forensic laboratories use presumptive saliva testing to identify probative staining as well as in Sexual Assault Examination Kits (SAEKs) to corroborate victim statements. Two types of presumptive saliva tests are currently used within forensic testing: one which detects the enzymatic activity of amylase and one which detects the amylase enzyme itself. Amylase is a key component in saliva that aids in the digestion of complex carbohydrates and is either produced by the salivary gland, salivary amylase, or the pancreas, pancreatic amylase. Amylase is present in various bodily fluids, including saliva, urine, breast milk, tears, perspiration, nasal secretions, and feces. An ideal presumptive saliva test would be sensitive enough to detect minimal amounts of amylase and specific enough to only detect amylase produced by the salivary gland.

**Aims/Purpose:** The purpose of this study was to determine the rates of cross-reactivity when testing vaginal swabs and urine with RSID™-Saliva and Phadebas® Amylase test methodologies as these fluids are known to contain non-salivary amylase. Additionally, this study noted the menstrual cycle phase from each participant to determine if menstrual phase increased the cross-reactivity rate. This research provided foundational knowledge on rates of false positivity when using presumptive saliva testing on samples that may contain vaginal fluid and/or urine.

**Methods:** Biological females were asked to abstain from any sexual contact for five days prior to collection. All participants collected eight vaginal swabs, followed immediately by collecting one urine sample. Testing was performed in duplicate on all samples using both RSID™-Saliva and Phadebas®. RSID™-Saliva is an immunochromatographic test method which detects the presence of the amylase and is ran on a test cartridge, while Phadebas® detects the enzymatic activity of amylase within a test tube. When performing the RSID™-Saliva testing, samples were extracted in either manufacturer provided Extraction Buffer or ddH<sub>2</sub>O to determine if the extraction method altered the test's specificity.

**Hypothesis:** It was hypothesized false positives would be seen on vaginal samples when participants were either in the follicular or luteal phase of their menstrual cycle, as amylase levels are highest during these phases. It was also hypothesized the urine samples would not have any false positive results.

**Results:** RSID™-Saliva had a false positivity rate of 10% for urine samples and an inconclusive rate of 10% for vaginal swabs, while Phadebas® had a false positive rate of 20% for urine samples and a false positivity rate of 5% for vaginal swabs. An inconclusive RSID™-Saliva result was determined when the test line was present but too faint to be able to testify about its presence in court.

**Conclusion:** RSID™-Saliva and Phadebas® both had detectable false positives when testing urine and/or vaginal swabs. There are multiple potential causes of this cross-reactivity, including the host's natural presence of pancreatic amylase within the vagina and amylase produced by bacteria present within the vaginal cavity. This research provides the groundwork for additional studies that can aid in determining best practices for detecting salivary amylase on vaginal swabs, such as testing a smaller portion of the collected swab. Additionally, this research allows for a recommendation to be provided to Forensic Nurse Examiners (FNE) to collect vaginal swabs prior to urine to prevent inadvertent urine deposition on the vaginal swabs.

**B14 Mitochondrial DNA Sequencing for Forensic Human Identification in a Saudi Arabian Context**

*Dina Al Oraer\*, PhD, UCLAN, Riyadh, Saudi Arabia*

**Learning Overview:** After attending this presentation, attendees will be aware that: (1) mitochondrial sequencing of HVI, HVII, and HVIII resolution increases with whole genome sequencing; and (2) validation of Massively Parallel Sequencing (MPS) analysis consistent with Sanger-Type Sequencing (STS) for Mitochondrial DNA (mtDNA) typing of samples that may be encountered in a forensic laboratory.

**Impact Statement:** This presentation will impact the forensic science community by developing strategies for a complete mtGenome sequencing platform and being the first to investigate mtGenome different haplotypes and observe the hypervariable regions of the Saudi population in order to evaluate their application in forensic sciences.

The mtDNA is inherited maternally; it has developed from one population to another in the presence of polymorphisms, hence it is widely used as a marker in molecular evolution, population genetics, and forensics. mtDNA has some unique features that make it a particularly useful forensic marker such as absence of recombination across many generations, maternal inheritance, accumulation of mutations over time and multiple copies per cell. Therefore, it is particularly characteristic and informative in kinship analyses.

The sequence of a particular mtDNA genome is its haplotype, which is a genetic locus inherited as a unit. mtDNA genomes that are not identical, but closely related, are said to be within the same haplogroup (a collection of related haplotypes with the same ancestral mtDNA molecule). mtDNA can be assigned to a haplogroup based on the characteristic mutations that it contains; some of these are within the hypervariable region, whereas others are dispersed around the genome; the evolutionary relationship of different haplogroups can be shown as a phylogenetic tree. There is much mtDNA sequence data produced from different global and regional populations. Information from the haplogroup for any mtDNA provides us with a rational arrangement of the mtDNA according to recognized phylogenetic principles. However, it demands a reliable platform for representation of data to be able to draw meaningful and simplified information about mtDNA distribution.

Currently, STS is the primary method to develop mtDNA profiles in forensic laboratories. However, this method is laborious, time consuming, and, therefore, subject to human error. The application of MPS to forensic genetics has rapidly expanded in recent years due to its potential to dramatically increase sample amount, detection resolution, workflow, and cost efficiency, especially when compared to Sanger sequencing.

The creation of regional reference databases is recommended for all forensic loci, but even more important for lineage markers. While there is already a large amount of mtDNA sequence data produced from different global and regional populations, limited mtDNA data exists for the Kingdom of Saudi Arabia, with most previous studies focusing on medical genetics aspects of the population, and so do not necessarily reflect forensic genetics population studies.

This study investigates the Saudi population from a mitochondrial perspective and aimed to establish a mtDNA forensic database; a total of 300 samples were analyzed that were collected from Saudi nationals.

Samples were collected, then DNA was extracted and quantified. After primer optimization using the chosen sample and primer concentration, samples generated a high-quality mtDNA control region dataset. The entire Control Region (CR) was amplified, sequenced, and analyzed by STS using six forward and reverse sequencing primers that generated full coverage with overlapping sequences across the entire mtDNA control region, representing 66.2% unique haplotypes and 7.5% shared. Whereas, with MPS of the whole mtDNA, 47% of these mitochondrial types were unique and 19% haplotypes were shared. The polymorphic sites of the whole mtDNA genome MPS were found in the CR with a total of 119 polymorphic sites and 85 in CR Sanger analysis, a large number of unique mitochondrial haplotypes suggesting the high mtDNA, especially in mtDNA control region for forensic identification context.

Haplogroups were assigned and showed that J, R0, and H are the major haplogroup with almost half of the population samples and L2, L3, and M for the rest of the sample haplogroup analyzed between both Sanger CR and MPS mtDNA whole genome. This frequency distribution of mitochondrial haplogroups shows that Saudi Arabia is genetically related to the Middle East and Africa, which was expected due to its geographical location.<sup>1-86</sup>

## Genetics; Mitochondrial DNA; Statistics

## B15 An Application of Chemometrics-Assisted ATR/FTIR Spectroscopy for the Identification of Human Biological Stains Exposed to Different Environmental Conditions and Estimation of the Time Since Deposition

*Anna Barbaro\**, SIMEF, Calabria, Italy; *Cristina Cano*, UAH, Alcalá de Henares, Madrid, Spain; *Fernando E. Ortega-Ojeda*, UAH, Alcalá de Henares, Madrid, Spain; *Carmen García-Ruiz*, UAH, Alcalá de Henares, Madrid, Spain; *Gemma Montalvo*, UAH, Alcalá de Henares, Madrid, Spain

**Learning Overview:** After attending this presentation, attendees will be informed about new applications of a non-destructive method (infrared spectroscopy) in forensic investigations.

**Impact Statement:** This presentation will impact the forensic science community by helping investigators at the crime scene, without consuming the sample, to rapidly discriminate the type and the species of origin of unknown biological stains and to establish their Time Since Deposition (TSD) in order to identify and collect only samples related to the criminal event.

**Introduction:** Different types of biological stains can be found at a crime scene, and sometimes they may be recovered days after exposure to different environmental conditions. The utility of a biological evidence consists in the ability to obtain a DNA profile that can be compared to the ones of a suspect, a victim, or can be inserted in a DNA database.<sup>1</sup> Therefore, it is important to correctly identify biological stains and to discriminate them according to date of deposition.<sup>2,3</sup> Traditional analytical methods are destructive and, in cases of scarce samples, they may compromise further analysis such as DNA typing. Attenuated Total Reflectance/Fourier Transform Infrared (ATR/FTIR) has great potential for forensic investigation since it rapidly provides detailed information about the chemical composition of a sample by means of the generated spectrum.<sup>4</sup> Here we evaluate the suitability of ATR/FTIR in combination with chemometrics for the differentiation of biological stains onto porous and non-porous substrates when exposed to different environmental conditions.<sup>5,6</sup> The aim of the study is to develop an innovative rapid, low-cost, and effective method that allows, without consuming the sample, one to rapidly discriminate unknown biological stains and establish their TSD in order to identify and collect only samples related to the criminal event.

**Material and Methods:** Blood, saliva, and semen will be collected from two adult anonymous donors (one woman and one man) in accordance with the Ethic Committee for Research and Animal Experimentation of the University of Alcalá. First, 100µL of each biological fluid will be deposited onto two substrates (paper and plastic) as representatives of porous and not porous substrates. Each stain will be divided in four parts and kept in different conditions for one week: 18-25° indoors; at 2-8°C in a fridge; in direct sunlight (>25°C); and at high humidity (>50°C). Temperature and humidity conditions will be monitored by a datalogger. Infrared (IR) spectra measurements will be performed at 24h, 48h, 72h, and 7days using an FTIR Spectrometer Nicolet iS10 equipped with the software OMNIC v9.6. Each sample will be measured five times to assure measure reproducibility. Samples will be measured between the range 2,000–800 cm<sup>-1</sup>.<sup>7</sup> IR spectra will be pre-processed using The Unscrambler X, then data will be used to make Orthogonal Partial Least Square Discriminant Analysis (OPLSDA) models using the SIMCAv17.02 software, useful to differentiate samples according to type, donor sex, and TSD.

**Results and Discussion:** ATR/FTIR relies on vibration of the molecules' bonds after their excitation with electromagnetic radiation.<sup>8</sup> In previous studies, we have demonstrated the suitability of ATR/FTIR spectroscopy for the identification of bloodstains and for the differentiation of human and animal oral fluids stains as well as for the estimation of their TSD.<sup>9-11</sup> Here we expect to demonstrate that the IR spectral signatures of blood, saliva, and semen allow their identification independently from the substrate where fluid is deposited and to observe spectra changing as each sample composition degrades over time when exposed to different environmental conditions. In addition, we expect to be able to construct a chemometric model able to differentiate stains according to type, donor sex, and TSD.

**Conclusions:** Rapid non-destructive methods (IR Spectroscopy and Raman) appear to have great potential in forensic science for many applications.<sup>12</sup> Challenges in the analysis of forensic samples are due to the wide range of biological samples, variation in the sample amount, high heterogeneity of the substrates, and exposure to factors that favor degradation (i.e., heat, humidity) and limit the samples available for the analysis. The present study is based on a novel approach to face a relevant forensic issue consisting in the rapid non-destructive identification of biological stains and in the TSD estimation and to expand knowledge in the field.

### Crime Scene Investigation; Bodily Fluid; Age Estimation

---

**B16 Cellular Autofluorescence for the Determination of Time Since Deposition of Blood Samples**

Hannah Elizabeth Lamer\*, Virginia Commonwealth University, Richmond, VA; Christopher Ehrhardt, Virginia Commonwealth University, Richmond, VA; Catherine Cupples Connon, Virginia Commonwealth University, Richmond, VA; Susan A. Greenspoon, Virginia Department of Forensic Science, Richmond, VA

---

**Learning Overview:** After attending this presentation, attendees will have a better understanding of the relationship between the autofluorescence of cellular components of dried blood and Time Since Deposition (TSD) over a period of six months.

**Impact Statement:** This work will impact the forensic science community by assisting in developing a screening technique for TSD of all bodily fluids to assess the probative value of biological evidence at a crime scene.

Knowledge of the relative time evidentiary biological material was deposited at a crime scene, referred to as the TSD, would assist investigators by determining which pieces of evidence are most relevant to a case and help with reconstruction of events. One of the most commonly encountered body fluids at a crime scene is blood, which has a complex matrix containing several endogenous fluorophores. Various methods for estimating TSD of bloodstains have been developed, primarily spectroscopic analyses centered around the oxidation of hemoglobin or the fluorescence lifetime of tryptophan residues. However, none of these methods to date have been validated for use in the forensic laboratory for several reasons, including lack of precision and reliability of TSD estimates, instrumentation, time, labor costs, and importantly, the consumption of the evidentiary sample. Flow cytometry measures the optical properties of cells by interrogating them with a laser, exciting either endogenous fluorophores or hybridized fluorescent tags. As a fast and non-destructive method, flow cytometry is a promising technique for use in forensic science. Past applications of flow cytometry in the field have focused on differentiating between contributors or cell types in sexual assault casework and has only recently been explored for age estimation of body fluids. Studies estimating TSD of epithelial “touch” and saliva samples have found a positive correlation between autofluorescent intensity and TSD.<sup>1,2</sup>

Thus, this study expanded on that research by investigating the relationship between autofluorescence and TSD for blood. Blood samples from ten donors were deposited in triplicate onto microscope slides (three separate stains for each replicate), air dried and maintained at ambient conditions, and collected after designated time periods ranging from fresh( $t=0$ ) to six months. One stain was designated for the analysis of whole blood and another for analysis of only the White Blood Cell (WBC) component, both using flow cytometry. The third stain was for DNA characterization at the time points. To obtain the WBC component, red blood cells were lysed using Ammonium-Chloride-Potassium (ACK) Lysing Buffer prior to characterization using flow cytometry. Samples were collected after the assigned interval using a sterile cotton swab moistened with deionized water and air dried. Prior to data gathering using a flow cytometer, samples were filtered through a 100 $\mu$ m mesh.

Results showed that over the course of six months, the fluorescent intensity of WBC samples increased with increasing TSD, with fresh samples showing median intensity ~2,250 Relative Fluorescence Units (RFUs) and six-month samples showing median intensity of ~15,000 RFUs. The whole blood data showed comparable but distinct trends showing little to no autofluorescence shifts between 0 and 7 days and then linear increases with time from 7 days until 6 months. This trend, consistent with that previously recognized in saliva and “touch” samples, is promising for the development of a screening technique to determine the TSD of unknowns at a crime scene using a comparison with a fresh sample from a person of interest. To test compatibility with the operational workflow of a DNA case-working unit, a series of blood samples were analyzed for TSD, collected from the flow cytometer, and then subjected to a DNA profiling workflow. Results showed that cellular DNA could be recovered with high efficiency (>95%) and that probative profiles could be generated that were consistent with the original contributor.

**Bloodstains; Flow Cytometry; Time Since Deposition**

**B17 The Accuracy of Semen Presumptive Testing**

Heather Rogers\*, University of Central Oklahoma, Oklahoma City, OK; Rhonda Williams, University of Central Oklahoma, Edmond, OK

**Learning Overview:** This presentation will use data collected from semen presumptive tests to demonstrate the importance of having accurate test kits in forensic science. After attending this presentation, attendees will better understand the importance of considering the possibility of false positive results when conducting semen presumptive testing with actual evidence.

**Impact Statement:** This presentation will impact the forensic science community by showing that presumptive tests have a chance of producing inaccurate test results. In the past, there has been very little research done on the accuracy of semen testing, and there hasn't been a single study done where researchers compare RSID Semen™, Seratec PSA™, and ABACard P30™. Investigators should take from this study that they need to confirm their results with secondary testing.

Semen presumptive testing is used to detect the possible presence of semen on evidence or at a crime scene. Semen presumptive tests work by detecting a particular enzyme, such as the Prostate-Specific Antigen, or PSA for short, and semenogelin. However, these tests are prone to false-positive results because PSA and semenogelin can be found in other parts of the body or even outside of the body. Despite this, some agencies still use semen presumptive test results at trial as a confirmation of semen.

In this study, three rapid immunochromatographic test kits were used to test the accuracy and sensitivity of semen presumptive test kits. One semen presumptive test used in this study was the Rapid Stain Identification Series, also known as RSID Semen™. RSID Semen™ works by indicating the possible presence of semen by detecting the semen component, semenogelin.<sup>1</sup> Semenogelin is the main component of the human semen coagulum and is highly concentrated in seminal vesicle fluid.<sup>2</sup> The other two test kits used were Seratec PSA™ and ABACard P30™. They indicate the possible presence of semen by detecting the PSA, one of the components of seminal fluid.<sup>3</sup> PSA is needed to degrade the other components of semen to keep the semen sample from coagulating.<sup>3</sup>

The study aims to determine the sensitivity and specificity of semen-presumptive tests used in forensic labs. This study aims to determine which of the three test kits had a higher accuracy rate. All three test kits were used to test 26 samples, most of which included no traces of semen. A variety of hygiene products, as well as urine samples, breast milk samples, blood samples, and vaginal swabs, were tested to determine how often false positive test results occur in each of the test kits. Some tests were expected to have a higher rate of false positive results. There is also expected to be a difference in sensitivity between the test kits. This study is important to forensics because these tests are still widely used by forensic labs. Several past studies have produced false positive results with all three presumptive tests.<sup>4-6</sup> This is dangerous because semen presumptive results have been used at trial as evidence. The results of this study will be able to help investigators determine which test kit they should use on evidence. This is vital information because using the wrong test could affect the investigation. The use of the correct kit will lead to a more accurate investigation.

**Semen; Accuracy; Bodily Fluid**

---

**B18 The Developmental Validation Testing of the Integrated Quantifiler™ Trio-HRM Assay**

*Chastyn Smith\*, Virginia Commonwealth University, Richmond, VA; Edward Boone, Virginia Commonwealth University, Richmond, VA; Tracey Dawson Green, Department of Forensic Science, Virginia Commonwealth University, Richmond, VA*

---

**Learning Overview:** This presentation will introduce the forensic DNA community to the optimal run conditions and limitations of the integrated Quantifiler™ Trio-HRM assay that allows for mixtures to be discerned earlier in the forensic DNA workflow.

**Impact Statement:** The completion of the project defined herein will impact the forensic science community by contributing to saving time and resources, which are limiting factors in forensic labs, that are consumed in the lengthy mixture detection, analysis, and reanalysis process. Furthermore, the additional information that will be provided about an evidentiary sample could help shape or redirect the path of an investigation prior to the development of a Short Tandem Repeat (STR) profile.

The forensic DNA analysis process is currently incapable of providing information about the number of contributors in an evidentiary DNA sample at an early stage. Although guidelines exist for resolving mixtures, these measures are often reactive rather than proactive and require substantial time and effort. To meet this need, we integrated a High-Resolution Melt (HRM) mixture screening assay into the quantitative Polymerase Chain Reaction (qPCR) step of the forensic workflow producing the integrated Quantifiler™ Trio-HRM assay. The assay, when coupled with a sequential statistical prediction tool, allows for the identification of the contributor status (single-source vs. mixture) of a sample. Data was previously presented demonstrating that the integrated Quantifiler™ Trio-HRM assay produced hDNA quantitative values, M:F ratios, degradation indices, and DNA profiles consistent to those obtained when the standard Quantifiler™ Trio assay was used. When 56 single-source and 16, 1:1, 2-person mixtures were used to evaluate the integrated Quantifiler™ Trio-HRM mixture prediction assay on the QuantStudio™ 6, an overall accuracy of 79.2% was obtained in which 57 of the 72 samples tested were correctly classified as single-source or a mixture.<sup>1</sup>

Many factors determine the complexity of a mixture, including the number of contributors, quantity of DNA from each contributor, and the quality of the DNA. Further, all new methods used for forensic DNA analysis must undergo developmental validation prior to being implemented in labs.<sup>2,3</sup> Thus, a select group of essential developmental validation studies were conducted to assess a variety of sample conditions and determine the performance limits of the newly developed integrated Quantifiler™ Trio-HRM assay. Initial developmental validation testing for this assay included reproducibility and accuracy testing for single-source samples and mixtures that had varying numbers of contributors or varying ratios. For each study, 10-40 samples were evaluated using the final formal protocol for the integrated Quantifiler™ Trio-HRM assay and the predictions for single-source vs. mixture samples were compared to knowns to determine the overall accuracy.<sup>1</sup>

First assessing for reproducibility, the assay was found to be 59% reproducible, 10/17 samples tested were concordantly predicted as a single-source or mixture across runs. Ten of the previously evaluated two-person mixtures were remade at the following mixture ratios: 1:2, 1:5, 1:10, and vice versa. Additionally, five of the existing two-person mixtures were remade with a third, fourth, and fifth contributor at equal ratios. Overall, 80.0% of the ratio mixtures and 90.3% of the increased contributor mixtures were accurately predicted as mixtures. Further studies will be conducted to evaluate mixtures with ratios from 1:20-1:100 and 100:1-20:1 and to assess the sensitivity of the assay using concentrations that range between 0.01-60 (ng/ul). Once the aforementioned validation studies are completed, mock evidentiary samples will be collected and tested using the final protocol established for the integrated Quantifiler™ Trio-HRM assay.

With these developmental validation studies and a user-friendly web interface (in development), the application will be ready to deploy to accredited practitioner laboratories for external testing. Upon successful validation and implementation, this tool will provide forensic examiners with a powerful way to screen and triage evidence items prior to the end point of analysis.

**Mixture Analysis; DNA; Validation**

---

**B19 A Qualitative Analysis of Natural, Synthetic, and Semi-Synthetic Cannabinoids in Vape Products by GC/MS**

*Mikayla Siegfried\*, Arcadia University, Northampton, PA; Joshua S. DeBord, The Center for Forensic Science Research and Education, Ambler, Pennsylvania; Alex J. Krotulski, The Center for Forensic Science Research and Education, Willow Grove, Pennsylvania; Heather L. Harris, Arcadia University, Glenside, PA*

---

**Learning Overview:** This presentation will provide the forensic science community with a new method to qualitatively analyze vape products that contain cannabinoids using a simple sample preparation and analysis by GC/MS. After attending this presentation, attendees will also have a better understanding of what other cannabinoids may be found in today's vape products.

**Impact Statement:** This presentation will impact the forensic science community by providing a closer look into what natural, synthetic, and semi-synthetic cannabinoids are found in vapes on the market in the Northeast United States that may be leading to adverse effects.

The use of vaping devices to consume cannabis, and more recently synthetic and semi-synthetic cannabinoids, has surged in the past two decades in individuals of all ages. More recently, the recreational market for vaping devices has pivoted, largely to skirt legal regulation, and now includes "alternative" cannabinoids. Vaping devices (vapes) are electronic products that allow users to inhale an aerosol that contains nicotine and/or other substances such as cannabinoids and is seen by many as a healthier alternative to smoking. Vapes that contain natural, semi-synthetic, and synthetic cannabinoids are of concern due to adverse effects and negative user experience. Additionally, while some cannabis vapes are regulated in states where cannabis has been legalized, there remain gray markets for all types of cannabinoid-containing products that may not be regulated. Overall, this subject area contains limited research as rapid evolution continues in cannabis and cannabinoid markets. To assess the cannabinoids found in vape products a qualitative GC/MS method was developed to provide chromatographic resolution and diagnostic mass spectral characterization for 18 target cannabinoids: CBD, CBG, CBN, D<sup>8</sup>-THC, D<sup>9</sup>-THC, D<sup>10</sup>-THC, HHC, 9(R)-HHCP, THCV, D<sup>9</sup>-THCO, THCM, THCB, THCH, THCA-A, THCP, D<sup>9</sup>-THC-C8, ADB-BINACA, and MDMB-4en-PINACA.

The GC/MS method employed an HP-5 column (5% phenyl-methylpolysiloxane) on an Agilent® 5973 N coupled to an Agilent® 6890N MS detector with a scan acquisition mode from 40 to 400amu. The e-liquid from the vapes were diluted in 1mL of methanol and spiked into a 50ug/mL solution of methanol with the two internal standards of amitriptyline and strychnine for analysis. Identification was performed by chromatographic retention time and mass spectral comparison to an in-house library database generated from purchased reference standards. Validation in accordance with the Scientific Working Group for the Analysis of Seized Drugs (SWGDRUG) guidelines was performed for interferences, sensitivity, and stability. Interference studies were designed to assess interferences from the matrix, internal standard, and analytes of interest. Assay sensitivity was determined using purchased reference standards and Signal to Noise (S:N). Finally, stability was evaluated for analytes in prepared samples.

To date, the method has been applied to over 50 diverse vape products (the sample population includes commercial, seized, and collected vapes) to accurately determine what cannabinoids along with new emerging THC isomers are present in various vape products: analysis continues, and future results will be provided. The study contains a unique sample subpopulation of vaping devices collected from teenagers and provides insight into differences in products among different populations. Our analysis shows that the most common cannabinoids found in vapes used by teenagers (among our limited samples) are D<sup>9</sup>-THC, D<sup>8</sup>-THC, CBN, and CBG. Analysis of authentic samples has shown major differences between labeled cannabinoids and the cannabinoids that were detected in the vapes.

This is a validated GC/MS method that can qualitatively identify 18 different cannabinoids including natural, alternative, and semi-synthetic cannabinoids in vape products. It has given insight into the unlabeled or mislabeling of cannabinoids within products, along with the most common cannabinoids found in vapes used by teenagers in the Northeast United States, some of which may be leading to adverse effects. Increasing the awareness of unlabeled or mislabeled cannabinoids within vaping products could positively influence a person's decision on whether to use vapes.

---

**B20 Quantifying Cannabinoids in Complex Matrices**

*Michael W. Gilbert, Pinellas County Forensic Lab, Largo, FL; Reta Newman\*, Pinellas County Forensic Laboratory, Largo, FL*

---

**Learning Overview:** After attending this presentation, attendees will understand how to validate streamlined analytical procedures to quantify cannabinoids in plant material, oil, and waxes.

**Impact Statement:** This presentation will impact the forensic science community by illustrating how laboratories keep pace with increasing analytical demands associated with recent marijuana regulation.

The marijuana industry is regulated by the 2018 United States Department of Agriculture (USDA) Farm Bill that defines hemp as cannabis containing less than 0.3% delta-9-Tetrahydrocannabinol ( $\Delta$ 9-THC) by dry weight and by multiple state statutes that govern medicinal and recreational use. Without innovative solutions and additional resources to help meet laboratory accreditation requirements, the increased analytical burden of quantifying  $\Delta$ 9-THC in a complex matrix is creating an unsustainable environment for publicly funded laboratories.

This study validates a novel analytical test kit for high-throughput testing applications in plant, oil, and wax products using Gas Chromatography/Flame Ionization Detection (GC/FID). A quantitative validation study that assessed accuracy, precision, measurement uncertainty, calibration models, reportable range, sensitivity, specificity, carryover, interference, and analyte stability was completed for each matrix in one week. Results show that validated testing procedures are accurate (% bias <20%) and precise (% CV <20%) and that the validated reportable range meets statutory requirements for hemp products. Similar results were obtained for oil and wax. Suitability was further assessed for drug chemistry cases by evaluating a certified reference hemp standard over multiple non-consecutive days.  $\Delta$ 9-THC and cannabidiol were adequately separated and quantified at the statutory limit for  $\Delta$ 9-THC (< 0.3%).

The pre-manufactured test kit is a custom-product designed to meet individual laboratory Quality Assurance/Quality Control (QA/QC) requirements and comes equipped with matrix-matched, injectable-ready standards and quality controls to speed sample analysis. Laboratories only extract unknown specimens with custom extraction solutions tailored for specific standard operating procedures. This increases laboratory efficiencies by alleviating many analytical burdens associated with the intricate task of preparing standards and controls required for accreditation.

**B21 Seized Drugs: Carrier Gas Conversion of Helium to Hydrogen for GC/MS and GC/IR Instruments**

*Cody Woltz\*, Orange County Crime Lab, Santa Ana, CA; Sadie Kasten\*, Orange County Crime Lab, Santa Ana, CA*

---

**Learning Overview:** After attending this presentation, attendees will be informed about the Orange County Crime Laboratory Seized Drugs conversion of Gas Chromatography/Mass Spectrometry (GC/MS) and Gas Chromatography/Infrared Spectroscopy (GC/IR) instruments from helium as a carrier gas to hydrogen as a carrier gas. The hardware changes required for the different MS instruments will be discussed. The attendees will also learn about how GC/MS methods were optimized to make the best use of hydrogen as well.

**Impact Statement:** This presentation will impact the broader forensic science community because most Seized Drug labs still use helium as a carrier gas, despite the growing cost and limited supply. This presentation hopes to show that there are alternatives that other labs can consider.

The cost of helium has been increasing over the past five years. With consistent supply potentially becoming an issue in the future, alternative options to helium should be considered for Seized Drug analysis. The most popular alternative is hydrogen as a carrier gas, but there are three major drawbacks to hydrogen. The first issue is that hydrogen can potentially be dangerous as an explosion or fire hazard. The second issue is that hydrogen can react with certain compounds and solvents, causing issues with Electron Ionization (EI) spectral matching with instrument libraries acquired utilizing helium. The third issue is that there is a loss in sensitivity when comparing hydrogen GC instruments to helium GC instruments.<sup>1</sup>

Safety issues can be mitigated by using features available on most GC instruments in combination with using hydrogen generators to prevent the build up of excess hydrogen. Seized Drug sections are capable of mitigating the sensitivity issues as typical drug submissions require only a small amount of material for GC/MS or GC/IR testing. Most drugs that Seized Drug sections typically see are not reactive with hydrogen. The few drugs that are reactive such as PCP or tramadol can be reacquired using the new hydrogen conditions for better EI spectral matching.

The Orange County Crime Laboratory Seized Drug section first experienced issues obtaining helium in 2018 due to price and availability from contracted sources. Since then, the section has converted most of their GC/MS and all of their GC/IR instruments to hydrogen. This presentation will cover the following points: (1) changes made to EI sources on different models of GC/MS instruments to allow for the use of hydrogen; (2) method optimizations made to both GC/MS and GC/IR instruments to mitigate issues with hydrogen; (3) drawbacks that were encountered using hydrogen that had to be mitigated; and (4) the overall impact that these changes have had on the Orange County Crime Laboratory Seized Drug section.

**B22 The Structural Characterization of Nitazene Analogs Using Electron Ionization/Mass Spectrometry (EI/MS)**

*Emma Hardwick\*, Huntsville, TX; J. Tyler Davidson, Sam Houston State University, Conroe, TX*

---

**Learning Overview:** After attending this presentation, attendees will have learned about conserved fragmentation pathways and diagnostic ions observed for 17 representative nitazene analogs using Gas Chromatography/Electron Ionization/Mass Spectrometry (GC/EI/MS). Attendees will learn about shifts in fragmentation behavior induced by the type and location of substitution to the core nitazene structure and how to apply this information to the identification of novel nitazene analogs.

**Impact Statement:** This presentation will impact the forensic science community by furthering our understanding about the EI/MS fragmentation of nitazene analogs with varying substitutions to their core structure. The identification of diagnostic ions that enable the differentiation of nitazene analogs based on the type and location of substitution will assist with the development of more accurate and reliable screening and confirmatory GC/EI/MS methods. Finally, the characterization of nitazene analogs with common substitutions across the nitazene core will help to establish a baseline for the identification of novel nitazene analogs.

Recent changes in legislation within the United States and China have led to a shift in the Novel Synthetic Opioid (NSO) drug market away from fentanyl analogs toward a new emerging class of NSOs known as 2-benzylbenzimidazoles or more commonly, nitazenes. The gold standard analytical technique used for the identification of seized drugs is GC/EI/MS based on the ability to gather both retention time and structural information through the combination of Category B and Category A techniques, as defined by the Scientific Working Group for the Analysis of Seized Drugs (SWGDRUG) and the American Society for Testing and Materials (ASTM) E2329-17. However, given the recent emergence of the nitazene analog class of NSOs, little information is known about the EI/MS fragmentation behavior of these compounds. In addition, many of the initial nitazene analogs to emerge have been classified as Schedule I controlled substances, leading to an influx of novel nitazene analogs designed to circumvent legislative restrictions. Therefore, there is a need to understand the impact of substitution to the core nitazene structure on the observed EI/MS fragmentation behavior, including the identification of diagnostic fragment ions, to assist seized drug analysts with the identification of novel nitazene analogs. The central hypothesis of this research is that the type and location of substitution to the core nitazene structure will impact the observed EI/MS fragmentation behavior, enabling the identification of diagnostic ions and characteristic ion ratios that can be used to differentiate even closely related nitazene analogs.

This study examined 17 representative nitazene analogs, including nitazene, metodesnitazene, isotodesnitazene, protodesnitazene, 5-methyl etodesnitazene, 5-aminoisotonitazene, menitazene, 4'-hydroxy nitazene, *N*-pyrrolidino 4'-hydroxy nitazene, *N*-piperidinyl 4'-hydroxy nitazene, isobutonitazene, *N*-desethyl etonitazene, *N*-desethyl isotonitazene, *N*-pyrrolidino isotonitazene, *N*-pyrrolidino metonitazene, *N*-piperidinyl etonitazene, and *N*-piperidinyl protonitazene. These compounds contain representative substitutions to the benzimidazole ring, benzyl group, and ethylamine functionality of the core nitazene structure, with at least two examples for each type and location of substitution. All standards were prepared at a concentration of 100ppm and analyzed using an Agilent® GC/EI/MS. The standards were analyzed individually to avoid issues with co-elution given the importance of collecting pure EI mass spectra for spectral characterization.

The results indicate that even though many nitazene analogs produce similar EI mass spectra, there are subtle differences in low abundance fragment ions that are due to the location and type of substitution to the core nitazene structure. For example, the base peak for nitazene analogs with two ethyl groups on the amine moiety is observed at  $m/z$  86, which is formed through an  $\alpha$ -cleavage adjacent to the ethylamine moiety. Any observed shift in the base peak indicates modification to the ethylamine moiety, such as the observation of a base peak at  $m/z$  58 for *N*-desethyl etonitazene, which has only a single ethyl substitution to the amine functionality. Likewise, the formation of fragment ions through a benzylic cleavage (e.g.,  $m/z$  135 or  $m/z$  149) provides information about the type of substitution on the benzyl group. Typically, this substitution is an alkoxy substitution, which fragments further to a common fragment ion at  $m/z$  107 through the loss of a neutral alkene. Finally, differentiation of compounds with different substitutions to the benzimidazole ring is based on observed shifts to the fragment ion formed through an  $\alpha$ -cleavage adjacent to the benzimidazole ring (e.g.,  $m/z$  324 for *N*-desethyl isotonitazene), as well as additional secondary fragmentation through the loss of the alkoxy chain (e.g.,  $m/z$  282). Even though several of these diagnostic ions are observed at relatively low abundance, they provide helpful information for the differentiation of nitazene analogs, especially for compounds with similar retention times.

---

**B23 The Effect of Solid Copper Bullets on Barrel Rifling Characteristics**

*Natali Hassett\*, Forensic Science Institute, University of Central Oklahoma, Edmond, OK; Eric Law, Forensic Science Institute, University of Central Oklahoma, Arcadia, OK*

---

**Learning Overview:** This presentation will utilize 3D bullet scans to demonstrate how solid copper bullets affect barrel rifling characteristics. After attending this presentation, attendees will better understand the degree to which the individual characteristics of barrel rifling persist after the successive firing of solid copper bullets.

**Impact Statement:** This presentation will impact the forensic science community by showing the effects of solid copper bullets on barrel rifling characteristics. Specifically, it will illustrate these effects on the enhanced polygonal rifling characteristics of the Generation 5 Glock® Marksman Barrels, which are present in some of the most common pistols in the United States.

Research on the persistence of barrel rifling features is typically conducted on one of the most common ammunition types on the market, full-metal jacket ammunition. However, solid copper bullets are becoming more commonplace, especially in the hunting industry. This is due to a push for lead-free ammunition supported by environmental legislation. As solid copper bullets become more widely used, crime laboratories will see an increase in the number of solid copper bullets submitted as evidence. For firearms examiners to better understand the effects of solid copper ammunition on the persistence of barrel characteristics, more research is needed. The purpose of this study is to determine if solid copper bullets can be identified after successive firing.

This study will include the successive firing of 500 solid copper bullets through a new Glock® 19 Gen 5 chambered for 9mm Luger® ammunition. The first ten, last ten, and every tenth bullet will be collected for a total of 68 bullets. These bullets will be scanned using the Cadre Forensics TopMatch-GS 3D System. The three-dimensional scans of the land-engraved areas will be used to compare the individual characteristics left on the bullets by the barrel rifling.

In contrast to previous studies that involved qualitative visual examinations, this study will be based on quantitative data. The TopMatch System's built-in algorithm will be used to generate similarity scores for each comparison. Similarity scores range from zero to one, with higher values indicating greater similarity between the features being compared. The algorithm's results will be used to support conclusions, and the similarity scores will allow for statistical demonstrations on the similarity between the fired bullets.

The results from this study will show if solid copper bullets affect barrel rifling characteristics to the point where identifications are no longer possible after 500 rounds. The three-dimensional scans from this study will be uploaded to the National Institute of Standards and Technology Ballistics Toolmark Research Database to allow other researchers and professionals to understand the effects of solid copper bullets. The results will also benefit firearms analysis by showing how solid copper bullets affect the rifling characteristics of Glock® barrels. Glock® is one of the most popular pistol manufacturers, so Glock® pistols are often involved in crimes. Understanding how solid copper bullets affect Glock® rifling characteristics will help firearms examiners better analyze such evidence.

**B24 The Loss of Latent Fingerprint Visual Quality: Natural Degradation vs. Depletion Series**

*Josep De Alcaraz-Fossoul\*, University of New Haven, West Haven, CT*

---

**Learning Overview:** After attending this presentation, attendees will understand the visual differences existing between “natural aging” vs. “depletion series” of latent fingerprints to estimate “absolute” vs. “relative” time-since-deposition, respectively, as examined by 2D and 3D imaging analyses.

**Impact Statement:** This presentation will impact the forensic science community by providing novel research methods and techniques to investigate the changing topography of latent fingerprints. In the current project, two different imaging approaches are combined (2D and 3D) to provide a robust interpretation of how fingerprints naturally age or deplete to obliteration using computer software, increasing the objectivity of results. These will undoubtedly contribute to the larger pool of data necessary to explain the mechanisms of visual degradation of fingerprints’ topography.

Despite its pervasiveness as crime evidence, fingerprints are considered circumstantial evidence and, thus, must be reinforced with unassailable expert testimonies. A suspect (in this case, the actual perpetrator) of a crime could easily justify that their fingerprints were placed months, days, or hours before the crime was committed. If a reasonable alibi is at hand, these fingerprints can be then invalidated as evidence and the perpetrator may walk free. On the other hand, an innocent person whose fingerprints just happened to be at the crime scene could unnecessarily be implicated. Either situation of a false negative or a false positive is undesirable for the victims of a crime, the innocent, and society based on fair justice for all. In practice, the age of fingerprints is a topic that has been implicitly or explicitly discussed in at least 28 court cases from 1961 to 2011 as reported in the literature, and it is a reoccurring issue in crimes involving fingerprints.<sup>1</sup>

This experiment addresses a question embedded within the general goal of estimating the age of latent fingerprints by utilizing optical means alone: can we objectively determine whether a fingerprint has naturally aged or has been depleted to obliteration? In this project, 3,000+ 2D and 3D fingerprint imaging data were compiled between 2018 and 2022 and were statistically examined and compared based on their “natural aging” vs. “depletion series” patterns. Although these are both temporal mechanisms of the loss of fingerprint ridge integrity, the term “aging” refers to the “absolute age or time-since-deposition” of the impression whereas “depletion” refers to the “relative time of deposition in a series of continuous touches,” usually within a few minutes. This distinction is important when attempting to reconstruct the specific order of events at a crime scene. Indeed, depletion series are very relevant in cases of two or more fingerprints falling within the same “absolute age range,” mostly because of the inherent limitations of the technologies employed at the time of providing an estimate of age with its standard deviation. Then, a method to distinguish fingerprints deposited in a narrow timeframe is by their “relative position” within a depletion series.

The substrate of choice was glass microscope slides exposed to indoor dark conditions. For the “aging” set, fingerprints were aged up to one year, whereas for the “depletion” specimens, up to 24 fingerprints were sequentially deposited. In all cases, sebaceous-rich impressions were created from 41 males and 34 females. The topographical parameters for discerning “aging” vs. “depleting” modifications have included data from 2D and 3D fingerprint images: Blue-Green metric (BG) from the Universal Latent Workstation (ULW) and *Sa* metric from an Optical Profilometer (OP), respectively.<sup>2</sup> ULW provides metrics on the levels of visual quality (clarity) of a fingerprint and the area extension (mm<sup>2</sup>) of “discernable and identifiable” ridges (BG). The OP provides data on the average height of ridges (*Sa*), among many others. These data were input into a Microsoft® Excel® spreadsheet and IBM® SPSS for further statistical analysis. Preliminary results revealed that *Sa* metric was more sensitive at detecting differences over time and across depletion series than BG values. At the same time, 2D and 3D metrics were able to distinguish the temporal processes visually and statistically. The results of this study are key to the goal of quantitatively and automatically defining the aging parameters of fingerprints and fueling research and innovation in fingerprint aging analysis.

*Disclosure: Thank you to all the professionals and students who, for over one decade, have helped with the collection of data: from the Universitat de Barcelona, Arizona State University, California State University, and University of New Haven.*

**B25 The Optimized Separation of Cannabis Terpenes/Terpenoids Via GC/EI/MS**

*Kristina Martinet\*, Burr Ridge, IL; James V. DeFrancesco, Loyola University Chicago, Chicago, IL; Emma Humphreys, AbbVie, Chicago, IL*

---

**Learning Overview:** After attending this presentation, attendees will learn how to optimize the separation of 23 terpenes in a standard terpene mix by Gas Chromatography/Electron Ionization/Mass Spectrometry (GC/EI/MS).

**Impact Statement:** This presentation will impact the forensic science community by informing attendees how this optimized method will improve the identification of terpenes in cannabis samples.

The cannabis plant (*Cannabis sativa* L.) produces a variety of compounds covering numerous chemical classes such as cannabinoids, flavonoids, terpenes, and terpenoids. The terpenes and terpenoids are recognized as important constituents in cannabis products by growers and consumers. They are responsible for the aroma characteristics in addition to a variety of purported medical benefits. Terpenes are oligomers of isoprene units, whereas terpenoids are oxidized forms of terpenes.

Analysis of these compounds is typically performed by GC using liquid or gas injection (headspace). Due to the wide boiling point range of these compounds, operational cannabis laboratories most often perform the analysis using liquid injection. However, separation of the numerous and wide variety of compounds in the relatively short period of time needed for high throughput is challenging. Separation of terpenes and terpenoids is necessary for proper identification and quantitation. The identification and quantification of these compounds has become increasingly important with the state-by-state movement towards cannabis legalization and the purported medical benefits of all compound classes in the plant.

In the first phase of the project, we determined that separation (selectivity) of terpenes and terpenoids commonly found in consumer products was improved by modifying GC column stationary phase chemistry and temperature programming. In this current phase, we focused on modifications to the column dimensions. These variables included internal diameter (0.32, 0.25, and 0.18mm), mobile phase thickness (0.32, 0.25, and 0.18µm), and stationary phase composition within the column (100% dimethyl polysiloxane vs. 95% dimethylpolysiloxane/5% diphenyl polysiloxane). These conditions were compared using a combination of two standard terpene mixtures available from commercial sources, for a total of 23 terpenes to be separated. Along with the improved separation in this phase, we also created a ChemStation® library of these compounds using the AutoQuant® feature for rapid identification. This improvement in selectivity ultimately achieved identification of these compounds.

Further work in this project will include quantitation of each compound, further optimizing resolution by testing a 1,4-phenylene stationary phase (which has a different polarity profile than di-phenyl), and implementation of these techniques on commercially available botanical samples. To date, the best separation was with a DB-5ms column (20m x 0.18mm x 0.18µm load). Full baseline separation was accomplished for 21 of the 23 compounds in the standard terpene mixture.<sup>1-3</sup>

## B26 The Quantitation of Furanocoumarins in Grapefruit Supplements Using High-Performance Liquid Chromatography

Nequa Griffin\*, Towson University, Nottingham, MD; Ellen H. Hondrogiannis, Towson University, Towson, MD

**Learning Overview:** After attending this presentation, attendees will understand the amounts of two furanocoumarins, Bergamottin (BGT) and 6'7'-Dihydroxybergamottin (DHB) in over-the-counter dietary grapefruit supplements and other products reported to contain grapefruit extract measured by High-Performance Liquid Chromatography (HPLC).

**Impact Statement:** This presentation will impact the forensic science community by informing attendees of the amounts of BGT and DHB in County Life® Chewable Acerola Vitamin C Complex, NutriBiotic® Defense Plus, NutriBiotic® Grapefruit Seed Extract, and Solaray® PhytoEstrogen & Grapefruit One Daily supplements with grapefruit extract. These furanocoumarins are important because they inhibit the CYP3A4 enzyme. Taking these supplements with drugs that are inhibited by this enzyme leads to increased drug concentrations that may cause potential harmful side effects and/or incorrect cause of death. Current Food and Drug Administration (FDA) guidelines do not require that the furanocoumarins be listed as an ingredient; thus, individuals using these products are often unaware of their presence. Our study will inform the forensic community of the amounts of furanocoumarins in these supplements and compare to the amounts of these furanocoumarins known to be present in grapefruit juice, since consumption of 240mL of grapefruit juice inhibits the enzyme.<sup>1</sup> Extraction efficiency and analytical figures of merit for the quantification of these furanocoumarins using an Agilent® 1200 HPLC will be reported.

In today's society, many people try to improve or maintain a healthy lifestyle by taking Over-The-Counter (OTC) dietary supplements and vitamins to obtain the nutrients that the body needs. While this may seem like the ideal route, many individuals do not realize that OTC dietary supplements are not regulated by the FDA under the normal set of regulations.<sup>1</sup>

Consuming grapefruit is known to result in health benefits, such as anti-inflammatory, anti-cancer, and anti-obesity.<sup>2</sup> As such, grapefruit extract or grapefruit seeds are commonly found in OTC supplements. The labels on these supplements, however, do not list the furanocoumarins present. Since two of these furanocoumarins, BGT and DHB, have been known to cause Drug-Drug Interactions (DDIs), several investigators have measured their concentrations in a variety of matrices such as supplements, grapefruit juice, lime juice, grapefruits, cosmetics, essential oils, and parsnip seeds.<sup>1-12</sup>

This work reports on the concentrations of these analytes (after methanol extraction) in different lot numbers of County Life® Chewable Acerola Vitamin C Complex and NutriBiotic® Defense Plus supplements as well as NutriBiotic® Grapefruit Seed Extract and Solaray® PhytoEstrogen & Grapefruit One Daily supplements. A statistically significant difference was found in the amounts of DHB and BGT among different lot numbers of the Acerola supplements and no significant difference for the same analytes among different lot numbers for the NutriBiotic® supplements. The overall mean concentrations of BGT and DHB in the NutriBiotic® supplements were ~11.7 and 11.4 times greater than those for the same analytes in the Acerola supplements, respectively. The amounts of BGT and DHB measured for one tablet were still well below those reported to cause DDIs in one serving of grapefruit juice. It is expected for the levels measured in the grapefruit seed extract and the One Daily supplement to be significantly lower. In addition to these supplements, there are a large number of natural products (noted above) that contain significant amounts of BGT and DHB. Without knowledge of possible DDIs from taking excessive amounts of supplements and/or combining with natural products, there exists the possibility of accidental overdose. The results of this work can help inform the forensic community about these potential effects and provide them with the extraction efficiency and analytical figures of merit for the quantification of these furanocoumarins using an Agilent® 1200 HPLC.

**B27 Ag-Ligand Ion Complexation: An Alternative Approach for Hemp and Marijuana Differentiation**

*Alleigh N. Couch\**, Sam Houston State University, Huntsville, TX; *Jayleigh M. Lanza*, Sam Houston State University, Richmond, TX; *Christopher M. Zall*, Sam Houston State University, Huntsville, TX; *J. Tyler Davidson*, Sam Houston State University, Conroe, TX

---

**Learning Overview:** After attending this presentation, attendees will be informed about the differentiation of hemp and marijuana using Ag-ligand ion complexation and a semi-quantitative decision-point assay. Attendees will learn how the presence of unique product ions of Ag-ligand cannabinoid complexes allows for the differentiation of  $\Delta^9$ -Tetrahydrocannabinol ( $\Delta^9$ -THC), Cannabidiol (CBD), Tetrahydrocannabinolic Acid (THCA), and Cannabidiolic Acid (CBDA), enabling the development of a semi-quantitative method to differentiate hemp and marijuana using a conservative 1% administrative threshold.

**Impact Statement:** This presentation will impact the forensic science community by providing a method for the differentiation of hemp and marijuana using Ag-ligand ion complexation and a semi-quantitative decision-point assay. Differences in preferential binding affinity of  $\Delta^9$ -THC, CBD, THCA, and CBDA to  $[\text{Ag}(\text{PPh}_3)(\text{OTf})]_2$  result in the formation of unique product ions in positive ionization mode, which can be then used to differentiate hemp and marijuana using a semi-quantitative decision-point assay.

The 2018 Farm Bill defined marijuana as *Cannabis sativa* L. or any derivative thereof that contains greater than 0.3%  $\Delta^9$ -THC, whereas hemp contains no more than 0.3%  $\Delta^9$ -THC on a dry weight basis. Due to the classification of marijuana as a Schedule I controlled substance, it is imperative that seized drug analysts are able to perform both the qualitative identification and quantitative or semi-quantitative analysis of the total THC content in potential marijuana samples, which includes  $\Delta^9$ -THC and its acidic precursor THCA. The main cannabinoids present in hemp and marijuana are the structural isomers CBD and  $\Delta^9$ -THC, which complicates analysis when using soft ionization sources due to their identical chemical formula and only slightly different structural arrangement, resulting in nearly identical product ion spectra. The differentiation is further complicated by the presence of additional cannabinoid interferences. The central hypothesis of this research is that hemp and marijuana can be differentiated using Ag-ligand ion complexation and a semi-quantitative 1% decision-point assay, even in the presence of other cannabinoid interferences.

An Agilent® 6530 quadrupole Time-Of-Flight (qTOF) mass spectrometer with direct injection Electrospray Ionization (ESI) was used for the analysis of the Ag-ligand ion cannabinoid complexes. The following cannabinoids were analyzed with and without the presence of  $[\text{Ag}(\text{PPh}_3)(\text{OTf})]_2$ :  $\Delta^9$ -THC, CBD, THCA, CBDA, cannabichromene (CBC),  $\Delta^8$ -tetrahydrocannabinol ( $\Delta^8$ -THC),  $\Delta^{6a,10a}$ -tetrahydrocannabinol ( $\Delta^{6a,10a}$ -THC), cannabinol (CBN), cannabigerol (CBG), exo-tetrahydrocannabinol (exo-THC), and cannabicitran (CBT). The corresponding product ions were collected for abundant precursor ions present in the full scan spectrum with collision energies of 15-45 eV, using a 4 Da isolation width. Spectral comparisons were used for characterization and to determine unique product ions capable of differentiating the Ag-ligand cannabinoid complexes.

The semi-quantitative decision point assay provides a more conservative approach by setting a 1% administrative threshold to reduce the potential for false positives. The 1% administrative threshold is set by fortifying authentic methanolic extracts of cannabis with a  $\Delta^9$ -THC-*d*<sub>9</sub> internal standard at 1% by weight. The resulting total THC abundance is then normalized to the  $\Delta^9$ -THC-*d*<sub>9</sub> abundance. If the value is larger than 1, then the sample is considered marijuana, whereas if the value is less than 1, then the sample is not considered marijuana. The total THC abundance is determined by removing the contribution of CBD and CBDA from the analytical signal of  $\Delta^9$ -THC and THCA using THC: CBD and THCA: CBDA unique product ion calibration curves and the abundance of the respective unique product ions at *m/z* 421 and *m/z* 465. The total THC content is the combined abundance of the precursor ions at *m/z* 683/685 and *m/z* 727/729, which correspond to  $\Delta^9$ -THC and THCA, respectively.

The results indicate that hemp and marijuana can be differentiated using Ag-ligand ion complexation and a semi-quantitative decision-point assay due to the formation of unique Tandem Mass Spectrometry (MS/MS) product ions. Due to the difference in preferential binding affinity of the cannabinoids to  $[\text{Ag}(\text{PPh}_3)(\text{OTf})]_2$ ,  $\Delta^9$ -THC and CBD can be differentiated by unique MS/MS product ions for CBD at *m/z* 421, *m/z* 353, and *m/z* 231. In addition, THCA and CBDA can be differentiated by unique product ions for CBDA at *m/z* 465 and *m/z* 379. The unique product ion calibration curves allow for the removal of CBD and CBDA contribution and the semi-quantitative determination of the total THC content. To highlight the method capabilities, 20 blind methanolic extracts of authentic cannabis plant material were analyzed and classified as either marijuana or not marijuana. The results support that the developed approach provides a method to both qualitatively identify and semi-quantitatively assess the total THC content in methanolic extracts of cannabis plant material, enabling the differentiation of hemp and marijuana without the need for lengthy chromatographic separations.

**B28 A Workflow for the Rapid Analysis of Trace Drug Residues Collected From Used Paraphernalia**

*Meghan G. Appley\*, National Institute of Standards and Technology, Gaithersburg, MD; Elizabeth Robinson, National Institute of Standards and Technology, Gaithersburg, MD; Edward Sisco, National Institute of Standards and Technology, Gaithersburg, MD*

---

**Learning Overview:** This presentation will show results from the development and implementation of the Rapid Drugs Analysis and Research (RaDAR) project being conducted at the National Institute for Standards and Technology (NIST). After attending this presentation, attendees will be aware of the method developed for analyzing trace drug residues collected from used paraphernalia, including both qualitative and quantitative results.

**Impact Statement:** This presentation will impact the forensic science community by introducing a workflow for rapid qualitative and quantitative analysis of trace drug residues collected from used paraphernalia. Preliminary results will also provide information on the drug landscape for several geographical regions across the United States.

Understanding the illicit drug landscape is a critically important task for law enforcement, forensic science, and public health entities as it can better inform investigations, scheduling decisions, addiction treatment approaches, and overdose prevention efforts. To accomplish this, timely, standardized, and complete—identification of drugs, adulterants, and cutting agents—analyses are required. From a forensic science perspective, this is often difficult because of high backlogs and the need to only report controlled substances.

In this project, a platform that is capable of providing rapid, near-complete, and standardized data was developed to capture the drug landscape in real time. A combination of ambient ionization mass spectrometry and traditional chromatography-based mass spectral techniques have been deployed to enable qualitative and quantitative analysis of trace drug residues from used or suspected paraphernalia. The workflow for this effort involves collection of drug residues from law enforcement, public health, or forensic personnel that is then mailed to the laboratory for analysis. An initial screening of the sample is completed, within 24 hours, using Direct Analysis In Real Time-Mass Spectrometry (DART®-MS) to quickly identify and report back all drugs, adulterants, and cutting agents found in a sample. A subset of samples is also tested using chromatography-based techniques for confirmation of newly identified compounds or to quantitate the relative proportions of compounds within a sample. These results are typically provided back within a matter of days.

The RaDAR project was first piloted in October 2021, through a collaborative effort with public health, forensic science, and law enforcement agencies throughout the state of Maryland. The results from the pilot were able to provide critical information on the influx of xylazine into the state's illicit drug supply, the emergence of nitazenes, and other drug trends that had not been previously found. This information was important to public health and law enforcement entities but also proved to be critical in acting as an early warning indicator to forensic laboratories so they could prepare for new compounds in their case samples.

Since the initial pilot project, RaDAR has grown to include additional regions throughout the country. In addition to discussing the development of the platform, key findings, regional trends, and information of the latest drug trends will be provided in this presentation.

---

**Rapid Drug Screening; Mass Spectrometry; Direct Analysis in Real Time (DART®)**

**B29 A Homemade Bomb Mistaken for a Terroristic Attack: A Variety of Forensic Analyses Can Help Substantiate the Investigations**

*Irene Pradelle\*, Università degli Studi di Modena e Reggio Emilia, Cappella Maggiore, Veneto, Italy; Michele Carpinteri, University of Modena and Reggio Emilia, Bologna, Emilia-Romagna, Italy; Laura Camilla Gasparini, University of Modena and Reggio Emilia, Ferrara, Emilia-Romagna, Italy; Luca Diani, University of Modena and Reggio Emilia, Bologna, Emilia-Romagna, Italy; Giada Rovito, University of Modena and Reggio Emilia, Bologna, Emilia-Romagna, Italy; Margherita Neri, Department of Medical Sciences, Section of Public Health Medicine, University of Ferrara, 44121 Ferrara, Italy, Ferrara, Emilia-Romagna, Italy*

---

**Learning Overview:** After attending this presentation, attendees will understand how useful a complete forensic analysis, including chemical analysis, on the cadaver can be in finding out the composition of an explosive device and the position of the victim in relation to it, thus helping investigations.

**Impact Statement:** This presentation will impact the forensic science community by providing an emblematic example of an explosive-related event and its management from a medicolegal point of view to obtain useful evidence to help investigators reconstruct the assumptive terrorist attack.

An explosion is an exothermic reaction that occurs when an explosive chemical substance (liquid or gaseous) reacts with oxygen, causing the rapid release of energy in the form of heat, noise, and pressure waves (called blast waves). In these reactions, lots of metallic fragments and gaseous particles also spread at very high speed, being able to reach objects and people, causing different grades of damage, depending on their distance from the epicenter of the explosion. Evaluating these fragments, their composition, and their distribution on the body can provide useful clues for investigations.

We present an emblematic case that occurred in May of 2012 in a city in Southern Italy when a bomb blew up near a high school. In the explosion, nine people were injured and one 15-year-old girl died shortly after she was taken to the hospital for the wounds provoked by the detonation. A complete postmortem examination of her body (including Computed Tomography [CT] scans, autopsy, histopathological and immunohistochemical analyses) was performed; we also performed a complete quantitative and qualitative chemical analysis of the commonest metals using an Inductively Coupled Plasma/Atomic Emission Spectrometry (ICP/AES). The CT scans and the autopsy revealed right otorrhagia, partial amputation of the right forearm, the widespread presence of splinters and other metal particles embedded in subcutaneous tissues, and skin burns on 90% of the body. Moreover, these investigations revealed left costal and scapular fractures, left hemopneumothorax, bilateral lung contusions and left pleural tears, presence of soot inside the trachea and the bronchi. Surprisingly, no lesions were found in the abdomen.

As mentioned above, a standard histopathological study was also carried out using hematoxyline-eosin staining. The main findings were acute pulmonary emphysema, massive intra-alveolar and subpleural hemorrhages, gas embolization, and heat-induced alterations of the tracheal epithelium. Skin samples, which were collected near the burns, were stained with sodium rhodizonate and Perls Prussian blue and examined with a phase-contrast microscope. These stainings, specific for the detection of traces of lead, barium, antimony, and iron, confirmed the presence of these heavy metals in the samples. Heat-induced alterations in cutaneous tissues were also confirmed thanks to immunohistochemistry. These samples showed strong positivity to antibodies anti-Heat Shock Proteins (HSP-27, HSP-70, HSP-90).

Considering all the findings, we could assume that the girl died from a severe primary blast lung injury, caused by the detonation of a bomb, without a blunt or penetrating chest trauma. In addition to this, the information about type, quantity, and distribution of the explosive residues was obtained by using an ICP/AES on lyophilized samples of skin containing heavy metals.

The results of our study and the parallel analyses performed by the police helped identify the chemical substances and the materials used to make the bomb, thus leading to the arrest of the culprit, an Italian citizen who used to deal with agricultural fuel for his job, who admitted having made the bomb detonate with a remote for personal revenge.

In conclusion, a complete postmortem study and the assessment of the composition, quantity, and distribution on the body of fragments spread by an explosion can provide important evidence for the reconstruction of explosion-related events.

**Explosion; Tissue Analysis; Fragments**

---

**B30 Hidden Traces: An Alternative Analytical Scheme for Seized Drug Analysis**

*J. Tyler Davidson\*, Sam Houston State University, Conroe, TX; Alleigh N. Couch, Sam Houston State University, Huntsville, TX*

---

**Learning Overview:** After attending this presentation, attendees will have learned about an alternative screening method for seized drug analysis using trace residues generated through sample weighing as part of routine casework processing. The attendees will be informed about the ability to rapidly screen for seized drug residues remaining on different types of weigh paper using Direct Analysis in Real Time-Mass Spectrometry (DART®-MS) and a comparison of the screening results to more classical Gas Chromatography/Electron Ionization/Mass Spectrometry (GC/EI/MS) analysis.

**Impact Statement:** This presentation will impact the forensic science community by demonstrating a rapid screening method for the detection of seized drug residues remaining on different types of used weigh paper generated through routine casework processing. Incorporation of this alternative screening method provides a rapid approach to acquire high-quality screening results prior to confirmatory analysis using GC/EI/MS that has the potential to improve laboratory throughput relative to traditional analytical schemes.

The traditional seized drug analysis process involves weighing an evidence submission prior to analysis. Typically, presumptive testing is performed with relatively rapid and inexpensive testing such as color tests or immunoassays, followed by more discriminating techniques such as GC/EI/MS. However, the drug residue transferred during the weighing process creates an opportunity for an even more rapid and reliable screening technique using DART®-MS. Rather than treating used weigh papers as chemical waste, the weigh papers can be used as a sample introduction method containing a representative sample of the weighed seized drug evidence. The central hypothesis of this research is that DART®-MS analysis of different types of used weigh papers will enable a rapid and reliable screening method for seized drug evidence without any additional sample preparation. The ability to rapidly identify controlled substances without additional sample preparation enables more targeted confirmatory analysis and a more efficient seized drug analysis process.

A DART® JumpShot® ionization source was coupled with an Agilent® 6530 quadrupole Time-Of-Flight (qTOF) MS to rapidly analyze the used weigh paper samples. The DART® ionization source, which used helium as the source gas, was operated in positive ionization mode with a 350°C gas temperature and a 350V exit grid potential. The MS was operated in positive ionization mode with a scan range of  $m/z$  40-450. Collision-Induced Dissociation (CID) was used to generate additional fragment ions under low (0 eV), medium (30 eV), and high (60 eV) activation conditions using All Ion Fragmentation (AIF). The controlled substances analyzed in this study were PCP, heroin, fentanyl, methylphenidate, phentermine, cocaine, methamphetamine, amphetamine, alprazolam, lorazepam, and diazepam. These compounds were analyzed pure and in simulated 2-, 3-, and 4-component mixtures at two different ratios with a total concentration of 50ppm. 10µL of each sample was spiked onto Whatman® 3 filter paper and glassine weigh paper to assess differences in substrate performance. Method validation was performed for glass capillary, Whatman® 3 filter paper, and glassine weigh paper to assess the selectivity, matrix effects, accuracy, repeatability, reproducibility, limit of detection, and robustness. All compounds were identified using the National Institute of Standards and Technology (NIST) DART®-MS Forensics Database and Data Interpretation Tool (DIT).

The results indicate that Whatman® 3 filter paper and glassine weigh paper can both be used as sample matrices for seized drug residue screening following routine sample weighing. Although there were slight differences in validation performance between the different weighing matrices, reliable detection of all controlled substances was observed. When the validated method was applied to 35 authentic seized drug samples that were acquired from a local forensic laboratory, the results demonstrated that powdered samples were readily retained by the weighing matrices in detectable quantities. However, matrices used to weigh capsules, tablets, and drug paraphernalia did not retain sufficient residue for reliable detection. The authentic seized drug samples were chosen to represent realistic combinations of controlled substances and cutting agents, mixture ratios, and quantities of evidentiary sample remaining on weigh papers to accurately assess the developed screening technique. All screening results were compared against GC/EI/MS confirmatory results and any discrepancies were investigated further. The developed DART®-MS screening method of used weigh papers provides an alternative screening technique that requires no additional sample preparation and provides accurate and reliable results for powdered seized drug samples.

**B31 Matricide: When Psycho-Social Fragilities Lead to Murder**

*Laura Camilla Gasparini\*, University of Modena and Reggio Emilia, Ferrara, Emilia-Romagna, Italy; Michele Carpinteri, University of Modena and Reggio Emilia, Bologna, Emilia-Romagna, Italy; Giada Rovito, University of Modena and Reggio Emilia, Bologna, Emilia-Romagna, Italy; Luca Diani, University of Modena and Reggio Emilia, Bologna, Emilia-Romagna, Italy; Irene Pradelle, Università degli Studi di Modena e Reggio Emilia, Cappella Maggiore, Veneto, Italy; Matteo Fabbri, University of Ferrara, Ferrara, Emilia-Romagna, Italy; Matteo Marti, University of Ferrara, Ferrara, Emilia-Romagna, Italy; Rosa M. Gaudio, University of Ferrara, Ferrara, Emilia-Romagna, Italy; Raffaella Marino, Azienda Ospedaliero-Universitaria di Ferrara, Italy, Emilia-Romagna, Italy; Letizia Alfieri, University of Ferrara, Ferrara, Emilia-Romagna, Italy; Margherita Neri, Department of Medical Sciences, Section of Public Health Medicine, University of Ferrara, 44121 Ferrara, Italy, Ferrara, Emilia-Romagna, Italy*

---

**Learning Overview:** After attending this presentation, which involves analyzing three cases of matricide that occurred between 2021 and 2023 in the province of Ferrara, Italy, attendees will understand that the psycho-social and family context in which matricides develop is the real starting point for the analysis and prevention of this type of crime.

**Impact Statement:** This presentation will impact the forensic science community by underlying the reasons, the psycho-social contexts and the pathological mother-child bond that lead a child to murder his/her own mother.

The murder of one's own mother, called matricide, is a rare event that has always attracted media interest because of its inherent nature as a violation of ethical and moral principles on which society is founded. Although each crime stands on its own, common pathological family dynamics can often be observed among these types of crimes, especially concerning the mother-child relationship. It turns out, in fact, frequently marked by an ambivalent relationship, connoted by both a strong emotional and economic dependence on the mother and a constant search of self-affirmation. In addition, the father is often a passive or absent figure. Studies show that the perpetrator generally suffers from a psychiatric illness (sometimes already known, sometimes diagnosed later), related mainly to psychotic or paranoid profiles with difficulties in social integration.

This report aims to illustrate three cases of matricide that occurred between 2021 and 2023 in the province of Ferrara, Italy, with the purpose of understanding and exploring the reasons and socio-familial contexts that lead the offenders to murder their own mothers.

The retrospective analysis of the three matricides that occurred in the province of Ferrara in the period between 2021 and 2023 was carried out by a compilative-comparative method. It proceeded to examine the crime scene investigation, the autopsy evidence, histological, toxicological and immunohistochemical analyses, as well as the killers' interviews with the judicial authorities. Thus, clinical and psychiatric evaluations were analyzed. Such in-depth research made it possible to highlight as much information as possible regarding the pathological-forensic aspects of the crime, the perpetrators, and the victims as well as the relationship between them.

The data analyzed showed that two out of three murders were committed by the male child. Both sons lived in their mother's home; the daughter, although not living in her mother's apartment, resided in the same building, and her home was owned by her parents. All perpetrators were adults, ranging in age from 38 to 52 years, and were unmarried and unemployed. One of the victims was under the age of 70; the other two were elderly and retired. Two out of the three victims were in good general health; one was bedridden and unable to walk and perform activities of daily living. Autopsy and histo-pathological investigation, as well as the analyses of the historical-circumstantial data, showed that in two cases, the cause of death was by asphyxiation by suffocation with a pillow; one case was attributable to acute nitrite intoxication by poisoning (ingestion). Interviews with the murderers revealed that in all cases there was a conflictual relationship with the mother, who was considered a dominant, intrusive, and judgmental figure. In all the cases analyzed, the father was absent. The offenders' social relationships were characterized by extreme isolation. Psychiatric examinations conducted in the period after the crime revealed that all the murderers suffered from a psychiatric disorder: chronic psychotic disorder, paranoid personality disorder, and anxiety-depressive disorder with multiple personality disorders. Only one perpetrator was determined to be suffering from diminished responsibility because of his acute psychotic crisis at the time of the act and his sentence was reduced.

In conclusion, the findings of this preliminary study confirm the data in the literature highlighting the complex socio-familial context in which matricide cases occur. Psychological and relational fragilities between mother-child and between the perpetrator himself and society are often the real starting point for the analysis and prevention of this type of crime.

**B32 Quantitation of Lysergic Acid Diethylamide (LSD) Using HPTLC**

*Tori Schaffer\*, Cedar Crest College, Stansbury Park, UT; Sandra E. Rodriguez-Cruz, Drug Enforcement Administration, Dulles, VA; Jeanne R. Berk, Cedar Crest College, Allentown, PA; Thomas A. Brettell, Cedar Crest College, Allentown, Pennsylvania*

---

**Learning Overview:** After attending this presentation, attendees will gain a better understanding of using High-Performance Thin-Layer Chromatography (HPTLC) with an internal standard to quantify LSD.

**Impact Statement:** This presentation will impact the forensic community by demonstrating that HPTLC can be a useful and viable alternative tool in the quantitation of LSD.

In recent years, TLC has fallen out of routine practice for the analysis of seized drugs in the forensic science community. This technique does not always provide the resolution or sensitivity necessary to accurately quantify substances of interest. However, with the advancement of HPTLC, quantitation of analytes can be done with a green, fast, and reliable method.

LSD can be a challenging compound to analyze and quantify. Using Gas Chromatography/Mass Spectrometry (GC/MS) to analyze and quantify LSD can cause issues due to it being thermally labile and a polar compound. LC methods can be used to quantify LSD, but these are usually long analyses and require large amounts of solvent to create a calibration curve and analyze samples.

In this study, HPTLC was used to quantify LSD using a mobile phase of 100% acetone. Several other mobile phases were evaluated, but this mobile phase provided the best separation between LSD and N-Methyl-N-Propyl Lysergamide (LAMP) as well as resolution from four LSD analogs and distinguishing LSD from four other analogs. Thymidine was used as an internal standard at a concentration of 200mg/mL. Six calibrators were used with concentrations ranging from 10–150mg/mL to create a calibration curve. The area ratios between thymidine and LSD showed good precision above the limit of quantitation (CV% <10%). Linear regression of this calibration plot produced a coefficient of determination >0.99, indicating the regression model best explained the data. Residual plots of the data displayed some randomness showing the calibration model was linear. In addition, the Limit Of Detection (LOD) and Limit Of Quantitation (LOQ) were determined to be 27.6ng/band and 83.5ng/band, respectively.

Four blotter paper samples were spiked with known amounts of LSD (90–100mg) to determine recovery of the LSD from the blotter papers. The blotter papers were extracted using 1mL of methanol for 20 minutes in an ultrasonic bath. Thymidine was added as the internal standard, and the area ratio between thymidine and LSD was used to determine the concentration of LSD extracted. Samples were analyzed three times. The average percent recovered was above 55% for all four samples with a CV% <10%.

Results from this study indicate HPTLC is a suitable method to determine the amount of LSD in a sample with good precision, resolution, and sensitivity. In addition, the mobile phase chosen for this study is considered a green mobile phase and had the added benefit of being easy to prepare.

---

**B34 The Odor Behind a Shot: Chemical Characterization of Volatiles From Ammunition**

*Salem Danielle Smith\*, Texas Tech University, Hobbs, NM; Paola A. Prada-Tiedemann, Texas Tech University, Lubbock, TX*

---

**Learning Overview:** After attending this presentation, attendees will be familiar with the advancing significance of understanding the chemical characterization of odor volatiles emanating from various ammunition along with possible variations due to caliber size and manufacturer, thus initiating proactive developments that directly address firearm threats and enhance sensor and canine-detection applications.

**Impact Statement:** This presentation will impact the forensic science community by providing a scientific foundation in the understanding of key odor markers emanating from an array of ammunition samples. While various studies have been geared to understanding gunshot residue transfer and composition, no studies to date have focused on understanding the bullet itself as a target odor source. This study presents a foundation to understanding volatile odor signatures from an array of bullets of different brands and calibers to provide forensic personnel as well as law enforcement officials with a basic understanding of odor volatile characterization from unspent cartridges. This effort aids in the development of sensor and canine technology aiming to identify ammunition samples on the scene and in various operational scenarios.

Due to the increase of mass shootings in the past decade, firearm detection is a critical tool in gun violence prevention. Within law enforcement applications, canine firearm detection teams are a valuable tool to combat these threats; however, there is a lack of scientific research and knowledge as to the chemical odor profile of this source of target odor evidence. Although previous studies have been focused on an understanding of gunshot residue components as they relate to firearm discharge events, this project is focused on using ammunition as a direct source for odor profiling for purposes of body worn/concealed weapon detection.

This study provides novel odor profiling instrumental analysis from a range of ammunitions comparing headspace odor profiles of 9mm caliber, 40 and 45 Automatic Colt® Pistol (ACP) live bullets. Utilizing Solid-Phase Microextraction (SPME) headspace sampling and Gas Chromatography/Mass Spectrometry (GC/MS), frequently occurring compounds were present across the sample matrices, including hydrocarbons such as dodecane, tetradecane and hexadecane, and acids such as 1,4-benzenedicarboxylic acid, dimethyl ester. Tetradecane was a common odor marker across all sample matrices. Nonanal, a compound reportedly found in smokeless powders, was emitted sporadically throughout the ammunition samples; however, frequently occurring in one 40 ACP brand. Statistical clustering analysis was implemented to analyze ammunition chemical odor profile clustering to monitor variations of odor signatures across sample groups.

The evolutionary advancements in manufacturing ammunition changes identification and interpretation paradigms over time, while, to date, there is no study emphasizing the evaluation of volatile odor signatures from brand ammunition and contrasting caliber size. By extracting Volatile Organic Compound (VOC) odorants from the various types of existing ammunition, the identification of volatile odor signatures can allow for the future creation of chemical training aids for detection training purposes as well as provide foundational knowledge for continued sensor development in routine firearm-related incident investigations and a step toward preventative detection.

---

**Ammunition; Volatiles; Canines**

---

**B35 An Analysis of Improved Methods for the Genetic Identification of Cremated Skeletal Remains**

*Kadir Dastan\*, Kadir Dastan, Istanbul Health and Technology University, Istanbul, Turkey*

---

**Learning Overview:** After attending this presentation, attendees will be aware that the results of this study indicate that low levels of nuclear DNA can be recovered from the cremated bone with partial Short Tandem Repeat (STR) profiles obtained from combined and concentrated extracts; however, exaggerated stochastic effects such as increased stuttering, allele fall, and peak height imbalance were observed in some profiles due to the low amount of initial template and the use of an increased cycle Polymerase Chain Reaction (PCR), thus complicating the interpretation of the profile.

**Impact Statement:** This presentation will impact the forensic science community by sharing the results of this study.

**Introduction:** The cremation process consists of burning the corpse at temperatures of up to 1,000°C, reducing it to bone remains or bone fragments, which are often ground to a consistency similar to that of sand. In the identification of forensic cases, it is critical to obtain information on the victim's identity from burnt bone and teeth remains.<sup>1</sup> When bone and teeth are burned, both their physical and chemical properties change significantly, which prevents anthropological evaluations and successful DNA profiling.

**Background:** Heat causes difficulties in the identification techniques in which bones and teeth are used, depending on the degree of temperature exposure. Therefore, it is necessary to evaluate the results of observation and analysis, and the information obtained in a certain order, with the changes occurring in bone and teeth during the burning period. The identification of burnt or buried bones and teeth has always been a difficult process due to the diminished quality and quantity of DNA, and it is still a challenge.<sup>2</sup> Due to heterogeneity in DNA due to the heterogeneity within the bone, unfortunately, the only reliable method for obtaining DNA from cremated samples such as burnt bones and teeth in the literature is still not available.<sup>3</sup>

**Results:** Previous research on DNA analysis of cremated remains has shown limited success.<sup>4</sup> This study examines adjustments or improvements throughout the DNA analysis workflow to improve methods of identifying human cremated remains. DNA was extracted from bone fragments using a commercial silica-based method or an enhanced extraction method that modifies the commercial kit to determine which process resulted in maximum DNA recovery. Several extracts from a single bone fragment were combined and then concentrated with an Eppendorf® Vacufuge. All extracts were quantified using the real-time Polymerase Chain Reaction (PCR) to evaluate the recovery of nuclear DNA. Concentrated extracts were amplified using the GlobalFiler® PCR amplification kit with an increased PCR cycle protocol and analyzed using capillary electrophoresis. Multiple samples from individual sets of remnants were examined to assess the consistency of the results.

**B36 An Examination of the EZ2 Connect Fx for Extra-Large Volume DNA Extraction and Purification From Skeletal Samples**

*Jennifer L. Snedeker\*, Sam Houston State University, Onalaska, TX; Sheree R. Hughes, Sam Houston State University, Huntsville, TX; Rachel Houston, Sam Houston State University, Huntsville, TX*

---

**Learning Overview:** This presentation will provide an overview of a DNA extraction and purification method from skeletal samples using the extra-large volume DNA extraction protocol of the EZ1&2™ DNA Investigator® Kit on the EZ2® Connect Fx system.

**Impact Statement:** Efforts to enhance DNA extraction methods for human identification have resulted in an abundance of methodologies, each with specific recommendations and requirements. In this study, we aim to demonstrate the applicability of an alternate DNA extraction and purification method utilizing the EZ1&2™ DNA Investigator® Kit and the EZ2® Connect Fx system. This presentation will impact the forensic science community by showcasing a method that offers easy adaptability, allowing laboratories to meet their individual needs by adopting a single, flexible protocol.

DNA extraction from skeletal samples plays a crucial role in identifying unidentified human remains, as DNA remains well-preserved within the tough hydroxyapatite matrix of bone. However, processing skeletal remains for DNA extraction presents challenges due to the low-template, degraded nature, and inclusion of Polymerase Chain Reaction (PCR) inhibitors in these samples.<sup>1</sup> Consequently, considerable research has been focused on the refinement of DNA extraction and purification methods from these complex skeletal samples, leading to the development of custom methods with varying parameters for sample input and incubation duration. The implementation of a chosen method is often dependent on the quality or quantity of the sample or the needs of the lab, requiring validation of multiple methods. This study explores the effectiveness of the extra-large volume protocol offered by the EZ1&2™ DNA Investigator® Kit for DNA extraction from challenging skeletal samples. The protocol allows flexibility in both sample input (100–800mg) and incubation length (2–24hrs) within a single method.<sup>2</sup> To evaluate its success, three variations of the protocol were tested and compared against a similar method using ten challenging skeletal samples, including surface exposed, burned, and buried remains.

The first variation involved lysing 50mg of bone powder for 2 hours, followed by automatic purification on the EZ2® Connect Fx. Despite being below the recommended input for the extra-large volume protocol, this input was chosen because this method was compared to the PrepFiler® BTA method, which requires 50mg for automated purification on the AutoMate Express™.<sup>3</sup> Secondly, 250mg of bone powder was lysed for 24 hours before automatic purification on the EZ2® Connect Fx. For comparison, DNA was extracted from 250mg of bone powder using an adaptation of the manual Loreille total demineralization method with MinElute® PCR purification.<sup>1</sup> Lastly, the third variation involved lysing 800mg of bone powder from a single skeletal sample for 24 hours before purification on the EZ2® Connect Fx.

Overall, no significant differences in DNA yield were observed between the extra-large volume protocol and its comparison method. As expected, using 250mg of bone powder resulted in a statistically higher DNA yield than using 50mg of bone powder with the extra-large volume protocol. Additionally, the application of 800mg of bone powder improved both DNA yield and allele recovery. Following traditional Short Tandem Repeat (STR) typing using the Investigator® 24plex QS kit, no significant differences in allele recovery were observed across all methods. Based on these findings, the extra-large volume protocol offers a versatile method to extract DNA from various challenging skeletal samples, catering to the laboratory needs. This single kit can efficiently process samples that require priority processing, have limited starting material, or are extremely challenging (e.g., buried or badly burned remains). The protocol's adaptability, combined with the convenience of automatic purification on the EZ2® Connect Fx, makes it a suitable addition to crime laboratories, with the ability to customize parameters based on their unique requirements.

**B37 The Development of a Custom qPCR Multiplex to Quantify Human and Microbial DNA**

*Miriam Foster\*, Pennsylvania State University, University Park, PA; Mitchell M. Holland, Penn State University, Port Matilda, PA; Jennifer McElhoe, The Pennsylvania State University, University Park, PA*

---

**Learning Overview:** After attending this presentation, attendees will be informed about the development of a novel quantitative Polymerase Chain Reaction (qPCR) multiplex for both human and microbial DNA and how this tool can be used to shed light on the analysis of microbial DNA in forensic investigations.

**Impact Statement:** With this tool and the information garnered by using it, the forensic science community will gain insight into when microbial DNA analysis would benefit an investigation, including when there is little to no human DNA available. Therefore, the results of this project will aid examiners in deciding which path of DNA profiling to pursue.

The analysis of microbial DNA in forensic science is not new. In recent years, there has been greater interest in determining how and when microbial DNA may be included in an investigation. For samples that are challenged with damaged or degraded human DNA, there is an interest in evaluating if detectable microbial DNA is present. Specifically, touch DNA samples, which tend to contain very small amounts of human DNA, may benefit from the option of microbial DNA analysis.<sup>1</sup> There is much to learn about how the behavior of microbial DNA differs compared to human DNA within the same sample. With the development of a tool that will enable the quantification of both bacterial and human DNA in one assay, the forensic science community will have greater knowledge of what can be expected from a touch DNA sample.

The overall goal of this project is to develop a procedure that will aid forensic investigators in deciding whether they should examine the human DNA or bacterial DNA in a touch DNA sample. Through this project, a tool has been created to conduct a multiplex qPCR analysis on the human and bacterial DNA present in a sample. This multiplex assay provides an easy method for comparing the two types of DNA. With the information of how much of each type of DNA is present, the transfer and persistence of human and bacterial DNA can be examined and compared.

To create this tool, the master mix components of the Quantifiler® HP DNA Quantification Kit were combined with primers and probes designed to target universal regions in the bacterial genome.<sup>2</sup> The standards included in the Quantifiler® HP Kit were used for the human standards. Standards for the bacterial part of the assay were created using synthetic double-stranded DNA fragments, gBlocks, with the sequence of the amplicon for the chosen bacterial primers.

Once created, this assay was tested for repeatability, as were the Quantifiler® HP and custom bacterial assays separately, to determine if the same results could be achieved consistently. Additionally, this set of experiments allowed for the comparison of the behavior of the separate assays to their behavior when multiplexed. The bacterial aspects have been consistently the same between the singular and multiplex assays. However, there were some differences between the human singular and multiplexed assays that appear to be predictable.

The information gained from the repeatability studies have been utilized to evaluate surface samples from objects such as computer mice, keyboards, and mobile cell phones; other researchers have previously examined cell phones as a sample source for bacteria alone.<sup>3</sup> Depending on how much of each type of DNA is associated with each surface, the merit of using microbial DNA when there is less human DNA can be assessed.

**B38 The Reassociation of Highly Degraded Human Remains Found in the East Marshall Street Well Using Insertion/Null Genotyping**

*Sierra Laveroni\**, Virginia Commonwealth University, Henrico, VA; *Andrea Malchow\**, Virginia Commonwealth University, Richmond, VA; *Daniela Frausto*, Houston Forensic Science Center, Houston, TX; *Michelle M. Woo*, Virginia Commonwealth University, Richmond, VA; *Baneshwar Singh*, Virginia Commonwealth University, Richmond, VA; *Filipa Simao*, Virginia Commonwealth University, Richmond, VA; *Tal Simmons*, Virginia Commonwealth University, Richmond, VA

---

**Learning Overview:** After attending this presentation, attendees will be informed about the ethical treatment of human remains in addition to an optimized workflow for processing severely degraded human skeletal elements.

**Impact Statement:** This presentation will impact the forensic science community by providing insight into the most efficient and effective way to obtain genetic information from severely degraded human skeletal remains. Additionally, the benefits of Insertion/Null (INNUL) genotyping in use with highly degraded samples will also be displayed.

The East Marshall Street Well (EMSW) was uncovered during the construction of the Hermes A. Kontos Building on the Medical College of Virginia campus in Richmond, VA. Human remains, artifacts, and other historical items dating to the mid-19<sup>th</sup> century were discovered inside the well.<sup>1</sup> These items were hastily removed from the EMSW with a backhoe and deposited outside a barricade for archaeologists to sort. This removal process resulted in a severe commingling of the human remains. To re-associate the remains, they were sent to the Smithsonian in Washington, DC, for anthropologists to assess and sort them osteometrically.<sup>1</sup> This assessment led to “paired” remains, which consist of arm element or leg element matches independently, and “unpaired” remains, which were not able to be matched with other elements. From cranial measurements, it was determined that most of the remains represented individuals of African descent.<sup>2</sup>

Historical records from the university’s archives indicate that they were likely victims of grave robbing, anatomical dissection by medical students, and amputation practice.<sup>1,2</sup> Although a significant amount was learned from the anthropological assessment, it was not possible to anthropologically re-associate bones of the upper limbs to those of the lower limbs or to associate any postcranial elements with skulls due to limitations on the methodology as well as the condition of the remains. The study aims to re-associate highly degraded human skeletal groups through INNUL genotyping.

This methodology uses ALU repeats throughout the genome to isolate and detect unique patterns. This method creates smaller amplicons than traditional Short Tandem Repeat (STR) loci.<sup>3,4</sup> The utilization of this chemistry will facilitate the linkage of disassociated and commingled human skeletal groups, such as the arms and legs, ensuring accurate and respectful reburial of individuals.

In this study, 221 “paired” human skeletal elements were sampled using a Dremel<sup>®</sup> tool, and 40mg of endosteal bonepowder was collected from muscle attachment sites on each element. All bone powder samples were extracted using the InnoXtract<sup>™</sup> Bone Extraction Kit following the manufacturer’s protocol. The human DNA extracts were quantified using the InnoQuant<sup>™</sup> HY kit following the manufacturer’s protocol on the QuantStudio<sup>™</sup> 6 Real-Time PCR instrument. Any samples that quantified over 25pg were amplified using the InnoTyper<sup>™</sup> 21 Human DNA Analysis Kit following the manufacturer’s protocol. Amplified fragments were separated on the Applied Biosystem<sup>®</sup> 3500xL Genetic Analyzer. All data was analyzed using GeneMapper<sup>®</sup> ID-X software. Likelihood ratios for kinship determination and direct matching of unknown samples were calculated using Familias, a statistical software.

One hundred profiles from the 221 highly degraded bone elements were obtained. Of those 100 profiles, 52 were suitable for analysis. Agreement and disagreement between the osteometric analysis and DNA analysis were examined and a majority of the data showed concordance (87%). However, 13% of the data showed discrepancies between the DNA results and what was previously decided by the anthropologist. Additionally, matches have been made between the upper and lower limb groups. At this time, a total of eight individuals containing both arm and leg elements from the EMSW have been identified. Connecting the upper and lower body was not previously possible when only utilizing osteometric pairing from an anthropologist. Additional testing for all “unpaired” human bone elements is ongoing in furtherance of reassociation efforts aimed at understanding the life histories of these individuals.

In conclusion, integration of the DNA workflow and INNUL analysis along with anthropological assessment have generated more confidence and accuracy in matches during the process of re-associating highly degraded and commingled human skeletal assemblages.

### **B39 An Overview of Cannabis Seizures and Methods for Distinguishing Between Cannabis and Hemp in Croatia**

*Slavena Cukrov Bezbradica, Ministry of the Interior, Forensic Science Centre "Ivan Vučetić," Zagreb, Grad Zagreb, Croatia; Lucija Barbarić, Ministry of the Interior, Forensic Science Centre "Ivan Vučetić," Zagreb, Grad Zagreb, Croatia; Kristina Jurković\*, General Police Directorate, Police Academy, The First Croatian Police Officer, University of Applied Sciences in Criminal Investigation and Public Security, Zagreb, Grad Zagreb, Croatia; Adela Makar, Ministry of the Interior, Forensic Science Centre "Ivan Vučetić," Zagreb, Grad Zagreb, Croatia; Maja Jelena Čop, Ministry of the Interior, Forensic Science Centre "Ivan Vučetić," Zagreb, Grad Zagreb, Croatia; Andrea Ledić, Ministry of the Interior, Forensic Science Centre "Ivan Vučetić," Zagreb, Grad Zagreb, Croatia*

**Learning Overview:** After attending this presentation, attendees will be familiarized with the structure of cannabis seizures in Croatia, along with methodology applied in cannabis casework and the results of cannabis genetic research conducted at Croatian Forensic Science Centre "Ivan Vučetić" (FSCIV).

**Impact Statement:** This presentation will impact the forensic science community by addressing the challenges in distinguishing between cannabis and certified hemp varieties by routine analysis as well as by applying additional genetic methods.

Cannabis is the most frequently seized and produced illicit drug in Croatia, as it is worldwide. The main psychotropic properties of cannabis are derived from  $\Delta^9$ -Tetrahydrocannabinol (THC). In accordance with Croatian legal acts, any cannabis plants except certified hemp varieties listed in the European Union Plant Variety Catalogue with a THC content not exceeding 0.2% in the dry plant material are prohibited, along with cannabis resin (hashish), extracts, and tinctures.

The aim of this presentation is to provide an insight into the structure of cannabis seizures confiscated in Croatia from 2018 to 2022. Furthermore, presumptive tests used at the crime scene, routine methods in cannabis casework conducted at the FSCIV are presented in addition to the results of genetic research carried out in order to differentiate cannabis and hemp.

Most commonly seized cannabis material analyzed at FSCIV includes herbal cannabis, cannabis plants, cannabis extracts, and hashish. In the abovementioned period, herbal cannabis was predominant with the average amount of 74.2% of total seizures, followed by cannabis plant seizures (18.7%). Less often-seized material was cannabis extract (4%) and, last, hashish with the average amount of 3% of total seizures.

Upon finding the material suspected to be cannabis, first preliminary tests are applied at the crime scene. The most common presumptive color tests used in Croatia are the M.M.C. International B.V. Cannabis test for THC detection and HEMPTTEST®-C for the detection of Cannabidiol (CBD), THC, or Cannabinol (CBN) predominance in tested samples.<sup>1-3</sup>

After crime scene processing, the first step of cannabis casework analysis in FSCIV includes morphology examination. Subsequently, Thin Layer Chromatography (TLC) is used for semiquantitative analysis, Gas Chromatography with Flame Ionization Detector (GC/FID) and High-Performance Liquid Chromatography (HPLC) for cannabinoids quantification, as well as Gas Chromatography with Mass Spectrometry (GC/MS) for qualitative analysis of cannabinoids. However, these methods are not always sufficient for differentiation purposes (i.e., when seeds and immature plants are being analyzed). Furthermore, non-certified potent CBD and Cannabigerol (CBG) varieties present new challenges in cannabis forensic examination.

Nevertheless, the application of genetic methods could provide additional information if routine methods were insufficient for differentiation. Therefore, the selected genetic markers were studied for their potential application at FSCIV. First, nine Short Tandem Repeats (STRs)—ANUCS302, ANUCS303, ANUCS305, ANUCS501, B05-CANN1, C11-CANN1, D02-CANN1, E07-CANN1, and H06-CANN2—were chosen. The results of selected STRs were not sufficient for differentiation between cannabis and hemp. Furthermore, since 98% of the analyzed samples confiscated in Croatia were propagated by seeds, STRs were not useful tool for tracking clonally propagated cannabis and linking the seizures.<sup>4,5</sup> Onwards, genetic research was continued with the THCAS marker developed by Kojoma et al., D589 gene marker and sequencing of THCAS gene.<sup>6,7</sup> The concordance of obtained results for marker reported by Kojoma and D589 markers was observed but these markers also showed lack of specificity for differentiation purpose. However, THCAS gene sequencing demonstrated effectiveness for distinguishing cannabis and certified hemp varieties.

Hence, future study will be dedicated to sequencing the THCAS gene in certified hemp and casework samples, along with establishing the database of THCAS gene variants.

**Learning Overview:** After attending this presentation, attendees will be informed regarding the application to real forensic caseworks of the DNA extraction assay, called the TBone EX Kit (DNA Chip Research Inc.), developed to digest bone chips without powdering. We empirically demonstrated the effectiveness of the kit in processing multiple bone samples simultaneously, recovered from different scenarios and exposed to extreme environmental factors, largely simplifying the DNA extraction procedure and the good yield of recovered DNA.

**Impact Statement:** This presentation will impact the forensic science community by providing additional support for the use of the TBone EX Kit for digesting bone fragments/whole teeth as an effective alternative to pulverization protocols. In addition, the present work turns out to be extremely useful for police force laboratories, to which the various actors of the criminal justice system—such as potential jury members, judges, defense attorneys and prosecutors—require immediate feedback.

DNA identification of human skeletal remains plays a valuable role in forensic field, especially in missing persons and mass disaster investigations. Hard tissues, such as bones and teeth, represent a very common kind of sample analyzed in forensic laboratories because they are often the only biological materials remaining. However, the major limitation in using these compact samples relies on the extremely time-consuming and labor-intensive treatment of grinding them into powder before proceeding with the conventional DNA purification and extraction step. In this context, a novel DNA extraction assay, called the TBone EX Kit, was developed to digest bone chips without powdering.<sup>1</sup> We simultaneously analyzed a total of 18 bone and tooth samples that arrived at our police laboratory and belonged to 11 different forensic caseworks occurring in Sardinia, Italy. The samples were recovered from different scenarios and were exposed to extreme environmental factors, including sunlight, seawater, soil, fauna, vegetation, and high temperatures and humidity. The TBone EX Kit was used prior to the EZ2<sup>®</sup> DNA extraction kit on the EZ2<sup>®</sup> Connect Fx instrument, and high-quality autosomal and Y-chromosome Short Tandem Repeat (STR) profiles were obtained for 73% of the caseworks in an extremely short time frame.

This study provides additional support for the use of the TBone EX Kit for digesting bone fragments/whole teeth as an effective alternative to pulverization protocols. We empirically demonstrated the effectiveness of the kit in processing multiple bone samples simultaneously, largely simplifying the DNA extraction procedure, and the good yield of recovered DNA for downstream genetic typing in highly compromised forensic real specimens.

**B41 Investigative Single Cell Genetics: Determining the Probability of a Genotype After Observing Single-Cell Data Enables Robust Database Searches Regardless of Mixture Complexity**

*Qhawe A. Bhembe\*, Rutgers University, Camden, NJ; Nidhi Sheth, Rutgers University, Camden, NJ; Leah M. O'Donnell, Pfizer, Fethard, Tipperary, Ireland; Ken R. Duffy, Northeastern University, Boston, MA; Desmond S. Lun, Rutgers University, Camden, NJ; Catherine M. Grgicak, Rutgers University Camden, Camden, NJ*

---

**Learning Overview:** After attending this presentation, attendees will better understand the way in which single-cell analysis can be leveraged to improve investigative processes. By constructing a probability distribution across all possible genotypes, the most probable genotypes can be reported and, subsequently, compared to a database.

**Impact Statement:** This presentation will impact the forensic science community by demonstrating that, regardless of the complexity of the original mixture, single-cell analysis can be leveraged to construct probable genotypes explaining the single-cell data in cases where there is no suspect. The single-cell revolution, therefore, has the potential to positively affect non-suspect cases for which the likelihoods were too diffuse and did not meet the laboratory's search criteria.

In scientific deduction, one of the primary goals of the analyst is to collect data that will discriminate candidate hypotheses. The traditional method of procuring the data is by way of bulk treatments, where the DNA of all contributors is extracted in a single vessel, resulting in identically and independently distributed DNA fragments. If the concentration of any one contributor is low, then allele drop-out can result. With all contributors' DNA being sampled together, the evidential strength (i.e., the likelihood ratio) approaches one as the number of contributors to a mixture increases since these data are comprised of many peaks that are a superposition of peaks associated with distinct individuals. These issues mean that there is scope to improve the robustness of mixture interpretation.

Profiles derived from traditional bulk pipelines are often encumbered by numerous peaks from many, possibly partial, contributors. As the peak heights decrease and the number of peaks increases, interpretation becomes arduous, sometimes requiring numerous propositions across multiple numbers of contributors and taking hours to complete.

One path forward is by way of single-cell analysis, which is defined as a system of laboratory procedures that: (1) isolate each cell, and then (2) extracts and directly amplifies the DNA within the same vessel. By applying single-cell treatments, alleles of each contributor remain coupled and variability due to extract fractionation is circumvented, leading to  $n$  single-cell, single-source contributor Electropherograms (scEPGs). The interpretation of these highly resolved signals, therefore, changes from one of determining the weights of multifarious genotype combinations to one that relies on dependable clustering by similarity. With this modification, the number of donors to the admixture no longer affects the ability to discriminate candidate hypotheses. For non-suspect casework, a multi-hypothesis evaluation that estimates the probability of genotype  $g$  given the cluster can potentially provide significant gains in investigative genetics. It is for these reasons we expound the legitimacy of single-cell data by evaluating the robustness of the system for investigative purposes. Specifically, we take 630 admixtures containing anywhere from 17 to 75 scEPGs from any of two to five contributors. We cluster the scEPGs into groups based on similarity using a package named `mcclust` in R. This results in  $k$  clusters with  $m$  scEPGs from a single-source contributor. We then use `EESCI` to estimate the probability of these  $m$  scEPGs that are in a cluster,  $C$ , given  $g$ , where  $G$  is the contributor's genotype and  $g$  is a given genotype within the set of all possible genotypes according to background frequencies. `EESCI` then applies the traditional form of Bayes' rule to estimate the  $P(G=g|C)$  for each locus allowing a decision threshold, such as 0.998, to define the credible set of genotypes explaining the cluster of cells.

To test the performance method, we report the proportion of loci for which only one genotype is in the credible set and that genotype is the true genotype. This occurred 84% of the time. Further explorations demonstrate when more than one genotype belongs to the credible set, it is affiliated with low peak heights. Specifically, the median total intensity was 11,432 Relative Fluorescence Units (RFU) for clusters with one credible genotype, while the median was 1,825 RFU for clusters where there were two credible genotypes. Mosaic plots demonstrate that this is affiliated with those clusters with two or fewer cells. With highly concentrated probability masses on only one or two genotypes, we show the potential of single-cell analysis to the forensic domain.

**B42 Locus Abundance Variation by ForenSeq™ DNA Signature Prep Kit Lot**

*Kim Eskey\*, National Biodefense Analysis and Countermeasures Center (NBACC), Frederick, MD; Kyleen Elwick, National Biodefense Analysis and Countermeasures Center (NBACC), Frederick, VA; Sana Enke, National Bioforensic Analysis Center (NBFAC), National Biodefense Analysis and Countermeasures Center (NBACC), Fort Detrick, MD; Claire Levy, National Biodefense Analysis and Countermeasures Center (NBACC), Frederick, MD; Marie Lovett, National Biodefense Analysis and Countermeasures Center (NBACC), Frederick, MD; April Manzella, National Biodefense Analysis and Countermeasures Center (NBACC), Centreville, VA; Christina Scott, National Biodefense Analysis and Countermeasures Center (NBACC), Ellicott City, MD; Rebecca S. Just, National Bioforensic Analysis Center (NBFAC), National Biodefense Analysis and Countermeasures Center (NBACC), Fort Detrick, MD*

---

**Learning Overview:** This presentation will demonstrate the variability in marker abundance of ForenSeq™ DNA Signature Prep Kit lots. After attending this presentation, attendees will see the need to include lot variation testing in validation studies and perform detailed lot test examinations when conducting Quality Control (QC) testing of newly received kits.

**Impact Statement:** This presentation will impact the forensic science community by detailing the variability observed across different lots of the ForenSeq™ DNA Signature Prep Kit. The information will benefit laboratories seeking to validate the kit and will provide strategies that may be used for QC testing of Next Generation Sequencing (NGS) typing kits.

The ForenSeq™ DNA Signature Prep Kit is a National DNA Index System (NDIS) -approved, NGS-based library preparation and sequencing kit. The full kit (Primer Mix B), used in this study, includes 27 autosomal Short Tandem Repeats (aSTRs), 24 Y-chromosomal Short Tandem Repeats (Y-STRs), 7 X-chromosomal Short Tandem Repeat (X-STRs), 94 identity **Single Nucleotide Polymorphisms** (iSNPs), 22 phenotypic SNPs, and 56 biogeographical ancestry SNPs (apSNPs).<sup>1</sup> The goal of this study was to assess variation across different lots of the Signature Prep kit. To this end, we evaluated locus abundance among positive control samples, typed in eight separate sequencing runs using five different ForenSeq™ DNA Signature Prep Kit lots. Library preparation for samples followed the manufacturer's protocol with a few modifications. Following the bead cleanup after PCR2, samples were normalized via a quant-based method instead of using the normalization beads. Samples were then pooled and purified using a 0.9X bead purification. Finally, the pool was quantified prior to denaturation to determine the final concentration for sequencing. Sequencing data was processed using ForenSeq™ UAS v1.3. Sample Detail and Phenotype Reports were exported and compiled using custom Python® scripts for evaluation of the sequencing data.

Overall, STRs resulted in the highest percentage of reads across kit lots, accounting for approximately 1% of reads per marker per sample. However, a single STR marker could range from 0.056% to 7.069% of sample reads across the five different lots. Read percentage across lots was most consistent among aSTRs as compared to Y- and X-STRs. When multiple sequencing runs were performed using the same kit lot, the percentage of reads was consistent for each marker type. However, there was high variability in the overall read percentage for each STR marker type between different lots.

In general, SNPs accounted for approximately just 0.3–0.5% of sample reads per marker, which was about two-fold less than STRs. On average, apSNPs resulted in a higher read percentage than iSNPs. Because each SNP accounts for far fewer of the sample reads than most STR markers, differences in read abundance by lot may impact SNPs to a greater degree than the kit STRs. For example, iSNP rs4530059 displayed a 5.3% difference in abundance for the positive control sample between two lots, which translates to a five-fold decrease, for a sample with an ideal DNA input (1ng), from one kit lot to another. Similarly, apSNP rs1805009 displayed a 2.5-fold difference between two kit lots. This issue is particularly important because low quality or challenging samples are more likely to result in allelic dropout. As SNPs make up the smallest percentage of sample reads, the chances of dropout at any given SNP will change with multi-fold differences in locus abundance by kit lot, even if all expected SNP alleles are present in the positive control.

The variability observed between ForenSeq™ DNA Signature Prep Kit lots indicates the importance of performing lot variation experiments during validation. Additionally, the variation highlights the need to conduct QC testing of newly received lots, with detailed data analyses, before using them for forensic casework.

**B43 Genotyping Strategies for Tissues Fixed With Various Embalming Fluids for Human Identification, Databasing, and Traceability**

*Cassidy Callaway\*, Sam Houston State University, Huntsville, TX; Madeline Ashton, Forensic Science South Australia, Prospect, South Australia, Australia; Natalia Czado, Sam Houston State University, League City, TX; Sheree R. Hughes, Sam Houston State University, Huntsville, TX*

---

**Learning Overview:** After attending this presentation, attendees will have a clear understanding of the possibility of collecting DNA from various formalin-fixed or embalmed remains for human identification purposes or for providing an additional layer of quality assurance and a last line of defense traceability for specimens in anatomical/pathological collections.

**Impact Statement:** This presentation will impact the forensic science community by providing informative data when determining which genotyping strategy may be best suited for the identification, re-association, and establishment of a database for the provenance of formalin-fixed human remains either in a forensic or anatomical/medicolegal setting.

Within forensic or anatomical willied-body programs and skeletal collections, whole bodies and their disassociated limbs, bones, and organs are currently identified and tracked using a combination of Radio Frequency Identification (RFID) tags, individual barcodes or labels, written records, and photography. However, if these tracking mechanisms fail, DNA recovered from the formalin-fixed tissues/organs could provide an additional layer of quality assurance and a last line of defense traceability for anatomical specimens. Embalming fluids such as formaldehyde preserve biological tissues; however, they also damage, fragment, and cross-link DNA and protein molecules. As genotyping success is highly dependent on the quantity and quality of the DNA amplified, often DNA profiles from embalmed tissues are only partially complete, are inconclusive, or fail entirely.

This project investigated the success of conventional Short Tandem Repeat (STR) -typing (the QIAGEN® Investigator 24plex and 26plex QS kits) from various soft tissue and bone samples that were fixed with commercial and in-house embalming solutions with a range of formaldehyde concentrations commonly used within anatomical facilities globally (1%–9.5%). Consecutive slices from both legs of five cadavers (to provide skin, muscle, and bone tissues), and the whole heart and one kidney of each cadaver were sectioned and immersed in preservatives for up to three months. In addition, 50 tissue samples from a wider range of embalmed organs and body parts stored for up to ten years and preserved using unknown fixative solutions were also examined to assess a more representative range of samples housed within anatomical and medicolegal collections. Based on our preliminary data, human tissues embalmed with a ~2.5–5% formaldehyde solution would be most amenable to DNA typing for Human Identification (HID) purposes. The tissues most likely to be successfully genotyped were skin and muscle (gastrocnemius) (also bone for Low Template DNA [LT-DNA] samples), and, therefore, these tissues may be prioritized for sampling when establishing the provenance of unknown embalmed remains.

Furthermore, we also investigated whether alternate DNA markers such as Insertion/Deletions (INDELs) using the QIAGEN® Investigator DIPplex kit would provide more probative identifications than traditional STR analysis from these challenging samples. In general, INDELs produced lower/more discriminatory Random Match Probabilities (RMPs) than STRs in the majority of samples when <27 STR alleles were reported.

The results of this project can provide informative data when determining which genotyping strategy may be best suited for the identification, re-association, and establishment of a database for the provenance of embalmed human remains. In addition, this DNA-based approach could provide a higher level of quality assurance within willied-body programs worldwide.

**B44 The Development of a Facial Phenotype Prediction Method Using Korean 3D Craniofacial Images and SNPs**

*Won Joon Lee, National Forensic Service Seoul Institute, Seoul, Republic of Korea; Joon Yeol Ryu\*, National Forensic Service, Seoul, Republic of Korea; Hyobong Jang\*, National Forensic Service, Seoul, Republic of Korea; Eunseo Park, National Forensic Service, Wonju, Kangwon-do, Republic of Korea; Eunsoon Shin, DNA Link, Seoul, Republic of Korea; Sohee Cho, Seoul National University College of Medicine, Seoul, Republic of Korea; Jong Eun Lee, DNA Link, Seoul, Republic of Korea; Soong Deok Lee, Seoul National University College of Medicine, Seoul, Republic of Korea*

---

**Learning Overview:** After attending this presentation, attendees will understand facial prediction methods using facial phenotype-genotypes and 3D facial images. In addition, attendees will be able to explore the potential applications of the methods in the identification of criminal suspects, unidentified bodies, and missing persons.

**Impact Statement:** This presentation will impact the forensic science community by providing the results of DNA-based facial prediction methods studied within a Korean population group. Additionally, the results from the current study can be compared with previous studies to evaluate the future potential of DNA-based facial prediction methods in the investigation of human identification.

Numerous studies exploring the correlation between facial phenotype and genotype have indicated the possibility of predicting the face of a suspect or an unidentified body using a series of **Single Nucleotide Polymorphisms (SNPs)** extracted from samples obtained at crime scenes. Currently, DNA-based facial prediction technology has been commercialized to provide predicted facial images to law enforcement agencies and individuals seeking suspects or missing persons. However, the reliability of predicted faces for Asian populations has not been extensively investigated, and few studies have focused on Asian ancestry, including Koreans. Along with this, it is necessary to identify facial morphological predictors and develop a method for predicting facial phenotypes based on genotypic factors. Therefore, the purpose of this study is to develop a technique for estimating the facial phenotype using high-density SNPs of Koreans to help predict facial phenotypes of criminal suspects or unidentified bodies using genotypes obtained at crime scenes.

Multiple Regression (MR) images of 4,388 subjects (2,959 of males and 1,429 of females) from the GENIE cohort at Seoul National University Hospital Gangnam Center were employed to collect anthropometrical dataset from 3D facial images of the subjects whose SNPs analysis using the Korea Biobank Array (~830K of SNPs) was completed previously. A total of 32 facial landmarks were selected, and 62 measurement values were measured between the landmarks to be analyzed with SNPs.

The association between genotype and facial morphological phenotype was investigated statistically using PLINK version 1.07. The significant differences among the genotypic frequencies of the phenotype were verified using parametric (student's *t*-test and Analysis of Variance [ANOVA]) and non-parametric (Mann-Whitney and Kruskal-Wallis test) methods. The Mann-Whitney and Student's *t*-tests were used for the dominant and recessive models and the ANOVA and Kruskal-Wallis tests were used for the codominant model.

In conclusion, the correlation analysis between the facial landmark-based parameters and DNA-based facial phenotype-genotypes yielded valuable information for effectively predicting the faces of criminal suspects and unidentified individuals.

**B45 The Development of Reagents, Software, and a Database for Kinship Determination in Missing Persons, Disaster Victims, and Human Rights Violation Cases**

*Gothami A. Padmabandu\*, Verogen, a QIAGEN Company, San Diego, CA; Joana Antunes, Verogen, a QIAGEN Company, San Diego, CA; Sarah M. Radecke, Verogen, a QIAGEN Company, San Diego, CA; Michaela Russo, Verogen, a QIAGEN Company, San Diego, CA; Erin McCarthy, Verogen, a QIAGEN Company, San Diego, CA; Juan Carlos Perez, Verogen, a QIAGEN Company, San Diego, CA; Kathryn M. Stephens, Verogen, a QIAGEN Company, San Diego, CA*

---

**Learning Overview:** After attending this presentation, attendees will understand the usability of a Next Generation Sequencing (NGS) -based assay, software, and database solution for missing persons/disaster victim identification.

**Impact Statement:** This presentation will impact the forensic science community by demonstrating the ability to utilize a dense Single Nucleotide Polymorphism (SNP) Polymerase Chain Reaction (PCR) multiplex for high throughput kinship determination for missing persons identification utilizing software that includes a database, the ability to build pedigrees, and a highly efficient kinship algorithm with likelihood ratios for relationship determination.

The International Criminal Police Organization (INTERPOL) has developed specific guidelines and protocols for Disaster Victim Identification (DVI) that refers to identification of victims after a mass casualty disaster, armed conflict, or human rights violation. Typically, dental records, fingerprints, or DNA-based methods such as mitochondrial DNA analysis or Short Tandem Repeat (STR) profiling are used for comparison of Antemortem (AM) and Postmortem (PM) samples for conclusive identification. While these DNA-based methods have been successful in DVI, they present several limitations. STRs cannot identify relatives further out than second degree. In addition, these PM samples are likely to be degraded and subjected to environmental insults and do not always provide a full STR profile. Mitochondrial DNA requires a matrilineal relative. To address these limitations, QIAGEN® developed ForenSeq® Kintelligence HT Library Prep Kit and Universal Analysis Software (UAS), including a local database containing AM and PM samples for the MiSeq FGx™ sequencing system.

The ForenSeq® Kintelligence HT system together with NGS (also known as MPS), is based on the ForenSeq® Kintelligence kit. We present the ability to sequence libraries generated with this kit with either 12 PM samples or 36 AM samples per sequencing run to determine relationships out to the 3<sup>rd</sup> order. The expected relationships were confirmed for samples with known pedigrees. DNA extracted from bones subjected to different insults and dental remains, as well as artificially degraded and low input DNA were utilized to simulate PM samples. DNA from diverse populations were typed to simulate AM samples. To address the forensic community's concerns on privacy, the server supporting the Universal Analysis Software also hosted a local database of these samples. Database management and pedigree tools were developed and integrated into UAS to assist with management of sample data and to calculate likelihood ratios. Overall, we demonstrate that by utilizing a high-throughput NGS library preparation kit, combined with a local database and kinship analysis with likelihood ratios in the UAS, will facilitate DNA analysis of missing persons cases.

**B46 A 353-Plex Panel for Forensic Identification Based on Massively Parallel Sequencing Technology**

*Yingying Cheng\**, FGI, Shenzhen, Guangdong, People's Republic of China; *Qiujuan Wang*, Biotechnology/Biotechnology researcher, Forensic Genomics International (FGI), Shenzhen, Guangdong, People's Republic of China; *Dong Li*, BGI Shenzhen, Shenzhen, Guangdong, People's Republic of China; *Bowen Li*, BGI Forensic, Shenzhen, Guangdong, People's Republic of China; *Shengjie Gao*, BGI-Shenzhen, Shenzhen, Guangdong, People's Republic of China; *Kunjie Pang*, BGI Forensic, Shenzhen, Guangdong, People's Republic of China; *Xianhua Jiang*, FGI, Shenyang, Liaoning, People's Republic of China; *Hongqi Wang*, FGI, Shenzhen, Guangdong, People's Republic of China; *Xiaosen Guo\**, BGI Forensic, Shenzhen, Guangdong, People's Republic of China

---

**Learning Overview:** After attending this presentation, attendees will be aware that a Massively Parallel Sequencing (MPS) panel is a powerful tool for individual identification and paternity testing.

**Impact Statement:** The presentation will impact the forensic science community by sharing our achievement with the attendees, which would promote the development of forensic genetics.

Fluorescence-labeled Capillary Electrophoresis (CE) that detects the length polymorphisms of Short Tandem Repeat (STR) has been widely used for forensic identification over the past 20 years. Conversely, MPS technology is more emphasized nowadays for its significant advantages in forensic DNA analysis with higher loci and sample throughputs, shorter Polymerase Chain Reaction (PCR) amplicons for STR genotyping, and more types of genetic markers detection. There is a wide range of forensic applications involving Single Nucleotide Polymorphisms (SNPs) in genetic analysis, such as kinship inference and phenotype characterization and the sequence of mitochondria DNA (mtDNA) can be used for maternal inferences.

Here, we present a 353-plex panel, which detects more than 350 forensic genetic markers in one amplification. It integrates 205 STRs, 142 SNPs, and 3 hypervariable regions of mtDNA (mtDNA-HVs). In these STRs, 69, 32, and 104 are located in 22 autosomes, X chromosome, and Y chromosome, respectively. With so many alleles in this panel, it is easy to detect more STRs to meet the statistical power for common forensic inferences. The STRs can be detected by sequencing DNA amplicons with less than 400bp in length. Each allele of STRs contains a repeating region and two flanking segments with less than 50bp in length, providing higher genetic polymorphisms of length and sequence. More STRs with shorter amplicons in the panel than that in CE panels result in more detectable STRs in degraded samples. For highly degraded samples, we provide 142 SNPs with shorter amplicons (<150bp), which can reach a great level of forensic statistical power for individual identification ( $TDP=1-4.03 \times 10^{-58}$ ) and paternity testing ( $CPE > 1-1 \times 10^{-7}$ ). Evaluation of panel performance showed that only 60 SNPs and 128 SNPs are enough to meet the basic requirement of statistical power of individual identification and paternity testing, respectively. In addition, we also provide 3 mtDNA-HVs for maternal inheritance analyses in specific forensic scenarios.

All markers of this panel can be amplified successfully from as little as 100pg of genomic DNA. The sequencing libraries are suitable for DNBSEQ™ sequencing platforms with single-end 400bp mode. With only one million reads, all sites can be covered by at least 200 high-quality reads. For the mixed DNA samples, all Y-STRs can be detected when the DNA amount of minor contributor is as low as 20% (female: male = 4:1), which is as well as that in CE panels.

It is easy to obtain high-quality and high-resolution genotype dataset by using this powerful multiplex panel. This high-performance tool could provide far more genetic information for global forensic DNA analyses and inferences.

**Forensic DNA Analysis; Multiplex Amplification; Massively Parallel Sequencing**

---

**B47 Differentiating Marijuana From Hemp Using an NGS Panel and Rapid Genotyping Assays Targeting Cannabinoid Synthase Genes**

*Ya-Chih (Jessica) Cheng\*, Sam Houston State University, Huntsville, TX; Rachel Houston, Sam Houston State University, Huntsville, TX*

---

**Learning Overview:** The goal of this presentation is to delve into the advantages of employing previously discovered potential markers in cannabinoid synthase genes identified by Next Generation Sequencing (NGS). These markers hold promise in facilitating the effective differentiation of various crop types of *Cannabis sativa* through the development of rapid genotyping methods.

**Impact Statement:** *Cannabis sativa*, known for its cultivation as hemp or marijuana, remains a topic of controversy in the United States. The 2018 Agriculture Improvement Act, legalizing hemp, presents a challenge for law enforcement to distinguish between the two crop types. This presentation demonstrates the use of novel polymorphisms discovered via NGS to develop two rapid genotyping assays, which could help law enforcement differentiate hemp, hemp seed, and illicit marijuana samples.

Genetic markers play a crucial role in identifying crop types, especially in sample types unsuitable for chemical analysis (e.g., trace residues, small leaf fragments, immature crops). Cannabinoid synthase genes are key enzymes in determining a crop's chemical composition or chemotype. However, existing markers often overlook the analysis of pseudogenes in the cannabis genome. Cannabinoid synthase genes are found to be highly repetitive in the cannabis genome and contain many incomplete coding sequences (pseudogenes) that can have 91–95% nucleotide identity to functional synthase genes. The risk of amplification of pseudogenes needs to be carefully evaluated in all synthase-gene targeting methods for genetic testing of cannabis. To address this, we previously developed a custom NGS panel targeting all synthase genes (THCAS, CBDAS, and CBCAS) as well as their pseudogenes. To ensure a comprehensive analysis, a diverse array of sample types was incorporated. These samples included reference *C. sativa* samples sourced from the National Institute on Drug Abuse (NIDA) and the National Institute of Standards and Technology (NIST), along with CBD, CBG, delta-8-THC, delta-10-THC, THCO, and CBDV hemp samples containing. Additionally, the study included hemp seed samples and extracts from seized marijuana provided by the Drug Enforcement Agency (DEA). The identified novel polymorphisms were then incorporated into two fast-genotyping assays.

The study developed a SNaPshot™ assay and a TaqMan™ quantitative Polymerase Chain Reaction (qPCR) **Single Nucleotide Polymorphism (SNP)** genotyping assay for hemp-marijuana differentiation. SNaPshot™, with four markers on the THCAS gene, THCAS pseudogene, and CBDAS gene successfully differentiated five hemp types and hemp seeds from seized marijuana across various locations in the United States, Chile, and the Mexico-United States border. Furthermore, this assay yielded valuable CBD information in the marijuana samples. On the other hand, the TaqMan™ qPCR SNP genotyping assays, using two markers on the THCAS gene and THCAS pseudogene, showed efficient differentiation of the majority of hemp samples from marijuana, offering the benefits of reduced analysis time and lower costs. However, these assays were unable to distinguish hemp seeds from marijuana or provide CBD information of the sample.

In summary, this presentation showcases the extensive findings from the custom-target NGS panel, leading to the development of two robust, rapid genotyping assays. The comprehensive evaluation of synthase genes enhances researchers' understanding of the diversity within and between *Cannabis sativa* crop types. This research offers valuable insights for forensic science and law enforcement in their efforts to accurately differentiate hemp and marijuana varieties.

**B48 Challenges of DNA Profiling After Firefighting Plane Crash: The Influence of Kerosene Biodegradation on Human Remains**

*Francesco Sessa\*, University of Catania, Department GF Ingrassia, Sicily, Italy; Martina Francaviglia, University of Catania, Sicily, Italy; Giuseppe Cocimano, Forensic Pathologist at the Department of Forensic Pathology, University of Catania, Sicily, Italy; Salvatore Roccuzzo, Department of Medical Surgical and Advanced Technologies "G.F. Ingrassia"-University of Catania, Sicily, Italy*

---

**Learning Overview:** After attending this presentation, forensic practitioners may comprehend the importance of management of a DNA extraction protocol in order to improve the quantity and quality of DNA, particularly when human remains are negatively influenced by external factors such as kerosene biodegradation.

**Impact Statement:** This presentation will impact the forensic community by highlighting the role of DNA analysis as the gold standard method in cases when the condition of the remains does not allow identification using classical recognition methods.

The extraction of DNA serves as a fundamental process in biological academia and research. In a forensic DNA context, this procedure takes on even greater significance, acting as the initial pivotal step in generating DNA profiles that can either support convictions or aid in exonerations within the criminal justice system. Nevertheless, this process often encounters hurdles due to the challenging task of obtaining sufficient quantities of uncontaminated DNA, free from environmental inhibitors. These obstacles are further complicated by the wide range of sample types, some of which may contain limited amounts of biological material. Despite advances in methods and technology, certain issues still require attention, such as improving disaster victim identification processes.

This presentation aims to describe the challenges of DNA profiling after a firefighting plane crash occurred in October 2022. Specifically, this presentation focused on the influence of kerosene biodegradation on human remains, describing the complex procedures to identify each human remains recovered in the geographical area of the accident.

At the end of October 2022, during a forest fire on Sicily Island, it was necessary for two men to board their Canadair airplane. While making a drop over a forest fire, their aircraft struck a rock with its left wing, causing it to lose altitude and fall into the forest. The Canadair crashed and, within seconds, was engulfed in flames. Several remains of the two fliers that died were recovered in the next days during complex recovery operations, which were due to the geographical conformation of the area.

Subsequently, the genetic investigations began to identify which biological samples belonged to subject A or to subject B. Specifically, DNA profiling was very challenging for all samples, considering the high contamination by kerosene and the exposure to high temperatures after the explosion. Indeed, several human samples were completely burned. In this scenario, several modifications to the standard DNA extraction protocol were applied to obtain the DNA profiles. Identification was possible thanks to comparison with the reference profiles obtained from personal items and through the comparison with the profiles obtained from the parents. Moreover, blood samples recovered on the glass of the aircraft allowed us to ascertain the presence onboard of subject A.

In conclusion, this presentation highlighted the role of DNA analysis as the gold standard method in cases when the condition of the remains does not allow identification using classical recognition methods (i.e., dental or fingerprint data). At the same time, it is important to apply several modifications to the extraction protocol to improve the quantity and quality of DNA.

**B49 The Development of a Multiplex SNP Genotyping RT-PCR Kit for Screening of Non-Koreans**

*Seyoung Nam\**, Department of Forensic Sciences, Sungkyunkwan University, Suwon, Republic of Korea; *Si-Keun Lim*, Department of Forensic Sciences, Sungkyunkwan University, Suwon, Republic of Korea; *Yukyong Sin*, Department of Forensic Sciences, Sungkyunkwan University, Suwon, Republic of Korea

---

**Learning Overview:** This presentation proposes that the use of Single Nucleotide Polymorphism (SNP) markers to predict the personal characteristics to narrow the suspect pool and help solve criminal cases, especially those involving foreigners in South Korea. This presentation will demonstrate that real-time multiplex Polymerase Chain Reaction (PCR) methods can be used to rapidly predict accurate characteristics from a small number of SNPs and, furthermore, the stability of SNP markers and the sensitivity and rapidity of real-time PCR can be reconsidered.

**Impact Statement:** This presentation will impact the forensic science community by showing that analysis of the four selected SNP markers using real-time PCR methods can quickly narrow the pool of primary suspect from evidence. Forensic scientists will learn about the importance of proper selection of SNP markers and their application to forensics through robust validation.

Direct-to-customer (DTC) genetic testing refers to tests that consumers can take directly to prevent diseases based on nutrition, lifestyle, and physical characteristics without visiting a medical institution.<sup>1</sup> As the global DTC genetic testing market is expected to grow at an average annual rate of 10.6% to reach \$117.9 billion by 2024, the scale and scope of DTC genetic testing market in South Korea are also increasing.<sup>1,2</sup> In this study, to investigate the forensic applicability of SNP markers used in DTC genetic testing, a sample collected from a single donor was tested by four of the DTC companies in South Korea. As a result, only 6 out of 54 common traits (iron storage and concentration, omega-3 concentration, triglyceride concentration, insomnia, sprinting ability, and handgrip strength) among the four companies were matched, resulting in a matching rate of only 11.11%. These results showed that the test SNPs for DTC genetic test traits were highly unreliable when applied to forensics, and further validation of SNP markers for potential forensic applications was needed.

Therefore, after selecting a few traits that can predict the characteristics of suspects, we decided to create a new multiplex real-time PCR kit using reliable SNP markers for screening of non-Koreans. The selected SNPs are rs17822931, rs671, rs12913832 and rs3827760, which can be used to estimate earwax type, alcohol flush, eye color, and hair, incisor, earlobe, chin shape, respectively.<sup>3-6</sup> Samples were collected from ten Koreans and ten foreigners from different continents using buccal swabs after completing a questionnaire about their ancestry, earwax type, presence of alcohol flushing, eye color, and hair curliness. DNA was extracted using the QIAamp® DNA Mini Kit, and all samples were sequenced after quantification to verify the accuracy of the test SNPs and for comparison with multiplex real-time PCR results. From the result of the experiment, it was confirmed that race could be distinguished at the continental level using phenotype information and allele frequencies for four SNPs, and, in detail, it was possible to distinguish between East and non-East Asians. In addition, the results were consistent with the sequencing results using Capillary Electrophoresis (CE), which verified the accuracy of the multiplex real-time PCR method and has the advantage of obtaining results in a relatively short time. In future studies, we plan to create an NGS SNP panel that can predict phenotype and ancestry by adding a large number of validated SNPs to improve accuracy.

**B50 The Utilization of a Single Nucleotide Variant (SNV) Panel for the Confirmation of Sample Identity in Two Clinical Genomics Applications**

*Mariana Voudouri\*, Dartmouth-Hitchcock Medical Center, Lebanon, NH; Donald Green, Dartmouth-Hitchcock Clinic and Mary Hitchcock Memorial Hospital, Lebanon, NH; Sophie Deharvenge, Dartmouth Health, Lebanon, NH; Joel Lefferts, Dartmouth-Hitchcock Medical Center, Lebanon, NH; Wahab A. Khan, Cytogenetics/Molecular, Dartmouth-Hitchcock Medical Center, Lebanon, NH; Parth Shah, Dartmouth Hitchcock, Lebanon, NH*

---

**Learning Overview:** The goal of this presentation is to address the effectiveness of a panel of SNVs in the context of clinical germline testing results from Chromosomal Microarray (CMA) and Whole Exome Sequences (WES), as a direct method of verifying sample identity. This method would eliminate the need for additional Short Tandem Repeat (STR) analysis, which would add cost and turnaround time.

**Impact Statement:** This presentation will impact the forensic science community by showing a small pilot initiative that utilized 40 overlapping positions in two genomic assays to verify sample identity. The findings showcase the potential of implementing genomic assays in human identification procedures comparable to STR analysis and the Combined DNA Index System (CODIS).

In the workup of suspected genetic illnesses, patients may undergo both CMA and WES. These tests can be performed on different DNA aliquots from the original specimen or from DNA isolated from different specimens. Currently, sample identity can be confirmed by running additional STR testing on the CMA and WES samples.<sup>1</sup> To eliminate the need for additional testing, a panel of 40 SNVs were selected from the 750,000 SNP markers included in the THERMO FISHER™ Affymetrix® Cytoscan HD.

Variants were chosen for inclusion in the study based on several specific criteria. First, they had to be located within an exon of a protein-coding gene. Second, they were required to be either benign or not known to be associated with genetic conditions. Additionally, the selected variants exhibited a relatively high minor allele frequency in the gnomAD database. Consistent genotype calls were made by Cytoscan HD for these variants. The regions in which these variants were located demonstrated consistently adequate depth in the Agilent® V8 exome. SNVs in regions of recurrent copy number variants were excluded from consideration. Lastly, there was a prioritization to include at least one SNV on each autosome (1-22) and the X chromosome.

A custom Python® script was written to compare the 40 selected positions from the CMA SNP and WES VCF files. A 14 CMA to WES trial was performed and consisted of seven known sample pairs, five unrelated patient comparisons, and two child-to-parent comparisons.

All paired samples had perfect concordance between CMA and WES SNV calls when no-call positions were ignored. Unrelated samples shared, on average, 37% of the genotypes. The comparison between child and parental samples had a 49% similarity.

The adoption of SNV data on a broader scale, along with the utilization of WES, holds considerable promise to exert significant effects on forensic science including increased ability to identify contributors to mixed DNA samples.<sup>2</sup> These advancements possess the capability to improve and refine identification and verification procedures by creating large scale whole exome sequencing databases similar to CODIS, hence playing pivotal role in diverse applications currently reliant on STR analysis both in forensic and clinical settings.

**Identification; Forensic Science; Genotypes**

---

**B51 Examining the Risk Associated With Qualitative Exclusions in Forensic DNA Casework**

*Samantha Orans Wandzek\*, Coconut Creek, FL*

---

**Learning Overview:** The goal of this presentation is to utilize validation data to examine the risks associated with qualitative exclusions of known individuals to forensic DNA mixture samples.

**Impact Statement:** This presentation will impact the forensic science community through the evaluation of the efficacy of qualitative exclusions in a range of samples, the types of profiles in which false exclusions may occur in forensic DNA casework, and the impact it can have on interpretation.

Based on practical experience, assessing the number of contributors in a forensic DNA sample can be confounded by multiple factors, including allele sharing, the presence of peaks below the laboratory's stochastic threshold, stochastic effects that can result in peak height imbalance, elevated stutter, and the possibility of allelic drop-in. As a result, a single locus that appears to have full representation of all contributors under certain assumptions, and therefore suitable for exclusionary assessments, may be affected by one or more of these factors. This can result in a false exclusion of an individual of interest. Many of the concerns that would make profiles uninterpretable for inclusionary purposes are likewise applicable and can be equally concerning when utilizing exclusionary criteria during manual interpretation efforts (i.e., interpretation without the use of a forensic expert software). Profiles, or portions of profiles, that are determined to be uninterpretable often present with incomplete or limited data. Additionally, profiles in which an accurate determination of number of contributors cannot be made or when the number of apparent contributors exceeds the laboratory's validation parameters may lead to an inconclusive result for comparison to known reference samples.

With the advent and implementation of probabilistic genotyping, available software can more conclusively determine an inclusion or exclusion for complex DNA profiles using statistics and considering phenomenon (e.g., drop-in, drop-out, stutter by allele including longest uninterrupted stretch) that analysts are aware of but do not have the ability to incorporate during qualitative exclusions. In addition, when the software is applied correctly by a trained analyst, assessing performance diagnostics can give additional insight into the number of contributors present in the profile.

Validation data, including known single source and two-person mixtures of varying templates, were used to assess drop-in, stutter, and allelic modeling with the addition of simulated drop-in alleles above and below the laboratory's drop-in cap. Limitations were further explored by varying peak heights of the alleles for the known donors (i.e., modifying major and minor peak heights to evaluate stutter where the peak in stutter position was consistent with the minor donor). In some cases, for the mixture samples, a false manual exclusion could be made based off the apparent number of contributors without accounting for stutter and/or drop-in, whereas STRmix™ was able to account for these phenomena and/or had diagnostic flags (e.g., LR=0 at one locus) that would warrant additional scrutiny by the analyst. Overall, the results of the study demonstrate how readily a false manual exclusion can occur when an analyst does not consider all variables (e.g., elevated stutter, drop-in).

---

**B52 STRBase Moving Forward**

*Lisa A. Borsuk\*, Bioinformatics, National Institute of Standards and Technology, Gaithersburg, MD; Angela Lee, National Institute of Standards and Technology, Gaithersburg, MD; Peter Vallone, Applied Genetics Group, National Institute of Standards and Technology, Gaithersburg, MD*

---

**Learning Overview:** This presentation will inform the forensic community of the new features implemented in the Short Tandem Repeat database (STRBase) website in the past year.<sup>1</sup> A content and interface-driven update to STRBase has been released, allowing greater engagement with the public it serves. After attending this presentation, attendees will be aware of the data being maintained on STRBase and future planned expansions to the site.

**Impact Statement:** This presentation will impact the forensic community by updating attendees on the priorities and content of STRBase. STRBase is an ever-developing website with the goal of serving the forensic community in both scientific research and practitioner communities. User feedback is valuable and always welcome to help guide how the site can better serve the human identity testing community.

The STRBase website was launched in 1997.<sup>2</sup> At the time, Short Tandem Repeat (STR) markers were new in the forensic community. STRBase was developed to gather information on the new forensic markers for the forensic community. This included information on the markers as well as research and other forensically relevant projects. Over the next 25 years, the site grew with information provided by the forensic community in the form of variant and tri-alleles observed. The National Institute of Standards and Technology (NIST) Applied Genetics Group also contributes research and educational resources.

The STRBase website, up until 2023, was built with HTML pages. The site was several hundred HTML pages and increased until the end when this site was archived.<sup>3</sup> This made maintaining the site complicated. There were a number of issues, including broken links and missing files, that could not be easily fixed in the old format. The archived site is still currently available, but no changes have been made to the site since March 2023. It was decided to move to the .NET platform with a backend database, which would allow for easier maintenance and expansion in the future.

The new website went live in April of 2023 and continues to expand with new content for the forensic community. The site is now more user-friendly, with a simplified layout and search capabilities. It allows users to submit data directly to STRBase using a login. This streamlines the data collection process for variant and tri-alleles, as well as other data types associated with active projects. All information contained in the old site was evaluated, and if it was within the scope of the new site, the content was moved. Not all topics on the previous site are still relevant to human identity testing. Making STRBase beneficial to the forensic DNA community is accomplished by working with the people.

**B53 Ten Years of Developing and Improving CSI Camps, Forensic Science Educational Conferences, and Science Museum Programs Toward Enhancing Interest, Attitudes, and Motivation in Forensic Science**

*Steven B. Lee\*, San Jose State University and FIU, Miami, FL; Mark Okuda, EVC, Los Gatos, CA; Bruce R. McCord, Florida International University, Miami, FL; Sara C. Zapico, New Jersey Institute of Technology, Newark, NJ; Sharon L. Plotkin, Miami Dade College, Miami, FL; Margie Phipps, Florida International University, Miami, FL; Analisa Duran, Frost Science Museum, Miami, FL; Mary Juno, San Jose State University, Sebastopol, CA*

---

**Learning Overview:** After attending this presentation, attendees will learn best practices evolved from ten years of research on developing and improving three informal, inquiry-based, out-of-school engagement programs: (1) Forensic Science (FS) and Crime Scene Investigation (CSI) Camps and Mystery dinners ( $n=10$ ); (2) Teacher Forensic Science Education Conferences (AAFS FSECs) ( $n=5$ ); and (3) Science Museum programs ( $n=2$ ). Attendees will gain knowledge from research results using pre- and post-engagement surveys, modifications to experimental planning and design strategies, methods for transitioning to on-line delivery, and lessons learned for developing public science programs in their universities and other settings, based on forensic science, to introduce Science, Technology, Engineering, and Math (STEM) careers to middle and high school students.

**Impact Statement:** This presentation will impact the forensic science community by presenting for the first time a ten-year-old study of the effectiveness of public programs in STEM education, including teaching resources and methods empirically tested, that may assist other forensic science educators, program leaders, CSI camp and FSEC directors, and other stakeholders to employ the modules, strategies, and lessons learned toward advancing our students' forensic science and crime scene investigation knowledge, skills, abilities, and confidence.

Tomorrow's science leaders are in our classrooms today. Educating and galvanizing the next generation of scientists is of paramount importance to our future as the impact of science and technology on society continues to expand.<sup>1</sup> A growing body of research indicates informal, inquiry-based, and science-rich resources have value in sparking, sustaining, and extending interest in and understanding of STEM disciplines, underscoring the importance of activities outside of the classroom.<sup>2-9</sup> Studies indicate the public learns more science over their lifetime in informal settings, such as programs in museums, science centers, zoos, parks, or science camps, than in formal settings, like classrooms and seminars.<sup>2</sup>

FS and CSI are by their very nature inquiry-based, inter-disciplinary, and collaborative. The hands-on, engaging, rigorous science and math applications and analyses have great potential to excite students about science, inspire them into STEM careers, and become lifelong science learners.<sup>10-14</sup> Connections of science to the real world are brought to life through the casework and testimony experiences delivered by FS and CSI experts and through hands-on, inquiry-based investigations of mock crimes. Integration of FS into hands-on programs can foster critical thinking and problem solving and "out of school engagements can help to develop high school students' identities as forensic scientists."<sup>10</sup>

In this presentation, we summarize ten years of lessons learned and research on improving three out-of-school engagement programs: (1) FS and CSI Camps and Mystery dinners (1 week,  $n=10$ ); (2) Teacher FS Education professional development conferences (AAFS FSECs (3 days,  $n=5$ ); and (3) Science Museum programs (1/2 day,  $n=2$ ). Research results using pre- and post-engagement surveys, modifications to experimental planning and design strategies, methods for transitioning to on-line delivery and lessons learned from ten years of developing, delivering, and reimagining these programs will be described.

Participants work in teams and are led by FS graduate student counselors. The counselors lead participants through the activities, providing both teaching experiences and more direct interactions for our participants. During the in-person CSI camp, families come together to help solve a case during a mystery dinner. In our museum Adult Overnight Mystery and Girl Scout FS Badge events, participants rotate through different experimental stations, examining and analyzing evidence to solve a crime. Programs culminate in a moot court with participants as expert witnesses and parents playing the jury.

Program improvements from participant feedback, in format, pedagogy and topical content have been used for redesigning our programs. Evaluations supported increasing inter-student engagement and increased hands-on experimentation. Programs now include multiple hands-on activities for each topic. Unexpected experimental results are included in at least one experiment (e.g., spiking expired reagents into one team's kit), providing critical thinking and problem-solving opportunities for students while emphasizing the scientific method and importance of controls.

Our programs have collectively served 504 student CSI campers between the ages of 12–21 years old, and 97 teachers/educators from 21 states; 71% female and 36% underrepresented campers from 15 states and 6 countries have participated in our programs. Both site cohorts have had a majority of female participants (71%).

Outcomes have demonstrated participant improvements in FS knowledge and an increased interest in pursuing FS studies observed based on pre- and post-assessments and evaluation surveys, post-event follow-up communications, and enrollment of some former participants and counselors into FS university programs.

Results of our redesigned program strategies, including detailed agendas, supplies lists, suppliers, protocols, on-line modifications, and teaching resources, may assist other FS educators, program leaders, CSI camp and FSEC directors, and other stakeholders to employ the modules, strategies and lessons learned toward advancing our students FS and CSI knowledge, skills, abilities, and confidence.

**B54 A Longitudinal Study on the Odor Stability of Decomposition Simulated Training Aids Under Freezing Conditions**

*Jonathan Bateman Locke\*, Lubbock, TX; Andrea Medrano, Texas Tech University, Lubbock, TX; Paola A. Prada-Tiedemann, Texas Tech University, Lubbock, TX; Chris Holleyman, Sirius Metrics, Inc., Burtonsville, MD*

---

**Learning Overview:** After attending this presentation, attendees will better understand odor behavior as a function of storage period under freezing conditions from animal-analog decomposition samples, thus presenting implications for prolonged shelf life and storage conditions for human remains canine detection team training regimens.

**Impact Statement:** This presentation will impact the forensic science community by depicting odor fate across a prolonged storage freezing condition of up to 16 months, thereby providing the first of its kind longitudinal study on the odor profile of simulated decomposition samples. By evaluating the headspace odor of simulated decomposition training aid samples across this length of time from a range of putrefactive stages, the research presents practitioners within human search and rescue as well as law enforcement personnel who utilize human remains canine detection teams a scientific understanding of how training aids change over time.

The utilization of canines as a biological detector tool has increased immensely as they assist various law enforcement agencies in locating a wide variety of target substances, such as explosives, narcotics, pests, and human remains. Human Remains Detector (HRD) canines—also commonly referred to as cadaver dogs or victim recovery dogs—are an evolved specialty from the search and recovery discipline. HRD canine teams are deployed in operational scenarios needing the recovery of whole bodies or body parts. Thus, these canines are trained on a wide variety of decomposition odor sources, including whole bodies, body parts, tissue, bone, and decomposition fluids. Additional odor sources utilized for training include, but are not limited to, clothing from a deceased victim, blood, soil, and even synthetic training aid formulations. Given that human decomposition is a highly dynamic and variable process, it is imperative for canine handlers to use a wide assortment of training aids to optimize the canine's ability to locate the target substances. Enhanced training on an array of decomposition training odor sources reinforces the canine's odor memory to respond to target odor compounds in operational contexts and thus maximizes their efficacy.

A canine's ability to accurately locate human remains is highly dependent on the training aid's ability to mimic the odor profile of decomposing human remains. Therefore, the chemical odor characterization of these training aids is critical knowledge to further understand odor stability and persistence. One of the biggest challenges within HRD canine teams is the procurement of representative decomposition odor sources for training purposes. Thus, when a canine team can obtain training aids for routine maintenance training and assessments, a crucial factor to consider is optimal storage and containment for preservation of odor samples. To date, there is limited knowledge on the stability of the chemical odor profile from decomposition training aids after prolonged storage periods. To further complicate the situation, the different decomposition stages depict unique odor profiles across the full putrefactive spectrum, thus raising concerns as to optimal protocols to safeguard the integrity of different types of odor sources.

Three animal models (*Sus scrofa*) were laid out on a field and allowed to reach a targeted stage of decomposition (fresh, advanced decay, dry/skeletal). Once the targeted stage had been reached, tissue samples were collected, stored, and analyzed via Solid Phase Microextraction-Gas Chromatography/Mass Spectrometry (SPME-GC/MS). The headspace odor concentration of each simulated-training aid was monitored at time of collection (week 0) and analyzed once more approximately 16 months later. Two different vial types were used as containment vessels (clear, amber) to further monitor if either vial would lead to higher indistinguishability. The results depicted a decrease in overall number of compounds detected when analyzed after two years of undisturbed storage. However, primary compounds that were observed at week 0 were also observed during months 14–16. Further statistical analysis will assist in portraying how distinguishable/indistinguishable the odor profiles of these samples were at time of collection versus 16 months post-collection.

Understanding how these odor profiles behave as a function of time concurrently with storage regimens is of high importance as it can gap the bridge of knowledge as to how the chemical odor characterization of decomposition training aids change over time, and how long they serve their purpose as an effective canine training aid.

**Decomposition; Odor; Sample Storage**

**B55 A Pre-Concentrating Polymer Coating for Improved Detection of Fentanyl and Fentanyl Analogs**

*Galpayage Dona Thouli Lochana Jayawardana\**, Florida International University, Miami, FL; *Lauryn DeGreeff*, Florida International University, Miami, FL; *Ashley Fulton*, United States Naval Research Laboratory, Alexandria, VA; *Braden C. Giordano*, Chemistry Division, United States Naval Research Laboratory, Washington, DC

**Learning Overview:** This presentation provides an overview on determining the most suitable acrylate-based polymer coating to pre-concentrate the target analyte vapor of fentanyl and fentanyl analogs based on the behavior of each coating toward the vapor using acrylate base-coated Quartz Crystal Microbalance (QCM) sensors.

**Impact Statement:** The technology of this research will be used to address the imperative need of improving sensitivity and selectivity of commercially available handheld Ion Mobility Spectrometer (IMS) to be effectively employed in vapor phase, non-contact detection of fentanyl and fentanyl analogs, thus impacting the forensic science community.

Field detection and identification of drugs of abuse is challenging and associated with many hazards. The Drug Enforcement Agency (DEA) currently has no advanced recommendations other than advising the first responders and law enforcement personnel to avoid direct contact with suspected drugs of abuse. Currently, the handheld IMS is an instrument that can be used for trace level, field detection of illegal drugs that utilizes swipe sampling and thus requires risking human exposure. Although research has been conducted to employ the IMS in vapor phase, its low sensitivity to trace level identification is a drawback. Therefore, this study explored the feasibility of deploying a novel pre-concentrator for target analytes of fentanyl and fentanyl analogs, which can be affixed on to the commercial handheld IMS.

The Naval Research Laboratory (NRL) in their prior efforts have found and tested a library of acrylate-based coatings that have enhanced analyte pre-concentration. The most favorable acrylate-based coatings that facilitate pre-concentration of vapors were investigated using a QCM. A QCM measures the frequency changes of a Quartz Crystal Resonator (QCR) as an analyte is introduced, and the mass deposited on the surface can be determined. By using acrylate-based sensors, or coated QCRs, the extent of vapor adsorption and desorption is observable, and therefore the ability of a coating to pre-concentrate can be determined. The main vaporous component (target analyte) in the headspace of fentanyl and fentanyl analogs has been identified as NPPA in previous research and NPPA is a potential target for IMS detection of fentanyl/fentanyl analogs by pre-concentration.

Several potential acrylate-based coatings from the library were screened to determine the ideal coating for NPPA. The phenyl-acrylate-coated sensor has an immediate significant adsorption of vapor that steadies out within a short time and is able to completely desorb in a short period of time. Ethylene Glycol Monomethyl Ether (EGMEA) -coated sensor uptakes significantly high masses of vapor through several hours and desorbs through an equally long period of time. Results depict that each coating has a different behavior with NPPA. The activity of the sensors shows that rapid significant uptake of vapor with equally rapid desorption are the ideal features necessary to be seen in a pre-concentrator coating for NPPA. Once the ideal coating is determined for NPPA, it can be applied to an array of Silicon Nanowires (SiNW) (developed by NRL) that is embedded in a micro-chip, fixable in the commercial handheld IMS.<sup>1-5</sup>

The outcome of this research caters the urgent need of improving sensitivity for non-contact detection, together with presumptive identification of trace-level fentanyl. This approach can further be generalized to detect other dangerous drug classes as well.

## B56 Toxic Adulterant Prevalence in the United States Illicit Drug Supply: Geographical Trends and Raising Awareness Regarding Their Dangers to Promote Public Health

*Mia Borrelli\**, Center for Forensic Science Research and Education, Willow Grove, PA; *Melissa F. Hehir*, Georgia Bureau of Investigation, Division of Forensic Sciences, Decatur, GA; *Trisha Conti*, Vermont Forensic Laboratory, Waterbury, VT; *Ryan Farrell*, IMCFSA, Indianapolis, IN; *Nicole Lattanzio*, NMS Labs, Willow Grove, PA; *Sarah A. Shuda*, Center for Forensic Science Research and Education, Willow Grove, PA; *Amanda L.A. Mohr*, Center for Forensic Science Research and Education, North Wales, PA; *Thom Browne, Jr.*, Colombo Plan, Huachuca City, AZ; *Barry K. Logan*, PhD, Center for Forensic Science Research and Education, Horsham, PA

**Learning Overview:** After attending this presentation, attendees will be able to assess the emergence and proliferation of toxic adulterants throughout the United States.

**Impact Statement:** This presentation will impact the forensic science community by raising awareness of toxic adulterant substances in the United States drug supply. Attendees will also be able to describe the toxic effects of the most commonly encountered toxic adulterants.

Adulterants are pharmacologically active substances that can readily be obtained and added to drug street samples to increase bulk. The addition of these agents can have dangerous and toxic effects to the consumer through additive or synergistic effects with the principal drug. Adulterants change all the time based on their availability and changes in market preference. Comprehensive testing of all substances in each sample allows monitoring of emerging drug trends that ultimately impact the treatment and outcomes of acutely intoxicated patients.

Deidentified seized drug samples (n=1,448) were received from eight forensic laboratories across the United States between March 2022 and January 2023. Sites included the Northeast (NH, PA, VT), Midwest (IL, IN, OH), and Southeast (GA, WV). All samples were shipped as dried extracts and reconstituted with 90:10 5mM ammonium formate in H<sub>2</sub>O: 0.1% formic acid in acetonitrile and analyzed using a Xevo® G2-S QTOF mass spectrometer coupled to an ACQUITY® UPLC® I-Class system. Data was processed using UNIFI® Scientific Information System against an in-house library containing >1,000 drugs, including a wide range of adulterants, precursors, and by-products along with controlled substances and a broad range of Novel Psychoactive Substances (NPS).

Of the 1,448 samples, adulterants were identified in 1,203 samples (83.1%). Six samples from Vermont were negative for any drugs or adulterants. The peak with the greatest abundance was considered the main component, while all other constituents identified were considered to be adulterants. Data related to the total number of constituents identified and number of adulterants by state is provided in Table 1. Throughout this study, 16 adulterants were identified across the samples including: acetaminophen, aminopyrine, benzocaine, caffeine, diphenhydramine, gabapentin, hydroquinidine, hydroxyzine, levamisole, lidocaine, phenacetin, procaine, quetiapine, quinine/quinidine, tramadol, and xylazine. Of the 1,436 drug positive samples, 7% contained diphenhydramine, 9% levamisole, 11% contained lidocaine, 12% contained quinine/quinidine, 14% contained caffeine, and 19% contained xylazine. All other adulterants were found at less than 7%. Results for individual states for the top six adulterants are shown in Table 2.

**Table 1.** Complexity of Drug Exhibits by State for Drug Constituents and Adulterants

State	1-4 Constituents (%)	5-8 Constituents (%)	9+ Constituents (%)	1-4 Toxic Adulterants (%)	5-8 Toxic Adulterants (%)	9+ Toxic Adulterants (%)
Pennsylvania	91	9	0	60	1	0
Ohio	84	11	5	51	6	3
West Virginia	81	13	6	28	10	5
Illinois	77	3	20	39	2	20
Georgia	73	19	8	45	16	6
New Hampshire	70	21	9	70	21	9
Indiana	60	35	5	61	24	3
Vermont	50	22	22	36	19	20

**Table 2.** Adulterant Positivity by State

	Total (n=1436)	IN (n=200)	IL (n=204)	GA (n=98)	NH (n=200)	PA (n=146)	OH (n=200)	WV (n=200)	VT (n=188)
<b>Xylazine</b>	19%	22%	13%	9%	21%	24%	18%	7%	37%
<b>Caffeine</b>	14%	21%	5%	5%	27%	6%	3%	11%	30%
<b>Quinine/Quinidine</b>	12%	15%	18%	12%	8%	0%	6%	19%	19%
<b>Lidocaine</b>	11%	12%	5%	11%	16%	4%	6%	8%	24%
<b>Levamisole</b>	9%	4%	12%	12%	8%	18%	4%	1%	10%
<b>Diphenhydramine</b>	7%	20%	3%	6%	2%	0%	11%	12%	2%

The identification of toxic adulterants is becoming more important in the field of drug chemistry as typically only controlled substances are reported. Continued surveillance of these adulterants may lead to a better understanding of the illicit drug supply and can enable better information to be distributed to the public regarding the potential toxic effects. This can assist clinical health professionals to treat patients, as well as educate people who use drugs. Toxic adulterant testing results give an important additional perspective for understanding the toxic effects of recreational drug use and emerging trends.

## Adulterants; Drug Chemistry; Surveillance

**B57 An Analysis of Plant Fragments Using X-Ray Fluorescence Spectrometry and X-Ray Absorption Fine Structure Technique Utilizing Synchrotron Radiation**

Suzuha Kurosugi\*, Kochi University, Kochi, Japan; Yoshinori Nishiwaki, Kochi University, Kochi, Japan; Masanobu Mori, Graduate School of Science and Technology, Kochi University, Kochi, Japan

**Learning Overview:** This presentation deals with plant fragments that may be left at a crime scene as evidence, using synchrotron X-Ray Fluorescence (XRF) analysis and X-Ray Absorption Fine Structure (XAFS) measurements, in addition to DNA identification to determine the plant species. This will provide information on the environment in which the plants were grown. After attending this presentation, attendees will understand the importance of studying the distribution of elements in plant fragments and their chemical morphology.

**Impact Statement:** Currently, morphological observation and DNA analysis are used for plant analysis. In this presentation, we will show that the distribution and chemical state of elements in plants by synchrotron radiation X-ray analysis and XAFS measurements are useful for identifying plant varieties and growing environments. This allows the use of previously unobtainable information in criminal investigations. This presentation will impact the forensic science community by introducing this method that will be a new tool for connoisseurs who analyze plant fragments.

Plant fragments are important evidence samples left at crime scenes. Plant roots are often found with bodies buried in the soil. Analysis of plant fragments makes it possible to identify the person, alibi, time of the crime, and location of the crime.<sup>1</sup> DNA analysis of plant fragments can be used to identify plant species. However, it is difficult to know the plant's growing environment by DNA analysis. Trace element analysis by Inductively Coupled Plasma (ICP) has been used to reveal the disguised origin of crops.<sup>2</sup> It is known that some plant species concentrate different minerals at specific sites depending on their growing environment.<sup>3</sup> Mineral distribution in plant tissues is important information on plant characteristics.<sup>4</sup> However, ICP analysis can only provide averaged information on minerals in plants. Synchrotron radiation X-rays are highly brilliant, and X-ray nanobeams of several hundred nm can be used for analysis. Therefore, XRF imaging of small areas in plant tissue is possible. The chemical state of the elements can be determined by XAFS measurement in the same condition after XRF analysis. The distribution of elements in plant root cross-sections and the chemical state of detected elements can provide information on plant species and their growth environment.<sup>5</sup>

In this study, the roots of Chinese chives (*Allium tuberosum*), a familiar plant in Japan, were used for the measurements. This study aims to obtain the basic information for the discrimination of different plant roots based on the Chinese chive varieties and growing environments using synchrotron radiation nanobeam XRF imaging and XAFS measurements. Two types of Chinese chives were used in the experiment: Tough Boy and Miracle Green Belt. They were grown in soils with about 0.5ppm and 25ppm of manganese. Chinese chive root slices were prepared using a Leica® Cryostat (CM3050S). Synchrotron radiation XRF imaging was performed at BL36XU of SPring-8. XAFS measurements were performed at BL9A of the Photon Factory of the High Energy Accelerator Research Organization (KEK). As a result of Synchrotron radiation XRF imaging, the root cross-sections obtained from soils with low concentrations of manganese were lower X-ray intensities of Ca, K, Mn, and Zn than the roots obtained from soils with high concentrations of manganese. The elements of Mn and Zn were concentrated in the outer bark of Chinese chive's (Tough Boy) roots obtained from the soil with a high manganese concentration. In Chinese chive's (Miracle Green Belt), K, Ca, and Zn were concentrated in the inner sheath. XAFS measurements showed that the valence of manganese in the roots of Chinese chives (Miracle Green Belt) obtained from the soil with low concentrations of manganese was divalent. On the other hand, the valence of manganese in the roots of Chinese chives (Miracle Green Belt) obtained from soil with high manganese concentration was trivalent. In Chinese chives (Tough Boy), the valence of manganese in the roots from both soils was divalent. These results indicate that the distribution and the chemical states of elements in the root cross section of Chinese chives differed depending on the variety and growing environment. Therefore, Synchrotron radiation XRF imaging and XAFS measurements are useful for characterizing Chinese chives' roots. This approach can be applied to other plants. This method could be used as a new forensic tool for plant fragment analysis that is effective in combination with DNA analysis.

**B58 An Analysis of Single Synthetic Fibers by Metallic Components in Dyes by Nanobeam X-Ray Fluorescence Imaging and X-Ray Absorption Fine Structure Technique Utilizing Synchrotron Radiation**

Keita Miyazaki\*, Kochi University, Kochi, Japan; Yoshinori Nishiwaki, Kochi University, Kochi, Japan; Masanobu Mori, Graduate School of Science and Technology, Kochi University, Kochi, Japan

---

**Learning Overview:** In this presentation, we demonstrate the use of synchrotron radiation X-rays to show metallic elemental information of dyes in a single synthetic fiber, which could not be determined by conventional fiber analysis. After attending this presentation, attendees will better understand the importance of collecting these evidence samples, the utility of metallic elements in dyes for discrimination, and the importance of analyzing dyes in single fibers.

**Impact Statement:** As this presentation demonstrates the usefulness of information on the distribution of metallic elements in dyes and their chemical states, which has yet to be focused on in conventional fiber analysis, fiber analysts in forensic science will be impacted by having an opportunity to recognize the importance of this information.

The analysis of synthetic fibers is important in forensic investigation. Conventional methods of fiber analysis focus primarily on the shape, material, color tone, and organic components of dyes.<sup>1</sup> On the other hand, it is known that synthetic fiber dyes contain many metallic elements such as Al, Co, Cr, and Zn to bind the polymer.<sup>2,3</sup> In this study, we used nanobeam X-Ray Fluorescence (XRF) imaging and X-ray Absorption Fine Structure (XAFS) techniques utilizing synchrotron radiation for analyses of metallic elements contained in dyes of single fibers. The advantage of nanobeam XRF imaging is that it provides sensitive and high-spatial resolution imaging of trace elements in small samples. The advantage of XAFS technique is that the X-ray Absorption Near-Edge Structure (XANES) spectra allow valence and chemical compound estimation of trace elements.<sup>4</sup>

The purpose of this study is to improve the ability to discriminate single fibers by combining the metallic element information obtained from this nanobeam XRF imaging and XAFS technique with conventional analytical methods. Nanobeam XRF imaging was conducted at SPring-8, BL29XU. The measurements were performed with a beam diameter of 200nm (H) × 200nm (V), 500nm per step, exposure time of 2sec, and under a helium atmosphere. Thin section samples of single fiber cross sections used in nanobeam XRF imaging were prepared using a microtome. XAFS technique was performed at a high-energy accelerator research organization, Photon Factory, BL9A. The incident X-ray energy was varied from 9.155keV to 10.760keV because the K-edge of zinc is 9.661keV. As a result of nanobeam XRF imaging, chlorine, titanium, and zinc were successfully visualized in polyester fibers, and phosphorus, sulfur, and zinc were successfully visualized in acrylic fibers, respectively. The elements of chlorine derived from the dyes in the polyester single fibers were visualized as permeating the interior while mainly being present outside the cross-section. Micro titanium dioxide particles, the matting agent in the single fibers, were visualized in the cross-sectional samples. Since the phosphorus and sulfur were uniformly present throughout the acrylic fiber cross-section, they were of polymer origin. The elements of zinc were present in the outline part of the cross-section in both the acrylic and polyester fibers, indicating that the zinc is of dye derivation. As a result of the comparison of the XANES spectra of the zinc detected, they were similar to those of zinc chloride for acrylic fibers and to those of zinc acetate for polyester fibers. The chemical state of zinc differed depending on the type of polymer.

The results show the importance of analyzing the metallic elements in the dyes of single synthetic fibers. Combining the distribution of metallic elements in single fibers, information on their chemical states, and conventional fiber analysis methods would allow for more detailed discrimination of single fibers.

Adeoye, Morgantown, WV; Jessica Orris, West Virginia University, State College, PA; Clarissa McQuain, Pennsylvania State University/West Virginia University, Hershey, PA; Stephen P. Hokanson, Virginia Department of Forensic Science, Roanoke, VA

---

**Learning Overview:** At the end of this presentation, attendees will understand that replicate mass spectra of known standards can be used to improve the confidence in compound identification for synthetic cathinones that have very similar structures and spectra.

**Impact Statement:** This presentation will impact the forensic community by providing a flexible, robust, and transparent algorithm that can minimize the risk of false positive and false negative identifications in their seized drug analyses.

Current mass spectral algorithms use an approach in which normalized query spectra are compared to normalized known (reference) spectra. For our purposes, the average of many reference spectra for a substance is termed the exemplar or consensus spectrum. For this presentation, at least 13 synthetic cathinone isomers were analyzed in replicate using Gas Chromatography/Electron-Ionization/Mass Spectrometry (GC/EI/MS) on at least five different instruments in two different laboratories. The database included dozens of cathinones and other drugs collected from several publicly available databases. The final database contained more than 3,000 replicate spectra of cathinones. For each compound as the model, the spectra were randomly divided into a training and a test set. The ion abundances for each spectrum were first normalized to the base peak, then the 20 most abundant ions for the training set were used to build 20 General Linear regression Models (GLM) by sequentially using the abundance of each ion as the dependent variable and the abundance of the 19 remaining ions as the covariates.<sup>1,2</sup>

The models for each compound were used to predict the ion abundances for all the Known Positives (KPs) and Known Negatives (KNs) in the database. The predicted abundances were compared to the measured abundances using various similarity and dissimilarity metrics, like the National Institute of Standards and Technology (NIST) match scores and the mean absolute residual. Each metric was then used as a binary classifier to determine the true-positive and false-positive rates over a range of threshold values. These classifications were used to plot a Receiver Operating Characteristic (ROC) curve from which we could calculate the Area Under the Curve (AUC) to determine the accuracy of each model.

For larger cathinones with a molecular mass of 249 Da and a base peak at  $m/z$  100, like N-ethyl pentylone, most of the KNs had smaller NIST scores than the smallest NIST score of all the KPs, thus enabling successful classification. EASI consistently outperformed the consensus approach with AUCs of 1.000 in the ROC plots for binary classification (i.e., no errors). The newest cathinone data includes several analogs of smaller cathinones like eutylone, dibutylone, and pentylone, which all share a molecular mass of 235 Da and a base peak at  $m/z$  86. For the smaller cathinones, Expert Algorithm for Substance Identification (EASI) using NIST scores had AUCs greater than 0.99 whereas the conventional approach had AUCs of ~0.94.

Ion abundances predicted with EASI models were typically 3–4 times closer to the measured values than the consensus spectrum for a given cathinone. Regardless of the spectral comparison method, EASI outperforms approaches that employ an exemplar or consensus approach to library identifications. In short, the new algorithm outperforms existing algorithms for accurately identifying cathinone analogs and a wide variety of other drugs, from their mass spectra, even in the absence of chromatographic retention times.

**B60 An Assessment of a Combined Field-Portable Raman Spectroscopy and Gas Chromatography/Mass Spectrometry Approach for the Analysis of Seized Drugs**

*Christina Chang\*, Sam Houston State University, Huntsville, TX; Geraldine Monjardez, Sam Houston State University, Huntsville, TX; J. Tyler Davidson, Sam Houston State University, Conroe, TX*

---

**Learning Overview:** After attending this presentation, attendees will have learned about the strengths and weaknesses of field-portable Raman spectroscopy and Gas Chromatography/Mass Spectrometry (GC/MS) instrumentation for the analysis of seized drug mixtures. Attendees will learn about the performance of each individual technique for both pure samples and seized drug mixtures, the improved identification rate when the two techniques are combined, and the resulting performance when the combined analytical scheme is applied to authentic seized drug mixtures.

**Impact Statement:** This presentation will impact the forensic science community by providing an assessment of the capabilities and limitations of three field-portable Raman and GC/MS instruments for the identification of seized drug mixtures across a range of drug to adulterant ratios. Assessing the performance of these three field-portable instruments will help inform policy decisions regarding the appropriate implementation of field-portable instrumentation for the analysis of seized drug mixtures.

Growing backlogs and lengthy turnaround times for seized drug analysis are causing significant strain on the judicial system. One potential solution is to improve the quality of field screening through on-site detection methods using field-portable instrumentation to reduce the amount of evidence submissions to forensic laboratories. Another benefit of field-portable instrumentation is that some methods, such as Raman spectroscopy, enable the identification of substances through transparent containers, minimizing contact between personnel and hazardous substances. In comparison, GC/MS analysis requires interaction between the sample and personnel but provides the ability to separate controlled substances from the presence of adulterants or diluents in the sample. However, the incorporation of field-portable instrumentation into routine on-site detection requires extensive empirical data to establish the capabilities, limitations, and performance characteristics for each instrument. This study involves evaluating the use of field-portable instrumentation for the detection of seized drugs and adulterants in increasingly dilute mixtures to assess the instrument-specific performance. The central hypothesis of this research is that the combination of field-portable Raman and GC/MS instrumentation will enable the detection of controlled substances even in increasingly dilute mixtures.

In this study, a Rigaku ResQ CQL Raman spectrometer with a 1,064nm laser, a Field Forensics HandyRam™ spectrometer with a 785nm laser, and a FLIR® Griffin G510 GC-MS were used to analyze the seized drug mixtures. The mixtures analyzed were cocaine with levamisole, procaine, caffeine, and phenacetin, and methamphetamine with levamisole, caffeine, and phenacetin at 1:1, 1:4, 1:10, and 1:20 ratios. An extra mixture of phentermine and methamphetamine was analyzed using GC/MS instrumentation only to demonstrate the benefits of chromatographic separation for isobaric compounds that produce similar Electron Ionization (EI) mass spectra. The target compounds were chosen based on substances commonly found in seized drug casework to assess instrument performance before the analysis of the authentic adjudicated casework samples. The internal libraries for the ResQ CQL and the FLIR® Griffin G510 were used for compound identification, whereas external Raman libraries were used for identification of Raman spectra collected with the HandyRam™ instrument. Method development involved designing reproducible sample introduction and analysis schemes for all instrumental techniques. The figures of merit assessed prior to authentic adjudicated casework analysis were the selectivity, limit of detection, repeatability, reproducibility, and robustness.

The results showed that both hand-held Raman spectrometers were able to reliably identify the pure compounds and that both constituents could be seen in the spectra obtained from the 1:1 mixtures. As the mixtures became more dilute, the characteristic peaks corresponding to the cocaine and methamphetamine ( $1,712\text{cm}^{-1}$  and  $1,003\text{cm}^{-1}$ , respectively) were less prominent or hidden by the adulterant entirely. In addition, higher levels of fluorescence were observed when using the HandyRam™ than the ResQ CQL, likely due to the shorter laser wavelength. In contrast, the FLIR® Griffin G510 GC/MS demonstrated superior sensitivity and the ability to identify both the controlled substance and adulterant in the more dilute mixtures. For example, even the isobaric phentermine and methamphetamine could be separated and identified based on their retention times and EI mass spectra. Even though there were issues with the identification of the controlled substance in the more dilute seized drug mixtures, when the analytical data from the individual hand-held Raman spectrometers and the portable GC/MS were considered together, all controlled substances were identified for each seized drug mixture.

**B61 An Assessment of Odorant Permeability for Canine Training Aid Mimics in Different Containers Utilizing HS/SPME-GC/MS**

Kayla Hogan\*, Florida International University, Cutler Bay, FL; Katherine Dias Castro, Florida International University, Miami, FL; Janet M. Crespo Cajigas, Florida International University, Miami, FL; Lauryn DeGreeff, Florida International University, Miami, FL; Kenneth G. Furton, Florida International University, Miami, FL

---

**Learning Overview:** After attending this presentation, attendees will have a better understanding of the suitability of various containers to determine an optimal storage system for reducing permeation and cross-contamination among canine training aids stored in the same case.

**Impact Statement:** This presentation will impact the forensic science community by showing how certain containers are more desirable in reducing cross-contamination from others stored in the same case, thus providing optimal information on the selection of containers for canine training aid storage, which could result in improving a canine's training ability to detect specific odorants.

Training canines to detect specific odorants corresponding to drugs, explosives, or human remains is beneficial due to their highly sensitive sense of smell. Unfortunately, when training aids are stored in non-optimal containers, such as plastic bags, odorants will tend to cross-contaminate.<sup>1</sup> If canines are trained on cross-contaminated samples, then this would hinder the canine's detection ability to an odorant, causing them to provide a false positive or false negative response. While eliminating all types of cross-contamination in canine training aids is difficult and nearly impossible to achieve in specific environments, limiting and reducing contamination by significant amounts is pivotal to help improve their detection ability. A recent study discussed the permeability and ab/adsorption of certain types of containers using an explosive odorant, Triacetone Triperoxide (TATP) using Direct Analysis in Real-Time Mass Spectrometry (DART®-MS).<sup>2</sup> Mylar® and Opask® bags, primary containers, were ideal for 24-hour short-term storage; however, a longer study depicted Mylar® bags in a mason jar, secondary containment systems, showed TATP permeated out after one week.<sup>2</sup> This presentation includes research utilizing HS/SPME-GC/MS to assess the effectiveness and permeability of odorants in drug training aid mimics at certain time intervals stored in various containers.

To examine the prevalence of cross-contamination in actual canine training aids, used aids containing cocaine, cocaine base, methamphetamine, MDMA, heroin, and black tar heroin were donated by a federal agency and analyzed using HS/SPME-GC/MS to determine if cross-contamination occurred. The used training aids were indeed cross-contaminated with odorants from co-located aids. After confirming the presence of cross-contamination on actual used aids, methods to mitigate cross-contamination by utilizing optimal storage containment was explored. Mimic training aids for heroin, with acetic acid as the major odorant, and MDMA, with dimethyl sulfone as the major odorant, were created by pipetting and weighing, respectively, small quantities of the pure odorant onto a substrate, cellulose or alumina. A vapochromic cross-contamination sensor was implemented to provide a visual color change cue from green to blue to assess if cross-contamination was possibly present. The containers assessed within this study included plastic Ziploc®-type bags, Mylar® bags, Bitran® bags, mason jars, and glass Training Aid Delivery Devices (TADDs). The mimic training aid for heroin and MDMA, and a vapochromic cross-contamination sensor were packaged separately in the same type of container and stored together in a case.

Optimal equilibrium and extraction times were optimized using HS/SPME-GC/MS. Calibration curves for each odorant were assessed to determine limits of detection and quantification. Samples were collected the initial day each mimic was placed within the container and then again over time to monitor for evidence of cross-contamination. For this purpose, a small amount of sample was placed into a 20mL vial to assess if the cross-contaminated odorant was present. Samples were collected and analyzed, at time intervals, 1, 4, 7, 14, 21, 28 days, etc. Additionally, the color change from green to blue in the vapochromic cross-contamination sensor, indicating potential cross-contamination, was analyzed with a digital microscope at each time interval.

The samples analyzed deemed the cross-contaminated odorant permeated at shorter time intervals from certain containers than others. The cross-contamination sensor results were in agreement with these findings. This study provides canine trainers and handlers, as well as other individuals, with a better sense of understanding optimal containers and their length of suitability before cross-contamination of odorants occurs within them, potentially causing skewed results or affecting the accuracy and reliability of a canine's search.

## B62 Color, Monogram, and Physical Measurements of Illicitly Manufactured Fentanyl Tablet Exhibits Seized Along the United States Southwestern Border

*Joshua William Kotchey\*, Center for Forensic Research and Education, Willow Grove, PA; Joshua S. DeBord, Center for Forensic Science Research and Education, Ambler, PA; Sarah A. Shuda, Center for Forensic Research and Education, Willow Grove, PA; Mia Borrelli, Center for Forensic Research and Education, Willow Grove, PA; Amanda L.A. Mohr, Center for Forensic Research and Education North Wales, PA; M.J. Menendez, Willow Grove, PA; Thom Browne, Jr., Colombo Plan, Huachuca City, AZ; Barry K. Logan, Center for Forensic Research and Education, Horsham, PA*

**Learning Overview:** After attending this presentation, attendees will be able to assess the utility of various methods of physical characterization and the ability of these characteristics to differentiate between batches of illicit tablets. This presentation will highlight the various physical metrics by which illicit tablets can be measured and compared, including colorimetric, microscopy, gravimetric, and caliper measurements.

**Impact Statement:** This presentation will impact the forensic science community by contributing to the overall understanding of batches of fentanyl tablets entering the United States from the Southwestern border. Further, this presentation will highlight the advantages and limitations associated with using physical measurements to differentiate fentanyl batches seized at various ports of entry.

Fentanyl is increasingly infiltrating the United States via the Southwest border with federal agencies and independent crime watch organizations reporting Mexico has surpassed China as the primary exporter of fentanyl to the United States. Seizures of fentanyl along the United States-Mexico border are often disguised as oxycodone pharmaceuticals, appearing as counterfeit round blue tablets monogrammed “M 30.”

This study aims to evaluate whether physical measurements, such as size, monogramming, and color could be used as a diagnostic tool to differentiate exhibits of fentanyl-containing tablets monogrammed “M 30” seized by Customs and Border Protection along the United States-Mexico border.

Over 90 exhibits containing 30–50 tablets per exhibit were received from three ports of entry. Up to 30 total tablets per exhibit were characterized using the following methods of analysis: photographs were taken using an iPhone® 13, with Red-Green-Blue (RGB) color code measurements recorded using ImageJ software; pill width and diameter were taken using General® UltraTech® No.147 calipers; weight was recorded using a Mettler Toledo® XPR105 microbalance; and monogram measurements of the “M” diagonal length and “O” height were recorded using a Zarlenco MiScope®-MP3 microscope.

A total of 540 intact tablets from 23 exhibits were statistically analyzed to assess the discriminative potential of the above methods. Descriptive statistics, including the Coefficient of Variation (%CV), were generated for each parameter, and normality tests were performed on each exhibit. Shapiro-Wilk normality tests showed the data sets were not normally distributed, prompting a non-parametric Kruskal-Wallis Analysis of Variance (ANOVA) test to determine whether significant differences existed between exhibits. When the Kruskal-Wallis null hypothesis was rejected (meaning significant differences of the median existed between at least two exhibits), a Dunn’s test, which is a post-hoc analysis for non-parametric hypothesis testing, determined whether all possible inter-exhibit pairwise comparisons were statistically different from one another at a 95% confidence interval. To compare the utility of the tested parameters in future multivariate modeling, the percentage of distinguishable exhibits from the population by each test was calculated. The proportion of differences to total pairwise comparisons are shown in Table 1. This serves as a direct indicator for how discriminatory a method of analysis is for the population of tested tablets.

**Table 1. Summary of descriptive statistics and Kruskal-Wallis/Dunn’s test pairwise comparisons for each parameter**

Parameter	N	CV (%)	Total pairwise comparisons	Number of pairwise comparisons significantly different at 95% confidence	Proportion of total
Diameter	466	0.3%	231	49	21.2%
Width	466	4.3%	231	39	16.9%
Weight	525	7.1%	253	23	9.1%
R	525	7.7%	253	100	39.5%
G	525	4.7%	253	93	36.8%
B	525	4.9%	253	88	34.8%
“O” Height	297	5.6%	136	51	37.5%
“M” Diagonal Length	297	7.1%	136	33	24.3%

Measurements of tablet diameter had a %CV less than 1% for the entire population, indicating little difference in the sample population. Tablet width and weight appear to be more varied than diameter but still hold the two lowest proportion of differences. RGB color code measurements boast a collection of relatively high proportion of differences and from data visualization showed better association within exhibits and discrimination between exhibits. Monogram measurements had a combination of high proportion of differences and %CV, indicating these measurements hold some discriminatory power.

In conclusion, this study suggests that color and monogram measurements may serve as effective diagnostic tools to differentiate exhibits of fentanyl tablets, whereas physical measurements such as diameter, width, and weight did not provide as much discriminatory/associative power. Based on these findings, original workflows were optimized to prioritize methods that provide the most discriminatory data. Additional tablets from new and previously analyzed ports of entry should be analyzed to confirm these findings.

**B63 The Detection of Airborne Methamphetamine in Contaminated Properties and Vehicles Using Active Air Sampling With Liquid Chromatography/Mass Spectrometry (LC/MS)**

Gemma L. Kerry\*, Flinders University, Bedford Park, South Australia, Australia; Emma J. Kuhn, Flinders University, Adelaide, South Australia, Australia; Jackie Wright, Flinders University, Carlingford Court, New South Wales, Australia; Kirstin E. Ross, Flinders University, Bedford Park, South Australia, Australia; Stewart Walker, Flinders University, Adelaide, South Australia, Australia

---

**Learning Overview:** After attending this presentation, attendees will better understand the importance of using supplementary methods of surface wipe sampling and air sampling to detect methamphetamine in contaminated sites.

**Impact Statement:** This presentation will impact the forensic science community by demonstrating the importance of using air sampling as a supplementary method to surface wipe sampling for determining overall methamphetamine contamination within properties and vehicles. This is important to help limit methamphetamine exposure to innocent individuals.

Clandestine manufacture and smoking of methamphetamine results in contamination of properties and vehicles. Individuals are then at risk of Third-Hand Exposure to Methamphetamine (THEM) through dermal adsorption, ingestion, and inhalation contributing to associated adverse health effects, including headaches, respiratory problems, skin irritations, and behavioral effects.<sup>1,2</sup> Additionally, the detection of methamphetamine in a property could lead to eviction of the innocent renter or significant costs and anxiety for innocent buyers of such a property. This presentation will illustrate the importance of using additional techniques to assess the environmental risks to people from previously contaminated places to ensure justice for all.

Currently, contaminated sites are quantitatively tested for methamphetamine using a surface wipe sampling method coupled with analysis commonly by Gas or Liquid Chromatography/Mass Spectrometry (GC or LC/MS).<sup>3</sup> Even after remediation or discarding contents, the property may still be contaminated with methamphetamine and other hazardous chemicals.<sup>4,5</sup> In particular, airborne methamphetamine that has sorbed and deposited onto and adsorbed into surfaces could be released in the air in the particulate or vapor phase, leading to inhalation exposure.<sup>6,7</sup>

Active air monitoring of properties and vehicles with suspected or known methamphetamine contamination was undertaken using air sampling pumps (1/min air flow rate) connected to sorbent tubes with either XAD®-2 sorbent or activated coconut charcoal. After sampling, the sorbent tubes were liquid extracted with 0.1M sulfuric acid with methamphetamine-d<sub>5</sub> deuterated internal standard. Blank and field-blank sorbent tubes were also analyzed. LC/MS analysis was performed using a single quadrupole mass spectrometer with positive Ion Electrospray Ionization (ESI) at a limit of detection of 0.02µg/sample methamphetamine. Higher methamphetamine concentrations were detected using the XAD®-2 sorbent tubes compared with activated charcoal sorbent tubes from the same sampling environment, either indicating more absorption onto XAD®-2 or more retention onto the charcoal. Comparisons between surface wipe samples and air samples will be presented. Results indicated that methamphetamine was detected from properties and from vehicles in the range of 0.3 to 2µg/m<sup>3</sup>. An adult breathing 2µg/m<sup>3</sup> at a normal breath rate of 6L/min would lead to an exposure of 0.72µg/hour.

Active air monitoring with sorbent tubes can be used to extract airborne methamphetamine to consider inhalation hazards that are overlooked when only surface wipe sampling contaminated media. It is recommended that active air sampling is coupled with surface wipe sampling to provide information on the extent of overall methamphetamine contamination in areas where exposure occurs and to assess the extent of third-hand exposure to innocent individuals.

**B65 The Development of a Novel Nanocomposite Using Polypyrrole and Single-Walled Carbon Nanotubes for Headspace Solid Phase Microextraction of Alkanes in Forensic Ignitable Liquid Analysis**

Ting-Yu Huang\*, Sam Houston State University, Huntsville, TX; Jorn Yu, Sam Houston State University, Huntsville, TX

**Learning Overview:** After attending this presentation, attendees will understand how to perform electrochemical preparation of nanomaterial-based Solid Phase Microextraction (SPME) fibers. The attendees will also learn about Ignitable Liquids (ILs).

**Impact Statement:** While Carbon Nanotubes (CNTs) have been widely tested, this study will impact the forensic science community by presenting the potential of microscale solid phase concentration combining CNTs and conductive polymers for forensic IL analysis. The new coating provides forensic analysts with an alternative opportunity in the SPME process.

In incendiary structure fires, ILs have been identified for more than 35% of cases involving civilian deaths.<sup>1</sup> The identification of the presence of an IL at a fire scene provides important investigative intelligence. Prior to Gas Chromatography/Mass Spectrometry (GC/MS) analysis, it is essential to pre-concentrate traces of an IL recovered from the scene. Headspace SPME is one of the standards for sample extraction in forensic IL analysis, as SPME gives simple and speedy extraction of volatile organic compounds from IL samples.<sup>2</sup> The performance of SPME relies on the distribution equilibrium between the analytes and the fiber coating. The fiber coating also decides the extraction capacity, stability, and affinity of SPME toward the target compounds in ILs.<sup>3</sup>

Carbon Nanotubes (CNTs) have gained increasing attention from the scientific community since their discovery in 1991.<sup>4</sup> Except for their thermal stability, the CNTs have a large surface area that improves extraction efficiency. The CNT's unique structure, including  $\pi$ - $\pi$  stacking, van der Waals forces, and hydrogen bonding, assists hydrophobic interactions with organic molecules.<sup>4</sup> Those characteristics make CNTs potential SPME sorbent materials for extracting IL samples.

This work aimed to prepare a CNTs-based nanocomposite for SPME using an electropolymerization technique and evaluate its characteristics in extracting saturated alkanes, which are commonly found compounds in ILs via GC/MS. The pre-polymerization solution was comprised of single-walled CNTs as adsorbents, pyrrole as a monomer, 0.2M Sodium Dodecyl Sulfate (SDS) as a surfactant, and 1M sodium chloride (NaCl) as electrolytes. The SPME nanocomposite was synthesized electrochemically via *in situ* polymerization from the solution and directly deposited on the stainless-steel wire using cyclic voltammetry. Parameters influencing the formation of the coating, including the amount of CNTs, pyrrole, and the bath voltage, were optimized. C8-C22 saturated alkanes reference material was utilized to test the proposed CNT-SPME fiber. Diesel fuel, one of the most-used ILs, was chosen as a real sample to validate the extraction capability of the CNT-SPME fiber.<sup>5</sup>

Results demonstrated the optimized coating procedure for the CNT-SPME fiber as follows: 8mg CNTs were ultrasonically dispersed in 6mL SDS for 5min, then 200 $\mu$ L pyrrole in 6mL NaCl was added and sonicated for 30min. The bath voltage applied to coat the stainless-steel wire with the sorbent composite was determined as 0.8V. The Relative Standard Deviation (RSD) of the yielded chromatographic peak areas of the analytes in the reference material was under 1%. The CNT-SPME fiber was applied to extract neat diesel fuel samples. The characteristic pattern of distillates and major ions in the extracted ion profiles for the target compounds in the diesel fuel could all be identified. The detection limit was 0.01 $\mu$ g mL<sup>-1</sup>, and the RSDs were under 6%.

To conclude, the CNTs could be electrochemically deposited onto a SPME fiber and ensure the sampling and analysis of alkane compounds in IL samples. The significance of this study was to demonstrate an easily made and sensitive SPME sorbent coating to facilitate ILs analysis. The selectivity offered by the CNT-SPME fibers could also improve the extraction efficiency of the SPME process.

**B66 Enhanced Ignitable Liquid and Substrate Database Functionality for Improved Casework and Research**

*Michael E. Sigman\*, University of Central Florida, Orlando, FL; Nikhil Prakash\*, University of Central Florida, Orlando, FL; Mary R. Williams, University of Central Florida, Orlando, FL; Larry Tang, University of Central Florida, Orlando, FL*

---

**Learning Overview:** This presentation will cover enhancements to the Ignitable Liquid and Substrate Databases that will facilitate casework. After attending this presentation, attendees will understand enhancements to these databases and how to utilize the databases to better determine the presence of ignitable liquid residues in fire debris samples.

**Impact Statement:** This presentation will impact the forensic science community by providing insight into new features of these two heavily used databases, which will make the analysis of casework data easier and more visual.

Fire debris analysis relies heavily on visual pattern recognition.<sup>1</sup> Current implementation of the Ignitable Liquids Reference Collection (ILRC) and Substrate Database does not promote direct comparisons of ignitable liquid and substrate pyrolysis chromatograms. In the current implementation, records must be viewed independently in separate browsers or within two tabs of the same browser. The new implementation of the databases will allow for side-by-side visualization of returns from independent searches of the two databases. All the current search capabilities will remain in the enhanced website. The returns from the two searches will be independently scrollable to allow side-by-side comparison of the ignitable liquid and substrate pyrolysis chromatograms.

An additional database will be created based on random in-silico creation of computational fire debris samples. The in-silico samples will contain a single ignitable liquid mixed with contributions from up to three pyrolyzed substrates randomly selected from the Substrate Database. Ignitable liquid weathering will utilize numerical kinetic-based evaporation models from Smith's laboratory, rather than relying on the limited number of weathered samples in the ILRC.<sup>2</sup> The new database will be substantially larger than the existing databases, with a current target of 100,000 entries. The database will be searchable based on products, carbon range, ratio of ignitable liquid to substrate, ignitable liquid American Society for Testing and Materials (ASTM) class, fraction of the ignitable liquid lost to weathering, and other parameters. The in-silico database will provide direct visualization of computational fire debris and eliminate the need for analysts to mentally merge two chromatograms to imagine the resulting chromatographic profile. The in-silico data will also be available for download as a standard set of total ion chromatograms and total ion spectra for machine learning research.

This presentation will provide an overview of the envisioned implementation of the databases as a web site plugin with improved security to serve the community into the future with minimal interruptions in service.

---

**B67 An Estimation of Dyeing Methods From Wool Single Fibers by Nanobeam X-Ray Fluorescence Imaging Utilizing Synchrotron Radiation**

Yoshinori Nishiwaki\*, Kochi University, Kochi, Japan

---

**Learning Overview:** The goal of this presentation is to demonstrate the use of synchrotron radiation X-rays to show metallic elemental information of dyes in a single wool fiber, which could not be determined by conventional fiber analysis. After attending this presentation, attendees will better understand the importance of collecting these evidence samples, the utility of metallic elements in dyes for dissimilarity identification, and the importance of analyzing dyes in single fibers.

**Impact Statement:** This presentation will impact the forensic science community by demonstrating the usefulness of information on the distribution of metal elements in dyes, which has yet to be focused on in conventional fiber analysis. Fiber analysts in forensic science will have an opportunity to recognize the importance of this information.

Single wool fiber is an important evidence sample in forensic investigations. Differentiating single wool fibers is complex, and there are reports of color analysis by microspectroscopy and analysis of organic components by Thin-Layer Chromatography (TLC) and Liquid Chromatography/Mass Spectrometry (LC/MS).<sup>1-3</sup> Wool fibers have a bilateral structure consisting of a paracortex with a high cystine concentration and high hydrophobic group content and an ortho cortex with a low cystine concentration and high hydrophilic group content attached together. Two dyeing methods are used to dye wool fibers for clothing: acid-mordant dyeing and metal-containing dyeing, using chromium or cobalt. If the distribution of dye-derived elements and wool's intrinsic elements in a single fiber could be measured, it would be useful for discriminating different wool fibers. Furthermore, forensic purposes would be beneficial if the dyeing method could be inferred from a single wool fiber.

In this study, nanobeam X-Ray Fluorescence (XRF) imaging and X-ray Absorption Fine Structure (XAFS) analysis using high-brilliance synchrotron radiation were performed on cross-sectional samples of single wool fibers prepared with a microtome to estimate the dyeing method from single wool fibers. The samples were wool fibers supplied by the fiber manufacturer with clear information on the dyeing method. Synchrotron radiation measurements were performed at SPring-8, a large synchrotron radiation facility where synchrotron radiation X-rays with a beam diameter of 100nm are available. As a result of XRF measurement, S, Ca, Cr, Co, and Zn were detected. Based on sulfur concentration differences, imaging measurements visualized the paracortex and ortho cortex areas. In chromium-containing dyeing, Cr was concentrated in the ortho cortex and cuticle but not in the central and paracortex. In chromium mordant dyeing, Cr was distributed throughout the wool cross-section but was concentrated in the paracortex and cell nucleus residue. The elemental distribution corresponding to the bilateral structure was successfully visualized from a cross-sectional section of a single wool fiber. The dyeing method may be estimated from the distribution of elements in the single fibers.

**B68 How to Minimize the Presence of Drug Residues on the Exterior of Drug Evidence Packaging After Analysis**

*Elizabeth Robinson\*, National Institute of Standards and Technology, Gaithersburg, MD; Edward Sisco, National Institute of Standards and Technology, Gaithersburg, MD; Rebecca Mead, Forensic Quality Manager, Vermont Forensic Laboratory, Waterbury, VT*

---

**Learning Overview:** After attending this presentation, attendees will understand how drug residues can be transferred onto evidence packaging as a result of common analysis protocols and what steps can be taken to minimize this phenomenon. Minimizing drug residues can be important in reducing potential cross-contamination and minimizing exposure risks for personnel handling sealed evidence.

**Impact Statement:** This presentation will impact the forensic science community by providing key information on how minor adjustments to the repackaging process, after drug evidence analysis, can reduce the spread of drug residue to the exterior of the packaging. Reducing the residue transfer will result in safer handling of drug evidence across the entire evidence handling process, from evidence handling technicians to crime scene technicians to submitting officers.

With the emergence of more potent drugs and novel psychoactive substances, the potential exposure risk to personnel who handle drug evidence is also increasing.<sup>1</sup> These exposure concerns are typically targeted at forensic chemists, due to their need to handle the actual evidence. However, there are a number of other personnel who handle the packaged drug evidence, typically without any protective equipment, and could possibly be exposed if the exterior of the packaging contained sufficient residue. Previous studies have shown that drug residues can be found on nearly every surface in a drug chemistry laboratory and can frequently be found in evidence receiving areas and police stations.<sup>2-4</sup> It has been demonstrated that the process of opening and analyzing drug evidence of a case in a forensic laboratory increases the level of drug particulate on the exterior of the drug evidence packaging, especially when repackaging.<sup>5</sup> These observations prompted the current effort to identify ways to reduce the spread of drug particulate during the evidence repackaging process.

This work investigated how minor adjustments to the evidence repackaging process could affect the level of drug particulate on the exterior of evidence packaging. Prior work showed higher residue levels resulted from reusing the original evidence packaging, therefore repackaging into a new Kapak<sup>®</sup> bag was examined. Four repackaging processes were investigated using real casework (25 cases each), including: repackaging drug evidence into a new Kapak<sup>®</sup> bag (normal), changing gloves prior to repackaging evidence into a new Kapak<sup>®</sup> bag, repackaging into a new Kapak<sup>®</sup> bag on a freshly laid underlying surface, such as butcher paper, and changing both the gloves and the surface prior to repackaging into a new Kapak<sup>®</sup> bag. Both the original packaging (pre-analysis) and the new packaging (post-analysis) were sampled using wipe sampling to understand, qualitatively and quantitatively, how the drug residue profile changed.

Qualitative analysis was completed by Direct Analysis in Real Time Mass Spectrometry (DART<sup>®</sup>-MS) on the wipe extract and screened against an in-house built library of over 1,200 compounds. This data was used to identify which drug residues were present on the original packaging, to determine if those identifications were consistent with the drug contents, and to evaluate if the same, or different, drugs were detected on the exterior of the new Kapak<sup>®</sup> after repackaging.

Quantitative analysis was completed by Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS). Measurements for 30 drugs were obtained. The quantitative data was used to determine the effect the different repackaging processes had on the amount of drug residue present on the packaging relative to other processes and relative to the amount present on the original packaging.

Quantitative data shows that, after repackaging, single to tens of micrograms of drug residue is present on their exterior surface, consistent with previous studies. The data also suggests that changing gloves prior to repackaging evidence can result in lowering the amount of drug residue that is transferred. For example, changing gloves reduced the likelihood of transferring drug residue onto the repackaging from 83% to 50%. This information is also being combined with qualitative visualization data using mock case samples that can better convey these results. A discussion on how the results of this work can be combined with previous efforts to understand particulate transfer during the opening and handling of drug evidence to reduce drug background and minimize exposure or cross-contamination concerns will also be provided.

**B69 The Identification and Classification of Major Cannabinoids Using Raman Microscopy, Chemometrics, and a Novel Artificial Intelligence Approach**

*John Hugo Laetsch III\*, Sam Houston State University, Katy, TX; Jose Grijalva, City of Phoenix, Phoenix, AZ; Ting-Yu Huang, Sam Houston State University, Huntsville, TX; Patrick Buzzini, Sam Houston State University, Huntsville, TX; Jorn Yu, Sam Houston State University, Huntsville, TX; J. Tyler Davidson, Sam Houston State University, Conroe, TX; Geraldine Monjardez, Sam Houston State University, Huntsville, TX*

---

**Learning Overview:** After attending this presentation, attendees will gain an understanding of the capability of Raman microscopy supported by traditional chemometrics and a novel Artificial Intelligence (AI) approach using the transfer learning technique to identify major cannabinoids.

**Impact Statement:** This presentation will impact the forensic science community by demonstrating an accurate, fast, simple, and automated AI approach to classify cannabinoids collected with Raman spectroscopy and a comparison to the results with a more traditional chemometric approach.

With the rise in the prominence of cannabis products and due to their widespread availability and varying legal status, there is an increased emphasis on the differentiation of cannabinoids present within cannabis. Various analytical techniques, including micro-Raman spectroscopy, have been applied to the detection of common cannabinoids. While chemometrics, such as Principal Component Analysis (PCA) followed by Linear Discriminant Analysis (LDA), have traditionally been used to classify forensic samples following their acquisition with Raman spectroscopy, AI approaches have become a more popular research topic. In this study, PCA-LDA and a novel AI approach were both applied to differentiate cannabinoids collected with Raman microscopy.

Seven of the most abundant cannabinoids naturally found in cannabis were selected for analysis, including  $\Delta^9$ -Tetrahydrocannabinol ( $\Delta^9$ -THC), its acidic precursor Tetrahydrocannabinolic Acid (THCA), Cannabidiol (CBD), its acidic precursor Cannabidiolic Acid (CBDA), Cannabigerol (CBG), Cannabichromene (CBC), and Cannabinol (CBN). The cannabinoids were analyzed as crystallized residue following the deposition and evaporation of each cannabinoid onto a microscope slide covered with aluminum foil to avoid interference. The solvent was evaporated at room temperature, and a 785nm laser was focused on the solid, crystallized residue to collect 34 spectra for each cannabinoid. The Raman microscope was used to determine the optimal sample area to collect Raman spectra based on the drying patterns of the cannabinoids. For the chemometrics, the raw data were baseline corrected. PCA was implemented to visualize and evaluate the variation of the data. The chemometric model was developed using LDA. In comparison, 238 Raman spectra were used to create the AI model using the transfer learning technique. Each Raman spectrum was converted into a two-dimensional image (i.e., a scalogram, a time-frequency representation produced from Continuous Wavelet Transform [CWT]). To evaluate the result of the training set, a new data set containing 70 Raman spectra (10 spectra per cannabinoid) was collected and analyzed separately.

The microscopy showed that the optimal sample area was located on the center of the dried residue for the nonacidic cannabinoids and along the edges of the dried residue for the acidic cannabinoids. The spectra exhibited distinct spectral patterns and peaks corroborated by vibrational bands in published literature for all cannabinoids. 93% of the variation across all seven cannabinoids was accounted for with the first principal component. The LDA model was 96% accurate in classifying the standard cannabinoids to their respective grouping. The developed model experienced the most difficulty with classifying THCA; the model misclassified three THCA spectra as CBC, CBG, and CBN. For the AI, the model training was conducted in less than 10min in a Graphical Processing Unit (GPU) environment. All scalograms were successfully classified into respective cannabinoid classes, with 100% classification accuracy. The average prediction probability for correct classification was 0.9931. The classification outcome provided by the AI model included both prediction labels and probability, which provided a comprehensive evaluation of the samples. The accurate, fast, simple, and automated AI model shows promise for cannabinoid differentiation.

**B70 One Gunshot Is Not Enough: A Case of Suicide by Double Gunshot Wound to the Head and a Literature Review**

*Eleonora Mezzetti\*, Institute of Legal Medicine, Dept. of Surgical Pathology, Medical, Molecular and Critical Area, University of Pisa, Pisa, Toscana, Italy; Federica Spina, Institute of Legal Medicine, Dept. of Surgical Pathology, Medical, Molecular and Critical Area, University of Pisa, Pisa, Toscana, Italy; Laura Panata, Institute of Legal Medicine, University of Perugia, Perugia, Umbria, Italy; Isabella Mercurio, Institute of Legal Medicine, University of Perugia, Perugia, Umbria, Italy; Massimo Lancia, Institute of Legal Medicine, University of Perugia, Perugia, Umbria, Italy; Marco Di Paolo, University of Pisa, Pisa, Toscana, Italy*

---

**Learning Overview:** Suicidal gunshots involving the use of firearms are not an uncommon occurrence. Typically, the preferred locations include the head, particularly the temples, or the oral cavity, leading to an outcome that is usually fatal. Despite that, descriptions of cases involving subjects committing suicide by inflicting multiple gunshots to the head have been reported in the scientific literature. The goal of this presentation is to present an interesting case of suicide involving two gunshot wounds to the head in which the trajectories were reconstructed with the help of radiological techniques.

**Impact Statement:** This presentation will impact the forensic science community by sharing an intriguing forensic case, along with a concise literature review, that will demonstrate to attendees that death may not be instant, even in instances of gunshot wounds to the head. Such a scenario poses a challenge in differentiating between suicide and homicide. In this context, the elaboration of autptic, radiological, and circumstantial data becomes crucial for reconstructing the dynamics of the events.

An 81-year-old man was found dead, lying on his bedroom bed, holding a Smith & Wesson® revolver. That night, the man's neighbors reported hearing multiple gunshots from his home. During the forensic examination, two gunshot wounds were documented: the first at the chin, and the second in the palate, without any other injury; however, at the crime scene examination, three bullets for five shells were found. The police found out that the weapon was regularly possessed.

Because of the peculiarity of the case, further investigations were ordered. The X-ray examination confirmed the presence of two metallic objects at the cranial level: the first in the nasal cavities and the second in the occipital fossa. Autopsy investigations confirmed a near-contact gunshot wound (entry hole) on the chin and identified a second entry hole in the hard palate. The black powder soot on the upper lip indicated that the second shot had been fired near the oral cavity. No signs attributable to a struggle were documented. The trajectories of the two shots were thus reconstructed: the first, a near-contact gunshot, was deflagrated close to the chin, crossed the palate, and ended in the nasal cavity; the second gunshot, which proved fatal, was deflagrated near the oral cavity, crossing the posterior portion of the palate, and ending in the posterior cranial fossa.

The case's successful resolution was only made possible by meticulously analyzing all the collected elements, concluding that the man had first shot himself at the chin level without hitting vital areas. Subsequently, he deflated a second shot inside the oral cavity.

Multiple self-inflicted gunshot wounds to the head or other sites are an uncommon occurrence and a real challenge to the forensic pathologist in determining the manner of death. The scientific literature offers various examples of subjects who committed suicide by multiple gunshots—for example, Jacob et al. exposed two cases of suicide by multiple gunshots to the head: the first victim exploded the first shot at the oral cavity, causing modest damage to his left optic nerve and frontal lobe.<sup>1</sup> Despite his injuries, the man could still drive his car home, where he deflagrated a second shot at the level of his right temple, only to die two days later. The second victim was a 58-year-old man found dead on his bed. Reconstruction of the case revealed that the first shot had gone through the tongue and slightly damaged the second cervical vertebral body.

In contrast, the second shot, fired at the left temple level and proving fatal, had damaged the temporal lobe. Also, Introna et al. described nine cases of multiple-shot suicides, showing that in these cases, the most common site of firing was the left hemithorax or precordial region.<sup>2</sup> Many other authors collected numerous cases of gunshots to the head without immediate incapacitation.<sup>3,4</sup>

In essence, a “lucid interval” following a deflagrated gunshot wound to the cranio-cephalic district is a possible occurrence, especially when combined with the lack of impairment of vital areas and the low caliber of the weapon. In the present case, the low caliber of the weapon and the fact that the first shot did not hit the cranial encephalic district allowed the man to deflagrate the second shot. In these cases, however, integration with the circumstantial data remains crucial as a decisive factor for accurately interpreting the dynamics.

---

**B71 The Optimization of Sample Preparation Procedures for the Determination of  $\Delta^9$ -THC and Its Isomers in Seized Cannabis Oils, Concentrates, and Vapes by LC-PDA**

*Walter B. Wilson\*, National Institute of Standard and Technology, Gaithersburg, MD*

---

**Learning Overview:** After attending this presentation, attendees will have learned about the sample preparation procedures, a Liquid Chromatography-Photodiode Array (LC-PDA) method at the National Institute of Standards and Technology (NIST), and inaccuracies of product labels for  $\Delta^9$ -Tetrahydrocannabinol ( $\Delta^9$ -THC),  $\Delta^8$ -Tetrahydrocannabinol ( $\Delta^8$ -THC), and  $\Delta^{10}$ -Tetrahydrocannabinol ( $\Delta^{10}$ -THC) in seized cannabis vapes, oils, and concentrates.

**Impact Statement:** This presentation will impact the forensic science community by providing a summary of sample preparation, cleanup, and analytical methods that NIST has developed for transfer to forensic laboratories in distinguishing seized cannabis vapes, oils, and concentrates as either legal hemp or illegal marijuana. This presentation will help inform the forensic science community of how product labels are inaccurate for  $\Delta^9$ -THC,  $\Delta^8$ -THC, and  $\Delta^{10}$ -THC in these type of cannabis products, while also gaining knowledge of some challenges potentially encountered in these laboratories.

In the 2018 Farm Bill, hemp was defined as cannabis containing 0.3 % or less of decarboxylated  $\Delta^9$ -THC and removed hemp from the United States Drug Enforcement Agency controlled substances list. As a result, the need for forensic laboratories to have access to reliable analytical methods for differentiation between hemp and marijuana in seized cannabis samples increased significantly. Before the new legislation, forensic laboratories were dependent on qualitative measurements from Gas Chromatography with Mass Spectrometry (GC/MS) for  $\Delta^9$ -THC identification in cannabis oils, concentrates, and vapes. Forensic laboratories have been switching from GC/MS to LC-PDA because of incomplete degradation of acidic cannabinoids to neutral cannabinoids in the GC inlet and LC-PDA permits them to be measured separately. In response, NIST developed a *Cannabis* Research Program to help provide forensic laboratories the necessary tools to quantitatively measure  $\Delta^9$ -THC, its isomeric compounds (e.g.,  $\Delta^8$ -THC and  $\Delta^{10}$ -THC), and its acidic precursor Tetrahydrocannabinolic Acid (THCA) permitting the calculation of a total  $\Delta^9$ -THC mass fractions (%).

This presentation will focus on an optimization of a sample preparation procedure previously published at NIST for the determination of  $\Delta^9$ -THC, THCA, and total  $\Delta^9$ -THC in commercial hemp oil samples by LC-PDA.<sup>1</sup> Approximately 0.5g of hemp oil samples were mixed with 25mL of methanol and shaken for 15min. The methanolic extract sample was further diluted with methanol through a 10-fold and 100-fold sample dilutions prior to LC-PDA analysis. The goal of the new research was to minimize the sample preparation time to make it more desirable to forensic laboratories and expand to include cannabis concentrates and vape solutions/cartridges. Data will be provided showing how the original sample preparation procedure was modified to include only 0.1g of sample, 5mL of methanol, and 1min of shaking. The new sample procedure was validated by a single laboratory at NIST for approximately 60 commercial and seized cannabis products. Product labels for the seized cannabis samples often included a THC mass fraction of 80% to 90%; however, in many cases the actual mass fractions of  $\Delta^9$ -THC were much less and its isomers (e.g.,  $\Delta^8$ -THC and  $\Delta^{10}$ -THC) were present at high levels. Additionally, significantly co-elution issues were observed at these high levels that will affect the accuracy of  $\Delta^9$ -THC measurements by forensic scientists.

---

**B73 Standards Development Activities in Human Forensic Biology**

*Jillian Conte\*, Peckville, PA*

---

**Learning Overview:** After attending this presentation, attendees will have a better understanding of the status of discipline-specific standards pertinent to the field of human forensic biology testing.

**Impact Statement:** This presentation will impact the forensic science community by creating greater awareness of standards development activities pertinent to human forensic biology, including serological and DNA testing. This presentation will also increase awareness regarding training, tools, and resources that support implementation, compliance monitoring, and broader understanding.

The Organization of Scientific Area Committees (OSAC) for Forensic Science was created to strengthen the nation's use of forensic science by promoting the use of discipline-specific forensic science standards. To this end, the OSAC drafts standards and best practice recommendations that are forwarded to Standards-Developing Organizations (SDOs), such as the Academy Standards Board (ASB), that further develop and publish them. The OSAC also reviews standards and recognizes them on the OSAC Registry, which serves as a central repository of high-quality, consensus-based, technically sound standards. The ASB approves consensus standards and best practice recommendations, including the revision, reaffirmation, or withdrawal of a document. This is done through consideration of comments, views, and objections collected during public comment periods.

During this presentation, updates related to standards development in human forensic biology testing will be discussed. These include: (1) recent standards that have been added to the OSAC Registry, (2) ASB New Work Products (NWP) that have been received from OSAC, (3) published standards from the ASB pending Registry approval process, and (4) documents currently being drafted by the Human Forensic Biology subcommittee of OSAC and those under development by the ASB.

Opportunities for supplemental training related to discipline-specific standards will be presented, as well as additional resources and tools designed to facilitate gap analysis, compliance monitoring, and outreach efforts. Information on implementation may also be shared with the attendees.

---

**B74 Human Factors in Forensic DNA Handbook Recommendations in Practice**

*Tiffany A. Roy\*, ForensicAid, LLC, West Palm Beach, FL; Sasha B. Colvin\*, ForensicAid, LLC, Riviera Beach, FL*

---

**Learning Overview:** After this presentation, attendees will understand the application of reporting and testimony recommendations in independent practice. They will also understand the rationale behind these recommendations and how their application intends to mitigate the possible harm from error and bias.

**Impact Statement:** This presentation will impact the forensic science community by not only serving to promote awareness of the recommendations, but also will serve to notify the DNA community of how current and past laboratory practice will be compared with the best practices described in the Human Factors in Forensic DNA Interpretation guidebook with a specific focus on forensic DNA testimony and reporting.

DNA analysis is critical to the success of the nation's criminal justice system. In fact, DNA left at a crime scene—referred to as trace DNA—is the most highly regarded type of forensic science evidence.

The examination of DNA evidence consists of a series of steps involving the comparison of a trace evidence DNA profile to a known DNA profile. During this process, DNA examiners must reach scientifically sound conclusions; they are also expected to produce records of the examination and, in some cases, present their conclusions—and the reasoning behind them—in court.

In recent years, the accuracy of DNA interpretation, especially as to mixtures of DNA, has been the subject of increased scrutiny, including from the President's Council of Advisors on Science and Technology Report on forensic sciences in 2015 and 2016. To help address this issue, the National Institute of Justice and the United States National Institute of Standards and Technology (NIST) convened an expert working group to do a scientific assessment of the effects of human factors on DNA analysis and interpretation to develop recommendations to reduce the risk of error.

The working group addressed issues ranging from the collection and preservation of DNA to courtroom testimony, and from laboratory design and equipment to emerging methods for assessing questions regarding how DNA came to be present on an item. In addition to an overview discussion of how human factors relate to all aspects of DNA examinations, this presentation will focus on human factors involved with conclusions expressed through reporting and testimony.

This presentation will include a practical demonstration of how these recommendations can be compared against casework documentation and testimony produced across the country by demonstrating actual testimony transcripts and reports that would flag against best practice. Forensic DNA reporting and testimony can be inspected by private consultants to determine compliance with and adherence to these recommendations to mitigate bias and error in forensic DNA testimony and reporting.

**B76 Processing Gun Crimes in NYC: How the Department of Forensic Biology Was Able to Meet a 30-Day Turnaround Time**

*Craig O. O'Connor\*, New York City Office of Chief Medical Examiner, New York, NY; Katey Nori, New York City Office of Chief Medical Examiner, New York, NY*

---

**Learning Overview:** This presentation will walk attendees through the approach employed at the New York City Office of Chief Medical Examiner's (OCME) Department of Forensic Biology for processing touch DNA from cases associated with gun crimes. Due to a city hall initiative to process gun crimes in an accelerated fashion from arrest to prosecution, the OCME's Forensic Biology laboratory needed to adjust its workflow to meet the testing time necessary to get results to the attorneys while keeping quality at the highest level. After attending this presentation, attendees will see the pre-testing protocols put in place as well as the adjustments to workflow introduced in the process, which may be of use in their own laboratories.

**Impact Statement:** This presentation will impact the forensic science community by showing how a large public laboratory is able to meet the demands of the criminal justice system, provide results to meet the accelerated time frame for bringing these cases through the court system, and lowering turnaround time from 60 days to 30 days in less than a year.

Timely reporting of DNA gun swab results is paramount to a robust criminal justice system. Criminal possession of a weapon has been a crime type that has been highlighted in New York City, and the submission of samples from guns has been on the rise over the past decade. As part of a 2018 City Hall initiative, "Project Fast Track," the criminal justice players have been tasked with bringing these cases from arrest to prosecution in an expedited fashion to help curb gun violence in New York City.<sup>1</sup> Law enforcement and the court system, with the help of crime labs, joined together to target the individuals driving gun violence. More recently, the Department of Forensic Biology was awarded \$2.5 million to establish the nation's first DNA gun crimes unit of its kind. The unit focused heavily on streamlining the workflow to establish a turnaround time (measured from receipt of evidence to distribution of the report) of under 30 days. Dedicated staff whose sole responsibility would be to process gun crime evidence were assigned to the unit as well as the hiring of 24 new staff. Additional upgrades were made to instrumentation, including more automation for DNA extractions and purifications. The workflow of these cases was adjusted to interpret and apply statistical analysis of complex mixtures only when a comparison sample was received. Other areas of the workflow were also adjusted to increase efficiency to meet this initiative.

This presentation will highlight the different modifications to workflow and challenges that had to be overcome to meet the needs of the criminal justice system in New York City. The presentation will also showcase how the unit was able to reduce the turnaround time processing gun cases from 60 days to 30 days in under a year without lowering quality or affecting other crime types.

**B77 A Global Survey on Activity-Level DNA Evaluative Reporting**

Devyn Pirtle\*, John Jay College of Criminal Justice, Long Island City, NY; Mechthild Prinz, John Jay College of Criminal Justice, New York, NY; Fabio Oldoni, Arcadia University, Glenside, PA

---

**Learning Overview:** By attending this presentation, attendees will gain an overview about the opinions and knowledge of global forensic practitioners regarding activity-level DNA evaluative reporting.

**Impact Statement:** This presentation will impact the forensic science community by providing an opportunity to discuss the current status of Activity-Level DNA evaluative Reporting (ALR).

For many criminal cases, the source of who deposited the DNA is not what the prosecutor and the defense are trying to dispute. In court, the question may be how the DNA was deposited at the crime scene and in response, Activity-Level Propositions (ALPs) can be used to evaluate the “How?”<sup>1</sup> Although some laboratories have begun to address ALP’s following guidelines, there is still a gap on the knowledge and opinions of activity-level reporting within forensic practitioners globally.<sup>2</sup> This study builds upon our previous study, which surveyed and gathered the opinions on ALP reporting from forensic DNA practitioners in the United States.<sup>3</sup>

To gather information about ALP reporting on a global perspective, a 21-question Qualtrics™ survey was sent out to 20 international forensic science organizations such as the Asian Forensic Science Network (AFSN), International Society of Forensic Genetics (ISFG), European Network of Forensic Sciences Institutes (ENFSI), and the Canadian Society of Forensic Science (CSFS) across Canada, South America, Europe, Asia, Africa, and Australia to disperse to their members via email. The survey reached thousands of members and contained open response and multiple-choice questions.

In total, there were 148 global respondents, of whom greater than 75% had over ten years of forensic scientist experience and the majority came from small labs. When asked about their understanding of ALR, over 80% of the respondents had basic knowledge about ALR and how it can be applied within the legal system. Another question asked who should provide input on possible activities leading to certain DNA results, and 56% of respondents answered that forensic expert witnesses should be providing input, 19% thought this should be the judge, 15% the prosecution, 9% the defense. Moreover, 88% of participants agree that having a formalized objective approach would help testimonies in court. Participants mentioned many obstacles to ALR implementation (e.g., lack of training and resources for the courts, or lack of pertinent case and scientific information), but 48% believe that their countries would be moderately to very likely to legally accept ALR. Twenty-eight percent considered this moderately to very unlikely. When asked about what is needed to introduce ALR in a crime laboratory, the three main points were: (1) training of laboratory scientists and the courts, (2) more research on realistic activity scenarios, and (3) established protocols with standardized criteria.

The survey clearly points to the need for a formalized and universal approach to ALR. Future research should also focus on how to properly educate and effectively communicate the information required for DNA ALP reporting between forensic laboratories and the legal system.

**B78 An Investigation of Handling Time on the Deposition and Persistence of Trace DNA in Pickpocket Scenarios**

*Lauren Hoopes\*, Arcadia University, Glenside, PA; Tiffany A. Kreidler, Arcadia University, Drexel Hill, PA; Bas Kokshoorn, Netherlands Forensic Institute/Amsterdam University of Applied Sciences, The Hague, MP, Netherlands; Fabio Oldoni, Arcadia University, Glenside, PA*

---

**Learning Overview:** After attending this presentation, attendees will have a better understanding of how multiple individuals that handled/wore the same object for different durations of time impact the relative percent DNA contribution to the overall Short Tandem Repeat (STR) profile.

**Impact Statement:** This presentation will impact the forensic science community by investigating the deposition and persistence of object users' DNA on items commonly encountered in pickpocketing crimes. This presentation will provide insight to aid investigators in determining the potential of detecting an individual's DNA profile when trace DNA is collected from evidentiary items with different substrate types that may have been handled by multiple individuals.

Trace DNA, also known as "touch" DNA, is a crucial piece of evidence found at crime scenes and is latent DNA traces that are found on an object or individual through direct or indirect contact.<sup>1</sup> Trace DNA samples are challenging due to the low amount of DNA present in the sample and the presence of multiple donors. Evidentiary items are collected from the scene of a pickpocketing crime and are submitted to crime laboratories for DNA testing, where Short Tandem Repeat (STR) profiles are uploaded to the Combined DNA Index System (CODIS) database to potentially match an individual's profile. This study was designed to simulate pickpocket crimes and investigate the relative contribution of DNA recovered from objects handled by a primary and secondary user for varying time durations.

A total of three simulations were designed, and nine pairs of participants (4 males and 11 females) were recruited to act as the primary or secondary handler of the objects with different substrate types. The objects used in each of the three simulations included a pair of sunglasses (plastic), a credit card (plastic), a money clip (metal), and a wallet (synthetic leather). In each of the three simulations, the primary user handled/wore the object for 40 minutes each day for four consecutive days. The second user handled/wore the object within 24 hours after the primary handler for 1, 3, and 20 minute(s) in the three separate simulations. A reference buccal sample was collected from all participants and lab personnel. Trace samples were collected using the double swab method, extracted using the QIAshredder®/QIAamp®, quantified using the Quantifiler® Trio Quantification Kit™ on a QuantStudio Real-Time PCR system, and amplified using the GlobalFiler® Amplification Kit. The STR fragments were separated using the SeqStudio™ Genetic Analyzer and the STR profiles were analyzed using GeneMapper® ID-X Software. Data analysis was performed to determine the relative percent DNA contribution of the primary handler, secondary handler, and extraneous DNA to the overall STR profile.

Overall, 72 trace DNA samples collected from the sunglasses, wallet, money clip, and credit card from the three simulations were analyzed. The major contributor in the mixed STR profiles in the first simulation was the primary user with an average of 67% relative percent DNA contribution for both the sunglasses and wallet and the secondary user with an average of 55% and 50% for the credit cards and money clips, respectively. The major contributor in the mixed STR profiles for the second simulation was the secondary handler with an average of 49%, 51%, 68%, and 74% relative percent DNA contribution for the wallet, sunglasses, money clip, and credit card, respectively. In the third simulation, the major contributor in the STR profiles for all objects was the primary handler with an average of 53% relative percent contribution for the wallet and the secondary handler with an average of 71%, 81%, and 89% for the sunglasses, money clip, and credit card, respectively. Extraneous DNA was detected on all trace samples analyzed with an average relative percent contribution ranging from 2–8% for all objects.

In conclusion, the relative percent DNA contribution of the secondary handler increases as the handling time increases, as reported in previous studies.<sup>1,2</sup> It was also found that substrate type of the object handled by two individuals affects the DNA persistence on an object. The major contributor for porous substrates tends to be the primary user, and the major contributor for non-porous substrates tends to be the secondary user.

**B79 An Evaluation of Transfer, Persistence, and Recovery of Touch DNA From Mobile Phones**

Ashley J. Moo-Choy\*, University of Toronto, Ajax, ON, Canada; Jamie E. McGregor, University of Toronto, Mississauga, ON, Canada; Nicole Novroski, University of Toronto, Mississauga, ON, Canada

---

**Learning Overview:** This presentation will demonstrate empirically generated data regarding DNA transfer and persistence involving mobile phones. After attending this presentation, attendees will understand how information on DNA quality and quantity as a result of specific activities can be used to provide statistical inferences for propositions in forensic casework.

**Impact Statement:** This presentation will impact the forensic science community by demonstrating the expansion of available literature in Transfer, Persistence, Prevalence, and Recovery (TPPR) of DNA for the purposes of commenting on activity level likelihood. Further, we seek to aid understanding of forensic biologists' capacity to comment on activity level propositions using published data.

Activity level evaluative reporting has become increasingly prevalent in scientific literature. While subsample level evaluation remains common, referring to propositions regarding who did or did not contribute to a DNA sample, assessment of propositions of how the DNA sample was deposited are being requested of forensic biologists.<sup>1</sup> Namely, researchers are now striving to expand the limited body of literature regarding activities for the purpose of making inferences regarding likelihood of propositions.<sup>2</sup> Studies involving TPPR of DNA in defined scenarios using specific items are essential to accurately assigning likelihood to the relevant hypotheses.<sup>3</sup> Our study presents an initial evaluation of quantifying DNA on mobile phones in scenarios of primary and secondary transfer. Herein, we define primary transfer as the direct transfer of DNA from one individual to a surface, whereas secondary transfer involves an intermediate medium between the individual and final sampled surface. Mobile phones, while commonly involved in crimes such as robbery and assault, have not been extensively studied in the scientific literature regarding DNA transfer and persistence. This study measured TPPR using participants (n=7) who handled either another participant's mobile phone or their own mobile phone following a handshake with another participant.

Using the resultant DNA profiles of 41 transfer and persistence mobile phone swabs, we assigned a minimum number of contributors to each profile and performed a comparison to reference genotypes from study participants. Trends regarding DNA deposition comparisons between primary and secondary transfer were consistent with expectations. In greater than 80% of samples, sufficient DNA was deposited from the study participants to yield a partial or complete DNA profile. Further, approximately 93% of sample profiles yielded at least one allele that could not be attributed to any study participant. The presence of non-participant DNA, or foreign DNA, was expected due to touch samples often containing DNA from multiple sources.<sup>4</sup> Obligate alleles were observed in multiple transfer scenarios in which the major contributor was not the mobile phone owner. Empirical study results were demonstrated to have value in modeling likelihood determinations using Bayesian statistics. Our study supports the potential for mobile phone swabbing to comment on activity level propositions involving mobile phone contact.

**B80 The Design of a Protocol for Detecting Trace DNA From Skin-to-Skin Contact in a Mock Physical Assault Scenario**

McKenna Bonn-Savage\*, Arcadia University, Philadelphia, PA; Bas Kokshoorn, Netherlands Forensic Institute/Amsterdam University of Applied Sciences, The Hague, MP, Netherlands; Megan Foley, The George Washington University, Washington, DC; Fabio Oldoni, Arcadia University, Glenside, PA

---

**Learning Overview:** After attending this presentation, attendees will have a better understanding of how the detection and persistence of DNA deposited on human skin changes over time.

**Impact Statement:** This presentation will impact the forensic science community by exploring the persistence of DNA on human skin in mock physical assault scenarios. This presentation will expand our current knowledge on the detection of an offender's DNA on a victim's skin.

Trace DNA can be left behind at a crime scene due to a person coming into direct or indirect contact with another person or an object.<sup>1</sup> The detection of trace DNA from an offender on the victim's skin can provide forensically relevant information, which can be used to support the proposition that places the offender at the scene in the investigations of physical or sexual assaults. Although there is growing knowledge on trace DNA deposited on objects, there is a paucity of data on how long DNA evidence can persist on human skin.<sup>2</sup> This study was designed to investigate the persistence of trace DNA on the skin of individuals simulating a physical assault scenario.

Simulations of physical assaults were conducted with a male participant grasping the wrists of a female participant. Fourteen pairings of volunteers (12 females and 12 males) were recruited in which the male "offender" firmly grasped both wrists of the female "victim" for either 1 minute or 3 minutes. Both wrists of the "victim" and the hand palms of the "offender" were sampled after 1 hour, 2 hours, or 4 hours in distinct simulations. Every pair of participants was involved in every simulation combination for a total of 196 samples from the palms and 196 from the wrists. Reference samples from all volunteers were collected from buccal swabs and extracted using Chelex<sup>®</sup> resin. Trace samples were collected using a double swab technique with water as the wetting medium, extracted using the QIAshredder<sup>®</sup>/QIAamp<sup>®</sup>, quantified using the Quantifiler<sup>®</sup> Trio Quantification kit on a QuantStudio<sup>™</sup> Real-Time PCR system. Trace and reference samples were amplified using the GlobalFiler<sup>®</sup> Amplification kit. The STR fragments were then separated using the SeqStudio<sup>™</sup> Genetic Analyzer and STR profiles analyzed with the GeneMapper<sup>®</sup> ID-X software.

Overall, preliminary results on an initial set of 62 trace samples showed that the quantification values of samples collected from the victim's wrists ranged between 0.002ng/μl to and 0.011ng/μl, and those collected on the offender's palms ranged between 0.007 and 0.289ng/μl. A mixed STR profile was observed in all trace samples analyzed. A general decrease in the proportion of offender's DNA in relation to the victim's DNA was observed over time from trace samples recovered from the victim's wrists, which is in-line with a previous work.<sup>3</sup> Moreover, a decrease in the proportion of victim's DNA recovered from the offender's palms was observed over time in addition to the detection of a greater percentage of extraneous DNA that did not belong to either of the individual pairs.

In conclusion, a comprehensive investigation of the full set of trace samples is in progress to reveal the persistence and two-way transfer of DNA from the mock offender to mock victim's wrists and from the mock victim to mock offender's hand palms.

**B81 Direct PCR Amplification for Forensic DNA Profiling From Adhesive Tape-Lift Samples**

Kevin W.Y. Chong\*, Home Team Science and Technology Agency, Singapore, Singapore; Hui Yin Tan, Home Team Science and Technology Agency, Singapore, Singapore

---

**Learning Overview:** After attending this presentation, attendees will have learned a new way of performing direct Polymerase Chain Reaction (PCR) amplification from adhesive tape-lift samples.

**Impact Statement:** This presentation will impact the forensic science community by discussing how this alternative method of directly processing adhesive tape-lift samples for DNA will not only shorten work processes but also provide better DNA profiles for low-level DNA.

Tape-lifting is a collection method where the sticky side of an adhesive tape is repeatedly pasted onto and peeled from an item, thereby sequestering any biomaterials from the item onto the tape. This alternative to the conventional swabbing method in biomaterial collection for forensic DNA profiling is recommended for sampling fabrics and ammunition cartridge cases.<sup>1,2</sup> Traditionally, the tape-lift sample is processed through the standard multi-step DNA profiling method: DNA extraction, purification, and quantification, followed by PCR and capillary electrophoresis of the PCR products. As DNA loss in each step is inevitable, the negative impact of loss is compounded for low levels of starting biomaterial.<sup>3</sup>

It is hypothesized that direct PCR amplification of tape-lift samples bypassing the DNA extraction, purification, and quantification steps could potentially reduce DNA loss, profiling time, and physical footprints. As such, our laboratory set out to devise a simple method to perform direct PCR amplification of tape-lift samples. A small manual punch tool was used to excise discs from the tape-lift that were small enough to fit into a PCR tube. PCR products obtained using the GlobalFiler® PCR amplification kit were subsequently electrophoresed in a 3500xL genetic analyzer.

Two commercial adhesive tapes from different suppliers and different disc diameters were evaluated in this study. The adhesive tape from Lovell Surgical and a disc diameter of 6mm were found to be optimal, as complete DNA profiles from blood stains were obtained. These optimized conditions were adopted for the comparative evaluation of direct PCR amplification and the standard method of profiling low starting biomaterial samples (50nL of dried human blood). Compared to the standard method, the direct PCR method achieved a consistently significant ( $p < 0.05$ ) higher number of complete loci and yielded three to six times higher allelic peak heights. Better DNA profile quality from the direct PCR method would translate into greater potential for database hits and reference matches.

This proof-of-concept study demonstrated that forensic samples with low-starting biomaterials, such as fabrics or porous materials, will reap the greatest benefit from employing tape-lift collection combined with the direct PCR amplification method. Moreover, the adhesive tape-lift remaining after punching out the discs can be conveniently kept for re-examination or further analysis in jurisdictions that have this requirement.

---

**B82 The Success Rate of Touch DNA**

*Jill Snyder\*, Eastern Kentucky University, McCordsville, IN; Kaitlyn M. Adams\*, Indiana University-Purdue University of Indianapolis, Martinsville, IN*

**Learning Overview:** After attending this presentation, attendees will have learned which types of evidence offer the best and worst success rates of touch DNA using data collected from evidence analyzed in the four Indiana State Police regional labs. This information could be useful in updating guidelines for which items are accepted for DNA analysis in other labs.

**Impact Statement:** This presentation will impact the forensic science community by providing information regarding what types of evidence develop the highest success rates for obtaining a useful DNA profile. This can be used to update guidelines for what items of evidence undergo DNA analysis.

Law enforcement agencies typically submit items of evidence that have been touched by an individual, but do not have body fluids present. At the Indiana State Police Laboratory, over half of the current case work that the lab receives is property crime, which may only have touch DNA evidence present. These items may require time and resources that could result in limited to no valuable information for the case.

To determine the success rates of items of evidence, a total of 2,070 cases from the Indiana State Police Laboratory were collected and analyzed. The information collected from these cases included the offense type, each item of evidence, the evidence category, how many swabs were made of the item, the amount of DNA present, and the conclusions drawn from the DNA profile if one was developed. A positive result was considered if a deconvolution was run, and the number of contributors was determined. A negative result was considered if there was not enough DNA present to continue analysis (less than 0.01ng/μL) or an inconclusive result was drawn. Inconclusive results occurred if there were more than four contributors, an uncertain number of contributors, inconsistent quantification results, or results not qualifying for calculation. Items with more than 20 data points (swabs made) were quantified based on positive and negative results to determine the success rate. Forty-nine items and item categories had over 20 data points. Containers had the highest success rate (72.73%). Matches were the only item with a 0% success rate, but as all of the data points came from one case, this information is not significant enough to draw any conclusion. The items that were at or under 10% included wrenches (7.14%), windows (8.85%), locks and deadbolts (9.43%), safes and cash registers (10%), and smudges (10%).

By observing the success rates of evidence, laboratories may be able to update their guidelines as to which types of evidence are accepted for DNA analysis.

---

**B83 Total Human DNA Sampling**

*Colino Neves\*, Forensic Molecular Biology Department, Institute of Forensic Medicine, University of Bern, Bern, Switzerland; Martin Zieger, Forensic Molecular Biology Department, Institute of Forensic Medicine, University of Bern, Bern, Switzerland*

---

**Learning Overview:** In this presentation, attendees will gain insights into an innovative and efficient DNA sampling technique that focuses on human skin cells found on the ground, specifically applicable to large areas.

**Impact Statement:** This presentation will impact the forensic science community by, for the first time, showcasing a method that presents the possibility of using sampled skin cells from a large area for forensic purposes. It has the potential to significantly enhance the identification and prosecution of criminals.

Introduced in 1986, DNA profiling is now a widely adopted forensic technique with global recognition. Until today, no efficient sampling technique existed to collect DNA from human skin cells from a large area, not to say from the floor of an entire room. However, there is enormous forensic potential in these DNA traces from the ground to provide clues as to who has been present at a particular location (i.e., at the crime scene). Humans shed several millions of skin cells per day, everywhere they stand, sit, or walk; and there is little they can do about it.

We present here a method by which we can make use of all those lost skin cells. We use a vacuum cleaner equipped with a specialized filter cartridge to sample the ground. The complexity of the dust mixture is significantly reduced by fragmentation of the filter membrane and subsequent parallel processing of the resulting fragments, using a modified Chelex® 100 extraction protocol. Our method is simple and fast and comes with reasonable costs. Overall, at least around 40% of the DNA profiles generated from the various tested surfaces fulfilled the submission criteria for single major contributor profiles to the Swiss DNA database. As demonstrated through a mock crime scene scenario set up in a private apartment, the perpetrator's DNA could be found on the floor even after a very short stay in the room of less than one minute. Testing the method in real forensic casework, already the first application of the method led to relevant case information for the police. Given its large investigative potential, we recommend Total Human DNA Sampling as a helpful complementary forensic tool to traditional DNA trace collection in all major crimes. Adopting this innovative approach has the potential to further improve crime scene investigations and significantly assist law enforcement in solving crimes.

---

**DNA Profiling; Total Human DNA Sampling; Skin Cells**

**B84 A Combined Method to Locate and Improve DNA Recovery From Fabrics**

*Makenzie Michelle Drier\*, University of Central Oklahoma, Noble, OK; Rhonda Williams, University of Central Oklahoma, Edmond, OK*

**Learning Overview:** This presentation will utilize a multi-method approach to demonstrate the possible alternatives to locating and collecting touch DNA from fabrics at higher concentrations than current collection methods. After attending this presentation, attendees will better understand the importance of surface type in regard to DNA collection methods, vacuum metal deposition's effects on touch DNA samples, and the M-Vac® wet vacuum's capability in obtaining DNA from different types of fabrics.

**Impact Statement:** This presentation will impact the forensic science community by showing that the use of Vacuum Metal Deposition (VMD) and the M-Vac® wet vacuum can be a possible combined collection method for touch DNA retained on a fabric's surface. DNA and latent prints evidence are known to overlap in cases; however, it is hard to know which takes precedence over the other at times. The acknowledgment and development of collection procedures for touch DNA found in latent prints on fabrics could be essential to the prosecution of a case.

The first step to collecting touch DNA is determining the location to target as touch DNA on surfaces is not readily identifiable.<sup>1</sup> Utilizing the VMD's ability to produce a visual negative print on an evidence item, analysts can determine the location of possible DNA present. VMD is a technique used to detect latent fingerprints of non-porous surfaces.<sup>2</sup> Once the touch DNA is located on the substrate, analysts must determine the best collection method to obtain the highest concentration of DNA available. Touch DNA samples do not contain large amounts of biological material and must be carefully collected to prevent the risk of degradation or contamination.<sup>3</sup> Currently, analysts employ swabbing techniques to collect touch DNA from clothing from crime scenes. The M-Vac® wet vacuum system could be a possible alternative to current collection methods. The Microbial wet-vacuum instrument (M-Vac® Systems Inc.) was developed for microbial sampling of large surfaces, using a chemical-based buffer for collection and stabilization.<sup>4</sup> The stabilization of the DNA sample allows for the creation of a more complete DNA profile. Nine fabrics with duplicates, 18 in total, are collected and cut into hand-sized squares for processing. Dark-colored fabrics are processed with 0.002g of silver and 1.0g of zinc, and the light-colored fabric samples are processed with 0.002g of gold and 1.0g of zinc. The samples in this study compare silica-membrane based (QIAmp®) and paramagnetic silica bead resin-based (DNA IQ™) extractions to determine the most efficient method to receive higher DNA yields. Each sample fabric type underwent each step, extraction to genetic analysis, in triplicates for statistical analysis. Samples also undergo size exclusion chromatography (Micro Bio-spin® column with Bio-Gel® P-30) to remove any metal ions that might be present that could inhibit the Polymerase Chain Reaction (PCR) process. All samples are quantified using Quantifiler® DNA Quantification kit and amplified using the PowerPlex® Fusion amplification kit. Preliminary results indicate that the M-Vac® wet vacuum has a higher average concentration of DNA than the wet swab method for DN AIQ™ extraction samples. However, QIAmp® extractions indicated that wet swab method samples contained a higher concentration of DNA compared to the M-Vac® wet vacuum samples. The combined method to locate and improve touch DNA recovery on fabrics could be an essential tool in the forensic science field, especially in regard to assault cases.

Touch DNA analysis has become an integral part of the forensic science community when other biological evidence may not be available and serves as a tool for investigators. Surfaces retain touch DNA samples differently, and it is imperative that investigators consider the appropriate collection method for the types of surfaces they encounter. The purpose of this research project is to identify touch DNA on different clothing surfaces and improve DNA recovery and efficiency. The results obtained will direct the proper downstream processing to obtain the best quantity of DNA from items of evidence.

**B85    The Identification of MicroRNAs for Forensic Biofluid Detection Using a MicroRNA Expression Profiling Method**

*Xiaomeng Yang\**, Boston University, Malden, MA; *Amy N. Brodeur*, Boston University Biomedical Forensic Sciences, Boston, MA; *Robin W. Cotton*, Boston University, Boston, MA; *Isabel Luisa Tan Palanca*, Boston University Chobanian and Avedisian School of Medicine, Dorchester, MA

---

**Learning Overview:** By attending this presentation, attendees will learn about differentially expressed microRNAs that can potentially be used to facilitate forensic biofluid detection.

**Impact Statement:** This presentation will impact the forensic science community by identifying additional microRNAs that show differential expression among forensically relevant biofluids to the current repertoire of microRNA markers.

Biofluid identification plays a pivotal role in forensic case investigation, as it assists in crime scene reconstruction and provides guidance for subsequent analysis. MicroRNAs are short, non-coding sequences that regulate gene expression.<sup>1</sup> MicroRNAs exhibit high stability during long-term storage and against environmental degradation due to their small sizes.<sup>2</sup> In addition, microRNAs demonstrate specific expression patterns in different biofluids and tissues, such as peripheral blood and semen.<sup>2</sup> The biofluid specificity and exceptional stability of microRNAs render them an optimal choice for biofluid identification assays. In this research, a next generation sequencing-based microRNA expression profiling method was used to determine potential microRNA markers for forensically relevant biofluids.

Human peripheral blood, menstrual blood, vaginal fluid, saliva, and semen were collected from various donors and analyzed with HTG EdgeSeq™ microRNA Whole Transcriptome Assay. This assay couples a proprietary quantitative nuclease protection assay and next generation sequencing for microRNA expression profiling. The sequencing data was investigated using computer software for principal component and differential expression analyses. A total of 2,083 human microRNAs were assessed to pinpoint those that offer the clearest differentiation among the biofluid types examined.

Principal component analysis was conducted using experimental data that showed distinctive microRNA expression profiles for different biofluid types. Following differential expression analysis, the top differentially expressed microRNAs based on p-values were assessed for observable trends in their fold changes. Several differentially expressed microRNAs aligned with some in the existing literature, including miR-451a and 486-5p for both kinds of blood, miR-185-5p for peripheral blood, and miR-888-5p and 891a-5p for semen. Previously unreported microRNAs with biofluid-specific expression patterns were also identified, such as miR-4306 for peripheral blood, miR-147a for vaginal fluid, and miR-184 for saliva. MicroRNAs such as miR-891a-3p and 891b demonstrated significant up-regulation in normal semen compared to azoospermic semen, suggesting that these microRNA markers are more closely associated with sperm cells rather than the fluid components of semen.

Shane Woolf, PhD, University of Virginia, Charlottesville, VA; Sadie Kiendzior, BS, University of Virginia, Charlottesville, VA; Kelsey O'Neill, BS, University of Virginia, Charlottesville, VA; Ellaha Momand, BS, University of Virginia, Charlottesville, VA; James P. Landers, PhD, University of Virginia, Charlottesville, VA

---

**Learning Overview:** After attending this presentation, attendees will have been introduced to a microfluidic platform that achieves enclosed fluid fractionation and automation of the forensic Differential Extraction (DE) process for analysis of sexual assault evidence.

**Impact Statement:** This presentation will impact the forensic science community by proposing the advancement of novel technology that stands to streamline the analysis of DNA-based sexual assault evidence.

The unique nature of biological evidence collected from victims of sexual assault and rape contributes to an increasing need for forensic DNA services due to slow turnaround times and subsequent backlogs of evidence.<sup>1</sup> To ensure the judicious prosecution of sexual predators from the population, it is crucial that the processing of sexual assault evidence occurs in an effective but timely manner. The conventional and most widely utilized sample preparation technique for the processing of sexual assault evidence relies on the separation of the critical Sperm (SF) and Non-SSperm (NSF) Fractions prior to downstream genetic analysis.<sup>2</sup> This traditional DE process is manually intensive, prone to cross-contamination and DNA loss due to sequential washing steps, and occasionally fails to generate adequate sperm cell DNA recovery for proper perpetrator identification. To address the limitations associated with standard DE techniques, we propose an enzymatic, enclosed microfluidic approach that retains the substrate cutting throughout the extraction workflow and therefore reduces the risk of contamination and genetic material loss.

Among the many advantages of microfluidic systems is the ability to improve throughput of processes and, in turn, decrease turnaround times.<sup>3</sup> We report a microfluidic approach to differential cell lysis that emulates the workflow steps associated with traditional DE: pipetting, mixing, centrifuging, and fractionating; is amenable to automation and provides timed-release of on-board reagents as well as temperature control for sequential enzymatic unit operations. Furthermore, we describe a fully enzymatic extraction method that precludes the use of hazardous reducing agents and other known Polymerase Chain Reaction (PCR) inhibitors associated with conventional DE. Rapid prototyping and testing of the proposed microdevice is afforded by leveraging common office equipment and inexpensive plastic materials for device fabrication, and fluidic control needed for successful fractionation incorporates laser-based valving methods for channel opening and closure.<sup>4,5</sup>

We demonstrate substantial progress toward the development of a self-contained, rotationally driven platform for forensic DE. Compatibility of the microdevice with an entirely enzymatic extraction process will be demonstrated. Eluates recovered from on-disc extraction will be shown to be amplification-ready and compatible with distinct downstream analysis modalities, such as quantitative PCR (qPCR). In addition, our approach permits substrate retention within the microdevice, enabling lysis of sperm cells directly from the cutting, thus, ultimately, improving the DNA yield from the alleged offender contribution. Advancement of the proposed microfluidic approach stands to transform the analysis of DNA-based sexual assault evidence in the criminal justice system, thus addressing the current societal crisis of backlogs and helping victims get justice.

**B87 A Comparative Analysis of Swabbing Solutions for Sexual Assault Evidence: The Direct Impact on Spermatozoa and DNA Recovery**

*Olivia Quinn Kassie\*, Virginia Commonwealth University, Sutherland, VA; Sarah Seashols Williams, Virginia Commonwealth University, Richmond, VA; Laura Gaydosh Combs, Suffolk County Crime Laboratory, Islip, NY*

---

**Learning Overview:** This presentation compares common swab-wetting agents used to swab sexual assault evidentiary items, including acetone, due to its active use in casework. After attending this presentation, attendees will understand how different wetting agents may impact spermatozoa recovery directly and the quality of the DNA recovered when swabbing sexual assault evidence.

**Impact Statement:** This presentation will impact the forensic science community by exploring how different wetting agents may affect the integrity of the DNA recovered when swabbing sexual assault evidentiary items. These results will shed light on the best option to be used in a casework setting. Additionally, the forensic science community will gain insight into differing laboratory protocols and their connection to quality control and standardization.

Forensic laboratories often face a backlog of sexual assault cases to process due to a multitude of reasons, not limited to a lack of resources and funding or the lack of qualified analysts to process cases at the rate that crime occurs.<sup>1</sup> Therefore, research on the most effective laboratory techniques can be used to develop uniform protocols between laboratories to help address the backlog issue and identify the scientific gaps observed in practice.

Recovering optimal DNA from sexual assault evidentiary items has proven to be challenging due to different factors such as the time of collection after the assault. It has been found that biological evidence can successfully be recovered within 24-96 hours after the crime occurred.<sup>2</sup> Additionally, several variables exist in recovery due to location, type, and condition of sampling and can have a significant impact on recovery. Thus, validated protocols are crucial to ensuring the development of a successful Short Tandem Repeat (STR) profile and often start with the swabbing procedure used when collecting a stain. However, laboratories may not follow identical standard operating procedures to one another, resulting in minor variations during evidence processing that can potentially result in dramatic differences in DNA yields, differential extraction success, and STR profile success.

This was observed in a state lab when protocols were developed allowing the use of acetone to swab sexual assault evidence. The use of acetone originated due to their case-routing protocols in multi-section cases involving latent fingerprints. These cases are first routed to the Fingerprint section to undergo superglue-fuming prior to DNA processing. This process is performed to develop prints on non-porous substrates for examination before sending them to the DNA section. In the DNA section, acetone is then used to melt the superglue layer in order to collect touch DNA from the print. While not necessary for sexual assault and porous surfaces, the laboratory included swabbing with acetone as an option, and thus it is routinely used in sexual assault casework. Consequently, the goal of this project was to compare different wetting agents, including acetone, when swabbing sexual assault evidentiary items. By exploring this methodology, insight can be gained into the different wetting agents' interaction with the protective plasma membrane of spermatozoa to address potential recovery differences as well as the determination of possible DNA degradation.

Acetone, SDS, TX-100, and water-moistened swabs were used to recover 1:5 dilutions of semen deposited onto cotton underpants. Sperm recovery, DNA yield, and integrity were compared to both cuttings of the same volumes of a sample as well as the liquid control. The same study was repeated using a 1:1 vaginal:semen mixture to mimic a mixture of DNA profiles from the male and female contributors.

In both sets of experiments, taking cuttings of the underpants produced the highest number of spermatozoa present. The Kruskal-Wallis Analysis of Variance (ANOVA) test was performed to determine if there was a significant difference between treatment groups and found the distribution of cell yield across treatments was not the same. However, the only significant difference between treatments was observed when comparing TX-100 and acetone to cuttings. While no samples demonstrated signs of inhibition, when assessing the average DNA yields, cuttings outperformed each of the wetting agents with the highest DNA yields. With these results, conclusions can be made that analysts should choose to take cuttings of sexual assault evidentiary items when the evidence permits; additionally, acetone does not seem to interfere with sperm integrity or recovery when compared to other swabbing methods.

**B88    The Discovery of Additional Male-Specific Protein Markers in Semen: Potential Applications for the Processing of Sexual Assault Evidence**

*Glendon Parker\*, University of California, Davis, Davis, CA; Kyle Burk, Scientific Assistant, University of California, Davis, Davis, CA; Mirna Ghemrawi, Center for Forensic Science Research and Education, Willow Grove, PA*

---

**Learning Overview:** After attending this presentation, attendees will have learned more about the composition of semen in Sexual Assault Evidence (SAE) and the discovery and validation of new SAE markers. Attendees will also learn about challenges in current SAE processing methods, and how these can be mitigated using new approaches.

**Impact Statement:** The detection of male-specific protein markers is essential in the processing of SAE. Investigators need to prioritize the testing of elements from SAE. They also need to reconstruct the context of the sexual assault and corroborate differing accounts. Most detection occurs through immunological lateral flow devices. These are affordable and easy to use, but they are not sensitive and are prone to false positive detections. There is a need for highly sensitive and specific testing that meets the standard of confirmatory evidence. This presentation will impact the forensic science community by introducing new approaches for the processing and detection of semen in SAE.

This project discovered additional semen-specific proteins that can enhance the specificity and sensitivity of body fluid identification in SAE. Three vaginal fluids and two semen preparations were purchased and applied to cotton swabs. These were then proteomically processed using liquid chromatography and shotgun mass spectrometry. The resulting spectra were matched to protein sequences using peptide spectra matching software. Proteins were measured semi-quantitatively and were compared between the vaginal fluid and semen groups. Proteins that were at least 64-fold more abundant in semen were identified and ranked in order of abundance.

The experiment detected and measured the abundance in 1,366 proteins. Of these, 868 were differently expressed proteins in vaginal fluid and semen. A statistical comparison of the two body fluids identified 59 proteins in semen that: (1) were at least 64-fold more abundant compared to vaginal fluid, and (2) passed the Benjamini-Hochberg correction for False Discovery Rate (FDR=1%). The proteins were then ranked in order of abundance in semen tissue and ranged over five orders of magnitude. The four most abundant are well known and have been the basis of semen detection assays: semenogelin-2, semenogelin-1, prostate-specific antigen, and prostatic acid phosphatase. An additional 55 proteins were detected as being male-specific. These proteins can form the basis of new and more specific assays for both body fluid detection and human identification. Interestingly, 15 proteins were also detected in vaginal fluid, including 7 of the most abundant semen-specific proteins. The average difference in abundance was  $2.2 \times 10^3$ . This indicates that these proteins are stable over the post-coital interval and that investigators need to be quantitative in order to establish activity levels.

New semen (male)-specific markers were identified using current shotgun proteomic methods. These can be the basis of new methods using new markers in SAE processing and development of accessible and confirmatory assays. These also demonstrate the need for quantitative approaches to establish activity levels in SAE processing.

**Learning Overview:** After attending this presentation, attendees will have been introduced to a rotationally driven microdevice that integrates messenger RNA (mRNA) extraction, multiplexed Reverse Transcription Polymerase Chain Reaction (RT-PCR) amplification, electrophoretic separation, and fluorescence detection for rapid, field-forward Body Fluid Identification (BFID).

**Impact Statement:** This presentation will impact the forensic science community by introducing attendees to a rotationally driven microdevice that integrates mRNA extraction, multiplexed RT-PCR amplification, electrophoretic separation, and fluorescence detection for rapid, field-forward BFID.

BFID is a critical component of forensic science as it contextualizes a crime scene and is the central caveat for telling a narrative.<sup>1</sup> Standard identification techniques, while rapid and simple, are presumptive and can require days of laborious microscopic analysis or chemical, enzymatic, or immunological assays, many of which are limited in specificity and sensitivity, particularly when applied to mixed samples.<sup>2</sup> Further, samples collected from crime scenes are often limited in volume, making serological analysis, which consumes the scarce sample, incompatible with DNA profiling. Conversely, transcriptomics, or RNA analysis, is a promising alternative to conventional BFID as it does not compromise the compatibility of DNA for profiling.<sup>3</sup> Unfortunately, existing transcriptomic methods, while sensitive and specific, require time-consuming and labor-intensive steps that require a skilled analyst and cumbersome instrumentation in a centralized laboratory. These limitations can be overcome on a microfluidic platform that integrates multiple sample processes and leverages the physics associated with the microscale to perform standard reactions in a fraction of the time.<sup>4</sup>

Microfluidic systems offer many advantages over conventional benchtop instruments, including decreased reagent and sample requirements, rapid analysis times, an enclosed format that minimizes the risk of contamination, and the potential for automation which reduces required user intervention.<sup>4</sup> We describe a microfluidic system that integrates multiple steps of the conventional transcriptomic analysis workflow to rapidly perform BFID from mRNA targets.<sup>3</sup>

This system includes a microfluidic disc that integrates co-extraction of RNA and DNA, rapid RT-PCR amplification, electrophoretic separation, and fluorescence detection all on one portable *sample in-answer out* system. A validated panel of mRNA markers are used for the identification of saliva, menstrual blood, venous blood, sperm, seminal fluid, and vaginal fluid; these markers were selected based on sensitivity and specificity of the targets.<sup>3</sup> Progress has been made toward the validation of these processes at the microfluidic level, with enzymatic co-extraction, multiplexed RT-PCR, and electrophoresis completed in 15, 30, and 10 minutes, respectively, with successful identification of tissue specific allelic markers. All assays are carried out on a single microfluidic disc that is operated by a fully enclosed instrument that minimizes manual intervention. Ongoing efforts are focused on developing a single multiplex primer panel to mitigate workflow time, decrease reagent cost, and further aid integration onto the microfluidic disc. This microfluidic system conserves DNA for genetic analysis, mitigates risk of contamination, and integrates multiple laborious benchtop processes into a single, portable device for rapid body fluid identification at the point of need.

---

**Learning Overview:** After attending this presentation, attendees will consider the possibility of integrating body fluid identification through immunochromatographic tests and direct Polymerase Chain Reaction (PCR) in one workflow, leading them to fully characterize the biological evidence.

**Impact Statement:** This presentation will impact the forensic science community by presenting for the first time a validation of a forensic protocol, applicable to a small amount of biological evidence, that allows performing both tests without losing evidence.

Frequently at crime scenes, it is possible to encounter a small amount of biological evidence, preventing the ability to perform all the analyses to fully characterize the evidence: body fluid identification, DNA extraction, quantitation, and profiling. In these situations, DNA profiling is favored with respect to body fluid identification. With the current advancements in forensic genetics, particularly direct PCR, this is also more feasible as it allows for skipping the steps of DNA extraction and quantitation to avoid losing sample. Though, in certain cases, as important as DNA profiling, is the identification of the body fluid.

The present study analyzed the possibility of integrating both body fluid identification and direct PCR in one workflow without losing sample, being able to fully characterize the evidence.

Blood samples (20ul) were deposited on a plastic surface and allowed to dry for 48 hours. Three replicates per experiment were performed. In the first set of experiments, three blood samples were swabbed with a regular cotton swab and the other three blood samples with 4N6FLOQSwabs®, both moisturized with SERATEC® extraction buffer for the detection of blood samples. The swabs were incubated for 10 minutes at room temperature in 400ul SERATEC® extraction buffer. Three drops of this extraction buffer were deposited into the sample well of the HemDirect test for the identification of blood. While the HemDirect test was still wet, a microFLOQ® swab was used to touch the sample well of the test, and another microFLOQ® swab was used to touch the result window of the test. Then, when the HemDirect test dried, the dry sample well and the dry result window were touched with microFLOQ® swabs. In the second set of experiments, three blood samples were swabbed with a regular cotton swab and the other three blood samples with 4N6FLOQSwabs®, both moisturized with SERATEC® extraction buffer. After swabbing, a microFLOQ® swab was used to touch a small surface of both swabs to perform direct PCR. Then, cotton and 4N6FLOQSwabs® were incubated in 40 ul SERATEC® extraction buffer and carried out the identification of blood with the HemDirect tests. In the third set of experiments, the microFLOQ® swab was directly applied to the blood samples, moisturized with SERATEC® extraction buffer, and eluted in different volumes of the buffer to perform the body fluid identification. The microFLOQ® swab was used to carry out direct PCR with the PowerPlex® Fusion 6C System in the three experiments. It was possible to identify blood with SERATEC® HemDirect test in the three set of experiments.

Direct PCR, applying PowerPlex® Promega Fusion 6C on the microFLOQ® swabs, was successful in experiment 2, obtaining full DNA profiles, though the quality of the profiles was better on the samples retrieved from 4N6FLOQSwabs® than cotton swabs. In experiment 3, the microFLOQ® swab eluted on 60ul of extraction buffer also provided full, good-quality STR profiles. In contrast, in experiment 1, the PCR from dry samples (sample well and result window) produced partial profiles, while wet samples did not retrieve profiles.

In conclusion, this study demonstrated for the first time the possibility of integrating both body fluid identification and direct PCR in one workflow, leading to obtaining as much information as possible from the evidence. Future research would be able to expand these results, assessing this identification in other body fluids, and additionally trying to optimize the detection of these body fluids with the microFLOQ® swabs.

**B91 The Development of a Novel Multiomic Assay for Biofluid Identification**

*Angela Proctor, Codetta Bio Inc., Durham, NC; David Korest, Codetta Bio, Inc., Durham, NC; Amy N. Brodeur\*, Boston University Biomedical Forensic Sciences, Boston, MA*

---

**Learning Overview:** By attending this presentation, attendees will learn about a novel multiplex assay for body fluid identification that targets protein and nucleic acid biomarkers in a single benchtop instrument.

**Impact Statement:** This presentation will impact the forensic science community by describing a sensitive, Polymerase Chain Reaction (PCR) -based biofluid identification multiplex assay that could be used in place of single target colorimetric and lateral flow chromatography assays.

Biofluid identification in forensic case work is important for providing context, demonstrating specific elements of a crime are present and helping to inform downstream analysis. Codetta™ Bio has developed a unique instrument and assay capability that enables multiomic, multiplex assays to be executed in a single benchtop instrument with minimal user hands-on time. The assay utilizes a proprietary strategy to develop sensitive and specific multiplex assays for both protein and nucleic acid biomarkers. The Codetta™ platform integrates elements of known methods, specifically immunoassay-based molecular recognition and Polymerase Chain Reaction (PCR) amplification. Target biomarkers are captured from 50mL samples using bead-based antibody capture and the bead mixture is introduced (pipetted) into the instrument by the user. The Codetta™ platform performs immuno-PCR for protein analysis and PCR for nucleic acid targets. Protein targets are captured using a sandwich immunoassay in which the detection antibody is labeled with a proprietary nucleic acid tag. Assay read-out is based on PCR amplification of the tag molecule, increasing assay sensitivity and specificity as compared with traditional sandwich immunoassays. Nucleic acid assays, such as those for X and Y chromosome targets, are performed via PCR. The instrument incorporates a proprietary microchip and detection strategy that enables combination digital and quantitative PCR (qPCR) readout for simultaneous multiplex, multiomic analyses with high specificity and sensitivity.

As an initial proof of concept to demonstrate the utility of a multiplex assay for forensic biofluid identification, Codetta™ developed an 11-plex assay for the detection of nine protein markers and two internal PCR controls. The multiplex assay includes select biomarkers for five specimen types: blood (glycophorin A, hemoglobin), menstrual blood (D-dimer, MMP7, hemoglobin), semen (KLK3, semenogelin 2), saliva (statherin, MMP7, cystatin SA), and urine (uromodulin). Liquid samples of human blood, saliva, semen, urine, and menstrual blood were purchased from a commercial vendor or collected from volunteers in accordance with an approved Institutional Review Board protocol. Initial studies were performed using a broad range of specimen dilutions in preparation for future studies using dried samples.

Preliminary results from ten biofluid specimens showed that the Codetta™ 11-plex assay was able to successfully differentiate the fluid types, demonstrating that biofluids can be identified based on detection of protein biomarkers present in each specimen, even from dilute samples. For example, a 1:10 semen sample showed a 95-fold and a 27-fold increase in signal over a blank sample for Semenogelin 2 and KLK3, respectively; the other seven biomarkers demonstrated statistically insignificant increases over the blank. Due to the high sensitivity of the assays, low concentration biomarkers can be detected. For instance, a 1:1,000 blood sample showed a 15-fold increase in the hemoglobin biomarker over a blank sample while other biomarkers remained at similar signals to the blank sample. This approach streamlines laboratory workflow to allow scientists to obtain more information from limited samples. The Codetta™ protein assay will be expanded to include genetic markers for X and Y chromosome identification, and additional sample testing on dried stains and mixed biofluids is ongoing to further demonstrate the utility of a multiomic, multiplex assay for biofluid identification.

**B92 A Comparison of Traditional Serological Techniques and DNA Methylation for the Identification of Body Fluids**

*Justin Frye, The Center for Forensic Science Research and Education, Willow Grove, PA; Lindsay Loughner Kotchey, Center for Forensic Science Research and Education, Willow Grove, PA; Leah Nangeroni, Center for Forensic Science Research and Education, Hockessin, DE; Mirna Ghemrawi\*, Center for Forensic Science Research and Education, Willow Grove, PA*

---

**Learning Overview:** After attending this presentation, attendees will have learned about DNA methylation techniques and how this emerging technology can be utilized by the forensic science community. Attendees will also learn about pyrosequencing, a cost-effective sequencing-by-synthesis methodology.

**Impact Statement:** This presentation will impact the forensic science community by highlighting how using pyrosequencing-based DNA methylation for the identification of body fluids can be a strong alternative to traditional immunoassay serological tests.

Immunoassay-based serological tests are commonly used assays in laboratories to presumptively identify fluids such as semen, blood, and saliva. These tests are quick and easy to use; however, they come with their share of limitations, including specificity and the lack of an assay to test for the presence of vaginal fluid and nasal fluid<sup>1</sup> These disadvantages have led some crime laboratories to bypass serological testing and encourage researchers to explore new techniques.

One of the emerging technologies is DNA methylation-based assays detecting epigenetic modifications that occur within the genome at CpG sites, which are locations in the genome where a cytosine is followed directly by a guanine. These sites can undergo methylation of the cytosine based on various environmental factors that can affect gene expression. There can also be methylation at tissue-specific methylation sites that were exploited as epigenetic markers to differentiate body fluids.<sup>2</sup> Bisulfite conversion is performed prior to target amplification to determine which CpG sites in the genome are methylated or are unmethylated. During bisulfite conversion, methylated cytosines are protected from the conversion, will remain cytosines throughout the conversion, and are read as cytosines in the final sequence. Unmethylated cytosines will be converted into uracil, which during the sequencing will be read as thymine. This percentage of cytosine and thymine at specific CpG sites is the percent methylation.

Pyrosequencing is a sequencing-by-synthesis method that measures chemiluminescent inorganic phosphate detection.<sup>2</sup> Newly developed DNA methylation assays that make use of single-amplicon-based pyrosequencing can serve as alternative tools to traditional serological assays to detect semen, vaginal fluid, peripheral blood, menstrual blood, saliva, and nasal fluid.<sup>3-5</sup> Percent methylation of the CpG sites within these amplicons is measured and is what determines the body fluid that is present in the sample.

In this study, two sets of 58 samples that include various types of single source and mixtures of body fluids were created, including off-targets (non-human) such as monkey blood. Prepared body fluids were deposited on a variety of substrates, including denim, leather, and cotton. Additionally, some samples were exposed to humic acid at several concentrations to simulate varying levels of inhibition. All samples were blind tested with both traditional immunoassay tests and DNA methylation assays. Immunoassay tests utilized include RSID™ Blood, RSID™ Semen, RSID™ Saliva, and Seratec® PMB. The DNA methylation assays were performed via the QIAGEN® PyroMark® Q48 Autoprep benchtop instrument to sequence ZC3H12D (semen), VE8 (vaginal fluid), CG06379435, MDFI (peripheral blood), SLC26A10 (menstrual blood), FAM43A (saliva), and SOX2OT (nasal secretions).<sup>3-5</sup> Results from each of the serological methods were compared and the body fluids present on each sample were determined. Specificity and sensitivity were computed as part of the concordance assessment of the two methods. Using the immunoassays, vaginal fluid was falsely identified as saliva and/or blood when in a mixture. Twelve of the 58 samples (20.7%) were false positives in the immunoassays, compared to only two menstrual blood (3.45%) false positives as peripheral blood using the DNA methylation assay. Interestingly, one sample that contained primate blood was incorrectly identified as peripheral blood with the immunoassays but was correctly identified as primate by analyzing the quality of the pyrograms and confirming using the SpeID assay.<sup>6</sup> This study demonstrates that emerging technologies such as DNA methylation show promising results to identify a variety of body fluids that the conventional strip-based immunoassays may fail to detect.

---

**B93 Alternative Direct-to-Amplification Cell Lysis Techniques for Forensically Relevant Non-Sperm Cells**

Rhea Arya\*, Fox Chase Cancer Center, Philadelphia, PA; Brittany Hudson, Fox Chase Cancer Center, Philadelphia, PA; Tracey Dawson Green, Fox Chase Cancer Center, Philadelphia, PA

---

**Learning Overview:** After attending this presentation, attendees will be informed about the following: (1) the significance of DNA testing in sexual assaults and the pervasive backlog of sexual assault evidence collection kits in the laboratories; (2) the traditional differential cell lysis process and its limitations; (3) the goal and approach toward developing an alternative differential extraction technique that would decrease the processing time, limit tube-to-tube transfers, minimize sample loss, and perform comparably, if not better, for comprehensively lysing the cells that are observed in sexual assault samples; and (4) the evaluation and comparison of different methods to identify the best non-sperm cell lysis method. This method, when combined with an already-developed alternative direct sperm cell lysis method (using 1M NaOH), would form a new differential extraction method that is quick, inexpensive, minimizes manual labor, and obviates the need for multiple purification steps.

**Impact Statement:** The forensic science community is looking for new ways to process sexual assault evidence more efficiently. The traditional differential extraction procedure is time-consuming, involves multiple purification steps, and is also labor-intensive, contributing significantly to the backlog of sexual assault kits. This presentation will share the results of their research on developing a new method for cell lysis and DNA liberation from forensically relevant non-sperm cells. The best method identified from the research could precede the current direct-to-amplification method employed for sperm cell lysis. This new alternative differential extraction method could replace the traditional differential extraction procedure and significantly reduce the time and labor required to process sexual assault samples. This presentation will impact the forensic science community by presenting a faster and more efficient method for processing sexual assault evidence. This method could potentially help to reduce the backlog of sexual assault kits and bring justice to more victims.

While efforts have been made to reduce the pervasive backlog of sexual assault evidence collection kits, the actual laboratory process remains very time-consuming due to the requirement of a differential lysis step before DNA purification, as well as intricate mixture analysis toward the end of the DNA workflow.<sup>1-5</sup> Recently, an alternative, direct-to-amplification sperm lysis method (using 1M NaOH) was identified.<sup>6</sup> However, a direct cell lysis method for non-sperm cells has not been identified yet. Thus, the primary objective of this work was to find an alternative method that is quick, inexpensive, and does not require multiple purification steps for the lysis of non-sperm cells in sexual assault samples. Ideally, this new non-sperm cell lysis method, when combined with 1M NaOH for sperm lysis, would potentially separate DNA fractions from sperm and non-sperm cells more efficiently than current methods and would enable an alternative in-tube differential technique that would be quick, inexpensive, and obviate the need for multiple purification steps.

In this study, vaginal swab samples were lysed with the control method, *prepGEM*<sup>®</sup>, as well as six alternative reagents: alkaline buffer with 25-200mM NaOH, high salt stain extraction buffer, modified Radioimmunoprecipitation Assay (RIPA) buffer, mammalian protein extraction reagent (M-PER<sup>™</sup>), digitonin buffer, and urea/thiourea buffer. Quantification using Quantifiler<sup>®</sup> Trio of vaginal and semen lysates revealed that the alkaline (25mM NaOH) and M-PER<sup>™</sup> methods were efficient for the lysis of vaginal epithelial cells without substantial sperm cell lysis. Following quantification, vaginal samples were amplified with the Promega<sup>®</sup> PowerPlex<sup>®</sup> Fusion 6C System and analysis of Short Tandem Repeat (STR) profiles from vaginal lysates revealed that the M-PER<sup>™</sup> method showed promising results across all metrics examined, including the percentage of detected STR alleles, mean peak heights, peak height ratio, and interlocus balance. Thus, this method was recommended as an alternative to traditional differential lysis method for non-sperm cells given its ability to produce amplification-ready lysates without any DNA purification step. Going forward, testing with additional donors and replicates, including mock sexual assault mixture samples, would strengthen the implications of these findings.

**Sexual Assault; Direct PCR Amplification; Non-Sperm Cells**

**B94 Decoding the Ocular Region From DNA: Building Predictive Models in Forensic Contexts**

Belen Navarro Lopez\*, BIOMICS Research Group, University of the Basque Country, Vitoria, Pais Vasco, Spain; Victoria Suarez-Ulloa, Panacea Cooperative Research S. Coop., Ponferrada, Castilla y Leon, Spain; Ruben Martos-Fernandez, University of Granada, Granada, Andalucia, Spain; Miriam Baeta Bafalluy, BIOMICS Research Group, University of the Basque Country, Vitoria, Pais Vasco, Spain; Oscar Ibáñez Panizo, Ramón y Cajal researcher, Faculty of Computer Science, CITIC, University of A Coruña, La Coruña, Galicia, Spain; Rebeca Guerrero, University of Zaragoza, Zaragoza, Aragon, Spain; Begoña Martínez Jarreta, University of Zaragoza, Zaragoza, Aragon, Spain; Susana Jimenez Moreno, University Lecturer, University Miguel Hernández, Alicante, Comunidad Valenciana, Spain; Marian M de Pancorbo, BIOMICS Research Group, University of the Basque Country, Vitoria, Pais Vasco, Spain

**Learning Overview:** The goal of this presentation is to highlight the importance of developing molecular morphofacial prediction algorithms. The ocular region is essential for the appearance of an individual's face. This region is often the only one that can be used for identification as perpetrators tend to keep their faces covered, leaving only their eyes exposed. Decoding the information contained in DNA to obtain ocular biometry dimensions is a very valuable source for generating useful information to guide human identification in situations where there are no viable alternatives, as well as providing additional evidence that can reduce uncertainty in identification work.

**Impact Statement:** This presentation will impact the forensic scientific community by showing the breakthrough of obtaining predictive models of facial morphology from the analysis of a DNA sample. Therefore, understanding the relationship between the genome and externally visible traits could greatly contribute to the identification of potential suspects as well as missing people. In addition, this encourages forensic collaboration and the creation of a stronger cooperative consortium to address the challenges posed by genetic identification.

Genetic identification currently requires the comparison of genetic data from remains against reference profiles of indubitable individuals or stored in forensic databases. However, lack of a matching genetic profile or an individual with whom to match the DNA profile found on a trace means that some cases remain unsolved. In such circumstances, advances in Forensic DNA Phenotyping (FDP) that seeks to determine Externally Visible Characteristics (EVCs) from the DNA could assist in guiding the search of suspects in criminal cases or the identification of missing persons in civil cases.<sup>1</sup> Although EVCs are multigenic and multifactorial traits, as well as being influenced by environmental factors, making it difficult to identify the genes involved, different assays have been developed and validated over the past decade in which **Single Nucleotide Polymorphisms (SNPs)** associated with appearance are analyzed simultaneously. One of the most recent is the VISAGE Enhanced Tool for Appearance and Ancestry system, which includes, in addition to the HIRISplex-S SNPs for predicting hair, iris and skin color, SNPs related to eyebrow color, presence of freckles, hair shape, male pattern baldness and biogeographic ancestry.<sup>2-9</sup>

When studying the major discriminating facial traits, the ocular region has been found to be one of the most striking and informative. It has been shown that this region is where we tend to look initially and more frequently than other features when considering a particular face.<sup>10</sup> Moreover, the ocular region is often the only one that can be used for identification as perpetrators tend to keep their faces covered, leaving only their eyes exposed.

Considering the interest of developing predictive models and that ocular region is critical for facial appearance, the possible association of the palpebral fissure length as well as the inner and outer canthal distance with 117 candidate SNPs has been studied in a sample of 413 individuals of both sexes and from the Iberian Peninsula.<sup>11-21</sup> Additionally, 37 SNPs of the HIRISplex-S system have also been studied to obtain information on eye color.<sup>3</sup> The anthropological study was carried out using the Skeleton-ID™ software while the study of genetic variability was conducted using a combination of Fluidigm and SNaPshot technologies. Based on all data obtained, association studies using Analysis Of Variance (ANOVA), Multivariate Analysis of Variance (MANOVA), and logistic regression analysis (categorizing the measures into smaller, normal, and increased) have been performed to obtain predictive models for the ocular region.

In view of the results obtained in this work, the presence of the genotypes rs62578082 AA/CC, rs1454072 AA/AT, rs10175706 CC/CT, rs9456748 AA, and rs6129564 AA/GG has shown a significant association with the studied measures. Combining this morphological information, which takes into account both the size and distance between the eyes, with data obtained from the analysis of iris pigmentation markers, which classifies the eyes into blue, intermediate and brown, a more comprehensive predictive model can be provided.

**B95 Targeted SNP Typing for Forensic Genetic Genealogy Using Hybridization Capture**

*Rebecca S. Just\*, National Bioforensic Analysis Center (NBFAC), National Biodefense Analysis and Countermeasures Center (NBACC), Fort Detrick, MD; Sana Enke, National Bioforensic Analysis Center, National Biodefense Analysis and Countermeasures Center (NBACC), Fort Detrick, MD; Karla Y. Garcia, National Bioforensic Analysis Center, National Biodefense Analysis and Countermeasures Center, Fort Detrick, MD; Rebecca Mitchell, National Bioforensic Analysis Center, National Biodefense Analysis and Countermeasures Center, Fort Detrick, MD; Michelle P. Ackermann, National Bioforensic Analysis Center, National Biodefense Analysis and Countermeasures Center, Fort Detrick, MD*

---

**Learning Overview:** After attending this presentation, attendees will understand how hybridization capture can be utilized to generate extensive, yet targeted, Single Nucleotide Polymorphism (SNP) profiles for forensic genetic genealogy applications.

**Impact Statement:** This presentation will impact the forensic science community by providing a method for developing forensic genetic genealogy profiles from challenging sample types without whole genome sequencing.

An alternative to Polymerase Chain Reaction (PCR) -based targeting, hybridization capture methods use long, biotinylated oligonucleotide probes to enrich a sample for DNA sequences of interest. The use of hybridization capture for enrichment is particularly beneficial when the DNA is too degraded for PCR, as is typically the case with nuclear DNA in hair shafts, and highly compromised samples, or in instances in which environmental DNA is present in far greater abundance than the human DNA of interest.<sup>1</sup> In addition, hybridization capture has utility when the number of genomic targets is large and multiplex PCR would be untenable, but targeted sequencing is still desired.

To enable targeted typing of more than 1.3 million SNPs for Forensic Genetic Genealogy (FGG) applications from challenging sample types, we developed a workflow that combines a custom hybridization capture probe set with single-stranded DNA library preparation for Illumina® sequencing and a custom informatics pipeline for data analysis. In this presentation, we will detail the workflows and results obtained from high and low DNA quantity samples and from both fresh and aged rootless hairs. Testing of the probe set and analysis workflow demonstrated that an average of 15x high-quality read coverage could be obtained for approximately 95% of the target SNPs from 500pg of pristine DNA, with higher read depth and greater than 99% SNP recovery obtained from increased DNA input amounts. Though multiple library preparation methods may be suitable for high-quality DNA samples, our testing indicated that with the degraded nuclear DNA present in hairs, a higher proportion of the target SNPs could be recovered when using the SRSly Pico Plus Kit (Claret Biosciences) as compared to two other library preparation methods that are not specifically designed for damaged and degraded DNA templates. Using this single-stranded method, more than one million target SNPs with high-quality base calls were typed from a 40-year-old cut hair, and a genealogical database matching of the SNP profile produced the expected outcome. The results presented will demonstrate the ability to use the approach to develop an FGG SNP profile without whole genome sequencing from single hairs and other challenging sample types.

**B96 Genetic Ancestry of the Unidentified Human Remains From the East Marshall Street Well**

*Filipa Simao\*, Virginia Commonwealth University, Richmond, VA; Baneshwar Singh, Virginia Commonwealth University, Richmond, VA; Tal Simmons, Virginia Commonwealth University, Richmond, VA*

---

**Learning Overview:** After attending this presentation, attendees will be informed about the usefulness of biparental and uniparental ancestry predictions applied in commingled human remains contexts. By illustrating the ancestry investigations performed for the East Marshall Street Well project, it will be highlighted how ancestry investigations can help to clarify historical records.

**Impact Statement:** This presentation will impact the forensic science community by providing information on the methodologies, analysis, and applicability of genetic ancestry prediction to commingled human remains forensic contexts.

The East Marshall Street Well was uncovered in 1994 during building construction at the Virginia Commonwealth University in Richmond, VA. Within the well, dated to the mid-19<sup>th</sup> century, human remains from over 50 individuals were found. Archaeological analysis suggested that the human remains were discarded following their use as cadavers for training in dissection and amputation. Historical records indicate that the early decades of medical practice in Virginia heavily relied on grave robbing.

Aiming for future genetic identification of the human remains, analysis of uniparental and biparental ancestries is being performed to shed new light on the history surrounding the well. Crania and/or mandibles belonging to 23 individuals were genotyped for either 46 AIM-InDels by capillary electrophoresis or for 56 autosomal SNPs, using Primer B of ForenSeq™ DNA Signature Prep Kit on the MiSeq® FGx sequencing system. Continental ancestry proportions were calculated using STRUCTURE software, for K=3 (African, European, and Native American continental contributions). Paternal haplogroups were predicted with NevGen software using data for 24 Y-chromosomal Short Tandem Repeats (Y-STRs), for those samples typed with Primer B of ForenSeq™ DNA Signature Prep Kit. Mitochondrial DNA typing is ongoing.

Although most individuals showed predominantly African autosomal ancestry, European and Native American input was also detected for some samples. Five out of the six Y-STR profiles obtained were predicted as sub-Saharan haplogroup E1b1a, while the remaining profile was classified as European. Principle Component Analysis (PCA) performed with Y-STRs from previously published African populations, which provided joint information for Y-chromosome Single Nucleotide Polymorphisms (Y-SNPs), helped to classify two samples within branch E1b1a-L485 and another within branch E1b1a-U175.

The results so far corroborate historic records suggesting a network of medical schools engaged in grave robbing and cadaver trading that disproportionately targeted African Americans. For those samples for which it was possible to obtain a more detailed phylogeography, the Central-West African region was pinpointed as the most probable origin of the paternal lineages. This is also supported by historical records indicating the regional origin of enslaved African peoples in Virginia. Ongoing analysis of the remaining skulls in addition to mitochondrial DNA (mtDNA) genotyping will deepen our understanding of enslaved and free African Americans in 19<sup>th</sup>-century Richmond, VA.

**B97 Estimating the Return on Investment on Forensic Investigative Genetic Genealogy: Using the Golden State Killer and the University of Idaho Cases as Case Models**

*Ray A. Wickenheiser\**, New York State Police Crime Lab System, Albany, NY; *Rachel H. Oefelein*, DNA Labs International, Deerfield Beach, FL; *Swathi A. Kumar, Sr.* QIAGEN, San Diego, CA

---

**Learning Overview:** After attending this presentation, attendees will understand the basic principles of the Forensic Investigative Genetic Genealogy (FIGG) process and the value of investigative leads provided by FIGG across the lifecycle of a case. Six cases cleared with FIGG provide data to assess the cost savings associated with a historical case and an active case under investigation to inform a business case model that demonstrates the Return on Investment (ROI) of this technique. Case triaging strategies and recommendations for future application of Next Generation Sequencing (NGS) technology will be provided.

**Impact Statement:** This presentation will impact the forensic community by providing a business case model and recommendations to improve the implementation of FIGG to provide investigative leads. Forensic cases that have gone cold and current cases benefit from leveraging new information derived from NGS and genealogical research earlier in investigations. This builds upon the positive impact of objective DNA-based evidence provided by forensic science. This model will assist forensic science service providers to justify investments and implement FIGG, supported by the cost savings demonstrated by these case examples.

A presentation will demonstrate the costs and benefits of FIGG, including time to provide investigative leads, and its ROI. The most common application of FIGG technology has focused on solving cold cases, such as the Golden State Serial Killer. Investigative leads provided by FIGG supported the apprehension and conviction of Joseph James DeAngelo, which had gone unsolved for over four decades. Similarly, on November 13, 2022, FIGG was applied to the quadruple homicide at the University of Idaho in Moscow, ID, leading to the arrest of Bryan Christopher Kohberger, who currently stands trial on four counts of first-degree murder and one count of felony burglary. Data from this historic case of Joseph James DeAngelo, an estimation for the University of Idaho quadruple homicide case, and six recently completed FIGG cases will provide the foundation for a business case model. The six cases were selected on the basis of covering a range of time required to result in identification as well as covering multiple technologies utilized for **Single Nucleotide Polymorphism (SNP)** profile development: SNP array, whole genome sequencing, and targeted SNP sequencing with the ForenSeq™ Kintelligence system. Recommendations will be provided for future application of FIGG in active cases earlier in the investigative process where DNA is found at the crime scene and there is no Combined DNA Index System (CODIS) hit.

A business case using data from the multiple homicide and sexual assault cases of Joseph James DeAngelo, the University of Idaho homicides, and six current cases demonstrate an extremely large ROI, ranging in savings from \$8,314.53 to \$30,375.21 for every \$1 spent for the model established for the eight cases examined. ROI was calculated using published peer-reviewed costs of various crime types, which includes victim costs, criminal justice system costs, lost productivity estimates for both the victim and the criminal, and estimates on the public's resulting willingness to pay to prevent future violence.<sup>1,2</sup> These costs of crime are in turn divided by the average expense from six FIGG cases to generate an ROI for each dollar spent on generating investigative leads that lead to solving a case. Even applied to a single case of homicide or sexual assault, the business case is compelling, saving \$2,078.63 and \$54.04 per \$1 spent, respectively. Strategies for triaging casework based upon the results of the database searches to efficiently allocate resources, considering the ongoing growth of genealogical research databases accessible to law enforcement, will be presented. Recommendations for FIGG implementation to enable forensic scientists to apply this technology to their outstanding cases will be discussed.

**B98 A Comparative Evaluation of Illumina® Global Screening Array BeadChip, Whole Genome Sequencing, and Verogen™ ForenSeq™ Kintelligence to Analyze Degraded and Low Template DNA Extracted From Semen**

*Sarah Cavanaugh\*, Bode Technology, Lorton, VA; Madalyn Bowers, Bode Technology, Hagerstown, MD; Robert Bever, Bode Technology, Lorton, VA; Jonathan Davoren, Bode Technology, Lorton, VA*

---

**Learning Overview:** After attending the presentation, attendees will understand how the quantity and quality of DNA affects the analysis of high-density Single Nucleotide Polymorphism (SNP) genotypes developed by Global Screening Array (GSA) BeadChip, Whole Genome Sequence (WGS) analysis, and targeted sequence analysis. Additionally, attendees will learn how the quantity and quality of DNA affect the ability to search and match high-density SNP genotype kits curated in GEDmatch, a third-party genealogical database accessible for criminal justice investigations and identification of missing persons.

**Impact Statement:** This presentation will impact the forensic science community by providing forensic scientists with technical data regarding the effect of DNA quality and quantity on the accuracy and call rate of high-density SNP genotype profiles produced by the three genotyping technologies currently used for forensic genealogical applications. Additionally, the data will allow practitioners to make more informed decisions when working with limited resources in forensic investigations.

Forensic Investigative Genetic Genealogy (FIGG) is a powerful investigative technique to aid in the identification of victims and suspects of unsolved crimes or missing persons. By establishing the capabilities and limitations of the three genotyping technologies, the forensic community will be able to address the inevitable court challenges and more effectively provide best practices to provide investigative leads associated with unsolved murders, sexual assaults, and missing person cases. Previous FIGG foundational studies have utilized DNA extracted from either blood or bone; this research is based on DNA extracted from semen.

This study evaluated the three technologies currently available for developing high-density SNP genotypes from human DNA samples and compared their abilities to generate profiles from semen samples. Using both fresh collections of semen and a well characterized human reference material extract, genotyping by GSA BeadChip, WGS on NovaSeq 6000, and targeted sequencing with Verogen™ ForenSeq™ Kintelligence Kit were compared for sensitivity to low-level DNA input concentrations and specificity for artificially degraded DNA. For sensitivity comparisons, GSA v2 BeadChips and WGS were tested with inputs ranging from 50ng to 250pg, and Kintelligence was tested with inputs from 2ng to 25pg, in accordance with recommended functional ranges of the various technologies. In line with other reports, Kintelligence is demonstrating sensitivity to DNA inputs as low as 25pg while WGS and GSA analyses are demonstrating high sensitivity to inputs of at least 25 pg when using semen extracts.<sup>1-3</sup> For specificity, three methods of chemical degradation were employed to produce damaged semen DNA extracts: Ultraviolet (UV) irradiation, oxidative damage via Fenton reaction, and depurination. Sample degradation was confirmed using Quantifiler® Trio Degradation Index values and Short Tandem Repeat (STR) profile quality metrics. The damaged samples were genotyped with all three methods using a DNA input of ~1ng. This presentation will provide cross-technology comparisons of the resultant SNP call rates, heterozygosity, and concordance with reference genotypes for each sample donor. We will also discuss the degradation effects observed, their impacts on each sample processing workflow, and the resultant call rates and genotype concordance to know references.

Additionally, the resulting SNP genotype profiles were uploaded to GEDmatch to assess limitations in matching kits from known relatives of varying genetic distances. High density genotypes developed with GSA or WGS consistently enable detection of known relatives past 2nd cousin (5th Degree relation) with the low input sensitivity data. GEDmatch comparisons with Kintelligence do show inconsistencies in distant relationship matches as the DNA input drops below 100pg, but 5th degree relationships are identified with inputs of >100pg.

**B99 Advances in Canine Science and the Implementation of National Standards**

*Kelvin J. Frank, Jr. \*, Florida International University, Pembroke Pines, FL; Kenneth G. Furton, Florida International University, Miami, FL*

---

**Learning Overview:** This presentation will allow attendees to gather more insight into the latest research involving Volatile Organic Compound (VOC) analysis and field testing of canine targets of interest.

**Impact Statement:** The presentation will impact the forensic community by providing recommendations for improved training protocols and explaining why the understanding of scientific advances is critical in fostering better detection canines.

Canines are well known for their odor detection capabilities due to a highly developed olfactory system. As a result, they have found regular use within law enforcement and private agencies for the successful detection of targets of interest such as explosives, narcotics, firearms, human remains, mass storage devices, etc. Analysis of the VOCs associated with these targets has become a key component of canine research as it allows for a better understanding of the odors that canines are responding to.<sup>1</sup> Research has in fact shown that canines often respond to the VOCs rather than the parent material of targets.<sup>2</sup> In cocaine, for example, dogs primarily respond to the VOC bi-product methyl benzoate instead of the cocaine molecule itself. Similarly, with the explosive C-4, dogs recognize 2-ethyl-1-hexanol, a VOC associated with plasticizers rather than RDX. Knowledge of these compounds has aided in improved training regimens, the development of safe, reliable training mimics that can closely replicate the odors of target materials, and consensus-based national standards for training and certifying canines for their respective disciplines.

This presentation will allow attendees to gather more insight into the latest research involving VOC analysis and field testing of targets. Specific examples that will be discussed, including differentiating hemp versus marijuana odors, mass storage devices versus electronic controls, and the detection of corrosion in structures. These topics will benefit the forensic community by providing recommendations for improved training protocols and explaining why the understanding of scientific advances is critical in fostering better detection canines. Additionally, the implementation of national standards in the United States through the International Commission on Detector Dogs (ICODD) will be discussed. ICODD's mission is to globally improve the performance of detector dog teams via information sharing and implementation of standards through expanded adoption of scientifically based national guidelines.

---

**B100 Current and Future Standards Development Activities Related to the Analysis of Seized Drugs**

*Agnes D. Winokur\*, Drug Enforcement Agency, Miami, FL*

---

**Learning Overview:** After attending this presentation, attendees will have a better understanding of the current status and future path of discipline-specific standards and activities pertinent to the analysis of seized drugs. Attendees will gain awareness of what challenges and obstacles are encountered in the development of standards for seized drugs as well as the opportunities presented to overcome those challenges and help prioritize the specific areas for the standard development process.

**Impact Statement:** This presentation will impact the forensic science community by increasing awareness of current efforts in standard development activities pertinent to the examination of seized drugs. This presentation will also increase understanding of current and evolving training, tools, and resources that support implementation and compliance monitoring.

The Organization of Scientific Area Committees (OSAC) for Forensic Science was created to strengthen the nation's use of forensic science by promoting the use of discipline-specific forensic science standards. The OSAC Seized Drugs Subcommittee has been drafting standards and forwarding them to the standards developing organization, ASTM International, to further develop and publish. Once published, the OSAC reviews the standard documents for inclusion in the OSAC Registry, which serves as a central repository of high-quality, consensus-based, technically sound standards.

During this presentation, updates related to the standards being developed at both the OSAC Seized Drugs Subcommittee and the American Society for Testing and Materials (ASTM) E30 Forensic Sciences Committee will be discussed. These include: (1) newest standards added or in the process of being added to the OSAC Registry; (2) documents currently at ASTM E30 for further development; (3) new and on-going documents currently at the OSAC Seized Drugs Subcommittee or ASTM E30; and (4) other highlights of activities related to standards and the analysis of seized drugs.

In particular, the status and updates for the following standard documents will be presented: Standard Practice for the Differentiation of Marijuana and Hemp in Seized Drug Analysis, Standard Guide for Court Testimony in Seized-Drug Analysis, Standard Practice for Reporting Results and Opinions in the Analysis of Seized Drugs, Standard Practice for Evidence Handling of Seized Drug Evidence, and many more standards related to training and education, validation and verification, chromatography, gas chromatography/mass spectrometry, gas chromatography/infrared spectroscopy, Fourier-transform infrared spectroscopy, colorimetric methods, spectral libraries, quantitative measurement uncertainty, assessment of structural similarity of substances, and others. The process for prioritization of specific areas for standard development will also be discussed as well as the tools to facilitate gap analysis of discipline-specific standards. Highlights of how standards progress through the ASTM process after they move from the OSAC Seized Drugs Subcommittee will also be shown, with specific emphasis on the challenges and successes encountered. The process for the revisions of standards once they are added to the OSAC Registry and how those revisions are balanced with the need for new standards is handled by the Seized Drugs Subcommittee.

**B101 Firearms and Toolmarks Standards and Best Practices: A Collaboration of the NIST OSAC and AAFS Standards Board**

*Robert M. Sanger\*, Sanger Dunkle Law, P.C., Santa Barbara, CA; Xiaoyu A. Zheng, National Institute of Standards and Technology, Gaithersburg, MD*

---

**Learning Overview:** After attending this presentation, attendees will have a better understanding of the work of the National Institute of Standards and Technology (NIST) Organization of Scientific Area Committees (OSAC) Subcommittee and the American Academy of Forensic Sciences (AAFS) Academy Standards Board (ASB) Consensus Body for Firearms and Toolmarks and updating the status of those discipline-specific standards.

**Impact Statement:** This presentation will impact the forensic science community by creating greater awareness of standards development activities pertinent to firearms and toolmarks focusing on the collaborative efforts of the NIST OSAC and the AAFS ASB on those standards.

The OSAC for Forensic Science was created by the NIST to strengthen the nation's use of forensic science by promoting the use of discipline-specific forensic science standards. To this end, the OSAC drafts standards that are forwarded to Standards Developing Organizations (SDOs) that further develop and publish them. The OSAC also reviews standards and recognizes them on the OSAC Registry, which serves as a central repository of high-quality, consensus-based, technically sound standards. The OSAC Firearms and Toolmarks Subcommittee is comprised of over 20 experts in the field from crime laboratories, academia, and government agencies. Its work includes the comparison of microscopic toolmarks on bullets, cartridge cases, and other ammunition components as well as firearm function testing, serial number restoration, muzzle-to-object distance determination, and forensic examination of tools and toolmarks.

The ASB was formed by the AAFS and is recognized as an SDO to accomplish the task of completing and publishing Standards, Best Practice Recommendations, and Technical Notes. The Firearms and Toolmarks Consensus Body (CB) was created by the ASB. The Firearms and Toolmarks Consensus Body is comprised of representatives of the various stakeholders in the firearms and toolmarks forensic discipline. It includes analysts, academics, prosecution and defense lawyers, industry representatives, and related forensic scientists. The Firearms and Toolmarks Consensus Body meets regularly and has done so over the past several years. The CB does most of its work through committees that meet on specific work proposals. Those proposals generally are originated by the Firearms OSAC, which promulgates draft standards. The Consensus Body reviews the proposed draft standards, then submits them for rigorous discussion and review by the relevant committee members and by the Consensus Body itself. The proposed standards are then circulated for public comment and often return for several rounds of discussion and revision.

During this presentation, updates related to firearms and toolmark evidence will be discussed. These include: (1) recent standards that have been added to the OSAC Registry; (2) OSAC-proposed standards; (3) published standards from the ASB that have yet to go through the Registry approval process; (4) documents currently in development at the OSAC or by the ASB; and (5) priorities for new documents or work proposals, and other highlights.

**B102 OSAC Is Ten Years Old—What Will the Next Decade Bring?**

*Mark D. Stolorow\*, Associate Guest Researcher, National Institute of Standards and Technology, Gaithersburg, MD; John Paul Jones II\*, National Institute of Standards and Technology, Gaithersburg, MD*

---

**Learning Overview:** After attending this presentation, attendees will have learned about the Organization of Scientific Area Committees (OSAC) for Forensic Science and its impact over the past ten years. This presentation will describe OSAC's purpose and how the implementation of standards will become expected in the future. In addition to reinforcing this knowledge for established examiners, this will provide an excellent foundation to help prepare new examiners for future testimony.

**Impact Statement:** The United States federal government is investing resources to facilitate the development of forensic science standards for use in the criminal justice system, and there are active efforts to encourage Forensic Science Service Providers (FSSPs) to implement these standards in their operations. This presentation will impact the forensic science community by informing new forensic scientists entering the field how the forensic science standards enterprise evolved over the past ten years and how it will impact their careers for many years to come.

The OSAC for Forensic Science is celebrating its tenth anniversary in February 2024. OSAC was first introduced to the American Academy of Forensic Sciences (AAFS) at the 2014 annual conference in Atlanta, GA, that featured a special session with the OSAC developing committee from the National Institute of Standards and Technology (NIST). OSAC has achieved significant milestones in its ten-year life. We would like to share some of the salient history of OSAC and explore what the next ten years may bring.

Published in 2009, the National Research Council (NRC) Report, *Strengthening Forensic Science in the United States: A Path Forward*, criticized the practice of forensic science in America for (among other things) its failure to have in place a network of nationally recognized, consensus-based standards with scientific merit.<sup>1</sup> In 2014, NIST and the United States Department of Justice (DOJ) responded by creating OSAC to facilitate the development and implementation of high-quality standards for the forensic science community.

OSAC is an organization consisting of more than two dozen forensic science disciplines. There are more than 400 members and 300 affiliates in OSAC. As of August 2023, more than 150 standards have been posted on the OSAC Registry, and more than 130 FSSPs have been recognized as implementers of these standards.

OSAC continues to evolve in its organizational structure, expanding from five Scientific Area Committees (SACs) to seven and consolidating its subcommittees from 25 to 22. Over that time, OSAC recognized additional forensic science disciplines, including digital evidence and forensic nursing. OSAC introduced the Scientific and Technical Review (STR) process in 2020 to provide an independent subject matter expert and peer review to all relevant drafted standards.

OSAC has entered into a cooperative agreement with the AAFS to develop an array of tools to help FSSPs learn about and implement standards on the OSAC Registry. These tools include fact sheets, checklists, and training modules to guide practitioners in the process of standards implementation.

What will the next ten years bring to the world of forensic science standards development and implementation? OSAC has established a cohort of FSSPs who have successfully implemented standards on the OSAC Registry. Their mission will be to help other FSSPs initiate standards implementation and address current and future implementation needs.

OSAC's efforts to improve the practice of forensic science through standards depend on the collaboration and dedication of more than 800 volunteers from all 50 states. It is a testament to the success of all our stakeholders that OSAC has achieved so many valuable milestones, and we look forward to many more in the next ten years.

**B103 Results From an Interlaboratory Study to Evaluate Analytical Schemes in ASTM E2329—Standard Practice for Identification of Seized Drugs**

Jeremy S. Triplett\*, Kentucky State Police Central Forensic Laboratory, Frankfort, KY; Michael J. Salyards, Compass Scientific Consulting LLC, Tucson, AZ; Sandra E. Rodriguez-Cruz, Drug Enforcement Administration, Dulles, VA; Jeremiah Morris, Johnson County Sheriff's Office Criminalistics Laboratory, Olathe, KS; Megan Grabenauer, RTI International, Research Triangle Park, NC; Darryl Creel, RTI International, Research Triangle Park, NC

---

**Learning Overview:** This presentation uses data from over 1,300 analytical tests performed by 71 forensic laboratories to evaluate the performance of analytical techniques categorized in the American Society for Testing and Materials (ASTM) E2329-17. After attending this presentation, attendees will know the relative sensitivity and specificity of the included techniques and technique combinations in identifying methamphetamine or cocaine in solid dose samples.

**Impact Statement:** This presentation will impact the forensic science community by providing evidence upon which to base decisions about the suitability of analytical techniques for testing seized drug samples. The study's findings confirm the importance of using multiple techniques to test suspected methamphetamine seized drug samples. The results obtained in this study apply only to methamphetamine and, to a limited degree, cocaine.

The Organization of Scientific Area Committees for Forensic Science (OSAC), sponsored by the National Institute of Standards and Technology (NIST), recently joined the Scientific Working Group for the Analysis of Seized Drugs (SWGDRUG) effort to vet existing standards and promote the development of additional consensus-based documentary standards for seized drugs. An important recommendation developed by SWGDRUG is the minimum standard for identifying commonly seized drugs related to the selection of analytical technique(s), which was formally developed into ASTM E2329.<sup>1,2</sup>

The technique classifications in ASTM E2329-17 have been well vetted, and there is little objection to the rationale behind the technique classification. However, there is a lack of empirical data demonstrating that one technique or combination of techniques is better (e.g., is more accurate or has a lower false-positive or false-negative error rate) than others.<sup>3</sup> There have been previous efforts to determine error rates for seized drug analysis processes, and the National Institute of Justice Technology Working Group for Seized Drugs has highlighted the need for additional error rate studies in forensic drug chemistry.<sup>4-6</sup> The study presented here uses known ground-truth samples to compare the accuracy of various single analytical techniques versus technique combinations for samples containing methamphetamine or cocaine.

This study involved 71 forensic seized drug laboratories performing over 1,300 tests analyzing 65 total samples; 17 were ground-truth positive (i.e., they contained methamphetamine or cocaine); 48 were ground-truth negative (i.e., they did not contain methamphetamine or cocaine). The positive samples were prepared at several target-analyte concentrations and included common cutting agents. The negative samples were designed to be challenging and prepared to contain positional isomers of methamphetamine. Participants were sent one sample set and directed to only use a single, pre-selected analytical technique. They were sent a separate second sample set and directed to use a specific analytical scheme consisting of multiple techniques in compliance with ASTM E2329-17. The results of the study showed good accuracy; sensitivity was 1.000 for all analytical schemes with 1-specificity (the false-positive rate) ranging from 0.000 to 0.250 when ASTM E2329-17-compliant analytical schemes were used. When only a single technique was used, accuracy was generally not as good; sensitivity ranged from 1.000 to 0.091, and 1-specificity ranged from 0.000 to 0.245.

---

**B104 Standards Development Activities in Trace Materials**

*Celeste M. Grover, Oregon State Police, Forensic Services Division, Clackamas, OR; Sandra Koch, PhD\*, National Institute of Standards and Technology, Washington, DC*

---

**Learning Overview:** After attending this presentation, attendees will have a better understanding of the status of discipline-specific standards pertinent to the examination and interpretation of trace materials in development by the Organization of Scientific Area Committees (OSAC) for Forensic Science.

**Impact Statement:** The presentation will impact the forensic science community by creating greater awareness of standards development activities related to trace material examination and interpretation. It will also increase awareness regarding training, tools, and resources that support implementation, compliance monitoring, and broader understanding.

OSAC was created to strengthen the nation's use of forensic science by promoting the use of discipline-specific forensic science standards. To this end, the OSAC drafts standards that are forwarded to Standards Development Organizations (SDOs) that ballot and publish them. The OSAC also reviews standards and recognizes them on the OSAC Registry, which serves as a central repository of high-quality, consensus-based, technically sound standards.

As of July 2023, the OSAC Trace Materials Subcommittee has 16 published and 4 proposed standards on the OSAC Registry. Work is on-going for over 25 additional documents making their way through the OSAC Registry and American National Standards Institute/ American Society for Testing and Materials (ANSI/ASTM) processes as well as continued partnership with RTI on the development of the Trace Evidence Collection App.

During this presentation, updates related to standards development activities in Trace Materials will be discussed. (Standards were placed in categories based on their status projected for February 2024. Thus, the status of a given document may differ at the time of presentation.) These include:

1. Recent Standards That Have Been Added to the OSAC Registry (published)
  - a. E2224 Standard Guide for Forensic Analysis of Fibers by IR
  - b. E2225 Standard Guide for Forensic Examination of Fabrics and Cordage
  - c. E2227 Standard Guide for Forensic Examination of Non-reactive Dyes in Textile Fibers by Thin Layer Chromatography
  - d. E2228 Standard Guide for Microscopic Examination of Textile Fibers
  - e. E3254 Standard Practice for Determination and Comparison of Color by Visual Observation in Forensic Soil Examination
2. Recent Standards That Have Been Added to the OSAC Registry (proposed—pending SDO approval)
  - a. WK78748 Standard Practice for a Forensic Fiber Analysis Training Program
  - b. WK78747 Standard Guide for Forensic Fiber Analysis and Comparison
  - c. WK78749 Standard Guide for Forensic Analysis of Fibers by Microspectrophotometry
  - d. WK84047 Standard Guide for Forensic Physical Fit Examinations
  - e. WK86723 Standard Guide for Interpretation and Reporting in Forensic Comparisons of Trace Materials
  - f. Standard Guide for Physical Fit Training Program
3. Published ASTM Standards Going Through the Registry Approval Process
  - a. WK72932 Standard Guide for Forensic Glass Analysis and Comparison
  - b. E3175 Standard Practice for Training in the Forensic Examination of Hair by Microscopy
  - c. E3295 Standard Guide for Using X-ray Fluorescence in Forensic Polymer Examinations
4. Standards Going Through the ASTM Process (5-year review)
  - a. E2926 Standard Test Method for Forensic Comparison of Glass Using Micro X-ray Fluorescence (u-XRF) Spectrometry
  - b. E2927 Standard Test Method for Determination of Trace Elements in Soda-Lime Glass Samples Using Laser Ablation Inductively Coupled Plasma Mass Spectrometry for Forensic Comparisons
  - c. WK84554/E3085 Standard Guide for Fourier Transform Infrared Spectroscopy in Forensic Tape Examinations
  - d. E2937 Standard Guide for Infrared Spectroscopy in Forensic Paint Examinations
  - e. E1610 Standard Guide for the Forensic Analysis of Paint
5. Standards Going Through STRP/Non-STRP Process
  - a. Standard Practice for a Forensic Glass Analysis Training Program
  - b. Standard Guide for the Recovery of Forensic Trace Evidence
6. Documents Currently in Development With the Subcommittee
  - a. Standard Guide for Using Scanning Electron Microscopy for Morphology and Energy Dispersive Spectroscopy in Forensic Soil and Geological Materials Analysis
  - b. Standard Guide for the Use of Polarized Light Microscopy in the Forensic Examination and Comparison of Sands and Soils
  - c. Standard Guide for Using X-ray Diffraction in Forensic Polymer Examinations

Copyright 2024 by the AAFS. Permission to reprint, publish, or otherwise reproduce such material in any form other than photocopying must be obtained by the AAFS.

- d. Standard Guide to Raman Spectroscopy in Forensic Polymer Examinations
  - e. Standard Guide for Assessing Physical Characteristics and Using Light Microscopy in Forensic Tape Examinations
  - f. Standard Guide for Forensic Examination of Textile Damage and Textile Impressions
  - g. Standard Guide for Forensic Examination of Fibers and Textiles Using Fluorescence
  - h. Standard Terminology Relating to Forensic Analysis of Trace Evidence Materials
7. Priorities for New Documents or Work Products
- a. Interdisciplinary development of technical guidance related to the examination of textile-related impressions
  - b. Interdisciplinary development of technical guidance related to the examination of General Unknowns
-

**B105 Standards Development Activities Related to Friction Ridge Examination**

*Heidi Eldridge\*, The George Washington University, Washington, DC; Henry Swofford\*, National Institute of Standards and Technology, Gaithersburg, MD*

---

**Learning Overview:** After attending this presentation, attendees will have a better understanding of the status of discipline-specific standards related to the examination of friction ridge detail from the hands and feet.

**Impact Statement:** This presentation will impact the forensic science community by creating greater awareness of standards development activities pertinent to the examination of friction ridge detail.

The Organization of Scientific Area Committees (OSAC) for Forensic Science was initially created in 2014 through a cooperative agreement between the National Institute of Standards and Technology (NIST) and the Department of Justice (DOJ) to address the lack of discipline-specific standards guiding forensic science practices. To this end, the OSAC facilitates the development of discipline-specific forensic science standards and guidelines that can be further developed and published by Standards Developing Organizations (SDOs). The OSAC also evaluates standards for placement on the OSAC Registry, which serves as a central repository of consensus-based standards that have been deemed high quality and technically sound. The Academy Standards Board (ASB) was established by the AAFS in 2015 as an American National Standards Institute (ANSI) -Accredited SDO. Both organizations are comprised of volunteer practitioners and other stakeholders, and they have a collaborative relationship in which documents created by the OSAC Friction Ridge Subcommittee (FRS) are passed to the ASB Friction Ridge Consensus Body (FRCB) for the standards development process, after which they are considered for inclusion on the OSAC Registry.

During this presentation, updates related to friction ridge standards development activities will be presented. These include: (1) standards and guidelines that have been proposed by the OSAC FRS and are currently being evaluated and further developed through the ASB FRCB; (2) standards and guidelines that have been published by the ASB and are being considered for the OSAC Registry; (3) standards and guidelines published by the ASB that have been placed on the OSAC Registry; (4) documents currently in development by the OSAC or by the ASB; and (5) priorities for new documents or work products by the OSAC FRS or by the ASB FRCB. This presentation will also highlight how the process of moving documents back and forth between the OSAC and ASB works for the friction ridge discipline, challenges and successes that process has encountered, and what the near future looks like for the promulgation of friction ridge standards and guidelines.

**Standards; Latent Prints; Professional Responsibility**

**B106 Standards Development Activities Related to Ignitable Liquids, Explosives, and Gunshot Residue**

*Brenda B. Christy\*, Virginia Department of Forensic Science, Norfolk, VA*

**Learning Overview:** After attending this presentation, attendees will have a better understanding of the status of discipline-specific standards related to Ignitable Liquids (IL), Explosives (E), and Gunshot Residue (GSR).

**Impact Statement:** The presentation will impact the forensic science community by creating greater awareness of standards development activities related to IL, E, and GSR.

The Organization of Scientific Area Committees (OSAC) for Forensic Science was created to strengthen the nation's use of forensic science by promoting the use of discipline-specific standards. To this end, the OSAC drafts standards that are forwarded to Standards Developing Organizations (SDOs) that further develop and publish them. The OSAC also reviews standards and recognizes them on the OSAC Registry, which serves as a central repository of high quality, consensus-based, technically sound standards.

During this presentation, ILs, E, and GSR standards development activities will be discussed. These include:

1. Recent standards that have been added to the OSAC Registry
  - a. ASTM E2451-21 *Standard Practice for Preserving Ignitable Liquids and Ignitable Liquid Residue Extracts from Fire Debris Samples*
  - b. ASTM E3196-21, *Standard Terminology Relating to the Examination of Explosives*
  - c. ASTM E3253-21, *Standard Practice for Establishing an Examination Scheme for Intact Explosives*
  - d. ASTM E3329-21, *Standard Practice for Establishing an Examination Scheme for Explosive Residues*
  - e. ASTM E3309-21, *Standard Guide for Reporting of Forensic Primer Gunshot Residue (pGSR) Analysis by Scanning Electron Microscopy/Energy Dispersive X-Ray Spectrometry (SEM/EDS)*
2. OSAC proposed standards
  - a. OSAC 2021-N-0009, *Standard Practice for the Collection and Preservation of Organic Gunshot Residues* (added December 7, 2021).
  - b. OSAC 2022-S-0002, *Standard Guide for the Identification of Compounds Related to Organic Gunshot Residue (oGSR) by Gas Chromatography-Mass Spectrometry (GS-MS)*
  - c. OSAC 2022-S-0003, *Standard Practice for the Identification of Compounds Related to Organic Gunshot Residue (oGSR) by Liquid Chromatography-Mass Spectrometry (LC-MS)*
  - d. OSAC 2022-S-0023, *Standard Practice for the Forensic Analysis of Explosives by Polarized Light Microscopy*
3. Published standards from the ASTM that have yet to go through the Registry approval process
  - a. ASTM E2881-18 *Standard Test Method for Extraction and Derivatization of Vegetable Oils and Fats from Fire Debris and Liquid Samples with Analysis by Gas Chromatography-Mass Spectrometry*.
  - b. ASTM E2998-16 *Standard Practice for Characterization and Classification of Smokeless Powder*.
  - c. ASTM E2999-17 *Test Method for Analysis of Smokeless Powder by Gas Chromatography-Mass Spectrometry and Fourier-Transform Infrared Spectroscopy*.
  - d. REVISION to ASTM E1386 *Standard Practice for Separation of Ignitable Liquid Residues from Fire Debris Samples by Solvent Extraction* (under revision as WK78319).
  - e. REVISION to ASTM E2997-16 *Standard Test Method for Analysis of Biodiesel Products by Gas Chromatography-Mass Spectrometry* (under revision as WK78732).
  - f. REVISION to ASTM E2998 *Standard Practice for Characterization and Classification of Smokeless Powder*.
  - g. REVISION to ASTM E2999 *Test Method for Analysis of Smokeless Powder by Gas Chromatography-Mass Spectrometry and Fourier-Transform Infrared Spectroscopy*.
  - h. REVISION to ASTM E3197 *Standard Terminology Relating to the Examination of Fire Debris*.
  - i. REVISION to ASTM E3255 *Standard Practice for Quality Assurance of Laboratories Performing Chemical Analysis of Ignitable Liquids and Ignitable Liquid Residues* (Annex).
4. Documents currently in development at the OSAC or by the SDO
  - a. Standard Practice for Training in the Forensic Examination of Fire Debris
  - b. Standard Practice for the Characterization of Solid Oxidizer/Fuel Explosive
  - c. Standard Practice for Collection and Preservation of oGSR
  - d. Standard Practice for Expert Opinions on the Interpretation of pGSR by SEM/EDS
  - e. Standard Practice for Training in the Forensic Examination of GSR Using SEM/EDS
5. Priorities for new documents or work products
  - a. Fire Debris and Explosives annexes for ASTM E2549
  - b. Standard Practice for Validation and Verification of Analytical Methods for Forensic Science Service Providers Performing Forensic Chemistry Analysis
  - c. Standard Guide for the Performance of Automated pGSR Analysis by SEM/EDS

**B107 A 2024 Update From the Scientific Working Group for the Analysis of Seized Drugs (SWGDRUG)**

*Jaclyn Iera\*, Secretariat, SWGDRUG, Springfield, VA*

---

**Learning Overview:** The goal of this presentation is to provide a summary of the most recent activities and work products developed by SWGDRUG.

**Impact Statement:** This presentation will impact the forensic science community by identifying how SWGDRUG supports the development of internationally accepted minimum standards for forensic examination, identifies best practices within the international community, and provides resources to help laboratories meet these standards.

SWGDRUG was formed in 1997 in a joint effort between the United States Drug Enforcement Administration (DEA) Office of Forensic Sciences and the Office of National Drug Control Policy (ONDCP). SWGDRUG works to improve the quality of the forensic examination of seized drugs and to respond to the needs of the forensic community by supporting the development of internationally accepted minimum standards, identifying best practices within the international community, and providing resources to help laboratories meet these standards. This presentation will provide attendees with information on SWGDRUG activities during the past two years.

The SWGDRUG core committee members met in the summer of 2022 after a hiatus due to COVID-19 and approved the most recent version of the SWGDRUG Recommendations, version 8.1, which includes revisions to PART IVA (*Quality Assurance/General Practices*) and Supplemental Document SD-5 (*Reporting Examples*). During the summer of 2023, core committee members revised sections PART II (*Education and Training*), PART IIIA (*Methods of Analysis/Sampling Seized Drugs for Qualitative Analysis*), and PART IIIB (*Methods of Analysis/Analytical Scheme for Identification of Drugs or Chemicals*). Revisions in these sections address virtual training, options for sampling when negatives are encountered, and the use of validated methods in an analytical scheme.

Revisions were also made to PART IVB (*Quality Assurance/Validation of Analytical Methods*) and definitions in the Annex. Revisions include additional background information and clarifications on the performance characteristics to be evaluated during the validation of both qualitative and quantitative methods. Future work will involve the revision of the currently existing Supplemental Document SD-2 (*Validation of Analytical Methods*) to better assist seized-drug practitioners during method validation activities.

This presentation will also summarize recent updates on multiple SWGDRUG resources such as the MS library, IR library, and Drug Monographs.

The SWGDRUG core committee includes representatives from regional, national, and international forensic organizations; educators, practitioners, and scientists from the United States; and representatives from the European Network of Forensic Science Institutes (ENFSI), the Academia Iberoamericana de Criminalística y Estudios Forenses (AICEF), the Asian Forensic Science Network (AFSN), and the United Nations Office on Drugs and Crime (UNODC).

## **B108 The Forensic Science Initiative (FSI): A Pathway to College and STEM Education**

*David Fisher\*, New Jersey Institute of Technology, Newark, NJ; Barbara Elder Weller\*, Program Development and Forensic Science Initiative, New Jersey Institute of Technology, Newark, NJ; Kevin D. Belfield, College of Science & Liberal Arts, New Jersey Institute of Technology, Newark, NJ; Jacqueline L. Cusack, Pre-College Programs, New Jersey Institute of Technology, Newark, NJ*

---

**Learning Overview:** After attending this presentation, attendees will be aware of the impact and success of the FSI in introducing underrepresented high school students to forensic science as a pathway to college and Science, Technology, Engineering, and Math (STEM) education, fostering increased interest in forensics, and preparing students for successful careers.

**Impact Statement:** This presentation will impact the forensic science community by showcasing the effective implementation of the FSI, demonstrating how targeted educational programs can enhance diversity, interest, and preparedness for STEM careers among underrepresented high school students.

Launched in 2022 through a collaboration among New Jersey public school districts, and New Jersey Institute of Technology's (NJIT's) College of Science & Liberal Arts (CSLA) and the Center for Pre-College Programs (CPCP), the FSI provides underrepresented high school students in New Jersey with a pathway to college by strengthening their skills in STEM through the gateway of forensic science. NJIT is committed to increasing the enrollment of underrepresented students from New Jersey public schools and feels an obligation to prepare students for admission, not just review their admission applications. Supported by a \$1.4M grant from the United States Department of Higher Education's Governor's Emergency Education Relief (GEER) fund, FSI was a part of the state's "Opportunity Meets Innovation" challenge. The initiative, spearheaded by the NJIT, introduced high school students to forensic science as a pathway to higher education through an intensive summer experience featuring class work, lab work, field research, tutoring, and college preparation. In the fall, students took a college-level course "FRSC 201—Introduction to Forensic Science," and in the spring, they completed a capstone research project with a faculty mentor. By using forensic science as a stealth mechanism to help students develop competency and preparation for college-level STEM work, the FSI program achieved a 100% college acceptance rate for all students enrolled in the program's first year, with 62% electing to attend NJIT.

Underserved students are frequently under-equipped to gain admission to STEM programs at universities, at least in part due to a dearth of highly prepared STEM teachers in K-12 schools nation-wide. Alongside the student component, we also provided professional development for high school forensic science teachers in both lesson plan development and gap lesson design to create a successful dual enrollment course, "Introduction to Forensic Science," that students can take in future years at their high schools. Professional development consisted of lesson study, content development, and flipped classrooms. The projected registration for Fall 2023 is 240 high school seniors.

**B109 What Is the Probability That a True Match Will Appear in the Top K Correlations After a Database Search?**

*Alicia Laura Carriquiry\*, CSAFE, AMES, IA; Heike Hofmann, Iowa State University, Ames, IA; Blanca I. Parker, Binghamton University, Schenectady, NY; Cathryn Barbour, Mount Holyoke College, Lexington, MA*

---

**Learning Overview:** After attending this presentation, attendees will understand that searches such as those conducted by firearms examiners using a system such as the National Integrated Ballistic Information Network (NIBIN) have a high probability of excluding a true match. The probability depends on the size of the local database that is searched, the number of potential candidate matches requested by the investigator, and the degree of overlap of the distributions of same-source and different-source similarity scores.

**Impact Statement:** This presentation will impact the forensic science community by informing attendees that some investigators may be inclined to heavily rely on the output of database searches that typically consist of a list of potential matches to the questioned item. Even though no practitioner would reach a conclusion without examination of the physical items, the fact that systems such as NIBIN produce lists of promising matches is suggestive and can introduce biases. Therefore, an important goal is estimating the reliability with which these systems include true matches among the candidate lists. If the probability that a true match is not included among the most promising candidates happens to be high, then the benefits of using a database search may be overshadowed by the introduction of bias.

A crime has been committed and firearms examiners have recovered spent bullets and cartridge cases from the scene. To generate investigative leads, examiners often rely on proprietary systems such as NIBIN. The NIBIN system was established over 25 years ago and includes a database of bullet and cartridge case images from real cases that have been uploaded by examiners in the course of their investigations. At present, the database includes 57+ million images that can, in principle, be searched by any NIBIN user to correlate a piece of evidence to potentially similar bullets or cartridge cases recovered from other crime scenes. Neither the database of images nor the correlation algorithm is publicly available, so they cannot be tested for accuracy or reliability.

Systems such as NIBIN work as follows. Investigators upload images of the crime scene item(s) onto the system and request a list of the top  $k$  most similar items from the database. Examiners then decide whether any of the  $k$  candidates are similar enough to the questioned items to warrant a physical comparison. Published statistics are impressive. According to data presented in the Bureau of Alcohol, Tobacco, Firearms and Explosives (ATF) website, over 640,000 leads were generated nationwide since NIBIN was established, and 145,000 of them have resulted in a confirmed “match.” Last year alone, examiners captured over 630,000 pieces of evidence and generated almost 200,000 leads.

But how reliable are NIBIN searches? Suppose that one or more true matches to a questioned piece of evidence is in the NIBIN database. How likely are those true matches to be included in the list of the top  $k$  correlations identified by the system? Because NIBIN is proprietary, there is no straightforward way to estimate how frequently a search may fail to include a true match among the  $k$  most promising candidates. The reason this is important has to do with contextual bias. If among the  $k$  items that are most similar to the questioned item there is one or more that are close non-matches, the investigator may be persuaded to find correlations that are not really there. In a similar situation, Federal Bureau of Investigation (FBI) latent print examiners incorrectly identified Mr. Mayfield as the perpetrator of the 2004 train bombing in Madrid.

To explore this question, we carried out a simulation where we varied the potential number of correlations ( $N$ ), and the size of the list of candidates ( $k$ ). In a small state such as Iowa, the size of the local NIBIN database is likely to be small, with  $N$  around 500 potential correlations. In other states such as Texas, California, or New York, the potential number of correlations may be in the order of a few hundred thousand. We used beta probability models to represent the distribution of Same Source (SS) and Different Source (DS) similarity scores, with parameters fixed at values that would reproduce the scores calculated from data obtained by Fadul and Weller, after rescaling their values to a (0, 1) interval.<sup>1</sup> We considered databases of size  $N=500, 5,000, 50,000$ , and  $5,000,000$ , and for each, requested the top  $k=10, 20, 50, 100$  most similar items when  $N-1$  items were sampled from the DS distribution and one item was sampled from the SS distribution. Our findings suggest that at least three factors have a strong impact on the probability of inclusion of the one true match in the candidate list. Those factors are: the size of the search space  $N$ , the number of candidates  $k$ , and the degree of overlap between the DS and the SS distributions.

**B110 The European Network of Forensic Science Institutes (ENFSI) Guideline for the Calculation of Measurement Uncertainty in Quantitative Forensic Investigation**

*Ivo Alberink\*, Forensic Netherlands Forensic Institute, Den Haag, Zuid-Holland, Netherlands; Rosario García-Repetto, Seville Department of the Spanish National Institute of Toxicology, Sevilla, Andalucia, Spain; Maria Luisa Soria Sánchez, Seville Department of the Spanish National Institute of Toxicology, Sevilla, Andalucia, Spain; Jos Tóth, Netherlands Forensic Institute, Den Haag, Zuid-Holland, Netherlands*

---

**Learning Overview:** After attending this presentation, attendees will have knowledge on the current version of the latest guideline of the ENFSI on how to determine measurement uncertainty when performing chemical or physical investigations.

**Impact Statement:** This presentation will impact the forensic community by illustrating solutions for typical issues that may arise when determining measurement uncertainty when conducting chemical or physical investigations.

The users of forensic expert reports have to interpret the contents correctly. This implies that the results and conclusions of quantitative measurements should also include the degree of reliability of measurement data provided, including the Measurement Uncertainty (MU) involved. The requirements of ISO 17025 underline the latter. Naturally, statistics and, as a derivative thereof, the performance of MU calculations have been part of the professional training of forensic experts. Nevertheless, forensic experts often experience the performance of MU calculations as a difficult necessity. To facilitate calculating of MU in quantitative forensic investigations, there was an existing guideline by the **Quality & Competence** Liaison Group-Quality and Competence standing Committee (QCLG-QCC) project of the ENFSI, which dated from 2006. In the period 2019–2022, a team of practitioners from several fields of expertise, combined with a team of forensic statisticians, wrote a revised version of this guideline.

The guideline aims to provide information and practical advice to anyone who is looking for applicable and understandable knowledge and worked out examples on how to apply MU in forensic technical methods. The scope of this guideline focuses on MU calculations as applied in quantitative chemical and physical forensic investigation methods. The manner in which information, originating from, for example, sampling aspects, results of validation studies, or Proficiency Tests (PT) can be used for calculations of MU, are present in the worked-out examples as included in this guideline.

The analysis consists of recommendations on how to calculate uncertainty in standard casework, where either measurements on certified reference material are present or results in proficiency testing, but also in complex casework, where typically small experiments have only a few measurements are present. The content of the guideline is structured along seven examples.

Examples of forensic chemistry include determination of ethanol in blood using headspace gas chromatography with flame ionization detector, besides determination of both cocaine and MDMA in powders/seizures by high performance liquid chromatography, and Tetrahydrocannabinol (THC) in blood. For this type of casework, the guideline describes several methods to determine MU, either based on measurements on certified reference materials or PT results, including a statistical background of the latter. Next to this, it is explained how free software may be used for this.

Examples of forensic physics include calibration of digital thermometers, determination of drug weight, excluding packing material, and velocity estimation of speeding cars in video footage. Here, typically MU is determined by devising statistical models like linear regression on a case-to-case basis.

The examples in the guideline are straightforward, even for the more complex examples. This allows a wide application of this guide. The examples are offering the reader, therefore, a framework to calculate MU, not a normative set of rules.

**B111 A Comparison of Computational and Laboratory-Generated Fire Debris Data**

*Larry Tang\*, University of Central Florida, Orlando, FL; Mary R. Williams, University of Central Florida, Orlando, FL; Michael E. Sigman, University of Central Florida, Orlando, FL*

---

**Learning Overview:** This presentation will cover machine learning aspects of enhanced ignitable liquid and substrate databases. After attending this presentation, attendees will understand how training data is generated computationally from the database records and how to implement machine learning methods on the training data.

**Impact Statement:** This presentation will impact the forensic science community by providing insight into how well calculated and laboratory-generated fire debris agree and the use of calculated fire debris to train methods for predicating the presence of ignitable liquid in casework samples.

In this study, we analyze: (Analysis 1) how computationally mixed fire debris data compares with laboratory-generated samples, and (Analysis 2) compare laboratory-generated samples and computationally mixed fire debris data utilizing the Ignitable Liquids Reference Collection (ILRC) with digital weathering and the Substrate Database. Statistical measures were used to assess how well the in-silico mixture data compared to the ground truth fire debris samples. The statistical measures utilized were the concordance and Pearson correlation coefficients. Concordance measures the agreement between samples and Pearson measures linear relationship. If two Total Ion Chromatograms (TIC) are in perfect agreement, the best fit line for an XY plot of the two TICs will fall completely on a 45-degree line from the origin, and the concordance Correlation Coefficient (CC) will equal 1. A high Pearson correlation between two TICs indicates a linear XY plot, but the slope may not fall on a 45-degree line. Preliminary results from Analysis 1 indicate almost perfect CC agreement between sets of TICs and a strong linear relationship. Preliminary results from Analysis 2 show a lower CC agreement and weaker linear relationship between sets of TICs compared to results from Analysis 1.

Under National Institute of Justice (NIJ) sponsorship, a large standard in-silico fire debris dataset will be generated and made publicly available for machine learning research. Examples of machine learning methods, including linear discriminant analysis, random forest, gradient boosting, and neural network for classification utilizing the standard dataset will be given. Classification accuracy measures, including false positive rate, false negative rate, and the area under the receiver operating characteristics curve, for the examples will be demonstrated. The accuracy measures will be plotted for various machine learning methods to visualize how the accuracy changes with different methods. The machine learning methods will also be applied to the laboratory-generated samples to evaluate the accuracy of these methods. The accuracy for laboratory-generated samples will be compared with the computationally mixed samples.

**B112 A Fire Debris Interpretation Using Quantitative Measures of Chromatographic Features in Medium-Range Ignitable Liquids and the Use of Graphical Display to Demonstrate Data Sufficiency**

*Kelsey R. Winters\*, Virginia Department of Forensic Science, Norfolk, VA; Brenda B. Christy, Virginia Department of Forensic Science, Norfolk, VA*

---

**Learning Overview:** The goal of this presentation is to introduce a validated method for the evaluation of fire debris Gas Chromatography/Mass Spectrometry (GC/MS) data that quantifies the support for a medium petroleum distillate identification using a sufficiency chart.

**Impact Statement:** This presentation will impact the forensic science community by introducing a quantitative sufficiency chart that will increase the objectivity and transparency of the fire debris expert's inferential process.

This presentation will discuss a method for the evaluation of fire debris GC/MS data for the presence of medium petroleum distillates using quantitative measures to determine the sufficiency of the sample to support an identification. This presentation will highlight the use of key chromatographic features to create a graphical display of the sufficiency of the data from the sample. This approach to data interpretation is the first step toward a validated method that will be a part of an objective, increasingly transparent process for the identification of medium petroleum distillates in the presence of complex matrices.

Ignitable liquid identification is based on chromatographic pattern recognition. While the analytical processes associated with the analysis of fire debris for the presence of ignitable liquids are based on fundamental chemical properties, the interpretation process is subjective. The degree of subjectivity is directly related to the abundance and type of interference from volatile compounds produced by the matrix (inherent, pyrolysis, and combustion products) and the concentration of any ignitable liquid residues present in the sample. This can, and does, lead to a lack of consistency in interpretation and reporting within the field for complex samples.

Previously, a study was conducted and published showing the application of quantitative measures of chromatographic features and graphical display of data sufficiency for gasoline.<sup>1</sup> This study was similarly designed to establish quantitative measures of assessing the chromatographic features of medium petroleum distillates and to apply statistical measures to create sufficiency parameters for use in interpreting data and rendering conclusions. The study involved the evaluation of medium petroleum distillate samples evaporated up to 90%, negative matrix samples, and real-world samples composed of mixtures of matrix and medium petroleum distillates. Key chromatographic features in over 150 medium petroleum distillate samples were evaluated. Up to 192 potential chromatographic peak heights were collected per sample and up to 122 ratios were determined for comparison. Statistical analysis was conducted to determine the variation observed for each of these ratios in known medium petroleum distillate samples and to determine the frequency of the presence of these key chromatographic features in negative matrix samples. This information was evaluated to determine relative scores for each of these features. The scores were used to create a sufficiency chart, a graphical display of the amount of data supporting a potential medium petroleum distillate identification. This sufficiency chart allows the analyst to objectively evaluate the data. Statistically developed decision lines on the sufficiency chart also identify the “gray” area where analysts are more likely to form differing opinions.

Ultimately, this project will help standardize fire debris experts' inferential process (by establishing a fully validated method) and increase objectivity (by establishing quantitative measures) and transparency (by implementing graphical documentation), all of which will be statistically based.

**Fire Debris Analysis; Interpretation; Sufficiency**

## B113 An Evaluation of Headspace Solid Phase Microextraction of Diesel Fuel From Cotton Swabs for Forensic Analysis

Ting-Yu Huang\*, Sam Houston State University, Huntsville, TX; Jorn Yu, Sam Houston State University, Huntsville, TX

**Learning Overview:** The presentation will demonstrate how the headspace Solid Phase Microextraction (SPME) procedure performs for extracting diesel fuel from cotton swabs. The attendees will understand that cotton swabs are promising for the collection of Ignitable Liquid (IL) residues in fire scenes. The attendees will also understand the performance between silicone-oxygen-based and conducting-based SPME polymer fiber for IL extraction.

**Impact Statement:** This presentation will impact the forensic science community by considering proper sample collection and extraction techniques to improve the recovery of trace ILs in fire scenes. Forensic analysts will learn the selection of different sorbent materials in achieving desirable affinity toward target compounds extraction in ILs.

The aim of sample collection at a fire scene is to provide forensic information on physical evidence critical to the fire investigation. Cotton swabs have been useful for collecting trace physical evidence, such as biological evidence, stains, gunshot residues, and explosive residues.<sup>1-3</sup> Cotton swabs are versatile to be adapted to different types of objects and surfaces, and they are relatively affordable compared with other sampling devices.<sup>4</sup> With their good absorption capability, cotton swabs are potential collecting media for ILs in fire cases. SPME offers a rapid, automated, and solvent-free approach for extracting volatile organic compounds from ILs samples.<sup>5</sup> The SPME fibers can be reused by a simple conditioning process at an autosampler. Those advantages have attracted increasing interest from researchers and made SPME one of the standardized test methods for fire debris analysis.<sup>6</sup> Therefore, this work aimed to investigate the feasibility of a headspace SPME method for determining an IL collected by cotton swabs using SPME fibers coated with different sorbent materials.

To test the research question, diesel fuel was chosen in this work. The SPME fibers used for the analysis included a commercial 100µm Polydimethylsiloxane (PDMS) fiber and a lab-built fiber made by electro-polymerization of pyrrole and Carbon Nanotubes (ppy-CNTs) on the surface of a stainless-steel wire. Eight levels of calibrator samples were prepared, and 5µl of each calibrator was spiked onto different swabs in a 20mL headspace vial. The SPME fibers were utilized to extract seven target compounds in the diesel fuel, followed by their identification and quantitation by Gas Chromatography/Mass Spectrometry (GC/MS). The effects of different collection time intervals and deposited time intervals on a glass surface for the diesel fuel were assessed.

The results indicated that the linear dynamic ranges were 0.01–0.6µg mL<sup>-1</sup> for PDMS fiber and 0.01–0.3µg mL<sup>-1</sup> for ppy-CNTs fiber in neat samples, and 0.01–1.3µg mL<sup>-1</sup> for both SPME fibers in spiked swabs, with the coefficients of determination all above 0.99. The relative recoveries were 24.2–49.2% for PDMS fiber and 24.2–39.1% for ppy-CNTs fiber, respectively. The proposed method could recover 1.3µg mL<sup>-1</sup> of diesel fuel after one hour of being spiked on a swab. The same amounts of IL deposited on a glass surface for up to four hours of exposure to air could also be identified by GC/MS.

In conclusion, the proposed headspace SPME-GC/MS method was successfully applied to the determination of IL traces from spiked swabs and direct transfer of swabbed samples. The qualitative and quantitative results obtained by commercial and lab-built SPME fibers were both promising. The importance of the proposed work was to demonstrate a more flexible, low-cost, speedy, and environmental-friendly approach for sample collection and forensic analysis of ILs. It is expected that the method offers promising opportunities for sampling and identifying other ILs to support fire investigation.

**B114 An Evaluation of Tape for the Collection of Ignitable Liquid Residues From Non-Porous and Porous Surfaces**

*Cynthia J. Kaeser Tran, Eastern Kentucky University, Lexington, KY; Laird Jarrett\*, Eastern Kentucky University, Richmond, KY*

---

**Learning Overview:** After attending this presentation, attendees will better understand the current methods for collection of Ignitable Liquid Residue (ILR) from porous fire debris evidence and the potential for using tape to simplify and improve the collection process.

**Impact Statement:** This presentation will impact the forensic science community by introducing a new method of ILR collection using tape. This method could provide a more cost-effective and practical method for the recovery of the Ignitable Liquids (ILs).

ILs are flammable mixtures used to accelerate a fire. ILs are composed of a broad range of hydrocarbons and include commonly encountered materials such as gasoline, diesel, and kerosene. In the event of a suspected arson, ILR may be found within the pores of materials at the crime scene such as concrete. Traditionally, the whole material is collected and packaged into air-tight containers to prevent evaporation and allow transportation back to the lab. However, this may require the use of heavy machinery, such as a jack hammer, which takes a lot of manpower to operate and may increase the probability of loss of the ILR during collection. Recent research has investigated other options for direct collection of the ILR, including the use of absorbent materials as they are able to penetrate the pores of the fire debris evidence and achieve a higher collection efficiency. These materials have included granular minerals, hydrophobic absorbent pads, or everyday absorbers such as paper towels and microfiber cloths.<sup>1-3</sup> Each of these have had limitations stemming from the ability to penetrate and/or be removed from a porous material as well as in compatibility with the individual components of an IL.

In this work, tapes of a variety of compositions are investigated for direct ILR collection from non-porous and porous surfaces. Tape is a cost-effective absorbent material selected because of its sturdy but flexible backing. Additionally, the adhesive is typically composed of non-polar films and resins that are chemically compatible with the hydrocarbons in the ILs.

This presentation will discuss six different types of tape to classify which tape provides the highest collection efficiency of ILR and has the least amount of interference with a standard passive headspace collection using activated charcoal strips and analysis using Gas Chromatography/Mass Spectrometry (GC/MS). The tapes used came from a wide variety such as normal household repair tapes to stronger industrial and laboratory tapes. All six tapes were checked for interferences from the adhesive and backing. The effectiveness of the tape's collection is assessed by comparing the amount of standard homologous n-alkanes collected by the tape to the amount left on a small area of non-porous tile or porous concrete (a relative collection efficiency). Overall, the most common household tape demonstrated some interferences with the process and the more specialized tapes showed more promise. This presentation will outline the results for all tapes' validation and provide a recommendation for which tape provides the highest relative collection efficiency from non-porous and porous surfaces.

**B115 Expert and AI Opinions: Machine-Assisted Analysis of Fire Debris**

Michael E. Sigman\*, University of Central Florida, Orlando, FL; Mary R. Williams, University of Central Florida, Orlando, FL; Frances A. Whitehead, University of Central Florida, Orlando, FL

---

**Learning Overview:** This presentation will discuss the use of subjective logic to describe expert opinions and application of the logic to Artificial Intelligence (AI) results in fire debris analysis. After attending this presentation, attendees will understand how to represent expert and AI opinions with subjective logic and how to combine the two opinions to reach a consensus.

**Impact Statement:** This presentation will impact the forensic science community by providing attendees with the opportunity to understand how computers can generate a forensic opinion, rather than a single answer, and how AI can assist analysts in the data interpretation process.

Subjective logic provides a method for reasoning about data under uncertainty and allows analysts to express their opinions, which are influenced by uncertainty. Subjective binomial opinions about two exclusive and competing hypotheses are often encountered in forensic science. An example set of propositions regarding a fire debris sample could be H1: the sample contains Ignitable Liquid Residue (ILR) and, H2: the sample does not contain ILR. A subjective opinion about the sample is characterized by four parameters: the belief mass that the sample contains ILR, the disbelief mass, uncertainty mass, and base rate. The application of subjective logic to quantitatively characterize an analyst's opinion will be demonstrated for the analysis of known ground truth fire debris samples.<sup>1</sup>

Opinions can also be obtained from AI using the principles of subjective logic. An ensemble of AI models is each trained on different training data to generate a set of probabilities that a test sample contains ILR. The set of probabilities is used to formulate the AI opinion. If the probabilities from applying the ensemble of models to a test sample are widely distributed, the uncertainty of the AI opinion will be high. If the probabilities are more narrowly distributed, the uncertainty will be smaller. When the probabilities of ILR in the sample are high, the belief mass will be larger, and the disbelief mass will be smaller. If the probabilities of ILR in the sample are low, the belief mass will be lower and the disbelief mass will increase. The belief, disbelief, and uncertainty masses are calculated from the shape parameters obtained by fitting the probabilities for a single sample to a beta distribution. The process of generating AI opinions will be demonstrated for known ground truth fire debris samples.<sup>1</sup>

The AI opinions are more useful than a single numerical result in assisting an analyst in data interpretation.<sup>2</sup> The AI opinion can also be combined with the analyst's opinion to form a consensus opinion.<sup>1</sup>

**Learning Overview:** After attending this presentation, attendees will have a better understanding of the strengths and limitations of Direct Analysis in Real-Time Mass Spectrometry (DART®-MS) to maximize the detection and identification of intact and explosive residues.

**Impact Statement:** This presentation will impact the forensic science community by demonstrating a workflow involving minimal sample preparation to rapidly and accurately detect and identify intact explosives and explosive residues using DART®-MS.

During the investigation of an explosion, the rapid identification of the explosive compound(s) is key to provide investigative leads for homeland security purposes. Due to military-grade high explosives being more difficult to acquire, domestic attacks are commonly conducted using Homemade Explosives (HMEs) with reagents sourced from common household materials and legal precursors that can easily be obtained commercially. Whereas current laboratory techniques such as Gas Chromatography/Mass Spectrometry (GC/MS) and Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) are used to accurately identify explosive compounds, they also present several drawbacks, such as extensive sample preparation and long chromatographic runs. This study aims to explore the use of DART®-MS to provide a rapid and reliable analysis of HME precursors and explosive residues that do not require complex sample preparation. Furthermore, DART®-MS can also provide useful additional information, including the presence of oils, binders, plasticizers, and polymers.

A targeted list of commonly encountered energetic materials was constructed with the aid of the Montgomery County Fire Marshal's Office (MCFMO) to create a representative set of explosive compounds relevant to current casework, including Ammonium Nitrate and Fuel Oil (ANFO), nitromethane, and smokeless powders. The DART®-MS method development involved optimization of the DART® source gas temperature and mass spectral acquisition parameters for each intact compound, with additional modifications for explosive residues.

Several simulated Improvised Explosive Devices (IEDs) were constructed and detonated with assistance from the MCFMO to collect the explosive residues. The simulated IEDs consisted of several witness materials, including batteries, metal shrapnel, wires, and cell phone parts placed in a plastic toolbox. Post-blast fragments were then collected and analyzed using DART®-MS via an indirect sampling method.

Ammonium nitrate and other inorganic oxidizing salts are not traditionally amenable to DART® ionization processes; however, the use of an unconventional solvent, namely 50:50 Deionized (DI) water:Methanol (MeOH), demonstrated successful detection and characterization of non-dissociated ammonium nitrate ion clusters at nominal  $m/z$  98,  $m/z$  178, and  $m/z$  258. A non-dissociated ammonium perchlorate ion cluster was also detected at nominal  $m/z$  135. Nitromethane was not able to be detected using DART®-MS due to only minimal direct Penning ionization of nitromethane relative to alternative outcomes. Smokeless powders were shown to produce consistent ion signal with DART®-MS analysis, with some additional challenges related to explosive residues. Characteristic ions for ethyl centralite, methyl centralite, and diphenylamine were detected at nominal  $m/z$  269,  $m/z$  241, and  $m/z$  170, respectively. Furthermore, 2,4-dinitrotoluene and dibutyl phthalate were also detected at nominal  $m/z$  181 and  $m/z$  279, respectively.

This study demonstrates the benefits and limitations of using DART®-MS for the analysis of intact and explosive residues from HMEs, as well as demonstrates the feasibility of using DART®-MS with only limited sample preparation using an indirect sampling method. Additionally, DART®-MS was able to detect challenging non-dissociated ammonium nitrate and ammonium perchlorate ion clusters using a custom 50:50 DI water: MeOH solvent enabling the wider applicability of DART®-MS analysis to ammonium-based inorganic oxidizing salts.

**B117 Combining Surface-Enhanced Raman Spectroscopy (SERS) and Paper Spray-Mass Spectrometry (PS-MS) for Illicit Drug Detection and Identification**

*Sevde Dogruer Erkok, Florida International University, Miami, FL; Roxanne Gallois, Ecole Normale Supérieure de Lyon and Claude Bernard University, Paris, Ile-de-France, France; Leon Leegwater, University of Amsterdam, Amsterdam, Noord-Holland, Netherlands; Pascal Camoiras Gonzalez, University of Amsterdam, Amsterdam, Noord-Holland, Netherlands; Arian van Asten\*, University of Amsterdam, Amsterdam, Noord-Holland, Netherlands; Bruce R. McCord, Florida International University, Miami, FL*

---

**Learning Overview:** After attending this presentation, attendees will be aware that many fentanyl analogs are developed and mixed with other illicit drugs such as cocaine and heroin. Detecting fentanyl and fentanyl analogs in these illicit drug mixtures gains more importance. Most confirmatory procedures require time-consuming and expensive, highly sophisticated laboratory equipment and experimental procedures, which can delay critical information that might save a victim or identify a suspect. In this project, we propose miniaturizing and accelerating this process by combining SERS analysis and mass spectrometry on a single microfluidic device. This procedure, known as PS-MS, can isolate fentanyl analogs from even complex drug mixtures. Thus, we propose to develop a novel device capable of simultaneously detecting fentanyl and fentanyl analogs in illicit drug mixtures.

**Impact Statement:** Coupling portable SERS and Paper Spray Ionization-Mass Spectrometry (PSI-MS) methods will provide strong confirmatory results for real-world samples and drug mixtures. The robustness, portability, and sensitivity of this study will provide important convenience for field applications, thereby impacting the forensic science community. The experimental results obtained in this project show that SERS analysis can be done in the field for identification followed by PS-MS in a laboratory setting for confirmation.

There is an ongoing effort in the black market to make new drugs that are more potent and addictive. Due to these continual modifications, many fentanyl analogs are developed and mixed with other illicit drugs such as cocaine and heroin. The presence of fentanyl analogs as mixtures in illicit drugs makes it hard to estimate their potencies. This makes the detection and differentiation of fentanyl analogs important. Most current screening methods have difficulty detecting the full range of opioid analogs due to a wide variety of structural variations. However, SERS can differentiate structurally similar fentanyl analogs due to its ability to yield spectroscopic fingerprints for the detected molecules. Once SERS has identified a fentanyl analog, an additional confirmatory technique is required to provide identification of the compound in a court of law. A second, more precise method, such as liquid chromatography/mass spectrometry, is necessary for typical mixtures, which include other drugs and diluents at very low concentrations. Most confirmatory procedures require time-consuming and expensive, highly sophisticated laboratory equipment and experimental procedures, which can delay critical information that might save a victim or identify a suspect.

To our knowledge, this is the first study to identify fentanyl analogs in real seized drug samples with SERS/PS-MS.

---

**B118 Evaluating the Sensitivity, Stability, and Cross-Reactivity of Commercial Fentanyl Immunoassay Test Strips**

*Sandra E. Rodriguez-Cruz\*, Drug Enforcement Administration, Dulles, VA*

---

**Learning Overview:** After attending this presentation, attendees will have a better understanding of the utility and limitations of using commercial Lateral-Flow Immunoassay (LFIA) test strips for the analysis of suspected fentanyl materials.

**Impact Statement:** This presentation will impact the forensic science community by providing an in-depth assessment of the performance of four commercially available Fentanyl Test Strips (FTS), under variable scenarios, at different target-analyte concentrations, and in the presence of other Fentanyl-Related Substances (FRS) and adulterants. This information will also influence how these commercial tools are used by seized-drug laboratory analysts, first responders, and harm-reduction organizations throughout federal, state, and local jurisdictions.

The United States of America has been fighting an unprecedented battle against opioids during the better part of the past ten years. According to the Centers for Disease Control and Prevention, the age-adjusted rate of overdose deaths increased by 31% from 2019 to 2022. In 2020, about 75% of the almost 92,000 drug overdose deaths in the United States involved an opioid, with the vast majority of those being synthetic opioids such as fentanyl or other FRS. Harm reduction centers funded by local governments or non-profit organizations have played an important part in this battle by reaching out and educating those at risk of overdose. In addition to providing educational and overdose-risk counseling, access to methadone or buprenorphine treatment, and a safe environment for drug use, many of these centers are equipped with opioid-antagonist nasal sprays such as NARCAN® and also distribute commercial LFIA strips so users can test their drugs prior to consumption. Recent studies have explored the impact that using FTS may have in the drug user's behavior, with some of them suggesting that, upon encountering a positive response using the FTS, drug users may discard their drug supply, avoid using the drugs alone, or alert others about the potential risks of using a particular drug batch.

Immunoassay tests are classified as Category C techniques by the Scientific Working Group for Analysis of Seized Drugs (SWGDRUG) and Drug Enforcement Administration (DEA) laboratories have implemented their use as part of their standardized analytical scheme for analyzing suspected fentanyl exhibits. FTS are designed to provide presumptive information about the presence of fentanyl in a suspected sample. However, their adoption by law enforcement personnel and seized-drug analysts throughout the general community has been limited because most products are advertised for urine testing, not for assays using water solutions. This study presents an evaluation of four commercial FTS: Rapid Response® from BTNX, Inc.; T-Dip® Fentanyl (FTY) Urine Dip Cards obtained from Amazon.com; Premier BioDip® FYL10 from Premier Biotech, Inc.; and MobileDetect® Fentanyl strips from DetectaChem, Inc.

Performance characteristics curves were used to compare the products' sensitivity, showing that all can reliably detect fentanyl in aqueous solutions at concentrations below 1 µg/mL, with some of the tests able to reliably detect the drug at 200ng/mL. A stability study demonstrates the performance of all four FTS brands was only slightly affected after 30 days of storage at two extreme environmental conditions. FRS are also evaluated using the Rapid Response® FTS, which showed high cross-reactivity with para-fluorofentanyl and acetylfentanyl, but lower with ortho-chlorofentanyl, carfentanil, and 4-ANPP. Users should be aware that FTS may give false negative results even when potentially dangerous levels of carfentanil are present. When testing other common drugs, adulterants, and diluents frequently encountered in seized tablets, concentration-dependent results were obtained, and multiple instances of false positives were recorded.

**B119 Exploring Evidence of Common Origin of Recreational Drug Exhibits by GC/MS**

*Joshua S. DeBord\*, Center for Forensic Science Research and Education, Willow Grove, PA; Barry K. Logan, PhD, Center for Forensic Science Research and Education, Horsham, PA; Alex J. Krotulski, Center for Forensic Science Research and Education, Willow Grove, PA*

---

**Learning Overview:** After attending this presentation, attendees will understand the chemical and data methodology used by the authors to profile drug samples. Attendees will also learn how the presented methods could be used as indicators that two or more exhibits of drug samples may have a common origin, based upon shared chemical signatures.

**Impact Statement:** This presentation will impact the forensic science community by providing deeper insights into the correlations among the physical and chemical properties of drug exhibits and improving the utility of drug evidence analysis in criminal investigations.

Across the landscape of recreational drug products, complex strategic intelligence efforts increasingly rely upon sophisticated analytical techniques and comprehensive chemical analysis. Beyond simply identifying controlled substances within a drug exhibit, identification of non-controlled substances and quantification of those components add informative points of comparison among samples. This presentation explores the application of Gas Chromatography/Mass Spectrometry (GC/MS) in addressing issues of possible common source determination for drugs and enhancing the utility of drug analysis as an investigative tool beyond its use simply for prosecution. The approach described involves the comparison of chemical signatures from recreational drug samples with the aim of determining if they share characteristics pointing to a common source.

Our laboratory performs drug markets' trend surveillance and confirmatory quantitative analysis for public health and safety agencies for the purposes of assessing drug safety and threats, monitoring drug market changes, and guiding public health harm reduction strategies. Our workflows include a qualitative analysis and an externally calibrated quantitative analysis, both performed by GC/MS. The data analysis of the qualitative results includes identification by retention time and mass spectral comparison to an in-house library, and a relative proportion analysis, determined for each compound in the sample by relating the peak area(s) to that of the major drug component. As an early step toward making common source determinations, this presentation will explore the relative proportion analysis and the quantitative data for their utility in creating comparable chemical profiles. A detailed explanation of the GC/MS methodology used to acquire chemical results and the data processing programs that were written in R, an open-source coding environment for statistical computation will be shared as part of the discussion.

Our GC/MS method includes a full-scan window acquisition method that is identical for both qualitative identification and quantitative measurement; however, samples are aliquoted and processed for both assays independently. All data is then manually reviewed by a trained analyst, then post-review data processing is performed by a custom R program, which automates the relative parts analysis, quantitative calculations, and data collection/reporting.

Analysis of the data identified some groups of exhibits with distinctive properties that were both internally consistent within the group, and distinct between groups, emphasizing the potential for linking exhibits with each other. For examples of such groups, one consisted of four independently submitted samples originating from Massachusetts having physical descriptions consistent with counterfeit oxycodone tablets. These exhibits each contained fentanyl, xylazine, para-fluorofentanyl, and 4-ANPP at concentrations of 1.0–1.2%, 2.7–2.9%, 0.40.5%, and 0.2%, respectively. A second group consisted of three powder opioid samples collected in Pennsylvania containing fentanyl, xylazine, and 4-ANPP at concentrations of 4.2%, 59.6–62.6%, and 0.7–1.0%, respectively. A third group consisted of two powder opioid samples collected in an undisclosed United States state, containing fentanyl, xylazine, heroin, 4-ANPP, and caffeine at concentrations of 15.9%, 9.4/9.5%, 9.1/9.3%, 1.6% and 0.5%, respectively. Apart from the close similarities in chemical composition, similarities with respect to physical morphology, packaging, date, and location of collection were also persuasive.

The traditional role of forensic drug chemistry has been to obtain analytical evidence of the presence of controlled substances in exhibits submitted for analysis. This exploratory work suggests that performing testing beyond the controlled substance identification, to quantitative analysis of the principal components, adulterants, and precursors/byproducts creates the possibility of linking exhibits between cases to provide further investigative leads and insights to investigators.

---

**B120 GC Derivative VUV Spectroscopy of JWH-018 Positional Isomers and Select Synthetic Cannabinoid Diastereomers**

*Annika Dombrowski\*, Arlington, VA; Ira Saul Lurie, The George Washington University, Washington, DC*

---

**Learning Overview:** After attending this presentation, attendees will understand the capability of Gas Chromatography-Vacuum Ultraviolet (GC-VUV) derivative spectroscopy for the identification of positional isomers and diastereomers of select synthetic cannabinoids. Additionally, attendees will have an understanding of the specificity of this technique as compared to both underivatized VUV and more staple forensic techniques such as Gas Chromatography/Mass Spectrometry (GC/MS).

**Impact Statement:** This presentation will impact the forensic science community by providing evidence for the value of derivative analysis of VUV spectra in the identification of isomeric compounds that remain difficult to distinguish by GC/MS and/or GC-VUV. Analysis of the first and second derivatives of VUV spectra can be used to improve confidence in the accuracy of identification of positional isomers and diastereomers that are currently difficult or impossible to distinguish without spectral manipulation. This research aims to demonstrate the consistency and specificity provided by derivative analysis, compared to underivatized spectra and traditional MS.

With the recent rise in emerging drugs synthesized to circumvent existing drug laws, the identification of isomeric compounds has become of increasing concern to the forensic science community. Traditional and widely used techniques such as GC/MS have proven insufficient to distinguish these isomers due to the similar mass fragmentation patterns of certain positional isomers and diastereomers. As a result, new techniques are required in order to analyze and identify these drugs. One such emerging technique is GC-VUV, which has been demonstrated to accurately distinguish between many positional isomers.<sup>1,2</sup> However, despite this improvement over traditional techniques, GC-VUV has remained unable to distinguish between some positional isomers and diastereomers<sup>2</sup>.

One technique with the potential to remedy this is the use of derivative analysis, which has previously been applied to Ultraviolet (UV) spectra of similar compounds to pull out greater spectral detail and allow for compounds with near identical spectra to be identified.<sup>3</sup> By applying first and second derivative manipulations to raw spectra, spectral details such as maxima, minima, and inflection points are highlighted, providing more points of comparison with library spectra, and highlighting small differences that may not be visible in raw spectra, such as potential differences in the spectra of diastereomers or indistinguishable positional isomers. As a result, derivative analysis has the potential to increase the specificity of existing spectroscopy-based methods.

The research presented here considers the application of derivative analysis to the VUV spectra of a select group of synthetic cannabinoids, including 16 positional isomers of JWH-018 and three pairs of diastereomers, that can be difficult to distinguish with raw VUV spectra.<sup>2</sup> For the positional isomers, derivative analysis of the spectra yielded greater consistency in accurate identification as demonstrated by library searches with repeatability analyzed for both day-to-day and run-to-run. Additionally, principal component analysis demonstrated that within groups of positional isomers and diastereomers, the first and second derivatives showed improved discrimination compared to raw data, demonstrating the power of derivative analysis for improving identification accuracy as well as specificity compared to non-derivative spectra. This research will also demonstrate comparisons between the discrimination power of this new seized drug analysis technique for VUV as compared to traditional electron ionization MS.

**B121 The Effect of Spectral Intensity on Mass Spectral Discrimination of Fentanyl Positional Isomers**

Isaac C. Willis\*, Michigan State University, East Lansing, MI; Victoria L. McGuffin, Michigan State University, East Lansing, MI; Ruth Waddell Smith, Michigan State University, East Lansing, MI

---

**Learning Overview:** After attending this presentation, attendees will have learned about a statistical method to distinguish spectra of positional isomers and identify reliable ions for discrimination.

**Impact Statement:** This presentation will impact the forensic science community by demonstrating the utility of a statistically objective method to differentiate mass spectra of positional isomers and will highlight the effect of spectral intensity on the ability to distinguish such isomers.

One of the most pressing concerns in seized drug analysis is the identification of novel synthetic opioids, primarily fentanyl analogs. Numerous analogs have surfaced within the past several years, and the proliferation of these analogs is only accelerating, with 73,000 opioid-related deaths being reported by the United States Centers for Disease Control and Prevention between July 2021 and June 2022.<sup>1</sup> These deaths are primarily attributed to fentanyl and its analogs and mark an increase of nearly 9,000 from the year prior.<sup>1</sup> Moreover, due to their structural similarity, the analogs are challenging to definitively identify based only on comparison of electron-ionization mass spectra.

To address this challenge, this presentation will discuss a method previously developed in our laboratory to statistically evaluate mass spectra. Briefly, the method relies on the unequal variance *t*-test to compare the intensity at each *m/z* value in two mass spectra. If the intensity of one or more ions is statistically different between the two spectra, then the spectra are statistically distinguishable, with any such ion being defined as a discriminating ion. Our previous work demonstrated the ability to associate and discriminate structurally similar compounds, including fentanyl analogs.

The present study will assess this ability with three sets of positional isomers of fentanyl analogs. As a further test of robustness, the effect of spectral intensity on the association and discrimination is also evaluated. The isomers selected for this evaluation are the following: *ortho*-, *meta*-, and *para*-fluorobutyl fentanyl (*o*-, *m*-, and *p*-FBF); *ortho*-, *meta*-, and *para*-fluoro methoxyacetyl fentanyl (*o*-, *m*-, and *p*-FMAF); and *ortho*-, *meta*-, and *para*-methylfentanyl (*o*-, *m*-, and *p*-MF). The FBF and FMAF analogs have a fluorine substituent on the aniline ring, while MF has a methyl group. Similarly, FBF and MF have an alkyl-chain substituent on the amide group, while FMAF has a methoxyacetyl group.

Each set of isomers was prepared at three concentrations (1.0, 0.5, and 0.1mg/mL) and analyzed in replicate by Gas Chromatography/Electron Ionization/Mass Spectrometry (GC/EI/MS). Spectra within each collection were statistically compared to evaluate the effect of spectral intensity on the ability to associate and discriminate the positional isomers. Additional spectral collections were completed in a similar manner for a total of four times over an eight-month period to evaluate the effect of inherent instrument variation.

In the first collection, at 1.0mg/mL, *o*-FBF was discriminated from the corresponding positional isomers *m*-FBF and *p*-FBF with 12 and 8 ions, respectively, responsible for discrimination at the 99.9% confidence level. Under the same conditions, *o*-FMAF was also discriminated from its corresponding positional isomers *m*-FMAF and *p*-FMAF with 25 and 21 discriminating ions, respectively. Similarly, *o*-MF was discriminated from the corresponding positional isomers *m*-MF and *p*-MF with 8 and 12 discriminating ions, respectively. As concentration decreased, discrimination was retained at 0.5mg/mL, albeit with fewer discriminating ions, but was lost for all comparisons at 0.1mg/mL.

Similar trends were observed across the four spectral collections. However, the number of discriminating ions per comparison differed, which is expected due to differences in instrument tune conditions. To allow for the consideration of both time and concentration of the comparison, the calculated *t*-values were ranked to determine the most reliable discriminating ions. For example, for the comparison of *o*-FBF and *m*-FBF, *m/z* 164 was the most reliable discriminating ion while for the comparison of *o*-FBF and *p*-FBF, *m/z* 102, 164, and 234 were the most reliable discriminating ions.

In this presentation, the statistical comparison method will be described in detail, the effect of spectral intensity on the discrimination of positional isomers will be discussed, and reliable ions for discrimination within each set of isomers will be identified.

**B122 The Classification of Cannabinoids Using Mass Spectral Data for the Identification of Novel Synthetic Cannabinoids**

*Kristopher Charles Evans-Newman\*, Department of Chemistry and Physics, Western Carolina University, Sylva, NC; Nuwan T. Perera, Western Carolina University, Cullowhee, NC; Garion Schneider, Western Carolina University, Cullowhee, NC*

---

**Learning Overview:** The goal of this presentation is to demonstrate the development of a drug classification system to facilitate the identification of previously unknown synthetic cannabinoids.

**Impact Statement:** This presentation will impact the forensic community by demonstrating the effectiveness of the use of classification models that were developed using mass spectral data and chemometric techniques in determining the presence of newly synthesized cannabinoids.

Detection and characterization of newly synthesized cannabinoids is challenging due to the lack of availability of reference standards and chemical data.<sup>1</sup> Identification of these substances usually involves the use of intelligence data, prior knowledge on New Psychoactive Substances (NPSS), and structural elucidation of these new compounds using expensive and time-consuming analysis methods such as High-Resolution Mass Spectrometry (HRMS) and Nuclear Magnetic Resonance (NMR) spectroscopy.<sup>2,3</sup>

The focus of this study is to develop a proactive solution to identify newly synthesized psychoactive substances. A classification system was developed using the existing mass spectral data of cannabinoids to determine the presence of previously unknown cannabinoid-related substances. Principle Component Analysis (PCA) and Partial Least Square Discriminant Analysis (PLSDA) were used to develop the classification system using mass spectra obtained from freely available spectral databases such as the Scientific Working Group for the Analysis of Seized Drugs (SWGDRUG) database. Genetic Algorithm (GA) was used to select the most discriminatory mass to charge ( $m/z$ ) ratios of the mass spectral data. First, a binary classification model was developed to discriminate cannabinoids and cannabinoid-related compounds from other drug classes. Then, a classification model was developed to discriminate classical and synthetic cannabinoids. Finally, submodels were developed to discriminate the presence and absence of functional groups found on commonly encountered synthetic cannabinoids. Hierarchical Cluster Analysis (HCA) was used to determine the possible drug classes, and HCA along with chemical structure similarities resulted in the different unique groups seen with synthetic cannabinoids that were classified. These groups include indole, indazole, naphthalene, 4-Fluorobenzyl (FUB), and 1-amino-3,3-dimethyl-1-oxobutan-2-yl (BUT).<sup>2</sup> Classification models were developed for the determination of the presence or absence of aforementioned functional groups in an unknown cannabinoid. Current results show that these models are highly accurate (>95%) and applicable in determining the presence of cannabinoid-related substances.

**B123 A Qualitative and Quantitative Analysis of Particulate Spread During Simulated Illicit Drug Manufacturing: Implications for Collection of Evidence and Crime Scene Safety**

*Edward Sisco\*, National Institute of Standards and Technology, Gaithersburg, MD; Matthew Staymates, National Institute of Standards and Technology, Gaithersburg, MD; Luis E. Arroyo, West Virginia University, Morgantown, WV*

---

**Learning Overview:** After attending this presentation, attendees will have learned about ongoing efforts to understand the spread of particulate that results from different illicit drug manufacturing activities and about considerations for maximizing the chances of collecting actionable evidence and minimizing potential safety concerns for those on scene.

**Impact Statement:** This presentation will impact the forensic science community by providing critical information on the spread of drug particulate throughout a home due to illicit drug manufacturing events through qualitative and quantitative data and visuals.

Illicit manufacturing of drugs of abuse—from small-scale personal use efforts to large-scale operations—continues to be a concern in the United States and abroad. These efforts can include synthesizing psychoactive compounds from precursors, packaging powdered material, and using pill presses or other means to prepare samples for distribution. When these operations are discovered, evidence must be collected that can provide a link to actual material(s) being synthesized or handled. If the house has been cleaned up in any way, this information may only be obtainable via collection of particulate residues. It is also important that personnel entering the home be aware of possible dangers, even if they are explicitly visible.

To help address these questions, we have begun a project where illicit drug manufacturing activities (i.e., weighing powders, grinding powders, packaging material, etc.) are completed using inert materials inside a home that has been equipped with numerous sensors and sample collectors to enable analysis of airborne and surface particulate movement and concentration. Particle counters are placed in rooms throughout the home to provide real-time information regarding the generation and movement of airborne particulate. These measurements are coupled with laser light sheet imaging to provide real-time visualization of the airborne particulate generation. This data is coupled with quantitative information on particulate concentrations from surfaces throughout the home, obtained using Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS). These surface collections are completed immediately after the activities take place, as well as one day and one week after to better capture the level of resuspension and resettling that occurs. Factors in the home (i.e., air temperature, whether the HVAC system is running) or how the activities are carried out (i.e., messy versus deliberate) are altered to see the effects these parameters have on particulate generation and movement. Finally, other targeted collections or activities, such as measuring the total amount of material on the person's hand afterward or understanding how much material is transferred to a doorknob, are completed to help develop informed, data-driven sampling practices.

Initial studies completed using an 80 % lactose, 20 % caffeine mixture have begun to provide insight into the level of contamination that can be expected throughout a home where these activities have occurred. Surface levels of caffeine, the minor component in the mixture, were found to exceed  $1\mu\text{g cm}^{-2}$  in the area immediately around where activities took place. Particulate concentrations in excess of  $0.01\mu\text{g cm}^{-2}$  were found in adjacent rooms. Surface concentrations changed over the one-week study, providing insight into redeposition throughout the house due to HVAC air circulation. Using laser light sheet imaging, the magnitude of airborne particulate that resulted from these different activities was easily visualized, and stark differences in particulate movement as the result of the HVAC being on or off could be understood. The persistence of the airborne particulate, and its implications for personnel entering a home where drug manufacturing is suspected, could also be captured. Through these studies, it was found that milligrams of material remain on the person's hand post-activity and can be transferred onto a range of different surfaces, increasing the probability of collection with targeted sampling.

Through this work, a combination of visual aids (videos and images) and quantitative data will be presented to convey ongoing efforts to inform best practices for collecting trace residues in homes where suspected manufacturing occurred. These tools can be used to determine what surfaces to sample, what contamination levels can be expected based on whether or not a room has been deliberately cleaned, and what considerations should be made to ensure the safety of those entering a contaminated scene.

---

**B124 Streamlining the Extraction of Challenging Samples Using the HID NIMBUS® Presto**

*Kayli N. Carrillo\*, Sam Houston State University, Huntsville, TX; Jennifer L. Snedeker, Sam Houston State University, Onalaska, TX; Natalia Czado, Sam Houston State University, League City, TX; Sheree R. Hughes, Sam Houston State University, Huntsville, TX*

---

**Learning Overview:** After attending this presentation, attendees will understand how the HID NIMBUS® Presto System can be used to increase lab efficiency and produce similar results in DNA recovery and autosomal allele recovery to manual extraction methods for challenging forensic sample types, including burned, buried, and surface decomposed bones, hair, nails, and teeth from decomposed cadavers, “touch” samples, and fired cartridge casings.

**Impact Statement:** This presentation will impact the forensic science community by demonstrating the HID NIMBUS® Presto System’s capability to extract forensically challenging samples and yield comparable or better results than via manual extraction.

Automated extraction enhances sample throughput, minimizes errors, and maintains consistency within a forensic laboratory. However, automation can lead to higher amounts of DNA loss compared to manual methods. Therefore, it is necessary to assess the efficacy of a new automated purification platform, the HID NIMBUS® Presto System, compared to manual extraction for challenging forensic samples. The HID NIMBUS® Presto system combines the THERMO FISHER™ KingFisher™ Presto Purification system and the Hamilton NIMBUS® automated liquid handling workstation, utilizing PrepFiler® and PrepFiler® BTA extraction scripts. In this project, various challenging sample types such as bones, hair, nails, teeth, “touch” samples, and fired cartridges were processed using both the HID NIMBUS® Presto System and manual PrepFiler® chemistry. Extracts were quantified on the ABI® 7500 system using QuantiFiler® Trio. Short Tandem Repeat (STR) analysis was conducted using the VeriFiler™ Plus kit, which targets 25 markers, including 23 autosomal STRs and two gender discrimination markers, with a maximum input of 0.5ng. This kit was specifically designed to maximize sensitivity for challenging casework samples by allowing up to 17.5mL of sample input for amplification.

This study found no significant difference in DNA recovery between manual extraction and the HID NIMBUS® Presto System for fired cartridge casings, teeth, surface decomposed, and burned bones ( $p > 0.05$ ). However, the HID NIMBUS® Presto System yielded statistically significantly higher amounts of DNA for “touch,” hair, nails, and buried bone samples ( $p < 0.05$ ). In terms of autosomal allele recovery, there was no significant difference for “touch,” teeth, surface decomposed samples, and fired cartridge casings ( $p > 0.05$ ). Generally, the HID NIMBUS® Presto System demonstrated significantly higher autosomal allele recovery for nail and hair samples ( $p < 0.05$ ). Conversely, manual extraction outperformed the HID NIMBUS® Presto System regarding DNA recovery for buried and burned samples ( $p < 0.05$ ). Importantly, more samples met the minimum threshold of 1pg/μL to proceed to STR typing when processed with the HID NIMBUS® Presto System compared to manual extraction. Overall, this study shows that the automated HID NIMBUS® Presto System can provide a more streamlined workflow and faster turnaround time compared to manual extraction without negatively affecting DNA recovery and allele recovery from extremely challenging samples.

**Automation; DNA Purification; Low-Template**

**B125 The Effects of Oily Contaminants on DNA Extraction Efficiency Using DNA IQ™**

Elizabeth Grace Gillece\*, Virginia Commonwealth University, Richmond, VA; Susan A. Greenspoon, Virginia Department of Forensic Science, Richmond, VA; William Eggleston, Virginia Department of Forensic Science, Richmond, VA

**Learning Overview:** The goal of this presentation is to demonstrate the challenges of DNA extraction in the presence of common oily contaminants and their effects on DNA yield. Following the presentation, attendees will better understand the impact that the contaminants have on DNA yield, the problem these contaminants pose to casework, and potential remedies for this.

**Impact Statement:** This presentation will impact the forensic science community by demonstrating the issues posed by these contaminants and the mitigation practices explored. Forensic analysts will be informed of the issue and encouraged to investigate further approaches to lessen the impact the contaminants have on sample DNA yields.

In forensic investigations, unknown evidence DNA profiles are compared to reference samples to include or exclude individuals. The DNA yield and profile quality from evidentiary samples are impacted by the origin, number of contributors, environmental exposure, and contaminants present within the samples. Widely used solid phase extraction chemistries remove most of the contaminants that can cause inhibition of Polymerase Chain Reaction (PCR) reactions, such as indigo dye.<sup>1</sup> Additionally, newer Short Tandem Repeat (STR) typing kits have improved capabilities to suppress the effects of PCR inhibitors. Despite these improvements, certain contaminants still negatively impact the DNA extraction process and ultimately the success of STR profile development. Common contaminants that can severely impact the DNA extraction process using solid-phase extraction chemistries include motor oil, hand cream, and personal lubricants.<sup>2,3</sup> The DNA IQ™ resin was reported to clump in the presence of certain contaminants, which is problematic when used on an automation workstation because it results in statistically significant reduced DNA yields.<sup>2</sup> Products such as Nivea® hand lotion, Silky® personal lubricant, and Replens® Vaginal Moisturizer, all commonly contain glycerin and carbomers.

This study examined whether adding Sodium Dodecyl Sulfate (SDS) and alcohol to the lysis incubation increased DNA yields and the quality of samples contaminated with Nivea®, Silky®, and Replens® for samples containing blood or saliva. Samples were processed using standard operating procedures for manual and automated extractions from the Virginia Department of Forensic sciences (VDFS).<sup>4</sup>

For blood, manual extraction using 0.75% SDS significantly increased DNA yield for uncontaminated samples and increased DNA yield for Silky®-contaminated samples, but not significantly. Adding 0.75% SDS to Nivea®-contaminated samples decreased yield, but the reduction was not statistically significant. Adding 0.75% SDS to lysis incubation prior to automated DNA purification increased DNA yield for all contaminated samples and significantly for uncontaminated samples. When 20% alcohol and 0.75% SDS were combined during manual extraction, the DNA yield increased for all sample types and significantly for Nivea®-contaminated and Silky®-contaminated samples. When the samples were incubated lysis buffer with combined SDS and alcohol, followed by automated DNA purification, all samples had an increased DNA yield; a significant increase for uncontaminated and Nivea®-contaminated.

A similar impact on DNA yield was observed in saliva samples with the additives in the lysis incubation buffer. For saliva, manual extraction using 0.75% SDS generated unchanged average DNA yields for all samples. The addition of 0.75% SDS to lysis incubations followed by automated DNA purification resulted in significantly increased average DNA yields for the uncontaminated samples. The Nivea®-contaminated samples had an increase in DNA yield and Silky®-contaminated had a decrease, neither of which was significantly different from controls for automated samples. Following incubation in lysis buffer with 20% alcohol, average DNA yields of all sample types were increased for both manual and automated DNA purification. The mixture of 0.75% SDS and 20% alcohol during lysis incubations significantly increased average DNA yields for uncontaminated and Nivea®-contaminated samples, while DNA yields decreased for Silky®-contaminated samples, but not significantly.

DNA yields for samples contaminated with Nivea® and Silky® can be increased when purifying DNA with the DNA IQ™ System through the inclusion of additives such as SDS and reagent ethanol during the cells' lysis incubation step.

**B126 The Development of a Method for Complete Collagenase I Digestion of *Bos Taurus* Bone Samples**

Reilly Elizabeth Price\*, Virginia Commonwealth University, Richmond, VA; Ciara Rhodes, Virginia Commonwealth University, Mechanicsville, VA; Sarah Seashols Williams, Virginia Commonwealth University, Richmond, VA

---

**Learning Overview:** After attending this presentation, attendees will understand a unique approach for sampling DNA from aged forensic bone samples, ways of integrating it into the traditional workflow, and how it can improve the collection of DNA from challenging biological samples. Attendees will also gain an understanding of the applications for chemical excision of cells in forensic analysis.

**Impact Statement:** This presentation will positively impact the forensic DNA community by optimizing a unique approach to forensic DNA analysis of degraded skeletal remains, which will have broad applications across numerous fields of study. This research aims to improve the ability to isolate genomic material from compromised skeletal remains.

Traditional methods for processing forensic bone samples involve pulverization of bone samples to achieve adequate exposure of genetic material to the extraction buffer.<sup>1,2</sup> However, this technique can introduce numerous Polymerase Chain Reaction (PCR) inhibitors, including those found in the extracellular matrix found in mature bone and competition from excessive microbial DNA, in addition to the degradation from pulverization that results in further damage to already degraded genetic material.<sup>3</sup>

Previous research by Li has demonstrated that collagenase I, a matrix metalloproteinase that breaks down Type I collagen in bone, can be a potent method for digesting forensic bone samples prior to DNA extraction.<sup>4</sup> Li did not observe any detrimental effects on Short Tandem Repeat (STR) profiles when utilizing collagenase alone, indicating that the combination of total demineralization collagenase I digestion utilized in this study may be an effective method for obtaining DNA from forensic bone samples. Additionally, research by Yonenaga et al. showed that cell viability was maintained when collagenase was utilized to digest cartilage samples.<sup>5</sup>

The purpose of this project was to evaluate a combination of the total demineralization described by Loreille et al. and treatment with collagenase I in aged and weathered bovine samples.<sup>1</sup> Bovine was chosen as a model organism due to reduced ethical restrictions and microscopic and collagen matrix similarity to human bone. The goal was to utilize chemical excision methods to release osteocytes from the matrix with minimal degradation and reduced inhibition.

Slices of demineralized bovine bone samples were digested with various concentrations of collagenase I solutions for varying lengths of time. Samples were evaluated using several different nuclear dyes and fluorescence microscopy, and the optimal dye was chosen based on binding mechanism, preparation time, and nuclear visibility to be used for visualization of the digested samples. Propidium iodide showed an affinity for collagen, as there was increased fluorescence with less-digested samples. Acridine orange allowed for some visualization of nuclei, but also required significant preparation time. Diamond Nucleic Acid Dye was ultimately chosen due to its ease of use and increased visibility of matrix structures and nuclei. Images were captured and efficacy of collagenase I digestion under different reaction parameters was evaluated.

Based on microscopy and observation of samples after digestion, collagenase digestion was demonstrated to be an effective method for removing the bone matrix while maintaining the integrity of the nuclei. At lower concentrations and shorter time periods for digestion, the demineralized fragments were still observable in the sample tubes. Bone matrix was still visible, and trabeculae and osteons were visualized. Under these parameters, nuclei were visible, but very few were free, and the majority trapped within the matrix. In contrast, under high concentrations and longer digestion times, the samples were easily pipetted from the tube onto the slide, more nuclei were freely visible against the black background, and no matrix was distinguished.

In conclusion, digestion of bone samples with collagenase I was shown to be an effective mechanism for improving front-end sampling of weathered, aged forensic bone samples. By utilizing tissue slicing and a chemical excision method, the PCR inhibitor-containing matrix can be removed with little damage to the DNA. Future research will involve investigating the usage of partial digestion with collagenase combined with cell capture methods to effectively isolate bone cells prior to DNA extraction.

**B127 A Simple Tooth Preparation Method for the Applied Biosystems® RapidHIT™ ID Instrument**

*Morgan Elizabeth Eaton\*, Virginia Commonwealth University, Richmond, VA; Shane Woolf, PPD, Richmond, VA; Samyuktha Pemmasani, Virginia Commonwealth University, Glen Allen, VA; Tracey Dawson Green, Virginia Commonwealth University, Richmond, VA*

---

**Learning Overview:** After attending this presentation, attendees will have a better understanding of rapid DNA technology and its ability to produce Short Tandem Repeat (STR) profiles from dental remains as an approach to reducing the backlog of Disaster Victim Identification (DVI) samples.

**Impact Statement:** This presentation will impact the forensic science community by introducing data to demonstrate an alternative method to processing dental remain samples. The implementation of the RapidHIT™ ID instrument could potentially allow for a more expedited, less labor-intensive processing of DVI samples to obtain STR profiles in forensic DNA laboratories or on-scene at disaster events.

DVI refers to the process of forensic identification of unknown individuals following a mass disaster or fatality incident.<sup>1</sup> In events of mass disaster, human dental structures are often the only viable DNA source remaining, as soft tissues are more easily degraded, contaminated, or otherwise compromised. Due to the protective nature of dental enamel and dentin surrounding the inner pulpal tissue, a labor-intensive sample preparation performed by extensively trained personnel is necessary to expose the nuclear material preceding the traditional forensic DNA workflow.<sup>2,3</sup> In high-volume cases, such as those often submitted for DVI, the current forensic laboratory procedures for tooth sample DNA processing have shown to simply be inefficient. Thus, this study evaluates the ability of the Applied Biosystems® RapidHIT™ ID instrument, which incorporates rapid DNA technology to develop an STR profile in as little as 90 minutes, to produce viable STR profiles from tooth samples when coupled with a simplified sample preparation protocol.<sup>4</sup> Although the RapidHIT™ ID instrument has been validated for use with buccal swab (reference) samples, minimal research exists describing its ability to process dental or skeletal remains.

In this study, a fast, low-tech tooth cleaning/preparation protocol, incorporating a Dremel® rotary tool and household hammer for pulverization, was developed and tested on a sample set of ten deciduous teeth, which were subsequently processed on the RapidHIT™ ID instrument. Additionally, a parallel sample set of ten deciduous teeth of the same type and age were processed using the same cleaning protocol paired with a coffee grinder for fine-powder pulverization prior to being processed using a traditional forensic DNA laboratory-based workflow. All samples were stored at -20°C for approximately 1 to 21 years prior to processing.

The average percent of expected STR alleles detected from tooth samples processed on the RapidHIT™ ID was 99.0%, whereas those processed manually using traditional methods was 99.8%. Although the average STR allele peak height for the RapidHIT™ ID sample set is significantly lower (2,483 Relative Fluorescence Units [RFU] versus 4,004 RFU for the manual set), both produced peak heights that were well within the internally validated optimal peak height ranges and well above established analytical and stochastic thresholds. Additionally, the average intralocus heterozygote peak height ratio was 0.80 for samples analyzed using the RapidHIT™ ID, as compared to 0.86 for those processed manually, demonstrating acceptable intralocus balance. Not surprisingly, the RapidHIT™ ID sample profiles exhibited greater interlocus imbalance; thus, caution should be used for analysis of challenged casework-type samples if more than a single contributor is expected. Minimal artifacts were noted in profiles of tooth samples analyzed using the RapidHIT™ ID, regardless of how aged the sample was; however, 9 of 10 samples analyzed did require analyst review due to incomplete adenylation (-A peaks) and/or high baseline noise in the Y-indel target area for female samples.

These results suggest that, when coupled with a simple, quick sample preparation protocol, the RapidHIT™ ID instrument can successfully produce complete STR profiles from aged tooth samples with minimal allelic drop-out and high-profile quality. Future studies should explore the viability of this method using more challenged tooth samples of varying ages, tooth pathologies, and those that are exposed to harsher environmental conditions. Further simplification of the sample preparation process should also be explored in order to make this approach more amenable to on-scene application.

Oldt, Arizona State University, Glendale, AZ; Anne Stone, Arizona State University, Tempe, AZ

---

**Learning Overview:** This presentation examines the incorporation of methodologies adopted from the analyses of ancient DNA applied to the isolation and analyses of degraded DNA from badly burned forensic samples. Attendees will learn about new techniques and guidelines for the successful DNA identification of severely thermally altered remains.

**Impact Statement:** This presentation will impact the forensic science community by serving as an optimal laboratory strategy guide for basic sampling strategies and locations, DNA extraction methods, and Short Tandem Repeat (STR) profiling when dealing with highly degraded, burned skeletal samples.

Identifying human remains using DNA analyses is a vital component of forensic investigation. These highly accurate analyses generally rely on the recovery of high-quality endogenous DNA that may not always be available. This is especially true when utilizing degraded source material.

The decomposition of DNA can alter not the amount of DNA retained in source tissue, the quality of the DNA, and alter its base composition, making downstream analysis problematic. As such, the field of ancient DNA (aDNA) analysis has invested heavily in the development of optimized protocols for the sampling, extraction, and analyses of DNA recovered from archaeological skeletal. In a forensic context, the use of these same techniques in modern, degraded skeletal samples may increase the likelihood of successful DNA identification<sup>1</sup>.

The exposure of tissue to extreme temperatures affects DNA recovery and quality in a similar fashion to that observed in archaeological remains. Additionally, while soft tissue may still be present, many current guidelines recommend the removal and discarding of this charred material, as it is hypothesized that the extreme levels of morphological degradation render this substrate unusable for DNA identification.

Here we present a systematic investigation comparing forensic and aDNA laboratory protocols: the Dabney 2019 extraction protocol and the Lorielle 2007 protocol.<sup>2,3</sup> We examine DNA yields across a range of levels of thermal alteration on different skeletal locations and an assessment of DNA preservation in severely charred soft tissues using the QIAGEN® DNeasy® blood and tissue extraction kit.

Ten donor cadavers were systematically exposed to extreme temperatures (i.e., burned) at the University of Tennessee Anthropology Research Center. From each donor, approximately ten samples representing all regions of the body (i.e., thorax, long bones, etc.) were collected and sent to Arizona State University for processing. Each sample was then visually examined and assigned a burn scoring on a 1–5 scale, with 1 being the least thermally altered and 5 being the highest (i.e., cremains) based on observed morphological condition. Using both extraction protocols, DNA was isolated from each skeletal sample, as well as from corresponding tissue samples. The resulting DNA extracts were then assessed for total DNA recovery (Qubit® HS DNA assay and Agilent® TapeStation D5000 HS), endogenous DNA content (Quantifiler® Trio), and STR profile recovery (Promega® Powerplex® Fusion 6C).

Preliminary results indicate that our standard DNA quantification techniques (Qubit® fluorometry, TapeStation, and Quantifiler® Trio) are not a reliable predictor of successful STR profile recovery, likely due to high levels of co-extracted inhibitors. We additionally find that charred tissue samples consistently returned higher concentrations of both raw and endogenous human DNA as well as more robust STR profile recovery. This indicates that a re-evaluation of previously established sampling guidelines for severely thermally altered remains recommending the removal of this substrate may be necessary moving forward. In terms of our skeletal samples, the complete demineralization protocol developed by Lorielle et al. generally performed well at lower-medium levels of thermal alteration while the aDNA Dabney protocol was more suited for STR profile recovery at higher estimated levels of thermal alteration.

---

**B129 A DNA Analysis of Degraded Skeletal Remains Obtained From the Petrous Bone, Tooth, Femur, Tibia, and Humerus: A Comparison Study**

Kadir Dastan\*, Istanbul Health and Technology University, Istanbul, Turkey

---

**Learning Overview:** The goal of this presentation is to determine that petrous bone yields significantly more DNA than teeth, the femur, the tibia, or the humerus; yet the number of alleles obtained from petrous bone and teeth is approximately comparable. In the former, more reportable markers are obtained than in the latter, which results in obtaining more valuable genetic data. In conclusion, it is highly recommended to sample both petrous bones and teeth when performing DNA analysis on highly degraded human remains. Petrous bone or tooth sampling is recommended if DNA typing will be performed on skeletal remains that have undergone environmental degradation. We have been able to increase the success rate in the remains that are currently being examined thanks to this insight.

**Impact Statement:** This presentation will impact the forensic science community by informing attendees that since only bones and teeth remain after long periods of environmental exposure and degradation, DNA typing from skeletal remains is a useful tool in forensic, archaeological, and ancient DNA studies. Humidity, high temperature, salinity, and low pH are environmental elements that have a detrimental effect on DNA preservation, causing molecular damage and fragmentation that renders laboratory recovery of the DNA difficult. In this situation, the forensic DNA community may find it advantageous to perform ancient DNA techniques.

The only biological material that remains for a long period of time is skeletal remains. However, environmental factors like humidity, temperature, and pH have an effect on DNA preservation, making skeletal remains a difficult sample for DNA analysis.

The selection of samples is an important consideration, and conventionally, the most valuable genetic material substrates have been suggested to be the femur and the tooth. Due to its higher DNA yield, the cochlear region of the petrous bone has recently been recommended as an alternative better option. The objective of this study is to assess petrous bone's efficiency in comparison to other cranium samples (teeth) and post-cranial long bones (tibia, femur, and humerus). From 42 different individuals, a total of 92 samples were collected. The samples were extracted using a procedure for organic extraction, and the DNA was measured using a Quantifiler® Trio kit and amplified using a GlobalFiler® kit. In quantification data, petrous bone performs better than other bone fragments, yielding 20–30 times more DNA than the others, as demonstrated by the results. Regarding observed alleles, DNA profile data showed similarities between petrous bone and tooth samples; nevertheless, the volume of DNA extracted from petrous bones allowed us to obtain more informative DNA profiles of superior quality.<sup>1-8</sup>

**B130 Comparing Likelihood Ratios of Degraded DNA Mixture Profiles Using DNA-View® Mixture Solution™**

*Cameron Filipe\*, Massachusetts State Police Crime Lab, Somerset, MA; Charles H. Brenner, DNA•VIEW, Oakland, CA; Robin W. Cotton, Associate Professor, Boston University, Boston, MA*

---

**Learning Overview:** After attending this presentation, attendees will have learned about the performance of a non-Markov Chain Monte Carlo (MCMC) continuous-model probabilistic genotyping software that was used in the analysis of complex three-person mixtures.

**Impact Statement:** This presentation will impact the forensic science community by demonstrating that the Mixture Solution™ software is a viable alternative to MCMC methods for the analysis of complex DNA mixtures, particularly mixtures that consist of degraded DNA.

Interpreting DNA profiles manually can potentially call into question subjectivity between analysts who may interpret specific results differently. There are multiple features of a DNA profile that can complicate interpretation, which include allelic drop-out and drop-in, allele sharing, and Polymerase Chain Reaction (PCR) artifacts, as well as degradation of the DNA itself, which can be caused by various environmental factors. Developments in DNA profile interpretation using probabilistic genotyping software have been made to assist in the complicated task of deconvoluting and interpreting a challenging mixture. Among these programs is DNA-View® Mixture Solution™, a continuous-model probabilistic genotyping software.<sup>1</sup> Mixture Solution™ is unique in that it is not based on the MCMC approach used by other programs such as STRmix™ and TrueAllele®. Mixture Solution™ starts with a hypothesis (either  $H_p$  or  $H_d$ ) and uses it to compute  $M$  (a representation of the mixture data), whereas MCMC methods use the mixture data to generate a probability computation for a list of multiple possible deconvolutions. This difference allows Mixture Solution™ to calculate the hypotheses independently, eliminating the need for the analyst to make a guess about the number of contributors to the mixture.

In this research, Mixture Solution™ was used to provide statistical analyses for three-person DNA mixtures where one or more of the contributors had been degraded by exposure to heat, through the assignment of a likelihood ratio between two given hypotheses based on the mixture data. The calculated likelihood ratio would either support the hypothesis that the person of interest contributed to the mixture, or support the alternate hypothesis, that the person of interest was not one of the contributors. The three-person mixtures were prepared at four different contributor ratios with varying combinations of three levels of degradation: no degradation, partial degradation, and full degradation, using controlled heating to systematically degrade the DNA template prior to amplification. Using two hypothesis tests, Mixture Solution™ was used to compute likelihood ratios for each of the mixtures with a variety of defined people of interest.

All computed likelihood ratios that favored the ground truth hypothesis provided “moderate support” or higher. However, when the DNA from a person of interest was degraded, decreases in the likelihood ratio values were observed when compared to the values computed for undegraded DNA from the same person of interest. These decreases occurred primarily as a result of allelic dropout caused by degradation. While allele sharing was also determined to be another major factor in the differences between likelihood ratio values across DNA mixtures with varying levels of degradation, stutter had little impact on changes in likelihood ratios. Results showed that Mixture Solution™ successfully generated appropriate likelihood ratios for 97% of the computations performed for each of the 20 mixtures. Significant levels of dropout resulting from the degradation of the DNA of the person of interest in the remaining 3% of computations pushed the likelihood ratio values into the “uninformative” range.

**B131 A Picture Is Worth 10,000 LR's: The Evaluation and Implementation of Tools to Improve Interpretation and Reporting of Mixtures Using Probabilistic Genotyping**

*Tim Kalafut\*, Sam Houston State University, Department Forensic Science, Huntsville, TX; Michael Coble, UNTHSC Center for Human Identification, University of North Texas Health Science Center, Ft. Worth, TX*

---

**Learning Overview:** After attending this presentation, attendees will have been introduced to tools that may help improve concordance between experts and laboratories for the final step of the DNA interpretation process for samples with low Likelihood Ratios (LRs) and whether to report the LR as inclusive or inconclusive with regard to the Person Of Interest (POI).

**Impact Statement:** This presentation will impact the forensic science community by introducing practitioners, investigators, and attorneys to a method that comprises a reporting utility threshold that is determined by the characteristics of the specific case sample itself rather than from some series of validation samples that have nothing to do with the evidence in question.

In the United States, there are two predominant options for Probabilistic Genotyping (PG); STRmix™ and TrueAllele®. These two software programs are based on different models yet reach similar results in most mixture examples. However, because of the differences between models, differences in the resulting LR's are both expected and observed in both published studies and in case samples.

This study recruited STRmix™ laboratories to investigate differences in the reporting of LR's for the POI from a set of common DNA samples. Two sets of samples from the publicly available PROVEDIt data set were provided, along with the DNA reference of a trace level true donor, to see if there are differences between laboratories that use the same PG software. The laboratories were told that the samples would range from single source to four-person mixtures, as the goal of this study was to focus on the reporting of inclusionary versus inconclusive conclusions for the POI.

There have been several concordance studies for both inter- and intra-laboratory experiments reported in the literature, but most of these focus on the entire process. Each laboratory uses their complete protocol, including the determination of Number of Contributors (NoC), Analytical Thresholds (AT), STRmix™ parameters, and, finally, reporting statements that mention the inclusionary, exclusionary, inconclusive, or uninformative status of the LR with respect to the POI. This study provided some basic information about NoC, and all laboratories used the same AT and STRmix™ settings in an effort to isolate differences to the final, and arguably most impactful step, the determination of the potential donor status of the POI.

Each laboratory agreed to committing at least two volunteers to interpret either Set A or Set B (n=8 in each set) mixtures according to the validated protocols of each laboratory. The LR's and the report wording used for each sample was submitted for comparison. The initial interpretations varied between exclusion, inconclusive, and inclusionary conclusions for the same samples and references.

Many of the inconclusive statements were related to complexity thresholds determined during validation using internal samples that had nothing to do with the samples in this study. Such statements were based on "inconclusive zones" (e.g., LR's between 2 and 1,000) or other forms of mixture complexity or minimum data requirements.

Two companion tools were then introduced to the laboratories; AdventLR and DBLR™ that allow for non-donor testing ( $H_d$  True) first proposed by Gill and others.<sup>1-4</sup> These tools allow for the exploration of 10,000 or more non-donor profiles and their resulting LR's and comparison to the LR of the POI in the case. Schuerman proposed a utility threshold of the 99.9 percentile LR as a decision point for reporting an LR as inclusionary or inconclusive due to a risk of an adventitious inclusion.<sup>1</sup> Both tools present a visual output that can show how the LR of the POI compares to the population at large.

Laboratories were trained on the use of these two tools and then asked to swab mixture set and repeat the experiment. The only difference is that the reporting statements in the second round of interpretation were to be guided by the 99.9 percentile utility threshold.

The reporting results using these tools will be presented along with the change in concordance for the most important step in DNA analysis: the inclusion or not of the POI as a possible contributor.

**B132 A Comparison of the Two Most Widely Used Probabilistic Genotyping Systems Supports Accuracy and Concordance**

*Susan A. Greenspoon\**, Virginia Department of Forensic Science, Richmond, VA; *Brad Jenkins*, Virginia Department of Forensic Science, Richmond, VA; *Lisa Schiermeier-Wood*, Virginia Department of Forensic Science, Richmond, VA

---

**Learning Overview:** This presentation will inform the forensic community on how STRmix™ and TrueAllele® Casework Probabilistic Genotyping (PG) systems generated concordant results for the majority of samples tested and provide possible explanations for those instances where the two PG systems disagreed.

**Impact Statement:** This presentation will impact the forensic science community and the DNA examiner's understanding of how PG systems function and will increase their expertise in this area of DNA analysis.

The development of PG systems to quantitatively analyze DNA mixture samples has been transformative in forensic science. TrueAllele® Casework (TA) and STRmix™ are the two most widely used PG systems. These systems model electropherogram data, utilizing both similar and dissimilar mathematical approaches.<sup>1,2</sup> The systems were interrogated with 48 challenging two-, three-, and four-person mock casework samples, for a total of 152 Likelihood Ratio (LR) comparisons. Of the 48 different mock casework mixtures, 35 contained at least one degraded DNA sample, and 46 out of the 48 contained at least one low-template DNA contributor (<100 pg). TA and STRmix™ converged on the same result ~91% of the time for mock casework (both systems included, were inconclusive, or excluded the reference profile). The 9% of the LR comparisons where results from the two PG systems were not in agreement corresponded to 14 LR comparisons. Seven of these comparisons resulted in one system including a low-level contributor and the other providing an inconclusive log(LR), and five of these resulted in one system excluding a low-level contributor while the other provided an inconclusive log(LR). The remaining two were contradictory (inclusion versus exclusion). The instances of differing results were likely due to dissimilarities in how the systems model allelic drop-out and stutter. The PG systems exhibited high correlations for both estimated contributor-specific template quantities (>92%) and log(LR)s produced (>87%) for mock casework samples. When log(LR) comparisons were parsed to those for contributors <100pg and those >100pg, the correlation dropped significantly for those log(LR)s < 100pg (~64%) and increased for those >100pg (~89%). Despite the differences between the systems in log(LR)s observed for low-template contributors, both were able to detect contributors at ~1% if sufficient allele information was present given their respective modeling systems, demonstrating very high sensitivity for both. The findings in this study comparing the results from the TrueAllele® Casework and STRmix™ systems will be presented as well as possible explanations to account for the limited instances of disagreement.

**B133 Beyond STRs: A Snippet Into the Challenges of Interpreting iiSNPs**

Kevin Cheng\*, Institute of Environmental Science and Research, Auckland, Auckland, New Zealand; Jo-Anne Bright, Institute of Environmental Science and Research, Auckland, Auckland, New Zealand

---

**Learning Overview:** The aim of this presentation is to summarize some of the considerations in the interpretation of Next Generation Sequencing (NGS) Single Nucleotide Polymorphism (SNP) mixtures and show some deconvolution results of NGS SNP mixtures using published biological models implemented for the interpretation of NGS autosomal Short Tandem Repeat (aSTR) mixtures using a probabilistic genotyping solution.

**Impact Statement:** This presentation will impact the forensic science community by providing the community with some background on SNPs and will demonstrate a possible probabilistic genotyping solution for the interpretation of mixtures generated using this technology.

Some forensic laboratories have shown a growing interest in adopting NGS or Massive Parallel Sequencing (MPS) technologies for a wide range of applications, including genetic genealogy, missing-persons identification, phenotyping, and paternity testing. A key advantage of these technologies is their ability to amplify a diverse set of markers in a single reaction, encompassing aSTRs, Y-chromosomal Short Tandem Repeats (Y-STRs), X-chromosomal Short Tandem Repeats (X-STRs), and SNPs.

Unlike contemporary Capillary Electrophoresis (CE) methodologies for the analysis of aSTRs, NGS can detect sequence variations in a stretch of STRs. Because of this potential benefit of detecting variation at the sequence level, numerous studies in recent years have investigated the behavior of aSTRs in NGS DNA profiles. This led to the development of quantitative models for describing expected NGS DNA profiles.<sup>1-4</sup> As a result, probabilistic genotyping solutions have been developed, enabling the interpretation of aSTR mixtures using sequencing technology. Several of these solutions have undergone rigorous developmental validation, gaining recognition through publication and presentations at conferences.<sup>5,6</sup>

Despite significant progress in the interpretation of aSTR markers in NGS DNA profiles and the added benefit of detecting sequence variation, current methodologies are still only harnessing a fraction of the information within a DNA profile amplified using sequencing multiplexes.<sup>7-9</sup> Notably, data regarding the identity of informative SNP (iiSNP) markers are often disregarded during the interpretation process.

This presentation examines the behavior of iiSNPs in forensic DNA profiles. We will highlight the distinctive characteristics of iiSNPs compared with aSTRs, including stutter, allelic balance, and the biallelic nature of SNPs. Additionally, we will present the Likelihood Ratio (LR) results obtained after the interpretation of 51 profiles each with 94 iiSNP markers using a probabilistic genotyping solution.

These profiles include 26 single-source profiles with varying target template amounts, and 25 two-person mixtures experimentally designed to exhibit varying mixture proportions and template amounts. To add depth to our findings, we compare the LR results from the interpretation of the iiSNPs with those derived from an alternative probabilistic method. Additionally, these results were compared with the interpretation of aSTR markers found within the same profile. The integration of iiSNPs alongside aSTRs in forensic DNA analysis aims to utilize more information from the DNA profile, potentially enhancing the discrimination power of forensic investigations.

---

**Learning Overview:** After attending this presentation, attendees will understand how low-level DNA samples, such as hair and fingernails, can be used as alternative reference samples utilizing the FORensic Capture Enrichment (FORCE) panel and Massively Parallel Sequencing (MPS).

**Impact Statement:** This presentation will impact the forensic science community by teaching about emerging technologies such as the targeted Single Nucleotide Polymorphism (SNP) panel that enables low-level DNA samples to be used as alternative reference materials in cases where buccal swabs are not easily accessible or when high-quality DNA are unable to be collected. Hence, this technology, when implemented, will support challenging cases such as identifying human remains of missing persons.

A frequent problem encountered in crime scenes is poor quality samples that may be environmentally degraded or contain low-level DNA. Short Tandem Repeat (STR) analysis for human identification requires samples of standard forensic quality, which is one reason that SNPs are becoming more accepted and validated in the forensic community.<sup>1</sup> Buccal swabs are considered the gold standard of reference samples; however, in cases where buccal swabs are unable to be collected (such as from elderly individuals), alternative reference materials can be used. Some examples of low-level DNA samples include naturally shed hair without the root, deteriorated bones samples, and fingernails. To implement a more efficient technique to analyze all qualities of DNA samples, the FORCE panel made of forensically relevant SNP markers was developed.<sup>2</sup> This panel targets SNP markers for identity, ancestry, phenotype, and X- and Y-chromosomal SNPs.<sup>2</sup> Furthermore, the FORCE panel is compatible with MPS. As a result, this panel is an effective assay for degraded DNA samples, which can ultimately reinforce criminal investigative clues of suspect genealogy that cannot be performed with STR testing.

This project evaluated the FORCE panel on alternative reference samples such as fingernails and hair in comparison to buccal swabs. Preliminary experiments were conducted to optimize the DNA extraction from three sample types: (1) hair with root, (2) hair without root, and (3) fingernails. In tier one of this study, an extraction method for hair and fingernails was developed. Male and female samples were collected for each alternative reference sample type and extracted in triplicate. To prevent exogenous DNA contamination, samples were washed with a 5% Tergazyme™ cleaning solution and rinsed with ethanol and deionized water. The QIAGEN® EZ1® DNA Investigator® Kit was used following the trace protocol to extract DNA on the QIAGEN® EZ1® XL and samples were quantified with the Quantifiler™ Trio kit on the QuantStudio™5. The results showed that the rooted hair produced low degradation index values (0.98) and high DNA concentration with an average of 3.3ng/μL. The fingernail samples produced relatively low degradation (3.7) and average DNA concentration of 0.6ng/μL. However, the rootless hair had very high degradation index (6.8) and low DNA concentration averaging 0.02ng/μL. After the initial extraction optimization phase, for tier two of this study, five donors were recruited for each sample type (n=15), in addition to buccal swabs (n=5), and each sample was extracted based on the optimized protocol. Following the extraction, quantification and normalization of the extracts were performed. Libraries were prepared using the QIAseq® Targeted DNA HC Panel following the manufacturer's guidelines. The libraries were quantified with the Qubit™ fluorometer and the Agilent® 2100 bioanalyzer was used as a quality control check. The purified, pooled libraries were sequenced on the MiSeq® FGx®. Analysis was performed on the QIAGEN® CLC Genomics Workbench system using a custom pipeline. The hair and fingernail profiles were compared to buccal swab results to determine whether low level DNA samples possess adequate quality and quantity of DNA for analysis.

The results of this study demonstrate that hair and fingernails may be suitable as alternative reference materials for the FORCE panel in cases where buccal swabs are not readily available. These findings will provide the forensic community with more options when it comes to reference materials for human identification.

**B135 Variant Allele Characterization in STR Markers Using Next Generation Sequencing**

Becky Steffen\*, National Institute of Standards and Technology, Gaithersburg, MD; Lauren Mullen, National Institute of Standards and Technology, Arlington, VA; Grace M. Finch, National Institute of Standards and Technology, Fredericksburg, VA; Katherine Gettings, National Institute of Standards and Technology, Washington, DC; Kevin Kiesler, National Institute of Standards and Technology, Gaithersburg, MD

---

**Learning Overview:** The goal of this presentation is to inform attendees about the development of a protocol for use in monoplex amplification and simultaneous sequencing of up to 24 autosomal Short Tandem Repeat (STR) loci used in forensic DNA Capillary Electrophoresis (CE) testing kits when unexpected CE results are obtained.

**Impact Statement:** This presentation will impact the forensic science community by demonstrating that a uniform monoplex Next Generation Sequencing (NGS) protocol for 24 autosomal STR markers makes the Variant Allele Sequencing Program a more efficient service that the National Institute of Standards and Technology (NIST) provides to forensic laboratories.

The Variant Allele Sequencing Program at NIST has traditionally used Sanger sequencing to identify genomic variations within Polymerase chain Reaction (PCR) amplicons containing STRs, particularly variants that result in CE null alleles and alleles that fall outside of the CE allele sizing bins provided by kit manufacturers.<sup>1</sup> However, this process has a low throughput capacity, making it time- and labor-intensive. To address this problem, a protocol was developed at NIST to provide the forensic community with a quicker and more straightforward sequencing method with NGS. NGS technology is a powerful tool for diagnostics and is already widely used in clinical testing to identify mutations across the genome.<sup>2</sup> By applying NGS technology to forensic samples with unexpected CE-STR results, additional information can be gathered about the molecular basis for variant alleles, and this information can be published and shared across the forensic community. The development of this protocol also increases awareness and encourages the integration of NGS technology in forensic laboratories to further improve forensic DNA typing for human identification.

The goal of this project was to identify uniform conditions (target input amount of DNA, PCR cycle number, and primer annealing temperature) for the initial monoplex amplification step that can be used for 24 autosomal markers found in commercial forensic CE typing kits. Primers for this protocol were originally designed to amplify regions differing from commercial kit amplicons.<sup>1</sup> For this work, amplicon size and annealing temperatures were also taken into consideration, and primers for 13 of the 24 loci were redesigned from the original primers to yield amplicon sizes below 500 base pairs (accommodating 2 x 250 read length sequencing chemistry). By designing primers with similar annealing temperatures, decreased amplification efficiency due to the thermal instability of these markers can be minimized.<sup>3</sup> Through empirical testing, the ideal amplification parameters were found to be 1 ng/μL input DNA with a 60°C primer annealing temperature, and 35 PCR amplification cycles. Following amplification, quantitation, and library preparation, the samples were sequenced using a Verogen® MiSeq® FGx® and resulting sequence data were aligned to the GRCh38 Human Genome Reference sequence. These results provide an understanding of the genomic basis (single nucleotide polymorphism, insertion, or deletion) causing the CE STR variant allele, provided the variant is included within the large NGS amplicon. A uniform monoplex amplification protocol that can be used for sequencing 24 autosomal STR markers either together or separately makes the Variant Allele Sequencing Program a more efficient service that NIST provides to forensic laboratories.

**Learning Overview:** The goal of this presentation is to compare Capillary Electrophoresis (CE) and Next Generation Sequencing (NGS) chemistries in forensic laboratories, focusing on the ForenSeq™ MainstAY Kit and Investigator® 24plex QS Kit. This presentation aims to develop a decision tree for streamlined selection between CE and NGS platforms for effective processing of degraded samples.

**Impact Statement:** This study's findings on the comparative evaluation of CE and NGS chemistries in forensic DNA analysis have significant implications for laboratories facing the decision of choosing the most suitable analytical method. The development of a decision tree to select between CE and NGS platforms will streamline the processing of degraded samples, improving efficiency and accuracy in forensic investigations. By providing valuable insight into the strengths and limitations of each technique, this research will impact the forensic science community by contributing to advancing forensic DNA analysis and enhancing the capabilities of forensic laboratories in handling challenging casework.

Forensic laboratories face a critical decision when choosing between CE and NGS chemistries for their analytical needs, especially with the recent approval of the ForenSeq™ MainstAY Kit by the National DNA Index System (NDIS). CE offers rapid and cost-effective DNA analysis, particularly for Short Tandem Repeat (STR) genotyping. On the other hand, NGS provides a comprehensive analysis of DNA, enabling the identification of sequence variants and complex mixtures, offering enhanced sensitivity, and generating large amounts of data. However, implementing NGS technologies requires significant investments in equipment, training, and data analysis expertise, which may be excessive for routine forensic casework.

To determine the suitability of NGS over CE chemistries, quantification and degradation indices can serve as decision points for forensic laboratories, given the reported sensitivity of NGS and smaller amplicon sizes in most NGS chemistries. The ForenSeq™ MainstAY Kit contains 21 autosomal STR loci less than 250bp, whereas the Investigator® 24plex QS Kit has only 10 autosomal STR loci completely less than 250bp.

This study evaluates the ForenSeq™ MainstAY Kit and the Investigator® 24plex QS Kit, both approved by NDIS. The MainstAY kit includes 27 autosomal STRs and 25 Y-chromosomal Short Tandem Repeat (Y-STRs), while the 24plex QS kit contains 21 autosomal STRs. The evaluation involved enzymatically degraded samples and real-world challenging samples. Controlled degradation was carried out using the Turbo DNA-free Kit with increasing amounts of DNase enzyme (0–2 units) to artificially degrade DNA extracts to different degrees. Preliminary results showed that 0.05 units of DNase severely affected the Investigator® 24plex, with only 22% of alleles recovered, while Signature Prep showed autosomal STR recovery at 66%. This trend is expected to be found with MainstAY as well. Furthermore, various challenging samples with degradation indices ranging from 1 to 300 were tested, with genotypes of shared loci consistent between the NGS and CE methods. The MainstAY kit demonstrated similar or improved percent recovery compared to CE for these samples, and even in cases with reduced percent recovery, it recovered more loci, providing more information than the CE method.

Additional studies will include controlled degradation experiments with the MainstAY kit and evaluate comparative recovery in a wider range of skeletal remains, leading to the development of a decision tree for laboratories to process degraded samples.

**Learning Overview:** After attending this presentation, attendees will understand how technical advances used in isolating and sequencing genomic DNA from ancient remains opens new doors for the analysis of modern degraded tissue. This presentation will discuss the efficiency of isolating genomic DNA using ancient DNA and modern forensic extraction methods and their success rates for subsequent Short Tandem Repeat (STR) and mitochondrial genome analyses. Attendees will also learn about DNA damage patterns as assessed using bioinformatic analyses of genomic data revealing how hot desert environments impact DNA preservation in skeletal remains in the American Southwest.

**Impact Statement:** This presentation will impact the forensic identification community by presenting the results of the use of ancient DNA techniques applied to challenging cases. When standard DNA techniques fail due to tissue degradation, DNA extraction and Next Generation Sequencing (NGS) methods targeting small DNA fragments are viable options.

According to the National Missing and Unidentified Persons System (NamUs), as of February 2023, there are over 600,000 unidentified human remains in the United States. An average of 4,400 are added each year, of which roughly 1,000 remain unidentified. Degradation of these remains presents technical challenges for their identification by researchers and government agencies alike. Techniques used to isolate ancient DNA (aDNA) from archaeological samples could be efficient in cases of highly degraded forensic remains. For example, a method for DNA extraction (using guanidine hydrochloride) was developed by Dabney et al. to recover DNA fragments as small as 30–50bp in size.<sup>1</sup> This method has been used to successfully recover analyzable mitochondrial DNA (mtDNA) data from paleoanthropological samples as old as ~400,000 years.<sup>2</sup>

For this study, the Maricopa County Office of the Medical Examiner (MCOME) provided 75 skeletal samples representing 42 individuals who have remained unidentified by standard forensic procedures, such as STRs. DNA from bone and teeth samples was extracted using the Dabney protocol as well as a forensic protocol developed by Loreille and colleagues for degraded samples<sup>3</sup>. The DNA extracted was used to create double- and single-stranded libraries. These libraries were then used for targeted enrichment of the mitochondrial DNA genome performed using biotinylated mitochondrial RNA baits synthesized from the *H. sapiens* Representative Global Diversity Panel (197 mtDNA sequences) (Daicel Arbor Biosciences, Ann Arbor, MI). **Single Nucleotide Polymorphism (SNP)** capture was completed using a custom SNP panel targeting ~4,200 SNPs (Daicel Arbor Biosciences, Ann Arbor, MI). These enriched libraries were then subjected to Illumina® sequencing.

We found that the Dabney extraction method resulted in an average 4.4-fold improvement in DNA yield when compared to the Loreille extraction method. From the double-stranded DNA libraries, we generated mitochondrial genomes ranging from 0.3–246.8x depth of coverage with average fragment sizes of 89bp from 62 samples. Sequencing reads were not recovered from 13 samples, likely due to lack of sufficient DNA. Analyses of the mtDNA sequence data from the single-stranded libraries and the sequencing of the genome-wide SNP enriched libraries are currently underway. Using these data as well as additional analyses of DNA damage patterns and preservation across skeletal elements and environmental contexts, we aim to identify the optimal means of DNA recovery from degraded skeletal tissues.

**Learning Overview:** After attending this presentation, attendees will learn about a novel technology using a Reverse-Complement Polymerase Chain Reaction (RC-PCR) -based Massively Parallel Sequencing (MPS) library preparation solution for Y-chromosomal Short Tandem Repeat (Y-STR) profiling. Attendees will learn its kinetics, performance, and how it is beneficial compared to the conventional Capillary Electrophoresis (CE) -based methodology. Attendees will also be introduced to a user-friendly custom pipeline to analyze the sequencing data using MixtureAce™.

**Impact Statement:** This presentation will impact the forensic science community by providing an alternative Y-STR amplification technology for Y-STR analysis utilizing IDseek® mYSTR™ Y-Chromosomal STR Profiling kit (v2.0) and MPS technology. The chemistry incorporates RC-PCR technology, which simplifies the library target enrichment step required for MPS.

RC-PCR is an efficient target enrichment method that helps to simplify the laborious and time-consuming processes of MPS. RC-PCR allows for simultaneous amplification and tagging of a targeted sequence in a single tube.<sup>1,2</sup> Due to the single tube reaction mechanics, there is a reduction for possible sample switches and a decrease in potential contamination. In addition to the manual advantages, RC-PCR is also highly sensitive and specific because the specific primers are synthesized during the reaction. This allows for the concentrations of primers and amplicons to be more congruent.

The IDseek® mYSTR™ Y-Chromosomal STR Profiling kit employs the RC-PCR technology for the amplification of 30 Y-chromosomal STR markers plus Amelogenin in a single multiplex, closed tube reaction. Previous work was completed to assess concordance of the IDseek® mYSTR™ Y-Chromosomal STR Profiling kit with a Lebanese population (N=83) on the MiSeq® FGx. This was completed by comparing the mYSTR™ haplotypes with data previously generated with the PowerPlex® Y23 and AB Yfiler® Plus PCR amplification systems and CE methods at the 24 overlapping loci. The assessment demonstrated that the IDseek® mYSTR™ Y-Chromosomal STR Profiling kit can produce high-quality results while simplifying the MPS library preparation method. Since the original study, the kit has been updated to include three rapidly mutating Y-STRs (DYS449, DYS518, and DYS612). This study aims to assess the new version (v2.0) of the IDseek® mYSTR™ Y-Chromosomal STR Profiling kit and validate the kit in accordance with the Scientific Working Group on DNA Analysis Methods (SWGDM) guidelines.

The IDseek® mYSTR™ Y-Chromosomal STR Profiling kit (v2.0) was assessed by comparing haplotype results to the AB Yfiler™ Plus PCR amplification system and CE method for a small subset of previously tested Lebanese samples. This assessment shows if the IDseek® mYSTR™ Y-Chromosomal STR Profiling kit (v2.0) performs reliably and as expected. Precision and accuracy studies, sensitivity and stochastic studies, mixture studies, mock evidence sample studies, and a contamination assessment were performed during the validation. Raw FASTQ data files were processed by MixtureAce™ via a custom pipeline. Male and female two-person mixtures with a range of concentrations were evaluated to determine the sensitivity of the IDseek® mYSTR™ Y-Chromosomal STR Profiling kit (v2.0). Additionally, inter-locus balance and stutter filters for each locus were determined and novel sequence-based alleles identified. RC-PCR has been shown to be beneficial for the MPS workflow and produces reliable results while reducing hands-on laboratory time as compared to other library enrichment methods. This technology would be useful for challenging forensic exhibits such as sexual assault or kinship cases due to its high sensitivity and incorporation of MPS technology allowing for increased recovery of genetic information.

**B139 Visualizing Sequencing Artifacts in ForenSeq™ NGS Data**

*Yao-Yuan Liu\*, Institute of Environmental Science and Research, Auckland, New Zealand; Kevin Cheng, Institute of Environmental Science and Research, Auckland, New Zealand; Jo-Anne Bright, Institute of Environmental Science and Research, Auckland, New Zealand*

---

**Learning Overview:** The aim of this presentation is to reveal the presence of a previously uncharacterized artifact in sequencing data and showcase the methods that led to their discovery.

**Impact Statement:** This presentation will impact the forensic science community by raising awareness of high-read sequencing artifacts in Next Generation Sequencing (NGS) data that can potentially be misidentified as alleles.

NGS has captured the interest of the forensic community leading to the emergence of novel sequencing kits and the development of analysis and interpretation methods.<sup>1-6</sup> Like other Polymerase Chain Reaction (PCR) -based assays for forensic DNA interpretation, one of the key objectives of sequencing technology is to amplify the allelic product or amplicon. However, two artifactual by-products of sequencing exist: stutter and noise sequences. An understanding of the behavior of these artifacts is important in order to generate models that can distinguish between allelic and artifactual sequences to aid in the deconvolution of a DNA profile.

Stutter sequences are fairly well characterized, and models have been built to aid in the classification of different types of stutter artifacts. However, noise artifacts or sequences have not yet been sufficiently modeled. Similar to the different types of stutters (for example, back, forward, and double back stutter), there are also different types of noise, including base substitutions, insertions, and deletions. While noise sequences often have a low number of read counts, there are instances where noise artifacts can confound the interpretation of a DNA profile, potentially leading to exclusions of a known contributor.

In our analyses of Verogen™ ForenSeq™ datasets with ground truth data, we encountered noise sequences of abnormally high reads that have the potential of being mistaken as minor alleles, such as those seen in mixed DNA profiles. Further investigation into these sequences revealed similar sequences from across several loci and samples within the multiplex. Analyzing at the base level, we found that a large portion of the error bases (insertions, deletions, substitutions) on the noise sequences from various loci and samples align to singular positions in the original read, forming a spike in the number of noise sequences. The positions of these noise spikes differ between plates and sequencing runs, and also correlate with a drop in base quality scores.

We hypothesize that these types of temporal, plate-wide noise spikes are produced during the sequencing process in the base-addition cycles, potentially from physical disturbances of the sequencing machine during its operation.

**B140 Expanding the STRSeq BioProject to Support Sequenced-Based STR Nomenclature**

*Lauren Mullen\*, National Institute of Standards & Technology, Arlington, VA; Katherine Gettings, National Institute of Standards and Technology, Washington, DC; Lisa A. Borsuk, Bioinformatics, National Institute of Standards and Technology, Gaithersburg, MD*

---

**Learning Overview:** This presentation will inform attendees about the development and expansion of the STRSeq BioProject, a Short Tandem Repeat (STR) sequence catalog. Attendees will learn how this expanded catalog addresses the need for STR sequence nomenclature guidance and its ability to increase interlaboratory communication, facilitating the implementation of Next Generation Sequencing (NGS), also known as Massively Parallel Sequencing (MPS), in forensic laboratories.

**Impact Statement:** This presentation will impact the forensic science community by providing an up-to-date resource for users of NGS for STR sequence nomenclature guidance.

The rise in the use of NGS in forensic DNA testing has led to a need for STR sequence nomenclature resources. This was highlighted in a 2016 European Network of Forensic Science Institutes (ENFSI) survey, which identified a lack of resources available to generate standardized formatting and nomenclature as the main concern for the integration of sequenced-based analysis in forensic labs.<sup>1</sup> In the same year, an International Society of Forensic Genetics (ISFG) Commission published considerations on minimal nomenclature considerations, and a second ISFG Commission on STR nomenclature was convened in 2021, with recommendations expected in 2023.<sup>2</sup>

To address the needs discussed in the ENSFI survey and 2016 ISFG Commission report, the STRSeq BioProject was initiated in 2017.<sup>3</sup> In the years since, GenBank records were created for unique STR sequences identified in population studies by the National Institute of Standards and Technology (NIST) and partner laboratories. Additionally, during this time, many other research groups have published STR sequence population data developed from commercially available assays; therefore, a search was performed for sequence data published between 2016 and 2023 and not yet considered for the STRSeq BioProject. These published STR sequences were compared against over 2,500 existing STRSeq GenBank records to identify sequence-based alleles novel to STRSeq. This resulted in the compilation of STR sequence data from over 40 publications, which consisted of 28 autosomal STR, 7 X-chromosomal Short Tandem Repeat (X-STR), and 28 Y-chromosomal Short Tandem Repeat (Y-STR) markers. Novel sequences were cataloged into STRSeq following the forthcoming guidance of the ISFG DNA Commission on STR Sequence Nomenclature.

This updated catalog will help to unify reporting of data regardless of the forensic STR sequencing kit used for analysis. In addition, this expansion of known allelic diversity will aid the development of bioinformatic and mixture interpretation methods. When using STRSeq for a search, the output generated will provide the user a more comprehensive list of characteristics than were previously available, including updated manufacturer recommended reporting ranges, ISFG minimum reporting range, bracketed repeat region according to current ISFG guidelines, and additional variations of flanking regions from the current human genome reference assembly (GRCh38). Overall, the addition of novel allele sequences from population data and updating associated characteristics facilitates implementation of STR sequencing and improves sharing of data between laboratories.

**B141 An Exploration of a Sequence-Specific Stutter Model for STR Analysis in Next Generation Sequencing**

*Damani Johnson\*, Sam Houston State University, Huntsville, TX; Tim Kalafut, Sam Houston State University, Department Forensic Science, Huntsville, TX*

---

**Learning Overview:** After attending this presentation, attendees will have learned about a proposed stutter model for Next Generation Sequencing (NGS) based on sequence characteristics rather than locus or allele number. Attendees will hear about the potential for more accurate stutter filters for human interpretation and improved stutter modeling in downstream Probabilistic Genotyping (PG) tools.

**Impact Statement:** This presentation will impact the forensic science community by introducing a novel stutter model based on the sequence of Short Tandem Repeat (STR) markers, which appears to predict the occurrence of stutter more accurately in complex loci than current models using simple locus thresholds or allele number. This model could be used to improve stutter filtering accuracy in Short Tandem Repeat (STR) analysis and probabilistic genotyping software and ease the adoption and validation of NGS technology in forensic laboratories.

Amplification of STRs using Polymerase Chain Reaction (PCR) is the foundation of current forensic DNA analysis methods throughout the world. While it remains the gold standard, an inevitable drawback of this process is the production of stutter artifacts due to strand slippage during PCR. Stutter appears as smaller peaks typically positioned one or two repeat units away from an allele peak on an electropherogram and can cause issues in interpretation or mixture deconvolution if not accounted for effectively. Current DNA analysis software attempts to recognize the expected occurrence of stutter and allow analysts to remove it from the allelic data. These stutter models have evolved over time from locus-specific thresholds to allele-specific filters based on a linear relationship between stutter peak height ratio and allele number.<sup>1</sup> While this allele-specific stutter modeling offers improvements over the locus-specific thresholds in more accurately predicting the occurrence of stutter in simple loci, loci with more complex repeat units tend to show major deviation from the linear model, suggesting that additional factors may still need to be considered.

The advancement and growing adoption of NGS technology offers exciting new possibilities for stutter modeling. NGS still allows laboratories to assess STR marker length but provides the additional ability to view their sequences, which can reveal differences in STR alleles that would have appeared identical on CE. These differences could potentially be used to develop a more accurate model for stutter filtering based not only on allele, but also on characteristics of the sequence.

This presentation details part of a study that sequenced batches of 96 and 32 single-source samples for autosomal and Y-chromosomal Short Tandem Repeats (Y-STRs) using the QIAGEN® ForenSeq™ MainstAY Kit. These sequence data were used to develop a model for sequence-specific stutter to explore its potential effectiveness in comparison to locus- or allele-based stutter filter model. While preliminary data suggests that additional sequence characteristics may still need to be considered, this presentation will demonstrate stutter ratio plots showing improved R2 measures of linearity at complex loci when considering the Longest Uninterrupted Stretch (LUS) in the repeat unit of the STR sequence rather than allele number.<sup>2</sup> Others have looked at various characteristics of NGS stutter before; however, this stutter model is the first to also incorporate the simplicity of the Sequence Identifier (SID) nomenclature first described by Young et al.<sup>3-5</sup>

These NGS stutter models will ultimately need to be incorporated into analysis and PG software to take full advantage of the potential interpretation and deconvolution improvements. While stutter data from many more samples will be needed, along with validation tools and downstream software, this presentation will serve as an introduction of sequence-specific stutter to the forensic community.

**B142 Using the Chelation Filtration Method to Improve DNA Profile Recovery From Fired Cartridge Casings (FCCs) Prior to DNA Processing**

*Ariana Harrison, MS\*, Broward Sheriff's Office, Fort Lauderdale, FL; Bruce R. McCord, Florida International University, Miami, FL; Karin A. Crenshaw, Broward County Sheriff's Office, Fort Lauderdale, FL*

---

**Learning Overview:** This presentation will allow a large and broad group of attendees to learn about a simple, cost-effective, and quick method of processing FCCs that can be used prior to DNA processing and will not interfere with the DNA processing steps or any other downstream analysis of the casings.

**Impact Statement:** This presentation will impact the forensic science community by addressing a topic that is a difficulty for the forensic community, which is the large amount of gun crimes that are increasingly common. The chelation filtration method is unique in that it is very simple to implement and can be done by crime scene personnel for a relatively low cost. The method does not require expensive instrumentation or any changes to the downstream DNA processing. It has been proven to succeed in 15–20% of real-world cases, helping to provide investigative leads where swabbing would not have helped.

Gun-related crimes are the cause of many homicides and injuries every year across the United States. According to the Federal Bureau of Investigation (FBI) statistics, firearms were used in 68% of murders, 41% of robberies, and 21% of aggravated assaults in 2011 alone.<sup>1</sup> Cartridges and casings left on the scene often link shootings to a firearm and many times are the only evidence. Traditional swabbing of FCCs has yielded usable profiles only approximately 1–2% of the time, causing many laboratories to refrain from processing FCCs.

A method for collection of the cellular material from the FCCs for downstream DNA analysis was developed and evaluated. Chelation filtration is a simple, easy-to-perform, two-step filtration method using Chelex<sup>®</sup> resin in the initial incubation step and only requires a vacuum device along with two filter devices. The process does not create any need for alterations to downstream DNA analysis. Comparisons of the Chelation filtration method (N=20) to traditional swabbing (N=20) were conducted and the quantity of DNA recovered (ng) as well as the percentage of expected alleles observed was evaluated using Analysis of Variance (ANOVA) analysis, resulting in 40% (P<0.001) more alleles detected with the Chelation filtration method. In addition, the process was further refined to enhance the DNA recovery by using different filter materials and incubation steps.

An anecdotal study of 122 cases was performed to evaluate the effectiveness of the Chelation filtration method on real casework evidence, where 21 interpretable DNA profiles were obtained yielding five Combined DNA Index System (CODIS) matches. With the assistance of STRmix<sup>™</sup> analysis, over 50% of those profiles were eligible for statistical calculations, and STRmix<sup>™</sup> was also used to deduce profiles for CODIS entry. The Chelation Filtration method can be an invaluable tool to help solve gun crimes when there is little to no other evidence besides FCCs. One case also showed that after the Chelation Filtration method was utilized, a fingerprint was also developed on the casing using the Recover Latent Fingerprint Technology (LFT) system.

**B143 Evaluation of Single Cells Produces Highly Informative Forensic Comparisons Across Multifarious Admixtures**

*Catherine M. Grgicak\*, Rutgers University Camden, Camden, NJ; Desmond S. Lun, Rutgers University, Camden, NJ; Nidhi Sheth, Rutgers University, Camden, NJ; Liliana Berrios, Rutgers University, Cherry Hill, NJ; Ken R. Duffy, Northeastern University, Boston, MA*

---

**Learning Overview:** After attending this presentation, attendees will know how to determine sub-source weights of evidence from single-cell data by clustering, evaluating the Likelihood Ratio (LR) per cluster, then averaging the LRs across clusters. Attendees will be aware of automated procedures that support the efficient construction and validation of single-cell laboratory procedures and will also be aware of numerous laboratory approaches to single-cell analysis.

**Impact Statement:** This presentation will impact the forensic science community by demonstrating that, regardless of the number of contributors that donated to the mixture, single-cell analysis results in LRs approaching the inverse of the random match probability and does so while being able to associate what DNA originated from what cell and cell-type.

The consistency between DNA evidence and Person(s) of Interest (PoI) is summarized by the LR: the probability of the data given the PoI contributed divided by the probability given they did not. It is often the case that there are several PoI who may have individually or jointly contributed to the stain. If there is more than one PoI or the Number of Contributors (NoC) cannot easily be determined, then several sets of hypotheses are needed, requiring significant resources to complete the interpretation.

Recent technological developments in laboratory systems offer a way forward by enabling production of single-cell data. The scale of a single-cell experiment ranges from tens to millions of cells per sample and is dependent on the isolation and preparation method employed. Smaller-scale experiments typically use micromanipulation strategies coupled with tube-based amplification, while large-scale experiments exploit the use of barcodes, nanodroplets or picowells, and next generation sequencing (NGS) to parallelize the data generating process. Regardless of scale, there are two features common to all single-cell data generating processes: (1) that intact cell or nuclei are isolated before the DNA/RNA is extracted, and (2) that the extraction and amplification (or library preparation) occurs in the same vessel to which the cell was added. These two features explain the strength of single cell processing in that by isolating the cell before lysis, the two alleles of any donor are paired and fully resolved from DNA of other interference donors, and by extracting and amplifying the DNA in the same vessel, allele drop-out associated with fractionating the extract into two components—one that is stored and one that is amplified—is abated.

We use an *in silico* laboratory system, named ReSOLVIt, to test numerous laboratory scenarios and automatically determine what laboratory treatment offers a limit of detection of one copy. We show that laboratory outcomes are consistent with theory. We then experimentally generate 643 single-cell Electropherograms (scEPGs) and stochastically mix them to produce admixtures with up to 5 contributors with 17–75 cells and minor ratios as low as 3.5%.

We describe the development of a forensically cogent single-cell interpretation strategy that: clusters scEPGs into collections, each originating from one genetic source; determines an LR for each cluster of scEPGs for each PoI; then provides a whole-sample or *sub*-source evaluation. By using Model-Based Clustering (MBC) and a bespoke algorithm, named EESCI for Evidentiary Evaluation of Single Cells, to compute *sub*-source single-cell LRs, we show that 99.2% of the comparisons gave logLR values >0, and of these all rendered log LR >5, regardless of the number of donors or whether the smallest contributor donated less than 20% of the cells, greatly expanding the collection of cases for which DNA forensics provides informative results.

---

**Learning Overview:** After attending this presentation, attendees will understand how long-term room temperature preservation of DNA extracts affects the survival and completeness of Short Tandem Repeat (STR) peaks, as well as the performance of phenotype panels for human identification.

**Impact Statement:** This presentation will impact the forensic science community by providing guidelines on the best approaches to conserve DNA extracts and informing attendees on the survival of DNA in less-ideal preservation scenarios, opening the path for potential future analyses on cold cases' material preserved in non-optimal conditions.

The appropriate storage of DNA extracts is crucial for the successful outcome of forensic genetic analyses, including human identification via STR analysis and the application of phenotype and ancestry panels to infer the morphological features and the geographical origin of the contributor of the trace. Despite the National Institute of Standards and Technology (NIST) guidelines recommending freezing DNA extracts for long-term preservation, it is possible that samples are kept in non-optimal conditions (such as in fridges or even at room temperature) for several reasons (e.g., faulty freezers, movement of the samples from the laboratory to crime bureaus at room temperature at the closure of the case).<sup>1</sup> In these circumstances, little is known regarding the survival of DNA and its suitability for future STR and **Single Nucleotide Polymorphism (SNP)** analyses.

Last year, an experiment was conducted to evaluate the preservation of DNA extracts originating from buccal swabs and their mixtures (ratio 1:15) when samples were stored at different temperatures (+20°C, +4°C, and -20°C) for up to 90 days.<sup>2</sup> Results showed a surprising survival of DNA at room temperature; quantification with Quantifiler® Trio showed a lack of degradation (degradation index 0.7) for all the three storage conditions and STR profiles obtained with GlobalFiler® PCR amplification kit run on both 3500 Series Genetic Analyzer and SeqStudio™ Genetic Analyzer revealed similar completeness for both -20°C and +20°C conditions, and less ideal results for samples kept at +4°C.

Due to the unexpected results obtained, the experiment was further prolonged for up to 400 days (expected completion in January 2024) to evaluate to which extent long-term storage of DNA extracts in non-ideal conditions affects samples quality. Specifically, after the initial 90 days of experiments, a subset of the samples was kept in the previously described conditions, and a second subset was moved to a cupboard located outdoors (uncontrolled temperature conditions). Under the controlled conditions, samples at +4°C were the most evaporated ones after 150 days, as showed by their increased concentration in comparison with the others kept at +20°C and at -4°C. Degradation indexes at T=150 days were comparable at all temperatures for both for the single profiles and for the mixture and generally showed no degradation (minimum degradation index = 0.83 and maximum degradation index = 1.17).

Regarding the subset relocated outdoors, after 150 days from the movement of the samples (overall age of the samples T=240 days), degradation indexes were still recorded to be between 0.8–1.0 for both single profiles and for the mixture. The STR profiles for all samples (e.g., both under controlled and uncontrolled temperatures) were generally complete even after 240 days, including the profile of the minor contributor to the mixture.

Degradation indexes and STR profiles will be evaluated again after 400 days from the start of the experiments and the latest results will be presented at the conference. Additionally, selected samples will be also analyzed with a newly developed in-house ancestry and phenotype panel, to evaluate the reliability of the NGS data on samples stored in non-optimal conditions.

Overall, results presented at the conference will clarify if single and mixture extracts preserved for long-time, non-optimal conditions can reveal information (STR, phenotype, and ancestry) useful to identify the contributor/s to the trace and may open new avenues for the analysis of samples originated from cold cases that were not always preserved by freezing.

**B145 Understanding the Stability of Environmental DNA (eDNA) From Four Biological Taxa and Their Association With Soil and Dust Evidence**

*Teresa Tiedge\*, North Carolina State University, Raleigh, NC; Kelly A. Meiklejohn, North Carolina State University, Raleigh, NC*

---

**Learning Overview:** After attending this presentation, attendees will better understand: (1) how picking/scraping was found to be an appropriate method for eDNA analysis, (2) how mock geologic evidence items were collected for eDNA analysis, (3) the steps in the eDNA analysis workflow, (4) the analysis of sequencing data using bioinformatics, and (5) the stability of bacterial, fungal, plant, and arthropod eDNA from mock geologic evidence.

**Impact Statement:** If the aims of this research are met, this presentation will impact the forensic science community by informing attendees that DNA from bacteria, fungi, plants, and arthropods in soil and dust may be used to supplement forensic geology investigations with additional evidentiary information.

Geologic materials, such as soil and dust, are valuable types of trace evidence and are submitted to crime laboratories. Forensic geologists aim to analyze the inorganic components (e.g., mineral content) and determine their physical properties (e.g., color and pH) for sample-to-sample comparisons or to identify an evidentiary sample's origin. However, sample size is often a limiting factor in these analyses; supplemental methods requiring a small amount of geologic material as input could provide additional evidentiary information. DNA metabarcoding is a commonly used approach to identify the biological taxa that are present in environmental samples by amplifying and sequencing short, informative regions of the genome and is not restricted by sample amount. The goal of this research was to determine the utility and stability of environmental DNA from four biological taxa associated with soil and dust for sample-to-sample comparisons and sample origin. To accomplish this, four taxa, bacteria (16S), fungi (ITS1), arthropods (*COI*), and plants (ITS2, *trnL*) recovered from each sample were characterized (n, 1,026) via DNA metabarcoding.

An initial soil isolation study was performed to determine the most suitable approach (picking/scraping, swabbing, and sonication) to remove soil from mock evidence for environmental DNA analysis. Following soil removal, DNA was isolated using the PowerSoil® Pro Kit. DNA extracts were amplified using Polymerase Chain Reaction (PCR) primers specific to 16S, ITS1, ITS2, *COI*, and *trnL*. Libraries were then prepared and sequenced on an Illumina® MiniSeq™. Raw sequencing reads are processed through a bioinformatic pipeline that identifies Amplicon Sequence Variants (ASVs) via DADA2 and searches the ASVs against GenBank for taxonomic identification. Picking and scraping of soil produced the highest amount of DNA compared to swabbing (p=0.0025) and sonication (p=0.0068). While all three methods recovered similar taxonomic assignments, picked/scraped samples tended to cluster more consistently together with the soil reference in multidimensional space and thus was the method chosen for soil isolation in subsequent experiments.

Following the soil isolation study, five mock geologic evidence items were collected monthly from an agricultural and urban location in North Carolina over a one-year period. Mock items included: (1) soil scraped from t-shirts, boot soles, and trowels; (2) exposed dust collected from brick pavers using polyurethane swabs; and (3) dry dust from air filters (~1" X 1" area used). DNA was isolated from mock geologic evidence using the PowerSoil® Pro Kit, and libraries were prepared using custom-indexed primers and subsequently sequenced using the Illumina® MiSeq™. After sequencing, the bioinformatic pipeline was used to process sequencing reads to characterize the bacterial, fungal, plant, and arthropod communities. Important findings from this research include: (1) despite the low DNA concentrations of dust samples, it is still possible to characterize the biological communities in dust; (2) the wet lab workflow successfully recovered taxa associated with forensic mock evidence; and (3) it is apparent that there are changes in the biological communities over time and between locations. This presentation will also include a preliminary assessment of temporal and spatial variables on the recovery of bacteria, fungi, arthropods, and plants from mock geologic evidence.

**B146 A New Method for Determining Time-Since-Deposition of DNA Samples Containing Saliva and/or “Touch” Epidermal Cells**

*Thilini M. Chandrasekara\*, Virginia Commonwealth University, Richmond, VA; Dillon S. Ryder, Virginia Department of Forensic Science, Vacaville, CA; Susan A. Greenspoon, Virginia Department of Forensic Science, Richmond, VA; Christopher Virginia Commonwealth University, Richmond, VA*

---

**Learning Overview:** After attending this presentation, attendees will better understand the correlation between median autofluorescence of cell populations and the time elapsed since their deposition and its implications in determining the “time-since-deposition” for a biological evidence sample.

**Impact Statement:** This presentation will impact the forensic science community by informing attendees that determining the time-since-deposition of biological material found at the scene of a crime can provide invaluable information for investigators. It can help define the time frame in which the evidence was deposited and, consequently, the period during which the individual who deposited the evidence was present at the scene.

With the increase in sensitivity of DNA profiling, questions about how and when the DNA was deposited have become a driving issue in forensic cases. However, there are few scientific techniques that can be coupled to a DNA profiling workflow to resolve these questions. The objective of this study was to investigate the changes in the autofluorescence of cell populations recovered from saliva and/or “touch” epidermal samples over time and evaluate its potential for determining the time-since-deposition of an unknown DNA sample. To develop this signature, a series of biological samples consisting of either epidermal cells deposited by handling a substrate or saliva cells deposited directly onto a non-porous surface were created. Imaging Flow Cytometry (IFC) was then used to characterize the morphology and autofluorescence profiles of individual cells within each sample, followed by multivariate modeling and predictive classification. Results from saliva cell samples showed noticeable differences in the autofluorescence profiles at different time points, primarily in wavelengths between 535nm and 580nm. Median autofluorescence intensity exhibited a directly proportional relationship with time ranging between 0 to 180 days. Additionally, a clear increase in the heterogeneity of autofluorescence values was also observed with increasing time (i.e., interquartile range of the distribution of fluorescence intensity). The increase was observed to be gradual for the time points between zero and seven days, where the median autofluorescence increased from ~200 Relative Fluorescence Units (RFU) to ~1,000 RFU, but showed a non-linear/exponential increase from T7 to T90, increasing from 1,000 RFU to ~9,000 RFU.

Results from “touch” epidermal cell populations also exhibited distinct changes across the time series, with the most pronounced differences occurring in three time-since-deposition groups: <1 week, between 1 week and 2 months, and >2 months. Differences across age groups were largely driven by decreases in brightfield contrast and increases in the intensity of autofluorescence in wavelengths between 535nm and 580nm. To further test this approach for forensic casework, 47 individual donor cell populations spanning each time-since-deposition group were classified blindly against the reference donor data set. Samples containing at least 75 cells showed classification accuracies of ~95%. Classification accuracies for individual cells varied slightly across time groups: ~97% (<1 week), ~92% (1 week–2 months), and ~98% (>2 months). Overall, these results indicate that autofluorescence and morphological analyses may provide probative information regarding time-since-deposition for many types of trace DNA samples in forensic casework.

**B147 A Biological Survey of Nucleated vs. Non-Nucleated Epithelial Cells Within Touch DNA Samples Using Autofluorescence Profiling**

*Wanyan Cai\*, Virginia Commonwealth University, Richmond, VA; Sarah Seashols Williams, Virginia Commonwealth University, Richmond, VA; Amanda E. Gentry, Virginia Commonwealth University, Midlothian, VA; Christopher Ehrhardt, Virginia Commonwealth University, Richmond, VA*

---

**Learning Overview:** After attending this presentation, attendees will better understand the proportion of nucleated epithelial cells in touch evidence samples and how this information can provide probative value to the analysis of biological evidence in forensic casework.

**Impact Statement:** This presentation will impact the forensic science community by providing a new method to rapidly survey the types of cells in touch DNA evidence and potentially predict the quantity of amplifiable DNA and the quality of the Short Tandem Repeat (STR) profile.

Touch biological samples are commonly collected in forensic investigations and can originate from multiple sources. While touch DNA can connect an unknown individual to the crime scene, these samples may contain epidermal cells, saliva cells, and free DNA from the individual and/or the surrounding environment. The relative contribution of each of these DNA sources to a given sample can have a significant impact on the quantity and quality of DNA recovered from the sample. It can also have implications for various activity-level propositions for the circumstances in which it was deposited. However, there are few methods that allow investigators to assess these components before subjecting the sample to a DNA profiling workflow. To address this issue, we developed a new method to characterize the proportion of nucleated epithelial cells, non-nucleated epidermal cells, and cell-free DNA in touch samples using flow cytometry in a high throughput and non-destructive manner.

To identify signatures for differentiating nucleated versus non-nucleated epithelial cells, a total of 30 saliva reference and 30 touch reference samples were collected from different individuals and compared across ten time points, ranging from immediate collection to three months. Results showed distinct differences in the intensity of autofluorescence between these cell sources, particularly at wavelengths between 450nm–500nm. For example, epidermal cells showed median fluorescence intensity in the range of 300 to 450 Relative Fluorescence Units (RFU), whereas saliva cells exhibited lower median intensity in the range of 150 to 300 RFUs. Additionally, we observed some disparities in autofluorescence profiles across contributor cell populations from the same tissue type as well as differences in the abundance of cells deposited onto the surface. As the time-since-deposition increased, median autofluorescence intensity decreased in saliva cells but did not show any systemic changes in epidermal cell populations.

Next, we used these differences to characterize the proportion of nucleated epithelial cells and non-nucleated epidermal cells in 40 mock casework samples that were composed of either saliva and epidermal cells, or epidermal cells deposited from multiple contributors onto the same substrate. Results showed that saliva cells could be easily detected and quantified in cell populations where the ratio of saliva to epidermal cells ranged between 1:10, 1:1, and 10:1. Interestingly, cells consistent with nucleated epithelial cells were detected in some mixtures (~1%) that were deposited only through touch, suggesting a possible role for these cell types in touch DNA samples. DNA profiling showed a strong correlation ( $R^2 \sim 0.94$ ) between the abundance of saliva cells, the quantity of amplifiable DNA, and the quality of the STR profile quantity of amplifiable DNA. Overall, these results indicate the potential to differentiate epidermal cells from other cell types and quickly predict the quantity of DNA in an evidence sample. This can enhance the analysis of trace biological samples and provide valuable insights into the possible mechanisms for presence, abundance, and quality of DNA in evidence samples.

**B148 Proactive Crime Scene Response Improves Criminal Investigations**

*Ray A. Wickenheiser\*, New York State Police Crime Lab System, Albany, NY*

---

**Learning Overview:** After attending this presentation, attendees will understand some principles of the proactive crime scene approach, utilizing targeted forensic results in real time to investigate crimes. Actual cases and business cases will further support the use of this technique to maximize the value of evidence in providing investigative leads.

**Impact Statement:** This presentation will impact the forensic community by providing a model to improve the positive impact on the objective evidence provided by forensic science. A model will assist forensic science service providers to implement the Proactive Crime Scene approach, supported by the cost savings of a range of business models, coupled with case examples.

The Proactive Crime Scene Response utilizes targeted forensic analytical results to direct criminal investigations in real time.<sup>1</sup> Forensic laboratories maximize the value of analytical evidence through recognition, documentation, collection, and preservation of evidentiary items located at the crime scene and subsequent identification of high value samples. A seamless flow of analysis is based on improved education, coordination, and communication between the crime scene investigators and forensic scientists. This approach enables greater focus on high-value evidence with decreased response time and greater impact on investigational direction. Real-time data from the resulting focused forensic analyses coupled with the use of databases provides primary investigative leads. These leads supply suspect identities, the whereabouts at the time of crime commission, links to other crimes, and other critical collaborative crime-solving information.

Forensic evidence provides actionable, objective information to investigators, including suspect identities and linking of similar crimes. Forensic evidence is perishable, as its value diminishes over time, with most investigative costs spent at earlier stages of the investigation. Timely objective forensic intelligence saves investigative resources, more accurately eliminating incorrect suspects from suspicion while directing investigations to the correct suspects. When a backlog exists at the forensic laboratory, a large component of the total turnaround time is due to the case waiting to start analysis, not the analysis itself. Providing targeted analysis on high evidentiary-value items is an interim step that can be provided immediately. Employing a two-step screening and confirmation process using Rapid DNA and the National Integrated Ballistic Information Network (NIBIN) provides quicker leads for suspect elimination and inclusion. These leads are then confirmed in accredited forensic laboratories for judicial proceedings as necessary.

The Proactive Crime Scene Response has several components, including communication, forensic scientist expert liaison, training, and education, streamlined analysis on high-value evidentiary items, and rapid reporting. Communication includes laboratory notification of crimes with a potential forensic component, active outreach to crime scene investigators, and real-time support with scientific expertise and dedicated forensic science expert liaisons. Ongoing education and training include in-person and remote learning, webinars, short videos, handbooks, and cheat sheets. Streamlined forensic analysis ensures analysis commences immediately on high evidentiary-value items with reduced impact on the standard evidence flow. Finally, streamlined reporting includes Laboratory Information Management System (LIMS) electronic reporting or other electronic means of providing timely results to investigators and justice system officials. LIMS also provides result compilation to provide bigger picture observations where Memorandum of Understandings (MOUs) between police agencies permit sharing of aggregate forensic laboratory-compiled information and data.

Resources providing timely forensic analysis are well spent as demonstrated by criminal and business case examples. Case examples are provided that highlight the successful application of key aspects of the Proactive Crime Scene Response model. Business cases covering a spectrum of forensic and database applications will illustrate a large cost saving, providing further demonstration of the effectiveness of this approach. Recommendations for implementation including Rapid DNA and NIBIN will be included.

Turnover of crime scene specialists and investigators and increasing forensic technology requires an ongoing forensic science education, to include interpretation of results impacting the investigation at hand. The presented investigator-forensic investigator partnership is a means to alleviate the risks of investigator turnover while realizing improvements in rapidly evolving forensic technology and optimizing the value of forensic intelligence. Quicker and more cost-effective crime solving, prevention, and elimination of the wrongfully suspected support implementation of this Proactive Crime Scene Response.

**B149 An Interagency Study of Scene Investigation Using Virtual Reality (VR) Tools**

*Kelly Keyes\*, RTI International, Yorba Linda, CA; Jaclynn McKay, RTI International, Research Triangle Park, NC; John H. Grassel, RTI International, Apex, NC; Edward Hill, RTI International, Research Triangle Park, NC; Nicholas Thomas, RTI International, Tampa, FL*

---

**Learning Overview:** After attending this presentation, attendees will understand how crime scene investigators across the nation compared processing virtual reality crime scenes as well as the capabilities of using VR as a crime scene training tool.

**Impact Statement:** This presentation will impact the forensic science community by providing empirical data related to how investigators across the nation process crime scenes with the goal of identifying areas in scene investigation that would benefit from standards development and exploring the capabilities of using VR as a crime scene training tool.

The actions taken during a crime scene investigation play a pivotal role in subsequent forensic analysis and ultimately case resolution. Because of this, incorporating quality assurance standards in the work being done at the scene is important to improving the overall quality of processing and collecting evidence being sent to the laboratories, thereby increasing the capabilities of laboratories. Currently, the two accrediting bodies for forensic testing, American National Standards Institute (ANSI) National Accreditation Board (ANAB) and the American Association for Laboratory Accreditation (A2LA), show less than 80 unique agencies across the United States are accredited under the International Organization for Standardization (ISO) 17025 or ISO 17020 standards in scene investigation. Additionally, when it comes to proficiency and competency testing, required quality assurance measurements for accreditation, there are very limited options for third-party testing due to the complex nature of scene investigation. While many agencies routinely perform scene examinations, the vast majority are not accredited, and the level of training, resources, and opportunities to practice actual scene investigation varies from jurisdiction to jurisdiction.<sup>1</sup>

To facilitate the development of standards for crime scene and improve the repeatability, reproducibility, and accuracy in the practice of forensic science, RTI International, in cooperation with the National Institute of Standards and Technology (NIST) as part of cooperative agreement 70NANB21H098, conducted a national interagency comparison study on crime scene processing using high-resolution VR scene recreations. VR has been found to be a successful training tool in many disciplines and enables the evaluation of problem-solving, decision-making, and technical skills in an immersive simulation of real-world experiences that can be easily repeated, amplified, and adapted as needed. After two initial phases of information gathering at the 2022 Organization of Scientific Area Committees (OSAC) for Forensic Science meeting in Orlando, FL, and the 2022 International Association for Identification (IAI) Conference in Omaha, NE, three virtual crime scene scenarios (sexual assault, assault, and overdose) and a training module were created along with a variety of crime scene processing tools. VR headsets were shipped out to 66 agencies across the country varying in jurisdiction, agency, and crime scene unit size. The participants (n=163) varied in years of experience, number of scenes processed in the past three years, and VR experience were asked to participate in the training module, then process two of the virtual scenes. Data was collected after each scene was processed and reviewed to compare participants' performance in crime scene processing, such as how long it took to process scenes, how many times gloves were changed, or number of photographs taken. Insight from this study would also be used to assess the effectiveness of VR as a training tool or potential means for agencies to assess members' proficiency and competency in scene investigation.

**B150 The Presence of Inorganic Gunshot Residue (iGSR) in Police Vehicles: A Study at the Zagreb County Police Administration in Croatia**

*Sunčica Kuzmić\*, Forensic Science Centre Ivan Vučetić, Zagreb, Grad Zagreb, Croatia; Hrvoje Senjes, Forensic Science Centre Ivan Vučetić, Zagreb, Grad Zagreb, Croatia; Ivan Jerković, University of Split, Grad Split, Splitsko-Dalmatinska, Croatia*

---

**Learning Overview:** This presentation will address the risk of contamination of police vehicles by iGSR, covering characteristic and indicative particles. After attending this presentation, attendees will understand which parts and to what extent police vehicles could be contaminated with GSR when the vehicle is used to transport people related to criminal events and other everyday police tasks and what could be contributing factors.

**Impact Statement:** This presentation will impact the forensic science community by demonstrating not only the prevalence of the contamination in the samples analyzed but also by showing a statistical relationship between the presence and the number of GSR particles at different parts of vehicles (driver's/back seats), as well as the connection between the indicative and characteristic GSR particles.

Although identifying iGSR particles has been a method of choice to prove that a person was involved in a firearm-related incident, it is crucial to remain aware of potential sources of contamination and secondary transfer of these particles. Studies have shown that iGSR can be present in the police environment, including police officers, facilities, and the vehicles used to transport potential suspects.<sup>1-3</sup> Therefore, the study aimed to analyze the vehicle contamination on the level of the police administration unit, examine the relationship between contamination of different parts of the vehicle and different types of particles, and identify factors that could contribute to the contamination.

A study was conducted at the Zagreb County Police Administration, the largest police administration unit in Croatia, on the vehicles used for event participants' transportation and other police tasks. The sampling was conducted from December 8, 2021, to April 13, 2022, and comprised 65 vehicles (margin of error:  $\pm 6\%$  at a 95% confidence level) from 17 police stations. The samples were collected from the driver's seat, back seat, and backrest with GSR stubs and examined using Scanning Electron Microscopy and Energy Dispersive X-ray (SEM/EDX) analysis by an accredited method within the Forensic Science Centre. Any vehicle with at least one GSR particle in at least one sample was considered a contaminated vehicle, whereby characteristic and indicative particles were considered separately. The proportion of contaminated vehicles and the number of particles were calculated depending on the location and type of particles. A logistic regression was used to examine the possible influence of variables collected by the questionnaire (conducted at the police station level) on vehicle contamination.

Characteristic particles were detected in 63.1% of vehicles, 33.8% on the driver's seat and 24.6% on the back seat/backrest. Indicative particles were found in 70.77% of vehicles, on the driver's seat in 33.8%, on the back seat in 30.77%, and on the backrest in 35.38% of vehicles. McNemar's chi-square test revealed no significant differences between the proportion of positive samples depending on the vehicle part nor the type of the GSR particles ( $P > 0.05$ ). Overall, 228 characteristics and 166 indicative GSR particles were found, but without significant correlation between them ( $P = 0.346$ ). The most common number for both types of GSR particles was one. Logistic regression showed that, among the considered variables, vehicle contamination could be affected by the transportation of persons who participated in firearm-related incidents ( $P = 0.030$ ), suggesting caution in such cases.

The high prevalence of contaminated vehicles may point to risk from secondary contamination, but to a limited extent, due to the low number of particles found. The study demonstrated that a similar degree of contamination could be expected in the driver's seat and back seat/backrest. The results indicate that contamination with indicative particles does not necessarily imply the presence of characteristic GSR particles, despite no difference in the proportion of vehicles positive for both types.

**B151 The Prevalence of GSR and the Mitigating Quality Procedures at Harris County Institute of Forensic Sciences**

*Brittany S. Claassen\*, Harris County Institute of Forensic Sciences, Houston, TX; Audrey Pless, Sam Houston State University, Santa Fe, TX; Leslie A. Dixon, Harris County Institute of Forensic Sciences, Cypress, TX; Jason L. Schoeder, Trace Evidence Laboratory, Harris County Institute of Forensic Sciences, Houston, TX*

---

**Learning Overview:** This presentation will summarize the results of an in-house Gunshot Residue (GSR) prevalence study and demonstrate the need for effective mitigating procedures. After attending this presentation, attendees will be familiar with the persistence of GSR particles, the need for appropriate quality controls, including universal and locally developed procedures, and why these procedures ensure robust analytical results.

**Impact Statement:** This presentation will impact the forensic science community by demonstrating what it means to ensure contaminant-free analytical results in the category of GSR testing and the applicability of GSR in a criminal investigation, given the prevalence of GSR particles in the operational forensic laboratory.

The persistence of GSR in a forensic laboratory is a concern for trace evidence analysts and the criminal justice community. To help mitigate this concern, a localized study of GSR within the Harris County Institute of Forensic Sciences was conducted to determine the presence and prevalence of background GSR. An additional objective was to determine the potential for transfer of GSR within the building and the effectiveness of mitigating quality assurance procedures.

In this study, a variety of surfaces were sampled throughout the five active floors of the building, including the hands of various employees, small surfaces frequently touched by hands (e.g., water dispensers, door handles, elevator buttons), and common areas, such as breakrooms and conference rooms. Each sample was collected using a commercially available GSR collection kit utilizing a carbon adhesive stub. Analysis was performed using Scanning Electron Microscopy/Energy Dispersive X-Ray spectroscopy (SEM/EDX) with an automated software to detect particles characteristic of GSR. The same procedures employed for evidence analysis were followed in this study. Quality control samples used to monitor GSR contamination in the analytical environment were also included as part of the study.

GSR was detected on surfaces and items frequented by firearms examiners and firearms evidence, such as evidence technician carts utilized in transporting evidence to and from the firearms laboratory. However, GSR was also detected on surfaces that, without targeted mitigating procedures, could lead to potential transfer to a trace evidence analyst and inadvertently affect GSR analysis. Surfaces testing positive for the presence of GSR particles included elevator buttons, hands of evidence intake personnel, and other surfaces within the evidence receiving area. No GSR was found to be in the vicinity of the trace evidence laboratory, including sampled door handles, office spaces, and breakrooms. The results of this study highlight the effectiveness of existing procedures and suggests the need for continuous monitoring and vigilance on the part of trace evidence personnel.

In conclusion, this presentation will demonstrate the prevalence of GSR in an operational forensic laboratory, the need to monitor background levels of GSR as an important consideration to ensure the quality of the results, and provide a set of procedures to mitigate concerns of GSR persistence.

**Gunshot Residue; GSR Prevalence; Quality Procedures**

---

**B152 Utilizing Gas Chromatography/Mass Spectrometry (GC/MS) to Determine the Effect of Solvent Extraction Parameters on Forensic Smokeless Powder Analysis**

*Leighann Rose Weber\*, Virginia Commonwealth University, Virginia Beach, VA; Kelli A. Simon, Bureau of Alcohol, Tobacco, Firearms and Explosives, Beltsville, MD; Ryan Bain, Bureau of Alcohol, Tobacco, Firearms and Explosives, Beltsville, MD; Eric Hazelrigg, Virginia Commonwealth University, Richmond, VA*

---

**Learning Overview:** This presentation will utilize GC/MS data to demonstrate how certain instrument parameters and an optimized solvent extraction method can increase the accuracy of forensic smokeless powder analysis. After attending this presentation, attendees will understand how instrumental parameters influence smokeless powder analytes during analysis and why current extraction methods are insufficient or impractical for forensic science applications.

**Impact Statement:** This presentation will advance the forensic science community's understanding of smokeless powder analysis and offer an optimized solvent extraction method that could strengthen the interpretation of data collected for cases involving such samples.

Since its invention in the 1800s, smokeless powder has served as an energetic material in ammunition for civilians and military applications. Due to its commercial availability and use in pipe bombs, it has also been an important component of forensic explosives casework. During wartime, research originally focused on developing methods that could evaluate the stability of powders, but today the focus has shifted to developing instrumental techniques that enable forensic identification and comparison work.<sup>1,2</sup>

The analysis of smokeless powders is analytically straightforward; however, the complex chemistry of these powders and the proprietary nature of production makes determining a powder's exact formulation difficult. GC/MS has typically been utilized for analyzing intact and post-blast smokeless powder.<sup>3</sup> The effect of instrument parameters (inlet, transfer line, and source temperature) on analyte detection was evaluated. Despite the vast amount of research that has been conducted to develop instrumental methods capable of analyzing smokeless powders, to this author's knowledge, no research has been conducted to develop an optimized solvent extraction method for use prior to instrumental analysis.

In this study, a 13-minute GC/MS method that can detect 14 analytes was utilized to develop an optimized solvent extraction method for 28 powders of double-base morphology. Results indicated that Dichloromethane (DCM), the solvent traditionally used for smokeless powder extractions, was not sufficient because it had an average extraction efficiency of approximately 4–30% and required a large amount of sample (approximately 10mg) to detect minor and trace analytes. When a solvent mixture of 1:1 DCM and Acetonitrile (ACN) was used with a 15-minute extraction time, the ability to detect minor and trace analytes present in sample amounts as low as 0.50mg was possible. This extraction method was applied to other selected morphologies. As the mass of the individual particle decreased, the number of particles needed for successful extraction of the minor and trace analytes increased.

**B153 Advancements in 3D Technology and Virtual Comparison Microscopy for Ballistic Identification**

*Logan Eickhoff\*, Leeds Forensic Systems, Inc., Minneapolis, MN*

---

**Learning Overview:** The goal of this presentation is to inform attendees that 3D imaging technologies are developing for use in firearms and toolmarks laboratories that can be used to supplement the current processes.

**Impact Statement:** This presentation will impact the forensic science community by reviewing how developing 3D imaging technologies can be implemented in laboratories to streamline the processing of evidence, provide easier access to imaging needed for examinations, and supplement the documentation and review process for casework, allowing the lab a more streamlined process to reduce the backlogs currently seen in many labs today.

In this session, we will explore the exciting advancements in 3D technology, database correlations, and Virtual Comparison Microscopy (VCM) as applied to ballistic identification, utilizing the state-of-the-art EVOFINDER® Ballistic Identification System. The system's capabilities enable the creation of a comprehensive database of 3D images of bullets and cartridge cases, revolutionizing the way forensic ballistic examinations are conducted.

Through the use of 3D imaging, historical sample images can be efficiently stored and organized in a database. This repository facilitates rapid and automated comparisons between samples, providing forensic examiners with unprecedented access to visualize and compare specimens virtually. This powerful combination of technologies helps expedite the identification process, leading to increased efficiency and better utilization of examiners' time while reducing backlog in ballistic investigations.

The utilization of 3D technology in ballistic identification represents a significant leap forward from traditional two-dimensional methods. By capturing intricate details and surface characteristics of bullets and cartridge cases, the EVOFINDER® system enhances the accuracy and reliability of forensic examinations. Furthermore, the implementation of database correlations enables the system to intelligently sort and match samples, presenting potential matches to examiners for further analysis.

The incorporation of VCM adds another layer of versatility to the EVOFINDER® system. With VCM, examiners can compare samples from different locations, facilitating collaboration and information-sharing among forensic teams regardless of geographical barriers. This capability not only enhances the accuracy of ballistic identification but also fosters a more interconnected and collaborative forensic community.

In conclusion, the EVOFINDER® Ballistic Identification System, powered by 3D technology, database correlations, and virtual comparison microscopy, has transformed the landscape of ballistic investigations. Its ability to efficiently manage vast image databases, enable virtual examinations, and accelerate the identification process has a profound impact on forensic science. By harnessing these advancements, forensic examiners can uncover critical evidence faster, leading to more effective criminal investigations and bolstering public safety.

---

**B154 Feature Similarity (FS) and Congruent Matching Features (CMF) Methods for Comparison of Impressed Toolmarks in Firearm Evidence Identification**

*Junfeng J. Song\*, National Institute of Standards and Technology, Gaithersburg, MD*

---

**Learning Overview:** The goal of this presentation is to introduce the FS and CMF methods for objective comparison of impressed toolmarks in firearm evidence identification.

**Impact Statement:** This presentation will impact the forensic science community by comparing the performance of the FS and CMF methods with the existing Areal Cross Correlation Function (ACCF) and Congruent Matching Cells (CMC) methods, respectively, using three datasets of breech face and firing pin impressions with granular, parallel, and circular mark characteristics, respectively. The FS and CMF methods show promising improvements in the separation of Known Matching (KM) and Known Non-Matching (KNM) comparison scores.

The FS and CMF methods are introduced for objective comparison of impressed toolmarks in firearm evidence identification. Both methods seek to combine the advantages of areal and feature-based comparisons of toolmark images (i.e., the pixel-wise comparison of the surface topography of both samples and comparison of the type and distribution pattern of individual features on the topography images). Both methods apply optimized height thresholding combined with the Maximally Stable Extremal Regions (MSER) method to generate pixel blobs that represent distinct features on band-pass filtered topography images.

For the FS method, we use a trinary feature map to represent the detected peak and valley features. The similarity of two compared feature maps is expressed by the Feature Similarity Score (FSS), which is normalized as the FS value that represents the correlation coefficient of the compared feature maps. A pattern search algorithm is applied to find the image registration position and orientation that yields the maximum FS value. Compared with other areal comparison methods, such as those based on the normalized ACCF, the FS method is less affected by local regions with poor mark visibility or spurious marks with relatively large heights or depths that can decrease the accuracy of identification.

The CMF method is an extension of the CMC method. We extend the CMC method by replacing the regular grid of square correlation cells with irregular feature cells whose shape follows the feature blobs identified on the reference image, while covering the entire image region.

We compare the performance of the FS and CMF method with the ACCF and CMC method, respectively, using three datasets of breech face and firing pin impressions with granular, parallel, and circular mark characteristics, respectively. The FS and CMF method show promising improvements in the separation of KM and KNM comparison scores.<sup>1-6</sup>

**B155 The Impact Behavior of 9mm Jacketed Hollow Point Bullets on Laminated Glass**

Zoe Timothy\*, *The Pennsylvania State University, State College, PA*; Michael Kuschki, *Pennsylvania State University Forensic Science Program, University Park, PA*

---

**Learning Overview:** The goal of this presentation is to describe the significance and analysis of critical angle behavior of a 9mm jacketed hollow point bullet on laminated glass. The systematic nature of the study allows for further discussion of various trends in impact behavior relative to the angle of incidence.

**Impact Statement:** This presentation will describe a systematic approach for determining the critical angle of incidence between an ammunition-substrate pairing as well as elucidate impact behaviors that may be observed and analyzed in the process. This presentation will further bolster the knowledge base of shooting reconstruction with regard to the behavior of laminated glass (commonly encountered in automotive windshields and side glass) as a substrate.

The reconstruction of shooting incidents in forensic science investigation is critical to determine the sequence and circumstances that occurred during an incident. This is especially true in officer-involved shooting incidents, where event details may be in question or under scrutiny.<sup>1</sup> A specific understanding of the position, orientation, and shooting distance of an officer are often necessary to determine if the actions taken were justified.<sup>2</sup> To do so is often crucial to determine the trajectory of projectiles based on impact behavior.

Shooting reconstruction is a highly dynamic and complex process that in part may attempt to determine the origin and sequence of fired projectiles. These attempts are further complicated by the impact behavior of bullets at the critical angle of incidence. Critical angle refers to the transition from perforation or penetration behavior to ricochet behavior as bullet incidence angle is decreased. At and near the critical angle of incidence, it becomes more difficult to predict whether a bullet will perforate, ricochet, or a combination of both (upon fracturing). The ammunition tested in this study is a standard-issue cartridge used by agents of the United States Department of Homeland Security. By studying the impact behavior of 9mm Luger® +P Speer Gold Dot 124-grain jacketed hollow point ammunition on AS-1 laminated glass, we attempt to describe the phenomena at the critical angle for reference in shooting reconstruction. Using empirical testing methods, we tested a range of incident angles around the critical angle to create a distribution of impact behavior and developed a method to provide a more precise determination of the critical angle.

A number of studies have been conducted regarding bullet impacts in float glass.<sup>3,4</sup> However, studies of bullet behavior on laminated glass have generally small sample sizes and involved multiple impacts to each windshield.<sup>5-7</sup> Aside from affecting substrate integrity upon successive shots, this multi-impact approach also necessitates that impact sites be spaced apart on the windshield, adding a target-curvature variable in the process. This study was conducted with 100 flat panes of laminated glass, with a single shot fired through each. This sample size is large enough to draw statistically significant inferences, provided consistent substrate integrity, and removed curvature as a confounding variable.

Ammunition was fired from an H-S Precision® Universal Receiver with a 9mm SAAMI® test barrel at the test panes held in a steel mount designed for this project. An Oehler Model 83 chronograph was used to measure the pre-impact. Post-impact behavior was recorded on witness paper, as well as with a Phantom® TMX 7510 high-speed camera. Trends in the distribution of glass fragments, the fragmentation of the bullet, and the relative loss of kinetic energy of the bullet from impact were recorded.

Unlike the full metal jacketed bullets of previous studies, the jacketed hollow point bullets in this study perforated the glass (at least partially) at much more oblique angles of incidence. These bullets also appear far more prone to jacket separation. Consistent perforation by jacket material occurred at an angle of incidence of 15-degrees and full ricochet of intact ammunition was not observed until an incidence angle of 10-degrees. In addition to reducing the maximum ricochet angle, the jacket separation created a broader transition across the critical angle than expected. Methods for defining the critical angle will be discussed.

**B156 The Interoperability of Firearm Toolmark 3D Measurements on Objective Similarity Metrics**

*Xiaoyu A. Zheng\**, National Institute of Standards and Technology, Gaithersburg, MD; *Johannes Soons*, National Institute of Standards and Technology, Gaithersburg, MD; *James Yen*, National Institute of Standards and Technology, Gaithersburg, MD

---

**Learning Overview:** After attending this presentation, attendees will better understand how 3D topography measurements of firearm toolmarks generated by different instruments and laboratories affect similarity metrics Areal Cross Correlation Function (ACCF) and Congruent Matching Cells (CMC).

**Impact Statement:** This presentation will impact the forensic science community by informing attendees that the adoption of 3D topography measurement is a major paradigm shift in the science of firearm and toolmark analysis. As with any novel technology, validation is required at a foundational level to ensure efficacy and meet *Daubert* criteria. The round robin inter-comparison proposed in this study is a well-established method to characterize, diagnose, and reduce differences in measurement results obtained by different labs and instruments. Equivalency of measurement results and comparison results is essential for building confidence in evidentiary findings obtained by forensic labs through this new technology. Results of the study provide data for *Daubert* hearings and will contribute to standardization efforts of procedures for measurement and quality control, as well as the development of standard operating procedures by forensic labs. Results will also help instrument manufacturers and researchers develop novel objective similarity metrics and weight of evidence estimation procedures.

There has been a major paradigm shift in firearm and toolmark analysis toward the use of 3D topography measurements. The new approach bolsters objectivity through the International System of Units (SI) traceable measurements. Several manufacturers are now offering specialized 3D microscopes for toolmark measurement that rely on differing measurement principles that each has advantages and challenges. These instruments are currently being used in laboratories for Virtual Comparison Microscopy (VCM). The ultimate goal for these instruments is to generate measurements used to report on the statistical weight of evidence of a comparison in case work.

For impressed toolmarks, there is no comprehensive study that characterizes the resulting differences in 3D data obtained at different forensic labs and their effect on objective similarity scores. This is an important gap in the quest for objective comparison results and quantitative weight of evidence reporting. This gap needs to be addressed to ensure consistency in results among labs and provide associated foundational data for future *Daubert* hearings.

The research evaluated the effect of measurement source variations on similarity metrics. This was accomplished through a round-robin study where each lab/instrument measures the same set of 120 cartridge cases fired from four sets of consecutively manufactured firearms. A similar inter-lab study was conducted for striated toolmarks on bullets where significant deviations were observed between some labs and instruments.<sup>1</sup> These findings were then used to improve measurement protocols, data processing, and analysis methods.

To quantify the differences between labs and technologies, each lab's measurements was analyzed using two well-established similarity scores: the normalized Areal Cross Correlation Function (ACCF<sub>MAX</sub>) and the number of Congruent Matching Cells (CMC).<sup>2,3</sup> The results were used to generate Known Matching (KM) and Known Non-Matching (KNM) score distributions that were be used to statistically analyze for differences between labs and systems. Results will facilitate improvements in consistency of measurement results while providing the foundational research data required to defend the future use and interoperability of 3D measurements in case work.

This research was funded through the National Institute of Justice under agreement#: DOJ-NIJ-2021.

**B157 The Effect of Gunshot Angle of Incidence on Distance Determination**

*Alexander W. Jason\*, ANITE Group, Pinole, CA; Andres Marco, ANITE Group, Barcelona, Spain*

---

**Learning Overview:** After attending this presentation, attendees will understand how the gunshot angle toward a person or object will affect the quantity, pattern, and density of Gunshot Residue (GSR) and the applicability of angled shots in GSR distance determinations.

**Impact Statement:** This presentation will impact the forensic science community by informing attendees that there are dynamics within angled shots that produce different GSR patterns and particle distributions. The angle at which the gun was held in relation to the target is one of the key conditions that can affect the deposition of GSR. Without consideration of this important element in the shooting incident, a distance determination can be significantly inaccurate.

GSR is a primary element produced by all firearms. The presence, absence, distribution and/or density, and overall pattern shape created by the various forms of GSR are widely used as a means of determining the distance between a firearm and a target: human, animal, garment, or other inanimate object. All forensic ballistics laboratories have protocols for making distance determinations based upon the GSR in which a test is performed with the same firearm and the same ammunition as was used in the actual incident.

These forensic distance determinations have been performed with the firearm aimed in an orthogonal (perpendicular) orientation toward a cotton fabric target. To determine the distance, several shots are made at different distances into the fabric target until the distance is sufficiently great that no GSR reaches the target material. The resulting patterns and density of GSR particulate (burned, partially burned, and unburned gunpowder particles) on the target material are then compared to the pattern diameter and density of GSR on the clothing, skin, or other objects from the actual incident. When a pattern and/or density on the test target material is similar in diameter and density to the actual shooting case object, a distance determination can be made.

This research project involved the use of 9mm and .45 Automatic Colt® Pistol (ACP) handguns. Testing was performed using four angles of incidence: 0°, 30, 45, and 60 degrees. A total of 36 test shots were made. The GSR particles were identified and quantified using scientific image analysis software (ImageJ). Quantity of particles, density, and overall patterns were identified. Data were visualized and statistically analyzed by using R and GraphPad® Prism® (v 9. 4. 1) software. Analysis of Variance (ANOVA) followed by Dunnett's T3 multiple comparisons tests were performed to find statistically significant differences with their associated p-values.

When properly performed, this method can be used to accurately determine the approximate distance between a gun muzzle and a target. But there is a significant flaw in the process that this paper will address. Many actual, real-life shootings are done with some degree of angularity between the gun and the target. The angle at which the gun was fired toward the target will affect the amount and distribution of GSR. The actual difference in the amount of GSR and the resultant pattern has never before been quantified and examined. The research represented in this presentation demonstrates that there is a significant difference in the GSR patterns produced with angled shots.<sup>1-8</sup>

**B159 Interdigital Frequencies of Pattern Types and Their Arrangements as a Key to Palm Print Identification**

*Angela Tonietto\*, State Police of Federal District, Brasilia, Distrito Federal, Brazil; Jemima Santos, Griaule, Brasilia, Distrito Federal, Brazil*

---

**Learning Overview:** After attending this presentation, attendees will be informed about important features to be taken into consideration when providing a human identification based on a palm print fragment collected from a crime scene. Our data on pattern frequencies, and their arrangements in the interdigital intervals and distal bases of palm prints, bring a useful complementary element for human identification in the comparative process and in research in automated systems.

**Impact Statement:** This presentation will impact the forensic science community by bringing a different approach to the identification of a palm print fragment. In addition to the elements commonly considered for identification, such as minutiae and deltas, when the pattern frequencies and their arrangements in the interdigital intervals and distal bases are also analyzed, the global value of the analyzed characteristics is increased, which helps the examiner's decision-making when determining an identification. This different approach is particularly important in the forensic field, where the fragments analyzed in most of the cases are of poor quality, since they are left at crime scenes in conditions that are nothing like the ideal palm print collection conditions. Also, along with its usefulness in the comparative process and research, the results of this study can be helpful for technology companies to make available search filters in automated systems that consider the pattern arrangement frequencies.

Palm prints are important evidence that contribute to identifying who was present at a crime scene. Knowing the line systems that form the palm print ridges, as well as the patterns that occur in the palm print regions, is fundamental for human identification purposes. Thus, the aim of this study was to provide the frequency of these patterns—independently and in combination—in the interdigital intervals and distal bases of palm prints, helping the examiner to properly orient the palm print, determine the hand (left or right), as well as increase their certainty in providing an identification. The data can also contribute to automated systems by providing frequency values to be used as search filters.

In this study, 4,000 palmprints, 2,000 from the right hand and 2,000 from the left hand, were analyzed regarding the pattern types at the interdigital intervals and distal bases: loop, whorl, composite and open field in the intervals, and delta, plain arch, and tented arch in the bases. Pattern frequencies of each interval and base and its arrangements were calculated through *R* software. Statistical comparisons were made between right and left hands in two steps. First, differences between right and left hands from different people (3,054 individuals) were calculated with chi-squared and Fisher's exact tests. Subsequently, the differences between both hands of 473 individuals were analyzed using the McNemar's test. The results obtained show that the number of deltas varies according to the pattern types that occur. Among all the pattern arrangements mathematically possible, about 13% were observed in the studied population. Few of the possible pattern arrangements are observed in both hands. Many of the possible pattern arrangements observed occur in less than ten palm prints regarding each hand. When left and right hands were compared, it was found that there is an association between side and pattern type at all the intervals and at the base 4 for the independent data. That is, the pattern observed at all the intervals and the base 4 is associated with whether the hand is the left or the right one. For paired data, where individuals had both hands analyzed, there is no association between the side and the incident pattern at interval 2 and the base 1. However, at base 4, there is an association between the side and the pattern.

In conclusion, when a palm print fragment has low quality and/or few minutiae, the study of the pattern occurrence at each interdigital interval and distal base along with their arrangements increases the value of the global characteristics observed. Taken together, all these aspects contribute to the examiner's decision-making when determining an identification.

**B160 Toward Consistency in Latent Print Examiners' Naming Conventions and Minutiae Frequency Estimations**

*Adele Quigley-McBride\*, Simon Fraser University, Burnaby, BC, Canada; Heidi Eldridge\*, The George Washington University, Washington, DC; Brett Gardner\*, University of Virginia, Charlottesville, VA*

---

**Learning Overview:** After attending this presentation, attendees will be aware of new data suggesting that fingerprint analysts vary in how they refer to fingerprint features (minutiae) and how often they estimate the frequency with which those minutiae appear in fingerprints. Attendees will also gain a better understanding of the extent to which fingerprint analysts report using these subjective estimates in their analyses. Finally, attendees will be able to identify and discuss potential sources of inconsistency in fingerprint analyses and conclusions.

**Impact Statement:** This presentation will impact the forensic science community by providing fingerprint analysts with a consensus view of naming conventions, perceived frequency of minutia types, and the use of subjective judgments about minutiae frequency in “value/no value” judgments and comparisons. This knowledge will allow for immediate reductions in variability between analysts and will also form the basis for future work comparing real-world minutiae counts to fingerprint analysts’ perceptions of how frequent those minutiae are.

Forensic science literature has increasingly emphasized the importance of consistency and reliability across forensic disciplines in recent years. Latent fingerprint comparison, in particular, has received a high level of scrutiny as research on some of the core aspects of these analyses remains lacking. Assessing the appearance and placement of fingerprint minutiae (the shapes and features within friction ridge patterns) is central to the task of a fingerprint analyst, as is an analyst’s ability to communicate their analytic process and the reasons for their expert opinion. Although we know that some minutiae are rarer than others, there are no large-scale studies assessing analysts’ perceptions of, or actual, minutiae frequency.<sup>1</sup> People generally struggle with the task of estimating how often events or features occur, and analysts’ estimates of the frequency with which different friction ridge patterns occur (loops, whorls, and arches) are often inconsistent with objective data.<sup>2,3</sup> Thus, we can expect that analyst’s estimates will vary and that analysts’ beliefs about minutiae rareness or commonness will affect how much weight is given to each feature during analyses.<sup>4</sup> Compounding these inconsistencies is a lack of conformity in the labels used for minutiae (e.g., the same circular shape is sometimes called a lake, an enclosure, or an eye), which adds to the variation seen in fingerprint analyses and reporting.

To assess analysts’ perceptions of minutiae frequency and their naming conventions, we collected data in two online studies from a diverse sample of fingerprint analysts ( $n = 132$  in Study 1, and  $n = 94$  in Study 2). Most participants performed casework weekly in the United States with an average of 13 years of experience. We surveyed examiners at two time points, one month apart, with 75% ( $n = 99$ ) completing both time points in Study 1 and 60% ( $n = 56$ ) completing both in Study 2.

Study 1 revealed three important types of variation in fingerprint analysts’ responses. First, there was considerable variation in the labels used to describe the same friction ridge shapes. Second, analysts often agreed on the relative rarity of minutia types (rank order data), but their estimates of the percentage of fingerprints in which they could expect to see examples of different minutia types varied substantially. Finally, analysts’ estimates varied across time, especially for rare minutiae when they had recently encountered an example in their casework.

Analysts also reported how they used minutiae frequency in their “value/no value” judgments and comparison decisions. Most analysts (84%) reported using their perceptions of minutiae frequency when making “value/no value” judgments and when evaluating the level of correspondence between two fingerprints during a comparison analysis (89%).

Participants in Study 2 were asked similar questions, but were also asked to indicate whether particular minutia types were more common in the center or periphery of fingerprints, or in particular friction ridge pattern types (i.e., loop, whorl, or arch). There was even less consensus observed in these judgments compared with Study 1, and most analysts changed at least some of their responses one month later in the second survey.

Taken together, these data provide new insights into sources of variation in fingerprint analysis and suggest a need for standardization in minutiae naming conventions. Analysts’ frequency perceptions varied substantially, both between analysts and for the same analyst across time. Thus, the weight that analysts give to different minutia types is likely to vary between analysts and at different times for the same analyst. How these subjective estimates compare to estimates calculated from actual counts will be assessed in future research. These studies can also serve as a model to other forensic disciplines seeking to increase consistency and reliability.

**Learning Overview:** This presentation will depict three very different cases of hanged subjects to demonstrate the importance of correctly interpreting the data collected on the crime scene and the subsequent postmortem examination. After attending this presentation, attendees will better understand the importance of an accurate analysis of the location and crime scene in order to not be deceived.

**Impact Statement:** This presentation will impact the forensic science community by demonstrating that things are not always what they seem. Indeed, the forensic pathologist should pay more attention to analyzing the scene and medical history of patients and promote collaboration with other agencies involved at the crime scene.

Hanging is one of the most common methods of suicide and represents the most important of mechanical asphyxia, in which the airway is obstructed by compression of the neck caused by a taut ligature or by the weight of the victim or part of the victim. Hanging may be complete or incomplete (depending on whether the body is fully suspended), typical or atypical (depending on the position of the knot), interrupted, simulated, etc. Consequently, ligature marks on the neck may have typical features that are usually helpful in distinguishing hanging from ligature strangulation. Other elements that can be used to support the hypothesis of the suicidal intent of the deceased are circumstantial data and findings at the death scene. However, in some cases, the forensic examination could reveal certain elements or confounding features that may suggest the involvement of a third party. This study presents three cases of hanged persons in different and unusual situations.

The first is the case of a 63-year-old man who was found in the backyard of his downstairs neighbor with a broken cord around his neck and a considerable wound on his head. Outside the house, on two different balconies, two pieces of rope were found, similar to the one found around the man's neck. Inside the house of the deceased, more disturbing elements were discovered, including copious bloodstains on the walls and floor.

The second case is the one of a 50-year-old man found hanging from a tree. The strange thing in this case is that the man was found almost decapitated, with only a fine flap of skin connecting his head to the rest of his body. All other structures, such as vessels, respiratory tract, and even vertebrae, appeared to have been crushed, and a blood pool was found under his feet.

The last one is the case of a 41-year-old man who was also found hanging from a tree near his house, several days after his disappearance. Curiously, a knife was recovered in his hand as if he was defending himself from a possible attacker.

In all cases, only a meticulous evaluation of the scene, the remote medical history, and the results of the ensuing investigations allowed them to be definitively classified as suicidal events, unequivocally excluding the hypothesis of third-party intervention. Therefore, the aim of this work is to highlight the importance of the correct analysis of the case, a combination of precise interpretation of circumstantial and autoptic data in the presence of ambiguous circumstances, to make a differential diagnosis between suicide by hanging and suspension after a homicide.

---

**Learning Overview:** The objective of this presentation is to demonstrate the value of existing literature in determining a production process and understanding the pathophysiology of lesion formation. Through this case of cervical wounds, we aim to illustrate that certain types of lesions can be easily confused. However, by considering the full range of injuries (cutaneous, subcutaneous, vascular, and bone), the mechanism becomes more apparent.

**Impact Statement:** This presentation will impact the forensic science community by serving as a reminder of the importance of considering both cutaneous and deep lesions as a whole in order to avoid confusion between different mechanisms of injuries.

A 24-year-old woman was brought to the emergency department following dog bites according to a witness at the scene. She quickly presented a cardiorespiratory arrest and, despite adapted treatment, passed away 12 hours later. Autopsy revealed 21 deep cervical wounds, with unclear bilateral carotid lesions, dilaceration of neck muscle masses, a laryngeal wound, and avulsion of the right lobe of the thyroid. Some of these wounds were buttonhole-shaped, with sharp edges and a rat's tail appearance, suggesting the use of a bladed weapon. In addition to these wounds, there were multiple circumferential superficial wounds in the cervical region, blunt facial trauma with no associated fracture, and ecchymosis on the internal face of the left arm. It was concluded that the cause of death was asphyxia and hemorrhagic syndrome. Considering all the lesions, the medical examiner suggested the intervention of a third person using a sharp object.

The investigation took a drastic turn following the coroner's findings, leading to the arrest and detention of the witness on charges of culpable homicide. A study of the medical records confirmed the presence of dissection of both carotid arteries, without vascular sectioning. Dissection of the left vertebral artery was also identified. Fractures of the cervical transverse processes had also been identified on a Computed Tomography (CT) scan performed in the emergency department.

This second forensic expert supported the conclusion that the cervical lesions were consistent with dog bites, particularly due to the dilacerated appearance of the muscle masses and the absence of clear tissue continuity. Furthermore, the association of vascular dissections and fractures of the cervical transverse processes can be attributed to hyper-extension and/or compression of the cervical spine<sup>1-6</sup>.

All these types of lesions have already been described in the scientific literature in cases of dog attacks. Moreover, several cases have reported the presence of wounds resembling knife wounds following dog bites<sup>7,8</sup>. Death was described as secondary to cerebral anoxia resulting from multiple dissections of the neck vessels and asphyxia related to the laryngeal wound, aggravated by blood spoliation. All the observed lesions were determined to be consistent with dog bites, leading to the release of the defendant.

**B163 Odor Contamination in Explosive Canine Training Aids and Steps Toward Contaminant Mitigation Through Off-Gassing**

*Katherine Dias Castro\*, Florida International University, Miami, FL; Lauryn DeGreeff, Florida International University, Miami, FL; Tyler Roberts, West Indies Oil Company, St John's, Saint John, Antigua and Barbuda; Reagan M. Bridges, Florida International University, Littleton, CO; Monica Lopez, Florida International University, Miami, FL; Jordi Cruz Sanchez, Escola Universitària Salesiana de Sarrià, Barcelona, Spain*

---

**Learning Overview:** After attending this presentation, attendees will understand how easily training aid contamination can occur during regular training and how to mitigate contamination through the use of off-gassing.

**Impact Statement:** The findings of this research will impact the forensic science community by directly aiding in improving explosives detection by allowing canine teams to be aware of how contaminants enter the headspace of their training aids as well as provide recommendations as to how to mitigate suspected contamination. The cleaner training material will allow for high proficiency in canines for lower false or missed alerts, heightening national security and improving current methods used by defense agencies. This research will also provide insight for standards boards to create standards for training aid handling, maintenance, and validation.

This presentation will inform attendees on the necessity of maintaining the integrity of canine training aids as they are prone to contamination, provide one technique for mitigating contamination, and understand how the headspace of training material can change in as fast as six months. This impacts the forensic community as it emphasizes the need for standards to ensure that training material for the sensitive biosensors are of high quality to yield high-quality detectors.

Explosives have become a major threat to those serving abroad or even to the civilian public. To ensure national security, it is essential to detect explosive threats before a detonation event. Canines have transformed explosive detection, becoming some of the most sensitive and reliable sensors available. To maintain the desired detection proficiency levels required by the American National Standards Institute/Academy Standards Board (ANSI/ASB) Standard 092 of a false alert rate of less than 10% and discrimination of non-target odors, it is important to train canines on materials with odors representative of true, clean explosives. Studies have found that originally certified canines have shown up to 40% false detection rates in non-testing scenarios, suggesting inconsistencies in training maintenance due to unsatisfactory training material.<sup>1</sup> With contaminants altering the odor profiles of explosive training aids, it is necessary to understand how unwanted odorants adsorb to and desorb from explosive training materials to mitigate contamination.

This study provides insight into how contaminants alter the headspace of training aids over time and how to minimize the detrimental effects of contaminated material. This was done in three experiments escalating in complexity. The first was understanding contamination in a laboratory environment and tracking contamination over a 2-week period to understand when contamination reaches its maximum. This was followed by allowing off-gassing of contaminated materials up to 24 hours to determine how long it takes to remove contaminants from the headspace of training material before storage. The next experiment used training aid surrogates to be handled and stored by canine teams in the same manner as their actual training aids. Surrogates were analyzed bimonthly to understand which environmental contaminants are easily adsorbed onto materials as well as which training materials are most prone to contamination and therefore must be monitored more frequently for presence of non-target odors.

The training aids in question were sampled by use of Headspace/Solid Phase Microextraction (HS/SPME) and their headspace profiles were analyzed by Gas Chromatography/Mass Spectrometry (GC/MS). The use of chemometrics during data analysis allowed for further conclusions regarding types of explosive materials and training aid substances that are most prone to contamination and would benefit most from contamination mitigation techniques. It was found that contamination of the explosives was less handler-dependent and systematic over time, while contamination of substrates was both handler-dependent and the dependent of the sorbent property of the material. It was also determined that some sorbent explosive materials will desorb quickly while others that may not initially adsorb large amounts of odor struggle with desorption of contaminants, affecting the contamination mitigation process.

All these experiments allowed for conclusions that can be directly presented to canine handlers and standards boards to form recommendations regarding training aid maintenance and validation. Results will also apply to those at defense agencies to modify current methods of training aid handling to uphold the integrity of the training material and canine detection proficiency to maintain the current expectations of national security.

**B164 An Improved Analysis of Nylon Microplastic Trace Evidence Through Enhanced Signal-to-Noise Ratio in Room-Temperature Fluorescence Spectroscopy**

Noah Michael Froelich\*, University of Central Florida, Orlando, FL; Andres D. Campiglia, University of Central Florida, Orlando, FL

---

**Learning Overview:** The goal of this presentation is to teach attendees the advantages room-temperature fluorescence spectroscopy provides in the analysis of nylon trace evidence, as well as the how to maximize the potential of the technique for small (<500µm) samples.

**Impact Statement:** This presentation will impact the forensic science community by demonstrating how room-temperature fluorescence spectroscopy can provide more information about nylon evidence samples than other non-destructive techniques alone. This additional information is important because nylon is well-suited for 3D printing of weapons and keys, and the increasing availability of 3D printing technology is also increasing the risk of 3D printing for illegal activities. The ability to link trace evidence to its source is always impactful, and fluorescence spectroscopy can be used to make that link even stronger.

As 3D-printing technology continues to advance and become more accessible, forensic scientists will need more reliable and effective techniques for the analysis of its associated trace evidence. The analysis of microplastic trace evidence is often done non-destructively through spectroscopic techniques, especially Fourier-Transform Infrared Spectroscopy (FTIR) and Raman spectroscopy. Destructive techniques, including Pyrolysis-Gas Chromatography/Mass Spectrometry (Py-GC/MS) and Direct Analysis Mass Spectrometry (DART®), are occasionally used for analyzing microplastics; however, destructive techniques are commonly discouraged in forensic settings, and especially in trace evidence analysis, due to the desire to preserve limited evidence.

Room-temperature fluorescence spectroscopy, a non-destructive technique, has recently been shown to successfully analyze nylon microplastics through the use of a fiber-optic probe connected to a commercial spectrofluorometer.<sup>1</sup> Nylons, or polyamides, are a class of durable polymers that can be used to 3D print objects like weapons and keys. Though the chemical structure of nylon is not expected to be fluorescent, the synthesis and processing of nylons imparts fluorescent impurities in the backbone of the polymer that create unique fluorescence spectra, and these spectra can allow for discrimination beyond general polymer class (e.g., Nylon) or monomer subclass (e.g., Nylon 6/6).<sup>2,3</sup> However, because the fluorescence arises from impurities and not the bulk polymer itself, the recorded signal is relatively low, particularly when analyzing small trace evidence samples (less than 500µm).

Herein, we present improvements to the room-temperature fluorescence analysis of nylon microplastics that have increased the signal-to-noise ratio by an order of magnitude. Utilizing a neutral-density filter as a sample substrate and orienting the fiber-optic probe at an angle to the benchtop, microplastics from Nylon 12 and Nylon 6/6 as small as 125µm were routinely and successfully analyzed. The experimental procedure proposed here provides forensic scientists with the necessary tools to confidently analyze nylon trace evidence, be it from 3D-printed materials or otherwise, and make compelling arguments as to whether that evidence came from a specific source.

**B165 An Evaluation of a Comprehensive Raman Spectral Library for the Identification of Soil Minerals**

*Jasmine Kaur\*, University of New Haven, West Haven, CT; Chase Notari, Connecticut Office of the Chief Medical Examiner, Stamford, CT; Brooke W. Kammrath, University of New Haven, West Haven, CT*

---

**Learning Overview:** After attending this presentation, attendees will understand the value of a comprehensive digital Raman spectral library for the identification of soil minerals.

**Impact Statement:** This presentation will impact the forensic science community by detailing the challenges and steps required for developing, testing, and utilizing a digital Raman spectral library for the identification of minerals.

Raman spectroscopy is a valuable tool for elucidating the chemical structure and more of an unknown sample. A comprehensive collection of data, or library, is required for the proper identification of any material. Searchable spectral libraries have demonstrated value for the identification of a plethora of different forensic samples, such as drugs, organic pigments, and polymers. Mineral analysis presents another opportunity where a comprehensive searchable Raman spectral library could aid in the identification of samples for both geological and forensic purposes. However, while there have been several collections of mineral spectra created, there remains to be a comprehensive searchable Raman spectral library. Software programs like KnowItAll currently only have a few hundred mineral spectra, while other online databases like RRUFF<sup>2</sup> allow one to view thousands of varying mineral spectra, but do not have a capability to compare an unknown sample to the library.<sup>1</sup> This demonstrates the need for a comprehensive searchable mineral database to provide for their automated identification.

The purpose of this research is to develop and evaluate a searchable mineral library of Raman spectra to assist in identification of the minerals found in unknown soil samples through our ongoing research with Particle-Correlated Raman Spectroscopy (PCRS). PCRS is an analytical technique that combines automated image analysis with Raman spectroscopy to provide morphological measurements and chemical identification of discrete particles within a complex mixture. Reliable and automated Raman spectral identification is critical for successful PCRS; however, it must also be rapid (no more than a few seconds for Raman analysis) because of the large number of particles to be targeted for analysis. Another challenge for mineral identification by Raman spectroscopy is the natural variations within a mineral variety that can cause spectral differences. Factors such as polymorphism and twinning can cause minerals of the same composition to have different spectral peaks from Raman spectroscopy. Additionally, the fluorescent properties of some minerals can cause effects on the spectra that overtake the weaker Raman scattering effect, making it more challenging to identify some minerals. Thus, it is important to evaluate the capabilities of a purpose-built, searchable, and comprehensive Raman spectral library of minerals.

The capabilities for the automated spectral library identification of mineral grains in soil were evaluated using a known set of 60 comminuted soil minerals. The RRUFF<sup>2</sup> database was imported into KnowItAll to create the comprehensive mineral library, and the ability to correctly identify the 60 comminuted minerals was evaluated using two laser excitation wavelengths (785nm and 532nm). When comparing the automated mineral library correct identification rate before and after the addition of the RRUFF<sup>2</sup> database, as expected, there was a noted increase in correct identifications of different minerals and a greater hit quality index regarding the strength of identification. With the addition of the RRUFF<sup>2</sup> mineral database to KnowItAll's searchable library, correct identifications went from 15 of 60 (25%) to 47 of 60 (78.3%) minerals. The ability of this Raman searchable library to identify more mineral spectra demonstrates the importance of having such a comprehensive library available for analysis of unknown samples. The results of this research have the potential to be applied to an overall mineral identification procedure that would be useful for both the forensic science and geology fields.

**B166 Pigment Identification in Solution-Dyed Fibers**

*Christopher S. Palenik\*, Microtrace LLC, Elgin, IL; Kelly Beckert, Microtrace LLC, Elgin, IL; Otyllia Abraham, Microtrace LLC, Elgin, IL; Ethan Groves, Microtrace LLC, Elgin, IL; Skip Palenik, Microtrace LLC, Elgin, IL*

---

**Learning Overview:** This presentation provides a primer on the microscopical recognition, classification, and identification of solution-dyed (i.e., pigment-colored) fibers. The goals of this presentation are intended to serve two main purposes: (1) to provide fundamental information about the pigment packages used to color solution-dyed fibers (e.g., the number and types of pigments used to color various polymers and brands of fiber); and (2) to provide a practical analytical approach to the study of solution-dyed fibers that can be integrated into existing trace evidence fiber comparison protocols.

**Impact Statement:** This presentation will impact the forensic science community by filling a knowledge gap regarding: (1) the recognition of solution-dyed fibers, (2) the characterization and identification of pigments used to color this class of fiber, and (3) the trends and significance related to solution-dyed fiber evidence.

Solution-dyed fibers are synthetic fibers colored during the manufacturing process by microscopic and submicroscopic solid pigment particles prior to extrusion. The use of pigments to color fibers provides improved weatherability and lightfastness over traditionally dyed fibers and represents an eco-friendly alternative method for producing colored fibers. As such, solution-dyed fibers have steadily gained market share and are being used in an increasing variety of polymers for an expanding range of applications (including trunk liners of vehicles as well as commercial and consumer carpeting). Despite their minute size, the visualization and identification of these fine pigment particles is accessible using robust methods that are already commonly employed (e.g., polarized light, fluorescence microscopy, and scanning electron microscopy/energy dispersive x-ray spectroscopy) or are becoming more common (e.g., Raman microspectroscopy) in trace evidence laboratories.

The act of recognizing that a fiber was colored by pigmentation represents a significant point of comparison in a fiber examination that is not presently included in many fiber examination protocols. This research aims to fill this knowledge gap by providing the results from an analytical approach that was developed and optimized to recognize and differentiate solution-dyed fibers from traditionally dyed fibers and has been expanded, in the present work, to characterize and identify the population of pigments in such fibers.

This research is based on the study of a population of 225 fibers selected from our internally developed, curated fiber reference collection consisting of thousands of solution-dyed fibers. The selected fibers were chosen to represent a range of manufacturers that span a variety of commercial applications, colors, and fiber types (e.g., polyolefin, nylon, polyester, rayon) selected to reflect market trends as well as the sources of fibers that are anticipated to be encountered as trace evidence. Building from our initial results, which provided a method to recognize solution-dyed fibers, this presentation is focused on expanding the approach to the process of identifying the range of pigments used in these fibers through a combination of chemical and elemental analyses.<sup>1</sup>

The identification process presented here explores several sample preparation methods and draws from prior microscopical examinations to direct analyses by Raman microspectroscopy (532 and 785nm lasers). Both “bulk” fiber analyses and particle-focused, confocal Raman measurements on cross sections have been explored to determine the optimal approach for identifying the suite of different pigments that are found in a given fiber. The identification is also supported by elemental analyses conducted by energy dispersive X-ray spectroscopy analyses of the fibers (longitudinal mounts) conducted in the scanning electron microscope. Ultimately, the approach as well as the tabulated identification data (i.e., the name of a pigment by its Color Index designation or chemical structure) provides new insight into the trends, and commonality (or rarity) of the pigments used to color fibers. The combination of this research is intended to provide examiners with a means by which these previously unexplored properties can be exploited in casework samples.

**Raman Microscopy; Fibers; Microscopy**

## B167 Polarized Light Microscopy of Vegetable Fibers

Walter Frederick Rowe\*, *The George Washington University, Woodbridge, VA*

**Learning Overview:** After attending this presentation, attendees will understand the role of polarized light observations in the microscopical examination of a variety of vegetable fibers that may be encountered in forensic science casework.

**Impact Statement:** This presentation will impact the forensic science community by providing data to aid in the microscopic identification of several vegetable fibers that are now part of the modern environment.

Vegetable fibers have been used since antiquity for textiles and cordage. These fibers derive from a variety of sources: there are seed fibers, bast fibers from the stems of plants, leaf fibers, fruit fibers and stalk fibers. Vegetable fibers may occur as trace evidence in criminal cases. In forensic science laboratories, these fibers are identified microscopically using brightfield and polarized light microscopy. Petraco and Kubik present an analytical procedure for the identification of vegetable fibers.<sup>1</sup> The fibers are viewed with transmitted light (brightfield illumination), between crossed polars with the fibers oriented for maximum birefringence, between crossed polars with the fibers oriented at extinction, and, finally, between crossed polars at extinction with a first order red accessory plate inserted. The last observation is the Herzog or red plate test used to distinguish bast fibers based on the S-twist or Z-twist orientation of the cellulose molecules in the fibers. These observations permit the microscopical identification of the most common vegetable fibers. Petraco and Kubik present data for a selection of common plant fibers: abaca (Manila hemp), sisal, cotton, flax, hemp, jute, ramie and kapok.<sup>1</sup> In recent years, many other plant fibers have come into use and may be encountered in forensic casework. Agave fibers are used in exfoliating wash clothes; coconut (coir) fibers are used for pet and plant bedding, upholstery stuffing, and floor mats; corn fibers are used in brooms; raffia fibers are used in floral arrangements; and wheat straw and barley straw are used for floral arrangements and water clarification.

Samples of agave, barley straw, coir, corn, raffia, and wheat straw were obtained from retail sources. Many of the fibers comprising the samples are composed of bundles of cells (called fiber ultimates). To free fiber ultimates, fibers were treated with a mixture of equal volumes of 6% hydrogen peroxide and glacial acetic acid at 100°C for eight hours.<sup>2</sup> Fiber cross-sections may be useful for identification.<sup>3</sup> Fiber cross-sections were prepared by embedding fibers in drops of hot glue (One World Technologies, Inc., Anderson, SC), then cutting sections free hand from the hardened glue using single-edge razor blades. The fibers, fiber ultimates, and the fiber cross-sections were mounted on microscope slides with PermMount® mounting medium. Two microscopes were used to examine the mounted samples: a stereomicroscope for reflected light and darkfield observations (AmScope, Irvine, CA) and a transmitted light polarizing microscope (AmScope, Irvine, CA). Photomicrographs were captured with an OMAC® 18-megapixel digital eyepiece camera (AmScope, Irvine, CA). The following photomicrographs were obtained for the fibers and fiber ultimates: (1) reflected light; (2) darkfield; (3) brightfield; (4) crossed polarizing filters (fibers oriented for maximum birefringence); (5) crossed polarizing filters (fibers oriented at extinction); and (6) crossed polarizing filters (fibers oriented at extinction with first order red plate inserted).

Photomicrographs were captured of the fiber cross-sections using the stereomicroscope using reflected light. The following results were observed for the fiber ultimates:

Fiber	Elongation	Estimated Retardation (nm)	Extinction	Herzog Test
Agave	+ve	200-800	Incomplete, lumen dark	Orange
Barley Straw	-ve	200	Incomplete	Blue
Coir	+ve	200	Undulose	Orange
Corn	+ve	200	Complete	Orange
Raffia	+ve	200-400	Complete, except at nodes	Orange
Wheat Straw	-ve	200	Incomplete	Blue

The most distinguishing features of the fibers were the colors and the fiber cross-sections. The fibers showed a number of colors: white (agave), tan (barley and wheat straw), light brown (corn and raffia), and dark brown (coir), reflecting the lignin retained in the fibers after processing. The cross-sections ranged from flattened ribbon (barley straw, raffia, and wheat straw) to flattened ovals (agave, coir, and corn).

**B168 The Application of Particle-Correlated Raman Spectroscopic Analysis of Soils to Mock Casework Scenarios**

*Samantha Gong\*, University of New Haven, Douglaston, NY; Brooke W. Kammrath, University of New Haven, West Haven, CT; Marisia A. Fikiet, University of New Haven, West Haven, CT; Peter R. De Forest, Forensic Consultants, Ardsley, NY*

---

**Learning Overview:** After attending this presentation, attendees will understand the comparative capabilities of Particle-Correlated Raman Spectroscopy (PCRS) for the analysis of soil minerals collected from mock evidence samples, including footwear and shovels.

**Impact Statement:** This presentation will impact the forensic community by providing attendees with an understanding of how PCRS can be applied to forensic soil analysis, through the lens of simulated casework of soil traces on footwear and shovels. This will draw a connection between instrumentation that is being explored academically and the potential for its integration for use in crime laboratories.

Soil is a continuous but complex mixture, reaching across geological bodies. It is primarily composed of minerals, organic matter, organisms, gases, and water. Although it is continuous, soil is distinctly variable and differentiable, based on aspects such as geographic location, seasonal factors, and human interference. In combination with its highly transferable nature, the complexity of soil composition makes it a valuable material for forensic trace evidence and object-to-scene association. The development of forensic soil analysis is currently focused on mineralogy, with the traditional tool for mineral identification being the Polarized Light Microscopy (PLM). One development in forensic mineralogy focuses on employing elemental analysis, most often using the Scanning Electron Microscopy equipped with Energy Dispersive X-ray spectroscopy (SEM/EDX), to simultaneously visualize and analyze mineral grains. Other methods, including several spectroscopies as well as X-Ray Diffraction (XRD), have also been explored for application to forensic soil analysis. One method with excellent potential for the interrogation of a range of forensically relevant samples is Raman spectroscopy.<sup>1</sup> In particular, Raman spectroscopy has a demonstrated history for use in the field of geology for mineral identification; thus, its application to the forensic analysis of soils is a logical extension.

PCRS is a novel analytical method that combines automated image analysis with Raman spectroscopy, thus providing both microscopic morphological and chemical information about a single sample non-destructively. PCRS provides both qualitative and quantitative information about a sample. When applied to soil minerals, this information includes their identification, microscopic morphological characteristics (e.g., circularity, elongation, brightness), and particle size distributions. This information is valuable for forensic soil comparisons, but more research is needed to understand the significance of an association of these properties given the complexities of transfer and persistence.

In this project, PCRS is used to analyze soil particles collected from simulated evidence samples. Shoes and shovels were used to collect mock evidence from three different geographical locations: an urban park, a suburban residential area, and a rural woodland area. Known soil samples were also collected from these locations to serve as reference samples for comparison under PCRS analysis. The mock-evidence items were prepared in a method detailed by Stoney et al. for the analysis of very small particles.<sup>2</sup> The collected adhering soil was then cleaned to isolate the mineral grains per the method described by Palenik.<sup>3</sup> The particles in the size range of 90nm–180nm in diameter were then dispersed onto a Raman-inactive microscope slide and analyzed using PCRS. The results were compared to the reference samples that were treated and analyzed with the same method. Source consistency could then be determined using a set of match criteria that includes mineral identity, particle morphology, and composition percentage.

Analysis of the soil samples showed that it was possible to determine the source of soil collected from mock evidence by using PCRS, when reference samples from suspected sources are available for appropriate comparison.

Maxwell*, University of New Haven, Hebron, CT; *Brooke W. Kammrath*, University of New Haven, West Haven, CT

---

**Learning Overview:** After attending this presentation, attendees will understand the advantages and limitations of the application of PCRS to the forensic analysis of soil minerals.

**Impact Statement:** This presentation will impact the forensic science community by critically evaluating the capabilities of PCRS for the analysis of soil minerals through a direct comparison of results obtained from traditional methods.

This study evaluated the capabilities and limitations of PCRS for the analysis of soil samples. PCRS is an automated, integrated technique that combines image analysis with Raman spectroscopy to provide morphological properties and chemical information from a mixture of discrete particles, such as the population of mineral grains in a soil sample. Considering how valuable soil traces can be in providing linkages in a case, along with the long-stated criticisms of forensic soil analysis (e.g., subjective, time consuming, and labor intensive), there is a need for an automated system that provides an efficient, objective, and statistically comparable approach to the interrogation of soil samples. PCRS has the ability to provide information regarding the particle size distribution, grain morphology, and mineral identification, which permit samples to be compared. To develop PCRS for inclusion in a forensic soil workflow, the limitations and advantages of the method (e.g., dispersion, sample imaging and analysis, Raman spectroscopic analysis and interpretation) need to be evaluated, which has been the goal of the research that will be presented.

For the evaluation of PCRS as a tool to analyze soil minerals, single-blind PCRS was completed on four unknown, four-component mixtures of comminuted minerals and an additional ten disparate soil samples collected from the northeast United States. The 90–180µm fraction of minerals were obtained from each soil sample after washing and sieving using traditional methods.<sup>1</sup> Next, a computer-controlled vacuum-type powder dispersion system (operating at -20Pa and with a high-sample volume) was used to create a uniform strew distribution of microscopic mineral particles with good spatial separation. Following the dispersion of particles on a glass slide, the sample was imaged, and an image analysis routine was applied to isolate individual particles and obtain a range of morphological properties (e.g., circularity, elongation, area, translucency). The individual particles comprising a sample were each probed by Raman microspectroscopy using two different lasers excitations (532nm and 785nm). The resulting Raman spectra were identified via spectral library searching of the RRUFF<sup>2</sup> mineral database that contains close to 10,000 different Raman mineral spectra.<sup>2</sup> The morphological data associated with the particles in each mineral class was then used to generate size and shape distributions, delivering mineral-specific morphological information. Mineral size and morphological distributions for each soil sample were compared using multivariate statistical methods to evaluate their discriminating potential. The results of the PCRS method were then compared to those obtained using traditional methods for mineral identification, including polarized light microscopy and scanning electron microscopy equipped with energy dispersive X-ray spectroscopy. Similarities and distinctions of the results between these approaches have been evaluated to explore the utility of the present PCRS method for use in forensic soil casework.

**B170 The Differentiation of Architectural Paint by Sheen Using Reflectance Spectroscopy**

*Alethea Nicole Morris\*, Cedar Crest College, Easton, PA; Lawrence Quarino, Cedar Crest College, Allentown, Pennsylvania*

---

**Learning Overview:** After attending this presentation, attendees will better understand a new method of differentiating architectural paint in trace evidence examination based on a determination of paint sheen using primarily reflectance spectroscopy.

**Impact Statement:** This presentation will impact the forensic science community by helping to increase the evidentiary value of architectural paint in an objective manner.

Architectural paint is a form of transfer evidence that can be found in cases involving contact between a coated surface and another surface. Common cases in which this evidence type is found are breaking and entering, assault, homicides, and vandalism. When paint evidence is found in these situations, physical fit, chemical analysis, and physical observations are often made. Parameters for comparative analysis include color, layer structure, presence of contaminants, surface features, type of pigment, resinous vehicle, and other additives. These observations are performed using light and polarized microscopy as well as other common instrumental techniques such as infrared microspectroscopy, Raman microspectroscopy, and pyrolysis-gas chromatography/mass spectrometry.

Architectural paint is often categorized by a type of sheen such as flat, semi-gloss, gloss, eggshell, and satin. In this study, sheen of architectural paint chips was determined by measuring the reflectance of light from the paint surface using reflectance spectroscopy. This could further help differentiate paint evidence and may be helpful in distinguishing paint samples that are analytically similar using chemical, microscopic, or spectroscopic methods.

Using an Ocean Optics® reflectance probe and spectrophotometer, percent reflectance measurements were recorded from 350–800nm on dried samples of paint obtained commercially at an incident angle of 45-degrees covering an area approximately 36.79mm<sup>2</sup>. Principal component to linear discriminant analysis was performed on this spectral data using RStudio.

A total of 50 white paint samples of one product type from a single manufacturer (ten samples for each of the five sheens tested) were examined by this method. Resulting linear discriminant plots showed that the five tested sheens (gloss, semigloss, satin, eggshell, and flat) were clearly separated when using between three to five principal components, indicating that paint within a product type of a manufacturer can be differentiated by sheen in this manner. Another 50 white samples from the same manufacturer, but from different products, were observed in this manner, and the result showed that sheens could still be differentiated from each other. Finally, 40 different pigmented samples from a second manufacturer were tested, and it was determined that color changes the resulting reflectance spectra necessitating that comparisons need to be made with similar colors. In total, 140 samples were analyzed, and from these results it can be concluded that when the manufacturer and the product type are identified through chemical and spectroscopic methods, the sheen can also be accurately determined when samples have similar pigmentation.

As was shown in this study, sheen was often the only distinguishing characteristic between paints within a product line and between manufacturers when Raman and infrared microspectroscopy yielded similar spectra. As a result, architectural and maintenance paints can be further differentiated by sheen, giving more evidentiary power to this type of physical evidence.

**B171 The NIST Footwear Impression Comparison System**

*Steven Lund\*, National Institute of Standards and Technology, Gaithersburg, MD; Sourabh Yelluru, National Institute of Standards and Technology, Gaithersburg, MD; Adam Pintar, National Institute of Standards and Technology, Gaithersburg, MD; Hariharan Iyer, National Institute of Standards and Technology, Gaithersburg, MD*

---

**Learning Overview:** After attending this presentation, attendees will better understand how the National Institute of Standards and Technology (NIST) Footwear Impressions Comparison System (FICS) evaluates evidential strength scores for wear patterns and acquired characteristics. Attendees will also learn FICS performed similarly well to human examiners when distinguishing between mated and close-non-match comparisons from the recent black box study for footwear examiners.

**Impact Statement:** This presentation will impact the forensic science community by informing attendees that the NIST FICS has been developed to provide algorithmic support to examiner assessments of evidential strength related to wear patterns and acquired characteristics (often called RACS). Its performance on comparisons from the recent black box study for footwear examiners demonstrates that FICS achieved a critical milestone in supporting examiner conclusions with quantitative algorithms.

In particular, FICS was built to discriminate between mated comparisons (i.e., two impressions from the same shoe) and close-non-match comparisons (i.e., two impressions from different shoes of the same make, model, size, and side). This presentation will overview the end-to-end FICS comparison process, including manual markup, alignment, and evaluation of similarity metrics for comparing wear characteristics and acquired characteristics (often referred to as RACs). We will summarize results from applying FICS to comparisons in the recent black box study for footwear examiners.<sup>1</sup> Two key aspects of this presentation are that FICS's performance is assessed using comparisons resembling casework, and the results can be compared directly with the performance of (anonymous) examiners who evaluated those same comparisons while participating in the black box study.

To apply FICS, a user annotates which image subregions contain information regarding the outsole pattern of interest (called the region of interest) and indicates the resolution for each impression image. Additionally, RACs are marked in the test impression. Test impressions are initially aligned to questioned impressions using manually selected anchor points, and the alignment is refined using numerical optimization. Following alignment, similarities used for assessing correspondence of wear characteristics are computed across a grid of overlapping tiles.

FICS then uses a blind lineup approach to convert wear similarity metrics into a score reflecting evidential strength. That is, each questioned impression is compared not only to a test impression from the Shoe Of Interest (SOI) but also to test impressions from other shoes of the same make, model, and size as the SOI. For each tile location, the maximum similarity score between the questioned impression and any of the test impressions in the lineup serves as an automated quality measure for the corresponding region of the questioned impression. Each tile also receives a score for evidential strength based on the extent to which the similarity for the SOI stands above the similarities obtained for the other shoes in the lineup (i.e., how strongly pattern information in the questioned impression tile picks the SOI out from a crowd of similar shoes). The evidential strength scores across tiles are combined using a weighted average that considers the tile quality score and how much of the tile falls within the region of interest.

For acquired characteristics, FICS performs local alignment and similarity evaluation for each RAC marked in the test impression. A RAC marked in a given test impression is compared with the corresponding region in the questioned impression as well as the corresponding regions in the other test impressions in the lineup. A score for the RAC's evidential strength is assigned based on the extent to which the RAC's similarity with the questioned impression stands out among similarities obtained when comparing the RAC to test impressions from other shoes in the lineup (i.e., how strongly a RAC pattern in the test impression from the SOI points to the questioned impression among a crowd of shoes similar to the SOI). Evidential strength scores for RACs and wear patterns are combined to produce a final evidential strength score.

Using this approach, the FICS system discriminated between mated and close-non-match comparisons in the Federal Bureau of Investigation (FBI) black box study with similar efficacy as participating footwear examiners. To our knowledge, this represents the first direct comparison between examiner and algorithmic assessments of evidential strength for footwear impression evidence. In total, the FICS results illustrate a promising pathway to supporting examiner conclusions with quantitative algorithms.

**B172 An Investigation of Extraction Protocols for the Analysis and Quantitation of Cannabinoids in Gummy Matrices Using Liquid Chromatography and Photodiode Array/Ultraviolet Detection**

*Haley Jensen\*, The George Washington University, Washington, DC; Aaron Urbas, National Institute of Standards and Technology, Gaithersburg, MD; Walter B. Wilson, National Institute of Standard and Technology, Gaithersbrug, MD; Ira Saul Lurie, The George Washington University, Washington, DC*

---

**Learning Overview:** After attending this presentation, attendees will understand current methodologies that utilize Quick, Easy, Cheap, Effective, Rugged, and Safe (QuEChERS), other enzymatic techniques, and non-enzymatic methods for the extraction of cannabinoids within seized and purchased cannabis edibles. In addition, this presentation will discuss the use of Liquid Chromatography-Photodiode Array/Ultraviolet (LC-PDA/UV) detection for the quantitation of cannabinoids in gummy matrices.

**Impact Statement:** This presentation will impact the forensic science community by providing cannabinoid extraction method comparisons in addition to quantitative results as they relate to product labeling. This information can be used to improve upon the extraction methods currently used within the field and provide important data as to the true cannabinoid content of edibles.

The passing of the Farm Bill (2018) resulted in a major change to the legal status of cannabis, reclassifying hemp and removing it from the Controlled Substances Act (CSA).<sup>1</sup> This bill differentiates hemp and marijuana from one another based on the amount of Tetrahydrocannabinol (THC) present, stating that to be classified as hemp, there must be no more than 0.3% THC by dry weight present. Because of this new distinction, labs are now faced with the new issue of having to determine whether a seized sample is marijuana or hemp. In this vein, low THC and relatively high Cannabidiol (CBD) are indicative of hemp. This project seeks to compare and contrast different extraction methods that could be used for the quantification of cannabinoids to help overcome this differentiation problem in complex matrices.

In this study, numerous extraction methods were evaluated on various gummy samples to examine cannabinoid recovery. A modified LC-PDA method previously developed was used to screen each sample for 11 cannabinoids.<sup>2</sup> The modification (an extended purge time) was necessary to reduce carryover of other matrix components between samples. Extraction methods were compared to one another across different cannabis-containing gummies and across a suite of non-cannabis gummy samples spiked with known concentrations of cannabinoids to assess recovery, repeatability, and to look for potential interferences.

Sample dissociation methods investigated included enzyme digestion (alpha-amylase), cryo-grinding, and agitation/shaking with and without heating. Dissolution was generally done in an aqueous solution, with the optional addition of base (ammonium hydroxide), followed by the addition of acetonitrile, methanol, or isopropanol to extract cannabinoids. Liquid-Liquid Extraction (LLE) via the QuEChERS method was investigated for acetonitrile extractions. At the time of writing, an amylase digestion followed by addition of acetonitrile and a QuEChERS extraction performed the best across all sample types and studies for cannabinoids analyzed. This extraction method had percent Relative Standard Deviations (RSDs) that typically ranged from 2–10%. Preliminary results showed good recoveries from spiked samples and consistency with label claims on a small number of commercial samples. In comparison, other extraction methods yielded lower recoveries or exhibited issues during the processing of some samples (e.g., problems filtering). Additional studies will be conducted with gummies made from scratch and spiked with known cannabinoid concentrations to quantitatively assess recovery efficiencies in realistic samples. Method comparisons and the results of these studies will be presented.

## B173 The Development of a $\Delta$ 9-THC Colorimetric Breathalyzer Using 3D Printing Manufacture

Wagner Pacheco\*, Virginia Commonwealth University, Richmond, VA; Igor Coreixas, Universidade Federal Fluminense, Rio de Janeiro, Brazil; Rafael Dornellas, Universidade Federal Fluminense, Rio de Janeiro, Brazil; Savannah Allinson, Virginia Commonwealth University, Richmond, VA; Shakyrh Golden, Virginia Commonwealth University, Richmond, VA; Justin L. Poklis, Virginia Commonwealth University, Richmond, VA; Emanuele Alves, Virginia Commonwealth University, Richmond, VA

**Learning Overview:** This presentation will demonstrate the development of a  $\Delta$ 9-Tetrahydrocannabinol ( $\Delta$ 9-THC) breathalyzer for the detection of  $\Delta$ 9-THC recent use in site. After attending this presentation, attendees will better understand the mechanism of the colorimetric reaction applied to detect  $\Delta$ 9-THC, the application of this reaction to a support base that will work as a prototype for a colorimetric-based  $\Delta$ 9-THC breathalyzer.

**Impact Statement:** This presentation will impact the forensic science community by showing the development of the basic chemical foundations needed for the development of a portable colorimetric device for the in site detection of  $\Delta$ 9-THC in air exhaled for the early detection of driving under the influence of marijuana.

Today, the recreational use of marijuana is legal in 31 states and the District of Columbia. Several studies show that after the legalization, a 6.0% increase in injury crash rates and a 4.0% increase in fatal crash rates were observed.<sup>1</sup> Several factors must be considered to reduce driving under marijuana influence, such as preventive, educational, and punitive activities. In site detection of marijuana recent use is one of the possible measures to be adopted. Alcohol breathalyzers are a reality, and they help law enforcement to perform site evaluations quickly and easily. Thus, a  $\Delta$ 9-THC breathalyzer could bring similar advantages. Unfortunately, this is not yet a reality for  $\Delta$ 9-THC. The current devices are collection devices where the exhaled air is stored and must be further analyzed in a laboratory to allow  $\Delta$ 9-THC identification.<sup>2</sup>

In this project, the development of the  $\Delta$ 9-THC breathalyzer is based on the application of an additive manufacturing solid device made by 3D printing.<sup>3</sup> To create this support, a commercial Anycubic® 3D polymerizable resin was mixed with different Fast Blue dyes and were evaluated in the presence of several cannabinoids. The Fast Blue dye family is known to produce a colorimetric response in the presence of THC.<sup>5-7</sup> Several dyes from the Fast Blue family were studied (B, BB, and RR), in concentrations varying from 1.0 to 6%w/v. The results showed that the Fast Blue B in a concentration of 4% w/v in the solid resin is capable of reacting with 0.01mg with a linear response ranging from 0.01–0.50mg of  $\Delta$ 9-THC. Achieving lower concentrations are extremely important as the concentration of  $\Delta$ 9-THC in exhaled air are described to be in the range of 1ng/30 L of exhaled air.<sup>2</sup> In recent years, due to the increasing demand for both product complexity and multi-functionality, many new materials have been tested for 3D printability, including a forensic science application.<sup>4</sup> The results obtained in this work are the initial fundamental chemical foundation needed for the construction of a reliable semi-quantitative breathalyzer device to be applied in Driving Under the Influence of Drugs (DUID) monitoring in the United States.

**B174 Then vs. Now vs. the Future: An Overview of Extraction Protocols for Cannabis-Derived and Cannabinoid-Infused Products and the Development of a Universal Extraction Method**

*Benedetta Garosi\*, University at Albany, Albany, NY; Rabi A. Musah, University at Albany-SUNY, Albany, NY*

**Learning Overview:** After attending this presentation, attendees will better understand how cannabinoids can be extracted from a broad range of cannabis-derived or cannabinoid-infused complex matrix products with a rapid and universal extraction protocol for detection and quantification purposes.

**Impact Statement:** This presentation will impact practices in the forensic science and criminal justice fields by providing a universal optimized procedure for the extraction of cannabinoids infused within complex edible and non-edible matrices.

In 2019, the National Institute of Justice's report to Congress stated that there is a critical need for the development of standardized protocols for the analysis of cannabis and cannabis-derived products. This is because well-established protocols for the analysis of cannabis plant material are generally suboptimal for the plethora of cannabinoid-containing goods that have become exceptionally popular since the decriminalization and legalization of marijuana at the state level in the United States. These processes, which are highly nuanced and complex-matrix dependent, are generally resource-intensive, time-consuming, and require extensive sample preparation. For example, products with high sugar and carbohydrate content, such as candies and honey, are subjected to dissolution in water, organic solvent extraction, sonication, and filtration, followed by evaporation of the solvent and derivatization (to protect the carboxylic groups if analyzed by Gas Chromatography/Mass Spectrometry [GC/MS]).<sup>1</sup> Lipophilic/oily products are extracted with solvents of varying polarity, washed, dried, and reconstituted or subjected to Solid-Phase Extraction (SPE). Solid foods such as brownies and cookies are often ground/homogenized prior to extraction.<sup>2,3</sup> Aqueous products (if carbonated) are degassed by sonication, extracted with acetic acid, acetonitrile, and "extraction salts" by applying the Quick, Easy, Cheap, Effective, Rugged, and Safe (QuEChERS) technique.<sup>4</sup> Usually, the QuEChERS extraction method involves two steps: (1) liquid-liquid extraction; and (2) dispersive solid-phase extraction clean-up. Recently, slight modifications of this technique have been employed for the extraction of cannabinoids from food products.<sup>5,6</sup> Although many of these protocols have been studied for decades and are routine, these approaches to sample analysis require a perpetual need for highly specialized and nuanced method development in order to accommodate the ever-changing complex matrices that are encountered by crime labs, often at great expense in terms of time and material resources.

To address the challenge of the need for nuanced methods development, this study focused on the creation of a more universal extraction protocol that is applicable to multiple matrix types, featuring the QuEChERS DisQue CEN salts.<sup>7</sup> The approach involves suspension of the cannabinoid-containing sample in water, vortexing of the suspension, sonication (only required for chocolates and gelatin candies), addition of acetonitrile followed by DisQue CEN salts (1g trisodium citrate dihydrate, 0.5g disodium hydrogen citrate sesquihydrate, 1g NaCl, and 4gMgSO<sub>4</sub>) and vortexing again before allowing the layers (top acetonitrile layer, which contains cannabinoids, and the bottom aqueous layer, which contains the salts and other matrix constituents) to separate. Rapid analysis of the layers by Direct Analysis in Real-Time High Resolution Mass Spectrometry (DART®-HRMS) revealed that the cannabinoids were reliably extracted into the acetonitrile layer in a single step with recoveries of up to 99%, with no cannabinoids detected in the water-salts-matrix constituent layer. This protocol was then successfully applied to a wide range of samples prepared or spiked in-house with CBD and THC standards, including: (1) gelatin candies; (2) chocolates; (3) marshmallows; (4) beverages such as coffee, sodas, and liqueurs; (5) butters and oils; and (6) personal-care products such as balms and lotions (commercially available).<sup>8</sup>

Overall, the development of this universal, simple, rapid, robust, and cost-effective analytical method for the extraction of cannabinoids can assist forensic science practitioners by: (1) streamlining sample analysis using a sample preparation protocol that can be applied to a vast range of matrix types; (2) saving time through fast analysis; and (3) contributing to a reduction in sample testing backlogs.

**B175 Trace Metals in Cannabis Seized by Law Enforcement in Ghana and Multivariate Analysis to Distinguish Among Different Cannabis Farms**

*Edward Bentil\*, Manassas, VA; Brian Eckenrode, PhD, Aldie, VA; Isaac Ayensu, PhD, Joseph Adu, PhD*

---

**Learning Overview:** After attending this presentation, attendees will be able to understand how trace metals are used as tools to predict the origin of the cannabis plant from different parts of Ghana.

**Impact Statement:** Attendees will be made aware of the impact of Inductively Coupled Plasma/Mass Spectrometry (ICP/MS) instrumentation for reducing the trafficking of narcotics across international borders using metal contents.

For hundreds of years, cannabis has been one of the most known cultivated plants due to its variety of uses, including as a psychoactive drug, as well as for medicinal activity. Although prohibiting cannabis products, the countries of the African continent are the largest producers of cannabis in the world; a fact that makes the trafficking of cannabis-based illicit drugs a high priority for local law enforcement authorities. The latter are exceedingly interested in the use of chemical analyses for facilitating quantification, identification, and tracing of the origin of seized cannabis samples.

A number of different analytical techniques, as well as the interpretation of their data such as chemometrics, have been used for probing the geographical sources of plants and soils.<sup>1-3</sup> Among them, ICP/MS has been the method of choice for the determination of toxic metals and metalloids of plants and soils, with low detection limits down to 0.1ppb, simple sample preparation, high throughput, and the ability to measure many elements simultaneously.<sup>2,4,5</sup> Targeting these goals, and focusing on the country of Ghana, the present study used ICP/MS for the determination of 12 elements (Pb, Cu, Ca, Mg, Mn, Zn, Cd, As, Hg, Fe, Na, and K) in cannabis seized by Ghana's law enforcement authorities and soils of cannabis farms. Furthermore, multivariate analysis was applied to distinguish among different cannabis farms and match them with the samples. As a result, 22 seized cannabis samples and 12 other cannabis samples with their respective soils were analyzed to reveal considerable As and Pb concentrations. As and Pb levels in cannabis were found to be up to 242ppb for As and 854ppb for Pb. Multivariate analysis was applied for separating different cannabis farms and seized samples based on elemental analysis, linking the seized samples with two Ghana regions.

**Toxic Metals; Cannabis; ICP/MS**

---

**B176 Are Smokable Hemp Products Correctly Labeled?**

*Walter B. Wilson\*, National Institute of Standard and Technology, Gaithersburg, MD; Aaron Urbas, National Institute of Standards and Technology, Gaithersburg, MD*

---

**Learning Overview:** After attending this presentation, attendees will be informed about the sample preparation procedures, the Liquid Chromatography-Photodiode Array (LC-PDA) method at the National Institute of Standards and Technology (NIST), and inaccuracies of product labels for commercial smokable hemp plant samples for  $\Delta^9$ -Tetrahydrocannabinol ( $\Delta^9$ -THC),  $\Delta^8$ -Tetrahydrocannabinol ( $\Delta^8$ -THC), Tetrahydrocannabinolic Acid (THCA), and total  $\Delta^9$ -THC.

**Impact Statement:** This presentation will impact the forensic science community by providing a summary of analytical methods that NIST would like to help transfer to forensic laboratories in distinguishing seized plant samples as either legal hemp or illegal marijuana. Additionally, the forensic science community will obtain an example of how product labels are inaccurate and the typical levels of  $\Delta^9$ -THC,  $\Delta^8$ -THC, THCA, and total  $\Delta^9$ -THC in smokable hemp products.

The passage of the 2018 Farm Bill has led to a large increase in hemp production in the United States in 2021 with approximately 76% of it focused on floral hemp that is used to produce hemp-derived finished products such as smokable hemp (e.g., manicured, roll your own, or cigarettes). As a result, forensic laboratories have seen a significant increase in confiscated cannabis samples, but few reliable analytical methods exist in the literature for differentiation between hemp and marijuana. Prior to the passage of the 2018 Farm Bill, forensic laboratories were required to perform non-quantitative confirmatory tests for the presence of  $\Delta^9$ -THC, but new legislation defined hemp as cannabis containing mass fractions of decarboxylated- $\Delta^9$ -THC less than or equal to 0.3%. In response to the need for reliable quantitative methods, NIST has developed and evaluated analytical methods to provide forensic scientists the tools necessary.

In this presentation, 53 smokable hemp plant products were analyzed for  $\Delta^8$ -THC,  $\Delta^9$ -THC, THCA, and total  $\Delta^9$ -THC by a published LC-PDA method using a methanol extraction procedure.<sup>1</sup> LC is the most widely employed separation technique by the cannabis industry because it permits the determination of total  $\Delta^9$ -THC, which is calculated as the sum of  $\Delta^9$ -THC and its acidic precursor, THCA. Over 90% of the samples analyzed by NIST were determined to have a total  $\Delta^9$ -THC mass fraction above this limit, even though samples were being marketed as hemp with  $\Delta^9$ -THC mass fractions below 0.3 %. Surprisingly, often the associated online documentation reported total  $\Delta^9$ -THC mass fractions of  $\geq 0.3\%$ . Mass fractions determined by NIST were compared with manufacturer's online documentation for 22 samples. Measurements differed by  $\approx 55\%$  for total  $\Delta^9$ -THC,  $\approx 68\%$  for THCA, and  $\approx 18\%$  for  $\Delta^9$ -THC. Poor agreement may result from method difference, sample inhomogeneity, batch-to-batch variability, changes due to storage conditions, and/or product labels or online documentation that are not representative of actual products.

**B177 The Application of the Expert Algorithm for Substance Identification (EASI) to Resolve THC and CBD ESI-Mass Spectra**

*Alexandra I. Adeoye\*, Morgantown, WV; Jacob King, Colorado State University, Latrobe, PA; Glen P. Jackson, West Virginia University, Morgantown, WV*

---

**Learning Overview:** After attending this presentation, attendees will have learned how the correlations that exist within the abundances of fragment ions in replicate tandem mass spectra can be used to effectively discriminate between compounds of notoriously high spectral and structural similarity, such as delta-9-Tetrahydrocannabinol (THC) and delta-9-Cannabidiol (CBD).

**Impact Statement:** This presentation will impact the forensic community by providing a flexible algorithm capable of resolving and extrapolating between compounds collected under different conditions or on different instruments. EASI aims to minimize false identifications and improve forensic analysts' confidence in their identifications and testimonies.

Our central hypothesis is that the relative abundances of mass spectra fragments are not independent but are correlated. This hypothesis is supported by unimolecular fragmentation theories like Rice–Ramsperger–Kassel–Marcus (RRKM) and confirmed by Pearson correlation matrices for each compound.

In most existing library search algorithms, a query spectrum is compared to a library of discrete spectra of standards or known spectra. In our discussions, the average spectrum of many replicate spectra of a substance can be considered a consensus or exemplar spectrum. One problem with library spectra is that inter-laboratory and inter-day measurements can easily introduce abundance variations of up to  $\pm 20\%$ . This variance is even more pronounced when collecting tandem mass spectra at different collision energies on different instruments. Such variance increases the difficulty in differentiating between compounds of similar mass spectra. EASI takes an informed approach that accounts for the different sources of variance by modeling the correlations within replicate spectra.

For this presentation, 60 replicate spectra were collected for THC and CBD at three different collision energies on an ESI-source Agilent® 6538 UHD Q-TOF. The total number of spectra is 360. The replicate spectra were randomly and evenly distributed to create training and test sets for General Linear Modeling (GLM). Since the branching ratios vary at different collision energies, the 29 most abundant mass fragments across all collision energies were selected as variables for the linear models and entered in a stepwise additional method. Additionally, one-way Analysis of Variance (ANOVA) was performed using the collision energy as the fixed factor to determine which fragments significantly differed between THC and CBD to better inform the variable selection. The models from each training set were used to predict each compound's fragment abundance. The measured and EASI-predicted abundances were evaluated using similarity and dissimilarity metrics, such as the dot-product and mean absolute residual. Each metric was then used as a binary classifier to generate a Receiver Operating Characteristic (ROC) curve to determine the true positives and false positive rates over a range of threshold values. The Area Under the Curve (AUC) was then calculated to assess the performance of each metric and its supporting model.

The residuals from the EASI models were generally smaller over the consensus-based approach at each collision energy.

Using all the modeled fragment abundances as input variables for classification, the consensus-based approach discriminated between THC and CBD with an average of 80% accuracy, but EASI distinguished between the conformers with an average of 91% accuracy. The residuals from the EASI and consensus-based models were used to build a binary logistic regression model at each collision energy using half the spectra ( $n=30$  known positives and  $n=30$  known negatives) as a training set and the other half as a test set. Using as few as two variables for discrimination (e.g., residuals for GLM models for  $m/z$  91 and 165), EASI was typically able to resolve THC and CBD with greater than 99% accuracy, which exceeds the accuracy of conventional algorithms.

**Algorithms; Correlations; Tandem Mass Spectrometry**

## C1 A Forensic Analysis of Veo Micromobility Mobile Application on iOS® Devices

*Nina Matulis\*, Purdue University, West Lafayette, IN; Umit Karabiyik, Purdue University, West Lafayette, IN; Marcus Rogers, Purdue University, West Lafayette, IN; Baijian Yang, Purdue University, West Lafayette, IN*

**Learning Overview:** Attendees of this presentation will learn about the forensic analysis of electric scooter and electric bike applications, specifically focusing on the Veo micromobility app on iOS®. This study aims to determine what forensically relevant data can be recovered from these apps to aid in investigations related to e-scooter and e-bike usage.

This presentation will cover the reasons behind the increasing popularity of micromobility vehicles such as e-scooters and e-bikes, including their ease of use, cost effectiveness, and environmentally friendly nature. The app-based nature of these vehicles, which allows users to start their ride by scanning the vehicle's identification and making payment, will also be discussed. Additionally, this presentation will provide a methodology for acquiring evidence from the Veo app and explore the artifacts that can be recovered from two types of forensic acquisitions. The focus will be on the specific data that can be obtained from the Veo app and other micromobility apps, considering their growing usage. Overall, this presentation will highlight the importance of forensic analysis in investigating e-scooter- and e-bike-related incidents and demonstrate how the data recovered from micromobility apps can be utilized in forensic investigations.

**Impact Statement:** This presentation will have a significant impact on the forensic science community by addressing the emerging field of forensic analysis related to micromobility vehicles and their associated applications in the following ways:

**Knowledge Expansion:** This presentation will provide valuable insights into the forensically relevant data that can be extracted from e-scooter and e-bike applications, focusing specifically on the Veo micromobility app on iOS®. This will expand the knowledge base of forensic scientists and investigators, enabling them to understand the potential digital evidence available in these types of cases.

**Methodology Development:** This presentation offers a methodology for acquiring evidence from the Veo app, which can serve as a foundation for further research and development in the field. By establishing a systematic approach, it helps standardize the process of extracting and analyzing data from micromobility applications, ensuring consistency and reliability in future investigations.

**Enhanced Investigation Techniques:** With the increasing prevalence of micromobility vehicles and their associated apps, forensic professionals need to stay updated on the latest investigation techniques. This presentation will equip attendees with knowledge on the artifacts that can be recovered from two types of forensic acquisitions, enabling them to leverage this information in their investigations. This knowledge can potentially assist in linking individuals to specific e-scooter or e-bike usage, identifying patterns of behavior, and reconstructing events relevant to a case.

**Adaptation to Technological Advances:** By focusing on the forensic analysis of micromobility apps, this presentation acknowledges the evolving landscape of digital technology and its impact on forensic science. It highlights the need for forensic professionals to keep pace with emerging trends and technologies, ensuring they can effectively analyze and interpret evidence from novel sources.

**Collaboration and Networking:** This presentation serves as a platform for forensic scientists, investigators, and researchers to connect and exchange ideas. It fosters collaboration within the forensic science community, promoting the sharing of knowledge, methodologies, and best practices. This collaboration can lead to further advancements in the field and facilitate interdisciplinary approaches to forensic investigations.

Overall, this presentation will contribute to the growth and development of the forensic science community, empowering professionals with the knowledge and tools necessary to navigate the challenges presented by the increasing use of micromobility vehicles and their associated applications.

The escalating use of electric scooters (e-scooters) and electric bikes (e-bikes) necessitates the identification of forensically relevant data recoverable from associated applications to support investigations. These micromobility vehicles have gained widespread popularity due to their user-friendly features, cost-effective and efficient transportation capabilities, as well as their environmentally friendly nature. Leveraging app-based functionality, users can seamlessly initiate their rides by scanning vehicle IDs and making payments. This study focuses on the forensic analysis of such applications, with a specific emphasis on the Veo micromobility app on iOS®. We present a systematic methodology for evidence acquisition from the Veo app, enabling forensic professionals to standardize the acquisition of evidence from the Veo app and similar micromobility applications. Additionally, the recoverable artifacts from two types of forensic acquisitions are discussed. The recovered artifacts bear significant practical implications for forensic investigations related to e-scooter and e-bike incidents, including accidents, thefts, or other criminal activities involving these vehicles. The extracted data can provide invaluable information about rider identities, travel patterns, usage frequency, geolocation data, payment history, and potential communication records. Such evidence assists investigators in establishing timelines, reconstructing events, identifying potential witnesses, linking individuals to specific vehicle usage, and ultimately facilitating case resolution.

Additionally, this study encourages collaboration and knowledge sharing within the forensic science community. Educators and law enforcement officials will have the opportunity to engage in discussions, exchange ideas, and explore interdisciplinary approaches to enhance their investigative capabilities in the growing domain of micromobility app forensics. Adapting forensic expertise to encompass the evolving digital landscape, including the analysis of emerging technologies like micromobility apps, is essential for professionals to stay abreast of technological advancements and effectively serve justice in the digital age. With Veo and other micromobility app usage on the rise, this study emphasizes the acquisition of forensically relevant data and its application in forensic investigations.

## Cyber Forensics; Digital Evidence; Apple® iOS®

## C2 A Forensic Analysis on Major Android™ Cloud SDKs

*Chen Shi\*, Iowa State University, Ames, IA; Yong Guan, Iowa State University, Ames, IA*

**Learning Overview:** After attending this presentation, attendees will understand how to use the comprehensive forensic analysis results of Android™ Cloud Software Development Kits (SDKs) in their casework investigation. This presentation will introduce the basics, challenges and limitations of the current mobile device forensics and demonstrate how to take advantage of the Android™ Cloud SDKs database and search/recover the possible evidence from the corresponding locations outside the mobile devices being investigated.

**Impact Statement:** This presentation will impact the forensic science community by demonstrating how this new forensic analysis results on the Android™ Cloud SDKs can simplify and speed up investigation procedures.

Forensic analysis on Android™ Cloud SDKs faces several challenges. Android Cloud SDKs often employ strong encryption techniques to protect user data. Forensic analysts may face difficulties in accessing and decrypting this data, especially without proper authentication credentials or encryption keys. In traditional digital forensics, physical access to a device is essential. However, with cloud-based data storage, the data is hosted remotely and obtaining physical access to the device may not be possible. This makes it challenging to conduct a standard forensic examination. On the other hand, cloud-based data can be distributed across various servers and data centers, leading to data fragmentation. Analyzing fragmented data and ensuring data integrity can be challenging, particularly when investigating time-sensitive cases.

Cloud data is dynamic, and real-time updates occur frequently. This makes it difficult for forensic analysts to capture a specific moment in time accurately, as the data may have changed by the time it is accessed. Cloud services can store vast amounts of data from numerous users. Analyzing such large volumes of data requires powerful and scalable forensic tools and techniques. Cloud service providers frequently update their Application Programming Interfaces (APIs) and SDKs to improve functionality and security. These changes can impact forensic tools that rely on specific APIs or access methods, requiring constant updates and adjustments to stay effective. Data transmitted between the mobile device and the Cloud is vulnerable to interception. Ensuring the security and integrity of network traffic during data collection is essential to maintain the integrity of the evidence. Many cloud services offer multi-device synchronization, where data is automatically shared and updated across different devices. This can complicate the forensic process, as the data may exist on multiple devices, each with its own unique challenges. Cloud service providers may implement anti-forensic measures to protect user data. These measures can include file obfuscation, data compression, or other techniques designed to thwart forensic analysis.

To address these challenges, we conducted a large-scale forensic analysis toward major Android™ Cloud SDKs where we manually analyzed the framework and APIs to determine how user data is processed by different Android™ Cloud SDKs. A comprehensive approach was proposed, and it's evaluated in terms of precision and time efficiency. Both static and dynamic program analysis approaches were applied on analyzing/resolving evidentiary data, such as the URL path and its corresponding evidence types. To preserve the advantages (e.g., better time efficiency) provided by our tools, a set of refined/improved automatic program analysis algorithms to analyze Android™ apps were implemented to create the forensic analysis results. The advantages of leveraging the results are: (1) mitigating errors caused by manual investigation; (2) improving the likelihood of discovering evidentiary data stored in specific format on the Cloud; and (3) fast-tracking the evidentiary date of real-world apps.

---

**Forensic Investigation; Data; Software**

## C3 Geodata Sleuthing: Geo-Contextualized Digital Footprints Analysis to Empower Cyber Forensic Investigations and Life Pattern Analysis

Mohammad Meraj Mirza\*, Taif University, Taif, Makkah, Saudi Arabia; Umit Karabiyik, Purdue University, West Lafayette, IN

**Learning Overview:** After attending this presentation, attendees will leave with the knowledge and understanding on unlocking valuable insights from geodata found in cyber investigations and the tools necessary for such a process. Moreover, this presentation will focus on geospatial techniques that can be harnessed to enrich various aspects of cyber forensics investigations by applying it to an iOS® case study. This empowerment will enable forensic experts to handle complex mobile forensics and incident response investigations confidently. This will help enhance their effectiveness and efficiency in solving cases. Finally, attendees will leave equipped with the knowledge, techniques, and tools necessary such as Geographic Information Systems (GIS) to embrace the power of geospatial analysis in their efforts to combat crimes and contribute to advancing forensic sciences.

**Impact Statement:** The presentation will have a significant impact on the forensic science community by demonstrating strategic integration of geodata and spatial analysis, showcasing its potential impact for mobile forensics investigations. Moreover, this presentation will provide cyber forensic professionals with techniques to reconstruct digital events, identify life patterns, and map locations crucial to investigations. By showcasing the potential of geospatial analysis in cyber forensics, this presentation will encourage researchers to explore further applications and advancements in the field. This newfound interest in research and development can lead to novel solutions and technologies that further strengthen the capabilities of the digital forensic science community.

As the digital landscape continues to evolve, cyber forensic professionals face an increasing need for up-to-date methodologies and tools to navigate the complexities of smart digital devices (e.g., mobile devices, the Internet of Things [IoT], and drones) investigations and deal with unprecedented challenges that are the results of complex digital incidents.<sup>1</sup> A National Institute of Justice (NIJ) -sponsored report emphasizes the growing significance of digital evidence in the investigation and prosecution of various crimes, as these devices often contain critical trails and information related to criminal activities, as well as actions and movements of the individuals involved (e.g., suspects, victims, and related persons).<sup>2</sup>

One of many critical personal data that can be found in these digital devices is geodata. Explicit geodata (e.g., Global Positioning System) and implicit (e.g., Wi-Fi Mac Address) evidence can play a significant role in criminal investigations where they can provide critical information about a user's whereabouts, their association with specific locations, and even help establish geo-timelines of events related to a crime. Therefore, the research provided a thorough process of leveraging geodata and spatial analysis to construct a representational geo-map of the digital trails involved in the case. By connecting what is known with potential insights from other intelligence domains, the research demonstrated how to enhance the digital forensic practitioner's ability to draw meaningful conclusions and make informed decisions by using an interdisciplinary approach. Throughout a case study, we highlighted the advantages of Pattern of Life (PoL) analysis, which unveils behavioral patterns and routine activities, shedding light on the user's actions and movements. Furthermore, the integration of activity-based intelligence, open-source intelligence, and location intelligence provides a geospatial context to the investigation, enabling cyber forensic analysts to visualize the subject's movements and interactions.

In addition, the research explored the confluence of cyber forensics, GIS, and intelligence domains to improve cyber forensic investigations in evidence collection, examination, analysis, coloration, and visualization. Moreover, we discussed interdisciplinary analytical techniques, including geospatial analysis to build knowledge with the help of geospatial intelligence, open-source intelligence, and activity-based intelligence. These geospatial investigation methods generate an exceptional understanding of the users' spatial-temporal behavioral patterns that can be mapped to identify spatiotemporal patterns to provide more accurate reasoning and explanation. Furthermore, the research highlighted the challenges that may arise in employing this interdisciplinary approach, such as data integration complexities. Finally, it emphasized the need for collaborative efforts between law enforcement agencies, legal professionals, and industry stakeholders to address the challenges and improve the use of geodata evidence in legal proceedings.

By the end of this presentation, attendees will gain valuable insights into overcoming challenges related to geodata and how to optimize the investigative process effectively. Moreover, they will have a comprehensive understanding of how geodata and spatial analysis, coupled with intelligence-related knowledge, can augment digital forensic practitioners' decision-making processes. Finally, the case study demonstrated serves as a tangible example of how to accomplish creating a transdisciplinary approach that can revolutionize digital investigations, providing a more comprehensive and geo-contextually meaningful analysis of incidents using GIS software.

## C4 The Development, Testing, and Comparison of Decontamination Methods for Drugs and Ignitable Liquids From Mobile Devices

*Christopher Michael Haser\*, Marshall University, Huntington, WV; Kimberly S. Kunkler, Marshall University, Huntington, WV; Lauren L. Richards-Waugh, Marshall University, Huntington, WV*

**Learning Overview:** This presentation will discuss potential methods of decontamination for mobile devices to protect the health and safety of the analyst while preserving forensic evidence. After attending this presentation, attendees will understand previous methods of decontamination and how the process can be improved.<sup>1</sup>

**Impact Statement:** This presentation will impact the forensic community by demonstrating how the safety of Crime Scene Investigators (CSIs) and analysts can be maintained with an effective decontamination protocol. The quality of analysis may also be improved through safety and timeliness in the field and laboratory, promoting decreased backlogs and improved safety measures within the forensic community.

Mobile devices collected from clandestine labs can be contaminated with hazardous materials, including illicit drugs, drug precursors, and ignitable liquids used during the synthesis process. If seized mobile devices are not adequately decontaminated, laboratory analysts can be exposed to health hazards while performing their examinations. VTO Labs in Broomfield, CO, has developed a decontamination method comprised of three solutions—Easy DECON<sup>®</sup> Parts 1–3—that they claim cleans devices of fentanyl, carfentanil, and methamphetamine residue, thereby protecting CSIs and analysts from these potential hazards.

However, there are many other dangerous substances in clandestine labs that may also contaminate these devices. Previous research demonstrated the VTO Labs decontamination kit was effective at removing heroin and cocaine. Although the liquid decontamination kit from VTO Labs has been shown to work with drugs, it is also important to consider that mobile devices from clandestine labs could also be contaminated with ignitable liquids. Having a vessel that contains a decontamination solution able to remove both drugs and ignitable liquids would be beneficial. Activated carbon has been used for ignitable liquid extraction, most commonly in the form of activated Carbon strips (C-strips) or loose activated Carbon powder made into an adsorption package (C-bag).

This project aimed to use loose activated carbon (FLUEPAC<sup>®</sup> MC) as a method for decontamination of mobile devices. This activated carbon powder could be added to any signal-blocking transportation container to serve the purpose of potentially decontaminating the device from drugs and ignitable liquids. During the study, devices were contaminated separately; one set of devices was contaminated with a street sample of heroin (obtained from the Huntington Police Department and previously analyzed by the West Virginia State Police Forensic Laboratory), and the other set of devices was contaminated with a 1:1 mixture of gasoline and diesel fuel (IL mix).

The devices contaminated with drugs were swabbed pre- and post-decontamination with a methanol-soaked Kimwipe<sup>®</sup>, extracted with methanol, vortexed to separate any drug from the Kimwipe<sup>®</sup>, and analyzed using a Liquid Chromatograph coupled to a Tandem Mass Spectrometer (LC/MS/MS). The devices contaminated with the IL mix were wiped with a Kimwipe<sup>®</sup> spotted with approximately 1 milliliter of the mix, rinsed with distilled water, decontaminated using three different methods, (Dawn<sup>®</sup> dish soap and water, Elma Ultrasonics<sup>®</sup> Elma Tec Clean A1 and water, and activated carbon powder and water), then processed in accordance with ASTM International standard E1412-19. The samples were analyzed using Gas Chromatography coupled with Mass Spectrometry (GC/MS) and compared to determine the effectiveness of each method. Finally, a preliminary test was performed on a decontamination method developed during this project. A final cleaning step was added to the activated carbon decontamination method. Clean glassware was contaminated with the IL mix, decontaminated using activated carbon, then placed in either the Dawn<sup>®</sup> dish soap and water mix or Clean A1 and water mix to remove any activated carbon and IL mix that may still be present on the surface of the glassware. These samples were also tested using GC/MS.

## C5 Using File Structure to Authenticate Video Files Uploaded to Cloud Storage Via iOS® Mobile Web Browser

Brandon Epstein\*, Medex Forensics, Freehold, NJ; Bertram Lyons\*, Medex Forensics, Madison, WI

**Learning Overview:** After attending this presentation, attendees will understand how video file structure can be used to authenticate video files that have passed through an iOS® mobile web browser despite changes to the file's hash and/or semantic metadata.

**Impact Statement:** This presentation will impact the forensic science community by informing attendees that cloud platforms provide a reliable and efficient way to share and store digital video files. In addition to commercial storage and sharing platforms, law enforcement agencies are deploying purpose-built public evidence submission portals that allow citizens to submit video files as evidence directly to the Cloud, often through a cell phone's mobile web browser. While a reliable and efficient way to share and store digital video files, this submission process often changes a file's hash and metadata values, particularly in iOS® devices, making it difficult to authenticate a submission or determine if a complete, unedited file was received. Additionally, open video file submission portals may be prone to a deluge of non-original, non-pertinent video files from multiple sources, challenging law enforcement agencies to identify pertinent evidentiary video when investigating large-scale incidents.

In this project, camera-original exemplar files were created on an Apple® iPhone® and the file hashes, stream hashes, metadata attributes and file structure for each file was recorded. The camera's original files were then edited on the iPhone® and uploaded from the iOS® photos app to commercial cloud storage as well as a purpose-built public evidence submission platform. Those files were then downloaded from the Cloud and the same data evaluated. A second set of videos were edited within the iOS® photos app on the iPhone® and then evaluated. The upload and download were repeated, and the resultant files evaluated as well.

The generated file hashes, stream hashes, metadata attributes, and file structure for each file were then examined to determine what, if any, data has changed, and the ability to use that data to determine authenticity or provenance of a video file.<sup>1</sup> It was found that file hashes of video files on iPhone® did not match hashes of resultant uploaded/downloaded video from cloud storage, regardless of editing or submission of the camera original video.<sup>2</sup> Although file hashes did not match, stream hashes for all uploaded and corresponding downloaded videos were consistent. Despite the matching stream hashes, certain metadata attributes did change or were removed from all files when uploaded/downloaded from cloud storage. The consistent visual display of the videos as demonstrated through stream hashing, coupled with "normalized" metadata values serve to complicate authentication examinations.

When comparing file structure of camera original vs. edited files on Apple® devices, structural changes were noted between original and edited files. Additional structural changes were found after they were uploaded/downloaded from cloud storage. Even though the file structures were different, they changed consistently for the camera original and edited file, such that a specific structure can be linked to the provenance of the file.

This research found that file structure is a valid method to evaluate provenance and authenticity of video files uploaded to cloud storage via iOS® mobile web browser, even though other file attributes have changed. Using file structure can allow an examiner to authenticate citizen-submitted evidence video or triage through multiple submissions of potential video evidence to identify camera-original video at scale.

### Video Analysis; Digital Evidence; Admissibility

## C6 An Overview of Deepfake Technologies: From Creation to Detection in Forensics

Luca Guarnera\*, University of Catania, Catania, Sicilia, Italy; Sebastiano Battiato, University of Catania, Catania, Sicilia, Italy

**Learning Overview:** After attending this presentation, attendees will be familiar with various deepfake creation and detection techniques. This presentation will attempt to present all existing solutions to date with a simple but schematic view. Attendees will gain that useful information in order to avoid being a victim of cyber attacks created through this powerful technology

**Impact Statement:** This presentation will have a major impact on the forensic science community by demonstrating the potential of deepfake technology and how it can pose a danger to every individual, industry, nation, and the entire world. An overview of the main methods of deepfake creation and detection will be given with the goal of giving users those tools and information useful to perform a critical analysis on any multimedia content in order to prevent cyber attacks carried out through this powerful technology.

Advancements in Artificial Intelligence (AI) techniques have given rise to significant challenges in the field of Multimedia Forensics, particularly with the emergence of the deepfake phenomenon. Deepfakes are images, video and audio generated or altered by powerful generative models such as Generative Adversarial Networks (GANs) and Diffusion Models (DMs).<sup>1,2</sup> While GANs have long been recognized for their ability to generate high-quality images, DMs offer distinct advantages, providing better control over the generative process and the ability to create images with a wide range of styles and content.<sup>3</sup> In fact, DMs have shown the potential to produce even more realistic images than GANs.

The AI-generated contents span diverse domains, including films, photography, video games, and virtual reality productions. A major concern of the deepfake phenomenon is the application on important people such as politicians and celebrities to spread misinformation. However, the most alarming aspect is the misuse of GANs and DMs to create pornographic deepfakes, posing a serious security threat. Notably, a staggering 96% of deepfakes available on the internet fall into this pornographic category. The malicious use of deepfakes extends to issues such as misinformation, cyberbullying, and privacy violation. In addition, deepfakes have been applied in the fields of art and entertainment, sparking ethical discussions about the limits of creativity and authenticity.

To counteract the illicit use of this powerful technology, novel forensic detection techniques are required to identify whether multimedia data has been manipulated or altered using GANs and DMs.

Regarding image deepfake detection methods in the state of the art, the primary focus lies in binary detection, distinguishing between real and AI-generated images.<sup>4,5</sup> Notably, some methods in the state-of-the-art have already demonstrated the ability to effectively differentiate between various GAN architectures and several DM engines.<sup>6-12</sup> Research showed that generative models leave unique fingerprints in the generated multimedia data, which can be used not only to identify deepfakes but also to recognize the specific architecture used during the creation process.<sup>13</sup> This can be extremely important in forensics in order to reconstruct the history of the multimedia data under analysis (forensic ballistics).<sup>14</sup>

In order to create increasingly sophisticated deepfake detection solutions, several challenges have been proposed by the scientific community such as the Deepfake Detection Challenge (DFDC) and the Face Deepfake Detection Challenge.<sup>15,16</sup> The latter has also launched a new challenge among researchers in the field: reconstructing the original image from deepfakes, a task that can be extremely important in forensics.

## C7 The Application of Artificial Intelligence in Forensic Science AI4Forensics From Deepfakes to Risks and Challenges

*Zeno J. Geradts\*, Netherlands Forensic Institute, Den Haag, Zuid-Holland, Netherlands*

**Learning Overview:** After attending this presentation, attendees will have learned what the risks of Artificial Intelligence (AI) in forensic science are, how to cope with these, and how to work with AI in a proper way.

**Impact Statement:** This presentation will impact the forensic science community by showing examples of how AI is used in forensic science, what the challenges are, and why validation is important.

AI for forensics is a rapidly growing field, and the AI4Forensics Lab at the University of Amsterdam and the Netherlands Forensic Institute is leading the way. The lab is home to four PhD students and a postdoc who are working on a variety of projects, including speaker recognition, facial comparisons, chemical analysis of illicit drugs, and tracing criminal money flows.

One of the most exciting projects at the lab is the development of computer models for recognizing hidden messages in photos or videos. These models could be used to identify steganographic images, which are images that have been altered to contain hidden data. Steganographic images are often used by criminals to communicate with each other or to store sensitive information.

Another project at the lab is the development of methods for recognizing deepfakes. Deepfakes are videos or audio recordings that have been manipulated to make it appear as if someone is saying or doing something they never said or did. Deepfakes can be used to spread misinformation or to damage someone's reputation.

The AI4Forensics Lab is also working on projects that use data from mobile phones and smart watches to track people's movements. This data could be used to identify crime scenes or to track the movements of suspects. The lab is still in its early stages, but it has the potential to revolutionize the field of forensics. By applying AI to forensic evidence, the lab can help law enforcement solve crimes more quickly and efficiently.

Here are some of the key benefits of the AI4Forensics Lab:

- The lab brings together experts from the University of Amsterdam and the Netherlands Forensic Institute who have a wealth of experience in AI and forensics.
- The lab has a strong focus on research, which means that it is constantly developing new and innovative methods for applying AI to forensic evidence.
- The lab is open to collaboration with other organizations, which means that it can share its findings with a wider audience.

The AI4Forensics Lab is a significant step forward in the field of forensics. The lab has the potential to revolutionize the way that forensic science and AI are used. Validation and also the proper use of artificial intelligence in relation to the AI Act from the European Union will be implemented.

---

**Artificial Intelligence; Forensic Analysis; Validation**

## C8 Searching for Hidden Data in Multimedia Files With UNCOVER

*Zeno J. Geradts\*, Netherlands Forensic Institute, Den Haag, Zuid-Holland, Netherlands*

**Learning Overview:** After attending this presentation, attendees will be aware of which methods exist for hiding data in many types of files. Attention will also be given regarding making new stego applications with language models such as ChatGPT. Detection of the hidden data as well as recovering the data is one of the aspects.

**Impact Statement:** This presentation will impact the forensic science community by presenting new methods for stego analysis and a real-world database.

Criminals and terrorists are increasingly using steganography to conceal incriminating information in digital files. Law Enforcement Agencies (LEAs) currently use commercial tools to detect hidden information in these files, but these tools are limited in their capabilities.

The UNCOVER project aims to fill the gaps in LEAs' ability to detect steganography.<sup>1</sup> With a consortium of 22 partners, including LEAs, forensic institutes, researchers, and industrial companies, UNCOVER will develop new steganalysis tools that are more powerful, user-friendly, and adaptable to the needs of LEAs.

The developed tools will be integrated into a flexible and user-friendly platform. End-users will play a key role in the project from proposal writing to final evaluation. Regular feedback loops with LEAs, forensic institutes, and external stakeholders will ensure that the developed solutions can be integrated into law enforcement's daily criminal investigation process. A set of clearly defined key performance indicators will allow for an objective assessment of progress and final results against defined objectives.

Below are some of the key benefits of the UNCOVER project:

- More powerful steganalysis tools that can detect a wider range of concealment methods.
- More user-friendly tools that are easier to use and interpret.
- Tools that are more adaptable to the needs of LEAs.
- A flexible and user-friendly platform for integrating the developed tools.
- Regular feedback loops with end-users to ensure that the developed solutions are fit for purpose.

The UNCOVER project is a significant step forward in the fight against steganography. The developed tools will allow LEAs to detect hidden information more effectively, which will help prevent and investigate criminal activity. A large database of 2 terabytes of images, videos, audio files, and text is developed to test the different tools. In this presentation, new challenges with language models such as ChatGPT are discussed on making new forms of data hiding based on python scripts, which may be harder to detect.

## C9 The Accuracy of Time Stamps on Surveillance Recording Devices

*Benjamin Tyler Molnar\*, JS Held LLC, Greenwood Village, CO; Toby Terpstra, J.S. Held, Greenwood Village, CO; Tilo Voitel, Denver Metro Forensics, Lakewood, CO*

**Learning Overview:** After attending this presentation, attendees will understand how to assess the timing between video surveillance frames based on the time stamp digitally inserted into the pixel information of the video. This research explores the accuracy of those time stamps and methods for establishing timing in cases where there is incomplete metadata, held frames, or a video recording of the surveillance playback monitor.

**Impact Statement:** This presentation will impact the forensic science community by informing attendees that in today's world, video is becoming more common in forensic analyses. Unfortunately, video evidence can be inconsistent in the way it is recorded. In many cases, the forensic analyst is given a non-native video file or even a video recording of the playback monitor. In these cases, there is very little or no information relating to the timing between recorded frames. This can affect our ability to properly analyze the video. However, many times these video files contain digital timestamps inserted into the pixel information of each frame. Based upon my research, these timestamps can be used to establish frame-to-frame timing, if done carefully and correctly. We will also discuss the limitations found in the research by employing the timestamp.

The presence of video surveillance data has been increasing in recent years. With this increase, video analysis plays a major role in many forensic fields. Many articles, publications, and presentations have covered the importance and difficulty in properly establishing timing between frames captured by any given recording device. This timing is crucial to the forensic analysis to ensure accurate results. In many cases, the analyst is given video files that either do not contain all native metadata or are missing important data required to establish the timing accurately. In some cases, the files contain video recordings of the surveillance playback monitor, which eliminates all original metadata from the video recording. However, within many of these video files, timestamp information is imprinted into the pixel information of each frame. This study examines the accuracy of these timestamps to establish if they can be reliably used to determine the timing between frames.

To accomplish this research, four common recording devices and six different camera devices were utilized. Of these four recording devices, three were digital video recorders and one was a network video recorder. For the three digital video recorders, tests were run with the same four cameras all plugged in, then with only one camera. For the one network video recorder, tests were run with two cameras plugged in, then with only one camera. All videos recorded the Axon® (formerly Input-Ace) Lightboard as the control measurement for timing between each captured frame. The Lightboard was set to 1, 2, 3, and 4 millisecond settings, and the requirements for the number of frames captured by Axon® were met. Videos were recorded with each device and each camera configuration at 30, 15, and 4 frames per second to determine if the capture rate affected the accuracy of the embedded time stamp data. Once recorded, each video was processed using Axon Investigate's™ native "VFR Lightboard Calculator" to establish the actual timing between each frame of test video.

Subsequently, ten timestamp seconds within each video were selected and compared to the actual elapsed time reported by the Lightboard. In total, 54 videos were recorded across all configurations. This study demonstrates the timestamp is not always accurate from second to second. However, a pattern was observed, and a methodology was developed to accurately establish approximate timing between timestamp seconds. The average error between the theoretical time (based on the timestamp) and the actual time reported by the Lightboard across all analyzed timestamp seconds was 2.86 milliseconds (approximately 0.29%). The maximum error between theoretical time (based on the timestamp) and actual time for any timestamp second across all tests was 22 milliseconds (approximately 2.2%). These errors can be considered reasonable for the purposes of analyzing videos in forensic analyses. Inherent in this methodology is the limitation of using the average frame rate of the video, which does not account for timing variability between any two consecutive frames or dropped frames of video.

## C10 Forensic Video Analysis of an Underwater Volcanic Explosion That Injured Multiple Tour Boat Passengers

*Parris Ward\*, Biodynamics Engineering, Inc., Pacific Palisades, CA*

---

**Learning Overview:** After attending this presentation, attendees will be aware of how forensic analysis of video recordings taken by passengers aboard a tour boat were used to determine the vessel's location and proximity to a volcanic underwater explosion.

**Impact Statement:** This presentation will impact the forensic science community by showing how important data about an incident can be derived from video evidence, beyond just watching it on the screen, if analyzed fully.

The prolonged 2018 volcanic eruption of the Kilauea volcano in Hawaii provided once-in-a-lifetime opportunities for visitors to the island to witness spectacular lava flows in person. Tour boats ferried tourists to where the flows entered the ocean along the East Rift Zone. On an early morning in July, a major underwater explosion, called a lava bomb, exploded near one tour boat, injuring 23 people. Most passengers sustained minor burns and soft tissue injuries; however, one woman's femur was shattered, and she was airlifted to a hospital. Questions arose as to whether the vessel had entered the Coast Guard Safety Zone perimeter and how far the explosion was from the boat.

Five passengers were recording video at the time of the explosion; however, the images were very dark, and no landmarks were visible due to smoke and poor lighting conditions. The videos were brightened and synchronized using forensic software. One recording made on a cell phone contained Global Positioning System (GPS) information. An identical model cell phone was purchased and tested to determine the accuracy of its GPS readings. During weeks of continuous eruption, the coastline of Hawaii was constantly changing. Determining whether the vessel was too close to shore required comparing the GPS location data to United States Geological Survey mapping performed at the time of the incident.

Determining the explosion's proximity to the boat was problematic as there was no scale to the video images. The only object of known scale was the boat itself. The tour boat was scanned using a laser scanner. The position and orientation of one camera near the bow of the ship and one further aft were determined using photogrammetry software. Calibrations for optical distortion were performed using exemplar cameras. The laser scan point cloud data, calculated camera locations, and image planes were imported into a 3D modeling program. The origin of the explosion was identified in synchronized images from both cameras. Vectors were plotted from each camera location through their associated image planes to that point. The vectors from both cameras converged at a distance from the boat model. This method of triangulation provided an approximate distance to the explosion. To verify the accuracy of this technique, measurements were made to objects known distance while the vessel was laser scanned in port. Details on the techniques and results will be presented.

**Forensic Imaging; 3D Technology; Explosion**

## C11 An MDCT Analysis of Copy-Paste Fragments Without Query in Digital Forensic Audio

*Cole Whitecotton, National Center for Media Forensics, Denver, CO; Catalin Grigoras\*, National Center for Media Forensics, Denver, CO*

**Learning Overview:** The goal of this presentation is to disseminate the application of the Modified Discrete Cosine Transform (MDCT) coefficients to determine the presence of copy-paste fragments in digital audio recordings. Attendees will be presented with the proposed methodology, collected materials, analysis results and interpretation, limitations, and future research as well.

**Impact Statement:** This presentation will impact the forensic science community by introducing the application of MDCT analysis for copy-paste detection and digital audio authentication of evidence recordings.

The Scientific Working Group on Digital Evidence (SWGDE) best practice guidelines for forensic authentication of digital audio recordings and the European Network of Forensic Science Institutes (ENFSI) best practice manual for digital audio authenticity analysis present frameworks to analyze and authenticate digital audio recordings.<sup>1,2</sup> Audio samples copy-paste, insert, or clone are editing techniques that can chance the meaning of a recorded conversation and alter the authenticity of the initial recording. Previous work reports on applications of Mel-Frequency Cepstral Coefficients (MFCC), Local Binary Pattern (LBP), Discrete Fourier Transform (DFT), Short Time Fourier Transform (STFT), Content-Based Copy Detection (CBCD), and partial matching without query.<sup>3-5</sup>

This study is part of a larger research project regarding the MDCT coefficients and Map analyses for forensic purposes.<sup>6</sup> This presentation will provide the results of a preliminary study on the discrimination between original audio recordings and different other copy-paste tampered signals.

This study is CBCD independent, partial matching without query samples based, and reports on: (1) applications of MDCT to analyze the artifacts introduced by copy-pasting audio fragments; (2) the robustness of the proposed method against editing techniques like inverting, amplifying, and attenuating the paste fragments; (3) the robustness of the proposed method against added noise; (4) the robustness of the proposed method against lossy audio re-compression including social media; (5) an unbiased method to report the comparison results; and (6) the actual limits of the method and future research.

Future presentations will present extended results and applications of the proposed method. With these findings, the use of the proposed framework in forensic audio analyses, together with other scientific validated methods, is recommended.

### Forensic Audio; MDCT; Clone

## C12 Navigating the SILK Road: An Examination of WeChat SILK Audio Files

*Andrew N. Crouse\*, Epiq Systems, Inc., Woodbridge, VA; Douglas S. Lacey\*, BEK TEK LLC, Stafford, VA; Brian Smith\*, Epiq, Bonaire, GA; In Yong Shin, Epiq, Wanchai, Hong Kong; Louis Chan, Epiq, Tokyo, Japan; Ricky W.K. Lam, Forensic Consultant, Epiq, Wanchai, Hong Kong*

**Learning Overview:** The goal of this presentation is to examine the file structure and forensic implications of SILK v3 encoding and the WeChat audio file structure in mobile device analysis.

**Impact Statement:** WeChat is a global mobile communication application that allows users to send and receive audio messages. WeChat saves the audio using a SILK v3 codec but with a one-byte offset in the header. This unique header has caused issues with standard forensic tools parsing and playing the data and causes additional complications when the audio files require review by attorneys in civil litigation. This presentation will not only discuss WeChat audio data structure but also recommended methodologies to examine and review the WeChat audio files outside of commercial tools. This presentation will impact both law enforcement investigations and civil eDiscovery matters.

WeChat is a mobile device communication application developed by Tencent, a multinational technology company based in Shenzhen, China. The application is used world-wide but is especially popular in Asia-Pacific countries for both personal and business use. The WeChat application family has three different versions: WeChat International, Weixin, and WeChat Commercial. The international version is available to all mobile numbers outside of mainland China and stores its data in Europe and Singapore. Weixin is similar to WeChat International but used for mobile numbers within China and maintains all data within China. WeChat Commercial is used by businesses and employees within mainland China. The WeChat application has the capability to record and send voice messages, similar to other mobile device communication applications. Up until 2015, WeChat audio files were stored using Adaptive Multi-Rate (AMR) encoding and standard audio players, such as Windows Media Player, would play the files. Starting in 2015 and continuing to today, WeChat audio recordings appear to be stored in a format using SILK v3 encoding using a customized one-byte header offset.<sup>1</sup> This causes issues in the digital forensics community, as commercial forensic tools have difficulty supporting or converting WeChat audio files for playback during analysis. In some cases, customized workflows using open-source tools are required to convert the files into a standard format, such as WAV.<sup>2</sup> In addition, litigation review tools used by law firms in civil cases cannot play these types of audio files in their native format. This has impacted both law enforcement investigations and civil eDiscovery matters where WeChat audio files extracted from a mobile device must be examined and played back using various audio software tools.

This presentation will explore WeChat audio files extracted from various mobile devices, their forensic importance in both civil and criminal cases, the SILK v3 audio codec and customized one-byte offset header used by WeChat, and recommended methodologies to examine and review the WeChat audio files outside of commercial tools.

## C13 Validation of Image Stream Hashing: A Forensic Method for Content Verification

Gregory S. Wales\*, Colorado Springs, CO

**Learning Overview:** This presentation uses five image file types transcoded with six different image conversion applications using various settings to test the image stream hashing method's "fitness for the purpose" of determining if two image file contents were identical. After attending this presentation, attendees will have gained knowledge from foundational validity testing of a forensic method to verify the digital image stream integrity when file containers may change during file handling and processing.

**Impact Statement:** This presentation will impact the forensic science community by providing an alternative to traditional file container hashing for data integrity verification, more precisely by verifying the digital image stream.

How does a forensic examiner know if they have altered an image stream when converting a digital image (photograph) from one codec or file container to another for subsequent forensic examination? Forensic standards and best practices recommend avoiding alteration or degradation of multimedia data during transcoding.<sup>1-3</sup> An image stream hashing method was recently introduced to the forensic science community to answer the question above.<sup>4</sup> This presentation offers an initial validation study of the image stream hashing method. The study tested the image stream hashing method's reproducibility and reliability as a forensic method. The validation study used empirical measurements of accuracy, precision, sensitivity, specificity, and error rates to evaluate the fitness of the image stream hashing method.

The validation study examined image stream hashing accuracy, precision, and reliability in predicting the contents of compared images. The study also evaluated the method for errors or limitations. In addition, the research also examined the need for image stream hashing standards controlling method operations. The quantitative research method used a quasi-experimental approach involving over 750 tests that used the image stream hashing method to compare two images to predict similar or different image contents.<sup>4</sup> Next, six image quality assessments provided "ground truth" between the reference and questioned images in each experiment. The results were used with a binary classification matrix to develop statistics for overall conclusion development. The research revealed that the image stream hashing method was "fit for the purpose" of determining if two image file contents were identical when using three of the five tested derivative image types. Two derivative image file types were determined not "fit for the purpose."

Additionally, using the method should only be done with implementing the proposed standards controlling the method operations developed as part of this research. Otherwise, systematic errors may develop during the method's use. Therefore, the study concluded that examiners could use the image stream hashing method for forensic science, but only if error mitigation techniques that utilize the proposed standards controlling the method operations are implemented.

### Stream Hashing; Image Stream Hashing; Data Integrity Verification

## C14 Modeling Influences on the Understanding of Digital and Multimedia Evidence (DME) by Attorneys and Digital Forensic Examiners (DFE) Within the United States Criminal Justice System

*Joseph Levi White\*, United States Army Criminal Investigation Laboratory, Forest Park, GA*

**Learning Overview:** After attending this presentation, attendees will better recognize potential influences on the understanding of DME by attorneys and DFEs, including motivation, experience, generational influences, communication, and education/training.

**Impact Statement:** This presentation will impact the forensic science community by providing a framework for better understanding how attorneys and DFEs approach and understand DME. The presented data may be used to identify areas for potential increased efficiency/effectiveness in DME-involved cases within the United States criminal justice system.

This presentation is based on the published dissertation research of the author/presenter.<sup>1</sup> As a Digital Forensic Examiner (DFE) with over 15 years of experience, the presenter has worked with attorneys on multiple cases involving Digital and Multimedia Evidence (DME). From these DFE/attorney interactions, it is believed that there is a difference between how attorneys and DFEs approach and understand DME. This research had a goal of determining potential themes that may influence the understanding of DME by attorneys and DFEs within the United States Criminal Justice System. To reach this goal, both qualitative (interviews/potential theme identification) and quantitative (questionnaires/statistical analysis) methods were utilized.

Qualitative semi-structured interviews of experienced criminal attorneys and DFEs were conducted to gather information regarding potential influences on their understanding of DME. The interview results were transcribed, and the data coded to allow for qualitative analysis. Five themes were identified from this data and are thought to play a potential role in understanding of DME by attorneys and DFEs: motivation for involvement in the criminal justice system (passion for the job, desire to work in law enforcement, monetary gain, sense of ethical obligation, and seeking justice), experience (and knowledge), generational influences (age and the CSI Effect), communication within defined roles, and education/training. A questionnaire was developed utilizing these five themes as a guide that was then distributed to attorneys and DFEs across the U.S.

Low response rates to the questionnaire were observed and will be discussed. Statistical analyses were conducted on the available survey results in relation to the five previously identified themes. Attorneys and examiners agreed on many facets of each theme. The most influential motivational factor for seeking a career as an attorney or DFE is a passion for the field. One of the most influential components to understanding DME was determined to be experience. Detractors to understanding DME included increasing age and the CSI Effect. A frequency increase in communication levels between attorneys and DFEs has the potential to affect DME understanding and case efficiency. Attorneys have higher educational levels much greater than even experienced DFEs; however, technical DME training levels (which have a greater influence on overall DME understanding) are much greater for DFEs. Attorneys tend to use online research as a primary learning method, while DFEs rely primarily on technical training. Each of the identified themes shows promise for describing influences on the understanding of DME by attorneys and DFEs within the U.S. criminal justice system and will be further discussed within the presentation.

## C15 Uncovering Ethical and Legal Issues Associated With the Rising Trend of Using Chatbots—Crime Scene Investigation and Scientific Publishing

Ankita Guleria\*, Panjab University, Chandigarh, India; Rakesh Meena, Panjab University, Department of Anthropology, Chandigarh, India; Kewal Krishan, Panjab University, Chandigarh, India; Vishal Sharma, Panjab University, Institute of Forensic Science, Chandigarh, India; Nandini Chitara, Panjab University, Institute of Forensic Science, Chandigarh, India

**Learning Overview:** After attending this presentation, attendees will understand the ethical and legal challenges associated with the rising trend of chatbots in this era of Artificial Intelligence (AI). This presentation will shed light on the issues associated with the use of chatbots in research and some professional domains such as forensic science, law, and medical science.

**Impact Statement:** This presentation will impact the forensic community by showing whether attendees should rely upon ChatGPT for the investigation of a crime and other forensic examinations due to various ethical and legal challenges associated with these chatbots. Attendees will also gain knowledge about the trend of chatbots as well as the strengths and weaknesses associated with these AI tools.

In the current era, most of the work is either guided or done by algorithms or machines. The concept of AI is not new. AI emerged some time ago but currently, AI-based machines/algorithms have become more efficient and advanced. These systems are being utilized in various domains such as academics, business, government, health care, etc. Chatbots are one of the wonders of AI. These are artificial conversation entities simulating conversations over the internet.<sup>1</sup> These chatbots interact with humans through natural language processing. Chatbots are gradually gaining popularity across various domains due to their capacity to simulate human conversations and the need for less effort. The time taken by these chatbots to respond to every single prompt is just a matter of seconds. A chatbot was recently introduced in November 2022 by OpenAI (i.e., ChatGPT) and gained millions of users within a week.<sup>2</sup> This chatbot became a hot topic of discussion in the internet world. After the launch of ChatGPT, more than 200 other chatbots have been released. Chatbots can generate essays, poems, letters, email writing, streamline written language, etc. depending upon the user's query prompted in the chat interface.

The present study focused on the ethical and legal challenges associated with the use of chatbots in scientific publishing as well as in crime scene investigation. In this study, the responses obtained from ChatGPT were analyzed for every prompt given to it. After thorough analysis, the strengths and weaknesses of this chatbot have been analyzed as well as how this technology can be misused by criminals.

The results of the study indicate that the information provided by ChatGPT is not always authentic and accurate. Various experiments have been performed relating to crime scene investigation and scientific paper writing. ChatGPT was prompted to suggest a method of deciphering chassis numbers in vehicles. The responses obtained from ChatGPT were not satisfactory. In one of the experiments, when the ChatGPT was prompted to write a narrative review on advancements in forensic science, the references generated by the ChatGPT were not accurate. This may be due to the fact it has been trained on the data available on the internet such as Wikipedia, books, news articles, blogs, etc. through September 2021. We are familiar with the fact that most of the information available on the internet may be fake and may have misinformation, rumors etc. So, can this tool be used in scientific publishing and crime scene investigation? If yes, then there will be no transparency, and the circulation of misinformation will be everywhere.<sup>3</sup> Moreover, a human cannot differentiate whether the text is written by a human or AI.<sup>4</sup>

In this study, some case studies related to ChatGPT have also been discussed. Therefore, this study tends to raise awareness among forensic scientists, medicolegal experts, and the scientific community to avoid the use of chatbots for solving medicolegal cases, crime scene investigation, writing case reports, and scientific publications. This study also recommends developing some stern ethical and legal guidelines and policies for the use of AI tools such as ChatGPT in forensic research and practice.

---

## C16 The Case of the Distracted Pedestrian: The Importance of Experts in Digital Forensics

Jason R. Lewis\*, CyForce, Inc., Lakeland, FL

---

**Learning Overview:** After attending this presentation, attendees will better understand the importance of not solely relying on forensic tools and the need to validate the data being presented. Additionally, attendees will learn more about messaging apps in general, particularly Marco Polo, and what artifacts these applications leave in an iOS® environment.

**Impact Statement:** This presentation will impact the forensic science community by providing details on examining an iOS®-based device for evidence of the usage of messaging apps in general and Marco Polo in particular.

Recently, our firm was contracted by a law firm representing the estate of a deceased individual. This person was a well-known resident of a mid-sized city and was struck by a motor vehicle while crossing the road. The question in dispute was, while crossing the street, was this individual actively using the Marco Polo app on their iPhone® and was thus “distracted” by the phone? The local police department had examined the victim’s iPhone® and “officially determined” that they were actively using a Marco Polo at the time of the collision. Thus, they were partially at fault for the collision that occurred. This question is so important because, like most states, the state where the collision occurred happens to be a “comparative fault” state, specifically a *modified comparative negligence* state, which means if the victim is found to be at fault, it could reduce the civil liability of the driver.

While examining the data, one curious fact stood out: the microphone, camera, and speaker of the iPhone® were never activated during the collision. The detailed logs and databases that make up the “pattern of life” on an iPhone® show in immense detail what is being utilized on an iPhone® and when. For example, it logs when the microphone is activated, where the output audio is sent (speaker, Bluetooth®, headphone jack, etc.), and when the camera is turned on. These logs did show that the Marco Polo was running, but it didn’t show that any of the usual hardware was being utilized while it was running.

After a thorough search of the literature, it was determined that research on this application was non-existent. Still, similar applications did show the camera, microphone, and speaker activation when used to play or record video messages. This led the author to conduct a scientific experiment utilizing the same model of iPhone® and the same version of iOS® to determine if the microphone, speaker, and camera activation was recorded when using the Marco Polo application.

This presentation will show the results of the subsequent research to show what data is captured by iOS® databases and logs and how this data can be utilized to show if video messaging apps are being actively used or running in the background.

---

**Social Media; Mobile Device; Traffic Accident**

## C17 The Potential for Impacting Unsolved Case Outcomes With the Inclusion of Digital and Multimedia Evidence (DME) Forensics Into Cold Case Units

*Joseph Levi White\*, United States Army Criminal Investigation Laboratory, Forest Park, GA*

**Learning Overview:** After attending this presentation, attendees will understand the way technological advances may greatly impact data access and extraction capabilities in cold cases involving DME. This presentation will provide an outline of some of these advancements and provide examples of the potential enhancement of Cold Case Units (CCUs) through the incorporation of updated DME capabilities.

**Impact Statement:** This presentation will provide an outline of how technological advances made over time have greatly impacted data extraction/duplication capabilities, especially within mobile device forensics. This presentation will impact the forensic science community by providing insight into the potential for increasing investigative leads within CCUs through the incorporation of DME forensic capabilities.

A “cold case” may be described as an unsolved crime that is expected to remain unsolved until new evidence or investigative leads are discovered/obtained. CCUs have been developed by investigative/law enforcement agencies for the purpose of reviewing case files, conducting additional interviews, and resubmitting original evidence for additional forensic analysis. These evidence resubmissions often involve requests for analysis based on advancements in science and/or technology that have been made since the crime was committed and originally investigated. The largest focus for evidence resubmissions has been due to advancements made in DNA (deoxyribonucleic acid) analysis, such as detection/extraction capabilities, sensitivity advancements, genetic genealogy, mitochondrial DNA analysis, and the greater availability of DNA databases for comparison/familial searches. Additional advancements in forensic science traditionally highlighted as affecting cold case outcomes include anthropology/biology (such as cause of death determinations and facial feature reconstruction) and latent prints (such as advancements in latent print detection/visualization and increased database search availability/functionality). However, advancements made in DME should not be overlooked.

Personal use of mobile phones increased beginning in the 1990s. With time, mobile device (cellular phone, tablet, and laptop computer) manufacturers and software developers have implemented hardware and software security features designed to protect these devices from unauthorized access and protect the data maintained within them. These features include hardware charging/data port modifications, knowledge-based locks (Personal Identification Number [PIN] and pattern locks), fingerprint sensors, and facial recognition (face-ID). Unfortunately for forensic examiners and law enforcement, these advances often prevent access to data maintained on devices submitted for data extraction and analysis. Depending on the security features enabled on the device at the time of laboratory submission, the ability to extract usable data from the device may be severely hindered or not possible.

Therefore, DME forensics is required to constantly evolve to account for each mobile device software and/or hardware security update. Data shows that, with time, digital forensics capabilities have been able to provide methodologies for bypassing these security features and gaining access to data maintained within these devices. Technological advancements related to data extraction have made data accessible on devices that just a few years ago would be considered completely inaccessible to most digital forensic examiners. A review of the most popular mobile devices will be provided in a timeline, listing current capabilities for device data extraction for multiple device types. This information will be used to highlight the potential benefit for the inclusion of digital forensic capabilities in CCUs to assist in unsolved crime investigations.

---

## C18 A Study of Digital Evidence (DE) Processing Efficiencies in Publicly Funded Crime Laboratories

*Christopher L. Williams\*, RTI International, Clayton, NC; Peyton Attaway, RTI International, Oak Island, NC; Hope M. Smiley-McDonald, RTI International, Research Triangle Park, NC; John H. Grassel, RTI International, Apex, NC; Crystal Daye, RTI International, Research Triangle Park, NC; Nichole D. Bynum, RTI International, Research Triangle Park, NC*

---

**Learning Overview:** After attending this presentation, attendees will be informed about a study to evaluate DE processing in the United States. The study data comes from DE crime laboratories and corresponding law enforcement agencies to assess allocation of resources, interagency communication, and DE evidence management and retention practices.

**Impact Statement:** This presentation will impact the forensic science community by explaining how, due to the rise in DE processing, crime laboratories and their law enforcement professionals are implementing strategies for triaging, processing, and managing DE.

As the usage of electronic devices rises, so does the need to process these pieces of evidence in criminal investigations. As such, the desire for data-driven evidence to advance the field of DE processing is stronger than ever. This study aimed to understand the areas in which DE crime laboratory and law enforcement professionals are experiencing their biggest challenges. Surveys were administered to DE crime laboratories and their law enforcement partners between February 2022 and March 2023. Respondents were asked about agency resources (e.g., budget, staffing), annual processing metrics of various DE types, interagency coordination, and DE submission, processing, and retention. Responding agencies included 32 crime laboratories with digital evidence sections and 24 law enforcement agencies. A purposive subset of DE crime laboratories and their law enforcement partner agencies were then selected for in-depth qualitative interviews.

Uncovered through the quantitative surveys, nearly half of DE laboratories did not have a policy for triaging DE, and about two-thirds did not have a policy on DE retention. On average, crime laboratories not accredited specifically for DE processing received 2.5 times the amount of testing requests that the DE-accredited crime laboratories did. The qualitative interviews revealed a consensus for DE-specific training and the need for more funding allocated for DE processing. Overall, these are just a few of the key takeaways from the evaluation that was conducted. Additional insights regarding submission, processing, and retention practices will be shared from the paired crime laboratory-law enforcement interviews.

This study is one of the first to examine the DE processing landscape in a multi-method approach and will serve as a foundation to uncovering the needs resulting from an incredibly high-paced evolution in the criminal justice system. The study findings enhance our understanding of how forensic digital professionals are promoting justice and maintaining scientific integrity amidst their quickly changing field.

---

**Crime Laboratory; Digital Evidence; Survey**

## C19 Standards Development Activities in Digital and Multimedia Forensic Science

*Tracy Walraven\*, DC Department of Forensic Sciences, Minneapolis, MN*

**Learning Overview:** After attending this presentation, attendees will have a better understanding of the status of discipline-specific standards pertinent to the field of digital and multimedia forensic science.

**Impact Statement:** This presentation will impact the forensic science community by creating greater awareness of standards development activities pertinent to digital and multimedia issues. This presentation will also increase awareness regarding training, tools, and resources that support implementation, compliance monitoring, and broader understanding.

The Organization of Scientific Area Committees (OSAC) for Forensic Science was created to strengthen the nation's use of forensic science by promoting the use of discipline-specific forensic science standards. To this end, the OSAC drafts standards that are forwarded to Standards Developing Organizations (SDOs) that further develop and publish them. The OSAC also reviews standards and recognizes them on the OSAC Registry, which serves as a central repository of high-quality, consensus-based, technically sound standards.

During this presentation, updates related to digital and multimedia standards development will be discussed. These include: (1) recent standards that have been added to the OSAC Registry; (2) OSAC proposed standards; (3) published standards from the American Society for Testing and Materials (ASTM) and other authoritative bodies that have yet to go through the Registry approval process or are currently undergoing the approval process; (4) priorities for new documents or work products, and other highlights; and (5) projects undertaken by working groups within the digital evidence subcommittee, specifically the new Data Sets Library project, the newest work surrounding privacy and digital evidence. The Data Sets Library project is a catalog of artifacts that can be used as a reference for the digital forensics' community during investigations. The Privacy and Digital Forensics paper explores the line between the examiner and evidence, with the consequences for the examiner if privacy is breached. Opportunities for supplemental training related to discipline-specific standards will be presented, as well as additional resources and tools designed to facilitate gap analysis, compliance monitoring, and outreach efforts. This presentation centers around the efforts of the Digital Evidence Subcommittee within the OSAC. As the Scientific Working Group on Digital Evidence (SWGDE) is now considered an SDO, the OSAC DE's efforts in combination with SWGDE is also highlighted as part of providing the best guidance for the digital evidence community.

### Digital Evidence; Standards; Mobile Device

## C20 What's VITAL When It Comes to Digital/Multimedia Standards? An Update From the OSAC Video/Imaging Technology & Analysis (VITAL) Subcommittee

*Christina A. Malone\*, OSAC, Smyrna, GA; Marla E. Carroll\*, OSAC/VITAL, Plantation, FL; Melissa Kimbrell, Amped Software USA, Inc., Manor, TX; Neil F. Johnson\*, OSAC/VITAL, Vienna, VA; Michelle Montonera, Boulder County Coroner's Office, Arvada, CO*

**Learning Overview:** After attending this presentation, attendees will have an understanding of the Organization of Scientific Area Committees (OSAC) Registry Process and the current work being conducted within the VITAL Subcommittee.

**Impact Statement:** Standards and their implementation are essential to ensuring the sound practice of forensic science across all disciplines, including digital and multimedia sciences. This presentation will impact the forensic science community by offering information on the current and upcoming OSAC standards in the areas of video analysis, image analysis, and photography.

The OSAC for Forensic Science “works to strengthen the nation’s use of forensic science by facilitating the development and promoting the use of high-quality, technically sound standards by the forensic science community. These standards define minimum requirements, best practices, standard protocols, and other guidance to help ensure that the results of forensic analysis are reliable and reproducible.”<sup>1</sup> OSAC forensic science disciplines are spread across seven major Scientific Area Committees (SACs). Video/Imaging Technology & Analysis (VITAL) is one of four disciplines that report to the Digital/Multimedia SAC (DMSAC). The three other disciplines include Digital Evidence, Facial ID, and Speaker Recognition. VITAL specifically focuses on creating and promoting standards related to methods and technologies used to analyze images. This includes all aspects from the capture of images or the acquisition of data to the processing of image or video files to the reporting of an opinion. To address the multifaceted nature of imagery, VITAL has task groups devoted to video analysis, image analysis, photography, and most recently, an exploratory task group on gait analysis.

Within OSAC, there are several processes in place to ensure relevant standards are developed and promoted. Both OSAC Proposed Standards and Standards Development Organization (SDO)/Standards Setting Organization (SSO) Published Standards are eligible for on the OSAC Registry. The processes in place for each of these types of standards will be discussed to provide an overview of OSAC operations.

Additionally, the OSAC partnerships with SDO/SSOs within the forensic community are key for the development and publication of standards. The standards within VITAL have generally come from and go to the American Society of Testing and Materials (ASTM) as an SDO. The Scientific Working Group on Digital Evidence (SWGDE) has also recently been approved as an SSO. SWGDE documents are eligible for the registry approval process and OSAC-proposed documents are able to move to SWGDE for publication. This presentation will discuss the interactions and steps needed for these organizations to work together on standards within the forensic multimedia community.

Finally, the current work products within VITAL will also be highlighted. Topics of these documents include: laboratory photography, postmortem photography, photogrammetry, image comparison opinions, digital video workflows, photography of scars/marks/tattoos, digital image management, synthetic media, image/video authentication, and relevant training for the applicable disciplines. The status of these documents, the impact they will have, and the next steps they will take will provide attendees with an understanding of what is being done to address the standards needs within image analysis, video analysis, and photography.

## C21 The Integration of Forensic Science and Artificial Intelligence: The Implications in Crime Scene Investigations

Nandini Chitara\*, Panjab University, Chandigarh, India; Damini Siwan\*, Panjab University, Institute of Forensic Science and Criminology, Chandigarh, India; Kewal Krishan, Panjab University, Chandigarh, India; Ankita Guleria, Panjab University, Chandigarh, India; Vishal Sharma, Panjab University, Institute of Forensic Science, Chandigarh, India; Rakesh Meena, Panjab University, Department of Anthropology, Chandigarh, India

**Learning Overview:** After attending this presentation, attendees will have learned the relationship and implications of Artificial Intelligence (AI) (deep learning and machine learning) in forensic science and criminal investigation. Additionally, attendees will be able to learn the AI models (i.e., neural networks [CNN, ANN, TINN], Support Vector Machines [SVM], Linear Regression [LR], Logistic Regression [log R], and Random Forest).

**Impact Statement:** This presentation will impact the forensic science community and criminal investigative agencies by providing ease in the investigative process by significantly reducing the time of investigation and increasing the accuracy of various evidence analyses with the aid of AI. Moreover, this presentation will explain the AI methods to extract information to a greater extent from crime scenes and analyze the forensic evidence with different AI approaches.

From its origin in a summer research workshop at Dartmouth College, NH, in 1956 to recent intelligent machines and chatbots, AI has fueled the fields of health care and medicine, agriculture, marketing and finance, engineering, transport, cyber security, neuroscience, logical reasoning, statistical analysis, disaster management, military services, national security, etc. Additionally, these AI tools have vast applications in criminal investigation. The primary objective of forensic science is to scientifically help in crime scene and medicolegal case investigation. The recent advances in scientific methodologies of evidence analysis fulfill the primary objective of forensic science. However, the integration of AI can possibly speed up the process of identification and evidence analysis and make the work of investigators closer to a higher accuracy.<sup>1</sup> For instance, the identification of future possible modus operandi can be accomplished through the technique of machine learning-based “Pattern Recognition” by feeding the machine with a large dataset of previous crime patterns. Moreover, AI (deep learning) can identify the perpetrator/victim/suspect of a crime, international criminals, drug peddlers, poachers, and terrorist from the images captured in Closed-Circuit Television (CCTV) by finding the matches against the large datasets without any biasness. Moreover, “Classification Models” of supervised learning can be used in the estimation of sex, population affinity, time since death, fingerprint and impression analysis, identification of diatom, handwriting identification, classification of firearms, bullets, and drugs, etc. Additionally, regression models can be utilized in age estimation, anthropometric studies, DNA analysis, and forensic odontological research.<sup>1-3</sup> For instance, PredPol software identifies the risk-associated locations and time (AI-based geospatial modeling) where crime is most likely to occur. Based on datasets on type, location, time, and date of crime, risk areas are identified and patrolling officers can be advised to patrol these specific locations.<sup>4</sup> Yuan utilized multi-task learning (machine learning) in criminal law for judgment prediction, recommendations of relevant laws, and analysis of legal documents with high accuracy.<sup>5</sup> Moreover, AI has also proven powerful in restricting money laundering through the detection of unusual transactions by introducing probabilistic retina.<sup>6</sup>

For this presentation, scientific literature was searched from various national and international research publications using online platforms and databases. The standard indexing agencies such as PubMed®, PubMed Central®, Embase®, Scopus®, Medline®, Cochrane®, and Web of Science® were searched. The key words used to search the relevant literature and research publications include “artificial intelligence in forensic science,” “artificial intelligence AND forensic science,” “artificial intelligence in criminal investigation,” “artificial intelligence AND criminal investigation.” After thorough screening of the titles and abstract, relevant literature was included in the study.

The present communication concludes that AI holds a bright future in criminal investigation and identification. The low accuracy, reliability, and speed of evidence analysis can be defeated by the introduction of AI in forensic examinations and research. AI can overcome the error and biasness prone in human judgments and evidence analysis and can provide a more reliable criminal justice system.

### Forensic Science; Artificial Intelligence; Crime Scene Investigation

## C23 Live Memory Acquisition for STM32-Based Microcontrollers with ARM TrustZone

*Karley Waguespack\*, Louisiana State University, Baton Rouge, LA; Aisha Ali-Gombe, Louisiana State University, Baton Rouge, LA*

**Learning Overview:** This presentation will give an overview of a memory acquisition tool developed for STM32-based microcontrollers. Attendees will learn how ARM TrustZone technology can be leveraged to securely obtain microcontroller memory dumps for forensic analysis. Specifically, this presentation will discuss how STMicroelectronics' HAL API was leveraged in conjunction with TrustZone to send full memory dumps of the Rich Execution Environment to a server for analysis.

**Impact Statement:** The presentation will impact the forensic science community by presenting a reliable mechanism for obtaining memory dumps from TrustZone-enabled microcontrollers. This tool can be used on Internet of Things (IoT) and other embedded devices for forensics triaging and thorough investigation of potential compromises and malfunctions.

Most currently existing memory acquisition tools for microcontrollers, such as JLink, are hardware-based. These techniques require additional equipment such as debuggers, which can be very costly. Debuggers are also often designed for development purposes rather than security solutions, making them insufficient for memory forensics applications. On the contrary, a software-based approach opens the door to automated memory forensics tools, which can be packaged directly into products. Coupling this type of memory acquisition tool with TrustZone provides a high degree of security, eliminating security concerns of exposed hardware interfaces like Joint Test Action Group (JTAG). Nonetheless, in practice, little has been done to develop such a tool, mainly due to the challenges involved in developing tools for microcontrollers, such as the strict requirement to use low-level languages like C and Assembly to interact directly with hardware resources.

Additionally, given the close interaction with hardware, tools cannot be ported to other microcontrollers without code changes that reflect the differing hardware. Thus, the overarching objective of this research is to present a generic approach for securely obtaining memory dumps for the STM32 family of microcontrollers. In addition, this work further provides a step-by-step guide to extending our methodology for developing software-based memory acquisition tools for other MCU families by discussing the overarching process.

Our proposed memory acquisition process starts with the Rich Execution Environment (REE) relinquishing its memory to TrustZone block by block. A watchdog timer mechanism is implemented to force the REE to comply. If the REE fails to submit its memory before the timer counts down, a device reset will be performed, ridding the device of malware or malfunctions that may be interfering with the process. Once TrustZone has a block of memory, it sends it to a network resource and uses Transmission Control Protocol (TCP) to send it to a server. Each of the blocks is concatenated into a binary file as they are received on the server. At the end of this process, the binary file contains a complete memory dump that can be used for forensic analysis and/or triaging. Throughout the acquisition process, technologies like DMA and SPI are used for optimization. TCP is used to securely transmit the dumps across the network, and a message protocol was added to tightly monitor the data and protect against signal injection. Last, since this entire process is carried out by TrustZone in an isolated region of the Central Processing Unit (CPU), malicious actors cannot use the tool to obtain firmware dumps, thereby improving the overall security of the process.

### Memory Acquisition; IoT; Microcontrollers

## C24 Live Memory Forensics of Field Devices in Industrial Control Systems

Irfan Ahmed\*, Virginia Commonwealth University, Richmond, VA

**Learning Overview:** After attending this presentation, attendees will understand the challenges of live memory forensics in field devices in Industrial Control Systems (ICS) and further explore a practical method of performing this task reliably on field devices such as programmable logic controllers to acquire and analyze volatile memory data on-demand, including process stack and firmware data structures. This presentation will also present experimental results on a real-world Programmable Logic Controller (PLC) to show the effectiveness of the proposed method.

**Impact Statement:** This presentation will impact the forensic community by discussing a new live memory forensic investigation method for field devices in ICS to investigate cyberattacks on power grid stations, nuclear plants, and other critical infrastructure. Physical access to the devices is required to read entire device data at the hardware level for further analysis. Proprietary engineering software provided by device vendors can also acquire device data remotely. However, this method is constrained by the engineering software functionalities not designed to support forensic data acquisition and can only acquire limited device data such as control logic and Input/Output (I/O) data; attackers can target device firmware and other parts of the memory, which are typically not accessible through engineering software.

ICS control and monitor power grid stations, nuclear plants, and other critical infrastructures. When ICS environments are under attack, the digital forensic investigation will help identify compromised field devices and understand attacker vectors.<sup>1</sup> Since these devices are supposed to work continuously 24/7 to control their attached physical processes in real time, they cannot be shut down. Thus, live forensics of these devices is a practical solution to perform a quick investigation while they are operational.

Programmable Logic Controllers (PLCs) run control logic in scan cycles to monitor and control physical processes continuously. These control logic programs are run as binary machine code and can be accessible and updated by design through engineering software. Our approach leverages this PLC's common design feature to develop live memory forensic capabilities at the device level.<sup>2</sup> Mainly, it attaches (installs) a benign code at the end of a control logic using ICS protocols to run continuously as part of the scan cycle. The code reads requested memory regions and copies them to an area accessible through PLC's network protocol. It allows accessing of any PLC memory region on request for further analysis. For instance, return-oriented programming attacks on PLCs manipulate the PLC stack.<sup>3</sup> Our approach can read the stack pointers and make them available to read remotely.

This presentation will provide a case study on a real-world PLC to demonstrate the proposed solution as practical and reliable. It will also discuss the scalability of the proposed approach since PLCs are heterogeneous and may have different microcontrollers affecting the underlying machine instruction set for the benign code attached to the control logic, such as Schneider Electric's Midcon PLC series uses RX630, and Allen Bradley's ControlLogix uses ARM. The potential solutions to handle heterogeneous instruction sets include cross compilers to have the code compiled from ARM to RX630 or MIPS to RX630. This presentation will provide examples to address scalability.

## C25 Provenience-Based Cross-Verification of Digital Forensic Artifacts Applied to NTFS

Alex J. Nelson\*, National Institute of Standards and Technology, Gaithersburg, MD; Sheldon L. Douglas, National Institute of Standards and Technology, Gaithersburg, MD

**Learning Overview:** This presentation will demonstrate a methodology for comparing the subject data exploratory coverage of two digital forensic processes that share some in-common goals in their reporting. After attending this presentation, attendees will better understand the distinction between identifiers, and identifying characteristics, when describing artifacts recovered and interpreted in the course of digital forensic analysis. Attendees will see how two metadata summary languages, Digital Forensics XML (DFXML) and Cyber-investigation Analysis Standard Expression (CASE), can implement a strategy to compare the results of two file system analysis tools and how a previous implementation of the strategy had relied on an artifact of unstable referential integrity, showing a need for using identifying characteristics with less chance of ambiguity.

**Impact Statement:** This presentation will impact the forensic science community by demonstrating cross-verification of digital forensic tool results and how choice of artifact identifiers can impact the ability to compare results algorithmically.

In digital forensics, file system analysis is a precursor task to event reconstruction. Often, unallocated content within a file system is content of interest to an investigation, and thus recognition, extraction, and ascription of unallocated files are typical intermediary steps en route to interpreting file system contents. The results of this general workflow form comprise a set of intermediary results worth cross-verification, due to potential impact on later interpretations of initial evidence. However, unallocated files often lack stable identifiers, presenting subtle challenges that can foil algorithmic comparison.

Unallocated content recovery requires careful understanding of the storage medium, or storage format, from which the content is recovered.<sup>1</sup> This work focuses on a model of a file system where an allocated file's definition comprises at least three key dimensions: the data structure housing its metadata such as timestamp and owner, often referred to as an inode; the data structure compactly housing its location within the file system's namespace, often implemented as a directory entry; and the range within the file system that houses its contents, which may be discontinuous.<sup>2</sup>

Prior work has used this model to implement differential analysis, both for comparing changes in a file system's state across time and across parse results when using multiple tools against the same subject image.<sup>3,4</sup> While the three-dimensional file model enables comparison of allocated content with seemingly little difficulty, some attempts to verify some POSIX-required characteristics of the allocated content show a weakness in the three-dimensional model that impacts interpretation of allocated and unallocated files.

We present a strengthening of the three-dimensional model, emphasizing a geometric representation of the three file dimensions as a first-order concern. This pattern extends in applicability beyond file system analysis but is presented initially in the context of New Technology File System (NTFS) file system analysis. We demonstrate corrections over a model improvement previously proposed by Casey et al. and show results from extending two independently developed open-source tools to enable geometric comparability between their NTFS results.<sup>1</sup> Using the tool-agnostic languages Digital Forensics XML (DFXML) and Cyber-investigation Standardized Analysis and Expression (CASE), the geometry-based identifier strategy corrects a previous measurement of unallocated content.<sup>5,6</sup>

## C26 Testing File Carving Tools

*James R. Lyle\*, National Institute of Standards and Technology, Mount Airy, MD; Barbara Guttman, National Institute of Standards and Technology, Gaithersburg, MD*

---

**Learning Overview:** After attending this presentation, attendees will be made aware of resources provided by the National Institute of Standards and Technology/Computer Forensics Tool Testing (NIST/CFTT) for testing file carving tools and some of the limitations and challenges for testing such tools for carving files from unallocated storage space.

**Impact Statement:** This presentation will impact the forensic science community by increasing awareness in the community of available resources for testing file carving tools. This presentation will aid forensic practitioners in using the test protocol and materials created by NIST/CFTT and using provided tools to develop materials that can be used for testing of file types not included in the NIST materials.

Extraction of digital evidence from digital systems is dependent on software to interpret and present relevant data. The courts need assurance that any testimony based on software is scientifically sound and reliable. The *Daubert* guidelines list testing as one of several criteria for the court to consider before deciding admissibility of evidence in court.

CFTT has been developing test methods for testing forensic tools for more than 20 years. About a decade ago, we produced a file carving methodology and applied it to ten graphic file carvers and eight video file carvers. We are releasing an updated version that adds new graphic (HEIC) and video (MKV) file types, simplified some aspects of the process, added tools for the user to create custom data sets as needed, and are incorporating the new test methodology into Federated Testing (see the CFTT web site).

The general process is to collect a set of six to ten source files of each file type to try to carve. For basic testing, two acquisition image files are created that are like an acquisition of unallocated space. The acquisition files contain content from the source files separated by varying amounts of other recognizable filler content. The layout of one acquisition file is to place each source file as one contiguous chunk followed by some amount of filler data. The layout of the other basic test image is to break each source file into several fragments with filler added between each pair of fragments. All blocks are aligned on 512-byte boundaries as a real data file would be placed by a file system. The two image files are then carved by the tool being tested and the results analyzed.

Results are analyzed by a pair of measures. The first measure is a visual inspection and classification into categories of *No Observed Defects*, *Minor Defects - Still Useful*, *Major Defects - Not Useful* and *Not viewable*. The second measure is an analysis of the source of each block of data in the carved object classified as follows: Source file, known filler, or unknown data.

Other file layouts are available for testing for scenarios such as files not aligned on sector or cluster boundaries and other file fragmentation layouts (fragments out of sequence, two files braided together or missing fragments).

---

### Digital Evidence; Software Testing; File Carving

## C27 The Latest Developments in Sailfish OS Forensics

*Krassimir T. Tzvetanov\*, Purdue University, West Lafayette, IN*

---

**Learning Overview:** The goal of this presentation is to acquaint attendees with a mobile phone Operating System (OS) that is not very popular but has significant importance from a geopolitical standpoint.

**Impact Statement:** With the ongoing conflict in Eastern Europe and the tension escalating in the South China Sea, it is important to understand the technologies a belligerent is using. This presentation will impact the forensic science community by bringing awareness to a mobile phone OS that has managed to gain popularity on those markets without being noticed in America.

SailfishOS is a Linux® kernel-based embedded device OS, mostly deployed on cell phones. It is rapidly deployed in BRICS countries such as Russia, China, and India. In Russia alone, the government has mandated the replacement of all Android™ and iPhone® devices in favor of their SailfishOS version called AuroraOS. In India, the OS is deployed by a couple of the major network providers, and in China, Huawei is investigating it as an Android® replacement, as economic tensions with the United States rise.

While popularity and adoption is growing, there is no sufficient research in this space, so it is likely for investigators to encounter it in the field.

Three years ago, we presented a mapping of forensic artifacts for SailfishOS 3.2. Since then, the OS has developed and has introduced robust support for Android® applications. In this presentation, we will go over what has changed in the way data and settings are stored and show the mapping of new digital artifacts, which are pertinent to an investigation or incident response. We will cover call logs, text messages, Wi-Fi Network settings, SIM card management, cellular network artifacts, location services, address book, email, browsers, and other important artifacts, and a large number of other artifacts. In addition, we will present how this platform runs Android® software packages, how they affect the system, and what forensic artifacts they leave.

Apart from our other work, there is no other known publicly available research in this space, and the commercially available solutions for acquisition and analysis of this platform are lagging. This is a major gap, as this OS' adoption is accelerating in emerging markets on low-cost devices. This presentation documents many of the major forensics' points of interest such as call and text, log, phonebook, and web browser artifacts as well as hardware specific features.

## C28 Deep Audio Analyzer: A Framework to Industrialize the Research on Audio Forensics

Valerio Francesco Puglisi\*, University of Catania, Catania, Sicilia, Italy; Sebastiano Battiato, University of Catania, Catania, Sicilia, Italy; Oliver Giudice, Banca d'Italia, Roma, Lazio, Italy

**Learning Overview:** After attending this presentation, attendees will be familiar with various audio deep learning techniques. This presentation will attempt to present existing deep learning solutions to analyze audio with state-of-the-art deep learning models without the need to develop code via the Deep Audio Analyzer framework. Attendees will gain useful information to analyze audio in different contexts through this powerful technology.

**Impact Statement:** This presentation will impact the forensic science community by demonstrating the potential of the proposed tool “Deep Audio Analyzer,” a framework based on Deep Learning Neural Networks, to demonstrate the importance of using recent Deep Learning models in the audio domain for conducting audio enhancement processes, automatic multilingual transcriptions, speaker verification, and voice activity detection, whose performance cannot be achieved by examiners using classical methods of audio forensics. After attending this presentation, attendees will understand how to improve specific aspects of audio analysis in the forensic domain compared to classical methods. Attendees will also learn how to employ this tool not only for stand-alone model usage, but also for combining them to achieve novel audio analysis processes that can be easily shared with the scientific community, thereby improving the reproducibility of conducted experiments.

Forensic audio, a subcategory of forensic acoustics, has taken on an increasingly prominent role in the field of law enforcement, criminal investigation, and justice over the past few decades. This specialized branch of forensic science, dedicated to the capture, analysis, and interpretation of audio recordings within the context of legal investigations, has enabled the provision of decisive evidence in an ever-increasing number of legal cases.<sup>1</sup>

Audio forensic investigations focus on three core aspects: authenticity, enhancement, and interpretation. Ensuring the authenticity of audio recordings is crucial as investigator deductions rely on the recording conditions. Examiners must validate the chain of custody, detect intentional tampering, and prevent accidental modifications. Audio enhancement is commonly requested to address non-ideal acoustic environments, emphasizing features of interest for court presentations. Interpretation involves reconstructing timelines, transcribing dialogs, and identifying unknown sounds, considering other evidence and testimonies.<sup>2</sup> Recently, applications of novel deep learning solutions to forensics investigations have experienced unprecedented growth in interest and obtained results, with many researchers developing innovative algorithms and models to solve these complex problems.<sup>3-7</sup>

However, reproducing published experiments and results remain a significant challenge due to the needed programming skills required. This challenge is further compounded by the lack of (or an extremely limited) standardization in the way experiments are conducted. This issue results in a significant amount of time being spent by researchers trying to get other researchers’ code to work, which leads to a significant waste of resources.

The development of speech-processing technologies has been largely driven by open-source toolkits.<sup>8-12</sup> With the emergence of general-purpose deep learning libraries, more flexible speech recognition frameworks have emerged as well as hubs where scientists load trained models for others to download.<sup>13-25</sup> While it can be challenging for non-experts users to prototype new deep learning methods, it requires knowledge of coding and environmental setup.

The present study aims to fill this gap by examining what are the main Deep Neural Networks that can help the Audio Forensic field in a better way than the traditional methods. The objective of this research is to provide a tool that covers enhancement and interpretation, which are part of the three main goals of Audio Forensics and to provide a tool that integrates these new technologies and enables users to visualize audio features, evaluate the performance of pre-trained models, and create new audio analysis workflows by combining deep neural network models.

Using Deep Audio Analyzer, examiners and researchers can perform these features without the need to develop any code. The tool also provides dedicated modules to test state-of-the-art models on customized data and combine models to create a new Deep Learning audio processing pipeline, combining for tasks such as Automatic Speech Recognition, Speech Enhancement, Speaker Separation, Speaker Verification and Voice Activity Detection.

## C28 Toward Personal Internet-of-Things User Attribution During Forensic Investigations

Shinelle Hutchinson\*, Purdue University, West Lafayette, IN; Umit Karabiyik, Purdue University, West Lafayette, IN

**Learning Overview:** After attending this presentation, attendees will have gained a comprehensive understanding of the application of machine learning in the digital forensics field to facilitate user identification. Attendees will learn how device handling can be leveraged as a new and effective method of identifying users during forensic investigations. Moreover, attendees will be introduced to a novel, privacy-preserving method of achieving user identification of Personal Internet-of-Things (PIoT) device owners through machine learning and simple mandatory actions.

**Impact Statement:** This presentation will have a profound impact on the forensic science community by introducing a groundbreaking approach to attributing specific pieces of digital evidence to individual users based on their handling of PIoT devices. As smart phones and wearables are increasingly prevalent in criminal cases, this novel method opens up new possibilities for Law Enforcement Officers (LEOs) to ascertain whether evidence found on a device was generated by the device owner or by someone else. This crucial distinction can help prevent wrongful accusations and convictions, safeguarding innocent parties from being wrongly implicated due to device misuse or unauthorized access.

User identification, the process of recognizing individuals based on various unique characteristics, has gained prominence with the widespread use of PIoT devices. These devices collect extensive user data, enabling the creation of unique user profiles. However, further experimentation is needed in creating user profiles using IoT data. Previous research on user identification within IoT has primarily focused on continuous identification or authentication, utilizing either physiological data such as heart rate or gait or non-physiological and behavioral data such as location data, screen touches, and accelerometer, gyroscope, and magnetometer data<sup>1,2</sup>. These studies mainly aimed to develop an identification method that could be integrated into other technologies or take place after training with the user performing prescribed actions.<sup>3,4</sup> Yet, the sensitive nature of this data, such as heart rate or location history, calls for protective measures or alternative identification methods, especially during Digital Forensic Investigations (DFI), where users may be reluctant to share their PIoT data due to privacy concerns. A plausible solution lies in the use of less sensitive, non-physiological data, thus minimizing Personally Identifiable Information (PII) exposure.

Despite the numerous security and privacy issues surrounding IoT technologies, the influx of these devices continues unabated. IoT devices have become deeply embedded in all aspects of human life, including government agencies, corporate settings, domestic environments, and now, through smart phones and wearables, they have become an integral part of our personal existence. Personal IoT devices can collect incredibly intimate levels of user data. For instance, a smart watch can monitor and record metrics such as heart rate, skin temperature, physical activity, and even geographical position. Simultaneously, a smart phone can access a broad range of user-specific information, including text messages, social media activity, browsing history, and app-specific data. Given the volume and detail of data these PIoT devices capture, they have become invaluable resources during forensic investigations. Nevertheless, it is crucial for digital forensic investigators to ascertain, with a high degree of certainty, that the data procured from these devices genuinely belongs to the alleged owner and not an alternate individual.

The focus of this presentation is to highlight the effectiveness and importance of applying machine learning to Digital Forensics for the benefit of the public, law enforcement, and the judiciary. To achieve this, the current research provides an inaugural exploration of utilizing PIoT device handling for user identification, implementing machine learning models to support forensic inquiries. The study explores the use of non-physiological sensor data from PIoT devices to record users' device-handling movements about the time a smart phone is unlocked and a smart watch is attached to the wrist. The results suggest that this approach is highly effective in distinguishing device owners, exhibiting performance metrics of .9621, .9618, and .9753 in terms of accuracy, F1-score, and Area Under Curve (AUC), respectively, when applied to smart watch data. On the other hand, the models using smart phone data showed performance that was marginally satisfactory, with accuracy, F1-score, and AUC values of .8577, .8560, and .8891, respectively. With further research to build and improve on these results, this method of user identification may one day be beneficial to LEOs. Furthermore, as this method addresses an essential aspect of user identification in the context of digital forensics, it has the potential to set new standards and best practices in the field. Its implications will extend beyond individual cases, guiding the development of more robust and sophisticated methodologies for future investigations. By reducing the risk of wrongful accusations and convictions, this innovative approach could play a vital role in upholding the rights of both victims and suspects, ensuring that justice is served with greater precision and integrity.

## C29 The Impact of Multi-Camera Smart Phones on Source Camera Identification

Stephanie Reinders\*, Center for Statistics and Applications in Forensic Evidence, Ames, IA; Danica M. Ommen, Iowa State University/Center for Statistics and Applications in Forensic Evidence, Ames, IA; Alicia Laura Carriquiry, Center for Statistics and Applications in Forensic Evidence, Ames, IA

**Learning Overview:** After attending this presentation, attendees will better understand how camera identification methods perform on images taken on recent models of multi-camera phones.

**Impact Statement:** This presentation will impact the forensic science community by exploring the impact of multi-camera phones on the error rates of source camera identification methods. The large authenticated multi-camera phone image database used for this research will be available and free to the forensic science community sometime next year.

An investigator has a questioned image from an unknown source and wants to determine whether it came from a camera on a person of interest's smart phone. This scenario is referred to as *source camera identification*. Researchers Lukas, Fridrich, and Goljan discovered that slight imperfections in the photosites of a camera's sensor array act as an identifying feature or *camera fingerprint* in this scenario.<sup>1</sup> They showed that in most circumstances, these imperfections in the sensor array carry through the image-capturing process and remain in the noise level of the image's pixel values, where it is unnoticeable to the human eye but detectable through computer processing. Source camera identification methods capture reference images with the person of interest's camera, extract the *noise residuals* from each reference image, and average the noise residuals to estimate the camera fingerprint. The noise residual of the questioned image is used to estimate the unknown source camera. Then, the two camera fingerprints are compared. With only a few exceptions, previous work in source camera identification relied on image datasets comprised solely of images from Digital Single-Lens Reflex (DSLR) cameras or the main rear cameras of mobile phones. Nowadays, most major smart phone brands offer a front-facing selfie camera and two or more rear cameras.

The Center for Statistics and Applications in Forensic Evidence (CSAFE) recently purchased ten iPhone® 11 Pros, ten iPhone® 12 Pros, ten iPhone® 14 Pros, ten Samsung™ Galaxy Note 10s, ten Samsung™ Galaxy S20s, and ten Samsung™ Galaxy S21s. These 60 phones have a front selfie camera, a telephoto camera, a wide-angle camera, and an ultra-wide-angle camera. CSAFE collected 100 flatfield and 100 natural scene images from each camera on each phone to build a large, authenticated image database. This database will be made available for free to the forensic science community. We used this image database to develop and explore source camera identification methods on multi-camera phones. This presentation will focus on our insights from this research.

## C30 Research and Development of the Next Generation Digital Forensic Image Transmission Tool

Kevin Fairbanks\*, The MITRE Corporation, McLean, VA; Mark Guido, The MITRE Corporation, McLean, VA

**Learning Overview:** As the state of digital media continues to evolve, so must the tools used to process, transmit, and store that data in a forensically sound manner. This presentation will present the research, development, and initial testing of a methodology for transmitting digital forensic images (e.g., phone images, hard drive images) over resource-constrained networks with the goal of optimizing usage of the available bandwidth to transmit unique data first. The presenters will review several design trade-offs and initial testing results of the prototype.

**Impact Statement:** This presentation will engage the forensic community in an impactful discussion of the best method, including, but not limited to, protocol selection to transmit data from one geographic location to another by presenting an early state prototype. The overall aim is to develop a better open and freely available tool that takes advantage of current technology and changes the way forensic images are transported over networks going forward.

The MITRE Image Transmission Tool (MITT) is envisioned as a novel way to send digital forensic images from one geographic location to another, particularly in resource-constrained environments. It combines techniques from Periodic Mobile Forensics (PMF) and block hashing in a client-server architecture with the aim of only sending data that is unique.<sup>1-5</sup>

Forensic imaging often requires accessing a device and reading its contents at the highest level of privilege that is feasible during an acquisition. In situations where it is possible to acquire a physical image of a device, the storage medium is read from beginning to end without the content being interpreted by any software or firmware on the target device. This enables the recovery of deleted file contents in many cases. In situations where it is only possible to acquire a logical image, the contents being read could be filtered through device firmware and/or Operating System (OS) software layers. This can lead to a situation where deleted contents may not be recoverable or only a partial image of a device is able to be obtained.

After imaging is completed, it may be necessary to transport the image to a different geographic location for processing either through physical or digital (i.e., network) means. Physically transporting an image can generate the most throughput as multiple petabytes of data can easily be shipped in a manner of days. The drawback to this method of transportation is the potential for a great amount of latency between when an image is created versus when it can be analyzed. Digitally transporting an image could significantly reduce the latency of receiving small images; however, transmitting massive amounts of data can actually require more time than physical transmission while saturating the bandwidth of a communications link.

PMF addresses the imaging and transmission problem by using an application of rapid differential forensic imaging to only collect and transmit information from a device that is unique. From a file layer of abstraction, this means that only unique files on a device would be collected while system files and media files previously seen on another devices (e.g., jpgs, pngs, etc.) would only be noted but not imaged or transmitted. This drastically decreases the collection time. Furthermore, cryptographic hashes can be employed to ensure that a precise image is reconstructed on the receiving side of a PMF transmission both on a per file as well as per device image basis. The PMF approach can also be extended to work on a per device or file system block level. Further research has been conducted into storage of the forensic images as sparse files to save space on a forensic server.

## C31 Poses and Grimaces: Challenges for Automated Face Identification Algorithms?

Petra Urbanova\*, Masaryk University/Department of Anthropology, Brno, Jihomoravsky Kraj, Czech Republic; Dominik Cerny, Masaryk University/Department of Anthropology, Brno, Jihomoravsky Kraj, Czech Republic; Tomas Goldmann, Brno University of Technology, Faculty of Information Technology, Brno, Jihomoravsky Kraj, Czech Republic

**Learning Overview:** After attending this presentation, attendees will have learned the challenges of state-of-the-art face identification algorithms. Attendees will be acquainted with performance results obtained on images with different head poses and facial expressions.

**Impact Statement:** This presentation will impact the forensic science community by demonstrating the effects of two behavioral factors (head pose and facial expression) on the performance of automated face identification systems.

Forensic image identification is based on the assumption that images can convey information about a person's identifying characteristics. While any aspect of physical appearance (motion, body build, stature, clothing) can be processed, facial appearance is the most common identifying feature. Nowadays, image identification tasks are gradually being automated and are therefore the subject of many machine learning algorithms, with Convolutional Neural Networks (CNNs) being the leading strategy. From the perspective of everyday forensic expertise, automation offers several advantages. It reduces the time required to process a large number of images, increases accuracy, and eliminates the human factor. Its quantitative nature provides the necessary scientific basis, testability, and a quantifiable probability of error—all critical requirements for a method to be considered applicable in forensics.

However, the performance of automated forensic image identification is susceptible to many factors. The constantly changing behavioral characteristics of the captured subjects (e.g., pose, expression, disguise) have been repeatedly cited as major challenges. In addition, the complicated and hidden nature of automated algorithms creates the black-box problem that prevents a complete understanding of the algorithm and its outcomes unless various real-world conditions are thoroughly tested.

This study tests two state-of-the-art face identification algorithms, ArcFace and SphereFace, and examines two factors known to complicate face processing, facial expressions and head pose.<sup>1,2</sup>

The tested sample consisted of an array of 3D faces that varied in nine different prototype facial expressions, including a neutral face. The dataset was collected from 41 participants, 13 males and 28 females of European descent, aged between 19.96 and 50.89 years. Prior to image processing, 3D models were automatically converted to 2D color images (256x256px). For 3D faces with neutral expressions, a set of nine images/individual was created with viewpoints that varied by 5° from left to right (yaw) and from up to down (pitch). These images formed the probes. In addition, a second set of 3,610 images/individual was created with viewpoints varying in 5° increments from -45° to 45° in both head movements and with different facial expressions. These images formed the targets.

The probes were compared with each target in the pair-wise manner and a dissimilarity score was recorded. A total of 54,615,690 pairwise comparisons were computed (53,283,600 eliminations and 1,332,090 matches). The performance of the tested algorithms was evaluated using Receiver Operator Curves (ROCs). Area Under the Curve (AUC), specificity, sensitivity rates, and likelihood ratios were calculated. In addition, scores and ROCs were tested in relation to facial typicality/uniqueness, biological sex, facial expression, and head pose. To explore the effects of head rotation, angles were expressed as sine and cosine values and treated as covariates.

The results showed that minor deviations of the head from the standard position in probes had little effect on the performances. In some cases, a slight movement to the right or left even led to better results than when the probe image was in a frontal position. Dissimilarity scores were consistently higher for males than for females across all studied factors. For head poses, AUCs decreased as targets deviated from the frontal head position. In general, right-to-left movements were less influential than up and down, as was downward pitch compared with upward movements. The lowest AUC of 0.631 was obtained for upward pitch at 45°.

For upward movements, performance rates in females were consistently poorer than in males. This discrepancy starts at 15°, where the ROCs for females and males reached 0.875 and 0.988, respectively, and continues as the performance rate worsens. Of the facial expressions tested, the best performance was associated with happiness and contempt, while disgust exhibited the lowest AUCs.

## D1 Technology Advances in Crime Scene Investigation

*Massimiliano Esposito\*, Department of Medical, Surgical and Advanced Technologies “G.F. Ingrassia,” University of Catania, Catania, Italy; Giuseppe Li Rosi, Institute of Legal Medicine, Department of Medical, Surgical and Advanced Technologies “G.F. Ingrassia,” University of Catania, Via Santa Sofia 87, Bldg B, Block 10, 90123, Catania, Italy; Elisa Pappalardo, University of Catania, Catania, Italy; Monica Salerno, University of Catania, Catania, Italy*

---

**Learning Overview:** The goal of this presentation is to demonstrate the importance and utility of 3D reconstruction in crime scene investigation, to assess the manner and cause of death, and all the data required in a judicial trial.

**Impact Statement:** A picture says more than a thousand words! It conveys a message more clearly and leaves less room for alternative interpretation than a verbal report, where the listener has to visualize in their own mind the narrative event and has to re-adjust constantly as the report progresses. Details might easily be omitted or wrongly imagined. This presentation will impact the forensic science community by imparting that graphic presentations, in particular 3D models, certainly produce a better common basis between the viewer and the interpreter.

In the death scene investigation, the forensic pathologist or medical examiner is the official primarily responsible for a complex act to reconstruct the dynamics of a crime scene. The main objectives of forensic medicine are freezing or fixation of the crime scene, findings, collection of traces, technical assessments, biological samples collection, and records of the crime scene investigation. Traditional methods of documentation of death scene include photography, sketches, notes, electrostatic lifting, or casting as well as field forms and video footage. An alternative, supplemental method of documenting transient evidence may be the three-dimensional (3D) laser scanner. The term “three-dimensional imaging” refers to techniques that can process accurate internal 3D data by obtaining volumetric pixels (or voxels) of the measured target. 3D imaging can generate high-resolution 3D digital images; laser scanners are available in both hand-held and stationary units.

**Case Series:** Four significant crime scene investigations were performed with the help of the laser scanner Leica® BLK360, from the Department of Forensic Pathology at the University of Catania from January 2019 to June 2020. The reconstruction is based on a comparison of the generated, real data-based 3D models and deals mainly with the geometric evaluation of the impact situation; with subsequent reconstruction in three dimensions through the specific software dedicated Autodesk® Recap™ Pro.

**Case 1:** A 35-year-old man, who was working on a “carrier car” cargo ship, was hit by a truck during a storm while executing an inspection of a flooded deck.

**Case 2:** A 34-year-old man suffered from anxiety and depression and was found on the ground in the inner court of his building about 7:00a.m. on February 20, 2019.

**Case 3:** An old homicide case that was the result of a robbery in a jewelry store.

**Case 4:** An 86-year-old man with a history of diabetes, leukemia, and both cardiac and respiratory disease, was found dead in his apartment. He suffered from depression caused by the death of his wife and his son.

In Case 1, the use of the Leica® BLK360 laser scanner enabled in only a few hours the creation of a complete diagram scale of the crime scene, allowing the rapid restitution of the ship to the judicial police officer. In Cases 2 and 4, the clarification of suicidal occurrence instead of a homicidal one was the focus of the investigation. By the study of the open spaces, internal courtyard, and balcony’s apartment of the subject (Case 2), as well as the distances between the bloodstains and the corpse (Cases 2 and 4), and the close position of the gun with the corpse (Case 4), it was possible to prove that there were no assault lesions on the body, in consideration of the circumstantial data and the findings of the judicial survey. Therefore, the study of the crime scene is essential for the investigation. In Case 3, the Leica® BLK360 laser scanner enabled the piecing together of the dynamics of the crime and, despite the obvious limitations of the case, it was possible to prove the matching of the bullet trajectory and the escape route. The 3D videos reconstruction will be presented.

---

## Digital Evidence; 3D Technology; Crime Scene Investigation

## D2 A Method for the Evaluation of Upper Rear Vehicle Structures

*Chris Clarke, PE, SAFE, Goleta, CA; Brian Herbst, PE\*, SAFE, Goleta, CA*

**Learning Overview:** This presentation explores three real-world rear impact crashes resulting in intrusion into the vehicle occupant compartment and serious or fatal injuries. In addition, several testing methodologies capable of generating comparable levels of structural deformation are presented.

**Impact Statement:** This presentation will impact the forensic science community by exploring passenger vehicle rear impact case studies and presenting methodologies for evaluating the crashworthiness of rear structures.

In rear impact collisions, larger striking vehicles may override the rear structures of smaller vehicles even if their bumpers align. Research shows Sports Utility Vehicles (SUVs) are twice as aggressive as passenger cars, while large vans and pickups are three times as aggressive.<sup>1</sup> These larger vehicles comprised less than one-quarter of vehicles produced in the 1970s and have grown to currently encompass over two-thirds.<sup>2</sup>

There are no regulations for structural performance or occupant protection in rear impacts. The government implemented a rear impact crash test for fuel system integrity in 1976. This test was conducted using a rigid barrier at 30mph with full overlap of the impacted vehicle.<sup>3</sup> The standard was upgraded in 2004 with an increased energy level, a deformable barrier, and only 70% overlap.<sup>4</sup> While the upgrade was a significant improvement, this regulatory test is limited in scope to the fuel system, which is located at or below the level of the bumper. Neither version of the standard addresses override, intrusion, or occupant protection. Some manufacturers have relied on internal rear impact testing requirements dating back decades that include offset barrier and vehicle-to-vehicle impacts to ensure occupant protection.<sup>5</sup> Despite this, a safety gap in the vehicle structures above the level of the bumper exists in many vehicle designs.

Three case studies have been evaluated, and each studied vehicle was found to have no significant energy-absorbing rear structures above the level of the bumper.

**Case 1:** A 2010s sedan was rear-ended by an SUV. The right rear occupant sustained fatal injuries as a result of intrusion. The structural members at the bumper level were overridden and relatively undeformed.

**Case 2:** A 2000s sedan was rear-ended by an SUV. The right front passenger sustained fatal injuries as a result of intrusion into the occupant space. This collision had a lesser degree of override.

**Case 3:** A 2000s coupe was rear-ended by an SUV. The right rear passenger sustained permanent injuries as a result of intrusion.

Quasi-static testing was utilized to evaluate the upper rear vehicle structures of the vehicles involved in Cases 1 and 2. A platen was pushed 46 inches into the upper structures of the test buck, generating a peak force of 21,000lb and a crush energy of 39,000ft-lbs. The damage pattern was similar to the Case 1 vehicle. Another test buck was modified with the addition of high-strength steel cladding and structural void-filling foam to reinforce the structures above the rear bumper. These modifications created an additional structural load path through the upper rear structures above the level of the bumper. When subjected to the same quasi-static crush test, the modified test buck absorbed 41,000ft-lb of energy with 22 inches of displacement. The stiffness of the modified test buck was more than double that of the production design. In addition, the intrusion was generally confined to the structures aft of the occupant compartment, resulting in minimal intrusion.

A full-scale rear impact test pair was conducted on a production vehicle and a second vehicle modified with the same reinforcements used in the quasi-static testing. Each vehicle was subjected to a 50mph 50% overlap rear impact with a sedan. The production test generated minimal override but resulted in 11 to 12 inches of intrusion at the rear seatback. The modified test vehicle sustained just 4 inches of intrusion measured at the rear seatback. In addition, the reduction of intrusion demonstrates the alternative design structure improves crash performance in rear impacts with compatible vehicles in addition to reducing susceptibility to override.

### Rear Impact; Accident; Crash

## D3 Rear Impact Crashworthiness Defects Proven by Forensic Analysis Combined with Static and Dynamic Testing: The Failures of Seats, Head Restraints, and Belts

Mark C. Pozzi\*, Sandia Forensic Sciences, Edgewood, NM

**Learning Overview:** The goal of this presentation is to demonstrate how and why a catastrophic child head injury was caused in a moderate rear impact with all vehicle occupants seated upright and properly restrained. The mechanics of the collision, the predictable failure of the front seats, head restraints, and belts, and the biomechanical trauma consequences for the front-seated adults and rear-seated children are demonstrated. Forensic analysis of physical and medical evidence, static seat testing, and dynamic sled testing are combined to prove how and why these injuries occurred. Safer alternative seat and belt designs from the same automaker are compared with Original Equipment Manufacturer (OEM) seats and belts, proving that the failures and injuries were readily preventable.

**Impact Statement:** This presentation will impact the forensic community by providing specific insight into not only how to properly investigate such vehicle crashes, but also the predictable failures of weak seats, unsafe head restraints, and slackened seat belts that are rendered useless. The biomechanics of catastrophic head injuries to children due to these predictable seat and belt failures are demonstrated. A series of dynamic sled tests show the significant improvements in occupant protection that were ignored by the automaker, despite the availability of their own safer alternative designs. The testing proved that the automaker did not meet their own internal corporate safety standards for seats and belts in a rear impact.

In moderate to severe rear impacts, predictable safety defects often cause restrained vehicle occupants to be significantly more vulnerable to catastrophic injury and death than in vastly more severe frontal impacts, all else being equal. This is due to no vehicle rear impact occupant safety regulations, and the “flawed and inadequate” Federal Motor Vehicle Safety Standard (FMVSS) 207 that allows weak seats that predictably fail, while also causing the front seat belts to slacken and fail. FMVSS 208 requires that vehicle occupants be protected from significant injury in frontal impacts of 30mph barrier equivalent. Since 1979, the New Car Assessment Program has tested vehicles at 35mph frontal barrier equivalent, and Insurance Institute for Highway Safety (IIHS) has tested vehicles in 40mph offset frontal crashes. The results of these far more severe crash tests are published, and automakers have responded by making significant improvements in frontal and side crashworthiness, to maintain sales. There has been no corresponding improvement in rear or rollover crashworthiness, despite the rear impact vector being the easiest in which to protect vehicle occupants, but only if the seat remains upright and maintains the occupant within their designated upright seating position.

This is a case study involving forensic accident reconstruction, biomechanical injury evaluation, and vehicle crashworthiness analysis, as well as static and dynamic testing to prove how and why a restrained child incurred catastrophic head injury in a readily survivable rear crash. A compact SUV stopped in traffic was struck in the rear by a medium truck, resulting in a moderate 21mph rear collision with a peak average crash pulse of 11-12G. Two adult females were seated upright and properly belted in the SUV front seats, and two children were seated upright and properly belted in child seats in the second-row seats. The 4-year-old left rear child incurred significant head injury when struck by the head of the driver, when she catapulted rearward because of predictable failures of the driver seat and vehicle-anchored belt. There was a corresponding laceration to the left occipital-parietal area of the driver’s head. The 6-year-old right rear child incurred moderate head injury when struck by the detached head restraint, and/or probable contact by the head of the right front passenger as she catapulted rearward due to front seat, head restraint and belt failure.

The predictable failures of both front seats, slackening of belts, and detachment of one head restraint caused the front occupants to ramp rearward head-first into the rear occupant survival space, with no effective restraint by the slackened belts. Absent the front seat failure and concurrent belt slackening, there would have been no inter-occupant contact, let alone significant injury, to any vehicle occupants in this collision. The front seat belts were equipped with pretensioners, which did not activate in rear impact.

The SUV rolled to a stop with no occupant compartment intrusion. All injuries occurred solely due to loss of rear survival space caused by front seat and belt failure. The automaker claimed that the seats “could not have failed because its corporate seat performance test was met, therefore there could be no defects in the vehicle.” The corporate sled test supposedly required there be no inter-occupant contact between a belted 50%-ile male and a 3-year-old child in the rear seat, in a “25mph Delta V, 15 G crash pulse,” which is significantly more severe than the subject collision. The forensic investigation and testing proved that the vehicle clearly did not meet its own corporate crash test requirements. It was also proven that the automaker already produced far safer alternative design seats in similar vehicles of the same and older vintage.

### Rear Impact; Failure Analysis; Head Trauma

## D4 Mapping Vehicle Headlights to Identify the Threshold of Human Visual Performance in a Nighttime Visibility Study

*Jorge Mendoza\*, Litigation Animation, Inc, San Jose, CA*

**Learning Overview:** After attending this presentation, attendees will understand how we mapped a vehicle headlight pattern in the field that defines the threshold of human visual performance. Attendees will also learn how a computer light simulation was performed to define diffuse lighting in a nighttime environment. Attendees will see how real-world light specifications (Illuminating Engineering Society [IES]) are used to illuminate a 3D model and how reflectance and transmittance material properties scatter and diffuse the light throughout the scene using a computer-rendering algorithm called radiosity.

**Impact Statement:** This presentation will impact the forensic science community by explaining the relationship between finite element analysis heat transfer algorithms and light simulation algorithms.

A nighttime visibility study was performed involving a pedestrian struck by a vehicle entering a parking spot near the back entrance to a big box store. The pedestrian was struck by the left front corner panel of a mid-size Sports Utility Vehicle (SUV) truck. Rainfall was light, and there was minimal lighting in the parking lot. The main source of light was from the turning vehicle's headlights. The collision reconstructionist provided the vehicle dynamics for the turning maneuver to the point of impact. An exemplar vehicle was obtained to perform headlight light measurements. An isolated environment was located to identify the headlight profile at 0.3-foot candles (the threshold at which human visual performance degrades).<sup>1</sup> The headlight profile was mapped at each of three elevations: zero feet, three feet, and six feet above grade. From these readings, a 0.3-foot candle distribution profile for the vehicle's headlights was created. At 0.3-foot candles, there is degradation in contrast sensitivity, color recognition, depth perception, visual acuity, and conspicuity. Acuity and contrast sensitivity are critical for visual recognition.<sup>2</sup>

The incident site was laser scanned and a model of the building, vehicle, and pedestrian was constructed in 3DS Max. VRayIES was also used to perform a photometric light simulation of the environment. Photometric lights use Illuminating Engineering Society (IES) files that contain the lights distribution profile. The IES file contains complete specifications of real-world light bulbs. VRayIES can accurately replicate physical lighting conditions that can be calibrated to real-world light measurements. The real-world materials' reflectance properties were measured with a light meter and applied to the corresponding materials contained within the models. The IES light specifications for each light in the scene were documented and applied to the corresponding lights. The VRayIES light simulation was then examined to evaluate the overall light levels from the driver's position.<sup>1</sup>

The 0.3-foot candle headlight distribution profile of the truck was combined with the photometric simulation within 3DS Max to produce an animation/simulation exhibit that showed the movement of the pedestrian from the sidewalk to the point of impact. The animation exhibits demonstrated what was available to be seen by the driver pulling into the parking stall, and that the pedestrian was struck outside the 0.3-foot candle headlight distribution profile. The results of the nighttime visibility analysis show that the pedestrian was struck in an area where the driver's visual performance was degraded.

### 3D Technology; Simulation; Visualization

## D5 An Experimental Analysis of How Non-Nominal Sitting and Pyrotechnic Seat Belt Pretensioners Interact

Adam Goodworth\*, Westmont College, Santa Barbara, CA

**Learning Overview:** After attending this presentation, attendees will be informed about non-standard sitting and how this can impact forensic analysis and injury. Attendees will learn about the standard pyrotechnic pretensioner that is deployed in many crashes (physical pretensioners will be shared with attendees). Attendees will appreciate how 3D motion capture can be used to track kinematics in humans. Finally, attendees will understand how a pretensioner physically impacts a forward-leaning occupant and how body size and belt fit may play a role.

**Impact Statement:** A better understanding of the interaction between an occupant and their seat belt is important for understanding injury mechanisms in many real-world crashes. The pretensioner is ubiquitous, but to my knowledge, no research study has yet described the kinematic responses following deployment in live subjects. The pretensioner has the potential to physically move an occupant and change their posture early-on in a crash event, which could have a direct effect on the type of injury that is sustained. Moreover, the forensic science community will benefit from understanding how body size and belt fit impact the response to a pretensioner deployment.

When analyzing an occupant's injury from a vehicle crash, the starting posture and interaction with a seat belt is often an important factor in the analysis. Occupants (especially passengers) may adopt non-standard sitting postures. Recent research indicates non-standard sitting may be very common and associated with a heightened injury risk.<sup>1-5</sup> Therefore, the study experimentally investigated the interaction of one common non-standard sitting posture (forward leaning) with a seat belt pretensioner deployment. Seat belt pretensioners are installed on nearly all vehicles. When deployed, they pull out about 8–15cm of slack from the belt very quickly. Pretensioners are typically deployed at the same time as airbags, and many vehicles also deploy pretensioners in rear crashes independent of airbags. While previous studies tested pretensioners on cadavers and dummies, it is observed that pyrotechnic deployment on live subjects has not been published. This presentation will first describe the inner working of pretensioners, outline non-standard sitting, and summarize experiments where the hypothesis was tested that a dual pretensioner could reposition forward-leaning subjects and characterized the influence of body size and initial belt fit.

Nine young and active subjects were tested because a pyrotechnic pretensioner provides a large force to the pelvis and torso. Subjects ranged from 50–110kg. Six were male. The D-ring location was adjusted for each subject to normalize the belt geometry across subjects. Each subject donned the belt in their typical manner. The subjects then leaned forward 26cm from C7 to the seat. At a semi-unexpected time, the outboard anchor pretensioner and retractor pretensioner were deployed. The subjects' kinematics were quantified through reflective markers on 12 bony landmarks. 3D kinematics were reconstructed with a nine-camera motion capture system. To explore the effect of initial belt tightness, a subset of four subjects were also tested with the belt pulled tight across the pelvis with removal of as much slack as possible prior to the deployment. The test order (typical vs. tight) was random for these four subjects.

For all nine subjects during the normal belt fit condition, there was a stereotypical pattern initially following deployment. During the first 50ms, the trunk (measured at C7) moved backward at a velocity that was dependent on body size (i.e., larger subjects moved significantly slower than smaller subjects). The subjects moved backward about 7cm (range of 4.6–8.1cm) at about 160ms. During this period, trunk rotation in the transverse plane occurred from asymmetrical loading of the belt onto the trunk. Specifically, the right shoulder of the passenger (nearest to the D-ring) was initially pulled back 4cm farther than the left shoulder. After the initial pull-back motion (about 160ms), all subjects slightly rebounded. After this 160ms, there was high inter-subject variance in responses. In the subset of four subjects where belt tightness was explored, the tight belt was associated with less inter-subject variance (more stereotypical responses) during the initial trunk movement (tight=8.7% coefficient of variation vs. typical=26%). Due to the small sample size, no metrics were significantly different between the tight and typical belt tests, although all four subjects had about 20% lower peak chest velocity (measured at the sternum) during the tight belt test.

The results show that the average forward-leaning person was pulled back about 7cm with the dual pretensioner deployment in the current study. The stereotypical pattern during the first ~160ms provides investigators new information about how current pretensioners influence head and trunk motion when occupants are leaning forward. Moreover, these results may help in validating crash simulations where pretensioners are included and may encourage other researchers to test pretensioners with live humans.

## **D6 Photogrammetry Software Used to Survey Site, Map Tire Friction Marks, and Recreate the Driver's View in Support of Alternative Collision Scenarios**

*Kurt D. Weiss\*, Case Study Collision Science, LLC, Santa Barbara, CA; Jorge Mendoza, Litigation Animation, San Jose, CA*

**Learning Overview:** The goal of this presentation is to share with the forensic science community how the photogrammetric analysis of collision scene photographs was used to correctly determine vehicle impact positions, assist in the creation in exhibit animation, and support alternative driver actions that were argued could have mitigated injuries sustained in a high-speed tractor-trailer versus a Sports Utility Vehicle (SUV) collision.

**Impact Statement:** This presentation will impact the forensic science community by stimulating thought while presenting an approach to collision analysis when tire friction marks are not fully documented on scene by law enforcement investigators when performing a comprehensive traffic collision reconstruction.

The driver of an SUV was stopped at the limit line of a T-intersection, awaiting traffic to clear before commencing a left turn onto a rural highway. Approaching from the left was a fully loaded tractor-trailer weighing nearly 78,000 pounds. Believing there was sufficient time to clear approaching traffic, the SUV driver accelerated across the near-side lane.

The tractor driver observed the stopped SUV. Anticipating its forward acceleration, he tapped the brakes to deactivate the cruise-control that was set to 57.5mph. When the SUV suddenly accelerated forward, the tractor driver applied the brakes, but also steered to the left. The SUV was struck when it was nearly straddling the highway center line.

The SUV was salvaged before the Event Data Recorder (EDR) could be imaged; however, the tractor's Engine Control Module (ECM) was interrogated. The ECM Hard Brake data was used to determine speed and position of the tractor up to impact. Tractor tire marks confirmed leftward steering before impact, however, the SUV's post-impact tire marks, while visible in several photographs, were not fully documented by law enforcement.

Three photogrammetric software packages and techniques were used to determine the SUV's movement and position from impact to rest. The collision site was documented with a drone, and Pix4D photogrammetry software was used to create an optical scan. PF Tracker software was used to track the camera movement of a video camera mounted at the eye height of the tractor driver.<sup>1</sup> The collision scene photos were analyzed using the survey in 3D Studio Max to reconstruct the collision scene camera's focal length, position, and orientation. Next, the reconstructed cameras and collision scene photos overlaid on the survey were used to locate the tire friction marks on the survey and rest positions of both vehicles.<sup>2</sup> 3D Studio Max compiled the results, and with ECM data, an animation of the collision event from the tractor-trailer driver's perspective pre-impact to rest was also created. This included aerial views of the incident.

The collision reconstruction accurately determined the collision pair's time-position history to impact. Four other collision scenarios based on the tractor driver's alternative actions were presented: (1) holding steering wheel straight, (2) steering to the right, (3) applying brakes sooner, and (4) reducing travel speed to 55mph, resulting in a favorable settlement.

## **D7      Recreational Vehicle Crashworthiness: Enhanced Injury Caused by Unsafe Vehicle Interior Structures Combined with Predictable Seat and Belt Failures**

*Mark C. Pozzi\*, Sandia Forensic Sciences, Edgewood, NM*

**Learning Overview:** The goal of this presentation is to introduce a forensic field investigation that has been conducted to identify the cause and effect of common, and dangerous Recreational Vehicle (RV) designs as well as static and dynamic testing that discovered the failure mode of seats and belts, as well as the predictable extreme hazards of unpadded interior structures. Safer alternative seat, head restraint, and belt restraint designs were discovered that would have prevented hazardous occupant contact with the unpadded force-concentrating structures. Dangerous force-concentrating structures should be reduced in lethality and should not be located where occupant contact will likely occur in otherwise survivable crashes.

**Impact Statement:** This presentation will impact the forensic science community by showing that these severe hazards commonly exist in RVs, why they exist, how they create enhanced injury, and how those injuries can be prevented using lightweight, economically and technologically feasible means to protect vehicle occupants. Vehicle crash investigators and pathologists will learn how to identify recreational vehicle seat and belt failure, vehicle interior occupant contact witness marks, and associated forensic evidence that will allow more accurate assessment of occupant injuries in such circumstances.

Seat and belt failure in rear impact has been known to cause severe injury and death to both front and rear seat occupants. Unpadded rigid interior structures located within predictable occupant contact zones exacerbates these hazards. A case of predictable enhanced head injury was discovered in a recreational vehicle where a multi-position seat without head restraint and lap-only belt failure was combined with rigid, unpadded force-concentrating structures in the vehicle occupant compartment. The causation of these enhanced injuries was proven by a combination of accident reconstruction, human surrogate testing, and dynamic sled testing. Prevention of injury by lightweight, technologically and economically feasible means was also demonstrated.

It has been known since the 1940s that lap-only belts can cause fatal injuries, and lap-only belts have been banned in Australia and much of Europe since 1972. It has been known since 1958 that human rear impact tolerance of 83G without significant injury can be achieved if a crashworthy seat and head restraint is utilized. Head impact into narrow, force-concentrating structures can result in skull fracture, brain injury, spinal injury, and death at much lower load levels than if those same structures were adequately padded, contoured, or otherwise modified to reduce their lethality. To reduce or eliminate such injuries, Federal Motor Vehicle Safety Standard (FMVSS) 201, Occupant Protection from Interior Impact, has been part of the Code of Federal Regulations related to vehicle crashworthiness since 1967, with updates in the 1990s. It has required certain interior structures within the range of occupant contact zones to be effectively padded, flattened, rounded, and otherwise made less lethal when contacted by vehicle occupants, whether belted or unbelted. Therefore, dash panels and other vehicle interior trim is padded, and this is why narrow, projecting controls and other structures have been eliminated in the forward areas of passenger vehicles for decades. These requirements are not applicable to the rear occupant seating areas of RVs, however, due to loopholes in very lax safety regulations.

Several contradictions to the well-known foregoing occupant protection principles have been discovered in late-model recreational vehicles, in which unpadded, force-concentrating structures have been placed into the predictable path of vehicle occupant heads and upper torsos that are allowed to catapult rearward or sideways because of obvious, predictable seat and belt design deficiencies and failures. RV safety regulations permit lap-only belts and do not require head restraints for anything other than the front outboard seats. They also allow side-facing seating while the vehicle is in operation. These dangerous conditions have resulted in enhanced catastrophic injuries to vehicle occupants that would otherwise not have occurred if the seat had been in a forward-facing position, was crashworthy enough to remain reasonably upright, was equipped with an effective head restraint, and had an effective belt restraint system. Unless the seat remains upright, the belts and head restraints are not effective at protecting the occupant. The absence of energy-absorbing padding and the multitude of rigid, force-concentrating structures in the rear of the recreational vehicle interior exposes occupants to these extreme hazards even while wearing the ineffective lap-only belts while seated in low-back seats.

The reason that these dangerous conditions are occurring in late-model recreational vehicles is that there are no effective occupant protection standards for such vehicles, especially because there are no dynamic seat or belt performance standards for rear impact, and there are no requirements for equivalent padded structures in the rear of vehicle interiors like those found in the front seating areas per FMVSS 201.

### **Rear Impact; Head Trauma; Failure Analysis**

## D8 Visibility Study Uses Camera Tracking Software to Analyze Dashcam Video in a Bicycle Collision

Jorge Mendoza\*, *Litigation Animation, Inc, San Jose, CA*

**Learning Overview:** After attending this presentation, attendees will know how to identify a High Dynamic Range (HDR) environment and the steps necessary to perform a visibility analysis. Attendees will also learn how to use match-moving software to track dashcam video and reconstruct the vehicle's movement.

**Impact Statement:** This presentation will impact the forensic science community by providing a better understanding of how illumination, reflectance, and luminance are related and their impact on a visibility study.

A cyclist was traveling downhill on a southbound, two-lane road in the bike lane. Tall trees casting shadows across the roadway camouflaged the rider. The downhill grade was 7%, and the cyclist's speed was between 25–30mph. At the bottom of the hill, a northbound vehicle approached the left-turn pocket in direct sunlight. The illumination in the bike lane averaged 152 lux, whereas the illumination in the turn pocket averaged 10,500 lux, producing a medium HDR.<sup>1</sup> As the cyclist approached the bottom of the hill, two vehicles passed in the number one lane. At the same time, the northbound vehicle entered the left-turn pocket, slowed to allow the two vehicles to pass, and without stopping, turned left in front of the cyclist. The cyclist impacted the right side of the vehicle and was critically injured.

The assignment included conducting a line-of-sight visibility analysis, focused on what was available to be seen by the northbound driver and the cyclist leading up to the collision.

The scene was laser scanned and 3D models of the site, vehicles, bicycle, and cyclist were constructed using 3D-Studio-Max. The physical evidence examined included the vehicle, bicycle, dashcam video, clothing, and helmet worn by the cyclist. Reflections of the dash on the windshield were also investigated.<sup>2</sup>

Using the laser scan model in 3D-Studio-Max, the sun position (altitude of 19.6° and azimuth of 255.9°) at the time of the collision was simulated. Next, a scaled 3D model of the vehicle and driver was positioned in the left-turn pocket (sun visor down) to demonstrate that the driver's eye height and position were not in direct sunlight to be affected by sun glare.

The incident vehicle was equipped with a dashcam, which captured the cyclist seconds from impact. The dash cam was mounted under the rearview mirror in direct sunlight and produced an under-exposed video in the area of the approaching cyclist. An exemplar vehicle and dashcam were obtained for analysis and testing at the collision site under similar lighting conditions. Test results showed that the dashcam video of the collision was not representative of the lighting conditions available to the driver.

The dashcam video was also processed using Camera Tracking software to generate the necessary scene and motion data to reconstruct the collision from the perspective of both the driver and cyclist.<sup>3</sup> A focal length of 50mm was used on the real-world cameras to match the human central angle of view between 40–60.<sup>4</sup>

An examination of the scene revealed that the direct sunlight falling on the left-turning vehicle and the shadows covering the bike lane created a medium HDR condition, making it difficult to see the approaching cyclist from the turn pocket. The effects of different colored materials, reflective clothing, and a blinking light on the bike were also evaluated. Green reflective clothing and a bike light increased the cyclist's conspicuity. Illumination light measurements were made in critical areas of the scene. The luminance of the reflected clothing was also measured.

In conclusion, had the driver stopped and carefully examined the environment allowing the eyes to adapt to the low light condition, the cyclist's movement through the shadows would have been available to be seen.

### 3D Technology; Accident; Multimedia

## **D9 Slip and Fall: Methods of Simulation and Validation of a Formula**

*Darren Franck\*, Advanced Engineering Associates, Inc., Charleston, WV; Harold Franck\*, Advanced Engineering Associates, Inc., St. Petersburg, FL; Vincent D. Franck, WVU Tech, South Charleston, WV; Alexander Franck, WVU Tech, South Charleston, WV*

---

**Learning Overview:** Attendees of this presentation will gain an understanding about the underlying physics during a fall.

**Impact Statement:** This presentation will impact the forensic community by presenting more accurate depictions of slip-and-fall accidents.

This case study involves a dummy used to model a real slip-and-fall accident. Using a grid background, its trajectory can be mapped as it falls to the ground. The data can be used to determine its velocity upon impact. This data will then be compared to a theoretical equation that calculates a person's impact velocity based on their height.

The current understanding of predicting impact velocity does not accurately simulate real-world conditions, so part of this investigation entails an improvement to this understanding via the aforementioned simulation. The current methods assume that someone falls directly downward once the fall begins, a situation that can easily be modeled by equating potential and kinetic energy. This situation is not an accurate depiction as it neglects the fact that people experience rotational movement upon slipping. Since a person's fall is not purely rotational nor translational, it is believed that the velocities will be somewhere between the values calculated based on pure rotation and those from pure translation. The investigation will also account for the buckling of the knees, which expands on the model of a slender rod.

An equation has been derived based on these fundamentals, which will be proven or disproven based on the tests with the dummy. The dummy height of 5 feet 3 inches will be used to predict its impact velocity using the equation. It will impact a solid surface with no cushioning, so the dummy can only decelerate upon the compression of the skin. During the tests, the head of the dummy will be instrumented with load cells and accelerometers that will measure the g-forces acting on the dummy at the point of impact. A high-speed camera will be used to describe its trajectory and measure its impact velocity. The testing will involve multiple types of falls, which will yield varying degrees of translational and rotational movement. This procedure can also be used to model the forces that injure other parts of the body, such as the elbow, knee, and shoulder.

## D11 Counterexamples for the Use of Spectrogram Comparison as a Method of Forensic Speaker Recognition by Law Enforcement and in Courts as Evidence

Jeffrey Nathaniel Holmes\*, Boles Holmes White LLC, Birmingham, AL

**Learning Overview:** The goal of this presentation is to urge caution in using spectrogram comparison as a method of speaker identification and to provide counterexamples that show visually similar or identical spectrograms produced from different speakers.

**Impact Statement:** This presentation will impact the forensic science community by urging caution in using spectrogram comparison as a method of speaker identification.

The practicum of speaker recognition entails the specific identification of a person by voice. There are three methods: listening, viewing spectrograms, and automatic speaker recognition.<sup>1</sup>

The predominant method used in courts and in investigations is the spectrogram comparison method. The notion that a spectrogram can be used for speaker recognition began with research conducted at Bell Laboratories in the 1940s, which suggested that a spectrogram produces a unique “voiceprint” analogous to a fingerprint.<sup>2</sup> This method has been used in the American legal system since the 1960s and has been used in many cases around the world.<sup>3</sup>

The idea behind the spectrogram as a voiceprint notion is that the acoustic signals of speech, such as energy, time, and frequency, can be recorded graphically on a spectrogram and visually analyzed by humans who can then determine or exclude the identity of the speaker by comparing it to the spectrogram of a known speaker.

This method is sometimes excluded as evidence in cases due to accuracy concerns. This research argues that this is a correct result. However, upon information and belief, there are no United States jurisdictions outright barring its use. In other words, it is feasible that an individual qualified by the court as an expert may be able to proffer speaker identification evidence using the spectrogram method in all jurisdictions in the United States, which indeed occurs regularly. Additionally, the spectrogram method is used in countries outside the United States, including China, where it is recommended by the Ministry of Justice and the Ministry of Public Security Guidelines.<sup>4</sup> These spectrogram comparison services are performed by forensic consulting firms that tout the reliability of their methods, analysis, and procedures.

Spectrogram comparisons are also used by law enforcement and often performed by members of the agency, instead of by a third-party consulting firm. According to the most recent Organization of Scientific Area Committees (OSAC) Speaker Recognition Committee Current Practices in Forensic Speaker Recognition, spectrographic analysis is used by the United States government in its investigation of crimes.<sup>5</sup>

Within the legal jurisdictions in the United States, there are no uniform standards on the admissibility of speaker identification evidence. Similarly, there are no standards or best practices worldwide. Moreover, much of the practices of law enforcement internationally is classified, which presents interesting and legally complicated issues on the fundamental rights of self defense versus the competing interest of the government’s duty to enforce the law and public policy interest in preserving safety. This issue is beyond the scope of this research but incumbent on lawmakers to resolve.

This research identifies counterexamples where different speakers produce visually similar or identical spectrograms. The methods used are as follows. First, select a large audio dataset with thousands of speakers and identify instances in which different speakers spoke identical sequences of words. This research used sequences of identical words that are of equivalent audio length to the segments that are compared by forensic examiners, in accordance with their methods. Second, generate spectrograms of the identical sequences. Third, extract features from the spectrograms using a Convolutional Neural Network (CNN). Fourth, reduce the dimensions of the CNN’s output vector using linear discriminant analysis. Finally, with this new low-dimensional data, split the data into classes of the same sequence of words by the same speaker and the same sequence of words by a different speaker and using Probabilistic Linear Discriminant Analysis (PLDA), train the PLDA to maximize the probability of identifying when the same person says the same sequence of words. From there, identify counterexamples by showing instances where the model still fails.

## D12 Using Statistical Analysis to Assist with Writer Identification

Mike Wakshull\*, Q9 Consulting, Inc., Temecula, CA

**Learning Overview:** After attending this presentation, attendees will have learned a new method of handwriting identification using statistical process control for decisions of writership.

**Impact Statement:** This presentation will impact the forensic science community by introducing a new method of handwriting identification that advances the scientific foundations of questioned document examination.

Identification of handwriting relies on the document examiner's ability to discover the variability of the subject's known writing. Although qualitative assessment is prone to judgment error by the document examiner, variability in forensic document examination is often presented in qualitative rather than quantitative terms. Qualitative analysis is typically neither repeatable nor reproducible. A quantitative approach to writer identification can and should be used to reduce bias and errors in document examiners' opinions.

This presentation applies aspects of statistical process control to determine whether a writer of a known document is a potential author of a questioned document, based on such variability. Further, this presentation presents the results of validation testing using ground truth handwriting data where the writership is known and the writers were not copying but producing spontaneous handwriting.<sup>1</sup> Using this dataset, the method was applied blindly, and the statistical control decisions for identifying writers was used to calculate error rate of the method.<sup>2</sup>

Literature shows that variability of the proportions of height and width of a person's written letters and words remains stable within common cause variability across writing sessions.<sup>3,4</sup> The ratio of height and width and slant angles are established ideas in forensic handwriting identification.<sup>5,6</sup> In this method, the ratio of the height of lower case letters extending into the upper zone and height of lower case letters remaining in the middle zone is calculated. The ratios of the length of lower case descenders to the height of middle zone letters are calculated. For each calculated ratio, a run chart is created for the ratios of the known writing. The same is performed for the slant angle of a given letter.

Tests are made for comparison of letters in the same order. As an example, the words [may] and [yam] contain the same letters. Studies have demonstrated that the structure of a letter depends on the order relationship with the letter with which it is being compared.<sup>7,8</sup>

The standard deviation of the ratios or angles are computed to one, two, and three sigma. These measurements are plotted to create a control chart. The measurement of the angle or ratio of the questioned writing is plotted on the control chart to determine how the questioned writing compares to the known writing with respect to the variability of the known writing. The number of standard deviations from the mean of the known writing is explored to determine writer identification and create a threshold for the decision.

If the ratio of the given letters in the questioned writing falls beyond 2.5 standard deviations from the mean, the questioned writing is evaluated as having been written by a person other than the known writer (i.e., the decision is different writers). If the ratio falls below the 2.5 standard deviation threshold, the questioned writing is evaluated as having been written by the writer of the known sample (i.e., the decision is same writers). The result is an indicator of authorship rather than a conclusive determination, in relation to the error rate.

### Metric Analysis; Forgery; Quality Control

## D13 Linguistics, Computer Vision, and Handwriting Identification: HANDLER

Carole E. Chaski\*, *Institute for Linguistic Evidence, Georgetown, DE*

**Learning Overview:** After attending this presentation, attendees will understand how language structure and patterning affects handwriting identification, and how linguistics—the study of language structure and patterning—can serve as a foundational science for handwriting identification with tools coming from computer vision.

**Impact Statement:** This presentation will impact the forensic science community by showing a new method of handwriting identification grounded in linguistics and computer vision.

Like other pattern-matching techniques in forensic investigation, handwriting identification originated from the layman's ability, rather than originating from an underlying, established science. Due to this origin, handwriting identification has not benefited from the standard operating protocols of a normal science, and instead it has struggled to create and sustain a research agenda and to formulate protocols and standards that are empirically validated. In 1996, a meeting to develop a scientific foundation and research agenda was hosted by the National Institute of Justice (NIJ) at the National Institute of Standards and Technology (NIST), involving all federal laboratories as well as NIST researchers.<sup>1</sup> The Technical Working Group on Digital Evidence (TWGDOC), (then the **Scientific Working Group for Forensic Document Examination [SWGDOC]**, then the Organization of Scientific Area Committees Questioned Documents [OSAC QD]) was born out of this meeting, but these projects have not developed methods that are grounded in established science. This presentation shows how handwriting identification can be grounded in linguistics and computer vision, and how methods can be developed and tested on ground-truth data of spontaneously written texts by known authors.<sup>2-7</sup>

Linguistics provides principles, while computer vision provides tools of measurement. There are several reasons for deploying linguistics as a foundational science for handwriting identification, including iconicity, anticipatory co-articulation, phonotactic frequency effects, morphological segments, and function word frequency effects. Linguistics is foundational to handwriting: handwriting systems are intimately associated with the languages they represent through iconicity. For example, the strokes in Korean hangul indicate tongue position (or the articulatory phonetics) for the sounds represented by the symbol. Even the Roman alphabet has some symbols that are iconic to articulatory phonetics, such as [i] for [+high +front -round] and [o] for [+round]. Anticipatory co-articulation, a feature of acoustic phonetics, appears at the graphemic level in Roman cursive handwriting, when letter shapes are modified in anticipation of the following letter. Each language has phonotactics, or allowed sound sequences, which are reflected in the frequency effects of letter sequences. Morphological segments affect handwriting when a handwriter copies, because the handwriter typically pauses at morphemic edges. Finally, almost all languages have function words (or function morphemes) that signify grammatical relations rather than entities or actions (e.g., prepositions, determiners, conjunctions, quantifiers). Function words are a closed set of words, and they are very frequent in any text.

Likewise, Computer Vision provides tools of measurements. Manual measurement has been available for decades from Sirchie®, but this is extremely time-consuming and subject to errors from human fatigue.<sup>7</sup> Some computational tools are proprietary, such as Adobe®, but others are open source, including JMicrVision, ImageJ, and OpenCV.<sup>8-10</sup>

When measurements based in computer vision are combined with principles of linguistics, it is possible to create a new, theoretically grounded method of handwriting identification that is testable, explainable, statistical, and objective, known as ALIAS HANDLER. In particular, handwritten function words are extracted and quantified from known documents, with measurements, then statistically analyzed by discriminant function analysis, logistic regression and random forest classifiers. Results of applying ALIAS HANDLER on a ground truth dataset of spontaneously handwritten are presented, with error rates for the method reported.

## D14 Presenting Model Uncertainty to Decision Makers

Willem A. Schreuder\*, *Principia Mathematica, Inc., Evergreen, CO*

**Learning Overview:** After attending this presentation, attendees will understand that model predictions presented as uncertainty distributions are difficult for decision makers to grasp. This can lead to incorrect decisions because uncertainty is misinterpreted.

**Impact Statement:** This presentation will impact the forensic science community by presenting lessons learned in terms of how model uncertainty can bolster a case or lead to a complete misinterpretation of the science.
