PROCEEDINGS

of the American Academy of Forensic Sciences 77th Annual Scientific Conference

The *Proceedings* of the American Academy of Forensic Sciences is an official publication of the American Academy of Forensic Sciences (AAFS). It is devoted to the publication of the abstracts of technical oral papers and posters presented at the AAFS Annual Scientific Conference. These include various branches of the forensic sciences such as anthropology, criminalistics, digital evidence, forensic nursing, engineering, jurisprudence, odontology, pathology, psychiatry, questioned documents, and toxicology. Similar submissions dealing with forensic-oriented aspects of the social sciences are also included.

Please note that some of the abstracts included in the *Proceedings* deal with topics, results, and/or conclusions that are controversial. The publication of abstracts does not imply that the AAFS, its sections, or the individual section program chairs/committee members have verified or agree with the studies, results, and/or conclusions of each abstract. During the process of planning a scientific program, it is impossible to "peer-review" each abstract and presentation to the degree that is accomplished during manuscript review. Abstracts and presentations are accepted, in part, so they can be critiqued and reviewed by other scientists. Thus, a forum is created to discuss controversial issues. The views expressed in this publication are not those of the AAFS. The data and opinions appearing in the published material were prepared by and are the responsibility of the contributor(s), not of the AAFS nor its respective employees, employers, officers, and agents. The AAFS does not supply copies of meeting papers. Please write directly to individual authors to obtain copies of specific papers. Presentation of some abstracts may have been scheduled or canceled after the publication of this document.

English is the official language of the AAFS and its meetings; neither oral nor written translations will be provided.

PROCEEDINGS

of the American Academy of Forensic Sciences **February 2025**
Volume XXXI

TABLE OF CONTENTS

S1 Standards Around the World: How Is the World of Standards Influencing the Future of Forensics?

Teresa L. Ambrosius, BA, AAFS Standards Board, Colorado Springs, CO; Erin P. Forry, MS*, RTI International, Research Triangle Park, NC; Allison Getz, MS*, National Institute of Standards and Technology, Gaithersburg, MD; Christoph Hemme, DMD*, German Bundeswehr/NATO, Munich, Germany; Samiah Ibrahim, BA, BSc*, ForensInk, Ottawa, Ontario, Canada; Brian Milewski *, ASTM International, West Conshohocken, PA; Mark Mogle, BS*, U.S. Department of Justice, ICITAP, Washington, DC; Niamh Nic Daeid, PhD*, Leverhulme Research Centre for Forensic Science, University of Dundee, Dundee, Scotland; Antonel Olckers, PhD*, African Academy of Forensic Sciences & DNAbiotec, Pretoria, South Africa; Carolina Rojas, MFS*, Department of Forensic Sciences, Organismo de Investigación Judicial, Poder Judicial San Joaquín, Heredia, Costa Rica; Sheila Willis, DSc*, Leverhulme Research Centre for Forensic Science, University of Dundee, Dundee, Scotland; Agnes D. Winokur, PhD*, Drug Enforcement Administration, Miami, FL; Ivana Wolff, MA*, International Criminal Court, Mendoza, Argentina*

Educational Objectives: After attending this presentation, attendees will have a better understanding of how labs and organizations around the world are developing and implementing both US and International Standards. Attendees will also have a better understanding of how they can get involved in standards development around the world.

Impact on the Forensic Science Community: The presentation will impact the forensic science community by creating greater awareness of how standards are currently being drafted, used, and implemented internationally and the impact of standards in forensic sciences.

Program Description: Multiple forensic and standards organizations around the world are working with the forensic practitioners and partnering with respective stakeholders across the standards community to develop standards that can increase reliability on forensic analysis results and public trust in the forensic disciplines. These responsive programs and activities are designed to engage professionals across the world of standards and conformity assessment and ensure the strength and efficacy standardization.

There are numerous routes to the development of standards around the world. ISO, the International Organization for Standardization is a non-governmental organization that develops and publishes standards for products, processes, services, and systems. They also help facilitate global trade by providing common standards across different countries. In the US, the American National Standards Institute (ANSI) accredits standards developing organizations that develop discipline specific standards. National Standards Bodies (NSB) are organizations that prepare standards for global use. Each country or economy usually has one recognized NSB.

The morning will have presentations from non-US labs and how they are implementing and getting involved in standards development. An international Forensic Science Academy and a National Standards Body on their involvement with the development and implementation of Forensic Science Standards. In addition, information will be presented on how international standards have been addressing the emergence of machine learning and artificial intelligence, as well as the challenges when developing these standards.

The afternoon will focus on ISO and the TC on Forensics, NATO development of standards, a perspective on international standards from a university, and law enforcement development organization.

Standards; International; Implementation

S2 Young Forensic Scientists Forum—Back to Your Future: Forensic Opportunities in the AI Era

Sara C. Zapico, PhD, New Jersey Institute of Technology, Smithsonian Institution, Newark, NJ; Joe Adserias-Garriga, PhD*, Mercyhurst University, Erie, PA; Joanna Collins, MFS*, LINUS Investigations and Consulting, San Antonio, TX; Victoria M. Dominguez, PhD*, Lehman College, CUNY, Bronx, NY; Sarah Ellingham, PhD*, International Committee of the Red Cross, Schwarzenbek, Germany; Brandon Epstein, MS*, Magnet Forensics, Freehold, NJ; Joe Adserias-Garriga, PhD*, Mercyhurst University, Erie, PA; Maryann Hobbs, PhD*, SNA International, Honolulu, HI; Cheryl Hunter*, American Academy of Forensic Sciences, Colorado Springs, CO; Douglas S. Lacey, MS*, BEK TEK LLC, Stafford, VA; Steven B. Lee, PhD*, San Jose State University and FIU, Miami, FL; Christina A. Malone, MSFS*, USACIL, Atlanta, GA, Katherine N. Scafide, PhD, RN*, George Mason University, Fairfax, VA; Valerie Sgheiza, PhD*, SNA International, Joint Base Pearl Harbor-Hickam, HI; Christopher Thompson, MD*, David Geffen School of Medicine at UCLA Los Angeles, CA; Dirk M. Vastrick, BA*, Dirk Vastrick Presents, Spokane Valley, WA*

Educational Objectives: The Young Forensic Scientists Forum (YFSF) offers students and young professionals the opportunity to interact with professionals in the forensic science community as they begin their careers. This session presents attendees with the chance to learn about the multitude of careers available in forensic science as well as develop professional skills that are essential for the job-hunting process. Our mission is to provide the education, mentorship, and resources necessary to champion students and young forensic scientists to promote interest, membership, and participation with AAFS and the forensic science community for years to come.

Impact on the Forensic Science Community: After attending this session, attendees will have a better understanding of the diversity of roles and career paths in the forensic science community and how each plays an integral part in furthering the field on a national and international level. Additionally, attendees will have the opportunity to sharpen their professional skills in resume writing and making impactful introductions.

Program Description: The overall theme of the 2025 AAFS Conference is *Technology: A Tool for Transformation or Tyranny?* This year the YFSF Committee has chosen the theme *Back To Your Future: Forensic Opportunities In the AI Era* to showcase the various career paths young forensic scientists can choose, particularly focused on technological specialties, but also displaying how new technologies impact current forensic practices. This full-day session will present the opportunity for attendees to learn about the many career paths one can take in the forensic science community, and how each plays a unique role in advancing the field.

The speakers have a vast range of knowledge and experiences that will shed light on the ways forensic scientists use technology in the pursuit of justice. Specifically, our presenters will showcase various disciplines in forensic science, speak about performing research in the field, and offer professional development advice as well as international perspectives and practices. The YFSF offers this session in an effort to integrate young professionals and students into the field through presentations by professionals with significant experience in forensic science. Further, the session this year will offer a resume review workshop, so do not forget to bring your updated resume to the session! We will offer an end-of-the-day mixer for attendees to have an opportunity to meet and speak with the session's presenters as well as other distinguished professionals representing a multitude of forensic science disciplines and expertise.

Professional Development; Students; Young Professionals

S3 Interdisciplinary Symposium—Technology: A Tool for Transformation or Tyranny?

Yong Guan, PhD, Iowa State University, Ames, IA; Katharine Pope, MA*, RTI International, Research Triangle Park, NC; Kenneth Aschheim, DDS*, NYC Office of the Chief Medical Examiner, New York, NY; JoAnn Buscaglia, PhD*, FBI Laboratory, Quantico, VA; Alicia Carriquiry, PhD*, Iowa State University, Ames, IA; Sarah Chu, PhD*, Perlmutter Center for Legal Justice at Cardozo Law, New York, NY; Nancy Downing, PhD, RN*, UNTHSC College of Nursing, Fort Worth, TX; Zeno Geradts, PhD*, Ministry of Security and Justice, Den Haag, Netherlands; Thomas P. Paonessa, Jr., MS*, The MITRE Corporation, McLean, VA; Katherine Scafide, PhD, RN*, George Mason University School of Nursing, Fairfax, VA; Hon. Donald Shelton, JD, PhD (ret.)*, University of Michigan-Dearborn. Saline, MI; Lucas Zarwell, MSFS*, National Institute of Justice, Washington, DC*

Educational Objectives: Participants will gain a comprehensive understanding of the transformative role of technology in forensic science, critically evaluating its dual capacity as a tool for innovation and a source of ethical and operational challenges. Attendees will learn about advancements in artificial intelligence and emerging technologies, their implications for forensic practices, and the evolving legal and societal standards shaping the future of forensic applications.

Impact on the Forensic Science Community: The 2025 IDS aims to provide attendees with an understanding of how emerging technologies are transforming forensic science and its applications in justice. Participants will gain insights into the dual role of artificial intelligence (AI) as both a tool for enhancing accuracy and a potential source of ethical challenges, such as systemic bias and privacy concerns. Presenters will also emphasize the importance of critical thinking and adherence to the scientific method in evaluating technological advancements, as well as the challenges of transitioning research into operational practice. By exploring real-world examples, legal implications, and case studies, attendees will learn how to responsibly adopt and integrate technologies such as probabilistic genotyping, forensic investigative genetic genealogy, and AI tools, while addressing ethical, legal, and practical concerns. Additionally, IDS aims to foster interdisciplinary dialogue on how technology can support victims of violence and uphold justice, ensuring that forensic innovations contribute positively to society.

Program Description: The 2025 AAFS Annual Scientific Conference's Interdisciplinary Symposium (IDS) spotlights the theme "Technology: A Tool for Transformation or Tyranny?" through a dynamic program of three keynote talks and two engaging panel discussions. The free event brings together leading experts representing all sections of forensic science in a mission to explore how technology shapes the field. IDS keynote speakers are Dr. Joanne Buscaglia from the FBI, Mr. Thomas P. Paonessa Jr. from MITRE, and Mr. Lucas Zarwell from the NIJ. Their presentations will address the integration of cutting-edge technology into forensic operations, the importance of adhering to the scientific method, and the challenges of transitioning innovative research into practical applications.

The first IDS panel, moderated by Dr. Yong Guan, focuses on "Artificial Intelligence (AI) in Forensics" and features insights from Zeno Geradts, JoAnne Buscaglia, Thomas P. Paonessa Jr., Kenneth Aschheim, and Alicia Carriquiry. This session explores the dual role of AI in forensic science—its potential to enhance accuracy and efficiency, alongside ethical concerns such as bias and privacy risks. Speakers detail real-world case studies and emerging AI tools to shed light on the question of whether AI serves as a transformative ally or a potential threat in the pursuit of justice.

The second IDS panel, moderated by Katharine Pope, delves into "Emerging Technologies and Legal Implications" and features insights from Alicia Carriquiry, Lucas Zarwell, Donald Shelton, Katherine Scafide, Nancy Downing, and Sarah Chu. This session explores how advancements in forensic tools transform investigations while raising critical legal and ethical questions. Topics range from probabilistic genotyping and forensic investigative genetic genealogy to policies safeguarding data collected during the criminal process. The entire IDS aims to provide forensic professionals with valuable insights into leveraging technology responsibly while addressing its challenges, fostering a thoughtful and collaborative approach to the future of forensic science across the sections.

Artificial Intelligence; Forensic Technology; Technology Ethics

CB1 "Excited Delirium": Abuse, Use, and Bias of This Term in the Courtroom

Stephanie Domitrovich, PhD, Administrative Office of PA Courts, Erie, PA; William M. Nuzum III, JD*, W. Milton Nuzum III, LLC, Vincent, OH*

Educational Objectives: Attendees will assume the role of the judge in each hypothetical case to determine the admissibility of expert testimony on the cause of death by applying the appropriate evidentiary standards for admissibility of the testimony. Underlying each scenario is the controversy of racial or ethnic bias affecting the diagnosis of cause of death. Attendees will understand how the diagnosis can impact the potential criminal or civil liability on the part of the responding law enforcement officers or first responders involved in each case. Is there qualified immunity for law enforcement? Attendees will understand the dilemmas that judges have in admitting testimony proffered by experts in these cases and how those dilemmas have been or are resolved.

Impact on the Forensic Science Community: This presentation will inform the forensic science community by presenting a series of hypothetical emergency scenarios based on actual court cases where law enforcement and first responders are dispatched to an emergency crime scene resulting in detention and treatment of an alleged perpetrator. Each scenario involves a tragic situation that results in the death of the perpetrator at the scene. Attendees will understand the dilemmas that judges have in admitting testimony proffered by experts in these cases and how those dilemmas have been or are resolved.

Program Description: After attending this presentation, attendees will understand legal principles for the qualification of expert witnesses and foundational requirements of admissibility expert testimony in civil and criminal cases specifically related to fatalities diagnosed as resulting from "Excited Delirium". While this diagnosis is recognized as a valid diagnosis in the medical community, not all embrace its validity. Attendees will understand the controversy of this diagnosis as a shield from liability for abusive injury and racial bias by law enforcement and first responders.

Each death is diagnosed by an expert as caused by excited delirium. At issue in each scenario is whether the death was from natural causes, self-inflicted, excessive force, or inappropriate medical treatment. Attendees will assume the role of the judge in each hypothetical case to determine the admissibility of expert testimony on the cause of death by applying the appropriate evidentiary standards for admissibility of the testimony. Is there qualified immunity for law enforcement?

Excited Delirium; Expert Witness; Bias

CB2 The Collapse of Surfside: A Multifaceted Approach to Disaster Victim Identification

Heather A. Walsh-Haney, PhD, Florida Gulf Coast University/Human Identity and Trauma Analysis Laboratory, Fort Myers, FL; Micki Besse, MS*, Florida Gulf Coast University/Human Identity & Trauma Analysis Laboratory, Fort Myers, Florida; Katherine Kenerson, MD*, Florida District 11 Office of the Medical Examiner, Miami, FL; Kenneth Hutchins, MD*, Florida District 11 Office of the Medical Examiner, Miami, FL; Benjamin Mathis, MD*, Florida District 11 Office of the Medical Examiner, Miami, FL*

Educational Objectives: After this presentation, attendees will understand the protocols and technologies implemented after a mass fatality event in Surfside, FL.

Impact on the Forensic Science Community: This presentation introduces the forensic science community to physical and digital decedent documentation following a mass fatality incident with a closed population from a forensic anthropological perspective as guided by the needs of the medical examiner and law enforcement personnel as well as the various community stakeholders.

Program Description: Forensic Anthropologists (FA) are called to assist in the discovery, recovery, inventory, and estimation of the Minimum Numbers of Individuals (MNI) represented by skeletal remains, irrespective of the decomposition state of the decedent. FAs also assist in the process of identification, trauma analysis, and reunification of human remains to their legal next of kin following mass fatality incidents.[1-3] On June 24, 2021, the South Champlain condominium collapsed, prompting the search, rescue, and recovery of a closed population comprised of 98 fatalities. Post-incident, the FAs were responsible for creating a skeletal inventory and MNI as requested by the medical examiner, law enforcement, families, and community leaders.

Though informed by prior mass fatality missions with open and closed populations (e.g., 9/11, ValuJet, hurricanes Wilma and Katrina) and published research, our protocols implemented post-incident allowed for the determination of MNI using a digital database. Using the medical examiner autopsy records, radiographs and photographs (total n = 4,348), and the FA analysis of the physical remains, 98 individuals were recovered with a minimum of 11,848 inventoried osseous elements. As large structural debris, thermal damage, water incursion, and other environmental influences obliterated the skeletal remains, this inventory focused upon MNI. Then these data were combined with medical examiner records, law enforcement information of associated physical evidence, and DNA information regarding sample processing success that corresponded to each decedent.

The average quantity of skeletal remains recovered per individual was 124 (or approximately 60% of the individual). Of the 8,340 elements not recovered, 56% were hand and pedal elements, 19% were vertebrae or ossa coxae, 12% were ribs, 5% were skull and hyoid, 4% were lower extremity long bones or patella, 2% were upper extremity long bones, and 2% were clavicles, scapulae, or sternal elements. When parsed by cranial element, the left zygomatic (61%) was the least recovered with the occipital (70%) being the most recovered cranial element. Postcranially, the hyoid (43%) was least recovered, with the left humerus (73%) being the most recovered postcranial element. Twenty-six non-human elements were discovered as well as four non-osseous items. These findings helped to inform the subsequent searches of the debris field, guide bone extraction points for DNA, as well as plan for future training opportunities for first and last responders. No less important, this study helps to guide and inform future recovery missions as is the responsibility of forensic scientists.

Mass Fatality; MNI; Database

CB3 Forensic Identification of Synthetic Data: Identification and Isolation Techniques

Joseph C. Sremack, MS, Forensic Data Analytics, Marcum LLP, New York, NY*

Educational Objectives: Attendees will gain an understanding of what synthetic data is and how it is used, scenarios in which synthetic data needs to be identified in an investigation, and the results of techniques applied to the identification process. The presentation will focus on a case study, in which synthetic data was present, on how fraud analysis techniques were applied to identify the special characteristics of synthetic data and the analysis findings and results.

Impact on the Forensic Science Community: The presentation will provide the forensic science community with a better understanding of the emerging area of synthetic data, why it matters to a variety of cases requiring forensic analysis, and how such data can be identified and isolated vis-à-vis ground truth data.

Program Description: Synthetic data represents a new class of data that poses risks to large-scale forensic data analysis if not properly accounted for and isolated during an investigation. The use of synthetic data extends beyond artificial model training data, as it can be used to create falsified transactions or simply be indistinguishable from ground truth data. The presence of synthetic data increases risks to data reduction efforts and increases the likelihood of false positives.

The current academic literature is limited with respect to the analysis of synthetic data, and forensic analysis is not addressed. While published research on forensic identification methods is not available, literature on synthetic data generation is growing.[1] More importantly, research is available on assessing synthetic data to determine whether the source data code can be identified or otherwise deanonymized, which is important for identifying the presence of synthetic data.[2,3] These techniques are valuable for analyzing the integrity and identifiability of synthetic data, but, by themselves, they are insufficient for forensic analysis.

Fraud analytics is a more established field, with a corpus of defined and defensible techniques whose results can be measured and admitted in court. The techniques generally relate to the identification of anomalies. The anomalies can be identified through a variety of data tests to isolate patterns that do not conform to patterns found based on time-series analysis, univariate or multivariate distributions, or even the distribution of specific digits within numeric fields. The fraud analytics tests, however, are insufficient for identifying synthetic data because the data is created to be statistically representative of the ground truth data and are largely immune to statistical fraud analytics tests.

Several analysis techniques to identify and isolate synthetic data using a combination of current research and fraud analytics tests have yielded strong results in the context of commercial forensic investigations. Synthetic data identification analysis can be successfully performed based on reverse engineering the standard models that generate synthetic data and applying fraud analysis techniques. This presentation will present a case study of a commercial forensic data analysis involving synthetic data and the results and limitations of performing the identification analysis. The identification of synthetic data requires ongoing examination of the techniques to identify and isolate this class of data by researchers and practitioners.

Forensic Investigation; Data; Statistics

CB4 Maximizing the Impact of Social Science Research and Evaluation on Forensic Science: The NIJ's Role in the Integration of Science

Danielle M. Crimmins, PhD, National Institute of Justice, Department of Justice, Washington, DC; Jonathan McGrath, PhD*, U.S. Customs and Border Protection, Houston, TX; Jillian Barnas, PhD*, AAAS/NIJ, Washington, DC*

Educational Objectives: After attending this presentation, attendees will understand: (1) how social science research and evaluation provides objective evidence to advance the fair and impartial administration of justice; (2) the application of social science research and evaluation methods to study the forensic science disciplines, including examples from the National Institute of Justice (NIJ's)'s Social Science and Forensic Research (SSRFS) portfolio; and (3) a discussion of the benefits, challenges, and future research directions to address the needs of the field.

Impact on the Forensic Science Community: This presentation will impact the forensic science community by discussing the benefits and challenges of using social science research to formulate meaningful research questions and develop rigorous research designs to advance the impact and understanding of the forensic sciences. This presentation will also foster a discussion between researchers and forensic science practitioners on ways to assess and measure the impact of forensic science disciplines.

Program Description: The effective use of forensic science provides timely and impactful answers to the criminal justice system. The application of social science research methods and multidisciplinary partnerships can shed light on how the criminal justice system and forensic science practitioners can maximize the role and value of the forensic sciences. As forensic science innovations are implemented into practice, advancements such as the identification of emerging drug threats, 3D virtual microscopy for firearms evidence, digital and multimedia evidence, and rapid DNA and other field deployable technologies offer opportunities to empirically examine their impact on justice system outcomes. For instance, social science methods can aid in understanding how the implementation of current and new technologies, methods, or workflow processes impact backlog reduction, capacity enhancement, cost relative to benefit, workforce development, and case closure efficiency.

This presentation will provide an overview of 20 years of social science and forensic research funded by the NIJ.[1] For example, over the past two decades, researchers have sought to improve their understanding of: how the forensic sciences are communicated and understood in the courtroom; the use and impact of forensic science to inform law enforcement investigations, actionable intelligence, and case outcomes; how forensic toxicology and seized drug analysis can inform community drug surveillance; and the need to strengthen the resiliency of the forensic workforce that is faced with unique stressors.

In addition, researchers have identified benefits and challenges of engaging in social science research to study the forensic sciences. Criminal justice practitioners, forensic science practitioners, and policy makers benefit from the use of innovative methods examining the effective and efficient use of forensic science. However, collaborations between social science researchers and forensic science practitioners are rare. In addition, rigorous studies that examine the effective and efficient use and outcomes of forensic science are complex, and as such, strategies to overcome challenges are needed. For instance, building partnerships between social science researchers and forensic scientists is critical. This presentation will discuss lessons learned and address solutions to overcome these barriers.

Presenters will also discuss future research and evaluation opportunities in order to develop a better understanding of the applications of social science on the impact of forensic science operations. This presentation will discuss various areas for research and evaluation that are relevant to the criminal justice community, including the examination of the role, value, and impacts of forensic science in the criminal justice system; evaluating the implementation of new and innovative policies and practices; understanding the costs and benefits of forensic science services; and assessing the safety, wellness, health, and workplace needs of forensic practitioners.

Social Science Research; Forensic Science; Multidisciplinary

CB5 The Role of Y-STR Analysis in Forensic Genetic Genealogy (FGG)

Colleen M. Fitzpatrick, PhD, Identifinders International LLC, Fountain Valley, CA*

Educational Objectives: Upon attending this presentation, attendees will gain insight into the evolution of Forensic Investigative Genetic Genealogy (FGG) from Y-chromosomal Short Tandem Repeat (Y-STR) analysis through autosomal SNP testing. Case studies will be presented illustrating the use of Y-STR FGG to generate investigative leads on cases where the DNA has been exhausted or where a mixture is present. Attendees will also learn how Y-STR FGG can reduce the complex genealogical research often required by autosomal SNP testing by narrowing the possibilities within a family tree to only individuals with a given last name. The presentation will include statistics indicating the probability of successfully obtaining a last name using the technique.

Impact on the Forensic Science Community: This presentation will impact the forensic science community by demonstrating the synergy that exists between Y-STR and autosomal SNP analysis techniques. The presentation will broaden the understanding of how FGG developed over the past few years to become a powerful tool that has brought resolution to over 1,100 cold cases as of December 2023.

Program Description: Y-STR testing was first introduced in 2000 by several Direct-to-Consumer (DTC) DNA testing companies as a means of complementing genealogical records with genetic data. The popularity of Y-STR analysis as a tool for genealogical research grew rapidly, especially among male adoptees, because of the patrilinear co-inheritance of the Y chromosome with the family surname. A male adoptee could take a Y-STR test; a match found in the FGG databases would indicate a possible name for his birth father.

The availability and increasing size of publicly available genetic genealogy Y-STR databases prompted their use by law enforcement as a source of forensic intelligence starting in 2011 with the 1991 Sarah Yarborough homicide.[1] Because of the overlap between loci included in the genetic genealogy Y-STR test panels and those included in Thermo Fisher Scientific's AmpFLSTR YFiler and Promega's PowerPlex Y23 PCR amplification kits, a forensic Y-STR profile could be compared to the genetic genealogy Y-STR databases without retesting the evidence. Genetic genealogy databases could be mined for matches to a Y-STR profile from a crime scene or from unidentified remains, to obtain a possible last name in the absence of a CODIS match or when a CODIS profile was unavailable. Even if a match was not found, the nationality or ethnicity of "near matches" could be informative. The first case solved using FGG, the Phoenix Canal Murders, was actually based on several matches to the surname Miller found in the genetic genealogy Y-STR databases to the YFiler profile from the crime scene. This led to the identification of Bryan Patrick Miller as a suspect.[2] Miller's DNA was found to be a CODIS match to the DNA profile developed from the victims in the original investigation.

More recently, DTC autosomal SNP testing has eclipsed genetic genealogy Y-STR testing in popularity for forensic casework because it is useful for discovering relationships along all branches of a family, both single- and mixed-gender lines. As of December 2024, over 1,100 publicly announced unidentified human remains and violent offender cases have been solved using autosomal SNP testing techniques similar to those developed by genetic genealogists for adoption searches.[3] Yet Y-STR FGG is holding its value for forensic casework in situations where SNP testing is not useful, that is, where a DNA sample has been exhausted or where a mixture is present. Y-STRs can also be used to reduce the complexity of the genealogical research that must often be put in to identify a suspect using autosomal SNP testing, by limiting the possible branches to be investigated to those bearing a surname that matches the corresponding Y-STR profile.

This talk will discuss the practical use of YSTR FGG for cold casework, including case studies where Y-STR FGG was the important factor in resolution. The presentation will compare various issues that arise for Y-STR FGG and autosomal SNP analysis, along with statistics on the probability of producing a last name.

CB6 Fiction vs. Science: The Yara Gambirasio Case on Netflix

Luciano Garofano, PhD, Italian Academy of Forensic Science, Parma, Emilia-Romagna, Italy; Michele Vaira, JD*, Vaira Law Firm, Parma, Italy*

WITHDRAWN

CB7 Unveiling Forensic Signatures: Leveraging Soil Microbiome and Enzymatic Responses to Detect Cyanide-Induced Deaths

Aby Joseph, Amity University Dubai, Dubai, United Arab Emirates; Jannath Manaf, MASc*, Amity University Dubai, Dubai, United Arab Emirates; Muhammad Safar S.P.S, MASc*, Amity University Dubai, Dubai, United Arab Emirates*

Educational Objectives: By the end of the presentation, attendees will have a comprehensive understanding of how soil microbiome and enzymatic responses to cyanide can enhance forensic detection methods, along with practical knowledge on implementing these techniques in real-world forensic settings.

Impact on the Forensic Science Community: This presentation will have a profound impact on the forensic science community by introducing innovative methodologies to improve cyanide detection in postmortem investigations. The proposed integration of soil microbiome analysis and enzymatic activity profiling represents a significant advancement over conventional toxicological techniques, which often fall short in detecting cyanide in extensively decomposed remains.

Program Description: This study investigates the responses of soil microbiomes and enzymatic activities to cyanide exposure from decomposing rodent remains, aiming to improve forensic detection methods for cyanide-induced deaths. Cyanide is a potent poison that poses significant challenges in forensic investigations due to its rapid degradation and the complexity of detecting it in extensively decomposed bodies. This research combines microbial community analysis, enzymatic assays, and advanced analytical techniques to develop more reliable methods for identifying cyanide exposure postmortem.

Forensic Microbiome; Necrobiome; Microbiology

CB8 Forensic Examination of Environmental Crime and Its Solutions

Ashfaq Ahmed Kharal, Jr., PhD, Lahore, Punjab, Pakistan*

Educational Objectives: The attendees are interested in a green and clean environment and are using technology to trace the elements of crimes creating pollution and hazards.

Impact on the Forensic Science Community: No one can deny the impact of a clean environment as it is a need not only in this era but is very emphatic all the time without any discrimination and the use of technology for highlighting these crimes by forensic analysis is the most important impact.

Program Description: Environmental forensic examinations are an essential component of environmental crime investigations. Environmental forensic whizzes assist factfinders in reenacting the occasion timeline, assessing the size of the destruction and causality. Their sentiments are of ultimate germaneness to environmental criminal stuff. Thus, it is critical to confirm that expert examinations are steered following scientific canons providing reasonably more truthful and steadfast results. In the article, two different slants to the organization of environmental forensic examinations were equated. Forensic examination has been conducted in two states, especially in Russia; the consolidated and more rigid model has been practical concerning environmental forensic studies, while in Poland, such inspections are navigated by decentralized forensic laboratories and self-regulating consultants. The authors deliberated existing variances and parallels between those two methods.

Crime Prevention; Digital Evidence; Chain of Evidence

DD1 Leveraging Forensic Science Standards Development to Boost Your Professional Growth

Kris Cano, MA, Signature Science, LLC, Scottsdale, A; J. Keith Pinckard, MD, PhD*, Travis County Medical Examiner, Austin, TX*

Educational Objectives: After attending this presentation, attendees will learn about the importance of documentary standards in forensic sciences, how the standards development process works, and how participating in standards development can help develop skills and abilities that can advance one's career trajectory while also advancing the field.

Impact on the Forensic Science Community: Participating in standards development is more than just a task; it is an opportunity to shape the future of forensic science and advance your career. By embracing this work, you not only contribute to the quality and consistency of forensic practice but also enhance your own professional growth and leadership capabilities. This session aims to help you recognize and leverage these benefits, turning what may seem like a thankless task into a powerful career-building tool.

Program Description: The process of standards development and implementation in forensic science can indeed seem daunting and underappreciated. Engaging in standards development sharpens your skills and deepens your understanding of the forensic science field. It challenges you to think critically, solve complex problems, and engage with a wide range of perspectives from professionals with diverse expertise. This process enhances your ability to lead, communicate effectively, and navigate complex scenarios—skills that are invaluable as you advance in your career. By participating in the creation and implementation of standards, you position yourself as a leader within your organization and the broader forensic community. These experiences not only boost your leadership credentials, but also amplify your influence in shaping your field's direction. By contributing to the development of these standards, you help ensure that forensic practices are consistent, scientifically sound, and widely accepted. Being involved in standards development can set you apart from your peers and open doors to new opportunities. It demonstrates your commitment to the field and your willingness to tackle challenging and sometimes unglamorous tasks. This proactive approach can lead to recognition, career advancement, and greater professional satisfaction. The skills you develop in standards development are transferable to other areas of your career. Whether it's crafting policies, handling crucial conversations, or managing public perception, developing the analytical and strategic thinking involved in standards work will serve you well.

Standards; Forensic Professionals; Education

DD2 Legal Admissibility of Digital Evidence in the Era of AI-Generated/Synthetic Media

Brandon Epstein, MS, Magnet Forensics, Freehold, NJ; Chichi Lee, LLM*, Middlesex County District Attorney's Office, Massachusetts, Waltham, MA*

Educational Objectives: Attendees with a legal background will learn the authentication issues surrounding AI-generated or -modified synthetic media such as photos and videos, including several proposals to amend the authentication rules under Fed. R. Evid. 901(a). They will also learn how to admit expert testimony on synthetic media under Fed. R. Evid. 702, including possible challenges to the experts' qualifications, principles, and methods.

Attendees with a forensic background will learn the issues that may come up in court from pretrial motions in limine to qualify the expert under Fed. R. Evid. 702. Forensic expert attendees will learn how an attorney will present their testimony in court and what an opposing party might contest as to their qualifications, principles, methods. While going through these, the attendees will also learn the relevant technology surrounding synthetic media.

Impact on the Forensic Science Community: Because synthetic media authentication is new, this presentation will introduce the admissibility of synthetic media authentication in court to the forensic science community. This presentation will allow the forensic experts to: (1) understand if their qualifications and their training that they provide to future experts will pass the legal muster, and (2) allow the forensic experts to have a preview of their future testimony in court; whether they are understandable to non-experts and reliable under the law, with a portion of a mock direct examination. With this presentation, scientists will be able to work with legal practitioners to overcome the hurdles in court and further their trustworthiness in the legal world with this new, developing authentication method.

Program Description: Although synthetic media, such as Adobe Photoshop, is not new, generative AI has created a new era of synthetic media. Now, synthetic media is accessible to the general public without training, is easier to manipulate, and is easier to create on a large scale. When AI-generated or -altered photos or videos are knocking on the court's door, they will undoubtedly impact how lawyers and judges look at both civil and criminal cases.

This presentation will introduce the issues surrounding the unavoidable challenges to the authenticity of photos and videos introduced in court where attorneys and judges have to deal with authentication under Fed. R. Evid. 901. This presentation will also discuss and comment on several proposals to alter Rule 901 in response to the rise in AI-generated synthetic media.

But there's more. With AI-generated synthetic media, the ability of detecting synthetic media and authenticating photos and videos becomes paramount. This is especially true in the era of synthetic media where the jury may start questioning everything they see or hear. This presentation will introduce how a synthetic media authentication expert passes Daubert v. Merrell Dow Pharmaceuticals, Inc. and Fed. R. Evid. 702. With a portion of a mock direct examination, the presentation will walk you through the expert's qualifications, the underlying facts and data, and the reliable principles and methods the expert uses. In that vein, we will also see some of the challenges the opposing party may present.

Artificial Intelligence; Expert Testimony; Admissibility

DD3 Balancing the Scales: Supporting Mental Health in Forensic Science

Kevin Kulbacki, MSFS, KDX Forensic Consulting, Chicago, IL*

Educational Objectives: By the end of this session, attendees will be able to: (1) identify common mental and emotional health challenges faced by forensic practitioners and their root causes, (2) apply at least two evidence-based strategies for personal mental health resilience shared during the session, (3) evaluate organizational practices that foster supportive mental health environments and determine how these can be implemented in their own workplaces, and (4) engage in peer-sharing to adopt innovative tips and ideas for enhancing mental well-being in forensic science roles.

Impact on the Forensic Science Community: The mental and emotional well-being of forensic practitioners is critical to maintaining the integrity and effectiveness of their work. This session highlights the importance of addressing mental health at both personal and organizational levels, creating a platform for open dialogue and shared learning within the forensic science community. By equipping attendees with practical tools, fostering peer connections, and promoting awareness, the session aims to cultivate a healthier, more resilient workforce. The insights gained will not only benefit individual practitioners but also contribute to a more supportive culture across forensic agencies, enhancing the overall quality and sustainability of the field.

Program Description: Forensic practitioners often face unique mental and emotional challenges due to the nature of their work. This session brings together insights from diverse perspectives to address these challenges and explore solutions. Through presentations by a practitioner, an organizational leader, and a mental health professional, attendees will gain actionable strategies to enhance individual resilience, foster supportive workplace cultures, and access professional resources. The session concludes with an open discussion, inviting participants to share practices, tips, and ideas to collectively improve well-being in the forensic field.

Mental Health; Resilience; Well-Being

DD4 Determining the Viability of Breathwork and Meditation as Intervention Techniques for Stress in the Forensic Science Community

Prateek Shetty, BSc, University of Central Oklahoma, Edmond, OK; Keisha Jones, MS*, University of Central Oklahoma, Edmond, OK*

Educational Objectives: Attendees of the presentation will learn about the impact of breathwork (cyclic sighing) and meditation as methods to mitigate workplace stress in the forensic science field. Data gathered from analyzing variations in stress among students studying forensic science and professionals working in the field before and after implementing the interventions will be discussed along with the future implications and research opportunities. Session attendees can expect to learn the methods implemented in the study, practice them during this presentation, and join a discussion about how these methods could be implemented in their everyday lives.

Impact on the Forensic Science Community: Attending this session will allow participants to learn about stress mitigation techniques such as breathwork (cyclic sighing) and meditation, which can be implemented in their personal lives and help them combat workplace stressors that come with being a part of the forensic science community. Learning and practicing these exercises can contribute to the growth of a holistically healthy forensic science workspace in the present and future.

Program Description: Are you stressed out because of the things that happen at work? Do you want to improve how you deal with stress in the workplace? Are you a prospective or present member of the forensic science workforce? If your answer to one or all these questions was a resounding, "YES," this session is for you!

Join the discussion to share personal stories of stress in the field. Learn what research has to say about how practicing breathwork and meditation could impact the busy life of a forensic science professional. But don't worry, you won't be bored with just the numbers from a research study. You will also get to practice these exercises and take these tools with you to use in your everyday life as a forensic science professional or student.

Join us in this session as we explore the possibilities of using our breathing patterns to help build a holistically healthy forensic science workforce for the present and the future!

Mental Health; Breathwork; Forensic Science

DD5 Misconceptions and Limitations of Words Commonly Used in the Forensic Sciences—What Do They REALLY Mean?

Charlotte Word, PhD, Charlotte Word Consulting, Richmond, VA; John D. Schmid, JD*, Sixth District Public Defender's Office, Duluth, MN*

Educational Objectives: After attending this session, both forensic science practitioners and members of the legal community should have an increased awareness of terms and associated language with a high susceptibility of being misinterpreted during judicial proceedings. Attendees should gain an increased understanding and appreciation of the meaning and strengths of the four focus areas to be discussed, along with their limitations and common misinterpretations. Insights into the need for effective training and communications with robust safeguards to ensure the reliability of forensic science evidence presented in court should be gained by the attendees, along with knowledge regarding mechanisms of improvement and potential ways to overcome any apparent obstacles.

Impact on the Forensic Science Community: This presentation will impact the forensic science community through training and discussions aimed to improve stakeholder competence, performance, and outcomes by facilitating an accurate understanding of common laboratory quality assurance terms frequently misinterpreted in court proceedings. By increasing awareness of the strengths and limitations of scientific and legal safeguards, forensic science practitioners will be better equipped to avoid misstatements and errors in testing, reporting, and testimony.

Program Description: Quality crime/forensic science laboratories routinely participate in audits to achieve accreditation as well as training competency and proficiency testing, conduct validation studies prior to commencing casework testing with a new method or product, and provide discovery following jurisdictional requirements. These practices are in place to ensure reliability of the testing conducted and the results reported. However, the roles and meaning of these processes are often misunderstood both by laboratory personnel and the legal community. The goal of this session is to address these issues by providing training regarding these topic areas and their potential to collectively ensure reliability while addressing the misunderstandings among stakeholders about the limitations of each individual safeguard.

The four primary discussion areas will focus on: (1) laboratory accreditation and audits; (2) competency and proficiency testing; (3) validation studies; and (4) legal rules of evidence and discovery. The training and discussions will address: (1) what each of these terms actually mean in the context of the laboratory, including their strengths and limitations; (2) how they are often misunderstood in the legal context; (3) ways in which they are miscommunicated through conversations and during testimony in court; and (4) an exploration of ways to overcome identified obstacles and common misunderstandings. The attendees will be encouraged to engage in discussions regarding the proper use of the terms, their perceived misunderstandings and communicating their own ideas for improvement.

This session will be targeted to a mixed audience of legal and scientific practitioners with diverse experiences and backgrounds.backgrounds.

Accreditation; Validation; Quality Control

DD6 Using Forensic Investigative Genetic Genealogy (FIGG) Technology Ethically and Responsibly

Catherine Cupples Connon, PhD, Virginia Commonwealth University, Richmond, VA*

Educational Objectives: After attending this deep-dive session, attendees will be aware of key concerns regarding the use of FIGG and the need to use this technology in an ethical and responsible manner. We will discuss: (1) what types of cases this technology should be limited to, (2) privacy considerations, (3) use of approved genetic genealogy databases, (4) the intersection of law enforcement, forensic laboratories, and FIGG investigators, and (5) appropriate and necessary documentation. Last, we will also address the needs for legislation, research, and FIGG certification/training.

Impact on the Forensic Science Community: This session will impact the forensic science community by offering much-needed guidance surrounding appropriate practices of the emerging FIGG field and its related technologies.

Program Description: FIGG is a new and emerging field of forensic DNA analysis that serves as an investigative tool for law enforcement. Though powerful, it is not appropriate for use with all forensic cases containing DNA evidence. Currently, it is specifically reserved for violent crimes in which a traditional Short Tandem Repeat (STR) profile has not been fruitful from an investigative standpoint, including unidentified human remains cases. Furthermore, when we think about privacy concerns, we must consider the fact that individuals unassociated with the crime may be linked to it for no reason other than being genetically related to the individual in question; thus, necessary precautions must be taken to protect their identities. As an extension of this, only genetic genealogy databases that have been approved for law enforcement use may be utilized—with strict regulation and oversight to boot. Such databases include GEDmatch Pro and FamilyTreeDNA. Throughout this process, cooperation and collaboration of law enforcement, the forensic laboratory, and the FIGG investigator is crucial. These roles will be discussed, including whether overlap is acceptable or if complete separation is needed. Accurate documentation is essential; we will discuss finding a balance between thoroughness and timeliness to ensure quality documentation.

The session will conclude with discussions of what is still needed with respect to legislative regulations, research related to the technology itself, as well as what kind of formal FIGG certification/training is needed, if any.

Forensic Investigative Genetic Genealogy; DNA; Ethics

LS1 Empowering Forensic Science: How Technology, Building Intelligence, and Human-Centered Design Can Revolutionize the Forensic Workplace

Jinhee Lee, Crime Lab Design, Royal Oak, MI; Ken Mohr, BS*, Crime Lab Design, Royal Oak, MI; Scott Morgan, BS*, Crime Lab Design, Royal Oak, MI; Jon Howard*, Crime Lab Design, Royal Oak, MI; Patrick Slattery*, Crime Lab Design, Royal Oak, MI*

Program Description: A new generation of predominantly female forensic scientists is revolutionizing the field, demanding state-of-the-art facilities/systems that support their important work and minimize physical strain. The integration of advanced technologies and intelligent-building systems represents a crucial shift toward enhancing case load processing, minimizing work-related injuries, and improving security within forensic environments. This presentation will highlight how cutting-edge automated systems, such as real-time tracking technologies with RFID and intelligent sensors, play a vital role in monitoring evidence, managing critical supplies, and ensuring the safety of staff, visitors, and occupants.

Global case studies from Asia and the Middle East illustrate the successful application of automated waste management, delivery systems, and Automated Guided Vehicles (AGVs) in addressing staff shortages and reducing physical strain. Notably, 95% of newly built hospitals in the United States now use Tissue Sample Movement Pneumatic Tube Systems, which enhance sample transport efficiency. Medical Examiner's Offices (MEOs) benefit from automated racking systems that increase storage capacity while reducing physical strain on staff, and Automated Mobile Robots (AMRs) streamline the handling of hazardous samples, thereby optimizing case load processing.

By embracing these advancements, forensic facilities can significantly improve operational efficiency, minimize manual labor, and better support a predominantly female workforce.

These technological innovations offer strategic solutions to counteract the projected shortage of over 30,000 forensic analysts in the United States. This session will provide critical insights, using real world examples and data, into how these technologies enhance the quality of life for forensic staff and set new benchmarks for industry best practices.

Educational Objectives: This session will explore how advanced technologies and intelligent building systems can support staff and transform their forensic environments by optimizing case load processing and reducing physical strain, while ensuring a secure and healthy work environment. Attendees will learn to implement Automated Guided Vehicles (AGVs), automated gurneys, RFID Tracking Systems, and Environmental Controls to enhance security, chain of custody, and indoor air quality. Through a data-driven review of global case studies, participants will see how these technologies improve safety, functionality, and efficiency in forensic facilities. By the end, attendees will have a clear understanding of how these technologies can drive measurable improvements in forensic outcomes today and into the future.

Impact Statement: A new generation of predominantly female forensic scientists is revolutionizing the field, demanding state-of-the-art facilities and systems that support their important work and minimize physical strain. Attendees will learn that by incorporating cutting-edge technology and optimizing case load processing, forensic facilities can not only ensure a healthier and safer working environment by reducing workplace injuries but can directly contribute to significant percentage gains in productivity and case load management. Attendees will leave the presentation with the knowledge needed to catalyze change at their facilities, armed with data proving that labs that embrace innovative technology, automation, and human-centered design are better equipped to meet the challenges created by the global demand for forensic science while mitigating the projected shortage of 30,000 analysts in the United States.

Technology; Transformation, Diversity

W1 Pediatric Fracture Healing in Cases of Suspected Non-Accidental Trauma: Clinical, Radiographic, Anthropological, and Histological Perspectives and New Technologies

Diana Messer, PhD, West Tennessee Regional Forensic Center, Memphis, TN; Donna C. Boyd, PhD*, Radford University, Radford, VA; Bradley J. Adams Office of the Chief Medical Examiner, New York, NY; Andrew Baker, MD*, Hennepin County Medical Examiner's Office, Minnetonka, MN; Farah W. Brink, MD*, Nationwide Children's Hospital, Columbus, OH; Jered B. Cornelison, PhD*, Western Michigan University, Homer Stryker MD School of Medicine Kalamazoo, MI; Carolyn V. Isaac, PhD*, Michigan State University, East Lansing, MI; Andy Tsai, MD, PhD*, Boston Children's Hospital, Harvard Medical School, Boston, MA*

Learning Overview: After attending this workshop, participants will understand how antemortem skeletal fractures can be used to help interpret, document, and adjudicate medicolegal cases of Non-Accidental Injury (NAI) in pediatric deaths. Attendees will learn the anatomical basis for and variables affecting pediatric skeletal fracture, repair, and timing (i.e., Time Since Injury or TSI). Using multidisciplinary technology, including histology, light microscopy, radiology, and machine learning, they will learn to critically evaluate current methodological approaches for evaluating pediatric fracture healing and estimating TSI. Applications of pediatric antemortem fracture data toward public health (including advocacy for children's health) will be explored.

Impact Statement: This workshop will impact the forensic community by providing multidisciplinary perspectives and methodological training for critically evaluating and interpreting skeletal fracture and its timing in pediatric death investigations. This training will help the forensic community determine best practice approaches to pediatric fracture interpretations that are scientifically based, legally defensible, and applicable to public health efforts toward prevention of non-accidental child injury.

Program Description: Physical abuse in children results in >500 deaths in the United States each year.1 Patterned and repetitive skeletal fracture is often observed in these decedents, reflecting the typically serial nature of pediatric NAI. Accurate estimation of TSI for antemortem fractures is critical for identification, evaluation, and adjudication of fatal pediatric NAI.

However, TSI estimation has been described as an "inexact science," due to lack of recognition, understanding, and scientific validation of existing TSI methods.2.3These methods derive from a variety of inter-disciplinary sources with unknown accuracy, reliability, consistency, and limited understanding of variables that impact fracture healing. This has necessitated extreme caution in use of TSI estimations in the adjudication of fatal pediatric NAI.

Multidisciplinary approaches to understanding pediatric fracture healing that focus on scientifically validated methodologies are imperative for developing best practice recommendations and standards for forensic pediatric skeletal trauma analysis in pediatric death investigations.

This workshop provides a multidisciplinary approach for understanding and estimating pediatric fracture TSI. Best practice recommendations for analysis and interpretation of pediatric skeletal fracture and its timing are presented using interdisciplinary technologies involving imaging (Computed Tomography [CT], radiology), microscopy (light microscopy, histology), and machine learning. The scientific foundation for pediatric fracture repair and its timing is considered, as is application of these methods to the broader context of pediatric case adjudication and public health. Hands-on examination of case study examples allows participants to put topics covered into practice with a focus on interdisciplinary collaboration.

Antemortem; Child Abuse; Anthropology

W2 Implementing Recommendations From the NIST/NIJ Expert Working Group on Human Factors in Forensic DNA Interpretation Report

Angela Spessard, MSFS, Maryland State Police, Pikesville, MD; Jarrah R. Kennedy, MSFS*, Kansas City Police Crime Laboratory, Kansas City, MO; Niki Osborne, PhD*, Human Factors Training and Consultancy, Remuera, New Zealand; Melissa Taylor, BA*, National Institute of Standards and Technology, Gaithersburg, MD; Hope Zagaria, MSFS*, Bureau of Justice Assistance, Washington, DC*

Leaning Overview: In this workshop, we will guide participants through the process undertaken by the National Institute of Standards and Technology (NIST)/National Institute of Justice (NIJ) Expert Working Group (EWG) on Human Factors in Forensic DNA Interpretation. We will highlight the key findings and controversial topics and present the final recommendations from the report published in May 2024. This workshop will focus on providing examples of how forensic science service providers are already implementing these recommendations in their practice.

Upon completion of this workshop, participants will: (1) be familiar with the published recommendations from the NIST/NIJ EWG on Human Factors in Forensic DNA Interpretation report, (2) understand the implications of these recommendations for their practice, (3) recognize how these recommendations aim to improve DNA examination practices, (4) critique the recommendations and discuss their relevance and feasibility in participants' own practices and the wider forensic DNA community, and (5) have the tools to implement the recommendations in their own practice.

Impact Statement: The study of human factors in forensic science is crucial to understanding the interaction between humans and the systems they use. By addressing human factor issues, we can identify and mitigate the likelihood and consequence of errors and biases, improve laboratory culture, staff morale, and productivity. This workshop encapsulates four years of effort dedicated to understanding human factors in forensic DNA interpretation, providing valuable guidance for DNA analysts, laboratory management, and legal practitioners to enhance practice and achieve safer justice outcomes.

Program Description: In May 2024, the NIST/ NIJ EWG on Human Factors in Forensic DNA Interpretation published a comprehensive report containing 44 recommendations for how to reduce the likelihood and consequence of errors in forensic DNA interpretation.

In this workshop, we will guide participants through the EWG's process, highlight key findings, discuss controversial topics, and present the final recommendations. The workshop will focus on the following areas:

- Training and Education
- Quality Assurance
- Cognitive Bias and Error Reduction
- Interpretation
- Reporting and Testimony
- Management
- Work Environment
- Expressing Evidence Strength
- Research
- Technology
- The "How" and "When" Questions in DNA Analysis

This workshop is relevant to DNA and other forensic science practitioners, laboratory management, researchers, legal practitioners, and anyone interested in improving decision-making in forensic science. Participants will be expected to actively engage with the material and provide feedback on the relevance and feasibility of implementing the recommendations in their practice.

We will use an interactive approach to help participants develop a plan to implement any recommendations that will provide value in their practice. Join us for a comprehensive session that aims to enhance your understanding and application of human factors in forensic DNA interpretation, ultimately contributing to better practices and safer justice outcomes.

Forensic DNA; Human Factors; Error

W3 A Military Criminal Investigative Organization and the Boon and Bane of Technology

Vanessa R. Neff, MFS, Department of the Army, Criminal Investigation Division, Woodbridge, VA; Matt Geniuk, MSc*, Department of the Army, Criminal Investigation Division, Fort Sam Houston, TX; Chris Adams, MFS*, Department of the Army, Criminal Investigation Division, Quantico, VA; Tim Bartman, BAS*, Department of the Army, Criminal Investigation Division, Fort Moore, GA; Ethan Dodson, MSFS*, Central Texas Field Office, Department of the Army, Criminal Investigation Division, Fort Cavazos, TX; Michael Allen Easter, Jr., MSFS*, Department of the Army, Criminal Investigation Division, Fredericksburg, VA; Pedro Hernandez, Jr., MFS*, Department of the Army, Criminal Investigation Division, El Paso, TX; Dale Sajdak, MSFS*, Department of the Army, Criminal Investigation Division, Stedman, NC; Jessica A. Veltri, MS*, Department of the Army, Criminal Investigation Division, Stafford, VA; Bryce Wolford, MA*, Department of the Army, Criminal Investigation Division, Quantico, VA*

WITHDRAWN

W4 Forensic Science Adaptation to Artificial Intelligence

Gina Londino-Smolar, EdD, IU Indianapolis, Indianapolis, IN; JCU Downs, MD*, forensX, LLC, Johns Island, SC; Carole E. Chaski, PhD*, Institute for Linguistic Evidence, Georgetown, DE; Brandon Epstein, MS*, Medex Forensics, Madison, WI; Ting-Yu Huang, PhD*, Central Police University, Taiwan; Michael A. Marciano, PhD*, Syracuse University, Syracuse, NY; David Pienkowski, MBA, PhD*, University of Kentucky, Lexington, KY; Kathryn C. Seigfried-Spellar, PhD*, Purdue University, West Lafayette, IN; Aaron M. Shaprio, PhD*, Provincial Health Services, Authority of British Columbia, Vancouver, BC, Canada; Henry Swofford, PhD*, National Institute of Standards and Technology, Gaithersburg, MD; Jorn Yu, PhD*, Sam Houston State University, Huntsville, TX*

Learning Overview: The proposed presentations are poised to significantly impact the forensic science community by integrating AI into various aspects of forensic analysis. They aim to enhance understanding of AI principles, propose strategies for implementing AI-enabled tools in pattern evidence analysis, and explore innovative biometrics solutions. They also seek to evaluate novel approaches to media authentication in the face of AI-generated content, apply AI in fire debris analysis and forensic DNA analysis, and use generative AI for rapid detection of novel drugs in toxicology samples. Last, they provide a historical perspective on the development of AI and discuss its challenges in forensic science. Collectively, these presentations could lead to more accurate, efficient, and objective forensic analyses, ultimately contributing to a more effective criminal justice system.

Impact Statement: This presentation will impact the forensic science community by providing examples of best practices with inter-agency partnerships, differing ways technology can be used to solve investigations, be a resource to assist with cold cases that may have a Department of Defense nexus, and how technology can be used in austere environments to solve investigations.

Program Description: This workshop was developed by the Forensic Science Foundation (FSF) Educational Committee. The workshop will explore the transformative potential of Artificial Intelligence (AI) in forensic science. It will delve into the basics of AI analyses, discuss strategies for implementing AI-enabled tools in pattern evidence, and present innovative biometrics solutions for digital forensics. The workshop will also evaluate novel approaches to media authentication in the age of AI-generated content, apply AI in fire debris analysis and forensic DNA analysis, and discuss the use of generative AI for rapid detection of novel drugs in toxicology samples. Last, it will provide a historical perspective on the development of AI and discuss its challenges in forensic science. Attendees will gain insights into the state of AI in forensic science, learn about current tools, and understand the considerations in the development and evaluation of AI-based techniques in the field.

Artificial Intelligence; Forensic Science; Education

W5 The Sherry Black Investigation — A Journey for Justice

Katherine M. Brown, PhD, Tarleton State University, College Station, TX; Kelsie Bryand, MS*, Sam Houston State University, Huntsville, TX; Heidi Miller*, Sherry Black Foundation, Sandy, UT; Erin BE Ryan, BS*, Sherry Black Foundation, Midway, UT; Patrick J. Zirpoli*, Sherry Black Foundation, Milanville, PA*

Learning Overview: After attending this presentation, attendees will gain a working knowledge of the process of violent crime investigation. Attendees will recognize: (1) the initial crime scene and evidence collection; (2) forensic analysis of the evidence; (3) crime acene assessment and behavior analysis; (4) Investigative Genetic Genealogy; (5) prosecutorial considerations and the impact on families.

Impact Statement: This presentation will impact the forensic science community by exploring a violent homicide from the initial investigation through the ten years of investigation, culminating in the identification and conviction of the offender. During this investigation, many forensics sciences disciplines were involved; this presentation discusses these practices and their application to homicide investigation.

Program Description: This program will take the attendees through the high-profile, 10-year investigation of the murder of Sherry Black. She was murdered in her small bookstore located on her property in South Salt Lake City, UT, on November 30, 2010. The program will start with the initial call to the South Salt Lake City Police Department and the processing of the crime scene by the Utah Bureau of Forensic Services Laboratory System. The evidence recovered at the scene and the impact the evidence had on the investigation will be discussed. The presentation will show the initial forensic testing and the results of the analysis. The Behavioral Analysis conducted on both the crime and offender will be reviewed with the attendees, and the evidence-based conclusions will be explained. Investigative Genetic Genealogy has become a critical tool in identifying unknown remains and unknown offenders in many violent crimes. We will discuss how this was used during the investigation, and how the offender was eventually identified. The attendees will learn the proper way to obtain reference samples to ensure that any results will not be questioned. This presentation will describe the prosecutorial process from the time of the offender's arrest through his sentencing. We will discuss considerations when prosecuting cold case homicides. Finally, the attendees will learn the steps that were taken to pass Utah SB156, also known as the "Sherry Black Bill." This legislative act introduces a more structured framework for law enforcement's utilization of optional genetic testing databases when investigating violent crimes.

Crime Scene Investigation; DNA; Genealogy

W6 NIST/MSP Hypergeometric Sampling Software for Seized-Drug Analysis

Sandra E. Rodriguez-Cruz, PhD, Drug Enforcement Administration, Dulles, VA; Catherine Savage, MS*, Maryland State Police, Forensic Sciences Division, Pikesville, MD; Laurel Bobka, MSFS*, Maryland State Police, Walkersville, MD; William Guthrie, MS*, National Institute of Standards and Technology, Gaithersburg, MD; Jack Prothero, PhD*, National Institute of Standards and Technology, Westminster, CO; Joshua Smith, BS*, Charles County Sheriff's Office, Windsor Mill, MD*

Learning Overview: After attending this workshop, the attendees will understand how different hypergeometric sampling tools can be used in a forensic laboratory to improve the information provided about the population of drugs submitted.

Impact Statement: This workshop will impact the forensic science community by providing an alternative to the sampling tools currently available on the Scientific Working Group for the Analysis of Seized Drugs (SWGDRUG) website. The presenters will highlight the reasons why Maryland State Police (MSP) decided to provide statistical data for evidence submitted with a possession with intent to distribute charge. One of the current challenges of statistical sampling of seized-drug evidence is that the complex mixtures of street samples do not always have the same controlled substances reported for each specimen tested. This sampling app will allow a statistical statement to be more easily made in more situations than the hypothesis testing approach.

Program Description: This full-day workshop will present a new statistical sampling app developed by the National Institute of Standards and Technology (NIST) and the MSP to apply hypergeometric sampling to seized-drug evidence. The theory behind the calculations in the app will be thoroughly discussed, along with tools and techniques for both conceptualizing and deploying statistical sampling plans in seized-drug laboratories. Topics covered will include sample size selection, uncertainty quantification, generation of appropriate population inferences for net weight and identification purposes, and appropriate reporting language for net weight, unit count, and extrapolation scenarios.

Seized Drugs; Sampling; NIST

W7 DSM Demystified: Medical Disorders in the Courtroom

Corina Freitas, MD; Freitas and Associates LLC. Alexandria, VA; Donna Coleman, JD*, Office of the Public Defender, Mental Health Division, Towson, MD*

Learning Overview: The goals of this workshop are to: understand and articulate the role of the *Diagnostic and Statistical Manual of Mental Disorders* (*DSM*) in legal settings; analyze the limitations and challenges of relying on the *DSM* for legal determinations of mental health issues; identify and compare alternative diagnostic manuals and systems used in mental health assessments; differentiate between legal versus medical definitions of mental disorders in the assessment and testimony of mental health conditions; acquire knowledge to effectively challenge the testimony and findings of opposing experts in court. learn to identify potential weaknesses or biases in expert evaluations and testimonies; evaluate the credentials, experience, and methodology of potential expert witnesses; and review landmark cases that have significantly influenced mental health law and discuss their impact on current legal standards and practices.

Impact Statement: By achieving these learning objectives, participants will gain a comprehensive understanding of the interplay between mental health and legal systems, particularly the role and authority of the *DSM* in court. They will be equipped with the knowledge to critically evaluate and challenge forensic limitations, alternative diagnostic options, and the legal versus medical definitions of disorders. Through case examples and practical strategies, attendees will enhance their ability to select and prepare expert witnesses, ensuring robust and credible testimonies. This training will empower legal professionals to effectively navigate the complexities of forensic mental health evaluations, ultimately improving the quality and fairness of judicial outcomes.

Program Description: This presentation is designed to equip legal professionals with the knowledge to confidently discuss the mental health in court proceedings, explore alternative diagnostic options, and understand the crucial distinctions between legal and medical definitions of disorders. Participants will delve into real case examples to see theory in action and gain practical insights into challenging opposing experts and selecting the right expert witnesses.

Interactive elements will include engaging group discussions and role-playing scenarios to enhance learning and retention. Role-playing in this session will involve analyzing various case scenarios from jurisdictions with different legal standards and tests. Participants will engage in mini mock trials with forensic evaluations where they will apply their understanding of the *DSM*'s authority, forensic limitations, and the distinction between legal and medical definitions of disorders. By attending this session, you will not only enhance your ability to navigate forensic evaluations but also ensure ethical and accurate representations of mental health in legal contexts. Join us to transform your courtroom strategies and become a more effective advocate for your clients.

Forensic Psychiatry; Law; Attorneys

W8 Forensic Postmortem Radiology and Medicolegal Death Investigations

Summer J. Decker, PhD, University of Southern California, Keck School of Medicine, Los Angeles, CA; Edward Mazuchowski, MD, PhD*, HNL Lab Medicine, Breiningsville, PA; Natalie L. Adolphi, PhD*, University of New Mexico, Albuquerque, NM; Jamie M. Elifritz, MD*, Forensic Radiology Group, Albuquerque, NM; Howard T. Harcke, MD*, Thomas Jefferson University, Wilmington, DE; Heather S. Jarrell, MD*, Office of the Medical Investigator, Albuquerque, NM; Michael J. Thali*, University of Zurich, Zurich, Switzerland*

Learning Overview: After attending this workshop, attendees will: (1) appreciate the evolution of forensic imaging: (2) develop an understanding the fundamentals of Postmortem Computed Tomography (PMCT), including interpretation; (3) gain insights regarding the applications of Postmortem Computed Tomography (PMCT), with a particular focus on its role during the opioid epidemic; (4) identify unique considerations for pediatric forensic imaging, and (5) discuss current advances, collaboration, and potential resources available to interested practitioners.

Impact Statement: This presentation will impact the forensic science community by providing attendees with expertise on best practices, interpretation of radiology imaging, and incorporation of forensic postmortem radiology into medicolegal death investigations.

Program Description: Forensic postmortem radiology is an essential element of a comprehensive medicolegal death investigation. State-of-the-art techniques and procedures will be discussed through case presentations and interactive interpretations of radiology images.

Forensic Imaging; Computer Tomography; Forensic Pathology

W9 Statistical Thinking for Forensic Science: From Probability to Black Box Studies to Likelihood Ratios

Michael J. Salyards, PhD, CSAFE, Tucson, AZ; Linton Mohammed, PhD*, Forensic Science Consultants, Inc., Poway, CA; Hal S. Stern, PhD*, University of California, Irvine, Irvine, CA*

Learning Overview: The workshop is intended to review basic concepts from probability and statistical inference and demonstrate their relevance in the current discussions regarding the assessment and interpretation of impression, pattern, and trace evidence. Participants will: (1) become familiar with the language and key concepts of probability, including the role of populations and sample, laws of probability, dependence/independence of events, conditional probability and Bayes' rule, and the likelihood ratio; (2) become familiar with the language and key concepts of statistical inference, including the role of data collection, measurement, error rates, reliability, and validity; (3) understand issues associated with the design, execution, and interpretation of black box studies; (4) understand statistical hypothesis testing and its relevance for the two-stage approach for analyzing forensic evidence; and (5) understand the likelihood ratio/Bayes factor-approach to assessing forensic evidence along with its strengths and weaknesses.

Impact Statement: Understanding the applications of statistics by the forensic science community will assist practitioners, attorneys, and jurists in evaluating evidence and opinions. The workshop is intended to leave participants in a position to better understand and engage in ongoing discussions (in the Organization of Scientific Area Committees [OSAC] and other places) about appropriate approaches to assessing forensic evidence and reporting forensic conclusions.

Program Description: This workshop provides an introduction to key concepts in probability and statistics by linking them to key topics that are currently impacting the forensic science community. The target audience is anyone (e.g., practitioners, lawyers, judges, educators, and stakeholders) with a desire to better understand ongoing conversations about validation studies, error rates, inconclusive findings, likelihood ratios, and general concepts in statistics and probability.

Probability; Statistics; Validation

W10 Alcohol Calculations and Expert Testimony: How ANSI/ASB BPR 122 and 037 Can Be Applied in Forensic Toxicology Cases

Jennifer F. Limoges, MS, New York State Police, Forensic Investigation Center, Albany, NY; Laura Liddicoat, BA*, Liddicoat Consulting, Fitchburg, WI; Patrick M. Harding, BS*, Robert F. Borkenstein Courses, Madison, WI; Chris Heartsill, BSc*, SOFT/NHTSA, Farmers Branch, TX; Marc A. LeBeau, PhD*, LeBeau Forensic Toxicology Consulting, LLC, Fairfax, VA; Karen Wittman, JD*, ABA Judicial Outreach Liaison, Municipa Court, Kansas City, KS*

Learning Overview: Attendees will be able to use the alcohol calculation guidelines in a wide variety of forensic case types. They will learn how different toxicologists apply those calculations to expert opinion testimony.

Impact Statement: This workshop will impact the forensic toxicology and criminal justice community by educating stakeholders in how the principles of American National Standards Institute/Academy Standards Board Best Practice Recommendation (ANSI/ASB BPR) 122 and ANSI/ASB BPR 037 can be applied to a variety of forensic case types involving alcohol calculations.

Program Description: Forensic toxicologists are frequently asked to perform calculations related to alcohol in a wide variety of situations. ANSI/ASB BPR 122 Best Practice Recommendation for Performing Alcohol Calculations in Forensic Toxicology, First Edition, 2024, outlines a scientific approach to improve the quality and consistency of this type of work. Those calculations can then serve as the basis for expert opinion in matters related to motor vehicle investigations, drug-facilitated crimes, workplace injury inquiries, and other criminal and civil cases. Performing the calculations in a standardized manner can also assist experts in meeting the recommendations of ANSI/ASB BPR 037 Guidelines for Opinions and Testimony in Forensic Toxicology, First Edition, 2019.

This workshop will review the alcohol calculation best practices and expert opinion guidelines, then demonstrate how the calculations can be applied to a variety of real-world case scenarios. Experts will also share how those calculations are then presented in court as part of their expert opinion testimony.

Alcohol Calculations; Retrograde Extrapolation; Expert Testimony

W11 Sequencing 101

Rachel H. Oefelein, MSc, DNA Labs international, Deerfield Beach, FL; Marybeth Sciarretta, MS*, DNA Labs International, Deerfield Beach, FL; Laurence Devesse, PhD*, Qiagen, Zurich, Switzerland; Kevin Lord*, Astrea, Austin, TX; Mandi S. Van Buren, MS*, DNA Labs International, Deerfield Beach, FL*

Learning Overview: The goal of this workshop is for attendees to walk away with a better baseline knowledge of sequencing and to provide a foundation for informed decision-making for those considering deploying sequencing in their laboratory.

Impact Statement: Sequencing can be intimidating for those that are used to the existing DNA technologies that have been available over the past several decades. This workshop will broaden that knowledge.

Program Description: What is a library? If it is whole genome sequencing, why don't I get the whole genome? This workshop is designed to be a crash course in all things sequencing. Existing commercial and custom panels for autosomal Short Tandem Repeat (STR), X-STR, Y-STR, mitochondrial, and Single Nucleotide Polymorphism (SNP) testing will be discussed. Additionally, the differences between targeted sequencing, shotgun sequencing, amplicon versus ligation-based libraries, and additional sequencing methods will be compared. Whether or not bioinformatics is required based on the sequencing method will be explored as well as the types of bioinformatic processes that may be employed, including imputation. With any new technology comes the introduction of this procedure in the courtroom as well as the inevitable court challenges. Successfully presented expert witness testimony will be previewed as well as a look at ongoing court challenges. Finally, cases where sequencing has been utilized will be highlighted. The presenters of this workshop will span industry experts, a bioinformatician, and active casework users of sequencing technologies.

Forensic DNA; Sequencing; Next Generation Sequencing

W12 Can Human Remains Detection Canine Teams Detect Residual Odor? Results of Odor Recognition Tests and Chemical Analysis

Dawnie W. Steadman, PhD, University of Tennessee, Knoxville, TN; Mary E. Cablk, PhD*, University of Tennessee Knoxville, Reno, NV; Shawn R. Campagna, PhD*, University of Tennessee, Knoxville, TN; Mary Davis, MSc*, University of Tennessee, Knoxville, TN; James C. Ha, PhD*, University of Tennessee. Knoxville, TN*

Learning Overview: Residual odor is an odor that persists after the target is removed. This workshop addresses canine detection of residual odor of humans, both deceased and alive. After attending this workshop, attendees will understand: (1) if Human Remains Detection (HRD) canine teams reliably detect residual odor of human remains; (2) if these canines differentiate between residual odors of deceased human remains and live human scent; (3) if analytical chemistry methods detect and differentiate residual odor of living and deceased individuals; and (4) how the integrated results of chemistry and canine behavior analysis help us understand if and how residual odor training can be improved.

Impact Statement: The legal threshold for admitting canine evidence relies on the experience of the handler and their description of the canine's training, neither of which provide the errors associated with the technique required by standard rules of evidence. This workshop will assist attorneys and judges in assessing the probative value of canine alerts that may be detection of residual odor and thus considered evidence by providing results of a coupled canine-analytical chemistry analysis of intact decedent residual odor study. In addition, the standardized Odor Recognition Test (ORT) design will establish guidelines for canine training and testing to improve Human Remains Detection (HRD) certification efforts.

Program Description: Dogs have keen olfactory senses and are deployed for a number of forensic purposes in criminal investigations. HRD canines (a.k.a. cadaver dogs) are trained to detect the odor of human remains, which is comprised of Volatile Organic Compounds (VOCs) that emanate from a deceased body. Despite their widespread use, the reliability of HRD canines is complicated and understudied.

Here, residual odor refers to the odor from a deceased human that remains after it is removed from its resting place, including transient places or objects a body touched. Little is known about deceased residual odor except that its VOCs degrade over time. However, canine alerts are being treated as scientifically valid indicators that an intact decedent was present at one time, even when no physical or corroborating (e.g., chemical) evidence exists, and without regard for the level of training, certification, or proficiency of the canine.

A study of 35 HRD canine teams (handler and dog) tested on residual odor from both deceased and living individuals provides the data and results presented in this workshop. The presenters will describe the development of a standardized, double-blind ORT for canine teams and discuss the accuracy of the canine teams in detecting deceased human residual odor. The presenters will explain the chemical characterization of the VOCs from the odor samples used in the ORTs. Finally, the presenters will utilize select video and audio recordings of the canine team participants from the ORT to contextualize the results and discuss implications of the study.

Cadaver Dog; Accuracy; Multidisciplinary

W13 The Body as the Crime Scene: Traces, Signs, and Scientific Methods

Michelle D. Miranda, PhD, Farmingdale State College, SUNY, Farmingdale, NY; Claude Roux, PhD*, University of Technology Sydney, Sydney, Australia; Patrick Buzzini, PhD*, Sam Houston State University, Huntsville, TX; Yanko G. Kolev, MD, PhD*, Medical University - Pleven/District Hospital MBAL, Gabrovo, Bulgaria; Antonel Olckers, PhD*, African Academy of Forensic Sciences (AFSA) & DNAbiotec, Pretoria, South Africa; Patricia M. Speck, DNSc*, Hoover, AL; Jessica Volz, DNP*, Adventist HealthCare, Shady Grove Medical Center, Rockville, MD*

Learning Overview: This workshop addresses the multidisciplinary approach to forensic investigations, drawing attention to the factors that connect forensic scientists, regardless of discipline or specialization. Specifically, forensic scientists rely on imagination, curiosity, observation, and reasoning in an effort to detect and assign meaning to traces in order to understand events of interest. After attending this workshop, attendees will: (1) understand what connects forensic scientists at our core, notably the scientific approach to problem-solving through observation, reasoning, and the detection and evaluation of traces; (2) consider the types of traces encountered across several disciplines (e.g., AAFS sections, including Criminalistics, Forensic Nursing Science, Pathology/Biology, Toxicology, General, and others); (3) apply what they have learned by considering traces in context and comparing and contrasting discipline-specific approaches to assign meaning to traces of significance; and (4) understand that the Sydney Declaration was developed with the goal of promoting a shared understanding of traces across forensic science.

Impact Statement: This presentation will impact the forensic science community by fostering the understanding that scientific problem-solving in forensic science extends beyond one's specific-area discipline and should be the foundation on which forensic science endeavors are built.

Program Description: This workshop highlights the multidisciplinary approach to forensic investigations, drawing attention to the factors that connect forensic scientists, regardless of discipline or specialization. After learning fundamentals common to forensic science as a whole, attendees will delve into knowledge specific to disciplines (criminalistics, nursing, pathology, toxicology, and scene investigation). Each discipline will focus on the observation, detection, and interpretation of traces to aid in understanding complex events. With a focus on sexual and gender-based violence, attendees will apply the knowledge gained from this workshop interactively via a case study that requires insight from and collaboration across various disciplines.

Sydney Declaration; Traces; Scientific Methods

W14 The Longest Journey Starts With a Single Step: Evaluating Biological Results Given Activity-Level Propositions—The Problem, the Theory, the Solution, and Strategies for Implementation

Tim Kalafut, PhD, Sam Houston State University, Huntsville, TX; Sheila Willis, DSc*, Leverhulme Research for Forensic Science, Dublin, Ireland; Simone Gittelson, PhD*, DC Department of Forensic Sciences and The George Washington University, Washington, DC*

Learning Overview: After attending this workshop, attendees will have a better appreciation of how to evaluate DNA results given activity level propositions. They will practice how to correctly formulate activity-level propositions, assign likelihood ratios for biological results given activity-level propositions, apply the Case Assessment and Interpretation (CAI) framework, and see how to use a probabilistic model (e.g., a Bayesian network). With this knowledge, attendees will be able to start to better address hypothetical questions commonly asked in court by recognizing poorly worded questions and providing scientifically correct answers to these questions.

Impact Statement: This presentation will impact the forensic science community by providing guidance on how to answer activity-level questions on biological results in a way that is useful to the court based on a sound logical framework and following international guidelines.

Program Description: It is clear that the court is interested in "how-the-DNA-got-there" questions. However, answering hypothetical activity-level questions with "it's possible" is not a scientifically justifiable, useful, nor recommended practice. The refusal answer of "I can't answer questions related to how DNA got there" is perhaps even more problematic. This workshop will engage participants in how to prepare and answer activity-level questions with answers that: (1) are not misleading, and therefore minimize the risk of a wrongful conviction; (2) are based on a sound, logical framework; and (3) follow international guidelines. A combination of lectures, demonstrations, and hands-on group activities will be used to show how DNA results may be evaluated with regard to activity-level propositions as well as how to communicate this information. This workshop will cover Case Assessment and Interpretation, existing guidelines, probabilities, likelihood ratios, likelihood ratio equations given activity level propositions, Bayesian networks and sensitivity analyses. In addition, this workshop will focus on how to assign probabilities and likelihood ratios using scientific, peer-reviewed publications. Since case-relevant publications do not always exist, we will also explore how to assign probabilities and likelihood ratios in the presence of limited information. This workshop will cover challenges in answering commonly phrased questions at court and communicating the value of the evidence. Finally, strategies to help with implementation via a series of achievable goals will be presented to equip and empower experts to give answers to these questions of importance to the court.

Activity Level; Evidence Evaluation; Forensic DNA

W15 Artificial Intelligence (AI) in Forensic Education: The Good, the Great, and the Truth

Gina Londino-Smolar, EdD, IU Indianapolis, Indianapolis, IN; Kelly M. Elkins, PhD*, Towson University, Towson, MD; Theresa M. DeAngelo, MSFS*, Maryland State Police, Forensic Sciences Division, Pikesville, MD; Amber L. Fortney, MS*, University of Central Oklahoma, Perry, OK; Meagan Raddatz, MS*, University of Central Oklahoma, Perry, OK; Claire E. Shepard, MS*, LA Delta Community College, Monroe, LA; Ying Zhang, MS*, University of Florida, Gainesville, FL*

Learning Overview: This presentation aims to examine and apply the use of AI in forensic science education, create learning opportunities for students using AI tools, and evaluate the ethics and challenges of using of AI in education.

Impact Statement: This workshop will have a profound impact on the forensic science community by highlighting the transformative potential of AI in education. The workshop targets all people in the forensic science community, especially educators, as the use of AI enters our disciplines. It will provide insights into the ethical implications of AI, explore the application of supercomputers, demonstrate how students can leverage AI for efficient exam preparation, and address complex issues of victimization. The workshop will delve into the ethical considerations of AI use within forensic education, discussing concerns such as privacy, bias, transparency, and academic integrity. The workshop will equip attendees with the skills to craft precise, context-rich prompts for AI-powered tools, facilitating the creation of engaging, adaptive, and industry-relevant learning experiences for forensic science students. This workshop promises to be a game-changer in harnessing the power of AI for the advancement of forensic education.

Program Description: This workshop offers a comprehensive exploration of AI's role in forensic education. It begins with an introduction to the ethical considerations of AI use in academia, highlighting the intersection of AI and plagiarism. The session then delves into the application of AI systems in higher education, including an overview of the HiPerGator supercomputer. Attendees will learn how students can leverage AI for exam preparation, utilizing AI-powered platforms, chatbots, virtual tutors, and flashcard apps. The workshop also addresses the application of AI in solving complex societal issues, specifically the Missing and Murdered Indigenous Women crisis. Ethical considerations of AI use within forensic education are discussed, with a focus on privacy, bias, transparency, and academic integrity. The workshop concludes with a hands-on session on mastering AI prompt generation, equipping attendees with the skills to create engaging, adaptive, and industry-relevant learning experiences for forensic science students. This workshop promises a deep dive into the transformative potential of AI in forensic education.

Education; Artificial Intelligence; Forensic Science

W16 How to Be a Long-Term Unidentified and Missing Persons Investigator: The Investigators' Toolkit

Lara Newell, MA, Virginia Office of the Chief Medical Examiner, Richmond, VA; Katharine C. Pope, MA*, RTI International, Fruitland, MD; Hannah Barcus, MS*, Bureau of Justice Assistance, Washington, DC; Mark A. Bush, BAS*, Loudoun County Sheriff's Office, Leesburg, VA; Bryan T. Johnson, MSFS*, FBI, Quantico, VA; Carol Schweitzer, MA*, National Center for Missing & Exploited Children, Alexandria, VA; Jennifer Randolph, MSc*, DNA Doe Project, Hanover, DE; Nancy Rissi, BS*, Riverside County Sheriff's Department, Riverside, CA*

Learning Overview: During this presentation, attendees will receive information and training on various resources used to investigate long-term unidentified human remains cases, as well as long-term missing persons cases. Attendees will learn how juvenile cases differ from adult unidentified human remains and missing persons cases. Information will be shared on best practices for investigation and will cover a case from start to finish.

After attending the workshop, attendees will: (1) have a better understanding of how to investigate unidentified human remains and long-term missing persons cases; (2) know how to start an unidentified human remains and/or long-term missing persons investigation; (3) understand the resources and support agencies available; (4) be able to determine the best resources that can be utilized for their own cold cases; (5) be able to discuss their own cases and investigations and receive real-time support from the speakers on how best to move their investigations forward.

Impact Statement: The workshop will impact the forensic science community by providing a toolkit for investigators to use during unidentified human remains and missing persons investigations. While there are some agencies who have a dedicated cold-case unit who is responsible for long-term unidentified human remains cases and long-term missing persons cases, the reality is that most agencies across the nation are too small, do not have the budget, and/or do not have the manpower to have a dedicated unit. This workshop will provide attendees with information how to begin a cold unidentified human remains case or missing persons case, and how to keep the cases active. It will also provide attendees with a knowledge base on investigations and a point of contact for resources on cold cases nationwide.

Program Description: The idea for the workshop came from the Long-Term Unidentified Coordinator at the Virginia Office of the Chief Medical Examiner (VA OCME). This position is relatively new with the VA OCME and is rare nation-wide. This is a dedicated position created in 2021 to provide designated care and coordination to the Commonwealth's long-term unidentified cases. The value of a long-term unidentified coordinator is immeasurable. The increase in violent and drug deaths leaves medical examiner offices across the nation overwhelmed with current cases. Without a dedicated individual who has defined duties and responsibilities to coordinate long-term unidentified investigations with law enforcement, these cases fall by the wayside and remain unidentified in perpetuity.

It has been called the nation's "Silent Mass Disaster:" in the United States there are in excess of 14,000 long-term unidentified human remains and 25,000 long-term missing persons. Often, cases have had a cause and manner of death assigned, and occasionally some homicides have been prosecuted, without knowing the identity of the decedent. Even if the case is resolve from a criminal and/or medicolegal standpoint, without resolution of the identity of the person, the case is still incomplete and deserves attention. Resources and tools needed to investigate each of these cases vary on a case-by-case basis. This workshop will give an overview on the resources from NamUs/RTI, NCMEC, the FBI, non-profit DNA labs, and local law enforcement.

One of the challenges with investigating unidentified human remains and missing persons cases is the lack of assistance, support, and resources. The speakers for this workshop are all well-established in their respective fields and are valuable resources for investigating unidentified human remains cases and long-term missing persons cases. At the end of the workshop, there will be a discussion panel where attendees can ask questions about the process of investigation, as well as receive individual support and assistance for their own investigations. At the end of the workshop, attendees will have a better understanding of the resources available to them and will hopefully be able to implement new techniques in their own agencies.

This workshop was designed to assist investigators from law enforcement agencies and medical examiners/coroners in investigating their long-term unidentified human remains cases as well as long-term missing persons cases. Representatives from the National Missing and Unidentified Persons System (NamUs), National Center for Missing and Exploited Children (NCMEC), the DNA Doe Project, the Federal Bureau of Investigation (FBI), and a cold case detective from Virginia will discuss how their agencies can assist and provide support to those investigating unidentified human remains and long-term missing persons cases.

The presentation on NamUs will include updated information on staffing, system services, and training. The Program Manager for the Forensic Services Unit at NCMEC will share resources and case examples on how NCMEC can assist and support juvenile investigations for both unidentified human remains and missing persons investigations. The Bureau of Justice Assistance (BJA) will discuss federal resources and grant opportunities for those investigating missing and unidentified persons cases.

The second block includes presentations that are more hands-on. The executive director from the DNA Doe Project will discuss Forensic Investigation Genetic Genealogy and the resources that the DNA Doe Project can provide. The FBI's Major Incident Program Manager will give an overview on the Latent Print Unit in the FBI and their support services, as well as a chemical demo on how to retrieve fingerprints on degraded human remains. The last presentation is from a local cold case detective who will present their case of an unidentified human remains case from start to finish.

Unidentified Persons; Missing Persons; Casework

W17 Practical Neuropathology for Coroners and Medical Examiners: Basic Concepts and Advanced Principles

Lorenzo Gitto, MD, Cook County Medical Examiner's Office, Chicago, IL; Ponni Arunkumar, MBBS*, Cook County Medical Examiner's Office, Chicago, IL; Jared Ahrendsen, MD, PhD*, Northwestern University, Chicago, IL; Anfisa Baiandurova, MD*, West Tennessee Regional Forensic Center, Memphis, TN; Rudolph J. Castellani, MD*, Northwestern University, Feinberg School of Medicine, Chicago, IL; Samantha N. Champion, MD*, Cook County Medical Examiner, Chicago, IL; Michelle A. Jorden, MD*, Santa Clara County Medical Examiner/Coroner, San Jose, CA*

Learning Overview: After attending this workshop, participants will have an enhanced knowledge base of neuropathology as seen in a busy forensic pathology office. Emphasis will be placed on natural diseases, trauma, microscopic sampling and examination, and pediatric non-accidental head trauma. Attendees will develop skills necessary for comprehensive brain assessments at autopsy and techniques to address both common and unusual pathologies. They will be exposed to various specimens and techniques through didactic presentations, and case-based discussions.

Impact Statement: This workshop will emphasize the multifaceted nature of brain pathology in the context of forensic autopsy. Didactic lectures and practical instruction using detailed anatomical images will be provided to enhance autopsy performance and competency, with an additional focus on the workup and evaluation of pediatric non-accidental head injury.

Program Description: Assessing Central Nervous System (CNS) trauma is critical in neuropathology and forensic pathology and encompasses closed- or open-head injuries, multiple types of forms of parenchymal brain injury, and secondary complications such as edema and increased intracranial pressure. Establishing a link between trauma and death is crucial for determining the cause and manner of death.

Child abuse, particularly abusive head trauma, is a complex and vital focus in forensic neuropathology. A comprehensive workup is essential to document the findings and determine their relevance in terms of evidentiary significance and to rule out potential confounders to pediatric head trauma and child abuse.

CNS disorders such as epilepsy may present significant challenges when associated with sudden and unexplained death (Sudden Unexplained Death in Epilepsy [SUDEP]), as they often lack morphological indicators. Other natural disease processes, such as undiagnosed brain tumors, aneurysms, infections, neurodegenerative diseases, and cerebrovascular accidents, can further complicate forensic assessments and may have public health implications.

Different brain pathologies necessitate varied approaches, including detailed external examinations, precise sampling for microscopic analysis, and specialized dissection techniques tailored to highlight specific findings.

This workshop will explore fundamental and advanced aspects of brain pathology in forensic autopsies, including but not limited to CNS anatomy, head trauma, neurovascular diseases, infections, specialized autopsy dissection techniques, and microscopic examination of rare or uncommon conditions. Attendees will participate in didactic sessions, case studies, step-by-step dissection guides, and evidence-based discussions led by forensic and neuropathologists, facilitating interactive learning and skill enhancement.

Forensic Pathology; Neuropathology; Central Nervous System Trauma

W18 A New Frontier — Federal Agencies Paving a Way for Forensic Drug Analysis With AI

Agnes D. Winokur, PhD, Drug Enforcement Administration, Washington, DC; Kimberly Westberry, PhD*, USACIL, Forest Park, GA; Sandra Ferreira, MSc*, Canada Border Service Agency, Ottowa, Ontario, Canada; Scott R. Oulton, BS*, Drug Enforcement Administration, Arlington, VA; Henry Swofford, PhD*, National Institute of Standards and Technology, Gaithersburg, MD; Melissa Taytlor, BA*, National Institute of Standards and Technology, Gaithersburg, MD*

Learning Overview: After attending this workshop, attendees will: (1) be able to better understand how federal agencies in the United States and internationally are using machine learning tools and other technological advances in seized drug analysis; (2) be able to evaluate the challenges with robotics and algorithms to improve laboratory analytical capabilities and seized drug workflow strategies; and (3) be able to explain how federal agencies are addressing the new frontier of machine-learning and artificial intelligence in support of forensic science investigations.

Impact Statement: This workshop will benefit the forensic science community by highlighting how federal agencies are considering the benefits, risks, and limitations that machine learning capabilities and technological advances have brought to forensic science seized drug analysis, such as collaborations on investigations, epidemiology, drug intelligence, and canine training, and operations. It will also highlight how embracing these opportunities can strengthen the efficiency of laboratory operations, utility of the results, and timeliness of testing.

Program Description: Federal agencies around the world are embracing the new frontier of machine learning and advanced technology and considering how to AI within the current systems. This workshop will provide insight into various examples of how federal agencies are applying machine learning capabilities and other technological advances to forensic science and drug analysis. The National Institute of Standards and Technology (NIST) researchers will be discussing their efforts in creating a catalog of AI-enabled tools currently being used by forensic science service providers and researchers for forensic science applications, to include available or near-market tools. Other examples include Drug Enforcement Administration's (DEA's) implementation of state-of-the-art automation for sample preparation related to screening and quantitative analysis. Using advanced robotics, samples are prepared for general screening of controlled substances and quantitative analysis. The Canada Border Services Agency will present on the transformative capabilities of existing software in conjunction with the portable mass spectrometers for narcotics detection at the Canadian Border. Participants will gain insights into the sophisticated software algorithm, which significantly enhances confidence in direct inject Mass Spectrometry (MS) spectral matching, providing rapid and precise results.

In addition, attendees will participate in an interactive exercise in which they will identify areas in seized drug processes where AI-enabled tools have the potential to be transformative (e.g., evidence analysis, quality control, reducing the likelihood and consequence of error and cognitive bias, and research activities. The workshop will finish with information on the progress toward establishing a road map for the responsible development, testing, evaluation, and adoption of trustworthy machine-learning and AI systems in forensic science.

Machine Learning; Algorithms; Forensic Analysis

W19 Unmasking the Evidence: How Defense Experts Prevented Wrongful Convictions

Anjali Ranadive, JD, SciLawForensics, Ltd, Phoenix, AZ; Hon. Roderick T. Kennedy, JD*, Retired Appellate Judge/Attorney, Los Ranchos, NM*

Learning Overview: By attending this workshop, attendees will: (1) understand the adversarial nature of the legal system and its implications for forensic evidence; (2) recognize the challenges faced by attorneys and judges in evaluating scientific evidence without a background in science; (3) explore the impact of prestigious institutions like the Federal Bureau of Investigation (FBI) on perceptions of evidence credibility; (4) analyze the role of language in forensic reports and testimony, including potential inaccuracies and biases; (5) enhance skills in scrutinizing evidence collection, chain-of-custody procedures, and testing methodologies; (6) develop awareness of confirmation bias and the dangers of tunnel vision in legal proceedings; (7) recognize the importance of competent expert testimony in challenging misleading evidence presentations; (8) examine real-life cases to illustrate systemic issues in handling evidence and presenting cases in court; (9) enhance critical thinking skills in evaluating laboratory procedures, interpretation methods, and statistical analyses; and (10) promote ethical practices in legal and forensic professions to ensure the pursuit of justice.

Impact Statement: The training program aims to empower legal professionals working in the criminal justice field with the knowledge and skills necessary to navigate the complexities of forensic evidence. By shedding light on systemic issues, promoting critical thinking, and advocating for ethical practices in evidence presentation, this program seeks to enhance the pursuit of justice in the legal system. Participants will be equipped to challenge misleading evidence, recognize biases in language, and ultimately contribute to a fairer and more transparent judicial process. Through real-case examples and expert guidance, this program strives to make a lasting impact on how forensic evidence is handled, ensuring that the quest for truth and justice remains paramount in legal proceedings.

Program Description: The program will highlight the challenges faced by legal professionals who may lack the scientific background needed to assess forensic evidence accurately. It emphasizes the critical role that defense experts play in preventing wrongful convictions by scrutinizing evidence, reports, testimony, and the actions of forensic analysts.

Anjali Ranadive and Tiffany Roy, both attorneys and forensic scientists with significant experience, aim to shed light on systemic issues within the legal system through real case examples. They will provide insights into various problems such as evidence mishandling, credibility of testing procedures, misleading language in reports, and biases in case theories. By bringing attention to these issues, they will emphasize the importance of having competent experts for the defense to challenge flawed evidence, interpretations, and statistical analyses that could sway court decisions unjustly.

The workshop underscores the notion that without the input of knowledge of experts on the defense side, there is a risk of overlooking crucial opportunities to question the validity of evidence presented by the prosecution. This can ultimately impact the fairness of legal outcomes and the dispensation of justice. By advocating for a more balanced and informed approach to evaluate forensic evidence in court, the speakers aim to promote a greater sense of integrity and equity within the criminal justice system.

Expert Testimony; Criminalistics; Language

W20 Signed by Hand or by Machine?

Linton Mohammed, PhD, Forensic Science Consultants, Inc., Poway, CA; Zain Bhaloo, MSc*, Canada Border Services Agency, Ottowa, Ontario, Canada; Jonathan Heckeroth, MSc*, Zurich Forensic Science Institute, Zurich, Switzerland*

Learning Overview: This workshop will introduce attendees to new methods of creating machine-generated signatures. Features of these types of signatures in comparison with handwritten signatures will be discussed and demonstrated.

Impact Statement: This workshop will provide Forensic Document Examiners (FDEs) with information on how to deal with the examinations of signatures that are possibly machine-generated. The examiners' knowledge should enhance the quality and reliability of opinions given as to signature authenticity.

Program Description: This workshop will introduce FDEs to new types of machine-generated signatures. There will be a significant hands-on session where attendees will examine and compare original handwritten signatures and original machine-generated signatures. There will be information given as to how the signatures were produced. Discriminating features of the signature types will be discussed by the attendees.

Forensic Analysis; Signature Identification; Machine Learning

W21 All Rise 2.0: Navigating the Judicial Process as an Expert Witness

Laura C Fulginiti, PhD, MCOME, Phoenix, AZ; Daniel W. Martin, JD*, State of Arizona, Phoenix, AZ; Katelyn L. Bolhofner, PhD*, Arizona State University, Phoenix, AZ; Betty Layne DesPortes, JD*, Benjamin & DesPortes PC, Richmond, VA; Kristen Hartnett-McCann, PhD*, CT Office of the Chief Medical Examiner, Farmington, CT; Gary C. McDonald, Jr., JD*, Dallas County Criminal District Attorney's Office. Dallas, TX; Andrew C. Seidel, PhD*, King County Medical Examiner's Office, Seattle, WA*

Learning Overview: After attending this workshop, attendees will be well-versed in the decorum, procedures, expectations, and environment of a modern United States courtroom through active participation in courtroom proceedings.

Impact Statement: This presentation will impact the forensic science community by offering real-world experience in expert testimony in an environment conducive to productive learning without the stress of an actual trial.

Program Description: Forensic scientists are trained in the techniques, theory, history, and standards associated with their particular discipline. Often lacking, however, is training in the application of those skills to the courtroom setting and, in particular, the presentation of expert testimony. A forensic expert's ability to effectively communicate in a courtroom setting is vital if that expert is going to make meaningful contributions to the justice system. This workshop seeks to improve courtroom communication skills by providing a combination of lectures and hands-on learning that will introduce the basic foundations of the United States court system, the roles of the participants, the types of pre-trial and trial processes that occur, and the opportunity for attendees to practice testifying in a true-to-life courtroom environment with case-based scenarios.

Expert Testimony; Court; Mock Trial

W22 Chasing the Dragon: Navigating Death Investigations in the Era of Novel Psychoactive Substances

Elisa N. Shoff, MS, Miami-Dade Medical Examiner Department, Miami, FL; Mary E. Zaney, BSc*, Miami-Dade Medical Examiner, Miami, FL; Kayla N. Ellefsen, PhD*, Travis County Medical Examiner, Austin, TX; David Fintan Garavan, PhD, MD*, District 10 ME Office, Winter Haven, FL; Alex J. Krotulski, PhD*, Center for Forensic Science Research and Education, Horsham, PA; Joshua Z. Seither, PhD*, Armed Forces Medical Examiner System, Division of Forensic Toxicology, Dover, DE; Chip Walls, BS*, Tox Lab, Miami, FL; Erin Worrell, BSc*, Franklin County Center of Forensic Science, Office of the Coroner, Columbus, OH*

Learning Overview: Upon completion of this workshop, the participant should be able to: (1) interpret key differences between the Novel Psychoactive Substance (NPS) classes and how they impact cause and manner of death; (2) discuss the difficulties encountered in investigating NPS in the context of forensic toxicology, seized drug analysis, death scene investigation, toxicological interpretation, and accurate certification of cause and manner of death and; (3) appreciate the importance of disseminating timely information regarding emerging NPS trends and the impact on public health and harm reduction.

Impact Statement: These presentations will impact the forensic science community by emphasizing the importance of collaboration and dissemination of relevant and accurate information across forensic science disciplines regarding the identification and interpretation of NPS. Additionally, these presentations will increase understanding of the different classes of NPS, how they are marketed and often mislabeled, types of products to look for on the scene, and the role these drugs play in death investigation and certification.

Program Description: This half-day workshop is a collaboration between the AAFS ad-hoc Opioid and Emerging Drugs Committee and the Society of Forensic Toxicologists (SOFT) NPS Committee. From the scene of a suspected overdose to the final determination of cause and manner of death, this workshop will demonstrate how information from a range of forensic scientists can be applied to a death investigation and subsequently further the understanding of NPS for both forensic practitioners and the public.

There are hundreds of NPS on the market today with a wide range of psychoactive effects; however, most of these substances have unknown pharmacological properties (e.g., potency, metabolism, toxicity), complicating the interpretation of their impact on public health and safety. In addition, keeping up with the drug market becomes a challenge, and forensic practitioners and researchers are left chasing information on NPS that quickly becomes outdated due to the volatility of the drug supply. Whether it is crime scene investigation, pathological findings, pharmacological and toxicological interpretations, or chemical analysis, when trying to understand NPS, the work of one forensic discipline is regularly influenced by that of another. By working together, forensic scientists can increase their chances of providing timely information that can aid in drug-related death investigation, updating drug trends, and maintaining public policy and drug prevention outreach in the community.

Novel Psychoactive Substances; Postmortem; Death Investigation

W23 A Skeletal Atlas of Elder Abuse: Beta Testing a Digital Diagnostic and Educational Tool

Katelyn L. Bolhofner, PhD, Arizona State University, Phoenix, AZ; Laura C Fulginiti, PhD*, MCOME, Phoenix, AZ; Jane E. Buikstra, PhD*, Arizona State University, Phoenix, AZ; Kevin A. Gary, PhD*, Arizona State University, Phoenix, AZ; Jacob A. Harris, PhD*, Arizona State University, Phoenix, AZ*

Learning Overview: After attending this workshop, attendees should be able to: (1) describe methods used to characterize/assess skeletal fracture patterns in elderly individuals and the ways in which aging affects fracture and recovery; (2) understand there are different patterns of trauma associated with abuse/neglect and with accidental falls, (3) understand how to navigate the presented digital atlas of elder abuse, both for educational and diagnostic purposes; and (4) participate in beta testing the atlas and contribute usability data toward its final construction.

Impact Statement: Ten percent of adults aged 65+ will experience some form of abuse annually. Physical abuse and caregiver neglect account for most cases, yet they remain difficult to prove. Skeletal expressions of abuse offer key indications of inflicted and untreated injuries but are masked by assignation to accidental falls. Funded by the National Institute of Justice (NIJ), our research aims to produce a standard for the diagnosis of elder abuse in the skeletal system. This presentation will impact the forensic science community by offering the first iteration of a digital tool for diagnosis and education and for collaboration and learning so that we may improve our understanding of fractures and their contexts in elderly individuals.

Program Description: Increasing rates of elder abuse in the United States over the past few decades have produced an urgent need for improved diagnostic criteria to better design intervention procedures, to implement recognition criteria, and to achieve justice for victims. Physical abuse of elders represents the most severe manifestation of this trend. Yet physical abuse is difficult to prove and may be masked by attribution of injury to medication or accident. In this workshop, attendees will learn how aging impacts skeletal trauma incidence and patterning. The presenters will provide an overview of differences in the skeletal patterns of injury between accidental falls and cases of abuse/neglect uncovered in our NIJ-funded research, as well as the impact of bone density loss on these patterns. Attendees will be introduced to the first complete iteration of the Skeletal Atlas of Elder Abuse — A Digital Tool for Diagnosis and Education. The presenters will discuss the development of the online platform, its aims and future direction, and will request attendee feedback through the beta testing of the site. Participants will have the opportunity to hear from the developers of the machine learning and AI models driving the diagnostics of the site as well as from the software development team responsible for the creation of the atlas and its many interactive features. This workshop probes the opportunities (and challenges) associated with the development of such a tool, asking attendees for participation, suggestions, direct interaction, and user experience measures.

Skeletal Fracture; Elder Abuse; Digital Atlas

W24 ANSI/ASB Standard 175 — Standard for Interpreting, Comparing, and Reporting DNA Test Results Associated With Failed Controls and Contamination Events: Understanding, Implementation, and Legal Issues

Charlotte Word, PhD, North Chesterfield, VA; Virginia Barron, JD*, Birkholz Law, Westbrook, MN; Tabitha Bandy, MS*, BODE Technology, Old Hickory, KY*

Learning Overview: Attendees at this workshop will learn about each of the requirements in the newly published Standard in relationship to requirements in other standards (e.g., Federal Bureau of Investigation Quality Assurance Standards (FBI QAS), International Organization for Standardization (ISO) 17025, American National Standards Institute/Academy Standards Board (ANSI/ASB) published, Organization of Scientific Area Committees (OSAC) Registry) while gaining insights for their implementation. Approaches to consider for evaluating, decision-making, and reporting data without re-testing will be presented along with hands-on problems and through interactive discussions. In addition, the attendees will learn about the legal necessity for implementing this standard when the DNA results are exculpatory to avoid contributing to a Brady violation.

Impact Statement: This presentation will impact the forensic science community by providing laboratory personnel, attorneys, and judges critical information regarding the responsibility of evaluating DNA data when a control has failed or a contamination event has been detected, especially when the DNA results may be exculpatory for an individual. The specific requirements in this Standard for: (1) the laboratory protocols for evaluating, interpreting and comparing data associated with failed controls and contamination events; (2) assessment of the risks of re-testing vs. not re-testing; (3) documentation; and (4) the reporting of the event, and the associated data and conclusions will be discussed along with considerations for successful implementation in the laboratory. Additional discussions will include the effective communication of the data, conclusions, and events in the criminal justice system through conversations, trainings, and testimony.

Program Description: Incidents of contamination of controls and evidence in laboratories conducting Polymerase Chain Reaction (PCR) -based Short Tandem Repeat (STR) testing have been increasingly detected as the sensitivity of the assays has improved over the past decade through improved technological advances and with the implementation of elimination databases to detect the DNA profiles of laboratory staff and other individuals involved in the collection and handling of evidence, along with the use of advanced software for evaluating data. Positive control failure may occur when the DNA is not added correctly or may be due to a technology failure.

Historically, when these events occurred, re-testing was conducted on a portion of the remaining evidence, and the new test results were reported. However, when the evidence and DNA extract have been consumed, re-testing is not an option. It is also not always prudent to consume more evidence with re-testing. Situations where this may be relevant and how this pertains to the requirements in the Standard for Interpreting, Comparing, and Reporting DNA Test Results Associated with Failed Controls and Contamination Events will be discussed. This Standard has recently been published as an ANSI/ASB Standard but has been listed as a Proposed Standard on the OSAC Registry (OSAC 2020-S-00040) and has been available for implementation in DNA testing laboratories for several years.

This workshop may be beneficial to DNA analysts/technical leaders/supervisors, QA/QC managers, trainers, and laboratory directors overseeing any type of testing where controls may fail or contamination can occur and to attorneys and judges encountering DNA tests results from these situations.

Forensic DNA; Contamination; Quality Control

W25 Death of an Expert Witness: Discrediting Document Examiners Who Violate Acknowledged Standards or Binding Laboratory Policies or Who Express Handwriting Opinions With Low Levels of Certitude

Andrew Sulner, JD, Forensic Document Examinations, LLC/Sulner Law Offices, New York, NY; Linton Mohammed, PhD*, Forensic Science Consultants, Inc., Poway, CA; Roderick T. Kennedy, (ret.), JD*, New Mexico Court of Appeals, Los Ranchos, NM*

Learning Overview: After attending this workshop, the attendees will have a better understanding of how lawyers can discredit an expert witness who failed to adhere to an acknowledged industry standard or binding laboratory policy. Attendees will also learn why handwriting opinions expressed with low levels of certitude such as "indications" or "probable" can easily be impeached and discredited and why it would be better if such opinions were excluded by gatekeepers.

Impact Statement: This presentation will impact the forensic science community by providing document examiners and forensic scientists in various forensic pattern-matching disciplines with a clear understanding of the basic unreliability of expert opinions expressed with a low level of certitude.

Program Description: A distinguished faculty comprising two highly credentialed forensic document examiners, one of the nation's leading evidence scholars, and a recently retired appellate court judge will provide attendees with a clear understanding of the problems facing document examiners who violate acknowledged industry standards or binding laboratory policies and the reliability concerns associated with handwriting opinions expressed with a low level of certitude. Attendees will be provided with actual case histories illustrating how handwriting opinions expressed as "indications" or "probable" are challenged and discredited. Attendees will also learn about the reliability issues gatekeepers must address when deciding whether or not to admit handwriting opinions expressed with a low level of certitude.

Discrediting Handwriting Opinions; Reliability; Standards

W26 Expanding the Forensic Professional's Toolbox: New Technological Resources for the Evaluation of Evidence

Alicia L. Carriquiry, PhD, Iowa State University, Ames, IA; Michael J. Salyards, PhD*, CSAFE, Tucson, AZ; Heike Hofmann, PhD*, University of Nebraska-Lincoln, Lincoln, NE; Steven Lund, PhD*, National Institute of Standards and Technology; Gaithersburg, MD*

Learning Overview: Individuals who participate in the workshop will learn about new computational tools developed by the Center for Statistics and Applications in Forensic Evidence (CSAFE) researchers in collaboration with the National Institute of Standards and Technology (NIST) scientists. The tools are designed to answer forensic questions of interest in several pattern comparison disciplines and enable practitioners to provide a probabilistic assessment of the evidence. At least in the near future, the new resources are meant to be used alongside traditional examination methods and serve to either confirm categorical conclusions or call attention to potential issues with those conclusions.

Impact Statement: Imaging, computational, and other tools are already used by forensic practitioners to analyze some types of evidence (e.g., DNA), but their introduction has been slower in the pattern comparison disciplines. Once they are more extensively tested and validated, the tools developed by CSAFE will empower practitioners to carry out quantitative analysis and interpretation of evidence and reinforce reporting and testimony with data-based results. The tools we will introduce at the workshop are free and placed in the public domain to maximize access and transparency.

Program Description: Forensic practice changes at a pace that varies by discipline. Sophisticated instrumentation and computational tools have been used by forensic DNA examiners for decades, but introduction of new methods has been slower in pattern comparison disciplines, probably because comparing images is complex. Yet, examiners in these disciplines are facing frequent challenges when relying on expert opinion alone. Research groups, including CSAFE, have, in the past decade, tried to address the lack of data-based methods for the forensic analysis of patterns. These groups have demonstrated that it is possible to quantify similarity between two images, even when one is degraded. While several new methods have been proposed in the scholarly literature, the gap between research and practice has not been breached, except by a few private companies that develop proprietary tools. To encourage adoption of new methodology, CSAFE researchers have created tools that enable forensic practitioners to implement quantitative methods for the evaluation of firearm, footwear, and handwriting evidence. During the workshop, participants will learn about and use three applications that are (or soon will be) ready for testing on real case work. These applications are all in the public domain and can be used at no cost. Participants will be asked to bring their own laptop and will get access to software and example data before the meeting. In addition to hands-on learning, the workshop will include lecture-style presentations to ensure that users of the applications have a reasonable understanding of the science and data that underpin the apps.

Artificial Intelligence; Error Rate; Statistics

W27 Mind Games and Machines: Navigating Cognitive Biases in Forensic Technologies

Michelle Patch, PhD, Johns Hopkins University, School of Nursing, Reisterstown, MD; Joyce P. Williams, PhD*, Stevenson University, Randallstown, MD; Victor G. Petreca, PhD, DNP*, Boston College/MA DMH, Chester Hill, MA; Tamar Rodney, PhD*, Johns Hopkins University, School of Nursing, Baltimore, MD*

Learning Overview: After attending this workshop, participants will be able to: describe Cognitive Biases: Participants will be able to recognize various cognitive biases, such as confirmation bias and anchoring bias, and understand how these biases influence decision-making processes within forensic science and related fields; analyze the Impact of Technology on Biases: Participants will gain insights into how forensic technologies like Artificial Intelligence (AI) and machine learning interact with and potentially exacerbate cognitive biases. They will learn to evaluate the strengths and limitations of these technologies in mitigating or amplifying biases in forensic investigations, and explain Strategies to Mitigate Bias: Participants will acquire practical strategies and best practices for addressing and reducing cognitive biases in forensic settings. This includes applying lessons learned from case studies and expert presentations to improve decision-making accuracy and fairness in forensic technology applications.

Impact Statement: This workshop will enable participants to effectively navigate cognitive biases within forensic technologies, offering strategies to enhance the accuracy and fairness of technological applications. By understanding the interplay between human biases and tech innovations, attendees will be better equipped to leverage technology while mitigating its potential pitfalls.

Program Description: Explore the critical intersection of cognitive bias and forensic technology in this engaging and interactive presentation. We'll start by illustrating cognitive biases through everyday life examples, helping you recognize these common mental shortcuts and their impact on our daily decisions.

Cognitive biases, while often beneficial for quick decision-making, can introduce significant errors, especially in high-stakes environments like forensic science. We'll review a range of biases — such as the halo effect, confirmation bias, and anchoring bias — and examine their effects on various stakeholders, including forensic professionals, law enforcement, jurors, and the public.

Next, we'll dive into the world of forensic technology, specifically exploring the fundamentals of AI and machine learning. We'll clarify what these technologies are, how they have evolved in recent decades, address misconceptions about their capabilities, and discuss challenges associated with their misuse.

Interactive segments will include case studies from past high-profile forensic cases, where we'll identify and analyze biases at play. This hands-on approach will help you see how biases can influence forensic outcomes and public perception.

Experts will present strategies to counteract cognitive biases related to forensic technology, offering practical insights into improving accuracy and fairness. We'll conclude with a Q&A session using live polls to engage with audience thoughts on the implications of AI in forensic science and beyond.

Attendees will gain a deeper understanding of how cognitive biases interact with forensic technology and discover actionable strategies to enhance justice and accuracy in forensic practices.

Forensic Science; Bias; Technology

A1 Epi and Histo: Partners in Improving Age-At-Death Estimation

Victoria M Dominguez, PhD, Lehman College, City University of New York, Bronx, NY; Sara C. Zapico, PhD*, New Jersey Institute of Technology/Smithsonian Institution, Newark, NJ*

Learning Objectives: After attending this presentation, attendees will understand the importance of utilizing interdisciplinary techniques to improve aspects of the biological profile.

Impact Statement: This presentation will impact the forensic science community by demonstrating for the first time that the combination of epigenetic and histological methods has the potential to increase the accuracy of age-at-death estimation in skeletal remains and merits further research.

Abstract Text: In the identification of unknown remains, reliable age estimates are essential for the creation of the biological profile that could match with a missing person. However, current methods of age estimation using gross morphology for adults are often less precise than estimates for juveniles. While multifactorial models that incorporate age estimates from various locations in the skeleton exist and demonstrate improved estimates, at present these rely solely on macroscopic assessments. Other techniques for the estimation of age, such as histological and epigenetic approaches, have individually demonstrated promise for accurately and more precisely estimating age, particularly in middle-age and elderly adults. These techniques have been around for a while; however, there are currently no studies focused on combining these techniques, as with macroscopic approaches. Based on this premise, the goal of this study was to use a combination of histological and epigenetic techniques in a sample of known age as a first step for developing a new method to improve age-at-death estimation.

The sample consists of 12 individuals of known age from whom both a femoral bone sample and a canine tooth were available. Samples were drawn from a donated cadaveric collection that allows destructive sampling in the United States. Samples ranged from 16 to 88 years of age, with an average age of 58 years (±26 years), with four females and eight males, though biological sex was not considered in these analyses. For histological analysis, a single midshaft section of the femur was prepared and data were collected following Crowder and Dominguez.[1] For the epigenetics DNA methylation analysis, DNA from dentin and pulp from a single canine were extracted following previous protocol from Zapico and Ubelaker.[2] DNA methylation of previously assessed genes (ELOVL2, FHL2, KLF14, SCGN, NPTX2) was analyzed by pyrosequencing on bisulfite converted DNA according to Zapico et al.[3] To assess the relationship of the variables with age, linear regressions were applied.

For the histological data, Osteon Population Density (OPD), a measure that combines the count of intact and fragmentary osteons over a given area, demonstrated the strongest relationship with age ($R^2$0.793), while fragmentary OPD had the second strongest relationship (R^2 =0.719). For the epigenetic data, FHL2, and particularly CpG4, show the strongest correlation with age in pulp (R^2=0.818) and a lower correlation in dentin (R^2 =0.686). These results align with previously published data supporting the utility of both these methods independently for estimating age. Combining these data, adding OPD to FHL2 at CpG4 in pulp increased the strength of the correlation (R^2 =0.940). The correlation with age increases further when combining OPD with FHL2 at CpG4 and CpG1 to R^2 =0.993. In dentin, the combination of OPD and FHL2 at CpG1 displays the highest correlation (R^2 =0.932), increasing when adding SCGN CpG9 (R^2 =0.968).

Thus, it is clear that the FHL2, a transcriptional co-factor involved in bone formation, plays a key role in the aging process and when combined with the histological variable of OPD, which quantifies bone remodeling, has the potential to improve age estimates. This is a preliminary study to establish the utility of these techniques to contribute and improve on existing aging methods, particularly in cases of limited or fragmented remains. Future research will expand these results, increasing the number of samples, skeletal elements, and genes analyzed and developing a new method for estimating age based on both techniques.

Age-at-Death; Bone Remodeling; DNA Methylation

A2 Age Estimation Through Osteon Histomorphometry: An Analysis of Autopsy Samples

Raffaella Minella, MS, Department of Cultural and Archeological Heritage, University of Salento, Italy, Bari, Puglia, Italy; Giada Sciâdi Steiger, MSc, Liverpool John Moores University, Liverpool, England, United Kingdom; Giada S. Steiger, MSc, Liverpool John Moores University, Liverpool, England, United Kingdom; Enrica Macorano, MD, University of Bari, Bari, Puglia, Italy; Francesco Introna, MD, PhD, University of Bari, Bari, Puglia, Italy*

Learning Objectives: Age estimation has a crucial role in forensic science. It is often necessary to estimate the age of skeletal remains. After this presentation, participants will get a broader overview of a proposed model for age estimation based on histological femur specimens and gather information on the conduct of research.

Impact Statement: Forensic age estimation is usually based on morphometric analysis of skeletal remains. The forensic pathologist and anthropologist also possess histological skills, being able to combine forensic expertise with the study of histological preparations of analyzed bone tissue. This presentation will have an impact on the forensic community by showing the importance and value of histomorphometry in the forensic and archaeological context, as well as an insight into variables that are significantly related to age.

Abstract Text: Age estimation in the forensic field is of fundamental importance. Different are the fields of application, where the traditional biological profile is based on gross bone morphology and morphometric analysis.[1] However, that is not always possible; therefore, the forensic expert must resort to a more multidisciplinary approach. Histomorphometry has proven over the years to be efficient and reliable mainly in older individuals and is quite useful in cases of highly fragmented or incomplete skeletal remains.[2,3] The main difficulty is to consider all the variables available to the forensic pathologist to achieve the expected result. The objectives of this study are thus to evaluate the possible correlation of some of the microstructures present in cross sections of autopsy samples with age and sex and to furthermore evaluate whether these variables can be used to derive a reliable model to estimate the age of the individual.

Osteons are functional and trophic units, almost autonomous, and they are made up of lamellar tissue arranged around the Havers' canal.[4] Bone tissue undergoes continuous processes of reabsorption and deposition of bone tissue, regulated by hormonal stimuli as metabolically active.[5] This remodeling, therefore, influences variables such as the number of osteons, their density, and their area.

The sample used for the analysis was composed of 95 cross sections of autopsy samples from the previous cases. The age at death of the individuals ranged between 18 and 92 years, of which 54 were females and 41 were males.

Following a thorough literature review, the number and densities of primary osteons, intact and fragmentary secondary osteons, and drifting osteons, were selected as variables to investigate their relation in expressing the age-related variations during the growth and aging process. Further variables included the mean osteoanal area and circularity. The primary objective of the research was to establish the correlation and significance of the variables considered in relation to the age maturation of the bone tissue. This was achieved by taking pictures from cross sections of the femoral diaphysis and analyzing them using the digital image processing tool ImageJ. The secondary goal was to establish a model to estimate age at death, computing the variables previously analyzed.

The statistical analysis showed that while there are no significant differences for each variable between males and females, the Number of Secondary Osteons and the Intact Population Density increased with age while the Mean Osteoanal Area decreased with age, confirming what has been previously observed in the literature.[6,7] Although these results align with previous research, the development of the model was limited due to the nature of the sample. Future research will be conducted using the same protocol analysis and statistical model proposed in this presentation that will include a broader sample size and a more uniform distribution of juveniles and older individuals.

Age-at-Death Estimation; Compact Bone Histomorphometry; Forensic Age Estimation

A4 Age Estimation of Young Adults in the Italian Population: An Application of Schmeling's Method Using Conventional Radiography

Giorgio De Donno, MD, Università degli Studi di Bari, Maglie (LE), Puglia, Italy; Gianfrancesco Di Nunno, MD, Università degli Studi di Bari, Canosa di Puglia, Puglia, Italy; Gianluca Gravili, MD, Università degli Studi di Bari, Grottaglie, Puglia, Italy; Alessandra Petruzzellis, MD, Università degli Studi di Bari, Bari, Puglia, Italy; Stefania Galizia, MD, Università degli Studi di Bari, Conversano (BA), Puglia, Italy; Maria Grazia Lorusso, MD, Università degli Studi di Bari, Bari, Italy; Antonio De Donno, PhD, Università degli Studi di Bari, Bari, Puglia, Italy; Lucrezia Ardito, MD, Università degli Studi di Bari, Bari, Italy; Amato Antonio Stabile Ianora, PhD, Università degli Studi di Bari, Bari, Italy; Arnaldo Scardapane, PhD, Università del Salento, Lecce, Italy*

Learning Objectives: Age estimation for forensic purposes is a crucial topic of international interest, especially in relation to the increasing number of migrants and asylum requests from citizens of war-torn countries. Numerous techniques have been proposed in recent decades, categorized into skeletal and dental methods. Therefore, our study aimed to assess the method of evaluating the degree of ossification of the clavicle for age estimation.

Impact Statement: Our study, which is the result of a joint effort between the Department of Forensic Medicine and the Department of Radiology of the University of Bari, provides a basis for developing a mathematical model capable of predicting the age of undocumented minors with the highest possible accuracy. This is essential for safeguarding the rights of minor asylum seekers and for various applications requiring chronological age estimation.

Abstract Text: A total of 366 chest radiographs taken in 2023 from Italian-born patients aged 10 to 30 years were collected at the AOUC Policlinico and the Paediatric Hospital "Giovanni XXIII" in Bari, Italy. Among these, 26 were excluded due to the presence of fractures at the medial third of the clavicle. The study population thus included 340 radiographs (M: 234, F: 106). The experiment was conducted in a blind way: patient demographic data were obscured, no clinical information was provided to the observers, and each image was assigned an identifying alphanumeric code. The images were analyzed separately by two observers. The degree of ossification of the Medial Clavicular Epiphysis (MCE) was assessed by each observer according to Schmeling's classification (stage 1-5), using the atlas by Yoon et al. (2016).[1,2] Interobserver Agreement (IOA) was then evaluated. A final score (1-5) was assigned subsequently. The results were compared with the chronological age of the patients: descriptive statistics of the results (mean, median, SD, minimum-maximum age) were performed. Receiver Operator Curve (ROC) analysis was used to assess the diagnostic accuracy of the method in determining whether the patient was over or under 18 years of age. The agreement between Observer A and Observer B, evaluated using Cohen's kappa, was found to be satisfactory (k = 0.652, 69%). The mean age, divided by sex, observed in each stage was as follows: Stage I (M: 14.26, SD: 3.10, Total: 42 – F: 12.82, SD: 4.26, Total: 11); Stage II (M: 17.72, SD: 3.59, Total: 50 – F: 17.09, SD: 4.57, Total: 22); Stage III (M: 20.76, SD: 3.65, Total: 55 – F: 21.18, SD: 3.55, Total: 34); Stage IV (M: 25.20, SD: 3.97, Total: 44 – F: 29.95, SD: 3.05, Total: 19); Stage V (M: 26.98, SD: 3.15, Total: 43 – F: 27.15, SD: 2.78, Total: 20). The ROC demonstrated a high diagnostic accuracy of the test (cutoff: 3, PPV: 89.77%, sensitivity: 82.13%, specificity: 79.05%). Furthermore, a linear regression analysis has been performed, which showed a positive, strong correlation between age and stages. The mean age, stratified by sex, observed in each stage was comparable to the results reported in previous studies.[3] The mean age for each category obtained were comparable to those of previous studies.

Although several skeletal and dental methods for estimating age have been developed, their main limitation is that they rely on specific reference populations. Researchers have yet to reach a consensus on whether these methods are suitable for all groups, particularly migrants, who may exhibit delayed bone development due to malnutrition or other medical conditions, such as growth disorders. Our study aimed to assess the reliability of the Schmeling method using a sample of Italian youths aged between 10 and 30 years as a reference. Consequently, our results are applicable to a Caucasoid population in generally good physical health. Hence, our study represents an additional step in the overall validation of the MCE method for age estimation. Future studies should examine different reference populations and incorporate various factors (e.g., malnutrition, developmental disorders) to assess the global reliability of the method. Our findings on inter-observer agreement (k = 0.652, 69%) underscore the importance of this method being performed by experienced and well-trained professionals in the field of forensic age estimation. Finally, to reduce the degree of overlap in stages, it would always be useful to combine this method with radiographic examinations of other districts (e.g., hand-wrist, dental), while awaiting the development and validation of future deep learning-based AI methods.

A5 Estimating Age-at-Death in Adults Using the Calce Method

Gloria B. Eddy, BA, Des Moines University, West Des Moines, IA*

Learning Objectives: After attending this presentation, attendees will gain knowledge regarding the utility of using morphological changes to the acetabulum for age estimation. Specifically, they will learn about the accuracy and reliability of the Calce method, which uses the acetabulum of the os coxa to estimate adult age-at-death.[1]

Impact Statement: This presentation will impact the forensic science community by providing data that could influence a practitioner's decision to apply the Calce method in their casework.

Abstract Text: For forensic anthropologists, age estimation is an integral part of producing a biological profile to aid law enforcement in identifying human remains. The Calce method suggests using morphological characteristics of the acetabulum of the os coxa to estimate age at death. This method uses observable changes to osteophyte development, the acetabular groove, and apex growth to provide an age-at-death estimation of young adult (17–39 years), middle adult (40–64 years), or old adult (65+ years). Digital renderings along with morphological descriptions of the traits in their different stages are provided to guide the individual employing the method. The Calce method was originally found to have 81% accuracy when estimating age at death for both males and females. Additionally, intra-observer and inter-observer tests found the method to display moderate to substantial agreement.

The present study sought to evaluate if the accuracy, inter-observer, and intra-observer results changed when applying the method to a different population sample. To achieve this, the Calce method was applied to a sample of 476 individuals of known sex, age, and ancestry from the Hamann-Todd Human Osteological Collection at the Cleveland Museum of Natural History. This sample included males and females ages 17–105 of Black and White ancestry. The study was conducted blindly to prevent any potential bias. After the method was applied to the entire sample, intra-observer and inter-observer tests were conducted on a random sample of 50 and 47 individuals, respectively. When applied to this sample, the method exhibited an accuracy of 56.51% with the intra-observer test showing substantial agreement and the inter-observer test showing fair agreement.[2] The results show a deviation from the findings in the original study.[1] Possible reasons for this discrepancy could be variation across different populations. Additionally, the use of digital renderings, rather than photographs of os coxae, could have caused confusion when categorizing each trait as they are not direct representations.

Age Estimation; Accuracy; Method Validation

A6 Exploring the Role of Early Life Stress in the Accuracy of Age-at-Death Estimation Among Adults

Caroline L. Znachko, MA, University of Tennessee, Knoxville, Knoxville, TN; Taylor Walkup, MA, University of Tennessee, Knoxville, Knoxville, TN; Derek A. Boyd, PhD, University of Nevada, Las Vegas, Las Vegas, NV*

Learning Objectives: After attending this presentation, attendees will better understand how early life stress impacts the accuracy of different age-at-death estimation methods commonly used by forensic anthropologists to report a final age range estimation to law enforcement agencies.

Impact Statement: This presentation will provide insights regarding the accuracy of common age estimation methods for unidentified human remains for individuals and communities who experience early life stress and structural inequities. Practitioners aware of these methodological and theoretical limitations will increase their competency in understanding the biocultural dimensions of health that impact skeletal senescence and, thus, affect the accuracy of forensic anthropological methods.

Abstract Text: Age-at-death estimation is a component of the biological profile created by forensic anthropologists to assist medicolegal practitioners with identifying decedents. Yet, our ability to accurately estimate chronological age from skeletal remains can be impaired when adverse lived experiences become embodied physiologically and impact the pace of biological aging. Previous research has shown that the long-term physical embodiment of chronic stress associated with structural inequities such as poverty can lead to premature biological aging and consequently decrease the accuracy of age estimations.[1] This process of premature aging, termed "weathering," originated from the discipline of social epidemiology and has been evidenced by widening health disparities throughout the life course of living United States Black and White adults.[2,3] The extent to which early life stress experienced during growth and development affects the accuracy of age-at-death estimation remains unclear.

This research examines the association between early life stress, as inferred from skeletal stress markers, and the accuracy of age estimation methods that rely on degenerative changes to the pubic symphysis and sternal rib ends. Skeletal stress markers were recorded and age at death was estimated for 83 adult donors from the University of Tennessee Donated Skeletal Collection. Vertebral Neural Canal (VNC) Anteroposterior (AP) and Transverse (TR) diameters (T1-L5) were measured, and the presence of porotic lesions of the skull, including porotic hyperostosis and cribra orbitalia, were scored. VNC AP and TR diameters mature in early childhood and adolescence, respectively, with small diameters suggesting disrupted development.[4] Similarly, porotic lesions may be caused by genetic or acquired chronic anemias that disrupt skeletal remodeling, reflecting early life health and nutritional status.[5] Age was estimated using the Suchey-Brooks, Işçan et al., and Hartnett methods, and accuracy was determined by whether the known age fell within the estimated age range.[6-9]

Fisher's Exact Tests failed to detect associations between the presence of porotic lesions and the accuracy of each aging method at the $p < 0.05$ level. A series of independent-samples t-tests were used to compare VNC diameter (in mm) between individuals based on method accuracy (correct vs. incorrect). Significant differences at the $p < 0.05$ level were detected for both VNC AP and TR diameters with positive findings frequently associated with the Suchey-Brooks and Hartnett methods in the former (AP) and Suchey-Brooks only in the latter (TR). In contrast, significant differences in VNC diameter were not associated with accuracy in either sternal rib method. These findings suggest that the accuracy of aging methods that rely on the pubic symphysis may be affected by experiences of early life stress. Moreover, the lack of positive findings associated with porotic hyperostosis and cribra orbitalia suggests that different skeletal stress markers may variably impact age-at-death estimates depending on the timing, frequency, or duration of early life stress experiences. Thus, it is recommended that forensic anthropologists acquire a deep understanding of the social contexts and communities in which they work so they may consider how experiences of physiological stress might impact their ability to accurately estimate age at death in their decedent population.

Age Estimation; Stress; Biological Profile

A7 A Validation Study of Bergs' Method for Aging the Pubic Symphysis

Amanda Schultz, BA, University of South Florida/ IFAAS, Bushnell, FL; Erin H. Kimmerle, PhD, University of South Florida, Tampa, FL*

Learning Objectives: The attendees will gain a better understanding of aging for the pubic symphysis among older-aged adults. Attendees will also understand when Berg's seven-phase method for aging the pubic symphysis should be used on males and the method performs, compared to females, as it was initially developed to be used on females.

Impact Statement: Proving the reliability of diverse methods for both older-aged males and females has a significant impact on unidentified person cases. Currently, most methods predict age to about 60 years old. Through this study, it is demonstrated that males and females can be accurately aged well into advanced age, 70+ years.

Abstract Text: There have been numerous studies testing Berg's method compared to standard methods such as Suchey and Brooks and others; however, none have focused on the accuracy and reliability of the method itself, nor have they expanded its use to male samples.[2-4] This study tests Berg's seven-phase system. The specific research questions test the accuracy, reliability, and repeatability of Bergs' method of aging older adults. This study also tests the method's applicability for males.

The data was collected from the University of South Florida Donated Collection, housed at the Florida Institute of Forensic Anthropology and Applied Sciences, University of South Florida. Data were collected for 55 males and 48 females, with ages ranging from 41 to 101 years old. To examine the research questions, this study will age 103 individuals based on a blind study. Repeated data were collected from three independent observers to test inter-observer variation. Intra- and inter-observer errors are used in this study to determine reliability and repeatability. One master's student and one Ph.D. candidate will perform a repeatability test for the study, analyze the data using statistics, and put them into charts to compare the accuracy, repeatability, and reliability of both males and females.

There were many statistical methods used within this study. One of those methods used for this study was the chi-square analysis to compare the author's observations with those of the other graduate students who aged some of the pubic symphyses. The study also used the Pearson correlation analyses to compare variations among my observations with the other graduate students who are aging the pubic symphyses. The Bayesian theorem was used as well to help explain the results from the study. The results show that Berg method for aging the pubic symphysis is statistically reliable and consistent for both males and females. This is especially true when it comes to older aged females that are 60+ years old. The data shows that there is not a statistically significant inter-observer or intra-observer error within the method.

Age Estimation; Bone; Anthropology

A8 Age Estimation of the Pubic Symphysis From 3D-Printed Proxies

Rhys Williams, PhD, Loyola University Maryland, Baltimore, MD; Phoebe Baker, MS, Thames Valley Police, Leighton Buzzard, England; Rebecca L.J. Strong, PhD, Teesside University, Middlesbrough, England*

Learning Objectives: After attending this presentation, attendees will understand the accuracy, precision, and suitability of using 3D scanners and printers for creating reproductions of skeletal human remains for analysis. This presentation shows whether established anthropological techniques (Suchey-Brooks) still apply on 3D reproductions with comparative reliability, and whether adjustments are required for these samples.[1]

Impact Statement: This presentation will impact the forensic science community by showing the suitability of 3D reproductions for anthropological techniques, thereby breaking down barriers and improving accessibility of education resources capturing worldwide skeletal variation.

Abstract Text: 3D scanning and printing have received much attention through many areas of forensic science, including evidence reproduction, geometric analysis, crime scene reconstruction, and courtroom presentation. Across studies, 3D models are shown to be topographically accurate, without significant differences in metric measurements between the original and the reproduced object. However, less attention is paid toward whether 3D prints can be used for tactile analysis in omission of the original object.

A selection of pubic symphyses of different ages and preservation conditions were digitized using a 3D surface scanner. 3D digital models were processed for 3D printing in plastic and resin. Each of the real bone, plastic print, and resin print counterparts were randomly arranged for participants to view and assign a Suchey-Brooks phase for age estimation.[1] The printed and real bones were within 1.0mm accuracy, with surface features presented well. However, the plastic prints maintained more topographic definition, whereas the surfaces of resin prints were smoothed out, resulting in resin prints being assigned the same age phase as the real bone less frequently than with plastic prints. Furthermore, bones within early age phases were assigned the same phases more frequently than bones within later age phases, partly due to the key features being more susceptible to damage.

Overall, this research shows that 3D printed reproductions of bone are suitable for tactile and morphological assessments, but care must be required when selecting suitable preserved bones and the printing medium of choice. The success of this helps to break down barriers to access; there is prospect for establishing a printable skeletal collection to capture and educate on skeletal variation in populations from across the world in the localized classroom. Attendees will be able to view the 3D prints and submit their own phase scores at the accompanying poster session.

Anthropology; 3D Technology; Age Estimation

A9 Observer Confidence Versus Accuracy: Analysis of 3D-Printed Pubic Symphyses

Rhys Williams, PhD, Loyola University Maryland, Baltimore, MD; Phoebe Baker, MS, Thames Valley Police, Leighton Buzzard, England; Rebecca L.J. Strong, PhD, Teesside University, Middlesbrough, England*

Learning Objectives: After attending this presentation, attendees will understand the disparity between observer confidence and assessment accuracy when analyzing 3D printed reproductions of skeletal material.

Impact Statement: This presentation will impact the forensic science community by showing the need for training and experience in analyzing 3D printed replicas in addition to experience handling real human remains.

Abstract Text: 3D scanning and printing have received much attention through many areas of forensic science, including evidence reproduction, geometric analysis, crime scene reconstruction, and courtroom presentation. However, there are concerns around whether 3D prints are suitable for morphological analysis and whether methods need tailoring for the reproduced surface to improve observer accuracy and confidence.

3D digital models of a selection of pubic symphyses of different ages and preservation conditions were processed for 3D printing in plastic and resin (39 samples total). Each of the real bone, plastic print, and resin print were randomly arranged for seven participants to view. Participants had varying levels of experience, from students up to active practitioners with years of experience. Participants assigned age phases to the real and reproduced samples using the Suchey-Brooks method and scored their confidence in each assessment on an ordinal scale of 1-5.[1] Estimation accuracy was determined by whether the assigned score matched the known age phase. Data were analyzed in R for data assumptions, Mann-Whitney U, and Chi-Square testing as appropriate.

The early age phases saw both the highest confidence scores and the most consistent phase assignments. Participants with more experience provided higher confidence scores and were correct more frequently, whereas less experienced participants showed wide variation in their assigned scores. Participants were most confident with real bones because some discreet features were visually less distinct in the reproductions. However, participants assigned age phases more quickly with prints than with real bones. Participants were more confident and accurate with plastic prints than resin prints because the resin surface was smoother and consequently less distinct, particularly at later age phases that require recognizing more discreet evidence.

Overall, this research shows that 3D printed reproductions of bone are an effective resource but require experience, consistency, and integrity as with established anthropological techniques. The success of this research helps break down barriers to access; there is prospect for establishing a printable skeletal collection to capture and educate on skeletal variation in populations from across the world in the localized classroom. The 3D prints will be available for viewing at this session, and attendees can submit their own sample phase scores to contribute toward this research.

A10 Sex Estimation Using Metrics of the Innominate: A Validation of the DSP2 Method

Alexandra R. Klales, PhD, Washburn University, Topeka, KS; Kate M. Lesciotto, PhD, University of North Texas Health Science Center, Fort Worth, TX*

Learning Objectives: The goal of this presentation is to inform attendees about the reliability and accuracy of the DSP2 method, which uses up to ten measurements of the innominate to estimate sex.

Impact Statement: This presentation will impact the forensic science community by presenting data that demonstrates high classification accuracy and low intra- and inter-observer error for the DSP2 method of sex estimation in a modern United States sample.

Abstract Text: Sex estimation is a critical component of the biological profile, and forensic anthropologists may use a variety of sex estimation methods depending upon the degree of completeness and state of preservation of the skeletal remains being analyzed. Most skeletal elements have been evaluated for their use in sex estimation; however, the innominate is widely accepted to be the most sexually dimorphic skeletal element. Methods for estimating sex from the innominate focus on either morphological or metric data.

The *Diagnose Sexuelle Probabiliste* (DSP) method, which uses ten measurements of the innominate, was introduced in 2005 and updated as DSP2 in 2017.[1,2] Both DSP and DSP2 are based on Fisher's linear discriminant analysis and require a posterior probability of > 0.95 in order for sex to be predicted. While DSP2 has been reported to have high classification accuracy rates in studies of South American and European populations, the method has not been widely tested in United States samples, and few United States practitioners incorporate this method into their casework.

The goal of this study was to test the reliability and validity of DSP2 using a large, modern sample from the United States (n = 174; 92M/82F). Two observers blindly collected the ten innominate metrics included in DSP2. Two-sample t-tests were used to test for significant differences between males and females for each of the innominate measurements. Observer error rates were calculated using the Technical Error of Measurement (TEM), relative Technical Error of Measurement (rTEM), and Intraclass Correlation Coefficient (ICC) with a 95% Confidence Interval (CI). Accuracy rates were calculated based on the proportion of individuals for whom sex was correctly classified by DSP2 with a posterior probability that exceeded 0.95. The inclusivity rate, or the percent predicted, was calculated based on the proportion of individuals that reached the posterior probability threshold of 0.95 and had sex predicted by DSP2 (either correctly or incorrectly).

Significant differences were found between males and females for all measurements except SA (p = 0.1954) and PUM (p = 0.0547). Intra- and inter-observer error analyses showed acceptable levels of agreement for all measurements (< 1.5% rTEM for intra- and < 2.0% rTEM for inter-observer error), except for IIMT (6.56% rTEM for interobserver error) and SPU (2.83% rTEM for interobserver error). Classification accuracies exceeded 95% for females and reached 100% for males for both observers and using various measurement combinations; however, an inclusivity sex bias occurred with approximately 15-20% more males than females reaching the 0.95 posterior probability threshold required by the DSP2 program to provide a sex classification estimate. Based on the high reliability and validity of DSP2, forensic anthropologists in the United States are encouraged to incorporate this method for sex estimation into their casework, although additional methods relying on morphological traits of the innominate will continue to be needed when the posterior probability threshold of DSP2 is not reached.

Sex Estimation; DSP2 Method; Validity and Reliability

A11 The Effect of Mental Eminence Trait Scores on Sex Estimation Accuracy Rates Using MorphoPASSE

Kate M. Lesciotto, PhD, University of North Texas Health Science Center, Fort Worth, TX; Arikka R. Carroll, Northern Michigan University, Peshtigo, WI; Alexandra R. Klales, PhD, Washburn University, Topeka, KS*

Learning Objectives: The goal of this presentation is to inform attendees about the effect of mental eminence trait scores and inter-observer error on sex estimation accuracy rates using MorphoPASSE.

Impact Statement: This presentation will impact the forensic science community by improving the reliability of the MorphoPASSE sex estimation program. Practitioners will be provided with data demonstrating that the mental eminence trait does not provide significant information contributing to sex estimation accuracy.

Abstract Text: Forensic anthropologists often assist in medicolegal death investigations involving unidentified human skeletal remains. To aid decedent identification, an anthropologist will develop a "biological profile," including estimations of the individual's biological sex, age, stature, and population affinity (ancestry). There are five sexually dimorphic traits of the skull that are commonly used for sex estimation: nuchal crest, mastoid process, supraorbital margin, glabella, and Mental Eminence (ME). MorphoPASSE is a free, online program that uses a random forest statistical model to analyze these traits.[1] Each morphological trait is scored on an ordinal scale from 1 (more gracile) to 5 (more robust), based on descriptions and exemplar images. Using these trait scores, MorphoPASSE will provide an estimate of the unknown individual's sex based on the calculated posterior probability, with a threshold of 0.50. Previous research has found high inter-observer error rates for ME scoring.[2-4] As a result, MorphoPASSE now recommends against using ME; however, no research has examined the effect of inter-observer error for ME on sex estimation accuracy rates. The project aims to test the effect of simulated inter-observer error for ME and exclusion of ME on accuracy rates using MorphoPASSE.

One observer blindly scored each of the five skull traits in a sample of 323 individuals (155 F; 168 M) from five modern United States skeletal collections. To examine the effect of ME scores on accuracy rates, several datasets were tested. The initial dataset included scores for all five morphological traits of the skull as a baseline for comparison. To simulate the effect of systematic inter-observer error, a dataset was created with ME scores increasing by 1 (except for original scores of 5), and a dataset was created with ME scores decreasing by 1 (except for original scores of 1), with both datasets leaving the other four trait scores as originally recorded. Ten additional datasets were created that simulated random inter-observer error with weighted, squared Cohen's kappa (k) values ranging from 0.0 (agreement no better than chance) to 0.9 (excellent agreement). Finally, a dataset was created that excluded the ME score entirely, such that sex estimation was based solely on the other four traits.

Trait scores from each dataset were entered into MorphoPASSE, with the estimated sex for each individual recorded as male or female, based on which posterior probability exceeded the 0.50 threshold. Accuracy rates were calculated for each of the datasets as the percentage of individuals for whom sex was correctly estimated. Chi-square tests of independence were used to determine if there were significant differences in accuracy rates between the datasets. Pooled accuracy rates ranged from 86.4% (original dataset) to 84.5% (simulated $k = 0.0$). While female accuracy rates generally decreased, male accuracy rates actually increased with decreasing k values, resulting in larger sex biases. Excluding ME resulted in a slight decrease in the female accuracy rate (85.8% to 83.9%) and an increase in the male accuracy rate (86.9% to 88.7%). However, there was no significant difference in accuracy rates between the original dataset and any of the simulated datasets or the dataset that excluded ME (all $p > 0.05$).

Based on these results, ME should not be used for sex estimation in the MorphoPASSE program not simply because of the risk of high inter-observer error but also because ME scores do not contribute significant information as part of the random forest statistical model. Even with a weighted, squared k of 0.0, there was no significant difference in accuracy rate or distribution of posterior probabilities.

Forensic Anthropology; Sex Estimation; MorphoPASSE

A12 An Assessment of MorphoPASSE Software for Undergraduate Forensic Anthropology Education: Integrating Sex Estimation Technology Into the Classroom

Elauna R. Hicks, BS, Middle Tennessee State University, Murfreesboro, TN; Shannon C. Hodge, PhD, Middle Tennessee State University, Murfreesboro, TN*

Learning Objectives: After attending this presentation, attendees will assess how the program MorphoPASSE, developed in 2018, can provide accurate results for sex estimation of skeletal remains at the undergraduate level of study in forensic anthropology.

Impact Statement: This presentation will help inform the forensic science community on how MorphoPASSE can assist with identification at all levels of education, which will further the scope of learning for sex estimation in forensic anthropology. This will be demonstrated by a case study where a student earning their undergraduate degree utilized MorphoPASSE[1].[1]

Abstract Text: Forensic anthropology, an evolving discipline within forensic science, gained significant attention following the 2009 National Academy of Sciences (NAS) Report, which highlighted deficiencies in forensic methodologies.[2] The report emphasized the need for reforms and standardization across forensic disciplines. In response, the Organization of Scientific Area Committees (OSAC) for Forensic Sciences was established in 2014 under the National Institute of Standards and Technology (NIST) to drive these necessary changes through the development of standards and funding of new research initiatives. Among the initiatives supported by OSAC is the "MorphoPASSE[1]: Morphological Pelvis and Skull Sex Estimation" program, developed by Dr. Alexandra Klales with National Institute of Standards and Technology (NIST) funding. Launched in 2018, MorphoPASSE[1] aims to standardize non-metric methods for estimating sex from osteological remains, thereby reducing potential biases. The program utilizes a set of eight morphological traits—five from the skull and three from the pelvis—scored on a scale from one to five. Scores of one and two are typically associated with female remains, while scores of four and five are associated with male remains. A score of three represents an ambiguous classification. Each trait has its own drawing, photographs, and verbal description that goes into detail on how the trait will be scored. After all the necessary information is provided, the program will generate a report that includes the probability of the individual's sex. The report also provides relevant statistical data, including percentages based on how accurate the program is when given a similar case.

This presentation evaluates the efficacy of the MorphoPASSE[1] program from an undergraduate perspective, focusing on the reliability of data generated by a non-professional student. Data for this study was collected during the summer and fall academic semesters from the Middle Tennessee State University (MTSU) osteological collection and the University of South Florida (USF) Donated Skeletal Collection. The MTSU collection is located at Middle Tennessee State University in Murfreesboro Tennessee and consists of six individuals who had limited known life histories. The USF Donated Skeletal Collection is located at the University of South Florida in Tampa and has 135 donated individuals. A total of 76 individuals were scored in the osteological labs using the MorphoPASSE[1] program by a student currently earning a bachelor's degree in anthropology. Each individual's MorphoPASSE[1] assessment was then compared to their known sex, and preliminary results indicate that 83% of the estimations matched.

The information gained from this case study was then utilized to create a curriculum integrating MorphoPASSE1 for the undergraduate's level of understanding of forensic anthropology. By integrating MorphoPASSE[1] at various educational levels, the curriculum aims to enhance students' proficiency in sex estimation and foster greater standardization within the discipline. This approach seeks to improve educational outcomes and promote consistency in forensic anthropological practices.

Anthropology; Sex Assessment; Morphopasse

A13 Assigned-Sex-at-Birth Estimation Using a 3D-Printed Replica of the Os Coxa: A Case Study of a Transgender Woman Who Used Gender-Affirming Hormone Therapy During Life

Taylor M.M. Flaherty, MSc, University of Nevada, Las Vegas, Henderson, NV; Jennifer F. Byrnes, PhD, University of Nevada, Las Vegas, Las Vegas, NV*

Learning Objectives: Attendees will learn the outcomes of a study conducted at the American Academy of Forensic Sciences (AAFS) conference in 2024, where forensic anthropologists estimated the Assigned Sex At Birth (ASAB) of an individual whom participants did not know was transgender using a 3D-printed replica of the decedent's left os coxa. This presentation will help attendees understand the reliability of commonly used methods for estimating ASAB and how the anthropologist's training, experiences, and demographics impacted their overall estimates.[1,2] Potential impacts of gender-affirming care on sexually dimorphic regions of the os coxa will also be discussed as part of the ongoing conversation surrounding sex, gender, and forensic anthropology.

Impact Statement: This presentation will encourage members of the forensic science community to better understand the nuances surrounding sex, gender, and their human skeletal embodiment as well as how practitioner experience and implicit bias may impact ASAB estimates in forensic anthropology. The forensic science community will feel called to action following this presentation as our results suggest that biases and forensic methodologies may inhibit the accurate identification of decedents and further perpetuate necro-violence toward gender-diverse populations.

Abstract Text: Non-metric skeletal traits impacted by ASAB are often used in forensic anthropology training and research due to their reported efficiency and effectiveness; non-metric methods are also preferred by forensic anthropologists in casework.[3] The os coxa is also generally favored when estimating ASAB in forensic anthropology cases because of reproductive differences between those assigned female and male at birth.[3] While these differences certainly impact skeletal presentation, the characteristics are not dimorphic. Rather, there is a spectrum of skeletal presentation influenced by biology, culture, epigenetics, and the sociopolitical medicalization of the body.[1,2]

To understand where transgender individuals fall on the spectrum of ASAB characteristics, this study explored the reliability of forensic anthropologists' ASAB assessments using a 3D-printed replica of the left os coxa from the only transgender woman in the New Mexico Decedent Image Database confirmed to use Gender-Affirming Hormone Therapy (GAHT) during life. Over 60 forensic anthropologists examined the 3D replica and analyzed four non-metric traits.[1,2] Each participant reported a final ASAB estimate, a rating of the replica's quality, their confidence, their academic background, and demographics.

We had three key hypotheses: (1) the anthropologist's demographics and background would impact their assessments and the classifications provided by each method, as well as their confidence; (2) the reported quality of the 3D replica would correlate with final estimates; and (3) there would not be strong agreement between participants due to group differences (i.e., trainees compared to American Board of Forensic Anthropology [ABFA] Diplomates). Additionally, we aimed to better understand if non-metric results correlate more closely with an individual's ASAB or lived gender when they used GAHT during life.

Surprisingly, our results showed only a few instances where participant experiences or demographics impacted trait scores or final ASAB assessments. For example, the participant's ASAB significantly ($p = 0.055$) impacted the scores attributed to the ventral arc, with those assigned female at birth interpreting this trait as more pronounced (mean = 2.84) than those assigned male at birth (mean = 3.42). Historically, a pronounced ventral arc is associated with those assigned female at birth, suggesting possible GAHT-induced alterations or that the participants subconsciously projected their own presumed skeletal characteristics onto the sample due to difficulty in assessing this trait. Participant's prior experience with MorphoPASSE also significantly impacted their assessment of the ventral arc ($p = 0.002$) and subpubic contour ($p = 0.022$), with chi-squared tests showing a significant ($\chi 2 = 8.80$, $p = 0.003$, $df = 1$) relationship between MorphoPASSE experience and the ASAB outcome reported by MorphoPASSE. An Intra-Class Correlation showed over 90% agreement between all participants, indicating consistent assessments of the 3D replica despite a few group differences (i.e., participant ASAB). Finally, participants gave an intermediate average rating of the 3D replica, but this did not correlate with their interpretation of the skeletal replica or their confidence levels.

A male bias was also observed, though not always statistically significant. Many participants provided intermediate scores for each of the four traits, yet the estimates provided by MorphoPASSE, Walker, and the participants were overwhelmingly "Male" (77.1% in MorphoPASSE, 96.7% using Walker, 60.7% of final participant estimates) or "Probable Male" (29.5% of final participant estimates).[1,2]

This study highlights the reliability of 3D-printed replicas of the os coxa among forensic anthropologists, but reveals a potential subconscious male bias that led to the transgender woman being overwhelmingly classified as "Male" or "Probable Male." This case study supports the use of a biocultural profile and continued research focusing on marginalized groups in forensic anthropology to improve identification efforts.

A14 A Geometric Morphometric Examination of Possible Patterns of Sexual Trait Expression Across Five Skeletal Elements

Kaleigh C. Best, PhD, Western Carolina University, Cullowhee, NC*

Learning Objectives: Attendees will learn how the degree of morphological sexual trait expression co-varies between sexually diagnostic regions of the innominate, skull, sacrum, and scapula. How these potential patterns may relate to intrinsic and extrinsic factors as well as the impact this may have on sex estimation within biological anthropology is also discussed.

Impact Statement: Sex estimation is an integral part of forensic anthropology. Understanding how sexual trait expression varies within the individual is important and is understudied within forensic anthropology. This presentation will examine the concordance of the levels of sexual trait expression throughout the individual and what these patterns may suggest in regard to possible contributing factors to sexual trait expression in human remains.

Abstract Text: Although sex estimation classification accuracy of some element-specific methods can exceed 90%, the relationship between morphological traits within the individual and how they may respond to different intrinsic and extrinsic factors remains poorly understood.[1-10] Previous research, while scant, suggests variable sexual trait expression between different skeletal regions, with a lack of concordance between regions in the level of expression.[11-16] Understanding these relationships are vital for forensic anthropologists, as subsequent analyses rely on correct classification of biological sex. Further, instances of commingling, fragmentary and partial remains, and inconsistent sex estimation also rely on accurate understanding of human variation in terms of morphological expression. Attendees of this presentation will examine the complex interrelation of sexual trait expression between five skeletal elements to better understand what, if any, pattern is present in skeletal trait expression and what factors may be contributing to these patterns.

Utilizing 3D surface scans of the cranium, mandible, innominate, sacrum, and scapula collected from 235 individuals from the University of Tennessee (UTK) Donated Skeletal Collection and the Robert J. Terry Osteological Collection, this research uses geometric morphometric techniques to evaluate how sexual trait expression is correlated across skeletal regions. The following hypotheses were evaluated: (1) human sexual trait expression is not correlated between all skeletal regions, (2) skeletal sexual traits withing a localized anatomical region are influenced by the same factors, but these factors differ by anatomical region, and (3) individuals from the same collection will demonstrate similar magnitude and pattern of sexual trait expression compared to the other skeletal collection. For each skeletal element, after landmarks were placed, data were subjected to a principal component analysis where the first five principal components (representing approximately 60% of the variance) were subjected to a matrix correlation test, strength of correlation test following definitions provided in Chan, and Pearson correlation tests to determine significance on correlations with greater than fair correlation strength (following Akoglu).[17,18]

Results indicate significant inter-skeletal element correlations in both skeletal samples, with the UTK Collection having a larger number of inter-skeletal element correlations than the Terry Collection. Different element correlations, with no clear pattern in pairings, were present in both collections, although cranium-mandible correlations were the most common and most statistically significant correlation pair observed in both. Other patterns for each collection are discussed. Interestingly, in both collections, females had more and more statistically significant correlations than males, with greater differences in correlations between sexes occurring in the UTK Collection than in Terry. Aside from integration, these results may suggest differential biocultural influences are impacting the magnitude and patterns of sexual trait expression across skeletal elements. Therefore, practitioners of forensic anthropology should consider dynamic nature of morphological traits and consider biocultural influences in studies of sex estimation.

Sex Estimation; Interindividual Sexual Trait Expression; Human Variation

A15 A Test of the (hu)MANid Analytical Program

Jordan K. Karsten, PhD, University of Wisconsin, Oshkosh, Oshkosh, WI; Christina L. Nicholas, PhD, University of Illinois Chicago, Chicago, IL; Hayley J. Hintz, BS, University of Wisconsin, Milwaukee, Fond du Lac, WI*

Learning Objectives: After viewing this presentation, attendees will gain knowledge regarding the ability of the (hu)MANid analytical program to accurately estimate ancestry and sex from mandibular metric and morphoscopic data. Specifically, they will learn about the strengths and weakness of the method as observed in a large test of the program.

Impact Statement: This presentation will impact the forensic science community by providing a study that critically evaluates the ability of the (hu)MANid analytical program to accurately estimate ancestry and sex from data derived from mandibles. The results of this study may influence how forensic anthropologists chose to employ (hu)MANid in the future and how they interpret the results.

Abstract Text: Sex and ancestry are key components of the biological profile estimated during routine forensic anthropological casework. Recently, Berg and Kenyhercz Introduced a new freely available web-based computer program called (hu)MANid that utilizes mandibular metric and morphoscopic data to estimate both sex and ancestry.[1] Such an analytical program should be very useful, as mandibles are relatively resistant to taphonomic destruction, especially as compared to the fragile bones of the facial skeleton. However, only a small number of studies have tested the performance of (hu)MANid, and the results of these tests have been mixed. For instance, while one study of dry mandibles found the program to accurately (82.7%) identify mandibles of American Indian ancestry, another found ancestry classification for Asians, Blacks, Whites, and Hispanics to be relatively poor (33.57%) using mandibular Computed Tomography (CT) scans.[2,3]

In an effort to continue to add to the literature testing (hu)MANid, we have conducted a study using a sample of dry mandibles from White (n=96) and Black (n=115) individuals of known sex and ancestry from the Hamann-Todd Human Osteological Collection and from American Indian (n=52) individuals derived from prehistoric archaeological sites in Wisconsin housed at the University of Wisconsin-Oshkosh. For each mandible, data were collected following the instructions provided on the (hu)MANid website and processed using the linear discriminant function option and composite group reference samples. Overall, 43.4% of individuals were classified correctly in terms of both sex and ancestry, while 75.8% of individuals were classified correctly when only sex was considered, and 69.6% of individuals were classified correctly when only ancestry was considered. A more detailed consideration of the results indicates that (hu)MANid's performance varied by ancestral group. While 86.1% of Black individuals had sex estimated correctly, only 60.4% of White individuals were accurately classified for sex. In terms of ancestry, although 82.7% of Native American individuals were correctly classified, only 57.3% of White individuals and 52.2% of Black individuals were estimated to be of correct ancestry.

Secondarily, we ran a pilot study of the utility of 3D printed models of mandibles derived from CT scans (n=10) for sex and age estimation using the application. Mandibular CT scans were measured as a part of a prior study using the *(hu)MANid* variables.[3] Models derived from the CT scans were 3D printed in plastic and measured. Overall, we found high (>0.80) intraclass Correlations (ICC) between the CT scans and 3D printed models for most linear and angular variables, but low ICCs for the visually scored traits. This could be due to various factors such as sample size, printing quality, or differences in raters. More work is needed to refine a protocol for working with 3D printed mandibular models for use with the (hu)MANid program.

Anthropology; Sex Assessment; Ancestry Estimation

A16 A Test of the (hu)MANid Program on Edentulous Mandibles

Natalie S. Wise, MA, University of South Florida/FL Institute of Forensic Anthropology & Applied Science, Tampa, FL; Erin H. Kimmerle, PhD, University of South Florida, Tampa, FL; Gregory E. Berg, PhD, Department of Defense POW/MIA Accounting Agency, Joint Base Pearl Harbor-Hickam, HI*

Learning Objectives: The Human Mandible Identification [(hu)MANid] program is a free, web-based program for estimating sex and ancestry from metric and morphoscopic mandibular data from dry bone. The aim of this presentation is to investigate the applicability of the (hu)MANid program to edentulous mandibles and inter-observer error in mandibular data collection from dentulous and edentulous mandibles.

Impact Statement: This presentation will impact all anthropologists who utilize the (hu)MANid program by expanding the application of the program to mandibles that may have initially been excluded from analysis. Applied forensic casework often involves remains of edentulous individuals, and when the cranium and pelvis are not present for sex and ancestry estimation, the mandible becomes a critical element for analysis of the biological profile.

Abstract Text: The (hu)MANid enables anthropologists to estimate the sex and ancestry of unidentified skeletal remains from metric and morphoscopic variables from the mandible.[1] The program is suitable for a variety of anthropological contexts, including forensic casework and bioarchaeological or paleoanthropological analyses. As a free, web-based program, (hu)MANid is particularity beneficial for student development and training in mandibular data collection. The purpose of this research is to test the accuracy and applicability of the (hu)MANid program for edentulous mandibles, with inter-observer error estimates included. While the creators of (hu)MANid warn against data collection for edentulous mandibles, there are many circumstances in applied forensic casework where the unidentified person is edentulous. Edentulousness is often associated with elderly individuals, but people can experience tooth loss at any age for a variety of reasons, including genetic predispositions to periodontal disease, lack of access to regular dental care, and chronic drug use. Edentulous individuals experience alveolar resorption, which is the loss of bone structure following the extraction or traumatic loss of teeth. Therefore, it is expected that the alveolar resorption that is experienced by edentulous individuals will affect the outcome and accuracy of (hu)MANid because metric and morphological landmarks are remodeled through the processes of bone loss.

The test sample consists of 40 dentulous mandibles and 40 edentulous mandibles, with equal quantities of males and females, from the University of South Florida (USF) Donated Skeletal Collection. Data were collected following the protocols established by Berg and Kenyhercz for analysis in (hu)MANid.[1] Three variables, chin height (GNI), height of mandibular body at the mental foramen (HML), and dental arcade width at the third molar (XDA), were excluded from analysis of the edentulous sample because the landmarks of tooth crypts required for these measurements are not present in edentulous mandibles. Inter-observer error for the entire sample (n=80) was also investigated in this research by comparing data collected by three observers of varying experience levels. The data were analyzed using multiple quantitative methods to quantify the estimation results from (hu)MANid and the mandibular data sets.

The results show that sex combined with ancestry estimates are correctly classified in 77% of dentulous mandibles and 56% of edentulous mandibles, when seven population groups are selected for comparison in the program. The dentulous results of this research are higher than the 70% correct classification reported by Berg and Kenyhercz for six compared population groups.[1] When using the sex-only approach in (hu)MANid, estimations were correct for 90% of dentulous mandibles and 85% of edentulous mandibles. The results of inter-observer error indicate a high level of agreement between observers with almost all metric variables within 3mm of variation. The only statistically significant differences that occurred between observers were for four morphoscopic variables, and these differences may be tied to experience level. This research demonstrates (hu)MANid is a reliable program for sex and ancestry estimation and the program may be reliably used in edentulous cases.

(hu)MANid; Biological Profile Estimation; Edentulous

A17 Evaluating a Greek-Cypriot Sample in FORDISC 3.1

Shivani Sanger, MSc, Wrexham University, London, England, United Kingdom; Joe T. Hefner, PhD, Michigan State University, East Lansing, MI; Xenia-Paula Kyriakou, PhD, University of West London, London, England, United Kingdom*

Learning Objectives: From this presentation, attendees will be able to: (1) understand the importance of the evaluation of FORDISC 3.1 (FD3) for realizing its fullest potential; (2) understand the necessity of incorporating contemporary and diverse population data sets into FORDISC to improve forensic analysis; and (3) examine the results of the study evaluating FD3's effectiveness in analyzing the contemporary Greek-Cypriot population.

Impact Statement: Our presentation will enhance the forensic anthropology community by highlighting the importance of using population-specific data for accurate sex and ancestry estimation when using specific software such as FD3. By demonstrating the limitations of current tools like FD3 and presenting evidence from the Greek-Cypriot population, we will drive improvements in forensic performance, ensuring more precise identification of human remains. Ultimately, these advancements will lead to aiding in the resolution of unidentified cases and supporting humanitarian effort.

Abstract Text: When technology is used without careful evaluation, its full potential cannot be realized. The most accurate method for sex and ancestry estimation utilizes discriminant function-based software leveraging morphometric data. Accurate classification of individuals requires population data from diverse global locations, outside of the United States. Due to this diversity, sex estimation can be biased if the data is insufficient.

FD3, a widely used software in forensic anthropology, calculates made-to-order discriminant functions using cranial and postcranial data. FD3 aids in constructing an individual's biological profile from unknown skeletal elements. Although FD3 is used worldwide, it currently lacks data outside of the United States, including samples representing a Greek Cypriot population. Representation for this population is crucial in humanitarian cases, such as the Turkish Invasion of Cyprus in 1974. This conflict left numerous individuals that are still unidentified. To remedy this, we evaluate a novel sample representing a contemporary Greek-Cypriot population using our sample and the data currently housed in FD3. Our study includes a contemporary (20th century) skeletal sample consisting of 202 Greek-Cypriot individuals (female = 101; male = 101) from the Cyprus Research Reference Collection (CRRC). An additional sample of 249 African American, 753 European American, and 222 Hispanic American individuals currently housed in FD3 were also included. Thirty cranial measurements were collected and implemented in the analysis. Utilizing the Custom Database function in FD3, we achieved an overall correct classification of 82.4%. The Greek-Cypriot sample correctly classified 90.7% of the cases. Incorrect classifications of this sample include 4 individuals as African American, 9 as European American, and 1 Hispanic American. Basion-Bregma height (BBH) and Nasal Breadth (NLB) were the most important variables in the discriminant function.

Our results will underscore the necessity of incorporating more contemporary, population-specific data sets to enhance the accuracy of analyses involving unknown skeletal remains. By addressing this gap, we aim to improve the identification process of human remains, thereby contributing to forensic anthropology and aiding in resolving historical and contemporary cases of unidentified individuals.

Anthropology; Software; Population

A18 Introducing FoRDent: A New Tool for Estimating Population Affinity From Dental Morphology

Heather Edgar, PhD, Office of the Medical Investigator, Albuquerque, NM; Joe T. Hefner, PhD, Michigan State University, East Lansing, MI; Ron Richardson, MS, R-Squared Solutions LLC, Erie, PA*

Learning Objectives: After attending this presentation, attendees will be aware of the availability, strengths, and capabilities of a new tool for estimating population affinity in forensic anthropological casework. They can apply this tool to improve the biological profiles produced toward resolutions for cases of unidentified human remains.

Impact Statement: The impact of this presentation will include improving the diversity of data sources available for estimating population affinity by providing practitioners with a new, freely available, statistically sophisticated, user-friendly method that is built on samples appropriate for forensic cases and other analyses. This method leverages underutilized data from the most taphonomically resilient parts of the body, the teeth, to address one of the most complex components of the biological profile, population affinity.

Abstract Text: FoRDent is a new tool for estimating population affinity from the permanent dentition. It is web-based and free access. Its interface is user-friendly, simple to use, and rich with images to facilitate use by practitioners who may not be experts in dental morphology. This simple-to-use interface is coupled with a large sample (n=4,600) appropriate for forensic casework in North America, cutting edge statistics, and an approach to population affinity informed by contemporary anthropological thinking.

Dental morphology is an excellent data source for the estimation of population affinity in forensic casework. Teeth are hard, so they are often retained in cases even when taphonomic damage is significant to the skeleton. Dental morphological traits are heritable and generally neutral, so patterns of characteristics reflect biogeographic ancestry. These threshold characteristics are often scored categorically; however, traditional statistical methods for their analysis have required dichotomization of trait scores.

FoRDent draws on a near-global sample representing 111 modern nations, focused on the United States and Mexico. United States samples include recent and contemporary African, Asian, European, Hispanic, and Native Americans from 11 different states in different regions of the country. Additional contemporary samples represent Australia, Japan, and Mexico City, Tlaxcala, and Yucatán in Mexico. For contemporary samples, population affinities are as described by members of each local community from the samples were drawn.

Up to 65 dental variants can be scored and included in the analysis. All data are analyzed using the original (non-dichotomized) scores, preserving subtleties of variation and allowing for more fine-grained analyses. FoRDent employs a Gradient Boosting Machine (GBM) approach. GBM is an ensemble learning technique that builds a number of decision trees sequentially, with each tree correcting the errors made by previous models and boosting the final prediction as the sum of the predictions across all trees. GBM is highly effective in classifying this sample, robustly handling this complex, multidimensional data. The FoRDent approach showcases the power of machine learning techniques in dental research and underscores their potential for dental morphology in population affinity estimates going beyond more naïve approaches that do not weigh variable importance. Users can refine analyses through variable selection approaches emphasizing these measures. Further, users are provided with multi-level results, with probabilities associated with continental, national, and community level affinities. Classification accuracies vary depending on the variables and samples included in an individual analyses. Including all groups and all traits, which provides the lowest estimate of accuracy, still correctly classified nearly 50% of the sample. A more typical analysis comparing an unknown individual to four regional samples results in classification accuracies between 83.9 and 91.1 percent.

Anthropology; Population; Methods

A19 Digital Archives: An Investigation of Skeletal (In)completeness Using IRIS

Hailey Scacciaferro, BS, Florida Gulf Coast University/Human Identity and Trauma Analysis Laboratory, Fort Myers, FL; Savanna Agilar, MS, Florida Gulf Coast University/Human Identity and Trauma Analysis Laboratory, Fort Myers, FL; Heather A. Walsh-Haney, PhD, Florida Gulf Coast University/Human Identity and Trauma Analysis Laboratory, Fort Myers, FL; Micki Besse, MS, Florida Gulf Coast University/Human Identity & Trauma Analysis Laboratory, Fort Myers, FL*

Learning Objectives: After this presentation, attendees will understand how digital databases and casework capture incomplete skeletal remains to inform forensic investigations.

Impact Statement: This research impacts the forensic science community by highlighting digital tagging in a cloud-based, Criminal Justice Information Services (CJIS) -certified, online case platform to capture the relationship between incomplete skeletal remains and identification of trauma in forensic casework. By tagging skeletal incompleteness within the database, the Forensic Anthropologist (FA)may help law enforcement and medical examiners identify the need for secondary or tertiary searches of a scene whether involving unidentified or unsolved cases, dismemberments, surface scatter scenes, and subaqueous sites.

Abstract Text: Consulting on a case-by-case basis, law enforcement, medical examiners, and coroners call upon forensic anthropologists to assist with the skeletal analysis of human remains irrespective of the decomposition state, skeletal completeness, or degree of fragmentation. Medicolegal cases require meticulous and detailed documentation that may be exchanged with the appropriate criminal justice agencies involved when permitted by law.1-3 Digital databases used as case and crime record repositories and as reporting entities (e.g., Uniform Crime Reporting [UCR] Program, National Missing and Unidentified Persons System [NamUS], Florida Unidentified Decedents Database [FluidDB], National Crime Information Center [NCIC], etc.) have long utilized forensic anthropological reports to supplement existing case data. Previous studies indicated that digital repositories often help solve cold (unsolved) cases.4 However, the utility of data tags in forensic anthropological casework (from initial consultation request through adjudication) has not yet been documented in the literature.

Researchers identified correlations between the percentage of elements recovered and subsequent identification and trauma analysis findings.5,6 Expanding upon previous literature that discusses the impact of skeletal incompleteness on forensic anthropological investigations, this study explores closed, adjudicated forensic anthropology trauma analysis reports (n = 486) in Florida from 2005–2022. In contrast to previous studies that relied upon physical case files, this study also incorporated a cloud-based, CJIS-certified, digital platform to assign digital tags of case attributes, including medical examiner district, quantity of elements evaluated, decomposition state, estimated biological skeletal sex, and trauma type. These data were culled using the respective tags for subsequent data analysis. When categorized by digital tag and evaluating only trauma cases, most cases consisted of incomplete (< 90%) skeletal remains (n = 375) compared to those with complete (>90%) skeletons (n = 111). Overall, an average of 86.18 elements (41.8%) were evaluated by the forensic anthropologist.

On average, the decomposition state tags allowed the FA to quickly sort cases that were skeletonized (31.9%), followed by fresh decomposition (27.4%), and advanced decomposition (21.6%). Age and sex were slightly positively correlated with the identification of trauma ($r = 0.011$, $p > 0.05$). The frequency of trauma type was the same for both sexes with no trauma present being the most common finding followed by blunt, sharp, and gunshot trauma ($r = -0.113$, $p > 0.05$). Of those without trauma (n = 74 females, n = 215 males), an average of 96.91 bones (or 47% of the skeleton) were evaluated. In contrast, when trauma was present, the FA was asked to evaluate only 33.1% (or approximately 69 skeletal elements) of the decedent (e.g., the medical examiner requested a focused analysis or limited the analysis to a particular part of the skeleton). Notably, 27.5% of females and 19.3% of males involved a focused analysis of the neck organ block (i.e., hyoid, thyroid cartilage, cricoid cartilage, tracheal rings). These findings help emphasize the need for FAs to have a secure digital repository with searching parameter capabilities to effectively aid in death investigations.

Skeletal Incompleteness; IRIS; Case Archival

A20 Assessing the Applicability of Subadult Stature Estimation Methods for Japanese Subadults

Amariah J. Trevino, BS, Texas State University, Floresville, TX; Elaine Y. Chu, PhD, Texas State University, San Marcos, TX*

Learning Objectives: From this presentation, attendees will understand that this research aims to expand population-specific data and evaluate the applicability of four subadult stature estimation methods on Japanese subadults. The goal is to assess subadult stature estimation methods that may be population-specific to adapt and improve the biological profile component among Japanese subadults.

Impact Statement: This presentation will impact the forensic science community by expanding the anthropological knowledge of subadult stature estimation methods and their accuracy when applied to Japanese subadults. The evaluation will investigate the current stature estimation methods utilized in biological profile assessments to assist with identifying unknown human skeletal remains of Japanese subadults.

Abstract Text: Stature is one component of the biological profile with limited applicability for subadults due to the lack of data sources available.[1] Some methods require prior data collection of age, sex, and even assignment of population group affiliation that may not be available further complicating subadult stature estimation.[1] Furthermore, current subadult stature estimation methods are population-specific and may not accurately represent the reference samples of other populations.

This research aims to investigate and compare the reliability of various stature estimation methods for Japanese subadults. It is expected that the chosen subadult stature estimation methods applied will overestimate the stature for Japanese subadults due to a potential difference in limb proportions between popualtions.[2]

Postmortem Computed Tomography (PMCT) scans were obtained from 274 male (n = 160) and female (n = 114) individuals from ages starting at birth to 25 years. Eighteen long bone lengths and breadths were measured virtually using the 3D models generated by 3D Slicer.[3] The stature for every individual was calculated using the subadult stature estimation methods based on Murray, Chu and Stull, Smith, and Robbins Schug.[1,4-6] The known stature was then compared to the estimated stature for accuracy and precision. Linear and non-linear model performance assessed testing accuracy, Standard Error of Estimate (SEE), and the Mean Absolute Deviation (MAD).

The testing accuracy based on Chu and Stull non-linear fibula length model resulted in 97% correct within the 95% prediction interval range, a SEE of 3.76cm, and a MAD of 3.26cm.[4] Based on Murray linear models, the resulting testing accuracy ranged from 68% for the femur to 80% for the ulna of known stature falling within the 95% prediction interval range, the SEE ranged from 12.77cm to 24.37cm and the MAD ranged from 5.39cm to 6.16cm.[1] For Smith, the SEE ranged from 11.32cm to 23.18cm and the MAD ranged from 4.25cm to 7.24cm.[5] Lastly, for Robbins Schug, the SEE resulted in 12.17cm and the MAD is 5.37cm.[6]

Based on the results, the Chu and Stull subadult estimation method performed more accurately compared to the other published subadult stature estimation methods and with the lowest amount of error.[4] Though this is the most promising method currently available, the method put forth by Chu and Stull can be further adjusted to perform more accurately in estimating stature among the Japanese subadult population.[4] While it is not recommended to apply population-specific stature estimation equations to other populations, this research reveals that Chu and Stull is a reliable source to apply to the Japanese subadult population for forensic anthropological casework, until population-specific methods can be created.[4]

Subadult Stature Estimation; Long Bones; Postmortem Computed Tomography

A21 CT Scan-Based Cranial Anthropometry for Stature Estimation: A Comparative Analysis Between Base of Skull and Front of Skull Parameters in a South Indian Population

Kirthika Ravi, MD, All India Institute of Medical Sciences, Jodhpur, India, Rajasthan, India; Siddhartha Das, MD, Jawaharlal Institute of Postgraduate Medical Education & Research, Puducherry, Puducherry, India; Harichandrakumar Kottyen Thazhath, PhD, Jawaharlal Institute of Postgraduate Medical Education & Research, Puducherry, India; Ambika Prasad Patra, MD, MBA, Faculty of Medicine, Department of Forensic Medicine and Toxicology, Jawaharlal Institute of Post-Graduate Medical Education & Research, India, Dhanvantary Nagar, Pondicherry-6, India, Pondicherry, Puducherry, India; Deepak Barathi, MD, Jawaharlal Institute of Postgraduate Medical Education & Research, Puducherry, Puducherry, India*

Learning Objectives: This presentation will provide the attendees with a better understanding of the role of the base of the skull and front of the skull parameter measurements taken from Computer Tomography (CT) scan images for estimating the stature in a defined native population. A comparative analysis will help in understanding whether the base or the front of the skull parameters give a better result when estimating the stature.

Impact Statement: This presentation will impact the forensic science community by exploring the importance of CT scan measurements of the base and front of the skull parameters for estimating the stature of a defined native population.

Background: One of the objectives of a medicolegal autopsy is establishing the identification of the individual, which may not be completely possible in the case of decomposed or mutilated bodies. Stature along with age, sex and race are the partial identification features of an individual. Researchers over the years have used different body measurements and bones for estimating the stature of individuals. The regression formula obtained from these studies is from different populations and may not apply to others because of the inherent genetic and geographic variations. This CT scan study was done to find out the importance of different skull measurements of the base and front of the skull for estimating the stature in a South Indian population.

Methods: This prospective observational study was started after obtaining the approval of the Institute Ethics Committee. All patients aged between 21 to 60 years posted for elective head and neck CT scans attending the Radiology department at our institute were included in the study. Patients who were unable to stand erect, sustained cranial fractures, or had visible cranial defects were excluded from the study. The CT scan was performed using the Somatom sensation 64-slice CT scanner (Siemens). The images were viewed using the Multiplanar Reconstruction and Volume Rendering technique (MPR-VRT). Fourteen parameters from the base of the skull and 11 parameters from the front of the skull were studied. The base of the skull parameters were Palatal Length (PL), Palatal Breadth (PB), Biauricular Breadth (BAB), Bimastoidal Diameter (BMD), maximum Length of Right Condyle (LCR), maximum Length of Left Condyle (LCL), maximum Width of Right Condyle (WCR), maximum Width of Left Condyle (WCL), maximum Bicondylar Breadth (BCB), Minimum Distance between condyles (MnD), Maximum Interdistance between condyles (MxID), Distance between two External Hypoglossal Canal opening (DEHC), maximum Length of Foramen Magnum (FML), maximum width of Foramen Magnum (FMB). Front of the skull parameters were Minimal Frontal Breadth (MnFB), Right Orbital Breadth (ROB), Left Orbital Breadth (LOB), Right Orbital Height (ROH), Left Orbital Height (LOH), Biorbital Breadth (BOB), Interorbital Breadth (IOB), Upper Facial Height (UFH), Bizygomatic Breadth (BZB), Nasal Height (NH), and Nasal Breadth (NB).

Results: Multiple linear regression analysis using backward elimination containing all the independent predictors revealed a statistically significant model, with an r2 value of 0.17 for both base of skull and front of skull parameters for the overall population. There was no violation in model assumptions such as linearity, constant variance and residual distribution. Multicollinearity was ruled out using the variance inflation factor. Among the various base of skull parameters studied, only MnD (< 0.001), DEHC (0.02), FML (0.03) in the males and BCB (0.002), BMD (0.01), FMB (0.03), MnD (0.03) in the females showed a statistically significant positive correlation with stature. The multivariate linear regression predictive model for base of skull parameters gave a statistically significant model with an r2 value of 0.10 for males and 0.15 for females. For the front of skull parameters, the observed r2 value was 0.104 with predictors BZB, NH and LOH for males and 0.06 with predictors NH and LOB for the females.

Conclusion: This study showed that there is no difference in the predictive value for male populations between base and front of skull parameters, whereas the predictive accuracy was more in the case of females for base of skull parameters in comparison to front of skull parameters.

Stature Estimation; Base of Skull Parameters; Front of Skull Parameters

A22 How Many Vertebrae Should Be Present to Estimate the Height of the Total Vertebral Column With Accuracy?

Yangseung Jeong, PhD, University of Tennessee, Murfreesboro, TN; Hyunwoo Jung, PhD, University of California, Davis, Davis, CA*

Learning Objectives: After attending this presentation, attendees will learn that vertebral column height can be estimated with minimal errors if a certain number of vertebrae are present. Attendees will also understand the pros and cons of different methods used to reconstruct the vertebral column height.

Impact Statement: This presentation will impact the forensic science community by demonstrating that anatomical methods remain effective for stature estimation even with a partially incomplete vertebral column. This effort aims to broaden the applicability of anatomical methods, thereby enhancing the accuracy of stature estimation from skeletal remains recovered in a forensic context.

Abstract Text: Anatomical methods are known for their higher accuracy compared to mathematical methods in stature estimation. However, these methods require all 29 bones comprising height to be fully intact, so fragmented or missing elements, particularly the vertebrae, often limit their use. Two approaches commonly address this challenge: (1) estimating the heights of the individual missing vertebrae using adjacent vertebrae, which are then used to approximate the entire vertebral column height.[1,2] However, this approach may encounter limitations when multiple consecutive vertebrae are missing or fragmented; (2) regressing the height of vertebral region(s) with missing vertebrae or the entire vertebral column height against intact region(s) if any region(s) of the vertebral column (i.e., cervical, thoracic, or lumbar) remains intact. One drawback of this approach is that all vertebrae in the incomplete region(s) must be excluded from estimating the entire vertebral column height.

This study aims to test the efficiency of an alternative method where the entire vertebral column height is regressed against any remaining vertebrae. We tested whether it is more efficient to utilize all remaining vertebrae to estimate the entire vertebral column height directly rather than estimating individual vertebral heights first and then aggregating those estimates. Additionally, it aims to determine the minimum number of vertebrae out of 23 vertebrae (from C2 to L5) needed for accurate estimates with minimal errors.

This study utilized complete vertebral columns of 153 Koreans individuals (75 males, 65 females, 13 indeterminate) to explore 22 scenarios with varying number of remaining vertebrae (i.e., missing 1 to 22 vertebrae). Given the uncertainty of which vertebrae would remain in specific contexts, 10,000 random samplings were performed for each scenario. In each randomly selected sample, the height of the entire vertebral column was estimated using regression analysis based on the heights of the remaining vertebrae. The square root of the estimated variance of the random error (SEE) and adjusted R^2 were calculated from 10,000 iterations for each scenario, then averaged for further analyses.

The findings indicate that a greater number of remaining vertebrae corresponded to smaller SEEs and higher R^2 values. Specifically, with at least nine vertebrae remaining, SEEs less than 5mm and R^2 greater than 0.97 were achieved. To achieve SEEs less than 3mm or 2mm, a minimum of 14 or 18 vertebrae, respectively, were required.

Using the same random sampling approach, this study also evaluated various scenarios involving incomplete vertebral regions. For example, when missing vertebrae were only in the cervical region or only in the lumbar region, the SEE did not exceed 3mm, regardless of the number of remaining cervical or lumbar vertebrae. However, when only the thoracic region was incomplete, at least four thoracic vertebrae were needed to achieve SEEs less than 3mm. If only one of the three regions was intact, between five to ten vertebrae from the incomplete regions were required to achieve SEEs less than 3mm.

In contrast to Auerbach's suggestion that estimating the entire vertebral column height using intact region(s) may suffice when individual missing vertebral heights cannot be estimated, this study shows that using at least 14 remaining vertebrae to estimate the entire column height always yields smaller SEEs compared to estimation using only intact regions.[1]

This study demonstrates that incomplete vertebral columns do not need to be a significant barrier hindering the application of anatomical methods in stature estimation, thereby benefiting future research and practice with practical guidelines for using anatomical methods in stature estimation.

Stature Estimation; Anatomical Method; Vertebra

A23 The Correlation of the Dimensions of Hands and Feet With Height in an Indigenous Population of the Tribal District of Himachal Pradesh, India

Yatiraj Meghraj Singi, MD, All India Institute of Medical Sciences, Bilaspur, Bilaspur, Himachal Pradesh, India; Dipen Dabhi, MD, All India Institute of Medical Sciences, Bilaspur, Bilaspur, Himachal Pradesh, India*

Learning Objectives: Attendees will gain a clear understanding of advanced techniques used for measuring hand and foot dimensions, focusing on precision and reliability in forensic contexts. They will learn about statistical models and the relationships between these measurements and height, emphasizing how reliable these models are for estimating stature accurately in forensic cases. The presentation will cover gender-specific and regional differences within the indigenous tribal population of Himachal Pradesh (India) and their importance in forensic analysis. Practical applications will be illustrated through case studies, showing how the research findings can be used in real-world forensic investigations, especially for identifying stature from fragmented remains. Additionally, the discussion will highlight how these findings improve the accuracy and reliability of stature estimation, contributing to more precise identification processes in forensic anthropology. This will enhance the attendees' expertise in applying these techniques in their advanced forensic work.

Impact Statement: This presentation, by highlighting reliable statistical models and the relationships between these measurements and height, will enhance the community's ability to estimate stature precisely, even from fragmented remains. The insights into gender-specific and regional differences within the indigenous population of Himachal Pradesh, India, will offer valuable data that can improve the accuracy of forensic analysis in diverse populations. Furthermore, the practical applications and case studies presented will demonstrate how these findings can be applied in real-world forensic investigations, leading to more precise identification processes. Overall, this presentation will contribute to the advancement of forensic anthropology, promoting more accurate and reliable methods for stature estimation and identification in forensic science.

Introduction: Stature is considered as one of the parameters for personal identification and one of the "big fours" of forensic anthropology. The stature of an individual is an inherent characteristic, the assessment of which is considered pivotal in the identification of unknown human remains. The current study focuses on understanding the relationship between hand and foot measurements with height in the indigenous population of Kinnaur and Lahaul and Spiti districts of Himachal Pradesh, India. Stature estimation is a crucial aspect in forensic and anthropological fields, especially for identifying individuals from dismembered bodies. This study aims to fill the gap in the existing literature by focusing on a specific indigenous population, thereby enhancing the accuracy of stature estimation methods in forensic science and physical anthropology.

The primary objective of this research is to analyze the anthropometric relationships between the dimensions of feet and hands with the height of the individuals. The study also aims to estimate gender variations in these dimensions and analyze the correlation between hand and foot measurements. The study involved 383 individuals aged between 18 and 50 years from the tribal areas of Himachal Pradesh, ensuring that participants were residents for at least three generations.

Methodology: The study was carried out after obtaining the Ethical Approval from the Institute Ethics Committee. The participants were recruited through door-to-door surveys and random sampling methods. After obtaining their consent, height was measured using a stadiometer (in cm), while hand and foot dimensions of both the extremities were measured using a digital vernier caliper (in mm).

Results: The overall mean stature of the population was found to be 163.78 ± 9.68cm, with a mean right foot length of 241.09 ± 15.68mm and a mean left foot length of 241.66 ± 15.67mm. For males, the mean stature was 168.43 ± 8.84cm, with the mean right and left foot lengths being 248.93 ± 12.38mm and 249.82 ± 12.51mm, respectively. For females, the mean stature was 156.71 ± 5.91cm, with mean right and left foot lengths of 229.17 ± 12.30mm and 229.24 ± 11.22mm, respectively. Foot length emerged as the most reliable metric for estimating stature across both genders. However, the study found regional variations, with right foot length being more accurate for predicting stature in Kinnaur and Lahaul districts, while left foot length was more reliable in Spiti district. The mean right hand length was 183.15 ± 12.17mm and the left hand length was 183.11 ± 12.12mm. Of both the hands, the right hand was a more reliable predictor of the height of the individual.

Conclusions: This study offers significant insights into the estimation of an individual's stature using anthropometric measurements of the hand and foot. It demonstrates that foot length is the most reliable metric for stature prediction. The findings can be applied in forensic science and anthropological investigations, aiding in the accurate estimation of stature from hand and foot measurements, particularly in the unique indigenous population of tribal populations living in the Kinnaur and Lahaul and Spiti districts of Himachal Pradesh, India.

Stature; Anthropology; Identification

A24 The Effects of Tibial Nutrient Foramen Location on Biological Profile Construction

Olivia H. Messenger, BA, University of Indianapolis, Gilbert, AZ; Krista E. Latham, PhD, Human Identification Center, University of Indianapolis, Indianapolis, IN; Stephen Nawrocki, PhD, University of Indianapolis, Indianapolis, IN*

Learning Objectives: This presentation aims to inform attendees how variability in the location of the tibial nutrient foramen can affect a metric approach to biological profile construction. It will address whether the position of the tibial nutrient foramen covaries with population affinity, biological sex, age at death, and limb length.

Impact Statement: Some measurements utilized for biological profile construction are taken from landmarks that are easy to define and locate, but for others, the landmark's absolute position may vary between individuals. Attendees will gain a better understanding of how the location of the nutrient foramen on an individual's tibia varies and the potential implications for the use of tibial metrics in biological profile construction.

Abstract Text: In the human skeleton, the pelvis and skull are considered the most useful indicators for estimating skeletal sex and the skull for estimating population affinity.[1] When these bones are unavailable, damaged, or incomplete, other skeletal elements must be considered. In such cases, forensic anthropologists will use long bones like the tibia and conduct metric analyses to estimate the living characteristics of the individual. Some commonly used tibial measurements are associated with the nutrient foramen (i.e., anteroposterior diameter, transverse diameter, circumference). In tibiae, there is typically a single nutrient foramen located on the posterior aspect of the diaphysis. However, the foramen's vertical position along the shaft can vary between individuals. Since the diameter of the diaphysis decreases as one moves away from the tibial plateau, an inferiorly placed foramen will yield absolutely smaller diameter measurements, potentially skewing analyses. Much of the previous literature addressing measurements taken from the nutrient foramen indicates that there is nearly always considerable overlap in the values obtained for males and females.[2,3] To better understand the effectiveness of measurements involving the nutrient foramen, this research explored how variables such as biological sex, population affinity, age at death, and limb length can influence the position of the foramen along the shaft of the tibia.

A contemporary sample of 180 adult individuals (102 males, 78 females) of European and African descent was analyzed from the osteological collection at the University of Tennessee – Knoxville. Tibiae were measured according to *Data Collection Procedures*, with the addition of a measurement from the posterior rim of the lateral condyle to the most inferior point of the nutrient foramen.[4] A ratio expressing the nutrient foramen's location along the shaft of each tibia was calculated by dividing the distance of the nutrient foramen from the proximal end by total tibial length. This ratio provides a standardized measurement of nutrient foramen position on the shaft. The following variance equation was used to express the relationships between the variables: measurement = biological sex + population affinity + biological sex*population affinity + tibial length + age + error.

Analysis of Covariance (ANCOVA) indicates the effects of biological sex, age at death, and the interaction between biological sex and population affinity do not significantly influence the position of the nutrient foramen. However, population affinity by itself does affect foramen position, with individuals of African descent tending to have a foramen positioned higher on the shaft. In addition, tibial length has a significant effect on foramen position, with longer left tibiae having a foramen positioned higher on the shaft; right tibiae showed no such correlation. The higher relative position of foramina in African and long-limbed individuals may skew metric analyses so that African and taller individuals of either ancestry are more likely to be called males regardless of their actual sex. However, these effects are absolutely small and account for only a small percentage of the total variance in foramen position, so corrections to existing metric methods may not be warranted.

Biological Profile; Sex Estimation; Nutrient Foramen

A25 A Glimpse Through the Veil of Lost Identities: Identification Practices and Outcomes in Greece

Despoina E. Flouri, MD, School of Medicine, University of Crete, Greece, Heraklion, Iraklion, Greece; Sophia Mavroudas, PhD, Forensic Anthropology Center at Texas State, San Marcos, TX; Konstantinos Moraitis, PhD, Head of Forensic Anthropology Unit, School of Medicine, National and Kapodistrian University of Athens, Athens, Attiki, Greece; Elena F. Kranioti, MD, PhD, Director of Forensic Medicine Unit, School of Medicine, University of Crete, Heraklion, Iraklion, Greece; Christina Karydi, MCS, National and Kapodistrian University of Athens, Athens, Attiki, Greece; Antonios Papadomanolakis, MD, PhD, Forensic Pathology Division of Crete, Hellenic Republic, Ministry of Justice, Transparency and Human Rights, Crete, Greece*

Learning Objectives: After attending this presentation, attendees will understand the importance of interdisciplinary investigation and the impact of advancing technologies to the identification of human remains in Greece, a country at the crossroads of migration into Europe experiencing migration flows across both land and sea borders.

Impact Statement: This presentation will impact the forensic science community by serving as an example of how incorporating advancing technologies such as a national DNA identification database, national missing persons investigative bureau, and digital record keeping into medicolegal casework can impact the medicolegal system's ability to successfully process and identify unidentified human remains particularly in regard to areas highly affected by the deaths of foreign nationals, including both migrants and tourists.

Abstract Text: The presentation uses retrospective case files of originally unidentified individuals over the span of 34 years (1988–2022) from across Greece to illuminate trends and patterns in identification methods and rates, demographic data, and technological advancements. A total of N=586 cases from the University and State Forensic Services of the Ministry of Justice were analyzed with the aim of recording information on the demography and country of origin of the deceased, the method of identification, the individual's status in the country (tourist, migrant, Greek national), the GPS location of recovery, as well as the cause and manner of death when available. Case files were collected from the Forensic Medicine Unit of the University of Crete (n=78), the Forensic Anthropology Unit, Department of Forensic Medicine and Toxicology at the National and Kapodistrian University of Athens (n=321), and the Forensic Pathology Division of Crete, Hellenic Republic Ministry of Justice Transparency and Human Rights (n=187). The caseload includes both anthropology and pathology cases from the island of Crete and mainland Greece.

For the entire dataset, 57.2% of individuals were identified. Identifications occurred most often through circumstantial evidence and DNA analysis (70%). The identified non-Greek nationals pertained to citizens of 21 different countries across four continents. Despite high levels of migration through Greece, the majority of non-Greek nationals in this dataset were tourists (55%), while migrants made up only (45%) of the identified non-Greek cohort. Results demonstrate regional differences within Greece regarding caseload types (primarily due to large tourist influxes on the island of Crete), as well as temporal and demographic patterns regarding identification methodology and approach. Specifically, case data highlights that after the introduction of the national DNA database of the Hellenic Police in 2003, the rate of identifications in these departments decreased (by 18%) likely due to a combination of over-reliance on DNA data on behalf of the investigative authorities and a reduction in the acceptance of circumstantial identifications. The introduction of the national Missing Persons Bureau within the National Hellenic Police in 2008 also appears to have had limited effects on the overall identification rates in this dataset, likely due a lack of centralized access to the system for departments outside of the Attica region and other intra- and inter-agency communication pitfalls.

This study also discusses the impact of digital casefile database systems on a department's ability to retrospectively analyze data as well as to extract and share information with investigative authorities and other relevant stakeholders. Together, this presentation shows that despite the introduction of technological advancements, without the implementation of protocols that encourage appropriate use of technology and interdisciplinary communications, identification outcomes are not necessarily improved by the introduction of technology alone. Continued research on the impact of technology, including the implementation of postmortem imaging in the protocol for migrant identification, will also be addressed.

Identification; Migrants; Unidentified Persons

A26 Applying Postmortem Fingerprinting Into Disaster Victim Identification in Maverick County, Texas

Victoria Swenson, PhD, Operation Identification: Texas State University, San Marcos, TX; Bryan T. Johnson, MSFS, FBI, Quantico, VA; Ivanna Robledo, MA, Texas State University, San Marcos, TX; Courtney C. Siegert, PhD, Operation Identification: Texas State University, Austin, TX; Chloe P. McDaneld, MA, Operation Identification, San Marcos, TX; Victoria S. Soto, MA, Operation Identification, San Marcos, TX; Kate Spradley, PhD, Texas State University, San Marcos, TX; Molly A. Kaplan, MA, Texas State University, San Marcos, TX; Molly E. Scott, Operation Identification, San Marcos, TX; Christopher L. McMillan, Operation Identification, San Marcos, TX; Veronica Flores-Guillen, BS, Texas State University, San Marcos, TX*

Learning Objectives: After attending this presentation, attendees will have a better understanding of the significance and utility of fingerprinting techniques following various postmortem changes in the positive identifications of unidentified migrants. This study was made by a collaboration with Operation Identification (OpID) and the Disaster Victim Identification (DVI) Unit with the Federal Bureau of Investigation (FBI).

Impact Statement: This presentation will impact the forensic science community by increasing the awareness of fingerprinting techniques following various postmortem changes for improving identification outcomes of unidentified remains from Maverick County, TX.

Abstract Text: In 2012, Texas surpassed Arizona as having the highest number of migrant deaths. According to the United States Customs and Border Protection statistics, a total of 1,976 migrant deaths occurred in Texas from 2012 to 2020, though more than 4,400 migrant individuals have died in the state since 1981.[1] Arizona has centralized medical examiner's offices like Maricopa County Office of the Medical Examiner (MCOME) and the Pima County Office of the Medical Examiner (PCOME) to investigate unidentified migrant deaths; whereas investigations in Texas are county dependent and rely heavily on elected justices of the peace. Of the 254 counties in Texas, only 14 have medical examiner's offices. Forensic experts are often not involved in the investigation of unidentified migrant deaths, despite the Texas Criminal Code of Procedure (TCCP) mandating that all unidentified remains be investigated, fingerprinted (if applicable), sampled for DNA, and tracked for a minimum of ten years. The degree to which South Texas counties are compliant is inconsistent, resulting in the burial of hundreds of unidentified persons without identification efforts. Shifts in migration routes have resulted in record-breaking deaths in Maverick County, making the county the new epicenter of migrant deaths. Medicolegal authorities and law enforcement there typically do not take fingerprints or DNA prior to burial due to the overwhelming number of deaths and exceeding local capacity, creating a mass disaster.

Decedent fingerprints are typically taken with ink and paper or powder and an adhesive for identification purposes. However, unidentified migrants recovered in advanced stages of decomposition make it challenging to process postmortem prints, and alternative methods must be employed. OpID therefore sought to investigate the question: can fingerprints help facilitate identifications of decedents recovered in Texas border counties, especially for decomposed individuals?

To address this question, in March 2024, OpID personnel participated in a fingerprint training workshop taught by the FBI's DVI Unit. The OpID team learned about the different methods by which to obtain fingerprints of decedents in various stages of advanced decomposition. Following the fingerprint training, the OpID team traveled to Maverick County to help collect and process fingerprints with the head of the FBI DVI Unit. The fingerprints of 26 deceased migrants were collected using various methods, such as an automated fingerprint identification system, wearing the degloved epidermis, injecting liquids beneath the dermal tissue, or submerging the hand into near-boiling water and printing the dermal ridges using fingerprint powder and adhesive lifters.[2,3]. Fingerprints were searched in various databases by the FBI DVI Unit, leading to the identification of 14 individuals.

A few months later, an additional 25 cases from Maverick County were transferred from the Webb County Medical Examiner's Office to OpID. Of the 25 individuals, 7 were identified prior to the transfer through fingerprint comparison, fingerprint database, or a DNA cold hit. OpID was able to use the boiling method to collect fingerprints from 14 of the 18 unidentified individuals, of which 2 were identified.

The objective of this presentation is to demonstrate that these methods should become standard practice for unidentified deceased persons in Texas and for any decomposed remains found in any jurisdiction. Further, the importance of international collaborations during the identification process will be discussed.

Migrants; Human Rights; Disaster Victim Investigation

A27 Unveiling the Role of Tattoos as Ink Trails in Forensic Anthropological Identifications: Exemplified From a Survey of a Northwest Indian Population

Jagmahender Singh Singh Sehrawat, PhD, PGDFS, Panjab University, Chandigarh, Chandigarh, Chandigarh, India; Shubham Thakur, MS, Panjab University, Chandigarh, Chandigarh, India; Tamanna Kumari, Panjab University Chandigarh, Barmana, Himachal Pradesh, India*

Learning Objectives: After attending this presentation, the attendees will be informed about the pivotal role of tattoo marks in mapping out the identity affiliations of missing persons or unknown corpses found in medicolegal or cultural settings.

Impact Statement: This presentation will impact the forensic community by informing attendees that tattoos can be used as adjunct soft biometric traits in forensic death investigations as well as identifying missing persons.

Abstract Text: Tattoos serve as powerful tool of cultural marker and identifier in the realm of cultural and forensic anthropology in situations when routine channels of inquiry like facial features or fingerprints are not feasible to identify an individual.[1] Tattoos are a common type of body modification to express the aesthetic, socio-cultural, and religious affiliations of the bearer. They can play a crucial role in identity affiliations of a person as to certain specific regional or ethnic groups. The recognition and analysis of individualistic tattoo patterns have been commonly used to discern gang affiliations, religious beliefs, criminal records, and periods of incarceration.[2,3] Historically, tattoos were employed for criminal identification and slave branding, with evidence of their existence discovered on ancient mummified corpses.

In the present review-cum-interview study, the relevant literature was searched from different scientific databases and scrutinized for the use of tattoo marks for different forensic purposes. Also, 155 Northwest Indian subjects were interviewed for an anthropological understanding of their psychology, motivations, and symbolism of having engraved tattoos on different body parts. Questions were drafted as to the intentional or unintentional, permanent or temporary, professional or amateur, traumatic or cosmetic, decorative, cultural, medical or religious, etc. thrust for having these marks on their bodies. The systematic review showed that tattoo marks have helped in postmortem victim identification, identifying missing persons and unidentified corpses, mapping-out affiliation of individuals to certain specific ethnic backgrounds, beliefs and cultures, and even to certain gangs or hate groups. Scars, Marks, and Tattoos (SMT) have been used as soft biometric traits in crime scene analysis by providing multifaceted advantages in suspect identification, mapping subcultures, and facilitating decedent identification to the law enforcement agencies.

The study results revealed that the majority of persons having inked tattoos belonged to the age group of 20–29 years, represented almost equally by both sexes (suggestive of comprehensive understanding of tattoo marks). Significant occupational and workplace-specific differences were noticed among the participants. Females preferred tattoos on their lower arms and "letter-number" combinations outnumbered the figures, portraits, or symbols in their marks. Northwest Indians tattooed different body parts to display their affiliation to certain specific organizations, ideologies, or religious and social groups, to hide a scar, and to commemorate important life events and individuality. These results can supplement other methods of forensic identification of northwest Indians found missing or dead in some mass-disaster events. A population- and region-specific catalog of common tattoo marks and scar patterns can be generated for envisioning an expedited and accurate human identification, thus providing culturally sensitive solutions for victim identification in post-disaster scenarios.

The detailed results will be presented in textual, tabular and graphical/diagrammatic form.

Forensic Anthropology; Tattoo Marks; Identification

A28 Using Images of the Ear for Postmortem Human Identification

Jane C. Harris, PhD, Center for Forensic Anthropology, Northern Michigan University, Marquette, MI; Aiden Gilbert, Northern Michigan University Center for Forensic Anthropology, Grand Rapids, MI*

Learning Objectives: After attending this presentation, attendees will understand the potential for using comparisons of human ear images to aid in the identification of unidentified human remains.

Impact Statement: This presentation will impact the forensic science community by demonstrating that the human ear continues to show comparable features well into decomposition and that comparisons of ear images can contribute to the suite of available approaches employed to aid in the identification of unidentified decedents.

Abstract Text: Numerous studies, based on everything from low-tech one-to-one image comparison to machine learning algorithms, have established the human ear as a viable comparable biometric that can be used as a means for assisting in the identification of unknown individuals. The ear is also among the facial components taken into consideration when practitioners are faced with comparing facial images for the purpose of identification verification, such as at a border crossing or during a police traffic stop, providing investigators with an investigative lead, in situations where images of persons of interest are captured by surveillance cameras, and when forensic examiners are asked to give a professional opinion regarding whether or not two images depict the same individual.

The facial image comparison community, however, does not always handle cases involving living persons. In situations where there may have been a mass-fatality event, whether it is human-caused, such as the detonation of an explosive device, or natural, such as a catastrophic hurricane or earthquake, victim identification is essential. It is helpful, therefore, to have multiple means for establishing disaster victim identification, depending on what is available to investigators and what is feasible.

This study was conceptualized as a pilot study to first establish whether or not the human ear is helpful as a biometric that could be used to facilitate human decedent identification in situations where the remains may be in an advanced state of decomposition. This pilot study focused on evaluating whether or not untrained examiners, mainly students at Northern Michigan University who have self-identified as having an interest in forensic science, are able to correctly determine whether images of human ears in varying states of decomposition depict the same or different ears and, by extension, the same or different individuals. All ear images involved in the study were taken of human remains that were donated to the Northern Michigan University (NMU) Center for Forensic Anthropology and placed in the Forensic Research Outdoor Station (FROST) as part of routine data collection procedures between 2018 and 2023. Students were invited to voluntarily participate in a Qualtrics survey through which the data for this study were collected. Participants were asked to provide some demographic information and to answer several questions aimed at ascertaining their self-evaluated ability to notice details and their familiarity with both image comparison and external human ear anatomy. They were also asked to compare ten sets of one-to-one image comparisons and ten sets of one-to-many image comparisons. For each one-to-one comparison, participants were also asked to rank each named anatomical feature of the ear for its usefulness in helping them reach their decisions.

Results of this pilot study indicate that external anatomical features of the ear persist well into decomposition, although there is a point at which many become unidentifiable, especially when the ear has been affected by insect activity. The untrained participants in this research demonstrated high success rates in both the one-to-one and one-to-many scenarios, meaning that the ear seems to be a viable biometric for aiding in the identification of unidentified decomposed human remains.

Victim Identification; Decomposition; Facial Identification

A29 An Intersectional Approach to Developing a Prediction Model for Adult Missing Persons Off a Major United States Corridor in Idaho Using Novel Computational Techniques and Multidisciplinary Data

Kirsten G. Mink, PhD, Idaho State University, Pocatello, ID; Donna Delparte, PhD, Idaho State University, Pocatello, ID; Miles Rhoads, BS, Idaho State University, Pocatello, ID; Kyle J. Paulekas, MS, Idaho State University, Pocatello, ID*

Learning Objectives: This presentation will report on the outcome of our pilot project entitled Predictive Locator for Missing Person's I15 Corridor. Specifically, this presentation will go over the creation of the inclusive and multidisciplinary database, which includes a combination of categorical, numerical, and spatial data and the computational techniques used to create the prediction model. Last, we will discuss the results of testing the database, the resulting data analysis, and its future impacts.

Impact Statement: This program has the potential to impact communities at local, state, and national levels by handling large amounts of data, enabling widespread use across various jurisdictions in the United States. It can be applied to various cases, including child abductions and crimes against vulnerable groups, reducing the financial burden on law enforcement and public services by narrowing search areas and saving time and resources. The goal is to make this program available to agencies, non-profits, and humanitarian groups to aid in search and recovery efforts for missing persons.

Abstract Text: Forensic anthropologists are uniquely positioned to work on missing person cases due to our expertise in the search and recovery of human remains, skeletal analysis of unidentified remains, and our ability to liaise between law enforcement and community groups or families with cultural awareness and competency. There are more than 500,000 people reported missing in the United States.[1] In Idaho, the Idaho Missing Persons Clearinghouse has reported over 35 adult missing persons since 2020, while NaMus has over 125 open cases in the state.[2,3] These cases often remain unsolved due to a lack of information, funding, resources, and various biases, conscious or unconscious.

Previous research has predominantly focused on children and White individuals, deemed as vulnerable and "important" subsets within American demographics, thus attracting more attention and resources.[4] Unfortunately, most missing persons do not fall into these categories. Existing repositories for missing persons and unidentified remains primarily focus on open cases, neglecting the potential of using data from closed cases to predict the location of individuals. Johnson highlights that despite the valuable information these repositories contain, they often do not connect, and there is no centralized database[5]. One goal of this research was to create a more centralized, culturally inclusive, and easily accessible database.

Law enforcement faces numerous challenges in resolving missing person cases, including limited funding, lack of community engagement, and insufficient manpower and resources. In Idaho, where many law enforcement agencies are rural and understaffed, these challenges are even more pronounced. Unidentified remains add another layer of difficulty, as they are hard to connect with open cases and often cannot be identified due to the high cost of bone tissue DNA analysis. Another goal of this project was to narrow down missing person cases to those most likely to be found in a specific location in order to make investigations more financially viable and increase the likelihood of solving these cases.

This research focuses on adult missing persons in Idaho who went missing or were found near US Highway I-15, a corridor known for human trafficking that runs from Canada to Mexico. This presentation introduces the creation of an inclusive, multidisciplinary reference database encompassing approximately 200 closed cases of missing adults from counties along the corridor from 2018 to the present. Ongoing projects like the National Missing and Unidentified Persons System (NaMus), the National Crime Information Center (NCIC), the New Mexico Decedent Image Database, and Operation Identification were analyzed to determine current data collection practices. The authors introduced new data points to create a comprehensive reference database compatible with a machine learning algorithm. The final goal of this research was to identify the specific characteristics that aid in locating the individual. Trials were conducted to identify the more significant data points. By using an intersectional lens, this project addresses inequities and biases in missing person cases, specifically regarding data collection on individuals. It demonstrates how incorporating new, inclusive data points can enhance law enforcement's ability to locate missing persons.

A30 Enhancing Forensic Human Identification in Emergencies and Disasters: Leveraging Technology for Improved Efficiency, Cost Reduction, and Ethical Practices

Megan Bassendale, MS, Forensic Guardians International, West Vancouver, British Columbia, Canada*

Learning Objectives: After attending this presentation, attendees will understand the benefits and ethical considerations of using advanced data collection techniques, Artificial Intelligence (AI), and data analytics in the recovery and identification of human remains in emergencies and disasters. This presentation will impact the forensic science community by demonstrating how these technologies can reduce operational costs, enhance efficiencies, alleviate stress on first responders, and provide quicker answers to grieving families, particularly in Disaster Victim Identification (DVI) settings.

Impact Statement: This presentation will impact the forensic science community by improving competence in using advanced technologies for the recovery and identification of human remains in conflicts and disasters. It will enhance performance by providing practical solutions to reduce the overall identification costs and the stress on first responders while expediting identification processes and ultimately improving outcomes for grieving families and communities.

Abstract Text: The deployment of AI in forensic human identification leverages vast amounts of available data to support forensic experts. This technology not only enhances accuracy but also ensures that resources are allocated more effectively, supporting human expertise in the most complex cases.

Key improvements include enhancing the chain of custody and evidence continuity, ensuring that remains are managed with greater precision and less risk of contamination, commingling, or misidentification. In addition, the expedited identification process facilitated by AI-driven data analysis and predictive algorithms allows victims' families to receive answers more quickly, providing crucial emotional and psychological relief.

Reducing the pressure on first responders is a critical aspect of these technological advancements. By automating routine tasks and providing real-time data analysis, first responders can focus on immediate rescue and recovery efforts rather than being overwhelmed by the intricacies of data collection and management. This not only improves the overall efficiency of disaster response but also contributes to the mental and physical well-being of first responders, who often operate under extreme stress and time constraints. Integrating portable data collection devices and real-time communication tools enables rapid information sharing and coordination, further enhancing the effectiveness of response efforts.

This presentation addresses the ethical implications of these advancements, emphasizing the importance of implementing technologies in a manner that is both just and respectful of the deceased and their families. The balance between probative value and fundamental fairness is examined, highlighting the need for robust protocols and oversight to prevent potential abuses. The ethical considerations include ensuring data privacy, obtaining informed consent where possible, and maintaining transparency in the identification process.

Finally, the presentation discusses strategies for effectively communicating and educating about the responsible use of these technologies. By fostering a better understanding of the capabilities and limitations of AI and related tools, we can ensure their integration into forensic science is both beneficial and ethically sound. Training programs for forensic professionals, workshops for legal and governmental stakeholders, and public awareness campaigns are crucial to achieving this goal.

This research underscores the transformative potential of technology in forensic science. It advocates for the use of technological advancements to provide timely, accurate, and respectful handling of human remains and upholds justice and dignity for all involved. The continued development and refinement of these technologies promise to revolutionize the field, making forensic identification more efficient, cost-effective, and dignified.

Artificial Intelligence; Disaster; Technology Transition

A31 Understanding the Role of CODIS and Familial DNA in Positive Human Identification for the Louisiana Repository for Unidentified and Missing Persons

Anthony V. Lanfranchi, MS, Louisiana State University, Baton Rouge, LA; Teresa V. Wilson, PhD, Louisiana State University, Baton Rouge, LA*

Learning Objectives: After attending this presentation, attendees will understand the complexity of DNA identification facilitated by forensic anthropologists though a retrospective case analysis. This study highlights the differences and variability in the time from receiving a case to having positive DNA identification in cases handled by the Louisiana Repository for Unidentified and Missing Persons

Impact Statement: This presentation will impact the forensic science community by demonstrating a method for better understanding how individual identification methods like DNA fit into a broader workflow for forensic anthropologists. By understanding the extrinsic and intrinsic factors that affect the average length of time for DNA identification, it is possible to implement plans for other assistive methods like facial approximation in remains that are truly unknown.

Abstract Text: Forensic anthropologists have a diverse toolkit that can assist in identification when unidentified human remains are recovered; however, it can be difficult to determine which methods should be employed to expedite positive identification. DNA is often used as a primary identification method and can be a logical approach for skeletal remains. This research explores the role of DNA in identifications handled by the Louisiana Repository for Unidentified and Missing Persons (Louisiana Repository) to build an efficient identification workflow for forensic anthropologists at the Louisiana State University Forensic Anthropology and Computer Enhancement Services (FACES) Laboratory where time-consuming methods like facial approximation are generated when other methods are unsuccessful.

Information from 156 cases (1980 to 2024) was collected from the Louisiana Repository. Seventy-seven of the positive identifications were generated from Combined DNA Index System (CODIS) "hits" and 79 cases were identified through comparisons to familial DNA samples. The following data was collected for each case: (1) date the case was received in the FACES Lab, (2) date the DNA sample was submitted to a DNA laboratory for processing, (3) date completed DNA report was received from the DNA laboratory, and (4) date of positive identification.

Cases that were identified through assistance from CODIS were true unidentified persons with no leads on a possible or putative identification. The earliest CODIS hit case was received as remains in 2001, a DNA sample was submitted in 2006, a DNA report was generated in 2008, and positive identification was established in 2017. This timeline is an outlier because most cases are resolved within months. With this outlier removed, CODIS cases averaged 92.14 days from the date the case was received to the date that an identification was made. The average time between submission to a DNA laboratory to identification was 65.49 days. On average, it took about 26.66 days from the time that a case was received by the FACES Lab to the time that a DNA sample was submitted to a DNA laboratory.

Cases where possible or putative identifications were established during the early stages of the investigation are compared to family reference samples collected for the assumed missing persons. Sometimes putative identifications are suggested long after a remains case has been analyzed by an anthropologist. The Louisiana Repository assisted with a case that was received in 1980, DNA samples were submitted for analysis over the years but were unsuccessful. In 2010, a final DNA sample was submitted, and a DNA report was generated the same year. The DNA profile was compared to familial DNA, and a positive identification was made in 2019. This cold case is an outlier with 14,120 days between the date the case was received to identification; however, it demonstrates the wide variation in time that identification through familial DNA can take. With three of the coldest cases removed from the data, the average days from that date a case was received in the FACES Lab identification was 283.21 days.

Our analysis revealed that CODIS hits facilitated faster identifications, with an average turnaround of 92.14 days from case receival to final identification, and reference sample cases tend to be more time-consuming, averaging 283.21 days. The advent of DNA technology has undeniably revolutionized forensic science by significantly enhancing the speed, cost-effectiveness, and precision of identifying individuals. Despite the advanced capabilities of DNA profiling, forensic anthropologists remain indispensable, particularly when dealing with complex cases involving unidentified and missing individuals. This study underscores that forensic anthropologists who rely on DNA identifications need to understand the realistic timelines for these identifications so that other methods can be used when it is apparent that a CODIS hit is unlikely.

A33 Vertebral Bone Density Variations in Scoliotic vs. Non-Scoliotic Juveniles and Their Implications for Schmorl's Node Development: A CT-Based Analysis Using the New Mexico Decedent Image Database

Ellen R. Shakeshaft, MS, Liverpool John Moores University, Liverpool, England, United Kingdom; Matteo Borrini, PhD, Liverpool John Moores University, Liverpool, England, United Kingdom; Constantine Eliopoulos, PhD, Liverpool John Moores University, Liverpool, England, United Kingdom*

Learning Objectives: Attendees of this presentation will learn specific insights into vertebral bone density variations in scoliotic versus non-scoliotic juveniles and the implications for Schmorl's node development. They will gain a comprehensive understanding of how scoliosis affects bone density, particularly as to how it correlates with the presence of Schmorl's nodes as observed through Computed Tomography (CT) scans from the New Mexico Decedent Image Database. The presentation will cover the methodology used for the CT-based analysis, the statistical significance of the findings, and the implications of these findings for clinical practices and future research. Attendees will also learn to evaluate and interpret statistical data related to bone density and scoliosis, enhancing their ability to apply these insights in their own professional practice. The measurable objectives include understanding the relationship between scoliosis and bone density, the prevalence of Schmorl's nodes, and the impact of these findings on potential treatment and prevention strategies for spinal pathologies. Attendees will also explore how advancements in CT imaging technology and data analysis can transform our understanding and management of scoliosis and related spinal pathologies, demonstrating the potential of technology as a powerful tool for medical transformation.

Impact Statement: Presenting this research at the AAFS conference will significantly impact the forensic science community by highlighting the transformative role of CT analysis in forensic contexts. By avoiding destructive methods, CT imaging allows for non-invasive examination of skeletal remains, preserving valuable evidence. This research underscores the importance of pathology analysis in postmortem investigations, offering insights into why individuals may exhibit unusual traits, such as lower vertebral density, which can be attributed to genetic or medical conditions rather than forensic factors. Additionally, comparing postmortem findings with CT scans can enhance identification accuracy, particularly when dealing with rare pathologies like Schmorl's nodes in children. This approach not only advances forensic analysis but also aids in distinguishing between medical conditions and forensic evidence, thereby improving overall case assessments.

Abstract Text: Scoliosis, characterized by an abnormal lateral curvature of the spine, is predominantly idiopathic, underscoring the need to delve into its underlying causes for effective treatment and preventive strategies. This study investigates a potential correlation between scoliosis and Schmorl's nodes (intervertebral disc herniations) influenced by Wolff's law, which posits that bones adapt to external pressures. We analyzed CT scans from 108 juvenile decedents, including 56 with scoliosis and 52 without. After running multiple statistical tests, there was no significance between the mean bone density when compared to having scoliosis. An independent t-test provided a t-value of 0.041, which, when compared to the original significance level of 0.05, is statistically significant, although weak. When compared to the Bonferroni correction level of 0.008, it throws out the significance to give a result of not being statistically significant. It was the same in the cases of L3 ($t = 0.103$), L2 ($t = 0.084$), and L1 ($t = 0.053$). If compared to the regular significance level of 0.05, T12 ($t = 0.012$) and T11 ($t = 0.042$) had weak significance, but that was then excluded when the Bonferroni correction was applied. When looking at any significance of densities in different vertebral regions, the results from a one-way Analysis of Variance (ANOVA) (p-value = 0.213) suggest that it is likely that the results are due to random variability or chance, and that there is no statistical significance. With a value of 0.273 from a Chi- squared ($\chi 2$)/Fisher's exact test, it suggests that there is no statistically significant correlation or difference between the variables of scoliosis and Schmorl's nodes. The general pattern seems to follow that as the spine ascends, the density increases, and this is true in both scoliotic and non-scoliotic individuals. As a whole, it is evident that those with scoliosis have a lower vertebral density than those without, in all of the vertebral regions. There is, however, a weak negative linear relationship between bone density and age in both scoliotic and non-scoliotic individuals. A p-value of −0.229 obtained from a Pearson correlation coefficient analysis in non-scoliotic individuals, as well as a p-value of −0.069 in scoliotic individuals, was obtained. Overall, the findings of this study are comparable to some existing studies on similar topics, but there are few results that hold statistical significance, so this would be interesting to research further.

3D Technology; Spine; Juvenile

A34 Vertebral Variation in Forensic Anthropology Casework

Andrew C. Seidel, PhD, King County Medical Examiner's Office, Seattle, WA; Kiana C. Miller, BS, King County Medical Examiner's Office, Seattle, WA*

Learning Objectives: After attending this presentation, attendees will have an increased awareness of the frequency with which anatomical variation within the vertebral column is encountered in forensic anthropology casework.

Impact Statement: This presentation will impact the forensic science community by providing a comparison between the rates at which spinal anomalies are observed in casework to the frequencies of such variations as reported in the clinical literature. Familiarity with this topic can help alleviate concerns related to recovery and commingling as well as contribute to the generation of a biological profile and identification.

Abstract Text: A series of recent forensic anthropology cases analyzed at the King County Medical Examiner's Office (KCMEO) in Seattle, WA, exhibited anomalous numbers of vertebral elements, prompting a review of cases examined in the past two years for which at least two regions of the vertebral column were observable. Of the 52 cases meeting these criteria, 15 exhibited some form of developmental anomaly of the vertebral column, with the majority (n=13) involving a shift of one or more segmental borders.

To ascertain whether the observed frequency of developmental anomalies is unusual, a review of the clinical literature was conducted. Of the developmental anomalies observed in casework, Lumbosacral Transitional Vertebrae (LSTV) are the most commonly studied. Owing to differences in imaging modality and definition, the frequency with which this variation is observed is recorded as being between 5.4% and 35.6%.[1-3] When definitions are controlled and individual studies are combined into regional samples, population frequencies for this anatomical variant are more stable, falling between 9.06% and 14.15%. Five cases (9.6%) with LSTV were observed in the KCMEO sample, consistent with reported population frequencies.

By contrast, the presence of 13 thoracic elements is rarely addressed in the clinical literature. Most studies that mention this segmentation anomaly report population frequencies of less than 1%.[4-6] Four cases (7.7%) with 13 thoracic elements were observed in the KCMEO sample. Interestingly, the only study reviewed that analyzed skeletal samples7 reported a population frequency of 5.3% for this anomaly, suggesting that the prevalence of this anatomical variant is underestimated in the clinical literature.[7]

Together, these results suggest that forensic anthropologists can expect to routinely encounter vertebral variation within their casework. When such variation results in the gain or loss of vertebral and/or costal elements, it may raise concern over recovery methods and/or commingling. Awareness of the expected frequency of such variations, together with careful articulation of skeletal elements and observation of taphonomic characteristics, can help resolve such anxieties. Additionally, the identification of anatomical variants of the vertebral column may aid in the formation of the biological profile and the establishment of a positive identification.

A35 The Ontogenetic Development of the Glabella and Its Association With Maturation of the Humeral Proximal Epiphysis in Accurate Subadult Sex Estimation

Stephanie J. Cole, PhD, Des Moines University, West Des Moines, IA; Marin Pilloud, PhD, University of Nevada, Reno, Reno, NV; Kyra Stull, PhD, University of Nevada Reno, Reno, NV*

Learning Objectives: After attending this presentation, attendees will have increased knowledge regarding the ontogenetic development of the glabella and its association with patterns of fusion of the Humeral Proximal Epiphysis (HPE).

Impact Statement: This presentation will impact the forensic science community by providing information regarding the utility of the HPE as a maturity indicator associated with puberty and in generating accurate sex estimates from the subadult skull.

Abstract Text: Forensic anthropologists have historically used a minimum age standard as the threshold on which to base whether a sex estimate should be attempted in immature individuals. However, if the age estimate is incorrect, this approach could also result in an inaccurate sex estimate. Further, several studies have shown that skeletal maturity is more closely linked to pubertal stage than chronological age.[1,2] Since the onset of dimorphism in most sex traits is associated with puberty, using maturity as the parameter on which to base a sex estimate is more appropriate than an age-at-death estimate.

The authors have previously shown that ossification of the iliac crest, which is associated with menarche in females, improves classification accuracy from the pelvis.[3] The goal of the current study is to evaluate skull changes associated with puberty to further illustrate the utility of skeletal maturity indicators in estimating subadult sex, but with a focus on male-based developmental processes (i.e., changes occurring in the skull rather than pelvis). The glabella was selected as the sex trait because it is the most accurate trait for estimating sex from the skull.[4] The HPE was selected as the maturity indicator due to its association with peak height velocity, or mid-stage puberty.

Postmortem computed tomography scans of known individuals (n = 563, m = 348, f = 215) aged 8 to 20 years from the Subadult Virtual Anthropology Database were used to evaluate the development of the glabella with refence to maturation stages of the HPE. Trait expression of the glabella was assessed following the five-stage scoring procedure outlined in The OnSEt User Manual, where a score of 1 represents the most gracile expression of the trait and a score of 5 represents the most robust expression of the trait.[5] Maturation of the HPE was assessed following the four-stage scoring procedure outlined in Stull and Corron, where Score 0 indicates absence of the epiphysis, Score 1 indicates presence without fusion, Score 2 indicates active fusion, and Score 3 indicates complete fusion.[6]

Differences in glabella score frequencies between males and females for each maturation stage of the HPE were first evaluated using Chi-square tests. The mean score of the glabella for each HPE maturation stage was also visualized with line plots for each sex to further illustrate the stage of maturity at which the glabella becomes dimorphic. Next, Random Forest (RF) modeling was used to evaluate classification accuracies for individuals with each HPE score to determine if maturation improves sex classification accuracy. Training and testing samples were generated using 75% and 25% of the original data, respectively.

Sex differences in trait score frequencies of the glabella were significant with active fusion of the HPE (p = 0.002), which is reflected in the high classification accuracies obtained by the RF models. When HPE is scored 1, the classification rate and sex bias were unacceptable for sex estimation (C = 67%, M = 100%, F = 0%). When HPE is scored 2, the classification rate was 91% and sex bias was greatly improved (M = 100%, F = 73%). Results were maintained when HPE was scored 3 (C = 89%, M = 96%, F = 75%).

The findings lend further support that maturity indicators associated with puberty can be used to guide the practitioner in deciding if a subadult is sufficiently mature for sex to be accurately estimated without needing to rely on age. Importantly, these results were obtained using only one sex trait and one maturity indicator. The incorporation of multiple sex traits and maturity indicators should improve confidence around the maturity estimate and accuracy of the sex classification.

A36 Intra-Observer and Inter-Device Error in Osteometric Data

Maggie M. Klemm, MA, University of Nebraska, Lincoln, Lincoln, NE; Dakota L. Taylor, MA, University of Nebraska, Lincoln, Lincoln, NE; William R. Belcher, PhD, University of Nebraska-Lincoln, Lincoln, NE*

Learning Objectives: After attending this presentation, attendees will understand the impact that inter-device and intra-observer error can have on osteological measurements and forensic anthropological estimates.

Impact Statement: This presentation will impact the forensic science community as it will guide the refinement of future forensic science standards and methods. This will contribute to the continued standardization of the discipline.

Abstract Text: With the implementation of the *Daubert* standards, the forensic science community is required to identify potential error rates of different methodologies to demonstrate they are reliable and have been tested.[1] Within forensic anthropology, osteometric data is commonly utilized to estimate the stature, age at death, and biological sex of unidentified individuals. Despite the frequent use of osteometric data, little research has been conducted to establish the intra-observer and inter-device error rates of the commonly utilized instruments for gathering these data. Inter-device error is the difference between multiple measurement devices performing the same measurement, and intra-observer error refers to the difference in repeated measurements taken by one individual.[2,3] The establishment of these error rates is critical as osteometric measurement devices are utilized by the forensic anthropological community without knowledge of their ability to produce consistent results. Additionally, intra-observer variability can influence inter-device reliability, and factors such as replicability, can affect the consistency of results.

This study aims to determine the error rates of intra-observer measurements and the inter-device reliability between two different sets of calipers, designated Caliper A and Caliper B, through standardized craniometric measurements as established in the Data Collection Procedures for Forensic Skeletal Material 2.0.[4] The craniometric data of two high-quality skeletal casts were collected from six different observers. Twenty-four cranial measurements were taken with reference to the Central Identification Laboratory (CIL) standard measurements.[5,6] Each observer took the measurements twice with both devices, equaling 96 measurements per cranium. The observers performed the measurements independently and with no outside assistance during an academic semester, and each observer had prior educational experience in osteometrics. Data were analyzed in RStudio by conducting one-way Analysis of Variance (ANOVA) to examine the inter-device and intra-observer error rates. This was done through a comparison of the spread of the measurements taken by both sets of calipers for each observer. Presently, an acceptable error range is for osteometric measurements to be within a 2-millimeter range of the known and/or repeatable measurements.

Results of this research demonstrate that Observer One was within the standard error range for 22.72% of the osteometric measurements for cranium one and 59.09% of the osteometric measurements for cranium two. Observer Two had 81.82% of their osteometric measurements for cranium one within the standard error range and 86.36% within the range for cranium two. Observer Three had 79.16% of their osteometric measurements for cranium one within the acceptable error range and 83.33% for cranium two. For Observer Four, 69.56% of measurements for cranium one and 75% for cranium two were within the standard acceptable error range. Observer Five had 75% of their measurements for cranium one and 70.83% for cranium two within the acceptable error range. Finally, Observer Six had the lowest error rates, with 95.45% and 87.50% of measurements falling in the acceptable error range for crania one and two, respectively.

Additionally, it was observed that for cranium one, 6.48% of the osteometric measurements taken with Caliper A were outside the acceptable error range, whereas 15.83% of measurements taken with Caliper B were outside the standard error range. The results were similar for cranium two, with 6.34% of the measurements taken with Caliper A and 14.69% of measurements taken by Caliper B falling outside the acceptable error range. This research demonstrates that intra-observer and inter-device error rates should be considered when gathering osteometric data as they may affect the accuracy of measurements and the outcomes of forensic anthropological estimates such as biological sex, age at death, and stature. Additional research is required to determine the error rates for postcranial measurements as this will further supplement current osteometric data research.

Osteometry; Intra-Observer Error; Inter-Device Error

A37 Morphological Patterns of Corresponding Atlanto-Occipital Joint Surfaces: Potential Applications for Sorting Commingled Human Remains

Janet E. Finlayson, PhD, Defense POW/MIA Accounting Agency, Ewa Beach, HI*

Learning Objectives: Attendees of this presentation will come away with a better understanding of shape patterns between articulating surfaces of the Atlanto-Occipital Joint (AOJ) and how these patterns may inform segregation of commingled human remains.

Impact Statement: This presentation will impact the forensic science community by identifying morphological patterns between corresponding joint surfaces that may be useful when assessing the articulating pair match potential at the AOJ. Recognition of these patterns during analysis may increase analyst competency and confidence in evaluating this joint in commingled scenarios.

Abstract Text: Assessment of joint articulation is a subjective process with little published guidance regarding normal variability for joint congruency. However, visual assessment of joint articulation is utilized as a traditional anthropological approach to sort commingled human remains. While visual evaluation of a joint fit is often perceived as reliable, the strength of the association between articulating elements is highly dependent upon the elements in consideration.[1,2] In particular, the AOJ has been documented as an articulation with a "moderate" level of analyst confidence during the visual assessment of fit and a "moderate" level of reliability, measured within a rate of 60%–90% correct classification when observation of fit is cross-checked with DNA results.[1,2]

This study presents an examination of patterns of matching outline shapes between articulating AOJ surfaces: the Occipital Condyles (OCs) and C1 Superior Articular Facets (SAFs). The objective of this study is to provide a foundation where analyst confidence and method reliability may be improved during visual evaluation of potential occipital-to-C1 matches by elucidating the rates and trends of shape matches between known articulating surfaces.

In this study, 78 individuals (35 female, 43 male) with at least one intact, articulating pair of AOJ surfaces were analyzed from the William M. Bass Donated Skeletal Collection. Of these, 73 individuals (31 female, 42 male) had bilateral AOJ pairs. Each articular surface was visually assessed and categorized as a shape type. The observed variation of joint surface outlines was not well-represented by extant typological methods, resulting in uncertainty of type assignment.[3,4] To accommodate this, a modified system defining six shape categories (five monopartite: ovoid, sigmoid, reniform, clepsydral, irregular; and one representing all bipartite presentations) was developed in this study and used to score each articular surface. Articulating shape patterns were examined by categorical shape type, sex, side, and AOJ type using R v.3.6.1.[5]

Clepsydral was the most prevalent shape (33.6%) for pooled sexes, sides, and OC-SAF types. Few deviations from this pattern were observed when analyzed by sex, side, or AOJ type, such as bipartite surfaces are the most frequently observed shape for pooled-sex left SAFs (33.6%). A Fisher's Exact test of paired AOJ shape patterns between sexes yielded no significant results ($p > 0.05$). Twenty-one combinations of articulating shapes were observed, with the same articular shape types matching in only 32.5% of the total joint pairs. The most frequent pair-matched types are clepsydral OC-to-clepsydral SAF (35.9%), followed by clepsydral OC-to-bipartite SAF (19.2%). Of particular interest are the broad patterns of matching between bipartite and monopartite surfaces. Bipartite OCs paired with bipartite SAFs but were not observed to be paired with monopartite SAFs. However, the converse of this latter scenario does occur; monopartite OCs commonly articulate with bipartite SAFs. When bipartite SAFs were present, they were observed to be paired with either bipartite (16.7%) or monopartite OCs (83.3%), most frequently with the monopartite clepsydral OCs (62.5%).

This study identifies two general patterns that may be particularly useful to the analyst when evaluating articulating match potential at the AOJ. More often than not, the outline shapes of articulating AOJ surfaces are not mirrored by one another, suggesting joint surfaces cannot be excluded as potential matches if their outline morphologies grossly differ. Additionally, the absence of observed bipartite OC-to-monopartite SAF articulating matches suggests observation of the partite nature of the AOJ surfaces has strong potential as a morphological exclusionary criterion, particularly in generating short lists of potential matches in large-scaled commingling scenarios.

Joint Outline; Articulation; Bipartite Surface

A38 Two Instances of Unusual Non-Human Remains Encountered in Routine Medicolegal Significance Casework

Nicholas V. Passalacqua, PhD, The Ohio State University, Columbus, OH; MariaTeresa Tersigni-Tarrant, PhD, Bexar County Medical Examiner's Office, San Antonio, TX*

Learning Objectives: The goal of this presentation is to demonstrate the importance of expertise in zooarchaeology/non-human osteology within forensic anthropology as well as the importance of detailed inspections of morphologies and peer review to avoid cognitive bias.

Impact Statement: This presentation will impact the forensic community by providing two unrelated cases of rare non-human remains encountered by law enforcement that were resolved by forensic anthropologists via assessment of medicolegal significance.

Abstract Text: While forensic anthropology is popularly considered to focus on the analysis of human remains in order to establish identity and contribute to the determination of the cause and manner of death, a routine aspect of forensic anthropology is the examination of questioned items in order to determine if they have forensic and/or medicolegal significance. The number of questioned item cases a forensic anthropologist encounters varies; however, forensic anthropologists traditionally perform many medicolegal-significance cases every year. Typically, these types of cases are relatively predicable and include the skeletal remains of local animals, often deer, bear, dogs, pigs, racoons, etc.

Case #1 represents a single skeletal element that was carried by a dog onto a private residence in Transylvania County, NC. Because of the large size of the element, the owner of the dog was concerned the remains may have been human and contacted the local Sheriff's Office, who subsequently reached out to Dr. Passalacqua for further assistance. The Sheriff's Office digitally sent a number of images of varying quality of the element for analysis. Based on these images, the skeletal element was clearly a large, long bone (400+mm long, estimated). While the proximal end of the element was obscured by adhering desiccated tissue and debris, the rest of the element was relatively clean and in good condition with minor taphonomic alterations. The shaft of the bone did not exhibit any notable morphological features aside from being very straight; however, the distal end presented with two large articular condyles with deep lateral grooves. The size and morphology of the skeletal element was consistent with an avian tibiotarsus; however, the size indicated that it was from a very large avian species, likely an ostrich or emu. The Sheriff's Office stated that they were unaware of any farms in the area, and the origin of the remains is unclear. Final species identification via genetic testing was not performed because the Sheriff's Office did not retain the element.

Case #2 represents a single skeletal element found in the yard of an individual in Fulton County, GA. Due to its size, the individual who found the element thought it may have been human. The medical examiner was unable to determine medicolegal significance and asked Dr. Tersigni-Tarrant for assistance. The bone had distinct epiphyseal morphology that was inconsistent with any of the bones of the human lower limb. Similar to Case 1, the morphology of the bone was suggestive of a large avian species. Emus and ostriches are known to have been farmed in this area of Georgia, although not on the property in question.

These cases represent two instances of similar, uncommon non-human remains being encountered in forensic anthropology casework. Most questioned items cases are typically relatively straightforward and come from the same few local non-human species (e.g., the femur of a deer). Being confronted with a large, long bone with unusual morphologies can lead to cognitive bias (i.e., "only a human long bone would be this large," etc.), which could result in erroneous conclusions. In both instances, the practitioners were surprised by the unusual size and morphologies of the remains that in some ways mimicked human morphologies (i.e., long tubular shaft with distal articular condyles). However, in both cases potential cognitive bias was mitigated via a critical assessment of the bone morphologies and unofficial peer review. Additionally, because the remains were relatively complete and in good condition, the analysts were able to assess the full gestalt of the remains, which assisted in reaching conclusions of non-human; however, if the remains had been damaged or incomplete, the assessment would have been much more difficult.

Medicolegal Significance; Non-Human Remains; Skeletal Morphology

A39 An Analysis of Non-Human Skeletal Remains in the Digital Age: An Examination of Temporal Trends (2014–2024) and Taxonomic Diversity in Northern California

Kendall A. Gehring, BS, California State University, Chico, Chico, CA; Keilani M. Adams, BA, Anthropology Department, Chico State, Thousand Oaks, CA; Eric J. Bartelink, PhD, California State University, Chico, Chico, CA; Amber Plemons, PhD, California State University, Chico, Chico, CA; Jazmin Borrayo, BA, California State University, Chico, Chico, CA; Samantha R. Robinson, BS, California State University, Chico, Chico, CA; Ashley Kendell, PhD, California State University, Chico, Chico, CA; Colleen Milligan, PhD, California State University, Chico, Chico, CA*

Learning Objectives: This presentation will examine ten years of non-human casework submitted to the Human Identification Laboratory at California State University, Chico (2014–2024), including the mode of human vs. non-human identification, taxon diversity, and skeletal element representation.

Impact Statement: After viewing this presentation, attendees will gain a better understanding of the non-human taxa commonly submitted to forensic anthropologists for identification in northern California and how the use of digital technology can provide rapid expertise to the law enforcement community.

Abstract Text: A large portion of forensic anthropology casework involves differentiating between human and non-human skeletal remains, and the ability to do so quickly and confidently is critical to law enforcement and in mass fatality scenarios. By determining which non-human taxa are most commonly encountered in the western United States, practitioners can prepare for analysis by keeping reference exemplars on hand for comparison with case material. This is particularly useful as non-human requests have become increasingly digital.

The Human Identification Laboratory (HIL) at California State University, Chico, has a large case load, providing services to over 87% of the counties in California and occasionally other states as well. Of the 1,075 cases submitted to the HIL from 2014–2024, 52.9% of them were requests for human vs. non-human identification. Most cases are found by the public or during search and rescue operations for missing persons or wildfire victims.

The records of 569 non-human cases were examined for characteristics such as mode of consultation, taxonomic identification, and skeletal elements represented. Possible modes of consultation were in-person, via email, via text, and a combination of digital and in-person assessments. Taxonomic identification was split first into large and small animals, with more specific identifications made when possible. Juvenile remains were also noted by the presence of open or unfused epiphyses. Elements were defined as axial, appendicular, or cranial (skull and dentition), or a combination of these.

Of the non-human cases included in this analysis, 74.9% consisted of digital consultations. In 2021, the number of text-based consultations surpassed the number of email consultations, and that trend has continued. An additional 3.0% included primary digital consultations but required in-person analysis for confirmation. Only 2.1% of cases consisted of solely in-person assessments. While technology has aided in casework efficiency, photo quality is often a limitation. Of the cases assessed, 33.0% were photos without the inclusion of a scale, 46.9% of cases included a proper scale, while the remaining 20.1% included improvised scales using objects such as pens, currency, water bottles, and shoes. While the majority of the photos were of high quality, a number of them were too blurry to examine detail on the remains or to observe the scale for reference.

Large mammalian remains were present in much higher frequencies than small animals, with 66.8% of cases including elements from large animals (most commonly deer, cow, or bear) and only 13.0% of cases including elements from small animals (typically bird, cat, or dog). Large animals are likely represented in higher frequencies because their size is more similar to humans compared to small animals such as birds. Juvenile animals were represented in 6.5% of cases. Appendicular elements were the most represented elements in casework at 52.6%. In contrast, only 11.1% of cases contained axial elements alone, while 2.3% contained only cranial elements. The remaining 24.1% of cases represented some combination of these.

The widespread use of technology – smart phones in particular—throughout the United States has greatly increased law enforcement access to forensic anthropologists for human vs. non-human identification. The HIL, located in northern California, regularly consults with law enforcement agencies hours and even states away through digital consultations, which in the past could have only been conducted through mailing cases or direct delivery. Instead, officers now send photos from the scene and receive a response within minutes, most often confirming remains as non-human, a practice that has also been used in wildfire contexts. It is important that the forensic community continues to optimize the use of technology to expand non-human casework capabilities and improve efficiency so as to allot resources to other cases of forensic significance.

Forensic Anthropology; Non-Human Remains; Casework

A40 A Multi-Isotope Approach for Reconstructing Residence Patterns of Massacre Victims of the Indian Uprising in Ajnala, Amritsar, India

Jagmahender Singh Singh Sehrawat, PhD, PGDFS, Panjab University, Chandigarh, Chandigarh, Chandigarh, India; Eric J. Bartelink, PhD, California State University, Chico, Chico, CA*

Learning Objectives: The goal of this presentation is to highlight the application of stable isotopes analysis for predicting possible region-of-origin for unidentified remains cases from India.

Impact Statement: This presentation will impact the forensic science community by presenting novel data to aid in predicting region-of-origin of Indian sepoy victims whose remains were recovered from a disused well in Ajnala, India, in 2014. This research will further aid in efforts to reconstruct the biohistories of these individuals who were killed by British colonizers.

Abstract Text: In 2014, the commingled remains of hundreds of individuals were unexpectedly discovered in an abandoned well in the town of Ajnala in Amritsar, India. The remains were excavated non-scientifically by amateurs, which resulted in the loss of much of the archaeological context. Ongoing research by Punjab University and collaborators has resulted in a long-term study of the remains, including studies of oral health, skeletal trauma, commingling, Minimum Number of Individuals (MNI), and dietary patterns and region of origin using isotopic analyses. Recently, the remains have been linked to the massacre of 282 Indian sepoys who were killed by British colonizers during the Indian Uprising of 1857.

Stable isotope analysis has been shown to be a useful identification tool in forensic anthropology that can provide investigative leads toward personal identification. Carbon and nitrogen isotope values ($\delta^{13}C$ and $\delta^{15}N$) of dentinal collagen provide important geocultural information reflecting dietary practices during infancy and childhood whereas carbon and oxygen isotope values ($\delta^{13}C$ and $\delta^{18}O$) of the carbonate of tooth enamel bioapatite provide information on whole diet and the source of drinking water during childhood, respectively.

This study presents isotope results for dentinal collagen $\delta^{13}C$ and $\delta^{15}N$ and tooth enamel bioapatite $\delta^{13}C$ and $\delta^{18}O$ of 101 individuals recovered from the Ajnala well. In total, 101 tooth samples were selected from separate dentitions, ensuring that no individuals were double sampled. Tooth enamel was separated from dentin, and each was ground to a fine powder for isotopic analysis. A stereoscopic microscope was used to remove soil and other potential contaminants. Dentinal collagen was demineralized in hydrochloric acid, contaminants were removed with sodium hydroxide, then solubilized, frozen, freeze dried, and weighed for Isotope Ratio Mass Spectrometry (IRMS). Enamel powder was soaked in hydrogen peroxide to remove organics, treated with a dilute solution of acetic acid to remove diagenetic contaminants, and dried and weighed for IRMS. Fifteen dentin samples failed to yield collagen and were excluded from the data set, leaving 86 well-preserved samples.

The mean collagen $\delta^{13}C$ value is –17.8‰ (±1.3‰, 1 SD; *range*=6.4‰) and the mean $\delta^{15}N$ value is +8.9‰ (±1.2‰, 1 SD; *range*=5.8‰) enamel bioapatite $\delta^{18}O$ value is –4.5‰ (±0.7‰, 1 SD; *range*=4.2‰). The collagen and bioapatite $\delta^{13}C$ results reflect a childhood diet consisting of a mix of both C_3/C_4 resources, and the collagen $\delta^{15}N$ values suggest consumption of terrestrial meat protein. The enamel bioapatite $\delta^{18}O$ results show minimal variation, suggesting that these individuals may all be from a similar geographic area. $\delta^{18}O$ values are elevated relative to previous research conducted on a smaller sample of individuals, suggesting some heterogeneity in region of origin within the broader sample.[1] Currently, there is limited baseline data and isoscape prediction maps for India. However, previous $^{87}Sr/^{86}Sr$ work on Ajnala remains suggests that some individuals may have been from the Varanasi region (Uttar Pradesh), the Gangetic plain, and the Bihar, Orissa, West Bengal.[2] The relationship between $^{87}Sr/^{86}Sr$ ratios and $\delta^{18}O$ values will be explored in further detail to better reconstruct probable region of origin for the Ajnala massacre victims.

Stable Isotope Analysis; Massacres; Human Remains

A41 A Stable Foundation for the Use of Tooth Enamel Oxygen Isotopes in Human Identification

Gabriel Bowen, PhD, University of Utah, Salt Lake City, UT; Chris Stantis, PhD, Southern Illinois University, Salt Lake City, UT; Gregory E. Berg, PhD, Department of Defense POW/MIA Accounting Agency, Joint Base Pearl Harbor-Hickam, HI; Lesley A. Chesson, MS, Defense POW/MIA Accounting Agency (DPAA) Laboratory, Joint Base Pearl Harbor-Hickam, HI; Kirsten A. Verostick, PhD, University of Utah, Salt Lake City, UT; Stephannie Covarrubias, MPH, University of Utah, Salt Lake City, UT*

Learning Objectives: Attendees of this presentation will learn the foundational principles, practical limitations, and best practices for the reconstruction of geographic life history using oxygen stable isotopes in human tooth enamel. They will learn the status of Project FIND-EM, a major collaborative program to develop an open database and the data science tools that support it, including how to access these resources.

Impact Statement: The impact of the presentation will be the development of a community that is aware of and able to confidently and robustly apply this technology in forensic casework. These capabilities will advance causes, including cold case resolution, humanitarian investigations, and identification and repatriation of the remains of American personnel lost in foreign conflicts.

Abstract Text: Stable isotope ratios of elements such as carbon, strontium, and oxygen in human body tissues have been shown to vary geographically and are potentially useful in reconstructing life history and identifying unknown decedents.[1] The oxygen isotope composition ($\delta^{18}O$ value) of tooth enamel carbonate is a particularly promising target for this work, but we lack a large, well-documented, standardized database of human tooth enamel $\delta^{18}O$ values as a foundation for forensic applications.

We report on Project FIND-EM, a collaboration between the academic research community and the United States Defense POW/MIA Accounting Agency to build such a database. We hypothesize that tooth enamel $\delta^{18}O$ values exhibit strong geographic variation that closely match previously documented patterns of tap water $\delta^{18}O$ values (a primary source of oxygen to growing teeth) across the contiguous United States. Third molars were collected from several hundred human donors through acquisition of existing collections, new sampling from skeletal collections, and contributions from living participants. Life history information (residence location and several health and demographic variables) spanning the period of third molar formation was also collected from donors, and all samples were prepared and analyzed using standardized, experimentally supported laboratory methods.

Comparisons show that most variation in enamel $\delta^{18}O$ values was explained by drinking water $\delta^{18}O$ values at the location(s) where individuals lived during tooth growth (adjusted $R^2 > 0.85$, residual error < 0.6‰ for individuals who reported a single location of residence during tooth formation). Given this result, analysis using the software package *assignR* suggests that on average, third molar oxygen isotopic composition could be used to exclude approximately 70% of the contiguous United States as a potential residence location for an individual with 90% confidence. Collectively, these results suggest great potential for high-quality tooth enamel oxygen isotopic data, interpreted in the context of the FIND-EM database, as a source of investigative information supporting human identification.

A42 Intra-Individual Isotopic Variation Within Teeth: Refining Forensic Applications Using Isotopes

Kirsten A. Verostick, PhD, University of Utah, Salt Lake City, UT; Chris Stantis, PhD, Southern Illinois University, Salt Lake City, UT; Gabriel Bowen, PhD, University of Utah, Salt Lake City, UT*

Learning Objectives: After attending this presentation, attendees will have an improved understanding of variation of oxygen and carbon isotope data values within individuals. Understanding these variations improves the use of stable isotopic data in geolocation and provenancing of unidentified persons.

Impact Statement: This presentation uses data compiled through Project FIND-EM, which is focused on developing robust methodology and a nationwide oxygen isotope dataset to aid in human identification efforts using oxygen isotopes in tooth enamel. Part of Project FIND-EM's mission is to inform and establish standardization in the use of isotopic measurements for forensic human identification.

Abstract Text: Individual teeth of the same type (e.g., central incisors, third molars, etc.) are generally understood to have similar development times within each dental arcade (maxillary and mandibular). However, there is some variation between the arcades, particularly in third molars.[1] Several studies have looked at isotopic variation between tooth types or intra-tooth isotopic variation within individuals.[2-6] To our knowledge, however, none have looked at isotopic variation with the same tooth type within or between arcades.

To examine intra-individual variability, we used oxygen and carbon isotope data from teeth collected for Project FIND-EM. We hypothesized that the variability between the teeth from different dental arcades would be greater than teeth from the same dental arcade due to somewhat larger differences in the time of tooth formation. We measured and calculated differences between teeth within an arcade (either maxillary-maxillary or mandible-mandible, n=14) and between different dental arcades (maxillary-mandibular, n=36). The range of differences for oxygen isotope δ-values for teeth from different dental arcades was -1.83 to 0.51‰, and for those within the same arcade was -0.54 to 0.56‰. The equivalent ranges for carbon isotope δ-values were -0.41 to 0.8‰ for teeth from different arcades and -0.37 to 0.3‰ for teeth from the same arcade. An F-test found the variance for teeth from different arcades was not significantly different from that for teeth from the same arcade (oxygen: $F(17,6)=3.09$, $p=0.17$; carbon: $F(17,6)=1.94$, $p=0.42$). Although we are unable to test with the current sample size, we hypothesize that higher variance between dental arcades would be more likely in individuals who lived in two or more locations during third molar crown development than in individuals who had static residential history. Real Interpretable Differences (RID; see) calculated by Stantis et al. for our lab protocol treatment (1.4‰ for $\delta^{18}O$ and 0.3‰ for $\delta^{13}C$) suggest that only 8% (n=2) of the between-tooth oxygen differences and 28% (n=7) of the carbon differences would lead to meaningful differences in the interpretation of the data.[7]

This initial assessment indicates that oxygen and carbon isotope values of enamel carbonate exhibit limited within-individual variation within the same tooth type, regardless of arcade sampled. That said, the existence of interpretable differences for some individuals, particularly for carbon, implies that within-tooth-type variation and its impact on forensic applications warrants further investigation.

A43 The Impact of Chemical Maceration on $\delta^{13}C$, $\delta^{15}N$, and $\delta^{18}O$ Values in Bone Collagen and Bioapatite

Julianne J. Sarancha, MS, Arizona State University, Tempe, AZ; Gwyneth W. Gordon, PhD, Arizona State University, Tempe, AZ*

Learning Objectives: After attending this presentation, attendees will be aware of how chemical maceration, the removal of soft tissue from bones, may affect $\delta^{13}C_{coll}$ and $\delta^{15}N_{coll}$ values in collagen and $\delta^{13}C_{ap}$ and $\delta^{18}O_{ap}$ values in bioapatite of bone samples.

Impact Statement: This presentation will impact the forensic science community by demonstrating how commonly analyzed stable isotope systems in bone are altered by chemical maceration. Because maceration is a routine protocol prior to sampling for isotopic analysis, this presentation will assist in determining if stable isotope analysis of bone collagen and bioapatite is suitable for a particular sample.

Abstract Text: Stable isotope analysis of bone collagen and bioapatite provides dietary and geographic information to assist with identification of human remains. Because altered isotope data can provide inaccurate life history inferences, understanding if a process such as chemical maceration alters the isotopic composition of a bone is important to determine if isotopic analysis is appropriate for a particular sample.

This study evaluated carbon and nitrogen isotopes of collagen ($\delta^{13}C_{coll}$ and $\delta^{15}N_{coll}$) and carbon and oxygen isotopes of bioapatite ($\delta^{13}C_{ap}$ and $\delta^{18}O_{ap}$) in bone for five chemical maceration treatments adapted from forensic anthropologists and medical examiners: (1) Alconox at 100°C for 24 hours, (2) Biz laundry detergent with sodium carbonate at 90°C for four hours, (3) Greased Lightning at 100°C for 24 hours, (4) Adolph's unseasoned meat tenderizer with Palmolive dish soap at 90°C for 10 hours, and (5) Tergazyme at 88°C for 24 hours.[1-4] Five racks of pig ribs from a single farm were obtained. From each rack, two samples were set aside as controls while seven samples were macerated using one of the methods above ($n = 7$ for each method). Experimental rib values were baseline normalized ($\Delta^{X}Y = \delta^{X}Y_{exp} - \delta^{X}Y_{avg,control}$) to the average value of the two controls from the same rack. The largest difference between two intra-individual control samples ("largest control difference") is used as an example of natural intra-individual variation

For both stable isotope systems of collagen, the Greased Lightning method displayed the largest average ($\pm 1\sigma$) shifts ($\Delta^{13}C_{coll} = 0.41 \pm 0.23$ ‰, $\Delta^{15}N_{coll} = 0.12 \pm 0.21$ ‰) and was also the only maceration method to bias $\delta^{13}C_{coll}$ values of macerated samples (all positive shifts). The largest average shift for both stable isotope systems fell below the respective largest control difference ($\Delta^{13}C_{coll} = 0.58$‰, $\Delta^{15}N_{coll} = 0.19$‰).

For $\delta^{13}C_{ap}$ values in bioapatite, average shifts were: $\Delta^{13}C_{ap} = 0.88 \pm 0.17$‰ (Alconox), $\Delta^{13}C_{ap} = 0.18 \pm 0.18$‰ (Biz laundry detergent with sodium carbonate), $\Delta^{13}C_{ap} = 0.45 \pm 0.12$‰ (Greased Lightning), $\Delta^{13}C_{ap} = 0.18 \pm 0.18$‰ (Adolph's with Palmolive), and $\Delta^{13}C_{ap} = 0.45 \pm 0.15$‰ (Tergazyme). All average shifts fall above the largest control difference ($\Delta^{13}C_{ap} = 0.14$‰). For oxygen, the Alconox ($\Delta^{18}O_{ap} = -1.24 \pm 0.46$‰) and Tergazyme ($\Delta^{18}O_{ap} = -1.33 \pm 0.40$‰) methods displayed average shifts in $\delta^{18}O$ values beyond the largest control difference ($\Delta^{18}O_{ap} = 0.74$‰), while the Greased Lightning method displayed the largest variability ($\Delta^{18}O_{ap} = -0.63 \pm 0.80$‰). In general, shifts induced by all maceration methods biased toward more positive $\delta^{13}C_{ap}$ values and more negative $\delta^{18}O_{ap}$ values.

Shifts in $\delta^{13}C_{coll}$ and $\delta^{15}N_{coll}$ values fell within the largest control difference, indicating any effects of chemical maceration were within intra-individual variation and did not meaningfully alter isotope ratio values. Bioapatite was less robust as average shifts in $\delta^{13}C_{ap}$ values for each method were larger in bioapatite than in collagen. Additionally, the Alconox and Tergazyme methods produced relatively large average shifts in $\delta^{18}O_{ap}$ values while all maceration methods biased data toward more negative $\delta^{18}O_{ap}$ values indicating a similar effect across methods. A better understanding of natural variation of $\delta^{18}O_{ap}$ values in pigs is needed to assess if these shifts induced by maceration are meaningful. Overall, carbon and nitrogen isotope analysis of collagen in bone chemically macerated under the parameters of this study are unlikely to meaningfully alter inferences while carbon and oxygen isotope analysis in bioapatite requires caution, particularly for the methods that produced the largest shifts.

A44 The Role of Cadaver Decomposition Islands on Soil Chemistry During Carrion Decomposition: Eco-Forensic Implications in a Southern Nigerian Ecosystem

Oghenefego Michael Adheke, PhD, University of Port Harcourt, Port Harcourt, Rivers, Nigeria; Loveday Ese Oghenemavwe, PhD, University of Port Harcourt, Port Harcourt, Rivers, Nigeria; Darlington Nnamdi Onyejike, PhD, Nnamdi Azikiwe University, Nnewi, Anambra, Nigeria; Josiah S. Hart, PhD, University of Port Harcourt, Port Harcourt, Rivers, Nigeria; Terkuma Fredrick Ujoh, BAg, University of Port Harcourt, Port Harcourt, Rivers, Nigeria; Bassey Udom, PhD, University of Port Harcourt, Port Harcourt, Nigeria*

Learning Objectives: At the end of this presentation, attendees will understand the role of cadaver decomposition islands and soil chemical properties in Postmortem Interval (PMI) estimation in southern Nigeria with respect to climatic differences.

Impact Statement: This presentation will impact the forensic science community by providing data for research and also for solving homicidal forensic cases.

Abstract Text: PMI is the time of death of an organism based on the body decay changes that have occurred.[1] Different factors affect the decay process of carcasses, especially climatic conditions, biotic factors, soil, carcass size, and age.[2-5] Studying the soil chemical properties could provide a taphonomic approach of carrion decomposition.[6] This study aimed to examine the relationship between soil chemical properties and decomposition timeline of remains in both dry and wet seasons of a southern Nigerian (Port Harcourt) ecosystem.

Using an observational and analytical design, the study observed the PMI of carcasses in dry season (December 2022 to February 2023) and wet season (April 3–18, 2023). A total of six healthy *Sus scrofa domestica* (domestic pigs) were used (three for each season) for this study and weighed between 40–60 kg. The pigs were euthanized using sodium pentobarbiturate injection that was administered intramuscularly as recommended by the Research Ethics Committee of the University of Port Harcourt and placed aboveground upon death confirmation. Decomposition was observed and scored quantitatively using Keough et al. Total Body Scoring (TBS) method based on the morphological appearance of three body regions; the head and neck, trunk, and limbs.[7]

Soil samples related to Cadaver Decomposition Island (CDI) were collected at weekly intervals, air-dried, sieved, and analyzed for chemical properties. Soil pH was determined using the standard water extraction method.[8] Soil exchangeable potassium (K) was extracted with neutral normal ammonium acetate.[9] Exchangeable calcium (Ca), magnesium (Mg), and sodium (Na) were determined using EDTA complexometric titration.[10] Exchangeable Acidity (EA) was determined from 0.1NaCl extracts and titrated with 1.0N hydrochloric acid. Effective Cation Exchange Capacity (ECEC) was determined by summing up total exchangeable bases and total exchangeable acidity. The control soil sample of the study location not affected by CDI (at day 0) was collected. Differences between control and CDI-affected samples at intervals were statistically examined using one-way Analysis Of Variance (ANOVA) and Post hoc test. Level of statistical significance of less than 0.05 was accepted.

Comparing with day 0 for dry seasons, the pH of CDI soil samples increased at day 7 (mean TBS = 16.3), day 14 (mean TBS = 21.3), and day 21 (mean TBS = 26.7). Both Ca and Mg concentrations increased at days 7 and 21 while K levels increased at days 14 and 21. EA levels increased at days 14 and 21 while ECEC values elevated significantly at both days 7 and 21. For wet seasons, pH values of CDI soil samples increased significantly at day 14. Concentrations of K were significantly higher at day 7 (mean TBS = 19.3) and day 14 (mean TBS = 31.3) while Na levels reduced at day 7. The study showed that CDIs significantly influenced soil chemistry as pig decomposition progressed for both seasons, thus serving as a reliable tool for PMI estimation. Furthermore, pH, Ca, Mg, and K levels were better PMI indicators during dry seasons while those of wet seasons were pH, K, and Na.

A45 Reassessing Forensic Significance With Radiocarbon Dating at the Oklahoma Office of the Chief Medical Examiner: A Cautionary Tale

Sara M. Getz, PhD, Oklahoma OCME, Oklahoma City, OK; Carlos J. Zambrano, PhD, Oklahoma OCME, Oklahoma City, OK; Angela K. Berg, MA, Oklahoma Office of the Chief Medical Examiner, Tulsa, Tulsa, OK*

Learning Objectives: After attending this presentation, individuals will better understand the limitations of assessing forensic significance from observational characteristics of skeletal remains and the risk of misclassifying modern unidentified cases as historic or archaeological. Individuals will also possess information on how radiocarbon dating can provide a more accurate assessment and mitigate misclassification risk.

Impact Statement: This presentation emphasizes the need for scientific evaluation of all remains of questionable forensic significance. These data can be used to advocate for the resources necessary to perform radiocarbon analysis and to facilitate discussions regarding the necessity of destructive testing to ensure that missing persons are not overlooked.

Abstract Text: Per state statute, the Office of the Chief Medical Examiner (OCME) must be informed when suspected human remains are discovered. Historically, the postmortem interval for skeletal cases was evaluated using observational data (e.g., color, texture, and density), combined with informant information and proximity of the discovery location to known cemeteries and archaeological sites. Given the extreme diversity of Oklahoma biomes and the poor documentation for many older cases, the Forensic Anthropology Division (FAD) became concerned that modern unidentified individuals might have been incorrectly classified as not being of forensic interest.

In July 2023, the FAD began reevaluating forensic significance for all cases that had not yet been reburied or put into the repatriation process. Cases exhibiting at least one of the following were classified as historic/archaeological: (1) direct evidence of a non-clandestine interment and/or the presence of non-modern artifacts; (2) artificial cranial deformation not practiced by modern communities; and/or (3) extensive dental wear typical of a pre-contact Native American diet. One hundred nine cases of questionable forensic significance were identified, falling into three overlapping categories: (1) isolated bones, commonly found in or around rivers/bodies of water; (2) remains with no provenience and limited information regarding acquisition, and (3) cases where the discovery circumstances, visual characteristics, and/or exam findings are unclear or conflicting. Between October 2023 and June 2024, 42 cases were reevaluated. Bone characteristics traditionally used to estimate postmortem interval were documented and cortical bone samples (~2g) were submitted to the University of Georgia Center for Applied Isotope Studies radiocarbon accelerator mass spectrometry facility.

Based on the calibrated radiocarbon data, 20 individuals (47.6%) were identified as having died prior to 1650 AD. Based on the population history of Oklahoma, these individuals are assumed to be Native American and will be turned over to the appropriate tribal representative or State Archaeologist for repatriation. Fifteen individuals (35.7%) were identified as dying between 1650 AD and the mid-twentieth century. These individuals include imported anatomical specimens, "trophies/souvenirs" from overseas conflicts, historic burials, and remains of uncertain provenance. These cases will be evaluated on a case-by-case basis and may require additional investigation or testing before final disposition. Seven medicolegal cases (16.7%) were identified: two suspected forensic cases confirmed to be modern and five cases (11.9%) previously misclassified as "not significant" in the 1990s that are likely modern unidentified persons.

Investigations have been reopened for these newly identified forensic cases. However, efforts are hindered by the loss of original personnel and investigative documentation. Given the likelihood of additional unidentified individuals in our possession, the OCME expects to continue testing remains of uncertain significance and has updated the evaluation processes for new cases to include radiocarbon analysis. Based on the findings from the first year of this project, the OCME strongly urges other medicolegal agencies and forensic anthropologists to use caution when visually assessing skeletal remains and to consider radiocarbon testing as part of the scientific evaluation of forensic significance.

Forensic Significance; Radiocarbon Dating; Anthropology

A46 The Biocultural Dynamics of Postcranial Skeletal Variation: A Focus on Ontogeny, Socioeconomic Status, and Population History

Micayla Spiros, PhD, University of New Mexico and Office of the Medical Investigator, NM; Micayla C. Spiros, PhD*, District of Columbia Office of the Chief Medical Examiner, Albuquerque, NM*

Learning Objectives: After attending this presentation, attendees will understand the potential biocultural contributory forces of postcranial Macromorphoscopic (MMS) traits. Age at time of appearance and sociocultural factors are investigated at various stages of growth and development throughout childhood and well into adulthood, exploring how they may account for skeletal differences.

Impact Statement: This presentation will impact the forensic science community by illustrating how technological advances, such as Computer Tomography (CT) databases, can allow researchers to understand the human skeleton from a more biocultural perspective. Utilizing the New Mexico Decedent Image Database (NMDID), associated metadata are paired with individuals to assess whole body CT scans to explore the embodiment of sociocultural factors on skeletal biology. Understanding the impact of biocultural factors will allow attendees to better understand the various pillars of the biological profile in forensic anthropology through the lens of postcranial MMS traits.

Abstract Text: The human skeleton offers insights into an individual's lived experience, which can be quantified as morphological changes brought about by intrinsic and extrinsic forces acting on aspects of human variability. This interplay can leave imprints on the human skeleton in a patterned (and thus predictable) way, reflecting environmental adaptation and the embodiment of an individual's social history over time, especially at their youngest age.

Considering growth rates and timing, particularly relative to developmental processes and puberty, this project utilizes a model designed to capture, measure, and quantify the age-of-appearance/age-of-stability of postcranial MMS traits. Age is a significant contributing factor in the ontogeny of postcranial traits, particularly when focusing on puberty and age-of-attainment for adult morphology. In this sample of juvenile individuals, sex and social race, in tandem, do not seem to contribute to differences in trait manifestation. These results suggest postcranial MMS traits should not be collected from individuals who have not reached puberty for estimation of an individual's population affinity or sex. The stabilization of traits occurs at distinct points in time; puberty is the best indicator of stability for most of these traits.

The embodiment of the health-wealth gradient and social racism are explored from an osteological perspective. Impacts of sociocultural factors—social race, Socioeconomic Status (SES), and education—are modeled to examine whether these influence postcranial skeletal morphology. Studying social categories in relationship to biology and forensic anthropological approaches to population affinity is important, especially when studies confound race and SES-related health disparities. Patterns of embodiment of structural racism can be correlated in various postcranial MMS traits as variation within and between social races and SES and/or education. Three traits show significant differences between social race alone. This does not mean that social race is biological in relation to these three traits, rather there should be further exploration of all postcranial traits in an evolutionary model related to geographic ancestry, climate, genetic flow, and genetic drift.

Overall, this presentation's aim is to better understand what influences the variability of skeletal morphology. Whether that is evolutionary processes of climate impacts and migration correlated with geographic ancestry or structural violence influencing the health of groups of individuals and, thus, the production (or lack thereof) of bone in certain patterns, this research shows that there is a call for a more comprehensive approach of mixed-methods to incorporate more multivariate, refined, multiregional approaches to understand the full picture of human variation across the human skeleton.

Anthropology; Biocultural Theory; Postcranial Skeleton

A47 Antemortem Tooth Loss as a Biomarker of Structural Vulnerability in a New Mexico Forensic Sample

Allysha P. Winburn, PhD, University of West Florida, Pensacola, FL*

Learning Objectives: After attending this presentation, attendees will understand how structural vulnerability approaches can enable the recognition of population-level patterns in forensic casework.

Impact Statement: This presentation will impact the forensic science community by showing one such pattern—the correlation between poverty and tooth loss—and arguing for its redress.

Abstract Text: The theory of structural vulnerability builds on the idea of structural violence—that inequitable social systems can themselves enact violence against human bodies—to describe how some individuals may be particularly vulnerable to (i.e., at greater risk for) negative health outcomes. In any society, the differing circumstances under which people are born, grow, live, and work can produce health inequities; those inequities are structured by that society's institutions, policies, and belief systems, often along social and economic fault lines like class, gender, race, and sexuality.

Structural vulnerability has been deployed in clinical medicine to direct attention toward the upstream, societal-level factors that produce poor health outcomes, rather than the biological and behavioral factors that are often perceived to be individual choices.[1] Recently, forensic anthropologists have proposed that viewing skeletal and dental variation through a similar lens would enable the aggregation of population-level data revealing socially produced patterns of suffering that could be reported to the state.[2-4]

Periodontal disease is one area where such socially structured patterns emerge, with previous anthropological researching linking it with experiences of marginalization among Mexican and Central American migrants to the United States and White Americans living in poverty in Eastern Tennessee.[5,6] This study proposes that correlations between poverty and Antemortem Tooth Loss (AMTL) will also be evidenced in a forensic sample from New Mexico.

A sample of 350 identified, anonymized forensic case decedents was selected from the New Mexico Decedent Image Database (https://nmdid.unm.edu), an open-access repository of CT imagery. All decedents in the sample were contextualized with antemortem demographic data by their next of kin, including age, gender, race, and Socioeconomic Status (SES). The sampling strategy was to select 25 age-matched low-SES and high-SES females and males who identified as Black, Hispanic, Native American, and White; however, due to low numbers of Black and Native females whose next of kin provided contextual data, these categories were not fully populated. Age-matched, roughly equal samples were amassed for the remaining groups (n=25 for Hispanic and White individuals and Native males; n=24 for high-SES Black males; n=18 for low-SES Black males).

All software used in this study was open source. Each individual's CT images were cleaned using DicomCleaner and analyzed using 3D Slicer. Two-dimensional slices and the 3D volume renderings created from them were scored for AMTL. The *R* statistical language was used to run non-parametric Wilcoxon signed-rank tests to assess differences in distributions of scores between low- and high-SES groups within each gender and race category.

For Black males, Hispanic females and males, and White females and males, median AMTL was higher in low-SES individuals (9.5, 8, 4, 6.5, and 6, respectively) than in their age-matched high-SES counterparts (1, 2, 2, 0, and 0, respectively). These differences were statistically significant for Black males ($p=0.0006$), White females ($p< 0.0001$), and White males ($p=0.04$). High-SES Native males exhibited more AMTL than their low-SES counterparts (median of 4 versus 1.5), but the difference was not statistically significant. When edentulism was considered, this pattern was reproduced, with most low-SES groups exhibiting higher frequencies of complete AMTL (low-SES BM 17%, HF 16%, HM 8%, WF 13%, WM 25%; high-SES BM 4%, HF 0%, HM 0%, WF 0%, WM 8%).

The power of a structural vulnerability approach is that, because the problems it highlights are socially created, they are also ultimately solvable. Poor dental health is linked with poor physical and mental health, but the poor dental health repeatedly evidenced among people living in poverty is solvable with changes to social policy and medical infrastructure. This research contributes to a growing body of scientific data that can inform social change.

A49 The Impact of Substance Misuse Behaviors on Skeletal Physiology and Premature Skeletal Senescence in an Autopsy Population

Christine M. Pink, PhD, Western Michigan University Homer Stryker M.D. School of Medicine, Kalamazoo, MI; Prentiss Jones, Jr., PhD, Western Michigan University Homer Stryker M.D. School of Medicine, Kalamazoo, MI*

Learning Objectives: This presentation demonstrates variable effects of substance misuse behaviors on skeletal physiology and aging. The study tests the hypothesis that effects on the noradrenergic system are consequential to skeletal physiological function and are patterned by substance of choice. Attendees of this presentation will have a better appreciation of the importance of underlying physiological processes affected by human behavior, and the resulting skeletal morphological variation.

Impact Statement: Forensic anthropologists have traditionally focused on skeletal morphology to estimate the chronological age of an individual with little attention given to the interaction of environment and biology influencing skeletal phenotype. The results of this study suggest that skeletal physiological function, particularly related to the noradrenergic system, is patterned by drug(s) of choice and affects bone quality and rate of skeletal aging.

Abstract Text: In the past ten years, the United States has experienced an unprecedented rise in drug-related morbidity and mortality. Simultaneously, important advances in research on the endocrine functions of the skeletal system have occurred. While superficially unrelated, both are critically important to forensic anthropology. Skeletal tissues like bone marrow adipose tissue (bmat) have recently been discovered to have osteoclastogenic and insulin-resistance properties.[1] Furthermore, accumulation of bmat near nerve fibers innervating bone correlated with Sympathetic Nervous System (SNS) activity has also been observed in murine models.[2] Increased SNS tone also promotes release of norepinephrine, which stimulates osteoclastogenesis in addition to its effects on blood sugar levels.[3,4] Since select drugs induce their subjective effects (the "high") by variable influences on release and/or reuptake inhibition of norepinephrine, serotonin, and dopamine bmat volumes (and bone quality by proxy) should also vary by substance use behaviors.

Volumes of bmat and bone marrow in the sternal body were calculated from postmortem Computed Tomography (CT) imaging data for 60 adult males (mean = 39.48 years; range 18-75 years) who received a postmortem exam at the Western Michigan University Homer Stryker M.D. School of Medicine (WMed) in Kalamazoo, MI. Tissues were isolated and volumes calculated following Suchacki et al.[1] Ratios of bmat to bone marrow volumes were used to control for size variation. Volume ratios were evaluated by drug of choice as indicated in the death investigation materials and include alcohol, cocaine, methamphetamine, opioids, opioids and methamphetamine, and a control group. The opioids, cocaine, and methamphetamine groups had the lowest values. Interestingly, the group that concomitantly used opioids and methamphetamine had the highest relative bmat volumes. A Kruskal Wallis test of ratio values by group was significant ($p = 0.00004$). And a Dunn test of pairwise differences with a Bonferroni correction resulted in multiple significant comparisons. The opioids and methamphetamine group had significantly higher ratios (relatively more bmat) than the cocaine ($p = 0.0037$), opioids ($p = 0.0041$), and control (0.05420) groups. Both opioids and methamphetamine individually affect noradrenergic system function, but the apparent cumulative effects of chronic exposure to both on bmat accumulation and skeletal physiological function is unclear.

Skeletal senescence was tested using the fourth sternal rib end as an age indicator. An autopsy population at WMed and donors from the WMed Skeletal Series were sampled and scored following Hartnett.[5] The mean age at transition from one phase to the next was evaluated for the collapsed substance misuse group (all substances; n=126) and control group (n=76) using transition analysis. As expected, differences between groups were more pronounced in older adults. The probability that an individual at a specific age would be in a particular phase was calculated from the cumulative probit model following Konigsberg.[6] Results indicate premature skeletal aging in the substance misuse group. For example, the probability of a 40-year-old in the control group being in phase 4 (43.3%) is higher than the probability of being in a later phase (35.7%). For the substance misuse group, the probability of being in phase 4 (31.6%) is lower than the probability of being in a later phase (50.0%). Therefore, a 40-year-old person with a substance misuse history has a higher probability of exhibiting advanced skeletal aging than someone with no misuse history.

The results of this study highlight the importance of understanding how skeletal physiological function is affected by human behavior with respect to drug and alcohol use. Premature skeletal senescence correlated broadly to substance misuse is also demonstrated. These data are compelling and should motivate forensic anthropologists to question the mechanisms influencing the morphological variation that age estimation methods are based upon.

Substance Abuse; Bone; Age Estimation

A50 Establishing a Skeletal Atlas of Elder Abuse: A Bayesian Examination of the Complex Relationships Between Age, Sex, and the Probability of Abuse or Accident as Related to Skeletal Trauma

Jacob A. Harris, PhD, Arizona State University, Phoenix, AZ; Kaitlyn J. Fulp, MA, PhD Forensic Anthropology, Arizona State University, Phoenix, AZ; Laura C. Fulginiti, PhD, Maricopa County Office of the Medical Examiner, Phoenix, AZ; Jane E. Buikstra, PhD, Arizona State University, Tempe, AZ*

Learning Objectives: After attending this presentation, attendees will be aware of the associations between decedent age and sex among elderly individuals (65+) and the probability their skeletal fractures noted at autopsy are due to abuse/neglect or a witnessed accidental fall.

Impact Statement: This presentation will impact the forensic science community by further describing the skeletal manifestations and patterning of elder abuse, contributing data to the ongoing effort to unmask elder abuse at a state and national level.

Abstract Text: Increasing rates of elder abuse in the United States produce an urgent need for improved diagnostic criteria.[1] Physical abuse represents the most severe manifestation of this trend, yet is difficult to prove.[2] Skeletal expressions of abuse offer key indications of inflicted injuries, but may be masked by assignation to accidental falls. Funded by the National Institute of Justice, our research aims to produce a standard for the diagnosis of elder abuse in the skeletal system.[3] Previously, we identified a significant difference in skeletal patterns of injury between those individuals involved in accidental falls and those for whom abuse/neglect is suspected, as well as differences in fracture patterning in non-ambulating individuals in both categories.[4,5]. We examined differences in osteoporosis between these categories and found a disproportionately high frequency of osteoporosis among individuals sustaining fractures in accidental falls.[6] Here, we further explore the skeletal patterns of abuse vs. accidental falls in cases from the Maricopa County Office of the Medical Examiner by examining age and sex as potential predictor variables.

Investigative summaries of 388 individuals over the age of 65 who sustained skeletal trauma were included in the study (ca. 2014–2021). From these, 64 individuals were included as representative of cases of abuse/neglect based on the following criteria. Decedent must: (1) have been admitted for exam, (2) be associated with an Adult Protective Services and/or law enforcement investigation, and (3) have radiographs/samples available for review. Given these strict criteria, this sample is known to be an underestimation of cases of abuse/neglect. Three hundred eighty-four cases of witnessed ground-level falls from the same pool were reviewed.

In sum, results reveal an age effect in the skeletal manifestation of injury for individuals involved in ground-level accidental falls, but not for those where abuse is suspected. There is no sex effect on either category.

We examined age associations by performing logistic regression in which the decedent's age was treated as a predictor variable for the binary dependent variables, having experienced skeletal fracture associated with documented or suspected abuse (model 1) or witnessed accidental fall (model 2). The results of model 1 suggest no age affect among victims of abuse (SlopeAbuse = -0.01346, SEM = 0.012, p=0.285). The results of model 2 suggest a significant positive relationship between age and the probability of a skeletal fracture due to an accidental fall (SlopeAccident = 0.03026, SEM = 0.014, p=0.029). To further examine the relationship between abuse and biological sex, we performed Bayesian multilevel logistic regression models. Models 3 and 4 examine the random (sex) and fixed (age) effects abuse (model 3) and accidental (model) breaks. The results are consistent with the logistic regression.

Bayesian Models 5 and 6 examine the fixed effect of *sex* (model 3) and accidental (model) breaks while treating *age* as a random effect and examine incidents of abuse and accidental falls respectively. The results of model 5 suggest no fixed sex effect (SlopeSex = -0.35, 95%CI: 0.29, 0.93). Similarly, the results of model 6 suggest there is no age effect with the probability of Accidental injuries (SlopeSex = 0.25, 95%CI: -0.34, 0.86).

Fractures remain the most common musculoskeletal condition requiring hospitalization among individuals aged 65+ in the United States, and rigorous diagnostic criteria must be developed to differentiate accidental injury from abuse.[7] Data that are easily obtained as part of a death investigation—sex and age—are here found to be significant variables in diagnostic criteria and could provide further probabilistic weight to a diagnosis when considered in light of the results described. Results from this ongoing study represent an extensive effort to develop and improve diagnostic criteria for a skeletal atlas of elder abuse.

Elder Abuse; Skeletal Trauma; Age and Sex

A51 The "Missing Migrant": Schrodinger's Cat of Legal Status and Applicable Frameworks

Skylar Joseph, MS, Leiden University, Leiden, Zuid-Holland, Netherlands*

Learning Objectives: After attending this presentation, attendees will: (1) gain a more comprehensive understanding of some of the main issues caused by the lack of a clear legal definition for the "missing"; (2) learn how and why "missing migrants" in particular fall through the cracks of existing legal frameworks both at national and international jurisdictional levels; and (3) discover how a global redefinition of the status of "missing" could help countless individuals and families worldwide.

Impact Statement: This presentation will impact the forensic science community by raising awareness about how the lack of a defined status for the "missing" (a widespread, yet seldom-discussed issue) impacts numerous aspects of the search process and practitioners' ability to resolve cases, as well as directly impacting the family of those missing. Through gaining a more comprehensive understanding of these issues, the forensic science community can begin to advocate for changes to the existing legal frameworks so that fewer missing individuals fall through the cracks in the future.

Abstract Text: "Missing migrants," as a demographic, epitomize a legal conundrum reminiscent of Schrödinger's cat: neither definitively alive nor dead until their fate and whereabouts are determined. Slipping between the cracks of existing legal frameworks, missing migrants are engulfed in a perpetual state of legal ambiguity because significant elements of their status are only determinable through the discovery of their body (alive or dead).[1] This paper makes three main arguments that seek to redefine how the "missing" are recognized across international and domestic legal frameworks.

First, this paper identifies that several legal regimes may apply to the missing. Identifying the applicable law requires determining status, and status cannot be determined without positive identification. As such, initiation of the search process might be inhibited or prevented due to unclear frameworks leading to systemic accountability gaps.[2]

Second, this paper argues that a universally recognized legal status for the "missing" is necessary to ensure families have access to their fundamental rights and that states uphold their obligations to search for the missing and identify the dead.[3-5] In law, being "missing" is not generally a distinct legal status. Factually, however, being "missing" has consequential effects. If a person's status is unknown, even if they are presumed dead, no death certificate can be legally issued. This causes families additional harm, including: legal problems related to the unclear status (alive/dead); impacting their ability to access social assistance and fundamental rights; and preventing emotional closure due to the prolonged trauma of ambiguous loss.

Third, this paper argues that there is a need for more comprehensive search processes and a broadening of the acceptable parameters for legally determining a missing individual's fate and whereabouts.[1,2]

This paper will discuss how the overlapping legal frameworks applying to migration, missing persons, and treatment of the dead can lead to different legal obligations dependent upon an individual's status. Domestically, laws governing border control are often inconsistent with international legal frameworks such as International Human Rights Law (IHRL), Refugee Law, and the Law of the Sea (LOTS).[6] As concerns the missing, under IHRL, states have a procedural obligation to investigate disappearances within their jurisdiction. When International Humanitarian Law (IHL) applies, this extends to heightened duties toward the missing and deceased.[5] In both cases, when at sea, obligations related to rescue and assistance apply. These complexities are more sharply pronounced again in disaster situations, especially when natural disasters occur alongside armed conflicts.

Overall, this paper suggests redefining how the "missing" are currently defined and recognized in law. A proposed legal definition for the "missing" as a unique category of person would aid in clarifying which state obligations toward the missing and the dead should be applicable in all situations. This necessary paradigm shift would allow for more equal protections and access to fundamental rights for the missing, the deceased, and their families, in all contexts.

Missing Persons; Migrants; Search and Recovery

A52 A Brief Introduction to Artificial Intelligence in Forensic Anthropology: Core Concepts and Ideas

Thomas A. Delgado, MA, University of Utah, Knoxville, TN; Taylor M. Flaherty, MSc, University of Nevada, Las Vegas, Henderson, NV; Samantha H. Blatt, PhD, Idaho State University, Pocatello, ID*

Learning Objectives: After attending this presentation, attendees will have a better understanding of why and how Artificial Intelligence (AI) has come to be integrated in contemporary forensic research. Attendees will also be introduced to key terminology, methodology, and best practices related to AI utilization, including a brief case example that highlights using AI in forensic contexts.

Impact Statement: This presentation will impact those developing novel research and identification methods within the forensic sciences. With this, we intend to highlight the utility of multidisciplinary research that is, currently, not widely incorporated into forensic anthropology. Methods incorporating AI have a demonstrated potential to increase the accuracy and reliability of many existing methods. This presentation will provide a succinct introduction to this likely unfamiliar mode of research and data analysis to help better inform the forensic community.

Abstract Text: Machine learning and AI have seen rapid growth in their development since the turn of the century. A rise in personal computing power has allowed complex processing to be completed in minutes and become integrated in daily life, where these tasks used to be limited to supercomputers. In tandem with this, the sciences have entered an era of "big data," where these same advancements in personal computing are used to curate large amounts of data. Curation of big data allows scientists to analyze large quantities of data with robust algorithmization to help answer novel research questions or create predictive models with high accuracy, reliability, and resolution. While methods incorporating AI and machine learning have shown promise, they have primarily been integrated into electrical engineering and computer science. Forensic anthropologists have not routinely tested these methods, putting the field at risk of falling behind in the current technological revolution. A handful of forensic anthropologists have begun to explore AI methodologies in recent years; however, there is still much debate about the utility, ethics, and operationalization of these techniques.

This presentation will provide a brief introduction to AI history and terminology, highlighting the nuanced differences between AI, machine learning, and deep learning. We will also explore how each can be uniquely incorporated into forensic research and training. Open-access resources that can allow any forensic researcher to incorporate AI into their research design regardless of background or funding will also be introduced. Best practices for utilizing AI within forensic anthropology will also be suggested with full transparency in methodology and algorithmization being encouraged for all forensic scientists, particularly when utilizing "black-box" methodology where the exact reasoning for algorithm-made decisions is unknown.

The presentation will conclude with a discussion surrounding the ethical concerns that have been raised surrounding AI-based research, particularly surrounding classroom usage, data curation, and "black-box" methodology. While acknowledging that the best ethical practices for utilizing AI methodology will take time to develop and implement, it is essential to highlight that there is utility in these methods to better serve individuals and communities, necessitating forensic anthropologists' involvement. The open-access nature of many machine learning and AI toolkits is also an advantage to underprivileged individuals who may lack access to much of the specialized software (e.g., MatLab, IBM SPSS) currently used to develop methods and predictive models. Ultimately, AI will continue to be developed and incorporated into nearly every field, and a base understanding of methods related to AI will soon become a necessity.

A54 Using Artificial Intelligence to Automate Human Stage of Decay Identification

Anna-Maria Nau, PhD, The University of Tennessee, Knoxville, Knoxville, TN; Phillip Ditto, MA*, University of Tennessee, Springtown, TX; Dawnie W. Steadman, PhD, University of Tennessee, Knoxville, TN; Audris Mockus, PhD, University of Tennessee, Knoxville, Knoxville, TN*

Learning Objectives: After attending this presentation, attendees will have a better understanding of how Artificial Intelligence (AI) can be applied to the field of forensic anthropology. Specifically, attendees will learn about the feasibility of using AI techniques to automate human stage of decay identification methods from digital photos.

Impact Statement: This presentation will impact the forensic science community by demonstrating an approach that utilizes AI, specifically deep learning methods, to automate human stage of decay identification methods. In doing so, it leverages a large-scale archival collection of human decomposition photos.

Abstract Text: Determining the stage of decay is an important and common task in human remains cases. Knowing the degree of decomposition is vital for estimating the postmortem interval and identifying human remains. Currently, labor-intensive manual scoring methods are primarily used to establish the stage of decay of a decedent. These methods, which rely on subjective interpretation made by humans, are more susceptible to bias and error, consequently affecting the accuracy of downstream tasks, such as estimating the postmortem interval. Additionally, due to their labor intensity, these methods do not scale well for the emerging large-scale archival collections of human decomposition photos. Therefore, this study explores the feasibility of automating two common human decomposition scoring methods proposed by Megyesi et al. and Gelderman et al. using AI.[1,2]

Evaluated were two popular deep learning model architectures, such as Inception V3 and Xception, by training them on a large dataset of human decomposition images to classify the stage of decay for different anatomical regions, including the head (and neck), torso, and limbs (including the hands and feet).[3,4] Additionally, an interrater study using the Fleiss' Kappa statistic as the evaluation metric was conducted to assess the reliability of the developed AI models compared to human forensic examiners for stage of decay identification. The Xception model achieved the best classification performance, with macro-averaged F1 scores of .878 for the head, .881 for the torso, and .702 for the limbs when predicting Megyesi et al.'s stages of decay, and .872 for the head, .875 for the torso, and .76 for the limbs when predicting Gelderman et al.'s stages of decay.[1,2,4] The interrater study results supported AI's ability to determine the stage of decay at a reliability level comparable to a human expert. This work demonstrates the potential of AI models trained on a large dataset of human decomposition images to automate stage of decay identification.

A55 Forensic Comparative Radiography Using Transformer-Based Neural Networks and Large Language Models

Carolyn V. Isaac, PhD, Michigan State University, East Lansing, MI; Redwan Sony, MS, Michigan State University, East Lansing, MI; Alexis L. VanBaarle, MS, Michigan State University, East Lansing, MI; Joe T. Hefner, PhD, Michigan State University, East Lansing, MI; Todd Fenton, PhD, Michigan State University, East Lansing, MI; Arun Ross, PhD, Michigan State University, East Lansing, MI*

Learning Objectives: After attending this presentation, attendees will understand how advanced neural-network transformers and large language models can be applied to scientific identifications via comparative chest radiography.

Impact Statement: This presentation will benefit the forensic community by presenting a unique approach to scientific identifications utilizing a Vision Transformer and a Large Language Model that can assist in comparing antemortem and postmortem chest radiographs for mass fatalities, missing persons databases, or routine forensic casework, while reducing practitioner bias

Abstract Text: Scientific identification is an integral component of forensic investigations, ensuring accurate death certification and that the correct remains are returned to loved ones. Forensic anthropologists routinely aid in scientific identifications utilizing comparative medical radiography. In typical forensic casework, antemortem medical imaging of the presumed identity is provided for comparison with postmortem medical imaging of the decedent to assess whether the images originated from the same individual. However, practitioners may be implicitly biased to believe that the antemortem medical imaging should match the postmortems. This research aims to develop an AI-assisted approach to comparative radiography to: (1) reduce practitioner bias; (2) allow for applications to mass fatalities, unidentified persons databases, and typical forensic casework; and (3) provide an explanation of the decision process.

Previous research demonstrated the utility of deep Convolutional Neural Networks (CNN) models to automatically generate a ranked list of chest radiographs that most closely match the input chest radiograph image.[1] A rank-1 accuracy of 92.38% was obtained when utilizing the entire chest X-ray, meaning that in 92.38% of the cases, the true match was ranked first on the list of potential matching identities. When an ensemble method combining the feature vectors from different models pertaining to different regions of interest was used, an accuracy of 94.08% was achieved. Despite the success of the CNNs, there were two notable limitations: (1) lack of explainability—it was not possible to ascertain the specific features the models were using to compare radiographic images to generate the ranked lists; and (2) absence of attention modules—the relationship between patches in the images was not explicitly exploited in the CNN framework.

To address these limitations, a new approach was explored utilizing Vision Transformers (ViTs), a neural network architecture that uses the so-called "attention module" to automatically determine correlated regions in an image.[2] Further, we combined this with a Large Language Model (LLM) to provide a descriptive output of the features utilized to compare radiographs.[3] The goal is to improve the accuracy of the comparison process while imparting explainability to the decision process.

A large sample of 5,165 anonymized chest radiographs of 760 individuals from casework from the Michigan State University Forensic Anthropology Laboratory and the National Institutes of Health (NIH) Chest Xray Dataset were used. The sample was split into training (n = 3,289 radiographs) and testing (n = 1,876 radiographs) subsamples. Two ViT-based models with a patch size of 16 and 32 were trained on complete chest radiograph images. Preliminary results demonstrate that the patch 16 model has an 84.21% rank-50 accuracy, the patch 32 attains 80.43% accuracy, and the ensemble has the highest accuracy with 84.75%. These promising results show the power of ViTs, whose performance is expected to improve with increased sample sizes and training. In addition, a preliminary experiment involving an LLM demonstrated its ability to analyze and describe the constituent images using medical terminology, thereby providing additional evidence about the similarities and dissimilarities in the shape, structure, and texture between the postmortem and antemortem images.

Our ongoing work involves integrating the ViT with the LLM in order to develop an automated system to assist practitioners in comparative radiographic identifications and provide rationale for the provided matches. The use of such a system could facilitate faster decedent identification in cases of mass fatality or could be used to identify decedents in large unidentified databases by decreasing the potential identity pool.

A56 Applying Machine Learning Methods to Age Estimation in Forensic Anthropology—From Glass Box to Black Box

Martin Lo, PhD, University College London, London, England, United Kingdom; Enrico Mariconti, PhD, University College London, London, United Kingdom; Sherry Nakhaeizadeh, PhD, University College London, London, England, United Kingdom; Ruth M. Morgan, DPhil, University College London, London, England, United Kingdom*

Learning Objectives: After attending this presentation, the attendees will learn the difference between explainability and interpretability in Machine Learning (ML) for forensic anthropology and how glass and black box ML methods are currently applied to age estimation in forensic anthropology. The attendees will gain an understanding of using 3D medical image files in ML for forensic anthropology.

Impact Statement: The presentation will provide the forensic science community with an understanding of the differences between explainability and interpretability in ML for forensic anthropology. The presentation will present applied examples of how medical images can be used in ML for biological profile estimations in forensic anthropology.

Abstract Text: The application of ML and Artificial Intelligence (AI) within the forensic science discipline has increased in recent years. The rise of ML-focused research has led to concerns and discourse over algorithmic opacity and transparency issues in governmental reports and literature. The application of new technologies in forensic anthropology is still relatively new, with ML in adult age estimation relatively unexplored.

The use of ML in forensic anthropology and biological profile estimation is, however, not new and has been increasing in recent years. ML algorithms vary in mathematical complexity, which impacts upon the understandability of their outputs.

This presentation will provide an overview of what interpretability and explainability are, and how these concepts relate to algorithmic opacity, understandability of output, and calls for transparency in forensic science. This will be showcased using results from three ML studies investigating the feasibility of using 3D ML for adult age estimation in the living in forensic anthropology. In this research, 3,093 CT studies containing the pelvis from University College London Hospital were converted to NIfTI file format to create a training, validation, and testing dataset to develop ML models varying in algorithmic opacity (glass box to black box). The ML algorithms used include Decision Tree (DT), Random Forest (RF), and Convolutional Neural Network (CNN), and a "voxel-feature" approach was used on the health care-derived dataset. The "voxel-feature" approach solely utilizes the individual voxels of the 3D pelvic NIfTI image to train 3D ML models, avoiding the use of nonmetric scoring.

The results of these studies confirms the feasibility of this approach to the pelvis and across three types of ML models from glass-box (DT) to black box (CNN), which was previously shown feasible by Joshi and Tallman in NIfTI files of the postmortem skulls using CNN.[1] In addition, the results indicate that classification accuracy increases as the ML algorithm become more complex and opaque.

Using the results, this presentation will discuss future responsible applications of glass-box and black box ML algorithms; raise questions on how algorithmic opacity can and should be related to the needs of transparency in forensic science; highlight potential ethical issues of using health care-derived data in ML model development for forensic science and by extension forensic anthropology

The insights gained from this research contribute to the ongoing discourse on the responsible development and application of AI in forensic contexts, highlighting the importance of open dialog that considers ethics, application contexts, and interpretability of ML and AI tools in forensic science to build trust and effectiveness of science evidence in the justice system.

A57 The Potential Applications and Uses of Neural Radiance Fields (NeRF) and Gaussian Splats: Artificial Intelligence in Forensic Anthropology

Katharine E. Kolpan, PhD, University of Idaho, Moscow, ID; Jeffrey R. Vadala, PhD, UPenn Brain Science Center VR/AI Lab, University of Pennsylvania, Philadelphia, PA*

Learning Objectives: After viewing this presentation, attendees will gain an understanding of the inner workings of Neural Radiance Fields (NeRF) and Gaussian Splats, their relationship to Artificial Intelligence (AI), and how they can be applied to projects and technologies relevant to the forensic anthropology community.

Impact Statement: This presentation will impact the forensic science community by highlighting how utilizing NeRF and Gaussian Splats technology can benefit forensic anthropologists.

Abstract Text: NeRFs and Gaussian Splats are emerging types of imaging that utilize AI to rapidly convert Computed Tomography (CT) scans into Augmented- and Virtual Reality-compatible (AR/VR) 3D representations. The rapid automated conversion process made possible by these AI technologies allows forensic researchers to create 3D AR/VR images from CT, significantly cutting down lengthy processing times, while reducing the manual manipulation that introduces bias and inconsistency into the data.

NeRF AI technology allows for the creation of AR and VR 3D meshes that can be used to reconstruct fractured and fragmented remains with minimal manual processing. Gaussian Splats, a more recent development, offer a complementary approach by representing 3D scenes as collections of oriented 3D Gaussian functions, providing faster rendering and potentially higher quality results in some scenarios. From a forensic anthropological standpoint, these technologies allow for the manipulation of fragile, burned, and fragmented remains while minimizing the possibility of damaging bony evidence due to overhandling. Bony elements can then be reconstructed within the virtual space, making it easier to determine traumatic injuries, such as gunshot wounds or blunt force trauma, that are not instantly detectable due to the fragmentary nature of the remains. Additionally, assuming the join is undamaged, and the bone is not warped, reconstruction using these AI technologies may also make measurements of skeletal elements possible.

NeRF AI and Gaussian Splats can be built into computer applications that convert CT scans of fragmentary skeletal elements into 3D AR/VR representations designed to aid in reconstruction. Here, the authors examine how these AI technologies can benefit forensic anthropologists via Cranial Tool AR, a computer application they designed that utilizes LUMA AI NeRF and Gaussian Splats as a means of reconstructing fragmented craniofacial images so they can be reconstructed in AR to assess the cranial and facial skeleton for signs of trauma as well as aspects of the biological profile, such as biological sex and population affinity.

In this case, craniofacial CT scans were imported into 3D Slicer to represent the scans as 3D surface volumes, which were then captured via videoframe recording and uploaded into Luma AI NeRF and a Gaussian Splats processing pipeline. The AI programs processed the videoframe captures as NeRFs and Gaussian representations, respectively, and exported them as 3D representations of the fragmented craniofacial remains that could be used in craniofacial reconstruction, trauma assessment, and analysis of the biological profile. These representations were imported into Cranial Tool AR, which utilizes the 3D gaming engine Unreal Engine to render them into manipulable holograms.

While there are other ways of employing CT scans, such as more traditional manual selection non-AI workflows, the authors found that utilizing NeRF and Gaussian Splats AI decreased processing time from a matter of hours to one of minutes, reduced workflow complexity related to creations of these images, and made it simpler for non-specialists in 3D Slicer to use, all while rendering highly precise images of the craniofacial fragments. Both NeRFs and Gaussian Splats produce 3D representations with higher levels of fidelity when it comes to the intricacies of the details captured by a CT scan, meaning the fracture margins produced by these AI technologies provide a more accurate picture of each fragmented element.

The integration of Gaussian Splats alongside NeRFs offers additional benefits, such as faster rendering times for real-time interaction, potentially improved preservation of fine details, and more efficient storage of large datasets. This combination of technologies provides forensic anthropologists with a versatile toolkit for analyzing and reconstructing fragmentary remains, enhancing the accuracy and efficiency of their work in both research and practical forensic applications.

Anthropology; 3D Technology; Artificial Intelligence

A58 Machine Learning and Artificial Intelligence in Forensic Anthropology: Ethical Considerations, Challenges, and Future Applications

Sherry Nakhaeizadeh, PhD, University College London, London, England, United Kingdom; Micayla C. Spiros, PhD*, District of Columbia Office of the Chief Medical Examiner, Albuquerque, NM*

Learning Objectives: After attending this presentation, the attendees will learn about the development of technology in forensic anthropology, specifically the use of Machine Learning (ML) algorithms and Artificial Intelligence (AI) using human remains. The attendees will learn how the use of any technology involving human skeletal remains poses challenges related to ethics, privacy, consent, and the potential for dehumanization in addition to the risk of bias within algorithms. The attendees will gain an understanding of the importance of glass-box algorithms and explainable AI models in the development of new and existing methods within forensic anthropology. Attendees will also learn how to responsibly apply technological solutions to address some of the existing challenges within forensic anthropological assessments and interpretations.

Impact Statement: The presentation will provide the forensic science community with an understanding of ethical and responsible use of ML algorithms and the differences between glass-box and black-box approaches. The presentation will provide the community with applied examples of how ML algorithms have been utilized across other domains, including medicine. The presentation will also explore how statistical modeling, ML, and AI algorithms could be part of one entity with human decision making, not replacing, but by extending the utility of experts.

Abstract Text: With technological developments, there has been increased incorporation and application of AI and ML algorithms within forensic science.[1] Research within this field has focused on the expansion of new automated approaches to some of the methods used, showing promising results in efficiency and accuracy across different forensic identification fields. In forensic anthropology, the utilization of ML algorithms to the estimation of a biological profile has begun to focus on the application of AI and Deep Learning (DL) in classification decisions through imaging.[2] However, the integration of AI/ML also raises critical ethical and legal concerns. While current literature has shown that it is possible to utilize the approaches, there is also a notion that the accuracy and performance of the algorithms currently used are relatively complex with varying degrees of explanation accuracy.[3] The need for transparent and explainable models is akin to the call for transparency in forensic science in terms of understanding the role of the expert and their decision making and the inferences and conclusions drawn from the evidence. Even though the forensic science community has seen the positive attributes of ML and AI across various disciplines, universally there is a need for caution when building and applying these systems within a forensic context.[4,5]

This presentation will provide an overview of the recent developments of ML and AI in forensic science broadly, and forensic anthropology more specifically. The presentation will highlight some of the key research studies in forensic anthropology where ML and AI algorithms have been used successfully to estimate sex, age at death, and population affinity from modern populations. The presentation will also emphasize some of the key challenges facing the forensic anthropology community for when developing automated models such as biases within the data (systemic biases), the algorithm (statistical/computational biases), or by the user themselves (human biases).

A step-by-step guideline will be presented on what to consider for when utilizing digital osteology for the use of incorporating decedents into ML and AI models. The presentation will discuss the path forward for ethical utility of ML and AI in forensic anthropology and how these systems could contribute to the decision-making process of the expert

A59 Fracture Characteristics of Human Ribs Vary With Intracortical Porosity

Mary E. Cole, PhD, The Ohio State University, Columbus, OH; Angela L. Harden, PhD, Injury Biomechanics Research Center, The Ohio State University, Columbus, OH; Amanda M. Agnew, PhD, The Ohio State University, Columbus, OH; Yun-Seok Kang, PhD, The Ohio State University, Columbus, OH*

Learning Objectives: After attending this presentation, attendees will understand the importance of considering bone tissue microstructure when investigating sources of variation in skeletal trauma.

Impact Statement: This presentation will impact the forensic science community by showing that cortical structure, and particularly intracortical porosity, is associated with variation in fracture characteristics in the same loading scenario.

Abstract Text: Skeletal trauma analysis often focuses on the description of fracture patterns, while little is known about the mechanisms that influence their variability. Rib fractures are particularly common and important in forensic trauma analysis, so their characterization should extend beyond simple presence or absence. Fracture characteristics of ribs have been shown to vary even within controlled loading conditions. The best predictor of rib structural properties in these bending scenarios is cross-sectional geometry, especially when calculated from a cortex with porosity removed. The objective of this study is to investigate whether variation in rib fracture characteristics is also associated with porosity.

Human midthoracic ribs (n = 189, [males = 118, females = 71], 22–108 years old, mean = 57.6 years) were dynamically loaded to failure in a simplified bending scenario representing a frontal thoracic impact. Rib behavior was classified as brittle (n = 23) or ductile (n = 166), fracture number as one (n = 144) or two (n = 40) fractures, fracture type as simple (n = 133) or wedge (n = 47), and fracture group as simple oblique (n = 41), simple transverse (n = 92), wedge partial (n = 27) or wedge intact (n = 20).[1] Fracture characteristic groups with < 10 ribs (three fractures, incomplete, or multifragmentary fractures) were excluded. Histological cross-sections adjacent to the fracture location were imaged at 100x magnification. A custom ImageJ macro, Pore Extractor 2D, quantified the morphometry of total, cortical, and trabecularized pores, and calculated cross-sectional geometry from each solid cortex and porous cortex.[2] Logistic regressions tested pore morphometry and cross-sectional geometry as predictors of rib behavior and fracture type, group, and number.

Fracture type, fracture group, and rib behavior significantly ($p < 0.05$) varied with pore morphometry, largely due to trabecularized pores, while number of fractures showed no significant association with porosity. Simple fractures showed significantly elevated trabecularized percent porosity ($p = 0.007$, pseudo-R^2 = 9.3%, Simple mean = 4.6 ± 5.2%, Wedge mean = 2.3 ± 2.3%) and trabecularized pore density ($p < 0.001$, pseudo-R^2 = 12.9%, Simple mean = 1.3 ± 0.8 pores/mm^2, Wedge mean = 0.8 ± 0.5 pores/mm^2), compared to wedge fractures. Analysis of fracture group suggested this was driven by simple transverse fractures, as simple oblique fractures also showed increased trabecularization but did not significantly exceed partial or oblique wedge fractures. Rib behavior also significantly varied with pore morphometry, with brittle ribs showing significantly higher trabecularized percent porosity ($p = 0.001$, pseudo-R^2 = 10.0%, Brittle mean = 7.3 ± 8.6%, Ductile mean = 3.5 ± 3.6%), trabecularized pore density ($p < 0.001$, pseudo-R^2 = 14.6%, Brittle mean = 1.8 ± 1.0 pores/mm^2, Ductile mean = 1.0 ± 0.7 pores/mm^2), and mean pore area ($p = 0.009$, pseudo-R^2 = 7.6%, Brittle mean = 0.01 ± 0.01mm^2, Ductile mean = 0.005 ± 0.004 mm^2) compared to ductile ribs. Simple fractures and brittle ribs were concurrently associated with significantly ($p < 0.05$) smaller cortical area and cortical bone distribution. More variation (Nagelkerke pseudo-R^2) was explained in fracture type (pseudo-R^2 = 4.5–10.8%) and behavior (pseudo-R^2 = 11.0–24.3%) when predictors were calculated from a porous cortex, compared to a solid cortex. Total area and external dimensions were weaker or insignificant predictors, suggesting that fracture characteristics are more influenced by cortical area and distribution than cross-sectional size.

Trabecularization of the cortex with large, convergent voids may facilitate the direct path of a simple transverse fracture, rather than deviating obliquely or along multiple paths into a wedge fracture. Weakening the cortex with trabecularization may also minimize the plastic energy absorbed before failure, resulting in brittle rather than ductile behavior.

A60 The Application of Forensic Fractography to Thermally Altered Bone

Cortney N. Hulse, PhD, SNA International, Joint Base Pearl Harbor-Hickam, HI; Rylan Tegtmeyer Hawke, PhD, SNA International supporting the Defense POW/MIA Accounting Agency, Bellevue, NE; Alexander F. Christensen, PhD, **Defense POW/MIA Accounting Agency**, Kailua, HI; Mariyam I. Isa, PhD, Lubbock, TX; Kristen Grow, MA, Defense POW/MIA Accounting Agency, Kailua, HI*

Learning Objectives: The goal of this presentation is to determine if and how forensic fractography can be applied to thermally altered bone. After attending this presentation, attendees will have a greater understanding about how fractographic features present in a sample of thermally altered human femora and how these features may be used to reconstruct crack initiation and propagation.

Impact Statement: This presentation impacts the forensic science community by addressing a current gap in knowledge about the utility of fractography for analyzing thermally altered bone.

Abstract Text: Forensic fractography of bone was recently introduced as a materials science-based approach for examining and interpreting skeletal fractures.[1] This approach is premised on the concept that fracture surface features reveal information about bone failure such as the origin, direction, speed, and stability of the propagating crack.[2] Fractography has been applied to identify crack origins and evaluate patterns of crack propagation in biomechanically fresh human bone.[1-3] Fractography is a potentially useful tool for analyzing thermally altered bone, which presents various analytical challenges, including complex fracture patterns and fragmentation.

The goals of this exploratory research were to: (1) evaluate the presence of fractographic features observed in the fracture surfaces of thermally altered bone, and (2) assess potential applications of fractography for analyzing fractures in thermally altered bone.

To achieve these goals, 39 fracture surfaces from 37 femora were evaluated for fractographic features. The femora are part of a commingled human remains assemblage from the **Defense POW/MIA Accounting Agency**'s (DPAA's) Tokyo Prison Fire project. Tokyo Military Prison was utilized during World War II to hold prisoners awaiting trial for war crimes. In May 1945, the prison was hit during a nighttime incendiary raid and burned down. It is estimated that 62 United States service members were imprisoned at the time, all of whom perished in the fire.

Fracture surfaces were photographed to facilitate scoring by observers without direct access to the samples and were scored for the following: presence of thermal (dry bone and/or heat induced) fracture; presence of perimortem (wet bone) fracture; presence of bone mirror, bone hackle, and arrest ridges; and direction of crack propagation. Scoring was completed independently by CNH, RTH, and MII and inter-rater agreement was calculated using Fleiss' kappa.

The three observers scored thermal damage present in 94.9% to 97% of fracture surfaces, with fair agreement among observers ($\kappa = 0.223$, $p = 0.0156$). They scored perimortem trauma present in 12.8% to 20.5% of fracture surfaces, with fair agreement among observers ($\kappa = 0.216$, $p = 0.0195$).

Observers identified bone mirror in 38.5% to 74.4% of surfaces, bone hackle in 25.6% to 71.8% of surfaces, and arrest ridges in 38.5% to 53.8% of surfaces. Inter-observer agreement on the presence of bone mirror was fair ($\kappa = 0.218$, $p = 0.0186$). While there was slight agreement among observers for bone hackle ($\kappa = 0.175$, $p = 0.0589$) and arrest ridges ($\kappa = 0.135$, $p = 0.145$), agreement was not statistically significant, indicating the observed agreement is not better than chance. The results of this study contrast with published data indicating higher frequencies of fractographic features and good interobserver agreement when observing fracture surfaces of biomechanically fresh, unaltered human femora.[1,3]

This study highlights challenges in applying fractography to the analysis of burned bone. One challenge was that fracture surfaces evaluated in this exploratory study of thermally altered bone appeared dissimilar to the fracture surfaces reported in fresh, unaltered bone.[1-3] A likely reason is that crack initiation and propagation are more complex in thermally altered bone, which may influence the presence or appearance of typical fractographic traits.

Before fractography can be appropriately applied to the analysis of burned bone, research is needed to understand how fractures form in thermally altered bone and how thermal exposure may alter perimortem fracture surfaces. While current guidelines center primarily on fractographic features in fresh bone, additional guidelines may be needed to help standardize identification of fractographic features in thermally altered bone.[2]

A61 Differential DNA Preservation in Soft and Osseous Tissues After Fire Exposure

Arielle Zohara Sperber, BA, California State University, Chico, Chico, CA*

Learning Objectives: Attendees will acquire a foundational understanding of the ways in which the material properties of muscle and bone differentially affect tissue burning and how these factors affect DNA preservation within the respective tissue types. This baseline can be operationalized to inform sample selection for use in identification efforts of fire-related fatalities, with specific consideration for the operating abilities of the ANDE Rapid DNA System.

Impact Statement: This presentation will impact the forensic science community by providing data-driven guidance for fire-related disaster victim identification efforts.

Abstract Text: Over the past two decades, the frequency and scale of wildfires has increased dramatically, nearly doubling globally.[1] Wildfire-related deaths have paralleled this global increase, necessitating the development of specialized recovery and identification strategies in response to fire's unique taphonomic process.[2] DNA is often the only means to identify victims of these fire-related fatalities, with rapid DNA technology increasingly replacing traditional DNA for use in wildfire responses. While extensive deployment of this rapid technology in recent fires has demonstrated its efficacy as a Disaster Victim Identification (DVI) tool, no formalized recommendations for sampling exist.[3,4] Anecdotal yield patterns reflect the role that tissue shielding plays in DNA preservation, but the mechanisms are not well understood by forensic anthropologists. Despite this gap in our own field's literature, a large body of literature from other scientific disciplines can be collated to establish a scientific basis for how fire affects tissues. When muscle and bone are understood as distinct materials, with distinct physiological responses to heat, and inherent differences in thermal capacity and conductivity, their material properties can be utilized to develop sampling protocols that are scientifically substantiated.[5-13]

In order to test this assumption, a series of experimental, simulated wildfires were conducted with temperatures recorded at both intramuscular and intraosseous sites for the duration of the burn. Both osseous and soft tissue samples were collected and subsequently tested using the ANDE Rapid DNA System. DNA was successfully amplified for 72.22% of soft tissue and 36.54% of osseous samples, reflecting muscle's material resilience to heat. Notably, where tissue color is frequently used as a proxy for tissue condition, in muscle especially, the color of the sample collected *in situ* bore almost no correlation ($r = -0.179$) with the color of the dissected portion of the sample ultimately used for amplification, providing evidence for tissue shielding. When considering the color of the ultimate dissected portion, muscle performs as expected. Bone color, however, is a less accurate predictor of DNA amplification success, with multiple samples initially assessed to be too calcined to yield having amplifiable DNA, and multiple charred samples failing to yield. These discrepancies between expected and actual yield in bone samples indicate a variable beyond tissue shielding is also likely contributing. Ultimately, results produced were in line with performance expectations as established by the larger body of non-anthropological literature, which contravened the literature from molecular anthropology regarding the performance of degraded DNA samples.

This research serves as part of a longitudinal study contributing to the development of data-driven recommendations for best sampling practices in response to fire-related fatalities and affirms that, when available, soft tissue samples have significantly superior DNA preservation than osseous samples. It positions interdisciplinary research as an invaluable tool to bolster the legitimacy of forensic anthropology practice and establishes a more robust theoretical basis for fire research to maximize efficacy of novel technological interventions for DVI work.

DNA Preservation; Thermal Damage; Disaster Victim Identification

A62 Re-Evaluating Temperature Data in Human Tissues Exposed to Fire

Ashley Kendell, PhD, Human ID Lab Co-Director, California State University, Chico, Chico, CA; Beth A. S Shook, PhD, California State University Chico, Chico, CA; David Silveira, MS, California State University, Chico, Chico, CA; Arielle Zohara Sperber, BA, California State University, Chico, Chico, CA; Shelby Saut, BA, California State University, Chico, Chico, CA*

Learning Objectives: Attendees will acquire a foundational understanding of temperature changes of osseous and soft tissue exposed to fire. The results of this research demonstrate that tissues (soft and osseous) do not reach the ambient temperature of the fire as quickly as has previously been reported in literature.

Impact Statement: This presentation will benefit the forensic science community by providing intramuscular, intraosseous, and interosseous temperatures for soft and osseous tissues exposed to fire. Our results indicate that tissue color does not strongly correlate with temperature, as previously suggested.

Abstract Text: In fire research, temperature measurements are routinely used to quantify fire behavior in various burn scenarios. For example, temperature measurements give valuable information on the performance of building materials and firefighter equipment, fire spread and patterns in vehicles, and correlation of bone and tissue temperatures with the observed level of thermal damage in forensic fire-death scenarios.[1-5] Most types of temperature sensors would be rapidly destroyed by fire and cannot be used in these environments. Properly selected and utilized thermocouples are an exception, though many models are unsuitable for fire exposure. Recent research has demonstrated that use of inadequate thermocouples can cause errors in reported temperature data that vary constantly and can range from -270°C to over 1,093°C.[6,7] With such erroneous data, no meaningful correlations or conclusions about tissue temperatures, tissue shielding, or DNA preservation can be reached. Improper equipment selection and practices in the past have caused an accumulation of invalid temperature data and interpretations in the literature.

Thus far, three experimental burns on human donors using a new water-cooled thermocouple system have been conducted. We have successfully produced accurate temperature plots from muscle, mirroring expected trajectories based on theoretical thermodynamics laws. We have seen that the simulated burn process can take multiple hours, and that the measured temperature will not increase past the boiling point of water until the tissues (osseous and bone) are directly exposed to the fire or the water boils away from the tissue. These results are contrary to much of the published literature.

We have successfully and repeatedly recorded temperatures from probes placed in areas of more robust muscles (biceps, quadriceps, vastus lateralis, gastrocnemius, etc.). In our most recent burn, we also successfully acquired medullary temperatures from thermocouples implanted bilaterally in both humeri. The donor was placed on two side-by-side stacks of four wooden pallets that were packed with paper and dry straw before ignition. The left humerus temperature stayed stable for 6.7 minutes from fire start, then gradually rose to a plateau around 100°C that lasted between 26.4 to 40.7 minutes. The right humerus temperature stayed stable for 11.5 minutes from fire start, then gradually rose to a plateau around 100°C that lasted between 22.2 to 48.3 minutes. Post-plateau, the left humerus temperature rose much more steeply than the right and displayed rapid swings after 50.8 minutes while the right humerus temperature did not. Post-burn inspection revealed that the left humerus had fractured mid-shaft and directly exposed the probe to fire. The right humerus had remained intact and shielded the probe from fire for the duration of the burn. The fire temperature in this scenario was recorded in the pallet stack under the pelvis of the donor and reached a maximum of 1,055.4°C, 14.2 minutes after fire start.

Between the intramuscular, intraosseous, and interosseous placements, we have begun to accumulate accurate temperature data for the appendicular body. Our results also suggest that tissue color does not strongly correlate with temperature, as previously suggested. With this new data, we can begin to reassess the relationship between temperature, tissue preservation, and DNA yield.

The temperature data acquired from this research will allow us to improve our understanding of how fire alters human remains, and ultimately impacts identification efforts. Accurate temperature data, paired with DNA quantification, will allow a suite of protocols to be established to guide tissue sample selection for any fire-related event. These protocols will ensure the most efficient use of time and resources when working with thermally altered remains, thus bringing closure to surviving family members as quickly as possible.

A63 Locating Clandestine Burial Grounds: A Forensic Approach

Erin H. Kimmerle, PhD, University of South Florida, Tampa, FL*

Learning Objectives: The learning objectives of this presentation include discussion of archival, ethnographic, bioarcheological, forensic, and remote sensing methods used in combination to identify possible unmarked burials and cemeteries. Strategies for georeferencing historic maps and images with current GIS data are demonstrated. Finally, the use of a demographic approach to reconstructing the population structures is shown as a highly effective way to locate communities and burial grounds that have been erased from the landscape or destroyed through predatory land practices.

Impact Statement: A significant number of lost, abandoned, and erased cemeteries exist in every state, most on government-owned properties affecting a disproportionate amount of Black Communities. A 1999 Florida State Task Force estimated there were as many as 100 unmarked burial grounds in every county. Participants will learn how a multi-method approach and demographic analysis can yield significant results for finding unmarked burials. This presentation is relevant to forensic anthropologists, bioarcheologists, and other investigators tasked with locating clandestine burials, unmarked burial grounds, or abandoned cemeteries throughout the country.

Abstract Text: In 2019, two African American cemeteries built over and lost to history in Tampa, FL, in the 1950s became known: the Zion Cemetery, located on property owned by the Tampa Housing Authority, and the Ridgewood Cemetery, located on the grounds of King High School, owned by the Hillsborough School Board Authority. The re-discovery of these cemeteries prompted the Hillsborough Board of County Commissioners (HBCC) to question whether there were additional unmarked cemeteries on county-owned property. An investigation into the location of possible unmarked graves was undertaken. A combination of archival, ethnographic, bioarcheological, forensic, and remote sensing methods were used to identify possible unmarked cemeteries and burials throughout the county. As a result of this approach, 44 additional unmarked burial grounds were located, just over half of which were African American or "Colored" cemeteries used and destroyed during the Jim Crow era, in large part by predatory land purchases that targeted Black and Afro-Cuban communities.

Unlike traditional archeological surveys typically used during construction surveys on government land, this project used a broader framework based on methods in forensic anthropology and incorporated several different lines of evidence and a demographic approach, resulting in the discovery of a high number of burial grounds. This approach starts with an understanding of the population structure and mortality trends for the community ca. 1500–today and combined a wide variety of archival documentation with GIS spatial analysis utilizing historic maps. In other words, it begins with asking the question of who was living in the area and *who should be buried* within the county. This approach enabled the identification of unmarked cemeteries based on historic land use such as homesteaded farms, pioneer towns, convict leasing and slavery, migration patterns, and ghost towns now abandoned or incorporated into larger communities. Reconstructing the population structure meant understanding the burial practices for diverse groups within the population, including those historically marginalized and consequently left out of the written record. It also considered the changing laws and practices over time used to marginalize certain groups of people based on the perception of race. Using a framework based on population structure builds on these considerations: the population size and ethnic diversity of the county; previously unmarked homestead or family burial plots; inclusion of the 1,000+ enslaved persons buried in the county, ca. 1830-1865; the settlement patterns of freed men and women following emancipation; changing settlement patterns over time associated with industry, technology, and population growth; and identification of convict lease contracts and possible burial areas within the county. A population approach also utilized data from undertakers, funeral home directors, and cemetery owners as these individuals significantly shaped mortuary practices throughout the past century. Similar patterns as identified here can be found in most cities throughout the Eastern United States. This presentation shares the results of a two-year, county-wide investigation and explores the unique approach and range of methods used and has relevance to a number of different applications in forensics and archaeology.

Anthropology; Clandestine; Archaeology

A64 Photogrammetric Documentation of the Changing Surface Morphology of Buried Human Remains

Mary C. Davis, MSc, University of Tennessee, Knoxville, Knoxville, TN; Mason Jones, BA, University of Tennessee, Knoxville, Knoxville, TN*

Learning Objectives: After viewing this poster, observers will understand some characteristics of how the ground surface above a human burial change over time. A timeline of observed morphological differences will be presented.

Impact Statement: This presentation will impact the forensic science community by enhancing investigators' ability to evaluate a site for the location of a clandestine burial. Moreover, an improved ability to estimate the antiquity of a human burial will guide and improve investigative efficiency.

Abstract Text: Considerable effort has been applied to determining the postmortem interval of human remains in both surface and burial contexts; however, the Post-Burial Interval (PBI) of human remains continues to elude a comprehensive understanding.[1] This study focuses on the evaluation of the antiquity of a burial based on visual observations and the measured change in volume of surface soil mounds or depressions.

The use of emerging technology, such as Light Detection And Ranging (LiDAR), to locate lost or forgotten cemeteries is becoming increasingly popular; however, guidance for the use of LiDAR to document crime scenes has only been published in the past few years.[2,3]. Not all law enforcement agencies have access to the necessary equipment or training required to deploy this technology during surveys for a clandestine grave. Thus, identifying potential grave locations with a simple pedestrian survey can increase the efficiency of subsequent surface and sub-surface investigations.

Although many surface characteristics of burials have been described, little is understood about the timing of the appearance and disappearance of these features.[4] Eleven burials at the University of Tennessee's Anthropology Research Facility were included in this longitudinal study to provide a reference for burial aging. Utilizing photogrammetry software, the settling of the soil was quantified via volumetric measurements and correlated with PBI.

Rain events correspond with alterations to the appearance of the ground surface of a burial: darkening of the color of the grave soil, fewer visible cracks on the soil surface, and a more homogenous appearance to the soil. However, these alterations are temporary, and the characteristics of the soil surface revert to their previous appearance as the ground dries. Therefore, it is important to consider local weather conditions the week prior to a visual search for clandestine burials.

Within five months, most initial surface characteristics indicative of a burial have diminished to the point of near invisibility. Other characteristics associated with a longer PBI, like a depression in the soil or changes in vegetation, did not appear for at least one year post-burial.

A65 Cellular Degradation and Migration in Bone as a Tool to Investigate the Postmortem Interval and Skeletal Break Timing

Ashley C. Smith, MS, University of Toronto, Memphis, TN*

Learning Objectives: After attending this presentation attendees will have a better understanding of how laser scanning confocal microscopy can be used to visualize and quantify the degradation and migration of osteoclasts in human bone as possible tools in assessing the postmortem interval and possible skeletal break timings.

Impact Statement: The presentation will impact the forensic science community by demonstrating a novel method for assessing the postmortem interval and the timing of skeletal damage using the degradation and migration of osteoclasts visualized using a laser scanning confocal microscope.

Abstract Text: Two of the more difficult assessments anthropologists are tasked with is assessing the Postmortem Interval (PMI) as well as any skeletal break timing. During the early skeletonized period, the assessed PMI can be wide as the soft tissue indicators have exuviated yet the skeletal elements have not undergone taphonomic changes. With break timing, while the assessment of damage that has taken place long postmortem can be easily distinguished from injuries that occur antemortem, damage occurring in the early postmortem period while the bone still maintains its "fresh" properties can be difficult to ascertain. The purpose of this study was to investigate the use of cellular degradation and migration as a means of assessing both the PMI as well as the skeletal break timing in the early postmortem period.

There are four stages of fracture healing beginning from the time of propagation to the terminal stage of remodeling. For the purposes of this project, it is the initial stage of induction that was of interest. This stage lasts a few weeks, beginning with fracture propagation and ending at the appearance of new bone. Due to the vascular nature of bone, once bone reaches the failure point, thousands of capillaries rupture, leading to a massive hemorrhage. Within minutes of fracture propagation, the vasculature will undergo blood clotting procedures and a hematoma will develop. Osteoprogenitor cells located in the periosteum will migrate, convert the hematoma to granulation tissue and ultimately osteoid. Once the hematoma develops, two processes initiate: inflammation of soft tissues and resorption of necrotic tissues.

Two major sample groups were used: a perimortem group of nine iliac biopsies from the Centre Hospitaller de l' Université de Montréal, and a postmortem group of nine iliac sections from donated remains collected from the University of Toronto Division of Anatomy. Each sample from the latter was further divided into three time groups: early-postmortem, 7-day, and 14-day postmortem. Samples were sectioned to 100µm, then labeled following the Coxon method.[1] They were imaged using a laser scanning confocal microscope using the 555nm emissions wavelength and analyzed using histology imaging software. The cortical bone section was isolated, allowing just an analysis of the cortical bone. Bone volume was standardized across all of the samples with cell counts occurring with both the raw numbers and standardized by volume. A Kruskal-Wallis *H*-Test and Spearman correlation were run to test if there was a significant variation and correlation in both degradation and migration between the four time groups. To verify if there was a significant variance of cells present in the migration portion of the study, a 700µm region of interest was placed over the break margin and the center of the cortical bone, with the results analyzed using a paired *t*-test.

The results of this study found that there was a sharp declination of cell presence (80%), and migration appeared to have ceased in most cases after the early postmortem period, with these results being both significant and strongly correlated ($p < 0.001$; $r = -0.815$, $p < 0.001$) when standardized by volume. Migration, though promising, however, was not statistically significant ($p = 0.051$), with migration seen in the perimortem and early-postmortem (< 72 hour) group, yet after this migration appears to halt. The results of the paired *t*-test found that there was a significant difference in those samples, which demonstrated migration ($p < 0.001$).

The results of this study have found that imaging osteoclasts could be useful in establishing PMI, particularly in fragments of an early (< 72 hour) period, and that there is a potential to use this cellular migration for establishing early postmortem injury timing, yet more research is necessary.

A68 Adapting Facial Approximations to a Modern Audience: The Use of Augmented Reality Filters and Profile Apps

Matteo Borrini, PhD, Liverpool John Moores University, Liverpool, England, United Kingdom*

Learning Objectives: After attending this presentation, attendees will be able to evaluate the potential of using Augmented Reality filters for facial approximation obtained with analogical techniques.

Impact Statement: This presentation will impact the forensic science community by demonstrating the possibilities of using Augmented Reality filters in conjunction with standard analogical forensic art techniques to create a more suitable facial approximation for the modern population.

Abstract Text: Facial reconstruction, more appropriately facial approximation, aims to outline the physical features of an unidentified subject's face from their cranial remains. This branch of Forensic Art involves a combination of artistic and anatomical techniques developed to recreate the appearance of an unknown deceased individual to aid their recognition; however, it is essential to clarify that it is not an identification method, and it is a non-accepted practice to compare the recreated face with photographs of one or more missing individuals and directly identify the subject. Instead, if appropriately disseminated, the result obtained through Forensic Art serves as an investigative aid by helping acquaintances and family members of a missing individual to recognize the features in the reconstruction, directing the investigative effort toward a potential identification candidate. The confirmation of the identity of the remains must then be verified by appropriate scientific means, such as genetic, anthropological or dental comparisons.

Based on the memory of the missing person's relatives, one key factor that makes a facial approximation successful is the wide dissemination through media and social media and the possibility that it is seen and recognized by those who know the missing. Following this and considering how the modern population has become accustomed to seeing pictures edited with "beauty filters," facial approximations could be presented by adopting a similar graphic style to be better received and recognized by modern society.

The author proposes revising a series of facial approximations achieved with 3D sculpting methods and two-dimensional drawing by applying popular Augmented Reality filters. Each reconstruction has been digitalized by photographing the sculpted face or by optically acquiring the drawing and converting it to a digital format. A reference scale has been included in the picture to check the final result with the original image against any undesired alteration of the facial proportions and features obtained with the standard and scientifically recognized methods.

The digital pictures of the facial reconstructions were processed using popular applications available for mobile devices. These applications, widely used by the general public, allow the addition of realistic texture to various parts of the face. The use of Augmented Reality filters was driven by the need to enhance the lifelike appearance of the image without altering the somatic features reconstructed following Forensic Art principles. At every step, the new textured image was cross-referenced with the original source image and to a 1:1 scale photograph of the skull by photo editing software, ensuring the integrity of the reconstruction.

The research demonstrates the potential of using Augmented Reality filters to enhance the realistic appearance of facial approximations achieved through traditional Forensic Art analogic techniques. This approach not only maintains the scientific reliability of the original result but also provides more modern-looking images that can be better perceived and positively identified by modern society. The author recommends conducting statistical tests to evaluate the impact of Augmented Reality filters on the recognition process, specifically assessing the effectiveness of Augmented Reality filters in enhancing the recognition of forensic art facial approximations by the public.

Facial Reconstruction; Artificial Intelligence; Forensic Art

A69 Comparative Identification in 3D: What Virtual Anthropology Can Do for You

Stephanie Melillo, PhD, Mercyhurst University, Erie, PA; Samantha Buck, BS, Mercyhurst University, Erie, PA; Brailey Moeder, BS, Mercyhurst University, Erie, PA; Stephen D. Hostetler, BA, BS, Mercyhurst University, Erie, PA; Jessica M. Cronin, BA, Mercyhurst University, Erie, PA; Graziella M. Durand Ortega, BA, Mercyhurst University, Erie, PA; Nicole Wray, BA, Mercyhurst University, Erie, PA; Rhiannon E. Toy, Mercyhurst University, Kittanning, PA; Chenoa D. Woods, Mercyhurst University, Erie, PA*

Learning Objectives: This presentation will outline a workflow for skeletal comparative identification that harnesses the power of the Virtual Anthropology (VA) toolbox. We will describe an assortment of equipment and computer software that varies in cost and the steepness of the technical learning curve. The workflow can either be abbreviated at the point of visual qualitative comparison or, for the more statistically minded practitioner, continued to advanced Three-Dimensional Geometric Morphometric analysis (3D GM).

Impact Statement: The terms "Virtual Anthropology" and "Virtual Morphology" refer to a collection of computer-based tools for: (1) generating and manipulating digital imagery, and (2) quantitatively describing differences in size and shape.[1] While the tools associated with digital imagery are becoming increasingly valued in medicolegal settings, the second component of the VA toolbox (morphometric analysis) has yet to be used to its greatest potential.[2-6] We use two case studies to highlight how 3D GM tools could expand the range of anatomical regions and "features" used for individualization.

Abstract Text: The goal of comparative identification is to document features that are either unique or rare enough in a population to be useful in individualization.[7] For this reason, evidence of medical procedures, trauma, and pathology accumulated over the lifetime are ideal individualizing features. Extreme morphological anomalies can also be considered individualizing, along with aspects of non-pathological skeletal variation like sinus shape and trabecular pattern. This variety of approaches highlights the gray area between individualizing features and normal skeletal variation. After all, every individual is theoretically biologically unique. The difficulty in comparative identification comes in the methodological details of demonstrating that uniqueness, given the antemortem data at hand.

The comparative identification workflow involves evaluating similarities between antemortem medical images and postmortem images collected by the forensic anthropologist or medical professional.[7] Traditionally, one or both of the images are two-dimensional (2D) radiographs, which imposes the well-documented challenge of replicating bone orientation as precisely as possible in post- and ante-mortem images.[4,5,8,9]

The orientation challenge is eliminated when both post- and ante-mortem images are 3D datasets. The superimposition of antemortem and postmortem digital models can be incredibly precise, which facilitates qualitative comparison and illustration of individualizing skeletal features.

More importantly, these 3D imaging tools can be combined with 3D GM to quantify overall shape similarity between a digital bone model derived from antemortem image and its postmortem counterpart. State-of-the-art capabilities include the measurement and comparison of 3D curves and surfaces.[10,11] Because these methods permit measurement of morphology in such detail, we suggest that overall bone morphology could be used as an individualizing feature.

We evaluate the utility of cranial morphology in individualization, using the real-life scenarios from two recent cases. In both examples, the target dataset consists of (*x*,*y*,*z*) landmarks derived from an antemortem Computed Tomography (CT) scan of the suspected decedent. The comparative dataset consists of the same configuration of cranial landmarks, collected from 50 cranial surface scans curated at the Mercyhurst Forensic Anthropology Laboratory and one additional scan of the unidentified cranium under study (total *n*=51). The landmark configurations from target and comparative datasets were subjected to a Generalized Procrustes Analysis, then pairwise comparisons conducted. Procrustes Distances were used to quantify overall shape difference between the antemortem target and every individual in the comparative sample. The resulting distribution of pair-wise Procrustes Distances can be used to estimate error rates of the identification.

With future research, the approach described here could be expanded to a variety of anatomical regions, thus enabling the forensic anthropologist to tailor the comparative identification to any anatomical region for which 3D medical imagery exists.

A70 Forensic Investigative Genetic Genealogy: A New Opportunity to Resolve Unidentified Cases

Bruce E. Anderson, PhD, Pima County Office of the Medical Examiner, Tucson, AZ; Jennifer M. Vollner, PhD, Pima County Office of the Medical Examiner, Tucson, AZ; Caitlin CM Vogelsberg, PhD, Pima County Office of the Medical Examiner, Tucson, AZ*

Learning Objectives: After attending this presentation, attendees will be made aware of the potential, and success, of Forensic Investigative Genetic Genealogy to provide new investigative leads in the effort to identify both short- and long-term unidentified persons that are under the jurisdiction of medical examiner and coroner's offices.

Impact Statement: This presentation will impact the forensic science community by illustrating the importance of properly retaining postmortem tissue samples, or the prior DNA extracts from these biologic tissues, as well as advocating for the routine publication of these unidentified person cases in the National Missing and Unidentified Persons System (NamUs).

Abstract Text: Perhaps no new investigative tool within the past decade has revolutionized our potential ability to identify previously unidentified John and Jane Doe cases as Forensic Investigative Genetic Genealogy (FIGG) as has already been demonstrated.[1] The Pima County Office of the Medical Examiner (PCOME) curates investigative records, and in many cases the skeletal remains, of more than 1,600 currently unidentified cases all entered into NamUs. Many have had their fingerprint records compared in the Automated Fingerprint Identification System (AFIS), most have DNA profiles in the Combined DNA Index System (CODIS), and a fair amount have viewable facial images. When these methods fail to generate an investigative lead through fingerprints, Single Tandem Repeat (STR) DNA profiles, mitochondrial DNA (mtDNA) profiles, or facial photographs, in the past there was little chance for identification.

FIGG has changed that scenario through the use of publicly available databases that contain Single Nucleotide Polymorphism (SNP) DNA profiles from an increasing number of people who are purchasing Direct-To-Consumer (DTC) genealogy kits. There are scores of these providers operating in the United States and a growing number of FIGG organizations who are contacting medical examiner and coroner's offices throughout the country offering to employ this familial DNA technology after the individualizing STR assays produced no matches in CODIS. These FIGG organizations are offering to accept (as well as arrange funding) select unidentified cases where traditional methods have not produced an identification. The FIGG groups contract with various DNA laboratories to perform SNP profiling, many times via whole genome sequencing, to produce a record that then can be entered into one of several publicly available SNP databases in the search of blood-relatives. If successful, usually at a level of distant cousins, traditional genealogical methods aided by the internet, can produce a "candidate" for a particular unidentified individual. From there, a one-to-one comparison is typically conducted using a closely related family reference sample to confirm the hypothesized identification. While it is well-known that past "abuses" of selected SNP data have occurred, it appears that the DTC genetic ancestry companies have now implemented the appropriate safeguards.

The PCOME has, as of August 1, 2024, been contacted by ten different FIGG groups resulting in 60 of our unidentified cases being subjected to this exciting new tool. Of these 60 cases, ten have been identified after the PCOME confirmed the identification of the candidate proposed by the FIGG group. These ten identifications have included an elder-abuse homicide from 1988, a child homicide case from 2020, and a third homicide case from 2012. These three identifications are now providing law enforcement with a crucial investigative lead in pursuit of the perpetrators of these still unresolved homicides. Nearly all 60 of these cases were chosen by the FIGG group or by the PCOME from our 1,600-plus NamUs unidentified cases. Maintaining a publicly viewable list in NamUs has proved to be a tremendous time-saver for case selection. Furthermore, the collection and retention of biological samples throughout the decades has proven fruitful in providing the necessary tissue or extracts to perform these powerful new investigations.

Although a few of the 50 cases that have not yet resulted in a proposed candidate have reached a "dead-end" as far as personal identification, important ancillary information regarding nationality and/or ancestry has still been provided to the PCOME. We hold out great hope that many of our 1,600 currently unidentified cases may someday be resolved through FIGG analyses. We advocate that the necessary funding sources be made available to keep this now-indispensable tool available to those medical examiner and coroner offices that have yet to be able to identify Jane and John Doe cases by conventional methods.

Genealogy; Genetics; Unidentified Persons

A71 The Sugar Land 95: A Forensic Genetic Genealogical Approach to Restoring Individual Identity

Samantha Hofland, MA, University of Montana, Missoula, MT; Meradeth H. Snow, PhD, University of Montana, Missoula, MT; Catrina Banks Whitley, PhD, Principal Research Group, Midlothian, TX; Helen Graham, EdD, Principal Research Group, Houston, TX; Abigail E. Fisher, MS, Principal Research Group, Dallas, TX; Felicia R. Sparozic, PhD, Principal Research Group, Wyckoff, NJ*

Learning Objectives: Attendees at this poster session will learn about the process of using Forensic Investigative Genetic Genealogy (FIGG) to identify individuals in clandestine burials. Attendees will also learn about the usefulness of the Qiagen Forenseq Kintellegence kit in identification of degraded teeth/bone samples.

Impact Statement: This presentation will give insight and support regarding the capabilities of FIGG in identifying unknown skeletal remains. It will also allow professionals to have a framework when attempting to restore identity to large numbers of unknown decedents from cemeteries or mass graves.

Abstract Text: The Sugar Land 95 are individuals who were victims of the convict leasing era in the United States that began after the ratification of the 13th Amendment abolishing slavery in 1865. This amendment, which is still in place today, made forced labor illegal except, notably, in the case of incarcerated individuals. As a result, the Sugar Land 95 were leased to sugar plantations, replacing slave labor in Sugar Land, Texas. This was not exclusive to the state of Texas as many other states also participated in convict leasing. These individuals sustained numerous injuries, including gunshot wounds, bone infections, fractures, head injuries, and many other ante- and perimortem injuries.

The remains of the Sugar Land 95 were disinterred in 2018 and subsequently analyzed to create biological profiles, as well as to assess traumas, pathologies, and taphonomic conditions. These analyses initiated the identification process, at which point historic records were examined to try and find the names of the interred individuals. Today, after receiving permits from the Texas Historical Commission, the Principal Research Group and the Snow Molecular Anthropology Laboratory have begun the process to genetically identify the Sugar Land 95 using FIGG.

Overall, the Sugar Land 95 cemetery represents a unique opportunity not only to bring justice to the Sugar Land 95 but also to test the limits of forensic technology. In turn, this will contribute significantly to the forensic community, using the insights gained from this research to inform modern day identification of mass graves and victims of natural disasters. Research will highlight best practices for large sample numbers, difficult sample types, and exclusively kinship-informative Single Nucleotide Polymorphism (SNP) markers. All work is being done with the ultimate goal of reliable identification of both the deceased and their descendants to uncover and restore the history of the Sugar Land 95.

Genetics; Genealogy; Human Remains

A72 The Wounds Time Does Not Heal: A Case of Historical Pitfalls and the Present-Day Identification of a United States Marine From World War II

Rylan Tegtmeyer Hawke, PhD, SNA International supporting the Defense POW/MIA Accounting Agency, Bellevue, NE; Cullen Black, MS, Defense POW/MIA Accounting Agency, Kailua, HI*

Learning Objectives: The goal of this presentation is to provide a real-world example of the benefit that a multidisciplinary approach can bring to the segregation and resolution of a commingled remains case, particularly when the recovery context and prior analyses introduce additional complications to the identification process. After attending this presentation, attendees will better understand how different lines of evidence, including historical records, anthropological and dental analysis, and DNA, can interplay to bolster an identification from a commingled assemblage.

Impact Statement: This presentation will impact the forensic science community by showing the contributions that a multidisciplinary approach can make to the resolution of commingled skeletal assemblages. It will also impact the forensic science community by demonstrating and emphasizing the importance of training in the recovery and identification process.

Abstract Text: In the heart of World War II, the United States military began an island-hopping campaign across the Pacific with the intention of capturing strategic strongholds from which to launch attacks against the Japanese homeland. As part of this initiative, from November 20–23, 1943, an amphibious assault was launched against the Japanese-controlled Betio Island, located in the southern portion of the Tarawa Atoll. The battle (known as the Battle of Tarawa) lasted approximately 76 hours and resulted in the loss of over 1,000 United States service members. Following the battle, casualties were buried in expedient cemeteries across the island; these cemeteries were subsequently "beautified," resulting in incorrect and incomplete records. In 1946, the American Graves Registration Services attempted to recover and identify the Tarawa casualties but faced several barriers to this effort, including the inaccurate burial records, a lack of archaeological or anthropological training, and a heavy reliance on the presence of personal effects to support identification. Individuals that were unable to be identified in the 1940s were buried as Unknowns in the National Memorial Cemetery of the Pacific (NMCP). In 2016, the Defense POW/MIA Accounting Agency (DPAA) began to disinter the Tarawa Unknowns from the NMCP for analysis and identification efforts, an effort supported by present-day excavations on Betio Island by a DPAA strategic partner.

This presentation details the process of segregation and subsequent identification of a United States Marine killed during the Battle of Tarawa. Identification was made using a multidisciplinary approach, including an examination of historical records, anthropological and dental analysis, and DNA. This individual was listed as historically identified in the 1940s; however, the identification was largely based on the presence of an identification tag. This individual was disinterred by DPAA in 2016; additional skeletal remains were recovered from Betio Island and turned over to DPAA in 2015 and 2023 and could be associated with the disinterred remains through articulation, pair matching, refitting of fragments, dental analysis, and DNA. Additionally, tracing the historical records and understanding the historical context of the historical identification, as well as the historical analysis and movement of the unidentified remains, DPAA was able to correctly identify this service member and return him to his next-of-kin.

Anthropology; Commingling; Personal Identification

A73 The Use of Antemortem Trauma in Identifications at the Defense POW/MIA Accounting Agency

Sam W. Coberly, PhD, SNA International Contracted with DPAA, Honolulu, HI*

Learning Objectives: The Defense POW/MIA Accounting Agency's (DPAA) mission is to "provide the fullest possible accounting for our missing personal to their families and the nation."[1] Antemortem trauma can collaborate with other evidence for an Identification (ID).[2]

Impact Statement: The presentation will impact the forensic science community by discussing how using antemortem trauma can be applied outside of the DPAA

Abstract Text: DPAA casework between 2016–2023 was reviewed and cases from four projects selected based on their workflow and specific documentation, including a project level preliminary report, a Forensic Anthropology Report (FAR), antemortem records, a report comparing the FAR and antemortem records (BCR), and a medical examiner report that compiles the information to make a final identification. The overall question this research seeks to answer is how the DPAA utilizes antemortem trauma in their identifications.

From the four projects, there were 308 cases that met the requirements: Cabanatuan (71), Tarawa (46), Korean War (164), and Pearl Harbor Ships (27). Skeletal trauma was noted in DPAA reports in 74 (24%) of cases with the majority written in FAR reports only. Seventeen cases (15%) with both skeletal trauma and antemortem records used the trauma in the final identification by the medical examiner. This was medical-examiner specific. Based on DPAA reports, the most common elements affected were nasals and clavicles (15% each). Thirty-nine cases (12.7%) had trauma noted in antemortem records only mostly due to those elements, such as the hands and feet, not being present for analysis (25/39 cases).

There was a significant difference in the amount of trauma ($p = 0.015$) between projects; Tarawa had the highest percentage (80.8%). The type of antemortem record that the trauma documentation (family letter, civilian medical records, military medical records, other) was significant ($p = 9.15E\text{-}59$). The Korea War (51.8%) and Cabanatuan (22%) projects had a higher percentage of family letters (51.8%) compared to the Tarawa (5%) and Ships (0%) projects due to the military requesting identifying information for the identification of POWs. Letters from family tend to be more vague than medical records, saying broken leg rather than femur. Tarawa had the highest number of cases where antemortem trauma was noted in medical records (93%), specifically military medical records. Antemortem trauma in medical records is either self-reported at the time of enlistment or occurred during service and was documented by the military. Four cases overall had non-military medical records.

Antemortem trauma is used in modern identifications as well, utilizing both medical records and family informents.[3-7] In a modern decedent population, 34% were found to have antemortem trauma, like the DPAA sample. The same study found that the ribs and femora were the most common elements with trauma.[6] Another study found that nasals were the most often damaged, the same as the DPAA sample.[4] One study found that elements of the hands and feet are the least likely to be recovered.[7] Radiographs are the biggest difference between modern and the DPAA populations as they are more available in modern cases.[3,4] Radiographs can have limitations as the antemortem records may be in an orientation that does not allow for comparison.[5] Like the DPAA sample, the biggest issue in the utilization of antemortem trauma is the lack of records as well as the fact that authorities must have a belief to be able to make a comparison.[8-10]

In conclusion, antemortem trauma was utilized in few identifications in this study. This is due to a lack of records and a lack of elements with recorded trauma being present. To better utilize this, if possible, the element with antemortem trauma should be sampled or brought into the individual by anthropological methods. The DPAA can also continue to make sure that they recover as complete of individuals as possible in the field to make sure these elements are brought in. Further research includes surveys with medical examiners to get a better idea of the use of antemortem trauma records in modern identifications and to learn the best way of obtaining information on antemortem trauma.

A74 Integrating Forensic Archaeology and Historic Battlefield Protocols at Historic Conflict-Related Aircraft Crashscapes: A World War II B-17 Case Study

Andrea Palmiotto, PhD, RPA, Indiana University of Pennsylvania, Indiana, PA; William Chadwick, PhD, Indiana University of Pennsylvania, Indiana, PA; Allysha P. Winburn, PhD, University of West Florida, Pensacola, FL; Robert Ingraham, MSc, Defense POW/MIA Accounting Agency, Joint Base Pearl Harbor-Hickam, HI; Parker Chadwick, BS, Indiana University of Pennsylvania, Harrisburg, PA; Dane Magoon, MA, Defense POW/MIA Accounting Agency, Arlington, VA

Learning Objectives: After attending this presentation, attendees will be cognizant of innovative modified approaches toward the recovery of probative materials from historic conflict-related aircraft crashscapes. Current excavation models depend on the correlation between metal and probative materials, which is inherently problematic, if convenient. A case study involving a complex World War II-era B-17 crashscape in Germany is presented to illustrate the increasingly complicated recovery efforts associated with aging historic losses.

Impact Statement: This presentation will impact the forensic science community by invoking practitioners to consider the myriad factors that complicate recovery efforts of decedents from historic aircraft crashscapes. It will provide insight that may be relevant for any practitioner undertaking similar or related field efforts and offer guidance on tackling complex historical recovery sites. The integration of modified protocols commonly used at present-day aircraft crashscapes with historical battlefield archaeology methods offers an effective way to approach these types of historic conflict-related scenarios, characterizing scenes through multiple and robust lines of evidence prior to emphasizing Phase III recovery.

Abstract Text: Recovery efforts of historic conflict-related aircraft crash sites, including those mitigated by the Defense POW/MIA Accounting Agency and their partners, require unique blends of historical archaeology and forensic investigation towards the recovery of probative materials. Aircraft crashes are extremely variable regarding circumstances surrounding the incident, trajectory of the aircraft crash and subsequent explosions, incident environment, and taphonomic mechanisms between the incident and archaeological recovery of the site. Traditionally, practitioners have employed methods based on assumptions about correlations between decedents and diagnostic wreckage, emphasizing evidence-free horizontal excavation margins. Additionally, the spatial extent excavated, reflecting the Law of Diminishing Returns, is frequently upheld as the primary indicator of successful recovery efforts, barring recovery of human remains or other probative materials. This traditional wisdom is typically applied to recovery designs regardless of the incident circumstances. However, crashscapes are often encountered where decedents or probative materials do not align with diagnostic wreckage (e.g., the pilot may not be found with materials from the cockpit); the horizontal boundaries of the site extend far beyond the immediate crash crater (e.g., incidents with oblique trajectories and/or late ejection attempts); and valuable investigative techniques do not always require intrusive excavation efforts.

This case study of a B-17 aircraft crashscape details the incorporation of innovative methods that adapt and expand beyond standard operating procedures. Multiple lines of inquiry are recommended, prioritizing non- or minimally invasive means of evaluating site boundaries and maximizing spatial assessment of potential recovery targets before focusing on evidence-free margins or extent excavated. Suggestions are provided for alternative measures of recovery progress beyond horizontal area excavated. Forensic investigative and historical archaeological techniques were modified over three field seasons based on excavation results, enhanced understandings of the historical event, site environmental context and history, previous recoveries by other parties, and observed patterning of aircraft wreckage within and beyond the associated crash crater. Previous investigations and excavations by other parties focused on witness interviews, wide-interval pedestrian and metal detection surveys, limited subsurface testing, and block excavation based on interpreted site boundaries from metal detection surveys. The crash crater boundaries were not delineated.

Phase-III recovery efforts were initiated based on this previous work, commencing with block excavation units (400+ m^2 since 2022). However, the complicated nature of the crashscape was quickly revealed, with the need for more intensive site delineation and characterization to develop targeted recovery strategies. This was achieved through a ground-penetrating radar survey (4,760+ m^2 in ~100 hours), delineating horizontal and vertical crater boundaries; close-interval pedestrian (7,140+ m^2 in ~16 hours), and metal detection (800+ m^2 in ~60 hours) surveys, highlighting wreckage distribution patterns; subsurface profile interpretation within, on, and outside the crash crater boundaries; and investigative excavated transects (400 m^2 in ~200 hours), identifying locations for targeted units. These approaches reflect modified forensic and commercial aircraft crashscape recovery protocols and battlefield investigation guidance.[1-6] Work occurred during three field school training programs, averaging 14 students over approximately six weeks per session.

While some may argue these operations are time consuming or detract from the mission, this case demonstrates these approaches can be implemented effectively and offer benefits beyond their initial time requirements toward extensive and robust recovery efforts, which themselves can extend over multiple field seasons with similarly sized teams. Through these efforts, the crash crater boundaries were identified and confirmed, and systematic surveys revealed new areas worth investigating and excavating, all while continuing block excavation units to reach incident-sterile contexts. Practitioners must remain open to flexible and innovative iterative strategies that align with the historical, environmental, and recovery contexts of complicated historical recovery sites to effectively recover such sites.

A75 An Anthropological Response to Mass Disaster: Lessons Learned From the October 7th Attack

Michal Peer, MASc, National Center of Forensic Medicine, Aurora, CO, Israel; Tal Simmons, PhD, Virginia Commonwealth University, Richmond, VA*

Learning Objectives: Following this presentation, attendees will learn the methods used by a lone, small anthropology lab to handle the largest mass casualty event in Israel's history. Attendees will understand: (1) the unprecedented increase in the number of cases, (2) the added challenge of limited contextual information from the field: and (3) the unceasing pressure from various authorities to identify the dead as quickly as possible.

Impact Statement: The mass casualty event resulting from the events of October 7, 2023, produced a large number of casualties and resulted in remains in many differing states of preservation. The idea of an "anthropological examination" changed from what it is during a normal workload, focusing instead on Minimum Number of Individuals (MNI), which formed the basis for a DNA sampling strategy. In addition, since lab anthropologists were too busy with the ongoing increase in workload to participate in the extensive recovery operations, differentiation between various burnt materials, human and non-human bone, based only on small fragments of burnt bone, required developing criteria that had not necessarily been used in the lab before. The attendees will learn about the experiences and struggles of the new head of the forensic anthropology lab, who took over the position on October 8, 2023.

Abstract Text: The State of Israel woke on October 7, 2023, to an unprecedented attack on many of the southern towns by the terror organization Hamas. Over the course of this attack, more than 1,200 civilians, first responders, and soldiers were killed and 250 men, women, and children ranging from 7 months to 85 years old were taken hostage. This is the largest mass casualty event in the entire history of the State of Israel. Even before the true extent of the attack was understood, plans were already being made at the National Center of Forensic Medicine on how to deal with the fallout.

With only one forensic center in the country, and a sudden and unexpected event nearly doubling of the number of annual deaths, the choices made for the management of the October 7th massacre were paramount in ensuring the successful identification of remains through any available means. This was particularly important considering the importance in bringing the deceased to burial in as short of a time frame as possible, as mandated by the religious practices of both Judaism and Islam, which together are practiced by approximately 94% of the total population.

This presentation will discuss the structure of the anthropology laboratory at the National Institute for Forensic Medicine in the context of other national authorities all assisting in the identification of the dead.

The current head of forensic anthropology, and the only person in the country then working in the field, took over the position on October 8, 2023, something that had been planned for a number of months, and was immediately thrust into the highest-pressure situation that the anthropology lab has ever faced. The number of cases increased dramatically within a compressed timeframe (a 411% increase of the average annual caseload). Collection of remains occurred in an active war zone with continuing rocket strikes and was undertaken by various groups with differing degrees of training, which resulted in limited contextual information accompanying remains recovered and brought to the lab. There was also unceasing pressure from various authorities to identify remains as soon as possible. The sheer volume of work that was undertaken by such a small anthropology laboratory necessitated volunteer assistance from highly experienced outside practitioners. In addition, the change required an adjustment in the methodology used in a direction that may not be the most traditional. The focus had to shift from complete biological profiles to MNI and DNA sampling for the fastest possible identification. Other non-traditional methods were used as well, in cases of severely fragmented burnt bone where DNA sampling was not possible due to the degree of calcination.

Mass Fatality; Human Identification; Laboratory Strategy

A76 Ethical Considerations of Cadaver Dog Training, Certification, and Field Use

Victoria A. Eacott, BA, University of Tennessee Knoxville, Oak Ridge, TN*

Learning Objectives: This presentation will inform attendees about the processes behind the training, certification, and handler use of Human Remains Detection Dogs (HRDD) in investigations requiring the discovery of suspected missing human remains. Additionally, it will underscore the importance of implementing a standardized ethical framework in HRDD practices.

Impact Statement: This presentation will impact the forensic science community by addressing ethical issues inherent in current HRDD practices and highlighting the existing lack of standardization. By doing so, it will catalyze discussions and initiatives aimed at establishing new standards in this field.

Abstract Text: HRDD are canines trained to detect the scent of human decomposition and alert their handlers of its location. Local law enforcement agencies often lack the budget to maintain their own HRD teams, resulting in the common practice of outsourcing this specialty. This presentation addresses the lack of standardization observed in three critical areas - training, handler use, and certification.

Training of HRDDs involves exposing the canines to training aids that mimic the olfactory profile of decomposing human remains. There is significant variability in the methods used for training dogs to detect this scent as well as in the types of training aids employed. This variability arises from limited access to whole cadavers and challenges in storing and maintaining proper training materials. Training aids can include fabric or soil that has been in contact with human remains, small tissue samples, pseudoscents, bones, and pig flesh. Further research is necessary to identify which training aids accurately represent the Volatile Organic Compounds (VOCs) emitted during human decomposition. Additionally, studies are needed to determine if the differences in VOCs of varying stages of decomposition are considerable enough to warrant training aids in all levels of decomposition. Without standardized storage practices, there is a risk of cross-contamination among training aids stored in permeable containers.[1]

Handler practices must be standardized and rigorously reviewed to ensure ethical procedures in the use of HRDDs. Given the variability in training practices, handlers are responsible for acquiring appropriate training aids and thoroughly exposing their canines to human remains. Handlers also play a crucial role in assessing whether their canines can effectively differentiate human remains scents from others. A survey conducted by the National Center for Biotechnology Information (NCBI) reveals that handlers often select their canines based on traits such as playfulness, sociability, and curiosity, rather than olfactory capabilities.[2] Further research is needed to understand the olfactory capabilities of different dog breeds and to identify which characteristics are essential for selecting and training effective HRDDs.

Currently, there is no centralized organization overseeing the training and certification of HRDDs. Existing guidelines from organizations like the Scientific Working Group on Dog and Orthogonal Detector Guidelines (SWGDOG), the National Institute of Standards and Technology (NIST), and the American Standards Board (ASB) lack definitive language and provide ambiguous certification requirements, leaving canine teams to establish their own training and practice protocol.[3,4]

This overview aims to highlight examples of variability in current HRDD training, handler practices, and certification processes, emphasizing the need for standardized protocols in training dogs used in forensic investigations. The variability underscores the necessity for additional research to enhance the scientific basis behind the reliability of training aids and the selection of HRDDs.

Anthropology; Cadaver Dog; Human Remains

A77 Examining Contributing Factors to Natural Human Mummification at FOREST in Cullowhee, North Carolina

Alex D. Vacca, Western Carolina University, Hillsborough, NC; Kaleigh C. Best, PhD, Western Carolina University, Cullowhee, NC 28723, NC; Rebecca L. George, PhD, Western Carolina University, Cullowhee, NC; Leilah Melerine, BS, Western Carolina University, Cullowhee, NC

Learning Objectives: After attending this presentation, attendees will have a better understanding of the effect of seasonality on the speed of mummification in relation to aggregate, humidity, temperature and precipitation. Mummification patterns at Western Carolina University's Forensic Osteology Research Station (FOREST) in Cullowhee, NC, will be discussed.

Impact Statement: This presentation will impact the forensic science community by contributing new information to the field of human taphonomy concerning the circumstances leading to mummification.

Abstract Text: Natural mummification occurs in a diverse range of global locations, including temperate climates.[1] Understanding when mummification occurs in temperate climates will allow forensic specialists to more accurately determine the Postmortem Interval (PMI) of a set of remains found in such locations. Despite being observed frequently, factors that contribute to natural mummification remain poorly documented in current literature. A recent literature review sought to better identify where geographically and what variables contribute to natural mummification.[1] The limited information available suggests factors are largely inconsistent and do not address mummification in temperate climates, highlighting the need for further research. This research contributes new information to the field of human taphonomy concerning the circumstances leading to mummification, specifically the effects of seasonality on the speed of mummification in relation to aggregate humidity, temperature, and precipitation.

This preliminary study utilized factors identified in Vacca 1 to better understand their impact on mummification at Western Carolina University's (WCU) in Cullowhee, NC, where mummification is frequently observed to occur. Using a series of photographs during the decomposition process of 12 donors placed at FOREST in 2022, variables of humidity, precipitation, temperature, and seasonality were assessed for an approximately 16-month period using data from the National Weather Service in order to determine if any of the variables contribute significantly to mummification. The donors were scored using the Connor et al. method, which was determined to be more accurate for scoring decomposition at FOREST by Melerine et al.[2,3] Out of the 12 donors, two did not reach mummification during the study period and were excluded from further analysis. For each donor, the number of days until the first area demonstrated mummification and the number of days until all sections showed mummification were recorded. Variable data were totaled until these days were reached and analyzed using Multivariate Analysis of Variance (MANOVA) to understand what effect the variables had on natural mummification. Inter-observer error analysis was conducted to assess the consistency in scoring using the Conner et al. method.[2] The Coh.en's kappa results showed weak-to-moderate agreement between two observers (0.597-0.712).[4]

A one-way MANOVA analysis showed that the variables of humidity, temperature, and precipitation significantly impacted the date when mummification was first observed and when it occurred on all body segments. To examine which variables were contributing to the first and all sections demonstrating mummification, ANOVA with a Tukey Honestly Significant Difference post-hoc tests were conducted on both data sets. Results indicate that for the date of first appearance of mummification, only temperature and humidity are significant contributors, while temperature, humidity, and precipitation were significant for when all sections of a donor demonstrated mummification.

In order to examine if seasonality was significant in terms of when first and total mummification observed, a two-way MANOVA indicated that seasonality is significant to the days until both total and first mummification, with ANOVA revealing the interactions between all other seasons and fall as significant. By examining histograms of the data, the donors went through the stages of decomposition the fastest in the spring and summer and the slowest in the fall. Examining trends related to seasonality, two donors demonstrated patterns of mummification and rehydration with no consistency in terms of timing of placement.

The results of this study reaffirm the need to further understand factors leading to mummification, specifically in regard to seasonality, and the influence temperature, humidity, and precipitation have in patterns of mummification. Future work on this project will include additional donors, further investigation into observer error rates, and examining how the factors impacting mummification affect the Total Body Desiccation Score (TBDS).

Taphonomy; Mummification; Seasonality

A78 First Donor of the Forensic Science Research and Training Laboratory (FSRTL): Exploring Unique Geographic Variation in Human Decomposition in the Mid-Atlantic Region

Nickolyn Jackson, BA, George Mason University, Arlington, VA; Molly Kilcarr, BS*, George ason University, Springfield, VA; An-Di Yim, PhD, George Mason University, Fairfax, VA; Emily D. Rancourt, MSFS, George Mason University, Fairfax, VA*

Learning Objectives: After attending this presentation, attendees will have a better understanding of the local environmental factors associated with the mid-Atlantic region that contribute to the rate of human decomposition. Attendees will also have new insight into the ongoing research efforts and opportunities for collaboration afforded by the FSRTL at George Mason University.

Impact Statement: This presentation will impact the forensic community by providing new insights into the geographic variation of human decomposition. Information gathered from this study and future studies will provide data that can be directly applied to local law enforcement cases by helping to establish a relevant timeline of decomposition

Abstract Text: The purpose of this study is to understand the geographic variation of human decomposition in the mid-Atlantic region through gathering data from the first donor at George Mason University's FSRTL. Information such as decomposition rate, insect activity, and scavenging patterns will be analyzed to provide a baseline for future studies at FSRTL.

Current methods for estimating the Postmortem Interval (PMI) are subject to regional variation. Methods derived from certain regions are inherently biased towards those regions.[1] The literature surrounding decomposition interval methodologies encourages practitioners in other parts of the country to complete their own documentation to better track the changes seen in local environments. Further literature reviews discuss how determining accurate PMI that are focused on specific regions is necessary in investigating cases.[2,3] A misinterpretation of PMI due to a lack of understanding of local environmental factors can mislead a case entirely.[2] Understanding the factors that contribute to the complex postmortem process are therefore imperative.[3]

The first donor of FSRTL was received in May 2024 and was placed above ground partially clothed in a consistently shaded wooded area with a metal cage placed over the top of the donor to minimize scavenger activity. Data collection included qualitative observation, photographic documentation, and decomposition scoring following the scale developed by Megyesi et al. at regular intervals.[1]

Insect activity steadily increased to approximately 25% body coverage for the first five days, progressing to approximately 50-100% on day 8. The progression of insect activity from larva to adult was documented for blowflies, beetles, and gnats. Scavenging activity from vultures was first observed on day 7 and last noticed on day 17. Vulture activity was predominately focused on the left hands and feet with less activity observed on the right. This is possibly related to a chemotherapy port implanted on the right side.

Qualitatively, decomposition progressed differently in each region for the body. The head stayed in the early decomposition phase from day 3 to day 7, entering advanced decomposition on day 8, and reaching skeletonization on day 13. The limbs were in the early stages of decomposition from days 3 to 10, advanced decomposition from days 11 to 16, and skeletonized after day 17. The early stage of decomposition was prolonged in the torso when compared to the head and limbs, lasting from day 2 to 11 and not reaching skeletonization until day 14, likely due to the clothing. Quantitatively, comparisons were made between the actual accumulated degree days and known PMI and the calculated accumulated degree days and PMI.

Similar to previous results, quantitative decomposition scores increase exponentially with increasing known PMI. However, when compared against the published data, distinctive deviations were observed with increasing PMI, indicating greater error in PMI estimation using existing method in later stages of decomposition.[1] The results demonstrate the importance of conducting studies on human decomposition in different regional areas to create accurate methods that can be used by local law enforcement when determining PMI.

Future studies at FSRTL will continue to establish baseline variation in human decomposition to provide information for practitioners.

Anthropology; Decomposition; Taphonomy

A79 Understanding Human Decomposition in the Great White North: A Review of REST[ES]'s First Five Years and Future Directions

Elisabeth Cuerrier-Richer, MSc, Université du Québec à Trois-Rivières, Trois-Rivières, Quebec, Canada; Noémie Bitschnau, MScFS, Université du Québec à Trois-Rivières, Trois-Rivières, Quebec, Canada; Hugues Leblond, PhD, Université du Québec à Trois-Rivières, Trois-Rivières, Quebec, Canada*

Learning Objectives: After attending this presentation, attendees will understand the Canadian human decomposition context from an anatomical, chemical, entomological, environmental, forensic, and thanatological perspective.

Impact Statement: This presentation will impact the forensic community by demonstrating the interdisciplinary approach used at a human decomposition facility in a cold, North American climate. It will highlight the wide range of disciplines that benefit from this non-traditional management structure, both within and outside of forensic anthropology.

Abstract Text: The site for Research on Experimental and Social Thanatology, or *Recherche en Sciences Thanatologiques [Expérimentales et Sociales]* (REST[ES]) in French, is a high security outdoor facility primarily dedicated to the physical, chemical, and biological study of human decomposition, with a sociological dimension.[1] As the site is located in southeastern Canada, research conducted at REST[ES] focuses on the study of death and the taphonomic processes that occur in a northern, cold, and forested climate. REST[ES] is currently the only human decomposition facility in Canada and the only bilingual site operating in both French and English globally, thus offering a unique niche to local, national, and international researchers, scientists, practitioners, law enforcement, and other professionals interested in postmortem changes in this particular environment.

As an extension of the Anatomy Laboratory at the *Université du Québec à Trois-Rivières*, REST[ES] benefits from the credibility and public awareness the Department of Anatomy has built with its willed body donation program over the past 30 years. Since the site welcomed its first donor in 2020, REST[ES] has received a total of 26 donors and hosted 21 research projects (as of August 1, 2024) in anatomy, chemistry, entomology, environmental science, forensic science, and thanatology, to name only a few. Research topics have been as diverse as the use of hyperspectral imaging for body detection, the characterization of cadaveric odors, the effect of winter on entomological fauna, the environmental impact of human decomposition in northern latitudes, the restoration of fingerprints in an advanced state of decomposition, and the assessment of postmortem interval through the thanatobiome, among others.[2-4]

Following an administration change in 2023, REST[ES] underwent a major restructuration, with the intent to bring the site closer to the American human decomposition facility model while also embracing the traceology approach recommended in the Sydney Declaration.[5] A substantial provincial grant obtained in 2024 also allowed REST[ES] to further integrate technology into the site's management strategy and optimize data collection. The purpose of this presentation is three-fold: (1) to provide a review of REST[ES]'s first five years as a taphonomy research facility, (2) to introduce the new management structure, and (3) to present future directions planned for the site in upcoming years, namely with regard to professional partnerships, research collaborations, and training opportunities.

Decomposition; Taphonomy; Canada

A80 Opening the Black Box: Explainability Tools in Postmortem Interval Estimation

Katherine E. Weisensee, PhD, Clemson University, Clemson, SC; Madeline M. Atwell, PhD, Clemson University, Columbia, SC; Carl Ehrett, PhD, Clemson University, Clemson, SC; Madeline Babcock, Clemson University, Hilton Head Island, SC; Brianna Cherry, Clemson University Watt AI Program, Clemson, SC*

Learning Objectives: After attending this presentation, attendees will learn how Machine Learning (ML) in forensic science can be leveraged to investigate aspects of the decomposition process. Specifically, we will present the use of ML explainability tools to enhance the ethical and responsible use of Artificial Intelligence (AI) in forensic science, particularly in Postmortem Interval (PMI) estimation. These methods support transparency and interpretability when integrating ML into forensic applications.

Impact Statement: This presentation will impact the scientific community by demonstrating how AI can be applied in ethical ways that advance our understanding of the decomposition process.

Abstract Text: Time since death, or PMI, estimation remains an enduring challenge to medicolegal death investigations despite decades of research. Existing methods continue to lack the scientific rigor required within the medicolegal sector due to continued reliance on small sample sizes, the lack of environmental heterogeneity, and inconsistent descriptions and methodologies, which impede our understanding of the decomposition process.[1]

GeoFOR began in 2019 and seeks to inform these longstanding issues by offering data-driven PMI estimations. The geoFOR application serves as a free forensic case entry platform that automates the collection of weather data from the discovery location using the Global Historical Climatology Network (GHCN) and utilizes ML methods to deliver statistically robust PMI predictions directly to users. Cases entered into geoFOR contribute to an ongoing, large, collaborative forensic taphonomy database (n= 3217) used to train and update the ML predictive model.

ML models, though powerful predictive tools, are often "black boxes" due to their complexity. To ensure ethical and fair application of ML, techniques for "opening the black box" must be combined with the use of ML to make these models transparent and interpretable. We leverage a variety of model explainability techniques in conjunction with our ML model to determine how individual variables of the body and surrounding environment contribute to the model's PMI estimation. Our analysis employs permutation importances, SHAP values, decision tree surrogates, and human-in-the-loop interactive tools to extract insights about the ML model of PMI prediction, providing quantitative assessments of how specific variables influence the complex decomposition process.[2-4]

Our results demonstrate the power of these explainability tools in interpreting PMI estimates. Feature importance analysis revealed that "desiccation" is the most critical feature, with a gain value of 205.461. This finding was corroborated by permutation importance analysis, where desiccation showed the highest importance of 0.193, indicating a substantial decrease in model performance when this feature is randomly permuted. SHAP analysis further validated these findings, with desiccation having an average SHAP value of 0.466, the highest among all features.

Interestingly, while advanced decomposition characteristics generally showed high importance, the early decomposition feature "skin discoloration" also emerged as significant, with the fifth-highest permutation importance of 0.032. Among environmental factors, our analysis identified "Precipitation standard deviation days 57-154" as the most important weather covariate, with an average SHAP value of 0.089.

To further enhance interpretability, we employed a decision tree surrogate model. Despite its simplicity, this surrogate achieved an R^2 of 0.675, comparable to our full model. The surrogate tree's structure reinforced our other findings, with desiccation as the top-level feature, followed by "livor mortis unfixed" and deposition site type at the second level.

By providing interpretable, and justifiable PMI estimations, we show how black box ML models can be made simultaneously to yield forensic insights and also to increase their transparency and openness to oversight.

Decomposition; Postmortem Interval; Machine Learning

A81 A Postmortem Interval Estimation Method for Surface Depositions: A Template Applied in Southeastern Louisiana

Sophia I. Reck, MA, Louisiana State University, Baton Rouge, LA*

Learning Objectives: After attending this presentation, attendees will have a better understanding of the progression of decomposition in southeastern Louisiana, particularly regarding surface deposition in wooded areas or fields.

Impact Statement: This presentation will impact the forensic community by demonstrating a practical method of Postmortem Interval (PMI) estimation that can act as a template for PMI estimation in any locale.

Abstract Text: Providing estimates of the PMI requires familiarity with regional sequences and patterns of decomposition. The Forensic Taphonomy Education and Research Facility (FTERF) at Louisiana State University provided anthropologists with the opportunity to study the progression of decomposition in southeastern Louisiana. The FTERF is located in the Cfa Köppen-Geiger climate zone (temperate climate, hot summers and no dry season) and eastern temperate forests (Level I ecoregion) on the Mississippi Alluvial Plain and Mississippi Valley Loess Plains (Level III ecoregions).[1-3]

Multiple predictive PMI estimation models have been developed by associating the stages and features of decomposition with accumulated degree days. Alternatively, the current method focuses on the first and last appearance of taphonomic features within a local sequence of decomposition. Predominantly, placement at the FTERF consists of surface deposition in wooded areas or grassy fields (under cages to mitigate scavenging); consequently, the method developed in this study focuses on taphonomic progression in those environments. It is expected that features included in the PMI estimation method would change according to the patterns observed in the ecoregion and depositional context in which it was developed.

For this method, the body was separated into four segments: head/neck, trunk, arms, and legs. For each section, the duration of expression was recorded for color changes, soft tissue changes, and degree of skeletonization by area (i.e., zero, < 50%, or >50% of the body segment was skeletonized). For example, green discoloration was visible on the trunk from day 1 to day 14 of placement at the FTERF. The duration of each taphonomic trait was obtained from photographs recording the progression of decomposition for 12 individuals; observation for each individual spanned the entirety of deposition at the FTERF. The dates of death and placement at the FTERF were never the same day; however, a fresh appearance (i.e., minimal color change) was required for inclusion. Both autopsied and non-autopsied individuals were considered.[4,5] Placement occurred throughout all seasons and the longest placement interval was 241 days.

To test the method, photographs from 15 observation days were culled randomly from the data of 14 individuals not used in method development. A single PMI estimate range was based on observed taphonomic features across all body segments while collectively considering the duration of each trait. Preliminary results indicate that 73% of the observation days fell within the estimate ranges. Additionally, while considerable overlap exists between the ranges of expression, some features can be broadly categorized as occurring in less than one month, between one and three months, and greater than three months. However, for every section except the trunk, a body segment could reach < 50% or >50% skeletonization by six days. Consequently, coloration and soft tissue changes should be given more weight than the degree of skeletonization when estimating PMI in southeastern Louisiana. Future refinement of this method will include increasing sample size, extending the maximum placement interval, examining pattern of skeletonization and weathering (rather than degree of skeletonization only), incorporating insect succession, and developing templates in different seasons, deposition contexts, and ecoregions.

Taphonomy; Postmortem Interval; Environment

A82 Examining the Effects of Two Freshwater Environments on Decomposition and the Associated Microbial Communities

Leah Bell, BS, Northern Michigan University, Marquette, MI; Jane C. Harris, PhD, Center for Forensic Anthropology, Northern Michigan University, Marquette, MI*

Learning Objectives: Research on human decomposition in freshwater environments is limited, forcing researchers and law enforcement to utilize research from saltwater or terrestrial environments, even though there are fundamental differences. A discussion of the factors influencing decomposition in freshwater environments will allow for a greater understanding of the challenges associated with aquatic decomposition research. These factors include submersion and the water environment itself as well as the microbial communities present during decomposition.

Impact Statement: This study serves as a pilot study and proof of concept for future research to better inform the investigative community of a potential means for estimating Postmortem Interval (PMI) in a cold freshwater environment.

Abstract Text: Research on decomposition in aquatic environments is limited, compared to what is known about decomposition on land. Additionally, many of the taphonomy studies that have been conducted in lacustrine or riverine freshwater environments have focused on morphoscopic changes and scavenging. This study sought to determine the effects of two freshwater environments on decomposition by examining the impact of submersion and the water environment itself as well as the microbial communities associated with decomposition.

This research involved the placement of six fetal pigs in three different, but spatially related, decomposition environments. Two pigs were placed in a creek with a notable current; two pigs were placed in a nearby pond created by a beaver dam, and two were placed in a wooded area adjacent to both. Over a one-month period, water samples were collected from near the four pigs in freshwater environments and surface swabs from the two pigs placed on land. Additionally, notes and photographs were taken to document morphoscopic changes to the research subjects; additional data collected were ambient temperature, water temperature, surface temperature (of the specimens on land), rate of the current in the creek, water depth, and scavenger activity. All samples that were collected were submitted for 16s rRNA sequencing and bioinformatics to determine which changes took place over time with respect to the quantity and diversity of microbial communities.

By using pig proxies, this study serves as a pilot study and proof of concept that the researchers intend to build into a study involving human donors from the Body Donation Program under the Northern Michigan University Center for Forensic Anthropology to better inform the investigative community of a potentially novel means for estimating PMI in a cold freshwater environment. Notable differences were observed between the rates of decomposition among the research subjects in the three environments, including their visible progression through decomposition and insect activity. Decomposition rate was found to be highly influenced by environmental factors such as weather, water type, and depth. Changes to the microbial communities over time were also affected by the environment, with notable differences having been observed between what was present prior to specimen placement and which microbes become or remain dominant over time in each sample collection location.

Decomposition; Freshwater; Postmortem Interval

A83 Differences in Tissue Consumption by Maggots

Emma M. Giacomello, MA, Texas State University, Huntsville, TX; Michelle D. Hamilton, PhD, Texas State University, San Marcos, TX*

Learning Objectives: From this presentation, attendees will gain insight into the differential consumption of soft tissue types by maggots during decomposition. They will understand how variations in body composition, particularly muscle and fat content, can influence decomposition rates and potentially affect Postmortem Interval (PMI) estimations. This knowledge will enable forensic professionals to consider body composition as a factor when estimating time since death intervals in forensic casework.

Impact Statement: This presentation will enhance the forensic science community's understanding of the relationship between body composition and decomposition rates, potentially improving the accuracy of PMI estimations. By highlighting the preferential consumption of muscle tissue by maggots, this research emphasizes the need to consider biomass and individual body composition when interpreting decomposition patterns, which could lead to more precise and reliable PMI estimations in death investigations.

Abstract Text: Several different families within the order Diptera, or flies, include insects that consume dead and decaying tissue and thus play an important role in the rate of decomposition and the estimation of the PMI.[1-6] The most common fly families associated with the consumption of dead tissues are Calliphoridae, Sarcophagidae, Muscidae, Piophilidae, Phoridae, and Stratiomyidae.[5] Fly larvae (maggots) are laid quickly after death occurs and utilize dead tissue as a main food source. A single female fly may lay up to 300 eggs, which will hatch and begin the feeding process within 1 to 2 days.[5] Once hatched, maggots will first consume serous fluids followed by soft tissues, which results in removal of the biomass of the remains.[5,6] As maggots are responsible for part of the decomposition process, the association between maggot feeding activity and decomposition rate has been examined closely in relation to its impact on determining time since death in forensic casework. However, it is unclear exactly which types of soft tissues are consumed by maggots, which may ultimately affect the estimation of time since death since individuals have different amounts of soft tissue types on their body.

To determine the soft tissue types maggots consume, four tissue samples were obtained from two willed body donors at the Forensic Anthropology Research Facility (FARF) at Texas State University. The tissue samples included subcutaneous fat, muscle, skin, and a cross section of the three tissues. The same amount and weight of tissue types were collected from each donor at the beginning of the data collection process and placed into separate open glass jars. The jars were placed in an open-air plastic tub and under a metal cage to avoid being scavenged while still allowing for insect activity. The jars were monitored and weighed daily at the beginning of data collection and then moved to every three days once insect activity began to slow. Data collection occurred in the spring of 2022 and 2023.

The data did not meet the criteria for parametric tests and a Kruskal-Wallace test was used on each data set. For each round of data collection, there was a significant difference ($P < 0.001$) in the biomass lost between tissue types, with muscle having the smallest mean rank and the greatest amount of biomass lost, followed by the cross-section sample (that included muscle). The observations made during the data collection process support these results as there was a significant amount of maggot activity on the muscle tissue and comparatively little on the other tissue samples.

The results of this study demonstrate significant differences in maggot feeding preferences among soft tissue types, with muscle tissue consistently showing the greatest biomass loss. These findings have implications for forensic science: individuals with higher muscle mass may exhibit accelerated decomposition rates during stages of maggot activity, while those with higher fat content may decompose more slowly, since maggots do not consume fat tissue. Future studies should expand on these findings by increasing sample sizes and examining seasonal variations, further refining our understanding of the complex relationship between taphonomic agents, body composition, and decomposition rates.

Decomposition; Soft Tissue; Postmortem Interval

A84 A Homogenous Diet in a Diverse City: Understanding Isotopic Dietary Variation and Its Forensic Implications in San Francisco, California

Taylor Lambrigger, MA, Wisconsin Historical Society, Chico, CA; Alina C. Tichinin, MA, International Archaeology, LLC, Waipahu, HI*

Learning Objectives: In this presentation, attendees will understand the variability of dietary isotopic signatures in cultural enclaves in the city of San Francisco. In reviewing current studies frequently demonstrating homogeneity within the country and increased heterogeneity between countries in assessing region of origin, the audience will see if cultural enclaves with roots in various countries around the world reflect isotopic trends in those regions or if the continental supermarket diet permeates cultural variations in increasingly diverse urban contexts.

Impact Statement: This presentation will impress upon the audience the necessity of context when applying dietary isotope methods in forensic science. When addressing region of origin estimates in a global context, regional trends in dietary isotopes may be appropriate; however, they lose their potency and accuracy when assessing region of origin in urban forensic casework.

Abstract Text: Stable isotope analysis as a method has grown in popularity in recent decades. Particularly in forensic anthropology, elements like carbon, nitrogen, and oxygen have demonstrated the ability to inform on the food and water consumed by an individual, which can be used to estimate region of origin. Much of the stable isotope applications first arose in the bioarchaeological literature, wherein the food that was consumed by an individual was somewhat diagnostic of the region of the world the individual was from. Isotope data indicating diets primarily composed of corn or millet versus wheat were indicative of different cultures in the archaeological record and could provide meaningful insight into where those individuals belonged.

The modern United States population exhibits a somewhat homogenized diet, often referred to as the "continental supermarket diet." Additionally, other regions, like Mesoamerica and Southeast Asia, have also been characterized by larger dietary patterns that differ isotopically from the continental supermarket diet. However as forensic anthropologists begin applying these broad categories into specific individualized forensic cases within the United States, the method and assumptions therein may be missing the mark. While there is isotopic evidence to support an increasingly homogenized diet within modern countries, much more data from diverse contexts throughout the United States and abroad is necessary for this pattern to hold.

Community-level isotopic data has the potential to challenge our current methodological assumptions when it comes to interpretation of region of origin by diet. While the United States as a whole has a diagnostic isotope signature, there are many cultural enclaves wherein the diet of community members may look different than what one would expect to see at a country wide level. Specifically, hair samples from the cultural enclaves of North Beach (Italy), Chinatown and the Sunset Chinese Cultural District (China), Calle 24 (Mexico), Japantown (Japan), and SOMA Pilipinas (Philippines) were studied and compared with average country-specific or regional isotopic dietary signatures.[1]

This poster assesses carbon ($\delta^{13}C$) and nitrogen ($\delta^{15}N$) from 47 samples of hair from six different cultural enclaves to assess if dietary homogeneity is true in the city of San Francisco. Mean values of carbon (-17.9‰) fit within the typical range in the United States (-17.6‰ ± 1.2‰) (1). Further, mean nitrogen for the San Francisco population (9.7‰) are captured by the upper bounds of the range of typical values for United States populations (8.9‰ ± 0.9‰).[1] When assessing variance of diet between populations of different enclaves, no statistically significant difference was seen in both carbon ($F(4,42) = 0.9$, $p = 0.46$) and nitrogen ($F(4,42) = 1.1$, $p = 0.38$). In individual comparisons of enclave means compared to source country average values, all San Franciscan enclave nitrogen fit in the typical range for each country of origin. However, those populations from SOMA, Chinatown, and the Sunset Chinese Cultural District fall outside of the typical carbon signatures for the Philippines and China, respectively.

Research within the method is increasingly indicating that socioeconomic and cultural factors play a significant role in the isotopic values in human tissues. Especially as the use of stable isotopes in forensic casework increases, understanding the nuances within populations on which the method is employed and the different factors that can influence our interpretations of data is critical. While results from this study suggest that the larger population level dietary data in the United States holds true, this research also underscores that forensic practitioners must be careful in their interpretation of isotopic data at the individual level.

Stable Isotope Analysis; Identification; Provenance

A85 On FIRM(S) Footing?: A Review of the Use and Reporting of Stable Isotopic Analysis in Forensic Anthropological Dissertations

Alina C. Tichinin, MA, International Archaeology, LLC., Waipahu, HI; Taylor Lambrigger, MA, Wisconsin Historical Society, Chico, CA*

Learning Objectives: Attendees will leave with an understanding of the rigor with which stable isotope best practices are being adhered to and taught within the field of forensic anthropology. They will specifically learn how well these best practices are being implemented in graduate student research, which can be extrapolated to assess the future use of the method as young researchers move forward in their careers. Attendees will come away with a thorough understanding of what best practices are recommended for the use of stable isotopes in forensic anthropology, where the field is doing well in their adherence to these standards, and areas for improvement.

Impact Statement: Stable isotope analysis is becoming a commonly used tool in forensic anthropology, and this presentation will provide important feedback on the effectiveness of its use in the field and the ways in which its use can be improved so as to better serve the purpose of medicolegal investigation and identification.

Abstract Text: Forensic anthropology is a subdiscipline born out of the social sciences that simultaneously requires the rigor of hard sciences. Analytical semi-quantitative methods have become increasingly prevalent within forensic anthropology, including stable isotope analyses. Yet while these methods grow in popularity, practitioners must be wary that the knowledge gap between those generating the data and those interpreting the data does not grow as well. While work has been done to call attention to this need for increased rigor in data reporting in anthropology at large, forensic anthropologists applying stable isotopes should also refer to the Forensic Isotope Ratio Mass Spectrometry (FIRMS) Network for guidance. FIRMS has produced best practice guides for data generation and reporting and interpretation in a medicolegal context and has been in place to address isotope data quality issues for over 20 years.[1,2]

As a preliminary step in understanding adherence to these best practices, this poster assesses theses and dissertations from 2008 to 2023 where stable isotopes were employed in forensic anthropological contexts. Academic products such as dissertations are unique in that academic programs allow for larger amounts of data collection, analysis, and interpretation. In these contexts, students learn how to do research under the guidance of practicing professionals. It stands to reason that in these documents, students will describe the methods for preparing samples and subsequent analyses. Thus, understanding where students are at in their understanding and application of best reporting practices in stable isotope studies is a telling metric as to how the subdiscipline is currently upholding these standards and how we will continue to do in the future.

Thirty-three university repositories were searched for papers from 2008 to present produced from a graduate of the department of anthropology with a focus on forensic anthropology and the inclusion of stable isotope analyses. From these 33 programs, 20 documents were attained. Scoring of these papers occurred according to a rubric that judged the presence and absence of a number of criteria related to sample preparation, as well as reporting of analytical accuracy and precision. These criteria were pulled from both best practice guides developed by FIRMS as well as similar work done in the field of archaeology and best practices developed for archaeologists.

All papers reported raw isotopic values for samples and all reported that the author conducted sample preparation. However, only 80% detailed what steps were taken to prepare tissues, 15% referenced the methodology discussed in an outside publication, and 5% did not detail prep methods at all. In understanding how these papers reported about the analytical side of their study, 95% reported the analytical lab where analyses were conducted; however, only 75% of papers discussed the instrumentation used in those analyses. The reporting of calibration standards was also assessed, finding that only 45% of papers detailed the standards used by analytical labs. Though 25% mentioned that standards were used with no further information, 30% of theses and dissertations did not discuss standards at all. It should also be noted that these criteria assessed presence and absence, variation in which prep methods were used, which instrumentation was employed, and when and how standards and error were disclosed were significant.

Though the sample size is small, the associated degree of variation is cause for deeper investigation. The lack of consistency in reporting, both of sample preparation and of analytical factors, underscore that best practices for data reporting and interpretations in forensics are not being taught. As the push for rigorous methods in the forensic sciences grows, forensic anthropologists must be cognizant of best practices when studying and applying stable isotope analysis in forensic contexts.

Stable Isotope Analysis; Best Practices; Student Training

A86 The Implications of Quantitative Spectral Analysis of Human Cremains in the Texas State Donated Skeletal Collection (TXST-DSC)

Anna K. Maier, MS, Texas State University, San Marcos, TX; Hailey Collord-Stalder, MA*, Texas State University, Redding, CA*

Learning Objectives: After attending this poster presentation, attendees will have a better understanding of the challenges of identifying burned human remains and the analytical techniques that are being tested to help investigators refine methodology.

Impact Statement: This presentation will impact the forensic community by providing attendees with new tools to use in the future regarding unidentified and/or commingled human remains. The proposed methods open a new realm of research and applied functions for the serious and growing global concern of unidentified, burned, and sometimes commingled human remains.

Abstract Text: Identifying thermally altered or burned remains presents a formidable challenge, as does the identification of commingled remains.[1] When these two complexities are combined, the task of making accurate, efficient, and cost-effective identifications becomes even more difficult and, at times, appears insurmountable. In situations where DNA extraction fails to address issues of commingled remains, often due to the condition of the remains, alternative methods must be explored to initiate the identification process by distinguishing skeletal elements.

Cremains are representative of the most highly thermally altered human remains and occur both as a product of past and present mortuary behavior as well as through accidental and homicidal means. While past studies have been primarily focused on examining intentional cremation produced in the execution of mortuary practices, very limited research has been done on cremains produced in the course of accidental or homicidal means, and no research has been conducted on elemental variation among individual sets of cremains.[1-5]

In this research, both portable X-Ray Fluorescence (p-XRF) and Fourier Transform Infrared Spectroscopy in the Attenuated Total Reflection (FTIR-ATR) mode were used to investigate the characteristics retained in human cremains that may help resolve future cases of commingling and unidentified persons.

A random sample of 13 sets of cremains was analyzed with the age at death ranging from 47 to 91 (mean 64) years old and the temperature of cremation ranging from about 1,100 to 2,300 degrees Fahrenheit. The cremains were sifted through a 35-mesh (500 microns) sieve, and about 5 grams of bone ash were retained for both analyses. Spectral data were produced using both chemometric methods and were analyzed for any individualizing characteristics.

Research on FTIR-ATR use for age estimation is very new and limited, but preliminary results show potential for accurate age estimations.[6,7] In this project, Kruskal-Wallis tests showed a statistically significant result when comparing age with the Crystallinity Index and Carbonate-to-Phosphate ratio in the baseline corrected cremains spectra. Additionally, the Crystallinity Index and the Carbon-to-Phosphate ratio showed some significant potential in Principal Component Analyses (PCAs) and decision trees. Decision trees on the data set created an accuracy of 38% with the Crystallinity Index as an important splitting factor.

Results from the pXRF analysis revealed multiple chemical elements, including Zn, Ti, and K, may be used for decommingling in the future with greater streamlining of analysis. Two individuals clearly separated as outliers from the other samples during a cluster analysis that was conducted. However, the high dimensionality of the data (more features than observations) precluded the pXRF analyses from being able to make broad statistical claims about the usefulness of pXRF on human cremains. A Technical Error of Measurements (TEM) and relative Technical Error of Measurement (rTEM) tests were conducted on the pXRF data and produced unacceptable error rates (>5%) of approximately 12% of the data, which suggests that the pXRF unit being used was producing unreliable readings.

Overall, the results of the FTIR analysis show significant differences in the Crystallinity Index and Carbonate-to-Phosphate ratio but no significant results in other parameters that might correlate with age and sex. Similarly, the pXRF results had some promise, but both methods suffered from a limited and relatively homogenous sample. Future research with a larger, more biologically diverse sample of cremains and a more reliable pXRF unit is indicated.

Cremains; Identification; Spectroscopy

A87 The Development of a Matrix-Matched Reference Material for Quantitative Elemental Analysis of Bone

Kristen M. Livingston, BS, University of Central Florida, Orlando, FL; Amanda Williams, University of Central Florida, Altamonte Springs, FL; Matthieu Baudelet, PhD, University of Central Florida, Orlando, FL; Juliana Baez, University of Central Florida, Orlando, FL*

Learning Objectives: This presentation focuses on the synthesis and application of reliable, matrix-matched calibration standards for the quantitative chemical analysis of bone. Attendees will understand the importance of chemical reference materials for forensic investigations of skeletal remains and how ongoing research is making advancements toward this analytical necessity.

Impact Statement: A matrix-matched bone reference material is critical for accurate and reliable chemical measurements of forensic bone samples. The development of calibration standards for bone improves the detection and quantification of trace elements in bones that may be attributed to biological or environmental factors.

Abstract Text: Elemental analysis of bone samples using chemical techniques, such as X-Ray Fluorescence Spectroscopy (XRF) and Laser-Induced Breakdown Spectroscopy (LIBS), is gaining popularity in the fields of forensic anthropology and bioarcheology. Detecting the elemental profile of a bone can help provide contextual understanding. For example, the presence of trace elements such as lead or mercury in bone may indicate toxic exposure within an individual's lifetime. Strontium and barium have historically been used in research as dietary indicators for skeletal remains. The elemental profile of bone has also been studied as a potential tool for sorting commingled remains.[1] Bone's elemental composition may also serve as a potential informer of any diagenetic chemical alterations that occur after death.

Quantifying the concentration of an element within a sample using analytical techniques requires calibration standards. Unfortunately, there is a lack of suitable reference materials that can replicate the chemical and physical matrix of bone samples. Commonly used calibration materials include glass, bone meal, or lab-synthesized hydroxyapatite pellets—all of which fail to fully mimic the physicochemical properties of bone. Therefore, a better bone standard must be created to ensure reliable measurements of elemental concentrations can be made for forensic bone samples.

The objective of this research study is to develop a matrix-matched calibration standard for the quantitative elemental analysis of bone. A fibrillar collagen framework mineralized with hydroxyapatite crystals has been synthesized using a co-precipitation technique. We have shown that this composite material chemically mimics bone through Fourier-Transform Infrared Spectroscopy (FTIR), X-Ray Diffraction (XRD), and Laser-Induced Breakdown Spectroscopy (LIBS) spectra. FTIR reveals the amide-based N-H, C=O, C-N, and C-H bonds from collagen, as well as hydroxyl, phosphate, and carbonate signal from hydroxyapatite. XRD confirms the crystalline structure of hydroxyapatite. LIBS spectra of the standard reflect an elemental profile that aligns with that of bone samples. Further, digital microscopy proves the presence of embedded crystals within a porous collagen matrix. Following the creation of a matrix-matched blank, trace elements of interest (Sr, Ba, Fe, Al, etc.) are incorporated at known concentrations into the material. Analytical validation of the elemental concentrations of these reference standards is performed using Inductively Coupled Plasma/Mass Spectrometry (ICP/MS) to build preliminary calibration curves. The results of this ongoing research show that critical steps are being made toward the production of a reliable, lab-synthesized reference material for bone. The development of such a material will benefit forensic practitioners in anthropology and archaeology through its ability to produce trustworthy quantitative elemental measurements from bone samples.

A88 An Examination of Volatile Organic Compounds Associated With Human Decomposition Byproducts in Soil

Savannah Struble, MS, Northern Michigan University Center for Forensic Anthropology, Olivet, MI; Jane C. Harris, PhD, Center for Forensic Anthropology, Northern Michigan University, Marquette, MI; Philip Yangyuoru, PhD, Northern Michigan University, Marquette, MI*

Learning Objectives: After attending this presentation, attendees will understand the complex issues and limitations associated with collecting, storing, and analyzing soil for the presence of Volatile Organic Compounds (VOCs) associated with human decomposition.

Impact Statement: This presentation will impact the forensic science community by presenting a novel means for testing soil for the presence of human decomposition byproducts and, more importantly, by highlighting the importance of appropriate sampling and analysis methodologies.

Abstract Text: VOCs are known to be released by all living organisms during life and after death. The presence of certain VOCs can serve as veritable signatures for specific types of organisms, for decomposition, and for human decomposition, particularly. This research was inspired by a question frequently asked by the law enforcement community—If I am looking for the remains of a missing person, but I don't know exactly where to look, what sort of non-invasive or minimally invasive detection technique(s) can be used to help narrow the search?

Samples for this research were collected from Cadaveric Decomposition Islands (CDIs) at the Northern Michigan University Forensic Research Outdoor Station (FROST), which remained visible to the naked eye after the donors who had been allowed to decompose in those locations had been recovered from the facility and relocated to the Forensic Anthropology Research Laboratory (FARL) for curation. Sample collection took place in November of 2022 and involved the collection of soil from CDIs that had held human donors at one time between 2018 and 2022. A total of 35 CDIs were sampled for this analysis. Some were as fresh as three days between the removal of the donor remains and collection of samples and as old as four years between donor removal and sample collection. Each soil sample was collected in a conical tube and submitted for gas chromatography/mass spectroscopy headspace analysis. Homogenized soil samples that were collected prior to the placement of any human remains at the FROST facility were analyzed as controls.

There are numerous complexities associated with the collection and storage of materials that are intended to be analyzed for the presence of VOCs. Results from this research were surprising in that even in locations where human decomposition byproducts were plainly visible and were still emitting significant odors detectable by the human nose, none of the CDI samples showed any significant difference from the pre-donor placement controls. This presentation focuses on the potential limitations of techniques used for sample collection, storage, and analysis for this particular approach to detecting VOCs and how these issues can and likely will affect the results and therefore, potentially, their value to the investigative community.

Decomposition; Volatile Organic Compounds; Soil Analysis

A89 Assessing the Micro- and Macroscopic Changes of Chemically Altered Bone

Shelby R. Feirstein, MS, University of Montana, Missoula, MT; Sara C. C. Zapico, PhD, New Jersey Institute of Technology/Smithsonian Institution, Newark, NJ; Luis L. Cabo, MS, Mercyhurst University, Erie, PA; Joe Adserias-Garriga, PhD, Mercyhurst University, Erie, PA*

Learning Objectives: Attendees of this presentation will gain a deeper understanding of the micro- and macroscopic alterations to bone that can be expected in scenarios in which human remains have been exposed to corrosive chemicals found in common household products. This is especially important in cases where perpetrators intend to obscure a decedent's identity through irrevocable harm, subsequently complicating the identification process.

Impact Statement: This presentation will impact the forensic community by describing the micro- and macroscopic changes occurring in skeletonized remains after exposure to common household chemicals. This research holds implications related to identifying taphonomically altered human remains and better understanding their taphonomic history.

Abstract Text: Forensic identifications may be hampered due to exposure to high chemical concentrations. Additionally, perpetrators search for unique ways of obscuring their victims' identities, such as readily accessible household corrrosive substances. Sodium hydroxide (NaOH), and hydrochloric acid (HCl) are known to change both the structural integrity and composition of skeletal elements. Both hydroxyapatite crystals and DNA become chemically modified by the pH of the depositional encironment.[1]

Chemical studies focus on total dissolution times, rather than on discrete changes over time. However, it is well documented that household corrosive substances are used to disfigure victims due to their high availability and apparent effects.[2] Sodium hydroxide (NaOH) is a corrosive base that effectively dissolves soft tissues and produces high temperatures through violent exothermic reactions, but ostensibly fails to alter the structure and color of bone. Hydrochloric acid (HCl, 31.45%) appears to be among the most destructive chemical agents with all biological tissue dissolving within 24 hours.[2] Studies are often difficult to compare, though, given the use of different brands and concentrations for experimentation.[1]

The aim of this study is to compare and analyze the micro- and macroscopic changes occurring in fully skeletonized remains exposed to household chemicals over the course of a maximum of two hours. Furthermore, this study intends to test how bone shape and volume to surface area ratios may affect the degree of alteration.

Hand bones, from three donated individuals, were exposed to three separate treatments: controlled fire, sodium hydroxide, and hydrochloric acid. Eight elements (carpals, metacarpals, and phalanges) were used for each treatment.

The chemical alteration protocol consisted of four intervals (total: 2 hours) with bone pairs being pulled every 30 minutes from their respective solutions (NaOH or HCl). The Power Crystal Lye Drain Opener (100%) was mixed into a 1:1 ratio (~25M) of 100g NaOH:100mL H20 per cup and the 100mL TransChem Muriatic Acid (31.45%) per cup was left undiluted. pH was tested after bone removal at each interval.

Pre- and post-treatment length, width, volume, and surface area data were recorded using the Artec Spider hand-held 3D scanner and bone weight was measured to the closest ±0.01g. Bones were examined and photographed with an Echo Revolve inversion microscope and Olympus SZX16 whole specimen microscope. All statistics were run using *GraphPad Prism 10*.

Bones soaked in NaOH showed changes in coloration and experienced minimal bone breakdown only after 1.5 hours. Changes in solution pH were minimal within the first hour but stagnated for the remainder of the experiment. The elements soaked in HCl showed changes within the first 30 minutes. The bony surface appeared crystalline and exhibited signs of cortical flaking and bone breakdown. The density of the bone appeared to be compromised after 1.5 hours, with a complete hollowing of the tubular bones after 2 hours. The solution pH remained unchanged throughout the experiment.

Surface area and volume displayed strong negative correlations, with bone surface area (and thus attack area) increasing as volume decreases. As expected, the relationship between these factors is not linear, and the results show a variable pattern of alteration depending on the treatment and duration of exposure. These observed trends provide justification for further analysis with larger sample sizes, longer durations, and more forensically significant conditions.. Additional research is currently ongoing to evaluate the possibility of DNA isolation and profiling.

Taphonomy; Forensic Analysis; Human Remains

A90 Bullet Grazing: Using Laser-Induced Breakdown Spectroscopy to Analyze Metallic Staining on Skeletal Remains

Morghan Montana Hogg, MS, Florida Gulf Coast University, Human Identify and Trauma Analysis Laboratory, Fort Myers, FL; Micki Besse, MS, Florida Gulf Coast University/Human Identity & Trauma Analysis Laboratory, Fort Myers, FL; Heather A. Walsh-Haney, PhD, Florida Gulf Coast University/Human Identity and Trauma Analysis Laboratory, Fort Myers, FL; Savanna Agilar, MS, Florida Gulf Coast University/Human Identity and Trauma Analysis Laboratory, Fort Myers, FL; Kevin Davies, PhD, Florida Gulf Coast University, Fort Myers, FL*

Learning Objectives: After this presentation, attendees will learn a new approach to evaluating materials that appear to be metallic staining on skeletal remains.

Impact Statement: This presentation will introduce the forensic science community to the detection of metallic intensities within potential metallic staining on skeletal remains using Laser-Induced Breakdown Spectroscopy (LIBS).

Abstract Text: Forensic anthropologists are not only tasked with creating a biological description of the decedent from skeletal remains, but they also provide information on antemortem pathologies and idiosyncratic traits, perimortem trauma, and postmortem change to help narrow down the parameters for positive identification of the decedent on behalf of the medical examiner/coroner. The use of LIBS can bring elemental analysis to forensic anthropological casework, like identifying metallic traces, formalin, and uniting isolated remains from mass fatality or commingled assemblages.[1,2] In recent years, LIBS has grown in popularity and has impressed scientists with its ability to perform spectral chemical analyses of organic and inorganic elements by utilizing a high-powered, minimally distractive pulsed laser that oblates the sample's surface, creating vaporized plasma for quantitative spectral analysis at various wavelengths (nm).[3] Though researchers and forensic laboratories are using LIBS to quantify typical qualitative observations (e.g., soil, ink, and glass discrimination), researchers have not addressed its ability to identify metallic elements from metallic oxidation staining on human remains.

In this case study, closed and redacted forensic anthological case reports and private anatomical donors from Florida Gulf Coast University's Human Identity and Trauma Analysis (HITA) laboratory where LIBS (System 150 Nano Series Pulsed Nd: YAG laser – RMA 0346-00) was used to detect traces of possible increased metallic properties on areas with presumed metallic staining were evaluated for this pilot study. Following the American Society for Testing and Materials (ASTM) and National Institute of Standards and Technology (NIST) standards, these skeletal fragments were examined for color change using the Munsell Soil Color Chart, consistent with the oxidation of copper, a common metal associated with firearm ammunition.[4,5] The LIBS pulsed the midpoint of the surface on the skeletal fragments and produced spectral analyses from 490nm to 730nm. The LIBS application software is linked with the NIST spectral standards library. The instrument identified peaks of Copper (Cu) and Lead (Pb) in the discolored bones—a finding consistent with bullets. The intensities (au) between the stained bone and the controlled sample without staining trended in a positive correlation ($r = 0.805$, $p = 0.015$; $r = 0.995$, $p < 0.001$; respectively) and suggested that there are statical differences between remains that had contact with oxidized metallic fragments. This study revealed that LIBS could detect increased metallic intensities on skeletal elements, bringing quantified analyses to forensic anthropological casework and deepening the identification of perimortem trauma.

Skeletal Remains; Metallic Staining; LIBS

A91 An Analysis of Color Changes in Thermally Altered Bones Using Spectrophotometery

Chelsey A. Juarez, PhD, California State University Fresno, Fresno, CA; Nicole M. Saenz, MS, California State University Fresno, Fresno, CA; Alison Galloway, PhD, University of California Santa Cruz, Volcano, CA; Elayne J. Pope, PhD, Fatal Fire Forensics, Knoxville, TN*

Learning Objectives: After attending this presentation, attendees will understand the need for renewed discourse, research, and standardized data collection for characterizing different heat-related color changes observed on burned human remains and bones in a forensic context. In this research we applied a spectrophotometer to burned bone samples to standardize the interpretation and communication of color changes in burned bones. Spectrophotometers can definitively identify colors and their components (density) and using the LAB color system can identify and quantify (ΔE) the difference between colors.

Impact Statement: This presentation will impact the forensic science community by discussing the standardization of assessing thermally altered burned bone color changes. Transitional colors develop superficially from the thermal decomposition of bone's organic tissues within the mineralized inorganic skeletal matrix.

Abstract Text: It is well established that color changes in thermally altered bones from forensic contexts cannot and should not be used to estimate maximum temperature ranges of the fire.[1-6] While color changes in burned bone cannot be reliably linked to temperature, they are indicators of thermal decomposition at the cellular level and thus differences in color are indicative of altered levels of in/organic degradation and destruction. In 2022, Pope, Juarez, and Galloway published a classification system for thermally altered human remains with forms for charting in situ burning damage.[2] This work is an extension of that classification system, providing a more nuanced understanding of bone color changes, and standardizing data collection applications of color changes for charting and data collection.

Ten fragments of burned bone were selected, measurement locations were identified using metric measuring tape with light adhesive backing applied to bone surfaces with distinct color changes. Bones were measured at 0.5cm intervals through the entirety of the color transition from unburned bone through either carbonization or calcination using a Nix Spectro 2 31 channel spectrophotometer. The spectrophotometer identified each data point as a specific color reporting a spectral curve, density readings, and LAB, CMYK, and RGB data. Five bones were retested within each visually distinct burned region (e.g., carbonization, calcination, etc.) five times using the Nix toolkit software quality control to test reproducibility (N=67 points). Regions between bone samples that appeared visually similar (e.g., carbonized, calcined) were also compared using the same methodology (N=25).

N=338 individual scans along the selected demarcated linear paths were made, and N=332 individual colors (ΔE=0) were identified between all samples. Reclassification of five study fragments had mixed combined results with 17.9% error. However, some fragments performed much better on reclassification with 0% error. When bones that appeared visually similar (appeared to have the same color) were compared across specimens, similarity was confirmed in only 20% of cases.

In the initial identification of colors, hundreds of colors were identified by the spectrophotometer, indicating both instrument sensitivity and also the depth of the range of color changes. Bone colors are evidence of the direction of fire and the level of bone alteration. Currently our discussions and descriptions of color are vague and unreliable. The use of a spectrophotometer allows us to standardize the discussion and description of color changes and provides a more nuanced understanding with mineable data for researchers. Repositories of cataloged color spectrums for burned bones can be shared and accessible to larger international libraries. The Nix Spectro 2 has a highly sensitive 2mm aperture, thus exact repositioning is critical for accurate reclassification. The higher-than-expected combined reclassification error for all tested fragments reflected positioning errors rather than instrument error, which was tested via calibration between samples. Future work using the spectrophotometer may provide a range of colors that can be classified as "carbonized" or calcined with shareable libraries providing researchers with detailed spectra to investigate.

Burned Bone; Color; Spectrophotometer

A92 The Statistical Relationship of Breakaway Spurs and Notches With Saw Class Characteristics in Experimental Dismemberments

Brigham D. McKay, BS, Des Moines University School of Osteopathic Medicine, West Des Moines, IA; Stephanie J. Cole, PhD, Des Moines University, West Des Moines, IA; Heather M. Garvin, PhD, Des Moines University, West Des Moines, IA; Meghan M. Gast, BS, Des Moines University, West Des Moines, IA*

Learning Objectives: Following this presentation, attendees will understand the statistical relationship between bony breakaway spurs and notches and saw class characteristics.

Impact Statement: This presentation will benefit the forensic science community by presenting statistical results from experimental dismemberments highlighting the potential utility and limitations of breakaway spurs and notches in forensic anthropological case interpretations.

Abstract Text: Bony breakaway spurs and notches that result from human dismemberments have been suggested to indicate saw power, with mechanically powered saws reportedly producing more and larger spurs/notches given their weight, torque, and force.[1] Experimental research supporting this relationship, however, is limited and many studies utilize de-fleshed bones and vices to stabilize the bones, creating a potentially different biomechanical environment than what one would expect in a forensic case. This study aimed to statistically investigate the relationship between breakaway spurs/notches and saw characteristics using two samples: a de-fleshed, viced sample and a fleshed free-sawing sample. Complete cuts were assessed from samples created by researchers at Mercyhurst University (n = 182; de-fleshed humeri and femora in vices) and Des Moines University (DMU) (n = 239; fleshed lower limb bones cut using a free-sawing methodology). A total of 33 hand or mechanical reciprocating saws were utilized. Breakaway spur and notch presence/absence were documented for each complete cut. When present, breakaway spur/notch length and width were recorded. These data were compared to sample, saw power, teeth-per-inch, tooth set, tooth shape, and cortical bone thickness using chi-squared tests, non-parametric Analysis of Covariance (ANCOVA), Mann-Whitney U tests, and correlation analyses

After removing outliers, the total sample size was 349 cuts. Chi-squared tests indicated significant differences in the frequency of breakaway spurs and notches between the Mercyhurst and DMU samples. Mercyhurst had breakaway spurs in 77.5% of the sample but only 37.5% displayed notches (some displayed a combination of spur/notch). DMU had spurs in 31.2% of the sample and notches in 52.4% of the sample. There were also significant differences in cortical thickness, spur width, and notch width between the samples ($p < 0.05$). Quade non-parametric ANCOVA results suggest that the group differences in spur/notch measurements remain even after considering cortical thickness as a covariate ($p < 0.05$). It is challenging to interpret the sample differences, as they could be related to fleshed/de-fleshed samples, sawing methodology, or specific saws utilized, and the current study is restricted to the published data from the Mercyhurst project. If analyzing the DMU sample in isolation, chi-squared analyses indicate no significant differences in spur/notch frequency with power, but significant differences in tooth shape (more likely to occur with rip saws). Mann-Whitney U tests indicate significant differences in cortical thickness between breakaway spur presence/absence groups ($p = 0.027$), but not breakaway notches ($p = 0.907$). Interestingly, when spurs/notches were present, significant correlations were found between cortical thickness and spur/notch size, as well as significant effects of power on spur/notch sizes ($p < 0.05$).

These results suggest that tooth shape (rip versus crosscut) influences breakaway spur/notch presence more so than power. If present, power and cortical thickness affects the size of the spur/notch. Interestingly, no significant relationships were found if the Mercyhurst sample was analyzed in isolation. This discrepancy highlights possible differences in the use of fleshed free-sawing and de-fleshed viced samples, which may be explained by the different biomechanical forces at play in the two different cutting circumstances. Additional research is underway to test a DMU de-fleshed and viced sample that is matched by saw and donor to the fleshed sample to control for all variables except sawing methodology.

A93 Damage to the Thorax From CPR and Vulture Scavenging: A Case Presentation From the University of South Florida Donated Skeletal Collection

Tuesday M. Frasier, MS, Florida Institute of Forensic Anthropology & Applied Science, Tampa, FL; Erin H. Kimmerle, PhD, University of South Florida, Tampa, FL*

Learning Objectives: This poster will present the case of a donor from the University of South Florida (USF) Donated Skeleton Collection that presented damage to the rib cage from both chest compressions and postmortem damage caused by vultures. Following this presentation, attendees will be able to use biomechanics to differentiate between injuries occurring in the perimortem interval and those created postmortem by vultures while bone is still wet.

Impact Statement: This case presentation highlights the importance of both biomechanics and forensic taphonomy in forensic investigations. This presentation will impact the forensic community by highlighting how the successful application of biomechanics can be used to differentiate a fractures origin.

Abstract Text: Vultures are prolific scavengers and have great potential to modify not only death scenes, but the physical body as well. Studies at other outdoor research facilities have shown that vulture scavengers can cause fractures to skeletal elements such as the ribs and scapulae.[1,2] Defects created by vultures can present a challenge in determining the timing of the injury depending on the wetness of the bone. In cases where remains are already skeletal, cause and manner of death may be impossible to determine without physical evidence on the skeleton. Decedents that are scavenged may present injuries that have the appearance of occurring perimortem with no other evidence of trauma, which may confuse cause and manner of death. For this reason, the value of taphonomy in forensic investigations cannot be underestimated, as many taphonomic alterations have the potential to be misinterpreted providing different context for the current condition of the remains.

The purpose of this study is to demonstrate how fractures created through perimortem trauma and vulture scavenging can be differentiated using a foundation in biomechanics. A donor was selected from the USF Donated Skeleton Collection and presented with both perimortem trauma to the thorax and extensive vulture scavenging throughout the body. The donor selected for this case study was a 67-year-old, White female whose cause of death was a combination of cardiomyopathy, respiratory arrest, sepsis, and congestive heart failure. In the perimortem interval, cardiopulmonary resuscitation was attempted, which was evident upon intake and placement. Bruising to the chest was observed, and following decomposition, fractures to the sternal body, left second, third, fourth, fourth, fifth, sixth, seventh, and eighth ribs and second, third, fourth, and fifth right ribs were observed. These fractures generally presented as complete fractures to the sternal third of the rib excluding the left third rib, which also had a complete fracture at the angle. The sternal body presented both incomplete and complete fractures. The force loaded upon these elements came from anterior as evidenced by where the bone ultimately failed. This donor was placed on the surface at the USF Facility for Outdoor Research and Training (USF-FORT) for 119 days. While placed at the USF-FORT, this donor was scavenged 11 times, which first occurred 12 days following placement. At analysis, the donor presented several defects throughout the body that were indicative of vulture scavenging, which included punctures to the sacrum, os coxae and the cranium from vulture beaks. An incomplete fracture was observed on the caudal surface of the first rib on the sternal third of the rib. Although this fracture appeared to occur during the perimortem interval, the position of the fracture suggests that its source was different from the other observed fractures. The fracture occurring on the caudal surface is indicative of tension occurring on that surface which is not consistent with the direction of force used during chest compressions. This could be the result of either vultures pulling on the first rib, creating tension on the caudal surface, or the weight of vultures standing upon it following disarticulation. Through the synthesis of biomechanics and forensic taphonomy, the true origin of fractures can be differentiated even in cases where both occur.

A94 Squirrels in the Desert: Regional Scavenging Patterns

Alexander J. Smith, BA, Colorado Mesa University, Grand Junction, CO*

Learning Objectives: After attending this presentation, attendees will understand the importance of considering environmental context in cases with scavenging activity.

Impact Statement: This presentation will impact the forensic science community by applying ecological data to better understand a less common scavenger.

Abstract Text: Scavenger activity can be heavily influenced by the local environment.[1] When resources are limited, animals are more likely to scavenge remains they discover and may consume more tissue.[1] Marginal environments, where resources are limited, may further emphasize these differences. The Forensic Investigation Research Station (FIRS) at Colorado Mesa University is in an environment that fits this description, a cool semi-arid steppe (BSk).[2] The FIRS facility studies the decomposition of human remains and the influence of the local environment on that process. The facility's surroundings are limited in water and food resources for local scavengers.

Rock squirrels (*Spermophilus variegatus*) are ground squirrels common in the American southwest and Mexico.[3] They are diurnal with active times that shift with seasonal temperature changes.[4] While most of their diet consists of plant material (e.g., berries, seeds, nuts, green vegetation), rock squirrels also eat insects and other animals (both carrion and prey).[3] Generally, rock squirrels are not selective in food choice during the early spring but discriminate more as resource availability increases later in the year.[4]

Over the span of seven days in March 2024, a rock squirrel scavenged soft tissue from the right arm of a 42-year-old female in early decomposition. Scavenging impacted skin and fat from the inner right elbow. There was minimal impact to muscle tissue and bone was not exposed. The squirrel scavenged exclusively in daylight, visiting the body one to three times per day for up to 16 minutes at a time. While rock squirrels do scavenge, this is not a large part of their diet.[3] Generally, rock squirrels target smaller animals (e.g., rodents, rabbits, birds), but given the time of year and limited resources in the surrounding area, scavenging human remains may be expected.[4]

A similar species, the eastern gray squirrel (*Sciurus carolinensis*), also supplements a predominantly plant-based diet with carrion.[5] When it comes to human remains, the eastern gray squirrel generally gnaws bone rather than consuming soft tissue.[5] This difference in scavenging behavior between the two species may relate to a drastic difference in habitat. While rock squirrels tend to live in marginal environments where resources are often limited, eastern gray squirrels tend to live in eastern woodlands, where resources are relatively plentiful. Limited resources may require rock squirrels to opt for a more diversified diet (including human soft tissue) to survive. Conversely, gray squirrels may not need the nutrients provided by moist soft tissue and so generally choose to only supplement their diet by gnawing bone.

Scavenger ecology is essential to understand how a scavenger may affect an investigation. Local environments can significantly impact which species live in an area and their behavioral patterns. Resource limitations, either temporary or persistent, can impact whether animals elect to scavenge, what they choose to scavenge, and how much they consume. Animals in marginal environments are likely to present different scavenging patterns than their counterparts in resource-rich environments. This all contributes to a scavenger's interactions with human remains. More research into the variation in scavenger behavior across environments can better inform on the potential impact of scavengers on a forensic investigation.

A95 Recovery Rates of Teeth From Outdoor Surface Contexts in Louisiana

Ginesse Listi, PhD, Louisiana State University, Baton Rouge, LA*

Learning Objectives: This presentation provides dental recovery rates for outdoor rural and suburban residential contexts in Louisiana and examines variation in recovery rates according to dispersal, who collected the remains, and estimated Postmortem Interval (PMI). After attending this presentation, attendees will better understand the recovery rates of different tooth types and how variables of interest affect their recovery.

Impact Statement: This presentation will impact the forensic science community by providing recovery data for different tooth types from forensic anthropology casework from outdoor contexts in Louisiana and by addressing how dispersal, estimated PMI, and who collects the remains affect recovery rates.

Abstract Text: Teeth are critical in forensic anthropology for identification, estimating sex, age, and population affinity if other skeletal elements are missing, and signifying nutrition, socioeconomic status, and cultural habits. Haglund writes that teeth recovery is affected by taphonomic processes, and that single rooted teeth may be lost postmortem more frequently, or recovered in lower frequencies, than other tooth types.[1] Empirical data on the recovery of different tooth types are not available.

The current study: (1) provides teeth recovery rates for cases from Louisiana; and (2) examines variation in recovery according to dispersal, estimated PMI, and who collected the remains. Data were gathered from case files at the Louisiana State University Forensic Anthropology and Computer Enhancement Services (LSU FACES) Laboratory. Cases included in this study (N=168) were recovered between 1980–2024 from outdoor surface contexts in rural or suburban residential areas. Tooth data were collated from dental inventories. Other variables, including whether the remains were dispersed or non-dispersed, the minimum and maximum estimated PMIs ($PMI_{e\text{-}min}$, $PMI_{e\text{-}max}$), and who collected the remains, were gleaned from case files.

All Teeth and Tooth Positions (TTP) were recorded as present, Lost Antemortem (AMTL) or Postmortem (POML), or Not Available (NA); AMTL and NA TTP were excluded from analysis. Descriptive statistics were calculated by tooth type for the maxilla, mandible, and full dentition, for the collective sample, and for dispersed and non-dispersed subsamples. Standardized variables were calculated to account for different numbers of tooth types, and inferential statistics were used to assess variation in the potential for TTP recovery (i.e., "availability") and rate of POML, for all subsamples and among other variables of interest. The alpha value for determining significance was .05.

Three thousand seven hundred ninety-four TTP were recorded, of which 744 (~20%) were lost postmortem (%POML). For the collective, maxillary, and mandibular samples, availability (i.e., the potential for recovery) varied among tooth types, but differences were significant only between molars and other tooth types. Overall, canines had the highest availability (n=559/672, 83%), molars the lowest (n=1136/2016, 56%). Conversely, differences in %POML were significant for all categories except between canines and premolars. Generally, incisors had the highest %POML (n=378/1086, 35%), molars the lowest (n=64/1136, 6%).

Between dispersed (D, n=1,981) and non-dispersed (ND, n=1,815) subsamples, significant differences in availability were found only for mandibular molars, canines, and incisors. Again, canines had the highest availability (n=295/364, 81% (D), n=264/308, 86% (ND), molars the lowest (n=584/1092, 54% (D), n=552/924, 60% (ND)). Regarding %POML, significant differences were found for all categories of data except mandibular molars. For both D and ND samples, incisors had the highest %POML (n=286/564, 51%; n=92/522, 18%, respectively), molars the lowest (n=42/584, 7%; n=22/552, 4%, respectively).

Because dispersal affected %POML, the effects of estimated PMI and who collected the remains were assessed separately for D and ND samples. For PMI_{emin}, significant differences in availability were found for the ND mandibular premolars, canines, and incisors, and for PMI_{emax}, the ND collective canines. Regarding %POML, significant differences were found for D collective incisors for PMI_{emin}, and ND mandibular canines for PMI_{emax}. Regarding who collected the remains, no significant differences were found in ND samples for availability or %POML; however, significant differences were found in D samples in availability of mandibular premolars and canines, and in %POML for collective and maxillary samples.

In conclusion, results support the supposition that single rooted teeth are lost more frequently than teeth with more complex roots, a situation exacerbated when remains are dispersed or collected by personnel less familiar with teeth. Alternatively, in this study, estimated PMI appeared to have more of an effect on the *potential* for recovery than the actual recovery.

A96 Assessing the Effectiveness of Alternative Light Sources in the Search for Skeletal Remains

Olivia L. Thompson, BS, Virginia Commonwealth University, Richmond, VA; James Russell, BFA, Virginia Department of Emergency Management, Virginia Beach, VA; Tal Simmons, PhD, Virginia Commonwealth University, Richmond, VA; Stephen Stockman, MPA, Virginia Commonwealth University, Richmond, VA; Jenise Swall, PhD, Virginia Commonwealth University, Richmond, VA*

Learning Objectives: The information disseminated through this presentation will reveal the success and feasibility of locating human skeletal remains in wooded environments using various Alternative Light Sources (ALS).

Impact Statement: Comparison of daytime search methods to nighttime searches with ALS resulted in significant differences in recovery rates, suggesting that this research will prove advantageous to those regularly involved in searching for whole and/or fragmentary human skeletal remains.

Abstract Text: Thousands of Americans are reported missing every year due to accidental events, mental health crises, or criminal activities. In many instances, law enforcement, search and rescue groups, dog handlers, and members of the community are confronted with the task of locating deceased individuals. The recognition and recovery of human skeletal remains in outdoor environments is difficult, and often searches in this context are unsuccessful even when evidence points to an individual's last known whereabouts.

Many types of biological evidence fluoresce under incident light, and ALS techniques are often used at the crime scene and in the laboratory to assist in the discovery of latent body fluids. Although the collagen component of bone is known to emit fluorescence at certain wavelengths, this property has yet to be leveraged consistently during searches for human skeletal remains.

A small study conducted by Brown and Christensen showed that nighttime searches with blue (455nm) ALS recovered significantly more bones than daytime searches; however, a wider range of wavelengths should be tested through a larger series of searches to draw distinct conclusions.[1] Still, it is suggested that the application of specific wavelengths to bone creates a distinctive appearance that is not achievable with the naked eye and that nighttime searches with ALS devices produce vastly improved results over those conducted during daylight hours.

A series of 36 mock searches were performed by volunteers of search and rescue agencies from across the Commonwealth of Virginia. Thirty bones of three size classes were placed in 5,000ft^2 zones; each zone had significant groundcover of fallen leaves and/or low vegetation. Bones were randomly scattered and partially concealed by leaf cover. Pairs of searchers, supplied with various ALS devices (from 385-530nm, ultraviolet to green light) and wavelength-appropriate goggles (clear, yellow, orange, or red, were allotted up to one hour to search in their usual pattern. Daytime searches were conducted under the same parameters, without ALS. To protect the health and safety of the volunteers, light sources requiring red goggles were discontinued after two searches as the red barrier goggles significantly impaired the searchers' awareness of environmental obstacles. Results indicate that: (1) nighttime searches with ALS produced a recovery rate more than twice that of daytime searches and were often finished in half the time of those performed in the daytime; and (2) ALS in the purple-blue light range were the most effective in locating skeletal remains of all sizes. The 395-425nm Crime-lite^{Ò} was superior as it both had a wider berth of illumination and elicited the most distinct fluorescent response from the bones compared to ~450nm blue lights (Crime-lite^{Ò}, ForenScope, and Labino AB) and the 385-395nm ultraviolet light (uvBeast). It is suggested that nighttime searches with ALS can be used both as the primary search method for the location and recovery of human skeletal remains and as a secondary method for recovering any bones expected to be present but not found during daylight searches.

A97 Standard Operating Procedures for Forensic Anthropology at Accredited United States Laboratories: A Preliminary Assessment

Marion E. Davidson, MS, University College London, Ellicott City, MD; Allysha P. Winburn, PhD, University of West Florida, Pensacola, FL; Jeff Kukucka, PhD, Towson University, Towson, MD*

Learning Objectives: After attending this presentation, attendees will have a better understanding of the existing heterogeneity in the standard operating procedures and quality assurance protocols designed specifically for forensic anthropological analysis at laboratories that are housed in ANAB-accredited facilities.

Impact Statement: This presentation will impact the forensic science community by presenting the findings from a small, preliminary assessment of available forensic anthropology standard operating procedures. This presentation will assist in the discussion around the continuous professionalization of forensic anthropology, specifically in how ANSI National Accreditation Board (ANAB) -accredited laboratories work to ensure quality and reliability in their forensic judgments and decisions.

Abstract Text: Recent discussions have included the topics of education, accreditation, certification, and qualification in regard to the growth of forensic anthropology as a discipline. Additional reports and research have highlighted the potential concern for the production of accurate, reliable, and repeatable judgements, including those impacted by irrelevant contextual information producing susceptibility to issues of cognitive bias. In response, forensic anthropologists and associated laboratories are diligently and consistently working to develop and improve standard operating procedures, best practice recommendations, and quality assurance protocols to improve the reliability of forensic decisions.

The aim of this pilot study was to assess both the uniformity and the variability of Standard Operating Procedures (SOPs) at multiple forensic anthropology laboratories. As an initial assessment, this preliminary research focused only on laboratories that were actively accredited under the ANSI National Accreditation Board at the time of data collection. SOPs, quality assurance protocols, and training manuals were either accessed as publicly available documents or were requested directly from the laboratory. These documents were examined overall, individually coded for the presence of various practices, and assessed for a better understanding of the nature of these practices. For example, this research considered the existing types of SOPs, the required proficiency testing, and the cognitive bias mitigation methods.

Preliminary results indicate heterogeneity at several structural levels, including the number of published SOPs and quality assurance manuals as well as the level of detail contained in the individual documents. There is also variation in the specific accreditation of the lab (e.g., **International Organization for Standardization** [ISO] 17020 vs. ISO 17025) and the scope of any additional certificates other than anthropology (e.g., odontology, scene investigation), which can impact the necessity for particular SOPs. Analyzing forensic anthropology SOPs at accredited United States laboratories can assist in discussions around the professionalization of the field and standardization of anthropological analysis. In the future, this data collection procedure can be repeated at other laboratories, including those with a sole practitioner, which can potentially stimulate discussions around improving the reliability of forensic judgements in laboratories that are substantially limited by physical constraints. Additionally, the coding system employed in this research is modeled after a similar analysis in friction ridge examination and was developed in tandem with another study examining SOPs in firearm and toolmark examination. This purposeful communication between disciplines allows for a cross-disciplinary discussion around variability and improvement in forensic laboratory procedures.

Forensic Anthropology; Standard Operating Procedures; Quality Assurance

A98 An Evaluation of the Forensic Anthropology DEIB Peer Engagement Program

Erin B. Waxenbaum, PhD, Northwestern University, Evanston, IL; Jaymelee Kim, PhD, Wayne State University/Wayne County Medical Examiner's Office, Detroit, MI; Rebecca L. George, PhD, Western Carolina University, Cullowhee, NC; Helen M. Litavec, PhD, Harris County Institute of Forensic Sciences, Houston, TX; Jesse R. Goliath, PhD, Mississippi State University, Mississippi State, MS; Vanessa C. Reeves, MA, University of South Florida, Tampa, FL

Learning Objectives: After reviewing this research, attendees will appreciate the specific benefits a peer mentoring program provides for those in the field of anthropology, a particular concern for maintaining and growing diverse representation in the field. Recommendations for improving the current program model are presented.

Impact Statement: This research will impact the scientific community by demonstrating how competency and performance can be improved through Peer Engagement (PE) programs. A PE program has the capacity to significantly impact the development of individuals and increase the retention of historically underrepresented groups. In particular, PE can allow each participant to contribute to the development of one another and ensure that all thrive in forensic anthropology by: (1) exposing one another to the diverse spectrum of professional work and research in forensic anthropology, biological anthropology, and related fields; (2) providing a window through which to view professional roles, obligations, and expectations; (3) serving as role models and advocates for one another; (4) offering advice and guidance; and (5) engaging in dynamic conversations regarding professionalism, challenges, and milestones of the field. The insight shared is invaluable to the professional development of the whole. In turn, active engagement also exposes us to new perspectives, experiences, and ideas.

Abstract Text: In recent years, forensic anthropology has faced substantial criticism regarding its support structures (or lack thereof) for early-career professionals, Black, Indigenous, and People Of Color (BIPOC) individuals, and historically marginalized groups. Concurrently, scholarly interest in this field has burgeoned, evidenced by a proliferation of publications across anthropological, forensic, and scientific domains.[1-6] These issues underscore the need to develop means for fostering Diversity, Equity, Inclusion, and Belonging (DEIB) in the field of forensic anthropology.

Addressing these concerns, a group of anthropologists hypothesized that a PE program could provide DEIB benefits to participants and introduced the Forensic Anthropology Diversity, Equity, Inclusion, and Belonging Peer Engagement Program (FA DEIB PEP) in June 2022, operating independently from established professional bodies. Participation in FA DEIB PEP was actively sought through various networks (e.g., the Forensic Anthropology listserv, personal communication, etc.). This initiative is designed as a voluntary platform open to forensic anthropologists at all career stages, from aspiring undergraduates to seasoned practitioners worldwide. The inaugural cohort of FA DEIB PEP comprised 29 participants encompassing a spectrum of roles, including students, full-time practitioners, academic researchers, and part-time consultants in forensic anthropology. Following the program's first year, a brief survey (IRB #STU00219722, Northwestern University) of PE participants was conducted to assess the impact and efficacy of their participation.

Purposive sampling was used to target program participants. Twenty-two individuals participated in the survey, which collected quantitative categorical data and qualitative data—54% of respondents have ten or less years' experience in forensic anthropology, while 45% had greater than ten years' experience. Eighteen percent of respondents were board certified in forensic anthropology, 27% held doctorates, 36% held master's degrees, and 18% held bachelor's degrees. Fifty percent of respondents noted that they held marginalized identities. Participants were asked about their personal experience with the program to date and suggestions for improvement. Quantitative data is analyzed in MS Excel and qualitative data is coded in MS Excel to identify themes.

Findings support the hypothesis that PE can positively impact perceptions of DEIB and benefit the field of forensic anthropology. Thematically, respondents noted benefits such as receiving advice and professional support, expanding one's professional network across regions/ranks/career paths, gaining new perspectives, and exposure to professional opportunities. These affirmative themes support the hypothesis that PE and support have the ability to significantly impact the development of individuals, promote inclusion and diversity, and increase the retention of historically underrepresented groups. Plans to broaden this initiative and improve the current FA DEIB PEP model will be discussed.

A99 The American Academy of Forensic Sciences Ad Hoc Committee on Vicarious Trauma

Katharine C. Pope, MA, RTI International, Fruitland, MD; Brian J. Gestring, MS*, 4n6Services, Guilderland, NY; Kathryn C. Seigfried-Spellar, PhD, Purdue University, West Lafayette, IN; Krista E. Latham, PhD, Human Identification Center, University of Indianapolis, Indianapolis, IN; Uzoma A. Okafor, PhD, Albany State University, Albany, GA; Gary C. McDonald, Jr, JD, Dallas County Criminal District Attorney's Office, Dallas, TX; Joseph Remy, JD, Atlantic County Prosecutor's Office, Mays Landing, NJ*

Learning Objectives: Attendees will be updated on the current activities of the AAFS Presidential Ad Hoc Committee on Vicarious Trauma and will be invited to join a greater discussion about the potential effect of vicarious trauma on forensic practitioners.

Impact Statement: Vicarious Trauma (VT) potentially impacts forensic practitioners' mental and physical health. This presentation will raise awareness about VT in forensic practice and highlight resources available to Academy members to develop resiliency and healthy coping mechanisms.

Abstract Text: VT is the cumulative effect of exposure to information about traumatic events and experiences. VT was first recognized in the early 1990s by mental health professionals who recognized that they were being affected by the trauma of their patients.[1] Today, it is described as an occupational challenge for those working in victim services, first responders, and emergency room personnel.[2] The work of forensic providers has only recently been considered a source of VT.[3] Each section of the Academy has members who are regularly exposed to traumatic content in distinctly different ways and with differing levels of exposure. To date, there have been no comprehensive studies evaluating how these differing levels of exposure influence VT or how to mitigate its effects. While research continues, AAFS President Laura Fulginiti proactively created an ad hoc committee on vicarious trauma to evaluate resources to assist Academy members in safeguarding their mental health and increasing their resilience. Under AAFS Presidents Ken Williams and Chris "Kip" Thompson, the Academy continues to support this mission. In 2023, Academy members were offered access to one month of free counseling through BetterHelp, a web-based counseling service that connects Academy members with licensed therapists across the country.

The committee is taking a multifaceted approach to addressing VT in the forensic community, starting with increasing awareness with discussions across and within sections. Many members may be unaware of how VT can negatively impact their professional and personal lives. They may even be unaware that they are experiencing it. Through the AAFS newsletter and presentations such as this one, the committee will detail the emotional challenges that forensic professionals can experience and coping mechanisms that can help reduce the risks of exposure.

Academy members will learn how to access resources currently available to them as well as resources that other professions have been able to use successfully. The committee aims to create a survey to identify the different mechanisms by which Academy members are exposed to VT and if their agencies have policies or resources available to address it.

A100 The Development of a New Pedagogy: The Professional Diploma in Forensic Archaeology at the National Forensic Science University, Gandhinagar, Gujarat, India

Gargi Jani, MSc, National Forensic Sciences University, Ahmedabad, Gujarat, India; William R. Belcher, PhD*, University of Nebraska-Lincoln, Lincoln, NE*

Learning Objectives: After attending this presentation, attendees will understand the importance of pedagogical development related to a major component of forensic investigative work, forensic archaeology, in the world's largest democracy, India.

Impact Statement: This presentation will impact the forensic science community by examining the development of an important subdiscipline in forensic anthropology within a South Asian context. This will contribute to the importance of forensic archaeology in a more global context.

Abstract Text: The curriculum related to a professional certification/diploma has been developed and started at the National Forensic Science University (NFSU) in the Gandhinagar campus, Gujarat. This certification has been in the planning stages for the past two years as a cooperative/trilateral agreement between the NFSU, the University of Nebraska-Lincoln, and the United States Department of Defense's Defense POW/MIA Accounting Agency (DPAA). The primary impetus of this program was a small cooperative excavation of a United States World War II-era B-29 bomber crash in the northeastern part of India in the State of Assam. The program is currently open to professionals in forensic, law enforcement agencies, and judiciary officers as well as for students who have graduated or are at the Master's level.

NFSU is an international-level university with the headquarters in capital of Gujarat, Gandhinagar, established by Government of India (GoI) through Act 2020(32 0f 2020) and is classified as an Institution of National Importance under the Ministry of Home Affairs (MHA), GoI. There are currently nine satellite campuses of NFSU in India and one international campus in Jinja, Uganda. Being the world's first and only one-of-its-kind university, the school was established with the vision and mission to meet the acute shortage of forensic experts by imparting education in various branches of forensic and investigative sciences. That said, the expansion of investigative and forensic sciences to include forensic archaeology is an obvious gap that will be filled with the teaching and practical exercises associated with the Professional Diploma in Forensic Archaeology.

This curriculum is composed of five modules that span a six-month period. The first module includes basics of forensic science, different branches of forensic science and understanding the Constitution, criminal justice system, and legal system of India. A module on forensic archaeology includes basics and definitions of forensic archaeology and understanding the criminal investigative aspects in archaeology and medicolegal exhumations. A module on forensic anthropology includes basics of forensic anthropology, comparative identification, the biological profile, and taphonomy. Practical modules include exercises that culminate in a project-based investigation and excavation associated with actual forensic archaeological material, and/or a project with investigating or excavation a World War II-era United States aircraft loss incident.

While India has a long history of archaeological endeavors on both the federal and state levels, the implementation of a forensic archaeological program and training has not been part of any scholarly or practical curricula till now. This Professional Diploma in Forensic Archaeology is the first of its kind in India and has become widely recognized among professional archaeologists and incoming students at the NFSU. The developed curriculum is approved by the Board of Studies of School of Medico-Legal Studies (NFSU), after which it was approved by the Academic Council of NFSU. The program offers 22 credits with 30 hours/week of teaching, laboratory, and tutorial work. The program spans over 6 months with a combination of online and offline classes.

Forensic Archaeology; Missing Persons; International

A101 Applying Multidisciplinary Methods to Forensic Casework in North Carolina

Nicole Long, MSCJ, North Carolina State University, Cary, NC; Devin N. Williams, MA, North Carolina State University, Raleigh, NC; Ann H. Ross, PhD, NC State University, Raleigh, NC*

Learning Objectives: Attendees will learn about the multidisciplinary approach to the investigation of Unidentified Decedents (UIDs) at the North Carolina State University Human Identification and Forensic Analysis Laboratory (NCSUHIFAL). The methods applied include anthropological analysis and population affinity estimation using 3D-ID, investigative genetic genealogy, and isotopic analyses. Several case studies will be presented that highlight this approach.

Impact Statement: This study will impact the forensic science community by providing examples of the framework for applying a multidisciplinary approach to casework as well as discussing the limitations and barriers encountered in the process. The decision-making procedure for implementing this approach will also be addressed.

Abstract Text: As of June 12, 2024, there are 161 unidentified persons cases listed in the National Missing and Unidentified Persons System (NamUs) for the state of North Carolina. A multidisciplinary approach has been adopted by NCSUHIFAL, state medical examiner's offices, and law enforcement to address this crisis.[1] Modern methods of skeletal analyses are employed when developing a biological profile (e.g., biological sex, age at death, stature, and population affinity) for UIDs, radiographic comparisons for identification, and trauma analysis, to assist medical examiner offices. Additional techniques are employed to develop standard operating procedures for North Carolina casework. In 2019, an interinstitutional grant funded the implementation of a holistic approach to identification involving standard forensic anthropological analysis, Investigative Genetic Genealogy (IGG), and isotopic signatures.[1]

More recently, NCSUHIFAL has partnered with the NC State Bureau of Investigation on a grant funded by the Bureau of Justice Assistance under their Missing and Unidentified Human Remains (MUHR) program in 2023 to advance the multidisciplinary approach to reduce the backlog of unidentified cases in North Carolina. Results from 17 cases sent for FGG have resulted in ten positive identifications, of which five also applied isotopic analyses. Here, we present the results of isotopic investigations from three of those cases using geolocation and dietary isotopes, anthropological analyses, including population affinity estimation using 3D-ID , and investigative genetic genealogy.[2] This presentation aims to highlight the multidisciplinary approach and to show the added value of using advanced testing in forensic anthropology casework in North Carolina.

A multidisciplinary approach in the investigation of UIDs applies a variety of scientific methods that have led to successful identifications using anthropological analysis including population affinity estimation using 3D-ID, investigative genetic genealogy, and isotopic analyses. Results from one scientific method can inform other investigative aspects by providing supplementary information about the decedent thus, enhancing the investigation and the probability of a positive identification. However, both population affinity and isotopic analyses rely on reference data with which to compare individual measurements or values. The continued collection and publication of these data are essential to obtain global coverage.

The three case examples selected for this presentation were recovered in Mecklenburg County, NC. Two of the individuals have been identified by the use of multiple methods, including modern methods of skeletal analyses, tooth enamel and bone apatite isotopic analyses for geolocation, bone collagen isotopic analyses for dietary analysis, bomb-pulse dating to confirm the antiquity of the remains and rule out historical origin, and investigative genetic genealogy. The third unidentified case has undergone anthropological and isotopic analyses and is presently undergoing investigative genetic genealogy.

Investigative Genetic Geneaology; Stable Isotope Analysis; Multidisciplinary

A102 To Scan or to Slice: A Holistic Investigation of One of Florida's Oldest Unsolved Murders

Olivia Loveridge, BS, District 12 Office of the Medical Examiner, Sarasota, FL; Micki Besse, MS, Florida Gulf Coast University/Human Identity & Trauma Analysis Laboratory, Fort Myers, FL; Heather A. Walsh-Haney, PhD, Florida Gulf Coast University/Human Identity & Trauma Analysis Laboratory, Fort Myers, FL; Savanna Agilar, MS, Florida Gulf Coast University/Human Identity & Trauma Analysis Laboratory, Fort Myers, FL; Russell Vega, MD, District 12 Office of the Medical Examiner, Sarasota, FL

Learning Objectives: After this presentation, attendees will understand the use of 3D rendering technologies (including Computed Tomography [CT] in conjunction with a Coordinate Measuring Machine [CMM] FARO Design ScanArm and RevEng software) to aid in the retroactive assessment of exhumed human remains associated with two of Florida's oldest unsolved murders.

Impact Statement: This presentation impacts the forensic science community by informing practitioners of the value of 3D scanning and CT in the analysis of forensic cases. By supplementing the slicing capacity of CT scans with the accurate topographical rendition of 3D CMM FARO Design ScanArm and RevEng software scans, these digital demonstrative aids that represented human remains may be useful proxies for re-analysis or subsequent court aids following the release of remains to funeral homes or reinterment of the remains, following permissions from the legal next of kin.

Abstract Text: Existing literature investigating the utility of CT and 3D surface scanning in forensic trauma analysis has found that digital renderings are accurate and effective representations of the human remains, such that they may be effectively utilized to assist with the visualization and interpretation of skeletal trauma.[1,2] This case study presented the double exhumation and forensic analysis of two of Florida's oldest unsolved murders. On December 19, 1959, two adults and their two children were found dead from apparent Gunshot Trauma (GST) in their home. Their remains were autopsied by the District 12 Office of the Medical Examiner and subsequently interred at the Oak Ridge Cemetery in Arcadia, FL. However, new investigative leads reopened this case, and the lack of an original autopsy report necessitated exhumation of the adult individuals.

Post-exhumation, following the medical examiner's autopsy and forensic anthropologist's analysis, the crania belonging to both adults were scanned using the Florida Gulf Coast University (FGCU) Human Identity and Trauma Analysis (HITA) Laboratory FARO Design ScanArm and RevEng software to render 3D topographical scans. During subsequent CT analysis at the District 12 Office of the Medical Examiner, a glass rod was positioned through the perimortem (at or around death) GST entrance and exit defects to highlight the directionality of the projectile. This provided the medical examiner, forensic anthropologist, and law enforcement with the endocranial perspective critical to the 3D preservation of projectile directionality.

Both decedents evinced a single GST entrance, and one decedent lacked an exit defect. More specifically, the forensic anthropological findings (using both gross and radiographic observations) for the first individual consisted of one entrance defect on the right maxilla that traveled through the spheno-occipital synchondrosis and did not exit the cranium. For the second individual, the projectile entered the left parietal, traveled inferiorly and to the right (crossing the mid-axial plane), and exited through the base of the occipital. This case study highlighted instances where the use of technology in modern death investigations helped to fill a gap in knowledge and allowed for a more holistic interpretation of perimortem trauma. While the CT imagery helped to capture the directionality of the projectile with an endocranial perspective, the FARO Design ScanArm precisely captured the perimortem trauma and foramina to aid the scientist's interpretation and presentation of death investigation findings.

3D Technology; Unsolved; Murder

A103 Three-Dimensional Research on Ancient Skeletons of South Korea With Computed Tomography

Dong-ho Eddie Kim, PhD, The Catholic University of Korea, Seoul, Seoul-t'ukpyolsi, Republic of Korea; Ji-Hyun Lee, BA, The Catholic University of Korea, Seoul, South Korea; Sang-Seob Lee, DDS, PhD, The Catholic University of Korea, Seoul, Seoul-t'ukpyolsi, Republic of Korea; U-Young Lee, MD, PhD, The Catholic University of Korea, College of Medicine, Seoul, Seoul-t'ukpyolsi, Republic of Korea; Yi-Suk Kim, MD, PhD, The Catholic University of Korea, Seoul, Seoul-t'ukpyolsi, Republic of Korea; Dae-Kyoon Park, MD, PhD, Soonchunhyang University, Cheonan, Ch'ungch'ong-namdo, Republic of Korea*

Learning Objectives: With this presentation, attendees will learn the application of Computed Tomography (CT) to archive information on skeletal remains from historic excavations. With radiographical imaging techniques, further research on the ancient skeletons was performed with access to three-dimensional (3D) models.

Impact Statement: The CT scans to create 3D models have improved the organization and study of ancient skeletal information. Forensic anthropologists can analyze these 3D models to inspect visually ancient remains. This computational analysis would have a broader application in research on ancient skeletons while preventing damage to these valuable human remains.

Abstract Text: CT has gained popularity in archaeology and has been called paleoimaging or paleoradiology. The methodology enabled non-invasive and non-destructive research of mummies, human remains, and artifacts. Also, the digital data provided easier access for researchers regardless of time and spatial limitations.

We first reviewed published excavational reports of possessing institutions, residual status, and availability of the Mahan and Baekje region (Gyeonggi-do, Chungcheong-do, and Jeolla-do) in the Three Kingdoms Period (4^{th}~7^{th} century C.E.).

Among 33 reports of archaeological sites, five excavated collections that are in poor condition, from different eras, or impossible to loan were excluded from this research. In addition, as radiological data from three sites had been procured in past studies, the skeletons of 25 sites were loaned to be scanned with Multi-Slice Computed Tomography (MSCT). The excavation sites were distributed as 1 in Seoul, 18 in Chungcheongnam-do, 2 in Jeollabuk-do, and 7 in Jeollanam-do.

Using Mimics 24.0, we created 151 project files containing 2,550 remodeled skeletal models. These 3D models were then used to deduce forensic anthropological information such as sex, age, pathology, and facial approximation.

Skeletal components like the os coxae and the skull could suggest the skeleton's sex. Though the 3D models could not generally present dental erosion of the occlusal surface, forensic odontologists could analyze eruption and loss of dentition to speculate age. If the auricular surface of the ilium or the pubic symphysis is intact, they were assessed to assume the age. In addition, pathological findings due to congenital deformity or aging were recorded, which were not reported in the previously published information.

We expect this study will contribute to comprehensive research on scattered archaeological skeletal data. In former studies, the radiological data were stored by individual institutions, but we performed to make a nationwide scale dataset. Any future researcher would utilize the result as an inventory and as a collection of 3D models to skim through the data remains and plan further research.

A104 Demographic Timelines: Postmortem Data and Structural Violence in the Southeastern United States

Elise J. Adams, MA, University of Nevada, Las Vegas, Des Plaines, IL; Jesse R. Goliath, PhD, Mississippi State University, Mississippi State, MS*

Learning Objectives: After attending this presentation, attendees will learn how demographic factors can impact the recovery time of missing persons in the Southeastern United States medicolegal system. Furthermore, attendees will develop an understanding of how structural barriers, lack of policy on recovery data, and underreporting can perpetuate and even exacerbate institutionalized violence, which often leads to adverse outcomes for marginalized and minority groups in the Southeastern United States.

Impact Statement: This presentation will impact the forensic science community by showcasing how the intersection of demographics, forensic casework, and institutionalized violence impacts missing persons in the medicolegal system, both negatively and positively. Through this research, medicolegal professionals can implement strategies to combat the systemic disparities that currently exist in the recovery of persons from marginalized groups, particularly those from the Southeastern United States.

Abstract Text: When an individual's remains are found, it is imperative to determine how long the person has been deceased prior to their recovery, also known as the Postmortem Interval (PMI).[1,2] Over the past few decades, forensic anthropological research has made significant strides in developing better methods for decedent identification and increasing the accuracy of time since death/PMI estimations.[2] Even so, little emphasis has been placed on how socioeconomic considerations might be connected, especially regarding recovery times for individuals from varying demographic backgrounds. Ongoing inequities and negative perceptions can impact factors relating to missing and unidentified persons, such as their likelihood of going missing and being recovered safely.[3-5] Specifically, casework associated with marginalized communities has commonly been fraught with difficulties; these challenges stem from structural barriers and biases in government policies, tensions between marginalized groups and law enforcement, and discrepancies in media attention, including underreporting or misrepresenting cases.[6-8] Implementing both an intersectional and biocultural framework, this research aimed to decipher the role that inequality, through instances of social vulnerability and structural violence, plays in recovery time data throughout the Southeastern United States. PMI recovery data from forensic anthropologists and medicolegal labs in Mississippi, Louisiana, and South Carolina were used. These data included recovery times and basic demographic information. Data received from South Carolina included individuals from a single county between 2021 and 2024 (n = 5,448), while Mississippi (n = 175) and Louisiana (n = 117) datasets were based on statewide repositories. Due to the statistical similarities in the datasets, the data from Mississippi and Louisiana were combined (n = 285).

All statistical analyses were performed using RStudio (v. 2021.09.2). Kruskal-Wallis One-Way Analysis of Variance tests were used to assess the possibility of a significant relationship between PMI and the three tested variables (Age, Sex, and Ancestry). Only the age category variable was significant ($p = 0.000182$) with the combined datasets. However, when the ancestry category was analyzed with just Black and White individuals (each n = 137), the results indicated significance ($p = 0.03835$). South Carolina results indicated that age ($p = 9.631e\text{-}9$) and sex ($p = 1.923e\text{-}4$) were significant, while ancestry was not. The combined repositories and South Carolina had more days prior to recovery for middle-aged (35–66 years old) adults and those who identified as White. Sex differed; females from the combined repositories had higher PMI averages, while South Carolina had higher averages for males. Finally, based on location, South Carolina had shorter PMI time spans, averaging a little over a day, while the combined repositories had PMI averages between 1.5–2 years.

Results from South Carolina and the combined repositories from Louisiana and Mississippi suggest a mix of demographic disparities in recovery times for medicolegal cases reported in these Southeastern states. Moreover, the lack of available postmortem recovery data across agencies in the Southeastern United States was evident. Overall, our findings suggested that individuals from marginalized backgrounds are more underreported than what is currently acknowledged. This result emphasizes the negative impact that the intersectionality of various identities can cause and contributes to instances of structural violence and vulnerability against populations that we cannot fully comprehend. Considerations of how systematic violence can impact socioeconomic and sociopolitical factors for a demographic group's recovery times highlight disparities in how politics, law enforcement, and medicolegal personnel assist and conduct casework.

A105 Demographic Trends in Resolution of Adult Skeletal Cases in the National Missing and Unidentified Persons System From 2020 to 2024

Valerie Sgheiza, PhD, SNA International, Joint Base Pearl Harbor-Hickam, HI*

Learning Objectives: From this presentation, attendees will learn about trends in the resolution of the National Missing and Unidentified Person System (NamUs) unidentified cases within the past four years. This will include intergroup differences and proxies for resource expenditure.

Impact Statement: This presentation will impact the forensic science community by highlighting areas in which distribution of case resources could be made more equitable and thereby improve case resolution rates. Specific resources (e.g., anthropological analysis) will be highlighted through proxy variables to make these findings actionable.

Abstract Text: The resolution of unidentified skeletal cases is a considerable challenge, with 5,312 open cases in NamUs as of July 2024.[1] NamUs serves as a repository for case information to aid in the resolution of missing and unidentified persons cases. The size and widespread use of this database provide an opportunity to examine patterns in case resolution in order to identify opportunities for improvement.

The study period spanned from September 2020 to July 2024 with monthly data capture of NamUs case entries. Criteria for inclusion were adult age and skeletal condition of remains. For 6,253 total cases captured, 943 new cases were entered, and 941 cases were resolved (i.e., removed from NamUs) within the study period. Out of all combined "Biological Sex" and "Race/Ethnicity" groups with at least 40 resolved cases, White female cases (n = 109) had the longest mean and median resolution time of 25.8 and 30.2 years, respectively, while unknown "Biological Sex"/unsure "Race / Ethnicity" cases (n = 68) had the shortest mean and median resolution time at 6.4 and 1.6 years, respectively. The groups with the largest and smallest resolution rates were White females and Hispanic males at 0.29 and 0.08, respectively. When only cases entered during the study period (i.e., within the past four years) were examined, White females showed the shortest mean and median resolution times (0.74 and 0.53 years, respectively) and a similar resolution rate (0.32) to White (0.36) and Black males (0.33). This suggests that the elevated resolution rate and long resolution times for White females are being driven by the resolution of older cases, which indicates a potential equity gap in resource allocation toward case resolution.

The "Biological Sex" designation was changed for 132 cases while the "Race / Ethnicity" designation was changed for 137 cases during the study period. For both variables, cases that had a designator change had a higher resolution rate relative to those that did not; however, this was only significant for "Biological Sex," with a negligible effect size according to a chi-square test ($p = 0.02$, $V = 0.03$). Designator changes were also associated with a shorter time to resolution. This was significant for "Biological Sex" according to a two-sample t-test, with a moderate effect size (5.5 vs. 13.8 years, $p < 0.001$, $d = 0.61$). Case counts were too low to examine group-specific trends for designator changes. Changes in case designators throughout the study period can be interpreted as a proxy for additional resource expenditure, meaning that a positive signal for additional resource expenditure is associated with a higher resolution rate and shorter resolution time. Since these are skeletal cases, the most likely resource for updating demographic designators is anthropological analysis.

In conclusion, metrics of case resolution in NamUs indicate demographic patterning and a positive impact from additional resource expenditure. These results suggest the utility of anthropology in resolving unidentified persons cases. While there are many reasons why some demographic groups might show higher resolution rates than others, these findings warrant further investigation of resource distribution equity in unidentified persons cases.

A106 Comparing Antemortem Trauma Prevalence and Reporting Frequency in Unidentified Migrants Compared to a Non-Migrant Sample: A Pilot Study for Identification Purposes

Victoria S. Soto, MA, Operation Identification, San Marcos, TX; Kate Spradley, PhD, Texas State University, San Marcos, TX*

Learning Objectives: Attendees will learn how prevalence of antemortem trauma differs between a migrant and non-migrant sample. Attendees will also understand how antemortem trauma is reported in missing persons' reports compared to the prevalence of occurrence.

Impact Statement: The purpose of this study is to determine if there is a difference in the frequency in antemortem trauma for unidentified migrants and non-migrants and to investigate if this trauma is equally reported in missing persons reports for migrants last known to be crossing the United States-Mexico border and its implications for identification. This presentation will ascertain if antemortem trauma is an individualizing characteristic that could be used for identification purposes.

Abstract Text: With the rise in migrant deaths along the United States-Mexico border, primary identification methods are not always available.[1] Under these circumstances, it is necessary to explore alternative ways to achieve identification, such as through antemortem trauma analysis. Between 2001 and 2006, 72% of identified cases of undocumented migrants on the United States-Mexico border in Arizona utilized visual identification methods, among others, to identify individuals.[2] It has been noted that skeletal pathological features might provide valuable information for the identification process, but further research is needed.[3] The goal of this research is to investigate whether there is significant antemortem trauma in presumed migrants found along the United States-Mexico border and the implications of using such data to aid in migrant identification.

The National Missing and Unidentified Persons System (NamUs) was used to gather antemortem trauma data on individuals who were last seen alive in Texas crossing the United States-Mexico border. The hypothesis is that there is an association between antemortem trauma in these reference samples. The null hypothesis is that there is no association between antemortem trauma and these reference samples. The frequency of antemortem trauma between the unidentified (Operation Identification [OpID]) and the missing (NamUs individuals) was analyzed by comparing the frequency of antemortem trauma in the OpID remains compared to the amount reported in the NamUs missing person reports.

Antemortem trauma is not as evident in comparison to a non-migrant population. This indicates that antemortem trauma, although present, is not present at the level needed to be useful for positive identifications in a migrant population. Although the data are statistically significant, the correlation is weak. Antemortem trauma analysis was documented in migrant remains from the OpID program (n=297). The frequency of trauma was compared to individuals in the Texas State Donated Skeletal Collection (TXSTDSC) (n=50). The long bones are examined for signs of antemortem trauma. Both the left and right elements were analyzed to rule out human variation, such as if an individual has non-standard skeletal traits that could be confused with antemortem trauma. This data was compared using a Chi-Squared test in SPSS.

Antemortem trauma in OpID is more evident than in NamUs reports, indicating it is underreported in NamUs (or missing persons reports). Although this research showed that alternatives to DNA are worth exploring, DNA is still needed for positive identification. DNA samples must be collected from these migrants, and the policies that hinder DNA collection and data sharing must be reviewed.

A107 Gendered Language Use in Forensic Science Publications (2003–2023)

Samantha M. McCrane, PhD, Co-Director of FAIR Lab, Lecturer, University of New Hampshire, Rochester, NH; Ella Tartsa, University of New Hampshire, Manchester, NH; Amy Michael, PhD, University of New Hampshire, Rochester, NH*

Learning Objectives: After attending this presentation, attendees will understand how patterns in gendered language use in AAFS presentations and flagship forensic science journals have changed over the past 20 years, as well as how proper use of gendered language in publications affects decedent identification and case resolution pragmatically.

Impact Statement: This presentation will impact the forensic science community by enabling practitioners across subfields to better align their case reports and scientific publications with timely and accurate gendered language, supported by the most recent *Diagnostic and Statistical Manual of Mental Disorders*.[1] Such shifts can positively impact identification of decedents.

Abstract Text: This research project explores if and how gendered language use has changed in forensic science publications as practitioners gain greater cultural awareness about gender diversity in forensic populations. More specifically, we address and analyze: (1) trends in gender-focused research and gendered language in the forensic sciences over the past 20 years; (2) subfield specific differences in gender-related research; and (3) how forensic scientists' framing of gender, specifically gender identity and gender expression, aligns with the mental health community.

Currently, there is an epidemic of violence, including homicide, committed against transgender and gender-nonconforming individuals, increasing the likelihood that individuals with these identities become a part of forensic casework.[2,3] Therefore, gender-centered research is essential to improving forensic identification methodologies. The language practitioners use to communicate their findings in reports is also equally important as this information must be translated and matched to language utilized in government system (e.g., NamUs), medical records, and social terminology.

This dataset was derived from the American Academy of Forensic Sciences Conference *Proceedings* (2003–2023), the *Journal of Forensic Science* (2006–2023), *Forensic Science International* (2003–2023), and *Forensic Science Synergy* (2019–2023). The following keywords were searched in all publications: transgender, gender, gender queer, queer, FTM, MTF, nonbinary, cisgender, transsexual, sexuality, transvestite, trans, gender identity disorder, gender identity, gender dysphoria, gender dysmorphia, gender variant, gender nonconformity/nonconforming, transsexualism, gender identity disorder, LGBTQ, and homosexuality. The search terms were necessarily broad to explore how forensic scientists write about and conceptualize gender in their research publications. Variations of terms (e.g., "transvestic" instead of "transvestite") were also searched to provide a comprehensive data set. Patterns in gendered language use were compared against the changing standards and classified conditions specified in the *DSM-5-TR* (2022).

The *DSM-5-TR* (2022) names the psychiatric disorders regarding gender as gender dysphoria and transvestic disorder, which falls under their Paraphilic Disorders section as a fetishistic disorder. Forensic science journals seem to have followed suit with the use of the term "gender dysphoria," as the oldest recorded use of it in our dataset was in 2015, and it is still used in forensic science journals presently. However, our results demonstrate that continued use of other, more derogatory terminology in forensic science is not in line with the most recent *DSM-5-TR* or social inclusivity. For instance, the term "transsexual" has generally fallen out of use in the forensic field, though it persists in a recent AAFS *Proceeding* (2018) and a *JFS* article (2021). Incorrect use and variation of gendered language can affect how individuals are entered into databases, negatively impacting the prospect of correctly identifying unknown decedents.[4] Additionally, the use of harmful or derogatory language does not afford non-gender conforming individuals dignity in death. The results of this study indicate that forensic scientists have taken an increased interest in identification of transgender decedents in recent publications and presentations, perhaps because of the increased rates of fatal violence in this population, although the term has been used throughout the past 20 years of publications.

Based on our findings, we suggest strategies to better align the research foci of forensic scientists interested in gender identity, expression, and identification of transgender and gender non-conforming decedents with the *DSM-5-TR*. Furthermore, we propose standardized and regularly updated gender-inclusive language for applied casework.

Gender; Transgender; Human Identification

A108 Technology You Can Stand On: Skeletal Changes in Human Remains With Lower Extremity Orthopedic Prostheses

Savanna Agilar, MS, Florida Gulf Coast University/Human Identity & Trauma Analysis Laboratory, Fort Myers, FL; Micki Besse, MS, Florida Gulf Coast University/Human Identity & Trauma Analysis Laboratory, Fort &, FL; Heather A. Walsh-Haney, PhD, Florida Gulf Coast University/Human Identity and Trauma Analysis Laboratory, Fort Myers, FL*

Learning Objectives: After attending this presentation, attendees will have gained an understanding of antemortem skeletal changes observable in human remains with orthopedic prostheses in the lower extremity.

Impact Statement: This presentation will impact the forensic science community by providing practitioners with a pattern of expected skeletal changes related to orthopedic implants in the lower extremity and aid in their ability to discern these changes from those related to other pathological or senescent processes.

Abstract Text: Existing research on the clinical effects of orthopedic device implantation in the lower extremities has identified issues related to alterations in gait, biomechanical loading, leg length discrepancies between antimeres, and, further, how these alterations influence patient functional outcomes.[1,2] From a forensic anthropological context, research has established the utility of using orthopedic prostheses to aid in human identification via radiographic comparison and serial number tracking.[3,4] Notably absent from current clinical and forensic anthropological literature, however, is an investigation into the grossly observable pathological effects of orthopedic implants arising from these established postoperative complications that affect biomechanical functioning in weight-bearing bones. Comporting with American National Standards Institute/Academy Standards Board (ANSI/ASB) Standard 134 for analyzing pathological conditions and anomalies, a comprehensive study into the pathological effects of orthopedic implants on non-implant bearing bones is warranted to inform forensic anthropologists of those changes that may be attributed to the implant and help to inform assessments of human identification.[5,6]

In this pilot study, we investigated the propensity of orthopedic implants in the lower extremity to influence the manifestation of grossly observable skeletal pathologies in weight-bearing bones. Further, we supplemented existing leg length discrepancy studies by examining the effect that orthopedic implants have on the severity of unilateral length differences between antimeres as assessed in dry bone.

We compared 14 human remains donations with orthopedic implant(s) in the lower extremity (i.e., total hip arthroplasty, hip hemiarthroplasty, total knee arthroplasty, and internal fixation) to a control sample of 14 implant-free human remains donations of a matched age-at-death and biological sex distribution culled from the Florida Gulf Coast University Human Identity and Trauma Analysis and the University of Tennessee National Forensic Academy Donated Skeletal Collections. We macroscopically evaluated the lower extremities, calcanei and tali, and the lumbar spine for the presence of antemortem fracturing, aberrant facets, Schmorl's nodes, osteochondritis dissecans, heterotopic ossification, and osteoarthritis. Further, we metrically assessed the femora, tibiae, and fibulae to evaluate the severity of leg length discrepancies between the samples. The data revealed a significant difference ($p < 0.05$) between the manifestation of severe limb length inequalities (>1cm), where those remains with an implant had more severe differences between antimeres. Further, those decedents with an implant comprised 65.55% of the total number of antemortem fractures among the samples and produced a higher total pathological frequency across L1 (56%), L2 (78%), L3 (68%), L5 (52%), patellae (57%), tibiae (69%), fibulae (57%), calcanei (79%), and tali (56%)—notably excluding the femora and L4. Conversely, the data revealed a significant difference ($p< 0.05$) between observations of osteochondritis dissecans between the samples, where the implant-free decedents evinced more. This pilot research demonstrates the potential for a pattern of observable skeletal changes that may be attributable to orthopedic hardware implantation in the lower extremity to be identified and used as a guide supporting the ANSI/ASB Standard 134 for analysis of pathological conditions and anomalies in forensic anthropology.

Identification; Antemortem; Anthropology

A109 Evaluating Cortical Bone Structural Variation in Association With Activity Level

Shelby Garza, MA, Texas State University, New Braunfels, TX*

Learning Objectives: After attending this presentation, attendees will have a better understanding of the practical application of high-resolution X-ray computed tomography for forensic case work.

Impact Statement: This presentation will impact the forensic science community by introducing a new method for assessing activity levels of unknown descendants. Additionally, the results of this project may introduce potential new lines of evidence for forensic practitioners to assist with narrowing down a missing persons list.

Abstract Text: Bone is an adaptive tissue that can change in mass and architecture throughout the course of life due to loading regime through modeling and remodeling processes.[1,2] Because of this, a relationship exists between bone mass, size, geometry, and mechanical usage.[3-5] Numerous studies have highlighted the effect of mechanical strain on cortical bone properties; however, few studies have used known activity patterns to investigate the effect of mechanical loading on a more individual level.

The purpose of this study is to explore the relationship between cortical bone structural variation and activity patterns, specifically occupation, to answer the following questions: (1) are there differences in cortical bone structural variation between individuals with manual and non-manual labor jobs; and, (2) if differences are observed, can these differences be used to provide new lines of evidence for forensic practitioners to aid in the identification of unknown decedents?

High-Resolution X-Ray Computed Tomography (HRXCT) scans of the left and right humerus were obtained for 79 individuals from the Texas State University Donated Skeletal Collection (TXSTDSC). Cross-sectional slices were then analyzed from the midshaft and proximal 65% of the humeral shafts using BoneJ. The "Slice Geometry" tool was used to obtain cross-sectional area (CSA) and maximum (I_{max}) and minimum (I_{min}) bending moments. Torsional rigidity (J) was calculated by adding I_{max} and I_{min}. Prior to analysis, all Cross-Sectional Geometric (CSG) properties were standardized by body size. For the analysis, the handedness of each individual was noted so that the dominant and non-dominant arms were compared, rather than all lefts compared to all rights. Depending on the results of the appropriate tests for distribution and variance, either a parametric Analysis Of Variance (ANOVA) or a non-parametric Kruskal-Wallis test was used to compare the CSG properties of the humeri between individuals with documented manual and non-manual labor jobs.

The results showed that there was a significant difference in the non-dominant arm between manual and non-manual labor workers in CSA ($p=0.0377$), I_{min} ($p=0.0120$), and J ($p=0.0187$) at the proximal 65% slice, with the manual labor workers having larger averages for all three variables. Additionally, there was also a significant difference in I_{max} ($p=0.0157$) and J ($p=0.0215$) in the non-dominant arm midshaft slice. The results of the comparisons between the dominant arm show there were no significant differences between manual labor workers and non-manual labor workers in the midshaft slice, although manual labor workers had larger CSG properties for all variables. The results from the proximal 65% slice of the dominant arm show that was a significant difference between I_{min} ($p=0.0282$) and J ($p=0.0459$), with the manual labor workers having larger CSG properties for all variables, not just those that were significant.

The results of this project indicate the practical use of cortical bone cross-sectional geometric properties and HRXCT to provide potential new lines of evidence for forensic case work. Individuals with manual labor jobs consistently had higher CSG properties in the humeral shafts when compared to individuals with non-manual labor jobs. These results may be explained by the higher levels of mechanical loading on the humeri of individuals with a manual labor job. Additionally, while some forensic practitioners have begun to evaluate musculoskeletal markers to incorporate potential activity levels into casework, these methods can sometimes lack standardization and statistical interpretation to support the claims. The utilization of radiologic imaging technologies to visualize cortical bone may be used to standardize methods for assessing activity levels of unknown decedents and may also help in a forensic context when there is evidence lacking from the remains of the scene.

A111 A Preliminary Comparison of Fracture Characteristics Between Fleshed and Defleshed Human Tibiae

Angela L. Harden, PhD, Injury Biomechanics Research Center, The Ohio State University, Columbus, OH; Christopher M. Goden, MA, PhD Candidate, Injury Biomechanics Research Center, The Ohio State University, Grove City, OH; Kyra Stull, PhD, University of Nevada Reno, Reno, NV; Amanda M. Agnew, PhD, The Ohio State University, Columbus, OH; Yun-Seok Kang, PhD, The Ohio State University, Columbus, OH*

Learning Objectives: After attending this presentation, participants will gain insight into the role of soft tissue and the presence of the fibula in tibial fracture characteristics resulting from blunt trauma.

Impact Statement: This presentation will impact the forensic science community by providing quantitative analyses that explore how fracture characteristics vary between paired tibiae loaded in the same loading conditions when one tibiae is defleshed and the other is still within a fleshed leg.

Abstract Text: Previous studies have demonstrated variation in injury outcomes, such as the number of fractures and fracture classifications, in human tibiae subjected to identical experimental conditions (6m/s, lateral-medial direction, 4-point bending).[1] However, these studies exclusively used defleshed tibiae to control for variations beyond the bone itself, which may not fully represent injury outcomes in real-world leg impacts. Previous research suggests that while the response to loading is delayed in fleshed specimens, the overall biomechanical response is similar to that of defleshed specimens.[2] Despite the reported similar biomechanical responses, the variation in injury outcomes between fleshed and defleshed specimens remains uninvestigated. The objective of this research is to analyze fracture characteristics in paired tibiae to identify variation between fleshed and defleshed specimens that were experimentally loaded under the same dynamic loading conditions.

Human tibiae and their corresponding antimere legs (11 pairs) were experimentally loaded at 6m/s in a lateral-medial direction using a 4-point bending scenario. Left specimens were fleshed legs (n=11), while right specimens were defleshed tibiae (n=11), and all were kept biomechanically fresh using saline-soaked gauze. The fleshed legs were dissected from postmortem human subjects at the tibiofemoral and tibiotalar joints. Soft tissue was removed at the proximal and distal ends to allow for fixation of the legs, but the flesh remained intact along the diaphysis, including the impact locations. For the defleshed tibiae, all soft tissue, except for the periosteum, was removed. Detailed specimen preparation protocols are described by Harden.[3] Specimens were potted at the 20% and 80% sites of the tibia, calculated from the tibia length excluding the medial malleolus, and impacted at the 40% and 60% sites. After post-test imaging, the flesh and soft tissue were removed from the right legs for fracture analysis. Trauma analysis was conducted on the defleshed tibiae and both the tibia and fibula of the legs; however, the focus of this study is on comparisons between the tibiae only. Trauma analysis included the identification of fracture type and group, and the number of fracture types per tibia, following the methods outlined in the AO/OTA Fracture and Dislocation Classification Compendium.[4]

Fracture number (number of classified fractures per tibia) demonstrated a match in 4 out of 11 pairs of fleshed and defleshed tibiae. Of the paired tibiae and legs with the same number of classified fractures (n=4 pairs), three pairs resulted in the same fracture type and two pairs resulted in the same fracture type and group. If the fleshed and defleshed tibiae had the same number of fractures, they tended to result in the same fracture classifications, indicating similar fracture characteristics between fleshed and defleshed specimens. However, these trends need to be further evaluated in a larger sample size, which is currently being addressed by the National Institute of Justice (15PNIJ-23-GG-04219-SLFO, Quantitative Assessment of Fracture Characteristics in Blunt-Force Skeletal Trauma for Forensic Interpretations).[5]

Trauma Analysis; Trauma Interpretation; Experimental Research

A112 A Preliminary Evaluation of Reliability in Long Bone Fracture Classification Methods Among Observers

Christopher M. Goden, MA, Injury Biomechanics Research Center, The Ohio State University, Grove City, OH; Amanda M. Agnew, PhD, The Ohio State University, Columbus, OH; Angela L. Harden, PhD, Injury Biomechanics Research Center, The Ohio State University, Columbus, OH; Emma Brzezinski, MA, The Ohio State University, Columbus, OH; Julia McGinley, The Ohio State University, Columbus, OH*

Learning Objectives: After attending this presentation, attendees will gain familiarity with trends of reliability of long bone fracture classification schemes among observers of varying experience levels.

Impact Statement: This presentation will impact the forensic science community by demonstrating the need to re-evaluate the utility and reliability of methodologies for long bone fracture classification.

Abstract Text: Fracture classification is a standard component of trauma analysis. The Standard for Analyzing Skeletal Trauma in Forensic Anthropology (Academy Standards Board [ASB] 147) states that trauma should be documented using peer-reviewed methods; however, guidance on which methods are applicable is not provided.[1] Further, limited methods exist to classify long bone fractures resulting from blunt mechanisms. Most classification systems stem from clinical practice, and prior work demonstrates variability in observer reliability of classifications.[2-4] However, reliability trends for long bone fracture classifications in forensic science are unknown. The objective of this research is to assess reliability of fracture classifications utilizing different systems.

Human tibiae (n=30) were experimentally loaded to failure under repeatable boundary conditions (6m/s, lateral to medial) as part of a larger ongoing research project. Resulting fractures were analyzed on three occasions by four observers of varying experience (novice, advanced, proficient, and expert). For each analysis, observers analyzed all bones independently, recorded the total number of classified fractures, and provided a classification for each fracture. For analysis one, no method was provided, and observers were instructed to employ their preferred terminology and/or method. For analysis two, observers were given the AO/OTA Fracture and Dislocation Compendium and instructed to strictly follow the method's guidelines.[5] For analysis three, observers were provided a preliminary novel classification system to follow. Reliability for number of fractures was assessed via Fleiss' Kappa. Since observers reported varying fracture counts resulting in uneven classification observations, overall percent agreement for fracture classifications was calculated as instances when the same number of fractures and classifications were reported per tibia.

Inter-observer reliability for number of fractures within methods ranged from poor (AO/OTA method [κ=0.079]) to fair (no method [κ=0.250], novel method [κ=0.219]). Overall trends between observers demonstrated that the novice observer tended to classify the greatest number of fractures while the expert observer tended to classify the least. Percent agreement for classifications among observers in analysis one was 3%. Since no method was provided, low agreement could be attributed to the lack of standardized terminology. For analysis two (AO/OTA), percent agreement for fracture type was 27% and only 10% for fracture group. This indicates higher inter-observer agreement for broad classifications (e.g., simple fractures) and lower agreement for specific classifications (e.g., oblique fractures). Analysis three (novel method) had the most fractures classified overall; however, percent agreement of initial classifications (complete or incomplete fractures) was 13% and decreased to 6% for specific classifications.

Reliability in number of fractures between methods ranged from poor (expert [κ=0.013], novice [κ=0.196]), to fair (advanced [κ= 0.230]), to moderate (proficient [κ=0.420]). When comparing classifications within observers, the advanced observer was the most consistent between methods (36%) compared to the proficient (16%), expert (13%), and novice observers (3%). Generally, more experienced observers exhibited greater variation in classification terminology, possibly due to differing interpretations of classification criteria provided.

Overall, low agreement evidenced in this study is likely due to unclear criteria and method variation for identifying and classifying fractures at varying experience levels. Even when agreement in number of fractures increased, observers frequently classified fractures differently. These disparities suggest that differential classifications for the same fracture are possible, potentially impeding documentation and interpretation of trauma in forensic casework. Improvements to fracture classification systems are warranted, with an emphasis on establishing explicit, well-defined classification criteria to better facilitate observer agreement. Findings from this investigation will be used to further develop the novel method for long bone fracture classifications resulting from blunt impact scenarios.

Trauma; Method Agreement; Blunt Force

A113 Investigating Differences in Methodological Approaches to Scoring Fracture Angle, Outline, and Surface

Carter A. Unger, MA, University of North Texas Health Sciences Center, Lubbock, TX; Mariyam I. Isa, PhD, Lubbock, TX, LUBBOCK, TX*

Learning Objectives: The goal of this presentation is to present data comparing results obtained when different methodological approaches are applied to score fracture characteristics commonly reported in bone taphonomy studies (fracture angle, outline, and surface). Attendees will learn how methodological choices influence scoring of fracture characteristics and, potentially, interpretations of fracture timing.

Impact Statement: This presentation impacts the forensic science community by critically evaluating how methodological choices may influence the documentation and interpretation of skeletal trauma.

Abstract Text: Fracture characteristics are expected to change as bone transitions from wet to dry over the postmortem interval. Various studies have investigated similar fracture characteristics (especially fracture angle, outline, and surface) to draw conclusions about this transition.[1-4] Because each study presents its own protocols for scoring fracture characteristics, results may not be comparable due to methodological differences. It is currently unknown how these differences may impact the results of bone taphonomy studies and, potentially, interpretations of fracture timing based on these characteristics.

The objectives of this study were to: (1) evaluate method agreement on fracture angle, outline, and surface scores; and (2) investigate whether different methods produce different distributions of scores.

Materials included 40 deer femora exposed to outdoor conditions for different intervals of time. Experimental blunt force impacts were delivered to five bones every two weeks from 0 to 14 weeks post-exposure. Four methods were applied to score fracture angle, outline, and surface expressions for each femur.[1-4] The most distal and proximal fragments of each bone were scored using all methods. One method (Green and Schultz) generated an overall bone score based on a combination of proximal and distal fragment scores.[1] Proximal and distal scores were considered separately for all other methods.[2-4]

Fracture angle, outline, and surface expressions were initially scored according to the original publications. To facilitate comparison between methods, these scores were converted to scores of "wet," "intermediate," or "dry" as presented in the original publications. Fleiss' kappa tests were used to assess method agreement for converted scores. Pairwise chi-square tests were used to investigate associations between methods and scores.

Method agreement was statistically significant ($p < 0.05$) for fracture angle, outline, and surface. Kappa values for fracture angle ($\kappa = 0.591$ proximal; $\kappa = 0.876$ distal) indicate moderate to near perfect agreement, suggesting fracture angle is scored fairly similarly across methods. Kappa values for fracture outline ($\kappa = 0.454$ proximal; $\kappa = 0.692$ distal) indicate moderate to substantial agreement in how this feature is scored across methods. Very low kappa values ($\kappa = 0.0594$ proximal, $\kappa = 0.0458$ distal) indicate considerable variability in how fracture surface is scored across methods.

The results indicate certain methods produce significantly different fracture angle, outline, and surface scores. Wheatley fracture surface scores differed from all other methods ($p < 2.2e\text{-}16$).[3] This method did not use an "intermediate" surface score, and therefore generated more "wet" and "dry" scores compared to other methods. Green and Schultz fracture angle and fracture outline scores differed from proximal fragment scores generated using all other methods ($p < 0.0003$).[1] More fracture angles and fracture outlines were scored as "intermediate" than "wet" compared to other methods. This suggests observation location influences fracture angle and outline scores.

The results of this study confirm that fracture angle, outline, and surface scores vary when evaluated using different methods. Researchers should be aware that studies reporting on similar fracture characteristics may not be directly comparable due to different scoring protocols. While the methods reviewed in this study were largely intended to explore fracture transition timelines and not to diagnose fracture timing, practitioners should be aware that different methods may produce different scores for certain fracture characteristics. If scores are taken at face value, methodological differences in scoring protocols could influence interpretations of fracture timing. Finally, the results highlight a need for clear, detailed, and widely accepted protocols for documenting skeletal trauma and taphonomy in research and casework. The next phase of research will assess intra-observer and inter-observer agreement to investigate which methods yield the most consistent and repeatable results and identify needs for clarification among scoring protocols.

Forensic Anthropology; Trauma Analysis; Methodology

A114 Taphonomic Change in Fracture Characteristics of Porcine Long Bones in the Sonoran Desert During the Summer

Kaitlyn J. Fulp, MA, Arizona State University, Scottsdale, AZ; Emelia B. Jensen, BS, Arizona State University, Gilbert, AZ; Katelyn L. Bolhofner, PhD, Forensic Anthropology, Arizona State University, Phoenix, AZ; Sophia Sedlacek, BS, Arizona State University, Phoenix, AZ*

Learning Objectives: After attending this presentation, attendees will better understand the characteristics used to differentiate perimortem fractures from postmortem damage and how the timeline at which bone becomes "dry" in the Arizona Sonoran Desert compares to other climates.

Impact Statement: This presentation is the first part of a multi-year project aimed at establishing an observed timeline of when bone transitions from "fresh" to "dry" in the postmortem interval and when fracture classification changes from perimortem to postmortem in the unique, extreme environment of the Sonoran Desert. The results from this and following studies will be tested in a medical examiner's sample to test the application of experimental methods in non-human models to real cases.

Abstract Text: Estimating the timing at which a fracture occurred is a critical aspect of skeletal analysis in forensic anthropology. Characteristics have been defined that are considered indicative of "fresh" and "dry" bone, or perimortem and postmortem timing. In general, fresh bones are expected to fracture with U- or V-shaped outlines, have smooth fracture surface morphology, and exhibit oblique or acute fracture angles. Conversely, dry bones typically fracture along transverse lines, with jagged surface morphology and right fracture angles.[1-4] As the drying of bone is a gradual process, the transition of fracture characteristics from those indicating fresh bone, or a perimortem break, to those indicating dry bone, or postmortem damage, occurs on a continuum.[5] A pilot study, conducted in the fall and winter, demonstrated a transition to postmortem characteristics up to one month sooner than previously studied climates, with"'intermediate" characteristics appearing in week 4, a majority of postmortem characteristics by week 8, and observation of all postmortem characteristics by week 12.

The Sonoran Desert, in the southwestern United States stretching through southern Arizona and California and into Mexico, presents a unique climate—in the summer months, extremely high temperatures compounded with low humidity can produce rapid initial decomposition that may lead to degradation of bone occurring faster than in summer months.[5] To observe the effects of the extreme summer in the Sonoran Desert on skeletal remains, 26 porcine (S*us scrofa domesticus*) femora were fractured using a custom drop apparatus. Two femora served as controls and were fractured after collection from a butcher shop without being frozen. The remaining 24 femora were placed in a fenced environment in direct sun exposure in Glendale, AZ, and were collected and fractured at one-week intervals. The drop apparatus applied a force of 567kg/cm^2. Temperature, humidity, and precipitation data were collected from local weather stations. Fracture angle, outline, and surface morphology were scored, and an overall determination of perimortem or postmortem was made for each bone. Two bones did not break on the first impact and so were excluded from the results.

During this study, daily high temperatures ranged from 67–116°F, while lows ranged from 50–93°F. Humidity ranged from 4% to 40% and 0.01 inches of rain was measured. Characteristics scored as "intermediate" were present from the control week through week 12. In this unique environment, perimortem or fresh characteristics cease to be observed a minimum of four weeks earlier than previously tested environments.[1-3] Perimortem characteristics were not observed past week 9. The overall determination of "perimortem" occurs through week 7, at which point the fractures are then scored overall as"'postmortem," although intermediate characteristics are still present. Differences in color between the cortical surface and the fracture surface were noted in the first week, and the cortical surfaces from this point onward were stained red and dark brown. Postmortem characteristics were first observed in week 7, with fracture morphology becoming jagged. Similar to other studies, there was not a complete transition to postmortem characteristics; however, determination of timing based on overall appearance classified the fractures as postmortem. The hot summer in the Sonoran Desert produces a more rapid transition—as much as 11 weeks earlier—from perimortem to postmortem fracture characteristics than has been documented in other climates.[1]

This project represents the first portion of a project encompassing deposition in all four seasons in order to account for the variation throughout seasons. Research further investigating the influence of the environment over the taphonomic change of bones and fracture characteristics is necessary as is testing of how these results translate to real cases.

Trauma; Taphonomy; Postmortem Interval

A115 Distribution Patterns of Trauma by Event Type: Examining the Differences Between Trauma Distributions of Decedents in Different Traumatic Events

Petra M. Banks, PhD, University of Alaska, Fairbanks, Fairbanks, AK*

Learning Objectives: This presentation will illustrate how trauma is distributed in different event types, including falls, blast events, aircraft crashes, and motor vehicle/pedestrian impacts. The results further examine the potential for these distributions to predict the correct event type using random forest modeling.

Impact Statement: While preliminary and limited in scope, this research shows that trauma distributions may have enough differences between event types to potentially create future predictive models using trauma distribution to determine the likelihood of different traumatic events.

Abstract Text: Skeletal trauma distributions by event types have been preliminarily studied, but the trauma distributions have rarely been comparatively studied. Furthermore, there are few studies which use rigorous statistical methods to compare trauma distributions and examine them in comparison to other event types.

In order to examine skeletal trauma distributions by different event types more thoroughly, four different event types were examined for skeletal trauma distribution. These four types were selected in order to be compared to skeletal blast trauma, an event type with little civilian data. In addition to blast events, falls from height, aircraft crashes, and motor vehicle pedestrian impact data were collected. Analysis was conducted using chi square analysis, comparing trauma presence and absence at the zone, element, region, and axial versus appendicular levels. These data were collected from deidentified decedent case files from medical examiner's offices and coroner's offices from across the United States. In addition, blast trauma and aircraft crash trauma data from the Defense POW/MIA Accounting Agency (DPAA) were included to provide a comparison from non-civilian contexts. Hard tissue trauma events were recorded by bone element, limb, and specific bone location using osteological zones described in CORA, a database designed and built by DPAA. Case-specific data were recorded, including a description of the cause of the event, basic demographic information, and a general inventory of the remains to indicate whether the absence of trauma is due to a lack of preservation or a lack of injury.

The data collected includes 227 individuals from blast events, 70 individuals from aircraft crash events, 42 falls from height, and 50 motor vehicle/pedestrian collisions. At all different levels of trauma specificity, there were significant differences in trauma frequencies. The aircraft crashes and blast events were most distinct from the other types of trauma, and falls and motor vehicle pedestrian impacts were most similar. However, there were distinct areas of trauma distribution for each event type. While the data are limited to only a few event types, these trauma distribution data are being used to generate a predictive model of trauma event type using random forest modeling, which will provide investigators with important trauma analysis comparisons to help assess trauma causes.

Skeletal Remains; Trauma; Blunt Force

A116 Is It All the Fault of a Fist? Forensic Reconstruction in a Case of "Imperfect" Skull Fractures

Enrica Macorano, MD, University of Bari, Bari, Puglia, Italy; Giovanni De Gabriele, MD, University of Bari, Bari, Puglia, Italy; Alessandro Cristalli, MD, University of Bari, Bari, Puglia, Italy; Angela Colucci, MD, University of Bari, Bari, Puglia, Italy; Sara Di Trani, MD, University of Bari, Bari, Puglia, Italy; Antonio Marzaioli, MD, University of Bari, Bari, Puglia, Italy; Francesco Introna, MD, PhD, Professor of Legal Medicine, University of Bari, Bari, Puglia, Italy*

Learning Objectives: The study of skull fractures is very complex in the forensic field. Traumatic fractures of the head have always been of significant interest in the courtroom, especially if caused by the action of other individuals. Osteogenesis Imperfecta is a bone pathology that causes fragility of the bone tissue, even at the cranial level, although this is poorly documented.

Impact Statement: The aim of our work is to present a unique case of traumatic head fractures caused by a punch. The victim was suffering from imperfect osteogenesis. Forensic analysis together with the radiological study of fractures is essential to highlight some salient data and arrive at a definitive diagnosis.

Abstract Text: The analysis of skull fractures represents an important field of forensic medicine. In some cases, the study of fractures, their origin, and propagation can be difficult.[1] Performing an accurate reconstruction of the injury, with the aid of radiological and digital techniques, is fundamental to have a complete picture of the fractures themselves and, therefore, of the dynamics behind them.[2]

The bones of the skull can be fractured by direct traumatic action, represented by the impact of a moving body against the head, or of this one against an obstacle, or by an indirect traumatic action (i.e., by recoil) transmitted by the spinal column due to a fall on the feet or on the trunk, or again by anteroposterior or later-lateral compression, producing in that case two bilateral symmetrical fracture complexes.

A punch thrown at a subject's face is unlikely to produce fracture lesions by direct action. More frequent is the presence of skull fractures symmetrically opposite to the point of application of the punch, for example in the case where the subject suffers a consequent head injury by crashing on the asphalt. What if a subject has a first lesion complex in the right maxilla and a second lesion complex, globe fracture, in the ipsilateral parietal bone? How can this typical fracture pattern be explained? And again, is the second lesion complex a direct consequence of the first lesion complex? If the subject is suffering from Osteogenesis Imperfecta (OI), can this pathology give cranial "manifestations"?[3] How does one answer these and other questions in a courtroom?

This paper originates from the analysis of a court case that came to the attention of the authors. A subject (Y1) lands a punch on the right hemilateral side of the face of another subject (Y2) suffering from OI in clinical stability. Y2 falls backward onto the asphalt, helpless, first impacting on the buttocks and then supine. The sequence of events is documented by, albeit unclear, images extrapolated from a surveillance camera. After the incident, Y2 was promptly subjected to diagnostic and therapeutic treatment.

Initial X-ray images revealed: (1) a first "molded" or small surface fracture complex, consisting of multiple decomposed bone plugs, in the right maxillary sinus, involving the floor of the ipsilateral orbit (anterior margin);and (2) a second C-shaped fracture complex, with anterior concavity, on the right parietal bone, the upper branch of which culminated at the frontal bone, and the lower branch culminated at the inferior lacerated fissure. Can a fist cause this particular, anomalous injury? Can a fist result in two fracture complexes of such magnitude, in the same haemilate of the skull? Can OI, although clinically stable, be a concomitant factor in the genesis of this fracture pattern?[4,5] For an in-depth analysis of the case, a Computed Tomography (CT) reconstruction of the skull was used, which revealed new peculiar findings: small, symmetrical, Wormian bones in the context of the lambdoid suture, which are characterized by fusion of the outer and inner plateau and absence of diploes.[6-9]

In the literature, there are no documented cases of cranial involvement in subjects with OI, let alone cases of cranial fracture trauma of similar magnitude and morphology. Therefore, carefully examining this atypical fracture pattern, on the basis of the fundamental feedback provided by the radiological reconstruction and the patient's clinical data, the authors believe that the bone lesion entity highlighted in the presented case may have been favored by a particular fragility of the cranial plate induced by OI, albeit in a state of clinical stability.

A117 Characterizing Entrance Wounds From Gunshot Trauma in Tubular Bones: Comparing Handgun and Rifle Ammunition

Alexandra Semma Tamayo, MS, Binghamton University, Binghamton, NY; Laure Spake, PhD, Binghamton University (SUNY), Binghamton, NY*

Learning Objectives: After attending this presentation, attendees will have a better understanding of the characteristics that are typically associated with entrance wounds from different types of gunshot trauma in tubular bones.

Impact Statement: This presentation will have a significant impact on the forensic community by presenting valuable data on the characteristics of entrance wounds in tubular bones that are useful for trajectory interpretation.

Abstract Text: Understanding and accurately analyzing gunshot wounds is a difficult task for forensic anthropologists. This is due to the wide variation in firearms, projectile characteristics, and the range of velocities involved, as well as intrinsic characteristics of the impacted bone.[1] The interpretation of entrance and exit wounds resulting from gunshot impacts in tubular bones is currently challenging, as existing knowledge primarily focuses on the wounds in the skull. There have been some experimental studies focused on gunshot wounds in long bones, but such studies remain scarce, with small sample sizes and little consistency between methodologies.[2,3]

Typically, trajectory analysis is performed by identifying entrance and exit wounds based on matching qualitative characteristics (e.g., shape of the defect, beveling, regularity of the defect edges) reported in the literature. However, there are still no systematic approaches aimed at describing the characteristics associated with entrance wounds in long bones that could support forensic investigations. This pilot study particularly focusses on the characteristics of entrance wounds in tubular bones resulting from the impact of 9mm and .223 Remington projectiles.

Deer metapodials (n=20) were donated by a local meat processor in upstate New York and were used as a proxy for human long bones. To replicate wounds that may be observed in casework, the bones were impacted by an expert shooter by using a handgun-type ammunition at 5 meters (9mm non-expandible projectile, n=8), and a rifle type at 20 meters (.223 Remington, n=12). The intact metapodials with soft tissue were vertically held by an industrial clamp in a wooden stand at 110cm from the ground, so that they were placed perpendicular to the weapon and were impacted at the mid-diaphysis region on the medial surface. A plastic tarp was positioned around the stand to collect all bone fragments ejected during the shots. After the shooting, the metapodials were dissected manually, and any remaining tissue was removed using detergent-enzymatic maceration in warm water. The fragments were then realigned using a dissolvable glue, and their qualitative (fracture and defect morphology for both entrance and exit defects) and quantitative fracture characteristics (size and number of fragments) were evaluated.

The .223 Remington caused more fragmentation, which resulted in fragments that were both larger and narrower than those produced by the 9mm. While extreme fragmentation prevented full reconstruction of some bones, both sample groups exhibited circular and semicircular defects with external beveling and cortical chipping. Additionally, both sample groups showed multiple radiating fractures emanating from the entrance wound, resulting in a triangular fragment that was only observed to be associated with the entrance defect. Further, the triangular fragment was usually larger in samples impacted by the 9mm projectile since these impacts had fewer radiating fractures compared to those produced by the .223 Remington.

Preliminarily, this study demonstrates that external beveling and cortical chipping are consistent characteristics of entrance wounds, regardless of the type of projectile. The appearance of a triangular fragment is also linked to the point of impact in long bones, and it could indicate the trajectory when incomplete bones are being analyzed. This triangular fragment, when used in conjunction with other fragment size metrics, may be useful in differentiating between types of projectiles. Further pattern analysis should be performed on more suitable proxies for human long bones to account for the range of variations in bone defects from gunshot trauma.

Gunshot Trauma; Long Bones; Entrance Wounds

A118 Exploring Inter-Observer Agreement in Assessments of Projectile Defects

Mariyam I. Isa, PhD, Lubbock, TX; Delaney Edwards, MA, The Ohio State University, Gahanna, OH; Jordyn Knysz, BA, California State University, Chico, Buffalo Grove, IL; Alexander E. Curry, BA, University Nebraska Lincoln, San Antonio, TX*

Learning Objectives: Attendees will learn about inter-observer agreement and reliability in assessments of experimentally produced projectile trauma. Potential implications for documenting skeletal trauma in research and casework will also be discussed.

Impact Statement: This presentation impacts the forensic science community by critically evaluating how skeletal trauma assessments may vary among analysts. This line of research may help identify training needs and/or inform development of guidelines for documenting trauma in research and casework.

Abstract Text: Visual and written documentation are required components of skeletal trauma analysis.[1] Current standards require written documentation of defect location and characteristics but offer minimal guidance about the characteristics to document.[1] Research investigating which types of characteristics are most and least reliably documented among analysts may help inform the development of practical guidelines for documenting skeletal trauma.

The objectives of this study were to: (1) determine whether there are statistically significant differences in trauma assessments made by different observers, and (2) identify which variables exhibit the highest levels of inter-observer agreement and reliability.

Four analysts (one PhD, one MA, and two BAs) independently assessed 39 porcine scapulae with experimental gunshot defects. The two analysts with graduate degrees had prior experience evaluating projectile defects for the investigated variables while the two analysts with undergraduate degrees did not. All four analysts evaluated the presence and number of cone cracks, radial cracks, circumferential cracks, and crack branches in all 39 scapulae. Experienced analysts measured entrance (enTFL), exit (exTFL), and total (TFL) fracture lengths and minimum and maximum entrance and exit defect dimensions in all 39 scapulae. Inexperienced analysts measured a subsample of 12 scapulae. Fleiss' kappa was used to evaluate inter-observer agreement on the presence of features. Intra-Class Correlation (ICC) was used to assess inter-observer reliability for fracture counts, lengths, and defect dimensions. Results with p-values less than 0.05 were considered statistically significant. Reported κ and ICC values are significant unless noted.

There were significant differences among observers in the presence of cone cracks, circumferential cracks, and crack branches, and in the number of radial cracks, circumferential cracks, and crack branches. Differences were primarily between experienced and inexperienced analysts. Inexperienced analysts tended to identify fewer features than experienced analysts.

Perfect agreement was observed on radial crack presence. An ICC value of 0.54 suggests a moderate level of inter-observer reliability in radial crack counts. There was moderate agreement on the presence ($\kappa = 0.45$) and number of crack branches (ICC = 0.53) and fair agreement on the presence of circumferential cracks ($\kappa = 0.20$). The presence of cone cracks showed poor agreement ($\kappa = 0.07$, $p = 0.30$).

In the subsample measured by all analysts (n=12), only TFL and exFL differed significantly by observer, with inexperienced analysts measuring shorter lengths than experienced analysts. Inter-observer reliability was high for enTFL (ICC = 0.91), while analysts measured exTFL (ICC = 0.49) and TFL (ICC = 0.43) with greater variability. Among defect dimension measurements, reliability was good for minimum exit measurements (ICC = 0.87) and moderate for maximum entrance (ICC = 0.54) and maximum exit measurements (ICC = 0.54). Minimum entrance measurements (ICC = 0.23) exhibited considerable variability, indicating poor reliability.

In the full sample measured by experienced analysts (n=39), fracture length ICC values ranged from 0.94 to 0.96, indicating excellent inter-observer reliability. ICC values were higher for minimum exit (ICC = 0.84) and minimum entrance (ICC = 0.73) than maximum entrance (ICC = 0.46) and maximum exit (ICC = 0.54) measurements, indicating greater inter-observer reliability for minimum than maximum dimensions.

This study explored inter-observer agreement and reliability across various trauma assessments. Analysts identified and counted radial cracks and crack branches more consistently than circumferential cracks or cone cracks. Among experienced analysts, fracture length and minimum defect dimensions exhibited the highest inter-observer reliability, suggesting these measurements may be particularly desirable in trauma documentation. Notably, the results indicate experience influenced trauma assessments. Standardized guidance and increased training may improve reliability of trauma documentation in research and casework. Further research is needed to investigate intero-bserver reliability among a larger pool of analysts and in different trauma types.

A119 The Validation of 3D Photogrammetry Models to Document Cranial Trauma

Samantha L. LaVake, BS, University of Tennessee, Knoxville, Farmington, MI; Carolyn V. Isaac, PhD, Michigan State University, East Lansing, MI*

Learning Objectives: After attending this presentation, attendees will understand a practical application of photogrammetry, specifically in documenting cranial fractures, as well as the accuracy of this method when investigating skeletal cranial trauma.

Impact Statement: This presentation will impact the forensic science community by providing a method to investigate and three-dimensionally document skeletal trauma in a concise and ethical manner. Possible future outcomes of this research include accurate three-dimensional models of skeletal remains that can be used in place of physical remains when necessary.

Abstract Text: Three-dimensional imaging is an ideal way to document skeletal trauma for independent evaluation by other forensic practitioners, which allows the physical remains to be released to the decedent's loved ones in a timely manner. This study investigated validating the accuracy of photogrammetry on fractured human crania. Photogrammetry is a method that consists of taking a series of photographs at various heights and angles to then compile into a three-dimensional model using a software program. The program used to create the models is called "Reality Capture." This program uses the photos to match points on the object and stitch the photographs together to render a three-dimensional model. This approach is both cost effective and convenient for ease of access and portability as it only requires a high-resolution camera. This makes it preferable to other three-dimensional imaging technologies of Computed Tomography (CT) scans and 3D laser scanning, which require specialized and expensive equipment.

While some studies have tested the use of photogrammetry reconstructions on cranial measurements, none have explored its utility in skeletal trauma analysis. Ten previously fractured crania were photographed and modeled using Reality Capture. The ten fractured crania were photographed 180 times from three different angles and heights as well as positioned three different ways: Anterior, Inferior, and Superior views. This setup was utilized to have a sphere-like pathway of the camera to result in many overlapping photographs to create a measurable three-dimensional model. The same three fractures were measured on both the physical crania and the digital model, using a sliding caliper and the measuring tool on Reality Capture. A paired t-test was conducted to compare the measurements between the physical hand measurements and the Reality Capture measurements. The p-value came out to be 0.05119, suggesting there is no statistically significant difference between these measurements. The mean difference was 0.8416, indicating that the program, on average, overestimates the measurements by 0.8416mm. To have the shorter and longer measurements on the same factor scale, a relative error test was conducted. The average relative error was 0.0274, which indicates that Reality Capture, on average, overestimates values by 2%.

A120 Enhancing Forensic Investigations: Leveraging Transfer Learning for Cut Mark Classification on Skeletal Remains

Giada S. Steiger, MSc, Liverpool John Moores University, Liverpool, England, United Kingdom; Ricardo O. Chavez Garcia, PhD, Istituto Dalle Molle di Studi sull'Intelligenza Artificiale, Manno, Switzerland; Matteo Borrini, PhD, Liverpool John Moores University, Liverpool, England, United Kingdom*

Learning Objectives: After attending this presentation, attendees will understand the challenges of classifying cut marks in forensic investigations, the principles of using Artificial Intelligence (AI) and Convolutional Neural Networks (CNN) for image classification, and the specific application of transfer learning in this context.

Impact Statement: This presentation will impact the forensic science community by introducing a novel approach to cut mark classification, potentially increasing the reliability of forensic investigations. Furthermore, this research offers practitioners a cutting-edge method that can be easily integrated into already established workflow.

Abstract Text: Sharp force tools, and most commonly knives, are one of the weapons most frequently used in homicides in the United Kingdom.[1] Recent research has demonstrated that the ability to reliably classify cut marks using traditional methods is greatly experience-dependent and can impact forensic investigation.[2,3] This pilot study explores the potential of AI to assist in classifying cut marks produced by knives, leveraging computer vision to analyze and process two-dimensional images. Neural Networks (NN) are usually the preferred choice for image classification as these machine-learning structures can detect complex patterns.[4]

Traditional NN models, which require large amounts of training data, are impractical in the forensic field due to the difficulty of obtaining sufficient cut mark images. To overcome this limitation, the present project employs transfer learning, a method where pre-trained algorithms are fine-tuned using a new specific dataset to solve the desired classification task.[4]

The pilot study aims to assess the effectiveness of transfer learning for classifying knife trauma produced by serrated or non-serrated knives and by single- or double-beveled blades.

For this purpose, the authors have produced a new dataset of cut mark images. The dataset, which includes 130 vertical and 130 profile images of cut marks, has been made by photographing 130 cut marks from different angles. The nine knives that have been used to generate cuts on sus scrofa defleshed ribs are: Knife 1—non-serrated single-beveled; Knives 2,3,and 4—non-serrated double-beveled; and Knives 5,6,7,8, and 9—serrated single-beveled.

Photographic images of the cut marks have been acquired using a stereomicroscope with an integrated camera at various magnification levels to mimic real investigative scenarios. Photographs have been taken vertically and at a 90° angle (profile) following the methodology proposed by Steiger and Borrini.[3] This kind of photograph is consistent with the documentation routinely provided by forensic practitioners, which could be easily integrated into this process in the future.

The cut marks images have been pre-processed following model-related requirements, and data augmentation procedures have been applied to generate additional training data. Two classifiers have been trained and fine-tuned with the vertical images dataset to distinguish between serrated and non-serrated knives and single- and double-beveled knives, while a second pair has been trained and tested using the profile pictures.

The implementation of AI and transfer learning in the classification of cut marks is a promising advancement in forensic science. This preliminary study serves as a starting point for further research and development to provide forensic practitioners with a machine learning method for cut mark analysis. Furthermore, the creation of the dataset serves as a preliminary version of a larger, standardized dataset for trauma classification.

AI; Machine Learning; Anthropology

A121 Cutting Edge Comparisons: Analyzing Saw Kerf Variables in Bones Versus Casts

Alexis L. VanBaarle, MS, Michigan State University, East Lansing, MI; Heather M. Garvin, PhD, Des Moines University, West Des Moines, IA*

Learning Objectives: After attending this presentation, attendees will have a better understanding of the differences in observing and measuring saw kerf variables from bony surfaces and their casts.

Impact Statement: This presentation will impact the forensic science community by providing a comparison of saw kerf data collected from bony specimens and their casts to contribute to best practices in forensic anthropological cases of dismemberment.

Abstract Text: In medicolegal cases involving sharp force defects, forensic anthropologists often create casts of defects. A cast is an impression of a defect surface that can be useful in situations where defect surfaces are not easily observable (e.g., incomplete cuts) and creates a permanent record of the defect. While previous research has looked at the use of casts to determine tool class for knives, its use in saw mark analysis has been largely anecdotal and based on knife research. The goal of this research is to compare saw kerf variable scoring and measurement from complete saw cuts in bone and their casts to assess inter-media error rates and provide recommendations for forensic saw mark analyses.

The research sample includes 258 complete cut surfaces created during a previous research project using 27 different saws with varying class characteristics.[1] Nineteen anatomically gifted human humeri and femora were macerated, then sawed while secured with a vice. Each of the cut surfaces was cast. Two kerf variables were selected for this study—tooth hop and pull-out striae. All surfaces were assessed under a stereoscopic microscope. The number and length of tooth hop chains and measurements between consecutive peaks and troughs as well as the number of pull-out striae groups, number of striations within each group, and measurements between each striation were recorded for all cut surfaces. Simple comparisons of kerf variables identified on cut surfaces were calculated using Excel. A McNemar test was used to assess differences in kerf variable identification between media, and Wilcoxon signed rank tests assed differences between the number of tooth hop chains or pull-out striae. Tooth hop chains found on both media were isolated and measured. Relative and absolute differences and relative Technical Error of Measurement (rTEM) were calculated, and a Wilcoxon test was used to assess the difference between the measurements.

The presence/absence of tooth hop was consistently identified on 66.28% of specimens. Tooth hop was identified on 14.34% of the bone specimens and 47.29% of the cast specimens, with a significant difference ($p < 0.001$) between the two media. Of the 36 times tooth hop was identified from both media, the number of chains identified matched in only 8.33% of the specimens; 2.78% had more chains identified on the boney surface as compared to 88.89% on the casts. On average, the casts had four times the number of chains identified. There was no statistical difference in measurements between the media ($p=0.503$), with average relative and absolute differences at -0.034mm and 0.092mm, respectively. rTEM was 14%. There were no systematic trends in measurements deviations, suggesting this is normal measurement error rather than systematic errors caused by the media. Pull-out striae presence/absence matched in 86.43% of specimens. Presence was noted in only 2.71% of boney specimens as compared to 13.95% of casts, with a statistical difference ($p < 0.001$). No significant measurement differences were found.

Both kerf variables were identified more often on the cast surface compared to the boney surfaces with no significant differences in measurements between the media. The use of casts to identify and measure tooth hop and pull-out striae on cut surfaces is recommended as these features are more identifiable in casts, likely because of the cast coloration and lack of glare.

A122 Testing Bias in Cut Mark Analysis: An Exploratory Study

Karin Dominko, MS, Liverpool John Moores University, Maribor, Maribor, Slovenia; Giada S. Steiger, MSc, Liverpool John Moores University, Liverpool, England, United Kingdom; Matteo Borrini, PhD, Liverpool John Moores University, Liverpool, England, United Kingdom*

Learning Objectives: After attending this presentation, attendees will have an opportunity to evaluate the accuracy of cut mark analysis among different levels of expertise and understand how the reliability of the observers changes when exposed to biasing stimuli.

Impact Statement: This presentation will impact the forensic science community by analyzing the implications of human errors when adopting morphological observation in real-life forensic cases involving knives as weapons of choice.

Abstract Text: Forensic anthropology plays a critical role in the criminal justice system and the overall security of our society; consequently, examiners' potential lack of reliability, objectivity, and independence can have far-reaching implications beyond the discipline itself.

In the past 15 years, there has been increased interest in studying the factors and stimuli that negatively affect forensic work, primarily cognitive bias, which influences experts' judgments. This is even more important when considering methods based on visual comparative analyses that are widely used in forensic anthropology, while having the highest potential of being influenced by bias. Therefore, the authors used cut-mark assessment classification standards as background for the present research that investigates susceptibility to cognitive bias.[1]

Four different types of knives (single- edged, double-edged, serrated, and non-serrated) were used to create 17 cut marks on pig ribs (*Sus scrof*a); the cuts were photographed under a stereomicroscope (38x magnification) with a tangential light source. Photographs were taken vertically and at a 90° angle (profile). Additional photographs of two cut marks per knife type stained with synthetic blood were also taken. Similarly, photos of each knife were taken, with the addition of some without a metric reference and some with synthetic blood stains on the blade and handle.

An online questionnaire containing photographs of cut marks and knives was created. The questions, randomly mixed, were divided into three categories: (1) 11 control questions; (2) 7 confirmation bias-evoking questions; and (3) 11 contextual bias-evoking questions. In the latter category, the context was provided through photographs of blood-stained cut marks and/or blades and pictures without metric scales. Each questionnaire page contained a single query and always provided the viewer with the classification standards.

The survey involved 70 forensic anthropologists of differing educational levels (23 BSc students, 23 MSc students, 6 PhD students, and 18 practitioners) who were tested for their susceptibility to bias.

The results show that the classification standards used offer an accurate basis for analyzing cut marks, with a statistically significant difference in accuracy among educational levels. The findings also demonstrated the statistically significant differences between educational levels and their susceptibility to contextual bias. While statistically significant differences between educational levels were not observed for confirmation bias, statistically significant decreases in the accuracy of answers were detected when comparing control and confirmation bias questions. This was especially true for the cases of PhD students and forensic practitioners, which implies they were more susceptible to confirmation bias than undergraduate and master's students.

The authors suggest that the biasing stimuli employed in this study, such as leading questions and specific contextual clues, need to be mitigated in the everyday work of forensic anthropologists. Effective procedures, such as blinding and the involvement of independent experts, should be employed to mitigate the effects of cognitive bias. In the future, the development of machine learning and AI-assisted software for the observation of cut marks could also improve the reliability of cut mark and blade classification.

Trauma; Anthropology; Evidence Evaluation

A123 Assessing Cranial Macromorphoscopic Traits Used in the Forensic Estimation of Population Affinity

Savannah R. Holcombe, MS, Michigan State University, Lansing, MI; Joe T. Hefner, PhD, Michigan State University, East Lansing, MI*

Learning Objectives: This presentation will provide a brief overview of cranial Macromorphoscopic (MMS) trait analysis in forensic anthropology. This research assesses the utility of a number of new MMS traits and explores the relationships between their various manifestations within a sample.

Impact Statement: This study will provide attendees with: (1) standard definitions for five underexplored cranial MMS traits, as well as a description of the character states for each; (2) a report of the frequency distribution of each trait within eight diverse samples, and; (3) the correlations between the traits and the samples. After attending this presentation, listeners will be well informed on the use of MMS trait analysis and provided with more robust methods for cranial non-metric assessment.

Abstract Text: MMS traits are minute variations in bone, feature, or suture morphology which contribute to overall cranial morphology.[1,2] These traits have been applied to methods for the forensic estimation of population affinity as well as biodistance studies more recently. Population affinity estimates are one component of the biological profile (along with sex, age, and stature) that forensic anthropologists generate for medicolegal death investigators and law enforcement. These profiles are used to help narrow the pool of potential individuals compared with the unidentified skeletal remains. Research has shown that MMS trait analysis can accurately classify unknown individuals into one of the reference groups for a given sample.[1-4]

To further explore cranial MMS traits and assess their potential to correctly classify population affinity for an unidentified decedent, this research tests the utility of five traits for the estimation of population affinity using data from individuals curated by the National Museum of Natural History (n = 720), previously collected by one of the authors.[1] Female and male adults from eight populations (African: n=30, American Black: n=150, American White: n=169, Chinese: n=59, German: n=8, Dutch: n=7, Japanese: n=15, and Native American: n=282) were included to assess any differentiation in trait manifestation by sex and/or population affinity. The cranial MMS traits assessed in this study include: Depression at Nasion, Trace Metopic Suture, Transverse Palatine Suture, Venal Etching, and Sub-nasal Grooves.

Initial data analysis was conducted using a variety of summary and descriptive statistics as well as base-level statistical analyses, including correlation and covariance and Kruskal-Wallis tests to determine significant influence of demographic data on trait expression. Classification models (random forest) were used to assess the classificatory power of these traits.

Results indicate the degree of manifestation of each MMS trait is significantly influenced by both sex and population, excluding the Trace Metopic Suture and the Transverse Palatine Sture by sex. A cluster dendrogram demonstrated significant association in the expression of Venal Etching and Sub-nasal Grooves and Depression at Nasion and the Transverse Palatine Suture. A random forest model correctly classified ~48% of the sample; Transverse Palatine Suture shape was the most important variable in that model.

The five MMS traits assessed in this study have been around for decades, but little or no frequency distribution data has appeared to document their manifestation. These traits are useful in population affinity estimates, but more importantly, they are also useful for exploring aspects of modern human variation.

Macromorphoscopic Traits; Population Affinity; Human Variation

A124 Exploring Cranial Macromorphoscopic Variation in a Modern American Indian Sample From New Mexico

Kelly R. Kamnikar, PhD, University of New Mexico, Marana, NM; Nicollette S. Appel, MS, University of New Mexico, Glen Head, NY; Heather Edgar, PhD, Office of the Medical Investigator, Albuquerque, NM; Micayla C. Spiros, PhD, District of Columbia Office of the Chief Medical Examiner, Albuquerque, NM; Hannah N. Cantrell, BS, University of Oregon, Eugene, OR*

Learning Objectives: After attending this presentation, attendees will be introduced to a new reference dataset of cranial morphological variables for a modern American Indian (AI) sample from New Mexico (NM).

Impact Statement: This presentation will impact the forensic science community by providing a new reference sample of cranial Macromorphoscopic (MMS) data for AIs and exploring patterns of variation within the data and compared to other population groups encountered in NM casework.

Abstract Text: Skeletal morphology can be used to examine human variation and assess population affinity in forensic anthropology using several different methods. Method performance is highest when populations present in forensic casework are represented in reference databanks used for methodological development. Cranial MMS traits are highly heritable, reflecting neutral traits under selection, and can be used to estimate population affinity in forensic anthropology successfully, serving as a proxy for genetic relatedness.[1] Currently, cranial MMS data for contemporary AIs are absent from reference databanks, leading to uncertainty when using these data in population affinity estimates. Here we present cranial MMS data from modern AI, identify patterns in the data, and compare biological distance among AIs and other samples.

Cranial MMS data were collected from Computed Tomography (CT) data housed in the New Mexico Decedent Image Database (NMDID) for individuals with American Indian (n=1022), Hispanic (n= 404); American White (n=47), American Black (n=270), and broadly Asian (n=95) affinities. These scans were collected during postmortem examination at the New Mexico Office of the Medical Investigator from 2010–2017.[2] Data for 12 cranial MMS traits were collected following available protocol for CT data based on original instructions for dry bone.[3,4] Initial Data Analysis (IDA) identified patterns among skeletal data for the AI sample and biological distance analysis examined relationships among samples.

IDA showed weak positive correlations between Nasal Aperture Shape (NAS) and Nasal Aperture Width (NAW; 0.13), NAW and Interorbital Breadth (IOB; 0.19), and Anterior Nasal Spine (ANS) and Inferior Nasal Aperture (INA; 0.13). Multiple correspondence analysis shows group separation was most significant with nasal derived traits (NAS, NAW, ANS) and Palate Shape (PS). The AI sample exhibited a wider NAW, minimal to no projection of ANS, a more bell- and bowed-shape NAS, and a more hyperbolic PS. Biodistance analysis using Smith's Mean Measure of Divergence indicated significant distances among all group pairs at the $p = 0.05$ level. The White sample was the furthest from the AI sample and plotted away from all other groups. The AI, Black, Hispanic, and Asian groups plotted in a cluster, but the distance matrix separated the AI sample slightly from the other three. A hierarchical plot separates the White sample at the first node, then Asian/Black and Hispanic/American Indian.

These patterns reveal that the AI sample is different from other samples encountered in forensic casework, and that the AI sample is the most like the Hispanic sample, aligning with the migration history of these two groups. Cranial MMS traits indicate group separation using midfacial traits of the nasal and palate area. Further exploration of the AI sample will include classification modeling to assess utility in casework in NM and the United States Southwest.

A125 Patterns of Covariation in Cranial Metric and Macromorphoscopic Variables

Briana New, MA, University of Nevada, Reno, Reno, NV; Kyra Stull, PhD, University of Nevada, Reno, Reno, NV; Leah E. Auchter, MA, University of Nevada, Reno, Reno, NV; Kate Spradley, PhD, Texas State University, San Marcos, TX; Joe T. Hefner, PhD, Michigan State University, East Lansing, MI; Christopher A. Wolfe, PhD, East Carolina University, Greenville, NC; Elaine Y. Chu, PhD, Texas State University, San Marcos, TX; Louise K. Corron, PhD, University of Nevada, Reno, Reno, NV; Matthew C. Go, PhD, SNA International, supporting the Defense POW/MIA Accounting Agency, Joint Base Pearl Harbor-Hickam, HI*

Learning Objectives: After attending this presentation, attendees will better understand the relationships between cranial Macromorphoscopic (MMS) traits, Interlandmark Distances (ILDs), and demographic variables from three samples.

Impact Statement: This presentation will impact the forensic science community by demonstrating the consistent patterning in relationships across cranial phenotypic variables regardless of geographic origin or temporal variation. This knowledge impacts how and when forensic anthropologists should mobilize cranial variables to estimate aspects of the biological profile.

Abstract Text: Previous research has quantitatively demonstrated that, except for traits assessing analogous nasal and interorbital breadths, craniometric measurements (ILDs) and MMS traits provide different information about cranial phenotypic variation in contemporary United States samples.[1] The current study quantifies patterns and associations among ILDs, MMS traits, biological sex, and country of origin in three temporally and/or geographically distinct samples. Data were obtained for 385 adult individuals for two 21st-century samples and one early 20th-century sample. These include the Subadult Virtual Anthropology Database (SVAD; n=240), a cemetery sample from Manila (n=75), and the Forensic Anthropology Databank (FDB; n=70). The SVAD and FDB samples were downsampled in a previous project to balance the biological sexes, and with the inclusion of the Manila sample, the total sample is slightly skewed to more males (n=201) than females (n=184).[1] Twelve MMS traits were scored and 22 ILDs were derived from either volumetric models of the cranium reconstructed from computed tomography scans (SVAD) or collected directly from skeletal remains (FDB and Manila). Unsupervised techniques, like Mixed Factor Analysis (MFA) and Factor Analysis of Mixed Data (FAMD), were employed to analyze both variable types using structured grouping (MFA) and variable level exploration (FAMD).

MFA analyses indicate the first four dimensions account for 40% of total variance. Dimension 1 captures the relationships between country of origin and the MMS traits. Dimension 2 captures the relationship between ILDs and sex. Dimension 3 captures the temporal and geographic variation across samples. Dimension 4 captures shared variation among ILDs and MMS. FAMD analyses indicate that country of origin is most closely associated with mid-face MMS traits and splanchnocranium ILDs. Additionally, biological sex is most closely associated with all ILDs and the more metrically assessed MMS traits, such as post-zygomatic tubercle and malar tubercle. Country of origin and biological sex are separated in every analysis across the first and/or second dimensions, demonstrating differential impacts of these demographic variables on cranial phenotype. While these multivariate relationships consistently differentiate between biological sex and between country of origin, the patterns among variables are consistent across all samples whether explored independently or in tandem.

These results support long-standing interpretations concerning the relationships between variable traits and population demographics mobilized in forensic anthropological casework. Furthermore, the analyses presented herein reinforce the intricate, multi-faceted nature of the cranial phenotype and provide empirically grounded results to guide practical applications. Incorporating advanced statistical methodologies and computational approaches capable of concurrently assessing categorical and metric data may better capture cranial variation and provide stronger estimates for the biological profile components in forensic casework.

A126 Exploring Population Affinity Analysis for Forensic Anthropology Casework in Latin America

Kelly R. Kamnikar, PhD, University of New Mexico, Marana, NM; Daniel A. Jimenez Gaytan, MS, Instituto Nacional de Ciencias Forenses, Guatemala City, Guatemala; Joe T. Hefner, PhD, Michigan State University, East Lansing, MI; Amber Plemons, PhD, California State University, Chico, Chico, CA*

Learning Objectives: After attending this presentation, attendees will better understand the relationship between cranial morphology and genetics. Using these data, we investigate variation among three regional samples from Latin American in a biological distance framework.

Impact Statement: This presentation will impact the forensic science community by providing biological distance estimates among paired skeletal data and genetic microsatellite loci to discuss the use of craniometric and cranial Macromorphoscopic (MMS) data in the estimation of population affinity on a regional scale.

Abstract Text: Variation in skeletal morphology has been used to estimate population affinity within the United States for decades, largely using craniometric and cranial MMS trait data. This is possible due to the correspondence between skeletal morphology and the genetic structure among population groups; however, this relationship is poorly understood among Latin American populations, which is problematic when unknown individuals cannot be identified through traditional means (i.e., DNA analysis, medical radiography). Herein we focus on the biological profile for identification. We investigate skeletal and genetic variation in three Latin American samples to understand the potential for population affinity modeling in the region. Given different skeletal features identify different aspects of variation, we explore relationships among matched craniometric and cranial MMS data, and test if these skeletal features can serve as proxies for genetic variation in population affinity modeling within Latin America.[1]

Paired data (craniometric and cranial MMS) were collected from Mérida, Mexico (n=111), Guatemala City, Guatemala (n=60), and Medellín, Colombia (n=158). Craniometric data were collected using a Microscribe digitizer and 3Skull software.[2] Cranial MMS data were collected using MMS v1.61.[3] In total, 24 Interlandmark Distances (ILDs) and 10 MMS traits were used in analysis. A set of microsatellite loci (n = 305) was selected from the Pemberton Genetic Dataset as population-genotype comparative data.[4] Initial Data Analysis (IDA) identified patterns among skeletal data; biological and genetic distance analysis assessed similarity and dissimilarity among groups and data types.

Results indicate metric and cranial MMS data separate the samples using different aspects of cranial morphology. The most influential ILDs for group separation include MAB, MDH, and several vault length and breadth measures, while cranial MMS traits (ANS, INA) were highly variable in character state among groups tested. When compared to genetic data, patterns of skeletal variation for both data types reflected those observed in the genetic samples. The craniometric and genetic data produced a strong correlation coefficient of 0.65 ($p < 0.05$), while the cranial MMS and genetic data produced a remarkably strong correlation coefficient of 0.93 ($p < 0.05$), suggesting a highly significant association between cranial MMS and genetic variation. These findings underscore the potential utility of cranial MMS as a proxy for genetic relatedness. Further research identifying the biological mechanisms underlying this correlation is warranted.

Results from this study show that craniometric and cranial MMS variables can be used separately or together to examine variation on smaller, regional scales. This study indicates that population affinity shows promise in Latin America and can be used to identify possible migrants or non-citizens in forensic casework.

Forensic Anthropology; Cranial Morphology; Biological Distance

A127 AI-Assisted Technological Advancements for the Collection of Cranial Landmark Data and Interlandmark Distances From Medical Imaging Software

Nicollette S. Appel, MS, University of New Mexico, Glen Head, NY; Kelly R. Kamnikar, PhD, University of New Mexico, Marana, NM; Heather Edgar, PhD, Office of the Medical Investigator, Albuquerque, NM; Kate Spradley, PhD, Texas State University, San Marcos, TX*

Learning Objectives: This presentation introduces a novel module for collecting craniometric landmark data using 3D surface renderings of Computed Tomography (CT) scans in the medical research imaging software Amira. Developed with Artificial Intelligence (AI), this module integrates with the Amira interface and is fully customizable to meet researchers' needs. Attendees will be introduced to the module and gain insights into data collection capabilities and the extensive information it can provide.

Impact Statement: The presentation will guide attendees through the complete process of using the craniometrics module, demonstrating how to leverage Amira's functionalities. This module exemplifies the potential of combining AI and CT scans in forensic applications, and represents an innovative approach to collecting craniometric data in virtual osteology.

Abstract Text: Virtual anthropology databases provide substantial benefits for research, offering large-scale, diverse cohorts that can be used to drive methodological advancements in research and allow for testing of theoretical models that may otherwise not be possible. As technology evolves, it is crucial to develop methods that utilize these new forms of imaging and visualization effectively.

Our interdisciplinary team developed a craniometric data collection module within the Amira software to enhance, improve, and expedite large scale data collection for cranial landmark data in virtual anthropology. This module's capabilities include 3D visualization of CT scans, creating reference data to be used as a standard for data collection, registering sample data to the reference data, AI-driven landmark plotting, and obtaining an output file containing the x, y, and z coordinate data of all plotted landmarks and the interlandmark distances. Using Amira's general functionalities, researchers can also plot floating landmarks and endocranial landmarks, enhancing the flexibility and comprehensiveness of data collection.

One of the most significant advantages of the Craniometrics Module is its complete customizability. Researchers can tailor the specific landmarks and the number of landmarks collected as well as the skull registration process, based on their research questions and goals. This customization ensures that the data collection process aligns precisely with the unique requirements of each study. The ease of data collection provided by this module is a marked improvement over other virtual craniometric data collection procedures. Here we demonstrate the module and cranial landmark data collection.

In its current form, the module allows researchers to load input files, register the sample skull, and plot 106 cranial landmarks (both ectocranial and endocranial) in approximately 40 minutes. Previous pilot studies requiring the collection of only 64 cranial landmarks using different methods took over an hour, not including the preprocessing time for CT scans. Since its implementation in April 2023, data on over 650 individuals have been collected to be added to the Forensic Databank, increasing reference sample sizes for underrepresented groups such as American Indians.

The Craniometrics Module represents a significant advancement in the field of forensic anthropology. By leveraging the latest in AI and medical imaging technology, it offers a faster and easier method for collecting craniometric data. Its customizability and integration with Amira's powerful tools make it an invaluable resource for anthropological research. As technology continues to advance, the Craniometrics Module sets a new standard for data collection in virtual anthropology, demonstrating the potential of combining AI and CT scans to push the boundaries of forensic science.

A128 An Evaluation of the Accuracy and Reliability of MorphoPASSE for Skeletal Sex Estimation Using the University of Tennessee Donated Collection

Derek A. Boyd, PhD, University of Nevada, Las Vegas, Las Vegas, NV; Kylie A. Williamson, PhD, University of Tennessee-Chattanooga, Chattanooga, TN; Sarah T. Schwing, MA, University of Tennessee-Knoxville, Knoxville, TN; Steven G. Lautzenheiser, PhD, University of Tennessee-Knoxville, Knoxville, TN; Devin L. Adcox, MA, University of Tennessee-Knoxville, Knoxville, TN; Emma C. Pullias, BA, Mississippi State University, Starkville, MS; Sarah T. Schwang, MA, University of Tennessee-Knoxville, Knoxville, TN*

Learning Objectives: After attending this presentation, attendees will better understand the accuracy, reliability, and limitations of the MorphoPASSE trait descriptions and associated random forest modeling approach to skeletal sex estimation. Attendees will also have a better understanding of the impact of previous experience using traditional sex estimation methods on the implementation of MorphoPASSE.

Impact Statement: This presentation will impact the forensic science community by informing practitioners of MorphoPASSE's ability to yield accurate sex estimates despite variation in skeletal trait scores among raters. This presentation will also draw attention to how ambiguous trait scores and by extension probability values for sex membership impact the accuracy and reliability of this program. Finally, this presentation will provide compelling evidence to support previous assertions that all practitioners regardless of experience level should calibrate using MorphoPASSE-specific trait descriptions prior to using this new program in forensic casework.

Abstract Text: Skeletal sex estimation is a component of the biological profile that contributes probative information during identification. Traditional methods consider pelvic and cranial non-metric traits separately, preventing the generation of a singular estimate of biological sex that exploits multiple aspects of human skeletal variation.[1,2] To address this issue, Klales introduced MorphoPASSE, which is an online open-access program that uses revised traditional non-metric trait descriptions and random forest modeling to statistically integrate these traits from both the pelvis and cranium.[3] To date, MorphoPASSE has only been independently validated once using cranial CT data, though practitioners have begun to incorporate this software and its revised trait descriptions into routine casework.[4] To address this issue, we evaluated the accuracy and reliability of MorphoPASSE using the intended methods of observation (visual and tactile) of both cranial and pelvic non-metric traits collected from 262 donors from the University of Tennessee Donated Skeletal Collection.

Donors were analyzed blind by six independent raters categorized as either experts or non-experts based on terminal degree held and years of experience applying traditional sex estimation methods. Donors were randomly selected from a list of donors not included in MorphoPASSE program development or its reference sample. Experts (n=2) analyzed traits for all donors included in this study, while non-experts (n=3) and one undergraduate with no previous experience analyzed a subset of 57 donors. Trait scores for each donor were run through MorphoPASSE using the contemporary United States reference sample with separate analyses for known and unknown ancestry, and male and female probability values were recorded.

An 80% classification threshold was chosen in consultation with current literature to assign donors to estimated sex categories of female, male, or undetermined.[5-7] Accuracy levels based on this threshold exceeded 85% for both experts and non-experts across analyses when compared with known sex. When donors classified as undetermined were excluded, accuracy levels improved, exceeding 98%. Cohen's kappa values comparing known with estimated sex indicated near perfect agreement at the $p < 0.001$ level for expert and non-expert raters.

Intra-class Correlation Coefficients (ICC) were used to evaluate inter-rater reliability in trait scores collected by expert and non-expert raters. Inter-rater reliability was good to excellent for experts (ICC >0.831) and non-experts (ICC >0.819) across all skeletal traits. Intra-rater reliability, which was evaluated for experts only using a subset of 36 donors, was also good to excellent with ICCs that met or exceeded 0.802 excepting the mental eminence.

A series of Wilcoxon signed-rank tests, which were used to compare probability values produced by MorphoPASSE among raters, identified small ($r < 0.300$) significant differences in these values between the two experts at the $p < 0.001$ level. Another set of these tests was used to compare probability values generated for two separate observations of the same 36 donors for experts only as an additional measure of intra-rater reliability. A moderate ($0.300 < r < 0.500$) significant difference was detected for one expert when ancestry was known ($p = 0.045$).

These findings suggest that, despite some variation in trait scores and generated probabilities among raters, MorphoPASSE produces accurate sex estimates at an 80% classification threshold, especially when undetermined donors are excluded. Importantly, accuracy and inter-rater reliability do not appear to scale with experience level once raters have at least two years of previous experience. It is strongly recommended that practitioners calibrate prior to implementing MorphoPASSE in casework regardless of previous experience and that the program be subjected to further validation across geographic regions and temporal periods. Moreover, further research and clarification is needed to understand the impact of ambiguous skeletal variation and associated trait scores on the accuracy and reliability of the MorphoPASSE random forest model.

Biological Profile; Sex Assessment; Method Validation

A129 The Application of Decision Trees and Random Forest Modeling for Combining Morphological and Metric Variables of the Skull for Osteological Sex Estimation

Morgan J. Ferrell, PhD, University of Kentucky, Lexington, KY; John J. Schultz, PhD, University of Kentucky, Lexington, KY; Donovan M. Adams, PhD, University of Central Florida, Orlando, FL*

Learning Objectives: This presentation will discuss the application of decision trees and Random Forest (RF) modeling for estimating osteological sex from a combination of morphological and metric variables of the skull. After attending this presentation, attendees will have a better understanding of the benefits of combining morphological and metric variables into one classification model for osteological sex estimation.

Impact Statement: This presentation will impact the forensic science community by demonstrating the applicability of decision trees and RF modeling for combining morphological and metric data for estimating osteological sex in forensic anthropology casework.

Abstract Text: Numerous recent publications have demonstrated the utility of decision trees and RF modeling for osteological sex estimation of the skull, yet none of these studies have incorporated both metrics and morphological traits into their models. Combining traits and measurements into one model has the potential to increase osteological sex classification accuracies for the skull, as well as allow the analyst to make their sex estimate utilizing one robust model, rather than making a decision based on multiple models. The main objectives of this research were as follows: (1) to assess intra-observer error for the selected morphological and metric variables, (2) generate multiple decision trees and RF models that incorporate various combinations of morphological and metric variables for estimating osteological sex, and (3) demonstrate the applicability of the models for use in forensic casework.

Twenty-one metric and 21 morphological variables of the skull were chosen from popular osteological sex estimation methods. A total of 220 males and 183 females were sampled from the University of Tennessee, Knoxville (UTK) Donated Skeletal Collection, the Texas State University Donated Skeletal Collection, the Southeast Texas Applied Forensic Science Facility Collection, and the Hamann-Todd Human Osteological Collection. Statistical analyses were conducted utilizing the R Language. Intra-observer error was assessed from 43 individuals from the UTK Collection to determine which variables to incorporate into the models. Intra-observer error for the morphological data was assessed using Krippendorff's Alpha, while the relative technical error of measurement was used for the metric data. Models were generated for the pooled sample (n = 403) as well as for African Americans (n = 191) and European Americans (n = 212) separately. Prior to generating the models, each dataset was split into a training sample (80% of the data) and a Holdout Validation (HV) testing sample (20%). Decision trees and RF models were generated for the skull, cranium, and mandible utilizing the training samples. In addition to the combined variable models, separate morphological and metric models were generated for comparison. The error of each tree and RF model was assessed using the HV validation sample. Additionally, the RF models were assessed utilizing the Out-Of-Bag (OOB) error.

Twenty-six of the morphological and metric variables achieved an acceptable level of intra-observer error and were incorporated into the models. The highest performing decision trees and RF models incorporated combined variables from the entire skull and achieved the same HV accuracy rates for both model types: 98.7% (pooled), 97.0% (AA), and 100% (EA). The OOB accuracies for the RF models were slightly lower compared to the HV accuracies: 93.0% (pooled), 89.9% (AA), and 94.2% (EA). The combined variable models for the cranium achieved similar accuracies to the skull models, while the models that included mandibular variables only produced the lowest accuracy rates overall. Further, the pooled sample models were tested utilizing the separate HV samples for African Americans and European Americans. In this additional test, the pooled sample models achieved higher accuracies for European Americans compared to African Americans. Overall, most of the models achieved classification rates over 80%, with most skull and cranium models achieving accuracies over 90%. Combining data types resulted in higher accuracies compared to the separate morphological and metric models as well as compared to popular osteological sex estimation methods for the skull. Future research should evaluate the accuracy of the present study's models on different population affinities as well as continue exploring the development of population-inclusive models. Additionally, future research should explore employing decision trees and RF modeling to generate osteological sex classification models that combine morphological and metric variables from multiple regions of the skeleton.

Sex Estimation; Biological profile; Machine Learning

A130 The Application of Non-Metric Sex Estimation Methods to Virtual 3D Cranial Models

Marion E. Davidson, MS, University College London, London, England, United Kingdom; Conner Welty, MS, University College London, Bloomsbury, London, England, United Kingdom; Sherry Nakhaeizadeh, PhD, University College London, London, England, United Kingdom; Ruth M. Morgan, D.Phil, University College London, London, England, United Kingdom*

Learning Objectives: After attending this presentation, attendees will have a better understanding of how non-metric sex estimation methods may be applied to virtual 3D cranial models in comparison to real human skulls.

Impact Statement: This presentation will impact the forensic science community by presenting the findings from a preliminary study comparing the decision-making between method application on human crania against their 3D virtual counterpart created from CT scans. These findings help to highlight the necessary research and training needed to continue development of virtual forensic anthropology.

Abstract Text: The possibilities of employing radiological data as a proxy for real human remains are increasingly being considered as the development and validity of forensic anthropological methods are being explored.[1,2] However, published research has not yet fully examined the application of existing sex estimation methods originally developed on human skeletal remains on 3D skeletal models. This study examined whether the commonly employed non-metric sex estimation assessments can be comparably applied to human skeletal remains and their virtual 3D bone model counterparts created from computed tomography.

Eight human skulls were selected from the archaeological assemblage housed at the University College London (UCL) Institute of Archaeology. The skulls were scanned with an O-arm Surgical Imaging System from Medtronic (cone beam computed tomography) and converted to three-dimensional models using 3D Slicer. Participants with osteological experience were asked to score non-metric sex indicative traits on real human skulls using the Walker method, make final sex estimations, and score their confidence.[3] Participants were asked to repeat this process on the virtual 3D cranial models approximately two weeks later.

This presentation discusses the results of the trait scores, the sex estimations, and the participants' confidence in the different sources. Weighted kappa values were consistent with other recent literature, ranging from fair to moderate for trait scores (0.242-0.528), and poor to moderate for sex estimation in five groups (0.027-0.600).[4] Participants who reported previous virtual osteological experience were consistently higher than the other participants, with kappa scores in the moderate range for five sex estimation groups (0.455-0.600) and even higher for three sex estimation groups (0.600-0.857). Additionally, participants overall were more confident in their scores and estimation on the real crania than on the 3D models.

Further discussion addresses the key factors surrounding the comparable application of methods as well as the variables that impacted this experiment. These include the difficulties in the direct transfer of traditional osteological knowledge to virtual bone models, the importance of specific training and experience, and the possible limitations of DICOM data from CT scans.

Forensic Anthropology; 3D Models; Sex Estimation

A131 Evaluating Subadult Age Estimation Methods From Long Bones Using a Contemporary Japanese Sample

Elaine Y. Chu, PhD, Texas State University, San Marcos, TX; Amariah J. Treviño, BS, Texas State University, Floresville, TX*

Learning Objectives: After the presentation, attendees will gain a better understanding of how current subadult age estimation methods for long bones perform when validated using a Japanese sample.

Impact Statement: This presentation will impact the forensic science community by demonstrating how skeletal variation can impact subadult age estimation. In addition, this presentation supports ongoing efforts to diversify skeletal reference material for validation of current methods by encouraging population-specific or globally inclusive methods.

Abstract Text: Age estimation using long bones is a well-established aspect of the subadult biological profile.[1-5] These methods rely on the strong relationship between age and long bone length and, therefore, size. However, most methods are primarily developed by, trained and tested on, and used for the skeletal remains of individuals of Western European descent.[6] The lack of appropriate skeletal reference materials for a variety of population histories may lead to biased (e.g., consistent over- or under-) estimates due to differences in growth patterns and proportions across the globe.[7,8] Technological advances have supported the increase of diverse skeletal reference material available for research by using alternative methods to dry bone such as Postmortem Computed Tomography (PMCT) or radiographic images.[9] The goal of this project is two-fold: (1) to evaluate the performance of currently available methods of subadult age estimation, and (2) to investigate whether differences between geographically disparate groups generate patterned age estimates in a contemporary Japanese sample.

Long bone lengths and breadths of 64 individuals (F=27, M=37) aged between birth and 16 years were measured from reconstructed skeletal models processed from full-body PMCT scans at the Education and Research Center of Legal Medicine at Chiba University in Japan. Known age was compared to point age estimates generated from long bone measurements using five common subadult age estimation methods: Cardoso and colleagues, Facchini and Veschi, López-Costas and colleagues, Rissech and colleagues, and Stull and colleagues.[1-5] Root Mean Squared Error (RMSE) was used to evaluate the average precision of each method. Bland-Altmann plots were used to evaluate the patterning of point estimates compared to known age. The accuracy of each method was evaluated as the number of times for which the known age fell within the 95% interval provided by a method.

RMSE values ranged from 0.97–2.79 years. Bland-Altmann plots demonstrate a general overestimation of age by all methods, with no systematic difference in error by sex. However, estimates generated by Stull and colleagues show point estimate bias around the age of seven, whereas the other methods show bias starting at age three.[5] Even considering these overestimation biases of point estimates, accuracies using methods from Cardoso and colleagues and Stull and colleagues ranged from 82.0%–96.7%.[1,5] As the global reach of forensic practitioners increases, methods for forensic identification will increasingly rely on technological advances, such as forensic imaging, to diversify skeletal reference material for use in method creation, validation, and application. Findings from this project demonstrate that while current methods of subadult age estimation can still be used to accurately estimate age for Japanese subadults, the patterned bias of point estimates warrant the consideration of population-specific methods, especially for individuals of Japanese descent who may be generally smaller than age-matched individuals from Western European descent.

Age Estimation; Subadult; Method Validation

A132 Variables Impacting the Application of Radiographic Age Estimation by Pulp/Tooth Ratios

Cirillo E. Laura, PhD, SNA International supporting the Defense POW/MIA Accounting Agency, San Francisco, CA; Katie Skorpinski, PhD, Defense POW/MIA Accounting Agency, Omaha, NE*

Learning Objectives: After attending this presentation, attendees will have a better understanding of how to apply radiographic dental age estimation methods on teeth from adult individuals and the factors that contribute to error in measurement within and between observers. Attendees will know the necessary parameters required to apply the method.

Impact Statement: This presentation will impact the forensic science community by identifying two main sources of error in a major dental age estimation method. It will highlight what factors need to be addressed prior to applying radiographic dental age estimation methods to ensure accurate results.

Abstract Text: The Cameriere et al. method of age estimation by pulp/tooth ratio has been popularly applied in many contexts.[1] As age estimation methods are limited for adults, especially in fragmentary cases, this is a valuable method in the forensic toolkit. However, practical conditions may deviate from the ideal scenarios put forth in previous publications. Based on observed scenarios within a forensic sample at the Defense POW/MIA Accounting Agency, this exploratory research tests a variety of experimental conditions to assess the potential impact of two common variables on the practical application of the method: superimposition of alveolar bone and tooth rotation.

Two types of periapical radiographs were measured to test the impact of image quality on inter-observer agreement. Measurements were recorded on periapical radiographs of 16 canines articulated in maxillary or mandibular alveolar bone, and on 27 extracted canines with no superimposed tissues. On the radiographs with alveolar superimposition, there was an average difference of 0.009 (ranging from 0.0009 to 0.03) in the pulp/tooth ratios between observers, constituting an average difference of 4.6 years in estimated age. For the radiographs without superimposition, the average difference in ratios was 0.007 (ranging from < 0.0001 to 0.02), with an average difference in estimated age of 3.5 years. While both radiograph conditions are viable for the method to be applied, radiographs without superimposition were associated with reduced observer difference. However, the difference in absolute error between radiograph types is not significant ($p = 0.24$). A comparison of the outlines recorded by each observer for the articulated canines demonstrated areas of particular concern in the pulp shape and tooth root perimeter.

The second variable tested was the effect of tooth rotation on the measurements. Radiographs of nine individual canines were captured in three positions: (1) standard labial/lingual orientation, (2) 45 degrees of rotation (representing a degree of rotation observed in multiple radiographs), and (3) 90 degrees of rotation (representing the maximum possible impact, but not a realistic scenario). When the tooth was rotated 45 degrees, the average impact on the pulp/tooth ratio was +0.05 (reducing the estimated age by roughly 25 years). When rotated 90 degrees, the average impact was +0.08 (reducing the age by roughly 40 years). Although the degree of rotation tested may be more extreme than is commonly encountered, this exploratory study indicates the severe reduction in estimated age that tooth rotation can create. These results demonstrate a significant impact on the age estimate and confirm that radiographs not taken in the correct orientation must be excluded from use.

The results of this exploratory research suggest caution is warranted in applying Cameriere et al. on radiographs of teeth that are not extracted, although the method can still be reasonably applied. It is important for observers to be able to identify possible rotation in the image, as this will significantly affect the age estimate and the method should not be applied.

Age Estimation; Dental Materials; Radiology

A133 A Multifactorial Method of Age Estimation in the Living From Computed Tomography (CT) Scans

Frankie Dunn, MS, University of South Florida, Urbana, IL; Lyle W. Konigsberg, PhD, University of Illinois Urbana-Champaign, Urbana, IL*

Learning Objectives: Attendees will be provided with an overview of a method of age estimation in the living that combines data from multiple regions of the skeleton. They will gain insight into the benefits of a Bayesian approach and probability as a way of presenting age estimates of living people in this specific type of case report.

Impact Statement: This presentation will contribute to the literature focused on improving statistical approaches to estimating the age of living people from skeletal and dental biomarkers.

Abstract Text: Age estimation in the living is undertaken in countries worldwide to inform legal decisions where the subjects' age is a factor. Scenarios where an age estimate may be sought range from immigration and criminal culpability cases, to sporting events, and international adoption.[1] A person having no verifiable proof of their age may occur for a large number of reasons but, commonly, there may be low rates of birth registration in their nation of origin, or there may be armed conflict resulting in documents having been destroyed.[2-5] Age estimation from multiple regions of the skeleton is preferable; however, conclusions from multiple age estimates are often presented as a discussion of variable estimates and error ranges.[6] This paper presents a method that utilizes a multivariate cumulative probit model for combining estimates from multiple regions to estimate age and give a probability that an individual has attained majority age.

A sample of 507 Computed Tomography (CT) scans were obtained from the New Mexico Decedent Image Database for individuals aged 10 years to 26 years. Numerous skeletal indicators were scored for each individual in the sample. The medial clavicular epiphysis was scored after Schmeling et al. and Schulz et al., with the enhancements described by Kellinghaus et al.[7-9] The hamulus was assessed after Shapland and Lewis.[10] The distal radius and ulna were staged using Tanner-Whitehouse 3.[11] The distal femur, proximal fibula, and proximal tibia were assessed using written stage descriptions by Kellinghaus et al. for the clavicle.[9] The left mandibular third molars were examined using Demirjian, Goldstein, and Tanner's method.[12]

The data were split into testing (n= 99; females= 50) and training (n= 408, females= 183) datasets. The training data were used to inform the model, and the testing was used to examine the models' performance. A multivariate cumulative probit model was used to generate posterior density regions and probabilities that an individual was above the age of 18.

Of the female testing sample, 58.00% of the individuals' known ages were within the 50% prediction interval with the 95% Highest Posterior Density Regions (HPDR) falling between 44.37% and 70.85% across the tested models. The model was less likely to accurately predict male age, with only 38.78% of known ages falling within the 50% prediction interval. The 95% HPDR was 26.14% to 52.53% across different models. The model overestimated the older female sample, but younger females and both older and younger male groups were estimated without significant bias. Further analysis to be presented will include the number of males and females who were correctly classified as minors by the model.

Age Estimation in the Living; Bayesian Statistics; Computed Tomography

A134 Applying Deep Learning Methods to Adult Age Estimation of Pelvic Joints

Krista E. Bennett, MA, Louisiana State University, Zachary, LA*

Learning Objectives: After attending this presentation, attendees will have a better understanding of how deep learning image classification methods can be applied to skeletal adult age estimation of the pelvic joints.

Impact Statement: This presentation will impact the forensic science community by addressing a gap in the current methodological approach to older adult skeletal age estimation. In particular, this investigation provides the first application of a Convolutional Neural Network (CNN) to multiple pelvic joints surfaces that can automate an age classification into middle (35–65 years) or older (66–102 years) adults from a digital image.

Abstract Text: Deep learning models are a type of artificial intelligence designed to mimic the neural pathways of human decision making for analyzing visual imagery, without the subjectivity of human biases. The architecture of a deep learning image classification model works by recognizing patterns of features through the analysis of high volumes of images and then classifying those images to a particular class or group. Researchers have used various deep learning models for the assessment of living individuals whose age can be a matter of legal concern (e.g., asylum-seeking minors or legal status for criminal proceedings), as well as for sex estimation, postmortem interval assessments, and radiograph identification; however, little research has been conducted using deep learning models with digital images for adult skeletal age estimation that focuses on multiple skeletal features.[1-7]

The average global life expectancy has risen over the past several decades from 66 to 73 years with many individuals living past 100 years.[8] The inability to provide more narrow age range intervals to distinguish older adults (i.e., those over 50 years) is a deficiency with many of the adult qualitative age estimation methods. Therefore, the objective of this investigation is to develop and validate a method for separating middle-aged adults (35 to 65 years) from older adults (66 to 102 years) with deep learning models. For this purpose, 2,085 digital images were collected from three pelvic joint surfaces (695 per joint surface), including the pubic symphysis and the auricular surfaces of the ilium and sacrum. High resolution images were obtained from three collections, the William M. Bass Donated Skeletal Collection, the John A. Williams Documented Human Skeletal Collection, and the Texas State University Donated Skeletal Collection using a Cannon 5DSR digital camera with a 100mm macro lens.

This investigation employed adapting the ResNet50 CNN to create three training models for each of the pelvic joint surfaces: the pubic symphysis (CNN_PS), the auricular surface of the ilium (CNN_IAS), and the auricular surface of the sacrum (CNN_SAS). Each model had ten layers with over three million training parameters and underwent 20 Epochs to classify an image into one of two categories: (1) middle aged (35–65 years) (2) older aged adults (66–102 years). The sample was divided into a training set (80%) and a validation set (20%), with an additional ten randomly selected images from the middle and older age categories to test the final models.

The results of the initial models are promising. The CNN_PS model was the best performing with a testing precision of 95%, a validation accuracy of 96%, and a test accuracy of 100% for both age categories. The CNN_SAS model performed second best with a training precision of 93%, a validation accuracy of 93%, and a testing accuracy of 100% for the middle age category and 80% for the older age category. The CNN_IAS model had the poorest performance with a training precision of 90%, a validation accuracy of 93%, and a testing accuracy of 60% for the middle age category, and 100% for the older age category.

This investigation suggests that deep learning models may be successfully used in forensic anthropology for adult age estimation. Specifically, they may be used to automate the distinction between middle and older adult skeletal remains. Additionally, the results suggest certain joint surfaces may be more suitable for aging older adults (i.e., the pubic symphysis and auricular surface of the ilium). Further work, with a larger sample, is needed to refine the model to provide more narrow age estimate intervals for adult remains from pelvic joint surfaces.

A136 Forensic Anthropology in China: History and Current Status

Qun Zhang, PhD, Wuhan University, Wuhan, Hubei, China*

Learning Objectives: Participants can learn about the history, research progress, and current status of forensic anthropology in China. Given the large number of Chinese people around the world, forensic anthropology research based on the Chinese may provide more targeted and specific information for forensic anthropology cases worldwide.

Impact Statement: China's forensic anthropology has not been well known by peers around the world. Many studies are published in Chinese in Chinese journals. This presentation can provide forensic science peers with more information about the progress of China's forensic anthropology.

Abstract Text: Forensic anthropology aims to search, recover, and examine skeletonized human remains in a forensic context, contributing knowledge of osteology and physical anthropology to the emerging needs of forensic science. However, in most countries except the United States, forensic anthropology work is still considered the responsibility of forensic pathologists. In China, the earliest record of handling skeletonized cases is in a book written during the Song Dynasty called *The Washing Away of Wrongs* in approximately 1247AD. However, there have been no further advances in this discipline, either in methods or techniques.

In 1956, the first internal textbook for training forensic specialists only briefly introduced the methods of bone examination, including species identification, commingled bone identification, sex identification, age estimation, height estimation, bone trauma, and bone tissue analysis, which basically covered the contents of forensic anthropology. In the 1980s, *Forensic Osteology* was the earliest Chinese monograph on the identification of skeletons. Since then, forensic anthropology courses have been offered in a few colleges, but the subject and the personnel are still blank. Currently, only very few institutions have collections of modern Chinese skeletal specimens that contain clear antemortem information.

The Institute of Forensic Sciences, Ministry of Public Security in Beijing owns a collection of more than 200 modern Chinese skeletons. Human osteoarchaeologists and bioarchaeologists often participate in the handling of skeletonized cases, but they only provide some professional consulting, which cannot be used as standard evidence. In the past 30 years, a series of specialized methods and formulas for the Chinese have been developed based on native Chinese skeletal collections and hospital clinical cases. Additionally, in the past ten years, new methods based on Computed Tomography (CT) images and larger sample sizes have also been developed and more internationally published. However, most of these studies were published in Chinese journals. There is no doubt that these studies will provide more potential support for worldwide forensic anthropology cases involving Chinese or Asian bones.

A137 The Progress in Standards Development in Forensic Anthropology: Updates From the OSAC and ASB

Julie M. Fleischman, PhD, Harris County Institute of Forensic Sciences, Houston, TX; Eric J. Bartelink, PhD, California State University Chico, Chico, CA*

Learning Objectives: After viewing this presentation, attendees will be updated on the status of proposed standards and best practices drafted by the Organization of Scientific Area Committees (OSAC) Forensic Anthropology Subcommittee and those published by the American Academy of Forensic Sciences' Standards Board (ASB) Anthropology Consensus Body.

Impact Statement: This presentation will impact the forensic science community by increasing awareness of forthcoming and existing standards and Best Practice Recommendations (BPRs) in forensic anthropology, including publication by the ASB and placement on the OSAC registry. This presentation will further highlight the need for the forensic anthropology community to engage in the development of these consensus standards.

Abstract Text: The OSAC was established in 2014 to facilitate the development of national standards for forensic science. The Forensic Anthropology Subcommittee (FACS) is one of four under the Medicine Scientific Area Committee and includes representation from academia, medical examiners' offices, government labs, and legal, quality assurance, and human factors. Each OSAC subcommittee is charged with drafting proposed standards, which are then submitted to a Standards Developing Organization (SDO) for further development and publication. The subcommittee submits draft standards to the ASB, established in 2015 as an SDO accredited by the American National Standards Institute, to publish forensic science standards. The Anthropology Consensus Body (CB) of the ASB includes representation from various interest groups, including academia, governmental and non-governmental users, general interest, and producers. Once a standard is published, the FACS reviews it for technical merit, makes a recommendation for its placement on the OSAC registry, and submits it to the Forensic Science Standards Board (FSSB) for final approval.

This presentation will describe the differences between standards and BPRs; summarize recent standards development activities by the OSAC FACS and the ASB Anthropology CB, including ASB standards currently on the registry; ASB standards eligible for the OSAC registry; proposed standards that are currently open for public comment or in comment adjudication at the ASB; and OSAC-proposed standards in progress. As of August 2024, ASB has published 11 standards and 1 best practice. The best practice is currently listed on the OSAC registry and all of the standards are eligible for the registry (several of which are in review by the FSSB). Three best practices are being drafted by the ASB, five proposed standards are currently under development and nearing completion by the OSAC FAC Subcommittee, one OSAC proposed standard was submitted to the ASB for development as a joint venture, and two published ASB standards are in revision for second editions.

Standards; ASB; OSAC

A138 The Roaring 20s: A 20-Year Review of a Forensic Anthropologist's Casework That Spans Pre-and Post-ABFA Certification

Micki Besse, MS, Florida Gulf Coast University/Human Identity & Trauma Analysis Laboratory, Fort Myers, FL; Savanna Agilar, MS, Florida Gulf Coast University/Human Identity and Trauma Analysis Laboratory, Fort Myers, FL; Heather A. Walsh-Haney, PhD, Florida Gulf Coast University/Human Identity and Trauma Analysis Laboratory, Fort Myers, FL*

Learning Objectives: After this presentation, attendees will understand the degree and distribution of a Forensic Anthropologist's (FA's) caseload pre- and post- American Board of Forensic Anthropology (ABFA) certification with a focus on the digital and physical case archival methodologies that facilitated this review.

Impact Statement: This presentation discusses with the forensic science community the physical and digital case archival methods used by forensic anthropologists and exposes the forensic science community to a Florida-based FA's caseload before and after ABFA certification. Positioned in Southwest Florida with consultation purview that spans the state and beyond, this research has implications for the forensic anthropological and forensic science communities as it pertains to method and database development as well as data security considerations.

Abstract Text: Published research on forensic anthropological databases emphasized method use and accuracy and highlighted the importance of forensic anthropological analyses in medical examiners' and coroners' offices.[1,2] However, the manners in which FAs archive case-related information and the distribution of their respective caseloads is largely unknown. Nevertheless, findings from past research found that FAs were underutilized in medical examiner contexts, following results from survey data that summed an average of 12.33 FA skeletal analysis reports and two FA field reports annually.[3]

For this study, we culled from a Florida-based board-certified FA with over 1,800 cases during a 20-year period (2004–2023) that were archived physically and digitally using a cloud-based, CJIS-certified IRIS platform. Though used the most by law enforcement agencies, the IRIS software can be used in the FA context to initiate case consultation, track case progress, and evaluate trends in the forensic analyst's caseload, among other benefits to the FA laboratory. This study revealed the FA received approximately 91 case consultations annually. This quantity increased from 77 cases prior to ABFA board-certification to 133 cases per year following ABFA board-certification. In the grouped sample, 10% of cases represented non-human elements, 14% involved field recovery components, and 22% utilized Antemortem-Postmortem (AMPM) comparisons to help establish positive identification in conjunction with the medical examiner.[4]

Overall, 13% of cases involved analysis of juvenile individuals. Fifty-five percent of cases involved both identification and trauma analyses with 30% of cases being trauma only and 15% identification only, as requested by the medical examiner. Fourteen percent of cases were related to establishing forensic significance of human remains. Since 2005, the quantity of cases and distribution of case trends varied dynamically (1 in 2004 to 212 in 2023), thus highlighting the sporadic nature of FA casework. This research supplemented existing literature regarding FA caseloads while exploring novel approaches to case consultation, documentation, and archival methods.

A140 Community Experiences of Forensic Anthropological Work in Human Rights Settings: A Case Study of El Mozote

Biannet Perez, MA, Binghamton University (SUNY), Johnson City, NY; Laure Spake, PhD, Binghamton University (SUNY), Binghamton, NY*

Learning Objectives: Forensic anthropology teams working in human rights settings are working not only with the deceased, but also with the living who are healing from traumatic events. Understanding the impact of the Argentine Forensic Anthropology Team (EAAF)'s work on El Mozote survivors and community members is crucial to recognize successful and unsuccessful strategies employed in the past by forensic anthropology teams. Such knowledge can enhance the development of frameworks that ensure survivor communities obtain the desired results from the work of forensic anthropology teams, specifically in human rights contexts.

Impact Statement: Attendees will learn some of the key strategies employed by the EAAF that are associated with community member satisfaction with the exhumation and identification process. Attendees will also learn some traits that may be associated with dissatisfaction. This knowledge will help forensic team coordinators plan forensic responses to ensure that these support rather than further traumatize and marginalize affected communities.

Abstract Text: The El Mozote massacre, in December 1981, was the largest mass killing event reported during the Salvadoran Civil war.[1-4] However, the occurrence of the massacre was denied by the Salvadoran government, and its survivors were ignored for almost a decade. A group of survivors, assisted by the non-governmental organization Tutela Legal, pressured Salvadoran authorities to open an investigation and prosecute perpetrators at the end of the 1980s. Tutela Legal petitioned the EAAF for assistance in conducting a forensic investigation of the El Mozote massacre. In 1992, the EAAF arrived in El Salvador and conducted exhumations intermittently between 1992–2004 in and around El Mozote. This investigation, coupled with other forensic work, clearly demonstrated that the victims were executed by the government soldiers and were not killed in combat action as the government had claimed.[5,6] The work done by the EAAF in El Mozote was pivotal in corroborating that a massacre occurred in 1981 and facilitated the prosecution of the perpetrators.

The aim of this research is to present how surviving communities experience forensic anthropology teams in human rights contexts. Though contributions of forensic anthropology to justice processes are well known in cases of human rights violations, very little is known about how survivors and community members experience this type of work. By considering the case study of El Mozote, this study contributes to the literature focused on survivors' experiences with large-scale forensic investigations.

Data for this study were collected through one-on-one in-person interviews conducted in 2023 in the Morazán region of El Salvador (El Mozote and nearby villages). Interviews were conducted in Spanish using a semi-structured questionnaire, including the following topics: exhumation experiences and long-term impact of exhumations, community engagement strategies used by EAAF's members, and participants' satisfaction with the work done by the EAAF. All interviews were voice recorded, transcribed in Spanish, then translated to English. A total of 20 interviewees participated, all of whom were alive at the time of the massacre in 1981 and were old enough in 1992–2004 to remember the EAAF's work.

Overall, all participants relayed mixed emotions during exhumations—joy because they would be able to properly bury their loved ones, and sadness due to reliving the memories of how their loved ones tragically died in the massacre. Survivors also reported feeling a sense of acknowledgment during the exhumations, which corroborated their narrative of the event. Participants reported that the EAAF team members were well integrated into the community throughout their stays in El Mozote. Specific actions that the team took to engage with the community included: introductions with stakeholders prior to onset of exhumation, regular updates to families about progress of the work, welcoming families to attend and participate in the exhumations themselves, and informal social interaction with community members. Lastly, participants provided positive feedback on the work conducted by the EAAF, with very few suggestions for improvement. All participants who had interacted with EAAF members described them as professional, polite, and very approachable. Interviewees affirmed the credibility of the EAAF versus that of other teams, potentially due to the team's efforts to engage with the community in combination with their status as an independent, international organization.

Given the positive appraisal of the EAAF given by the survivors at El Mozote, this case study can be seen as a precedent on how forensic anthropology teams should engage with the communities they serve. More research should be conducted to understand how survivors experience forensic investigations in both the short and long term in order to continue to improve working processes.

A141 Rated or Ratioed? Using Open-Source Software to Investigate Public Perception of Human Taphonomy Facilities on Social Media Platforms

Anna Williams, PhD, University of Central Lancashire, Preston, England, United Kingdom; Xenia-Paula Kyriakou, PhD, University of West London, London, England, United Kingdom; Kelda Stagg, MS, Swedish Police Authority, Stockholm, Stockholms Lan, Sweden; Martin Bateman, PhD, University of Central Lancashire, Preston, England, United Kingdom*

Learning Objectives: By attending this presentation, attendees will learn about the role of social media in the dissemination of forensic science topics and how social media can be interrogated to find meta-data regarding public opinion about, in this case, human taphonomy facilities or "body farms." They will see how social media engagement can be measured to assess positive and negative attitudes toward controversial subjects, and how they can change over time. They will also see how opinions expressed on X and Reddit may differ from those expressed on professional social platforms such as LinkedIn.

Impact Statement: This presentation will impact the forensic science community by revealing the potential for analysis of social media as a source and record of ever-fluctuating public sentiment toward a variety of forensic science topics and how attitudes toward taphonomy and human taphonomy facilities have evolved over the timescale studied.

Abstract Text: Social media, in all its forms, is inescapable today. It is a powerful medium for communication of entertainment, news, gossip, and criticism, used by 62.6% of the global population.[1] Much has been published about the use of online digital evidence, including social media, in forensic investigations.[2,3] However, the role of social media in the dissemination and communication of forensic science is yet to be fully identified, and few have recognized the hitherto untapped potential for interrogating social media to measure and analyze public perception of forensic science. The billions of posts, uploads, tweets and retweets, and comments made every day are a rich source of public sentiment about endless topics, including potentially controversial ones such as human taphonomy facilities.[4]

Human Taphonomy Facilities (HTFs), or "body farms," are outdoor laboratories where donated human cadavers are used to understand how human decomposition progresses in a variety of conditions. There are currently 11 facilities globally. Their work is, by its nature, controversial. There are objections on scientific grounds, mainly based on concerns about scientific rigor and reproducibility, as well as ethical, moral, and religious opposition.[5-7]

Here, we explore how forensic science topics of interest to the public, such as HTFs, are presented and represented on social media and mainstream media to determine whether the reporting is skewed toward positive, negative, or neutral sentiment. We examine whether we can quantitively assess how HTFs are perceived and received by the public (as represented by social media users) by collating social media posts from X (formerly Twitter) and Reddit. These platforms were chosen as they are widely used, can be anonymous, and therefore lend themselves to freer expressions of opinion with fewer repercussions for users. Open-source web scraper tools were used to collate posts from these platforms using keywords such as "human taphonomy facility" and "body farm." Open-source sentiment analyzers were then used to categorize posts into those expressing either negative or positive emotion. Data including the content of the post, location of the post, date/time of the post, whether it was original or retweeted, and the presence of URLs or emojis was recorded. In addition, we scrutinized the professional platform LinkedIn to ascertain how professionals perceive and express their opinion about HTFs, in comparison to "lay people" on X and Reddit. We also compared opinions expressed via social media to opinions expressed more formally through academic questionnaires.

Preliminary results suggest that the opinion of "lay people," as expressed on X or Reddit, has grown more positive toward HTFs over time. Comments analyzed were recovered from 2010–2024 in English and were mostly of United States/Canadian/United Kingdom origin. Comments on X have expressed surprise and fascination, such as, "*It's gross, but really fascinating, too*," to disgust and repulsion, such as, "*Dead bodies? But why? I feel so scared*," and "*This is very horrible and terrifying scene*." The trend of rising acceptance of HTFs is less visible in LinkedIn posts and comments, which suggest professionals are more circumspect about HTFs or less willing to express their true feelings on the platform. Our findings could be useful to campaigners wanting to recognize and address specific public or practitioner concerns or could be used to evidence public objection to HTFs.

In conclusion, our results demonstrate how social media reflects attitudes of our peers and the public, compared to more traditional academic surveys and how it is a hitherto under-utilized, yet powerful, tool to gauge opinion about forensic topics. We use the example of HTFs to illustrate the potential for social media meta-analysis as a valuable tool for academic and practitioner forensic scientists to scrutinize and quantify the zeitgeist.

A142 An Exploratory Study of Human Skeleton Sales on E-Commerce Platforms and Social Media

Kaitlyn Glavee, BA, University of Indianapolis, Human Biology Program, Indianapolis, IN; Krista E. Latham, PhD, Human Identification Center, University of Indianapolis, Indianapolis, IN*

Learning Objectives: Attendees will gain insight into the current state of the human skeletal trade online. Attendees will learn the kinds of human bones available for sale, the reason individuals are buying/selling human remains, and the methodology sellers use to effectively violate prohibitory policies.

Impact Statement: The world of online skeletal trade exists primarily through the exploitation and dehumanization of already marginalized people. By publicizing the harmful culture of the commodification of the human skeleton, forensic science practitioners can begin to contribute to conversations about ethical human remains procurement and combat this through public outreach and education. This presentation brings awareness and context to forensic anthropologists who may encounter these kinds of remains.

Abstract Text: The sale of human skeletal remains is, for the most part, unregulated. The Native American Graves Repatriation Act applies to Native American remains located in Federal or Federally funded agencies, and only a few states have laws regarding the sale of human remains. It is only in recent years that some e-commerce websites have begun to regulate the sale of human remains. The general lack of legal guidelines has contributed to a lucrative business in which human remains are sold through online platforms. Concurrently, a greater focus has been placed on ethical considerations concerning the origins of skeletal collections in anthropology and anatomy. Many institutions are critically examining the procurement and provenance of their osteological collections. Therefore, an evaluation of modern sales practices would contribute to the important conversations already occurring in the field today.

This study sought to find if posts advertising the sale of human bones continued to exist regardless of new policies. Etsy, eBay, Craigslist, Facebook Marketplace, and Instagram were searched utilizing keywords to discover posts attempting to sell human skeletal remains. Over 12 weeks, 403 posts of this nature were found, the majority advertising the sale of skulls (51%) or appendicular elements (23%). Most of the posts were in some way targeted toward educational or teaching purposes (89%) and oddities collection (70%). Of the posts discovered, 23 were in direct violation of website policies. In some of the posts, sellers circumvented policies through deliberate means such as misspelling or mislabeling items. Other posts were direct policy violations that were not detected nor removed by the online platform.

This research confirms that the human skeletal trade remains active on social media and e-commerce websites even if consumers from academia no longer use these means to curate osteological collections. The popularity of oddity collection potentially accounts for the prolific commodification of human skeletal remains, particularly those belonging to groups that have been marginalized and exploited in life. This commodification includes the purposeful comingling of remains in the creation of more desirable products, purposeful damage or disfigurement of remains, disrespectful treatment of individuals or their culture, and more. The rampant commodification of human skeletal remains is potentially fueled by the idea that these remains have been and continue to be "ethically sourced." In addition, there is always the concern that some of these remains are of medicolegal significance. Thus, forensic anthropologists have both a scientific and ethical obligation to be apprised of modern sales practices involving human remains.

Human Remains Sales; E-Commerce; Commodification

A143 Expanding the Forensic Anthropology Database for Assessing Methods Accuracy (FADAMA): Standardizing Case Management Systems, Real-Time Reliability Metrics, and Promoting Training Accessibility

Cris E. Hughes, PhD, University of Illinois Urbana-Champaign, Urbana, IL; Chelsey A. Juarez, PhD, California State University Fresno, Fresno, CA; An-Di Yim, PhD, George Mason University, Fairfax, VA; Runzhao Hu, National Center for Supercomputing Applications, Champaign, IL; Matthew Berry, MS, National Center for Supercomputing Applications, Urbana, IL; Lisa Gatzke, BA, BFA, University of Illinois at Urbana-Champaign, Urbana, IL; Fangyu Zhou, MDes, National Center for Supercomputing Applications, Urbana, IL; Jackson Vaughan, BS, University of Cincinnati, Cincinnati, OH*

Learning Objectives: Attendees of this presentation will learn how the enhancements in FADAMA 2.0 can be used for casework application and research needs.

Impact Statement: This presentation will impact the forensic science community by increasing awareness and the ability to use the new case management system in FADAMA that can improve case work tracking and security as well as increase competency through centralized method trainings.

Abstract Text: Forensic anthropologists employ methods from myriad sources (publications, online tools, computer download, etc.) when estimating the biological profile in casework. Published standards governing the estimation of the biological profile exist, yet because of the uniqueness of each case context, these standards call on forensic anthropologists to use the most reliable methods with integrated statistics for the case at hand. However, the practice of forensic anthropology suffers from both a lack of up-to-date understanding of methods performance and a disaggregation of methods tools. These issues are compounded by a fundamental lack of accessible training opportunities in new methods. As a result, studies show that forensic anthropologists continue to use older methods—devoid of validation and/or probabilistic frameworks—in casework, while newer methods are slower to be applied in casework, regardless of typically having more representative sampling and better statistical approaches.[1,2,3] Research has indicated that providing a comprehensive and accurate biological profile can increase the odds of an unidentified decedent case being resolved—thus, sound method selection and application are critical.

This presentation will cover our project's overarching goal to improve and streamline the practice of forensic anthropology by integrating real-time methods performance measures, methods training, and method access in a single web interface, all of which can be considered the first formalized active Case Management System (CMS) for estimations of the biological profile not tied to a single agency/entity. The ideal location for this CMS is the FADAMA, an existing tool developed for centralizing data on resolved cases for research purposes.[4] This presentation highlights, in collaboration with the University of Illinois Urbana-Champaign's National Center for Supercomputing Applications, the enhancements from FADAMA to FADAMA 2.0, which integrate an active case user platform. Three objectives are encompassed within this upgrade: (1) consolidation of forensic anthropology method interfaces into a centralized user-friendly web platform with state-of-the-art HIPAA-grade security in place to protect casework data, (2) development of an automated real-time computational approach for accuracy-informed method selection based on real-world case outcomes, and (3) implementation of training modules associated with frequently used methods for the biological profile estimation. FADAMA 2.0's upgrades directly benefit forensic anthropology by addressing the National Institute of Justice's established forensic science research priorities, including the consolidation of forensic anthropology tools and calculators, and accessible high-quality training on forensic anthropology methods into a single user-friendly program, and interdisciplinary innovation.

A146 Testing the Effectiveness of Virtual Reality Training in Teaching Mass Fatality Response

Jade S. De La Paz, PhD, University of Otago, Dunedin, Otago, New Zealand; Charlotte L. King, PhD, University of Otago, Dunedin, Otago, New Zealand; Ivett Kővári, PhD, International Committee of the Red Cross, Islamabad, Pakistan*

Learning Objectives: After attending this presentation, attendees will understand the efficacy of Virtual Reality (VR) as a training tool for mass fatality incident responders.

Impact Statement: This presentation will impact the forensic science community by showcasing how VR technology can be used to enhance mass disaster training programs, ultimately contributing to better-prepared responders and more effective incident management.

Abstract Text: VR is emerging as a tool for training in various areas, including forensic science and mass disaster/fatality response.[1-3] Studies have found that VR can be useful in training first responders and students in dealing with crime scenes, mass casualties, and hazardous materials.[1,3,4] These studies suggest that VR training has improved expertise and confidence in many trainees, although some findings show there can be limited expertise improvement when emergency responders already have high levels of knowledge in the field.[1,3,4] Therefore, VR has significant potential as a training tool for individuals with limited experience in disaster response, such as students and new staff. This project, which is a collaboration between the Forensic Analytical Science program at the University of Otago and the International Committee of the Red Cross (ICRC), tests if training outcomes can be improved by adding VR scenarios to student education on mass fatality response. This represents the first quantitative research of the efficacy of the ICRC's own VR program for training first responders in management of the dead following disasters.

Participants in this study was comprised of students enrolled in a third-year forensic science course (n = 19) at the University of Otago New Zealand (Ethics Reference D23/268). Participants' knowledge of managing the dead following disasters was tested at four points throughout training using a 16-question survey administered via an online learning platform. The questionnaire was given: (1) before any training had commenced, (2) after a lecture teaching ICRC protocols for disaster management, (3) after a lab session using the VR scenario to apply skills learned in the lecture, and (4) two weeks following the complete training to measure knowledge retention.[5]

Preliminary findings indicate that initial knowledge of mass disaster response protocols was limited (average questionnaire score of 63%), but improvements were seen in performance both after attending a lecture outlining ICRC protocols (average score to 77%), and further after VR training (average score 84%).[5] These improvements in scores after training were statistically significant (Kruskal-Wallis, $p = < 0.01$). Results also suggest that knowledge was retained two weeks following the complete training, with similar average scores between the third (84%) and fourth questionnaires (83%). These preliminary results indicate that the use of VR to supplement more traditional pedagogical techniques improves learning outcomes through simulated practical application of knowledge.

This research provides evidence supporting the integration of VR into forensic training programs, emphasizing its effectiveness in preparing responders for real-world mass fatality incidents. This study supports the idea that further maintenance and/or development of VR training scenarios to supplement existing educational programs in disaster response is important.[2] Future research will explore long-term retention, practical application of skills acquired through VR training, and training of more experienced cohorts.

Virtual Reality; Forensic Training; Mass Disaster Response

A147 Investigating Sample Bias in United States-Based Documented Skeletal Collections

Rhian R. Dunn, MS, Michigan State University, Lansing, MI*

Learning Objectives: After attending this presentation, attendees will be familiarized with collection-specific biases in United States-based documented skeletal collections.

Impact Statement: This presentation will impact the forensic science community by addressing a significant gap in current understanding of the representativeness of United States-based documented skeletal collections.

Abstract Text: Documented skeletal collections are essential to the field of forensic anthropology as the primary source of skeletal samples for the development and testing of analytical methods. Best practice recommendations include using modern collections to minimize sample bias from more historic collections, which are no longer representative of the modern, living population. However, few studies have directly compared demographic information of individuals across modern collections to assess collection-specific bias. Investigating collection-specific sample bias is essential for employing appropriate mitigation practices during study design and validation.

This study investigates collection-specific sample bias using a sample of individuals with demographic data from six United States-based skeletal collections (n=1,173): Maxwell Museum (MM), Michigan State University (MSU), Texas State University (TSU), Western Carolina University (WCU), Western Michigan University Homer Stryker M.D. School of Medicine (WMed), and University of Tennessee (UTK). Individuals were included in the study sample if at least one demographic parameter was available; the dataset was filtered for each analysis. Factors investigated include sex, population, age, height, birth year, year of death, birth state, state at time of death, Socioeconomic Status (SES), donation type, cause of death, and occupation. All analyses were conducted in R.

Males constituted a majority of the total sample (56.89%), but an Analysis Of Variance (ANOVA) revealed the ratio of females to males significantly differ by collection ($p< 0.01$). Although American White individuals comprise the largest population group in every collection (75-99%), overall population composition still varied significantly between collections ($p< 0.01$); post hoc comparisons using a Tukey Honest Significant Difference (HSD) test revealed these differences are attributed to MSU (adjusted $p< 0.01$), MM, and TSU, as these collections contained a higher proportion of non-White individuals than UTK, WCU, and WMed. Mean adult age differed significantly between collections ($p< 0.01$), which post hoc comparisons using the Tukey HSD test attributed to a lower mean adult age in MSU. Females were younger than males across all collections ($p< 0.01$), but this age difference is most prevalent in MSU (adjusted $p< 0.01$). Mean height did not differ significantly by collection ($p>0.05$) or birth year ($p>0.5$) but did differ by sex ($p< 0.01$).

Although all collections included in this study are considered modern, significant differences in mean birth year ($p< 0.01$) and year of death ($p< 0.01$) were noted. Comparisons using the Tukey HSD test revealed MM had a significantly earlier mean birth year than all other collections (adjusted $p< 0.01$), while MSU had a significantly later mean birth year (adjusted $p< 0.01$) than all other collections, excluding WMed. In accordance with the various geographic locations of the six collections, a series of ANOVAs revealed significant differences in state of birth ($p< 0.01$) and state at time of death ($p< 0.01$). Neither childhood SES ($p>0.05$) nor adult SES ($p>0.05$) differed significantly between collections, as most individuals reported middle SES. Type of donation (e.g., self, next-of-kin) differed significantly between collections ($p< 0.01$) and by population ($p< 0.01$).

Cause of Death (COD) and occupation were analyzed using the "tidytext" package. Cancer was the leading COD at all collections except MSU, whose leading COD was high-velocity projectile trauma—likely attributable to MSU's sole connection to a forensic laboratory, while other collections are associated with medical examiners, medical schools, and/or decomposition facilities. Common occupations were consistent across collections and included teachers, homemakers, and laborers.

Significant differences in demographic factors indicate a level of collection-specific sample bias is present; however, the type of sample bias (e.g., age, geographic origin, etc.) varies by collection. Researchers must account for collection bias during sampling and future research should assess potential ramifications.

Bias; Documented Skeletal Collections; Demographic Data

A148 Biomechanical Testing of Non-Human Analogs Used in Skeletal Trauma Research

Lillian S. Antonelli, MA, University of Nevada, Reno, Reno, NV*

Learning Objectives: After viewing this presentation, attendees will understand that porcine and biofidelic femora are poor analogs for skeletal trauma research. Further, they will appreciate the contributions from biomechanical engineering to skeletal trauma research in forensic anthropology.

Impact Statement: This presentation will benefit the forensic science community by critically examining the utility of porcine and biofidelic femora toward the study of human skeletal trauma and recommend additional research with biomechanical engineers to address the use of human and non-human analogs.

Abstract Text: Forensic anthropologists often contribute to medicolegal investigations by performing skeletal trauma analyses. These analyses are performed using knowledge garnered from decades of experimental research, though much of this work is built on experience and anecdotal information (e.g., case studies). Much of the experimental research comprising this foundation is based on unvalidated non-human analogs such as porcine femora. This study employes a multidisciplinary framework that combines biomechanical concepts and experimental design with forensic anthropological theory and applications to address the validity of porcine and biofidelic analogs in skeletal trauma research.

Porcine (n=21) and biofidelic (n=16) femora were subjected to concentrated 4-point bending, modified 4-point bending, and 3-point bending. Data from human femora (n=7) were also included to use as a comparison.[1] The experimental sample were loaded posterior to anterior at a rate of 600mm/min using an Instron (model 68-TM-50) machine, and all experiments were filmed at 40,000 frames per second. Biomechanical data and fracture patterning were evaluated between femur types and loading conditions.

Both porcine and biofidelic femora did not behave discriminately between loading conditions. With porcine femora, an analysis of variance revealed no statistically significant differences ($p > 0.05$) in mean peak force, deformation at peak force, energy absorbed, or peak moment across loading conditions. With respect to fracture patterning, a Fisher's Exact test showed no relationship between fracture type outcomes and loading condition ($p=0.806$), and 57% of the porcine sample exhibited a notable continuity in overall fracture pattern morphology. In biofidelic tests, only mean peak force was significantly different between loading conditions ($p=0.007$). Statistical analyses were not performed to compare fracture type classifications across loading conditions as 15/16 of the biofidelic sample were classified as transverse fractures.

When comparing porcine and biofidelic femora in concentrated 4-point bending, significant differences were found between deformation at peak force ($p=< 0.001$) and energy absorbed ($p=0.022$). Concentrated 4-point bending tests also showed significant differences between human and biofidelic femora in mean peak force ($p=< 0.001$) and energy absorbed ($p=0.015$).

In concentrated 4-point bending, significant relationships were found between femur type and fracture type when comparing porcine and biofidelic ($p=< 0.001$), and biofidelic and human femora ($p=< 0.0001$). Some similarities were observed between fracture type classification in porcine and human femora ($p=0.216$), but a distinct difference between porcine and human femora with respect to overall fracture pattern morphology.

The culminative results indicate a strong likelihood that neither porcine nor biofidelic femora are an appropriate non-human analog in experimental trauma research. The stark differences observed in both biomechanical and fracture data necessitate questioning the validity of previous research. However, additional research aimed at further investigating these non-human analogs under different loading conditions is warranted. Further research using a multidisciplinary framework is required to critically evaluate the appropriateness of these and other non-human analogs with respect to specific loading conditions.

Forensic Anthropology; Skeletal Trauma; Non-Human Analogs

A149 Proposing Sustainable and Cruelty-Free Proxies for Bones in Cut Marks Analysis

Beth Lawrence-Skitch, MS, Liverpool John Moores University, Dukinfield, England, United Kingdom; Giada S. Steiger, MSc, Liverpool John Moores University, Liverpool, England, United Kingdom; Matteo Borrini, PhD, Liverpool John Moores University, Liverpool, England, United Kingdom*

Learning Objectives: After attending this presentation, attendees will have an opportunity to evaluate a non-human and a cruelty-free alternative for tests on cut marks.

Impact Statement: This presentation will impact the forensic science community by providing the possibility to use a sustainable and cruelty-free composite material as a non-human proxy on which tests cut marks for forensic and educational purposes.

Abstract Text: In Forensic Anthropology, multiple studies on sharp force trauma have used animal skeletal elements instead of human-donated material. Although *Sus scrofa* is usually considered the closest animal proxy for humans, there is still an ongoing debate about the accuracy of experiments performed on pig bones and the ethical principles behind how they are supplied.[1] Few studies consider using alternative non-animal-based proxies such as polyurethane, plaster, and wax to simulate impressions of sharp force trauma.[2-4] Polyurethane bone substitutes are becoming increasingly common in forensic investigations, although it is an expensive resource and not readily available to researchers.

In a novel approach, this study tests four different non-animal proxies for human bone: paraffine, plaster, beeswax, and a compound for bone reconstructions.[5,6] This unique mixture includes beeswax, paraffin, pine rosin, casting powder, and calcium carbonate (limestone flour).

The proxies have been used to test and examine cut marks according to the following traits: shape of the cut mark (general morphology/entrance/exit); rising of the walls (entrance/exit); feathering; shards; and mounding (entrance/center/exit/general morphology). The test has been performed on serrated knives, as this category exhibits the most characteristics.

The synthetic bone replicas have been molded in five rectangular prisms with a d-shape top (mail-box shape) per proxy: 10 cut marks were executed using a serrated knife on each prism for a total of 200 cuts. The results on each proxy were then compared with an additional 50 cuts on porcine ribs in order to evaluate the similarity between the artificial material and the animal one. The same knife was used at a 90° angle perpendicular to the sample for all the marks, moving the knife forward through the sample and backward.

The traits have been observed under a stereomicroscope with 38x magnification and compared. Intra-observer analysis has been performed and no significant difference between the observations has been detected, (p = >0.05) confirming the reproducibility of the study. Based on the findings, the reconstruction compound and beeswax emerge as the most suitable materials for crafting an alternative to animal bones for use in cut mark analysis and observation.

In the future, the authors propose to replicate the study by comparing the two most suitable proxies with incisions on fleshed porcine ribs to better assess their applicability in forensic contexts. Furthermore, a comparative analysis between the proxy and human bones is planned.

This research presents an opportunity to consider the feasibility of using readily available, sustainable, and ethical composite materials as cruelty-free surrogates for human and animal bones in forensic research and educational applications.

A150 Ethics Around the Creation and Use of 3D-Printed Human Remains in Crime Reconstruction: Toward the Ethical Use of Technology in Forensic Anthropology

Rachael M. Carew, PhD, Coventry University, Coventry, England, United Kingdom; Ruth M. Morgan, DPhil, University College London, London, England, United Kingdom; James French, PhD, University College London, London, England, United Kingdom*

WITHDRAWN

A151 A Water-Cooled Probe Thermocouple System for Accurate Temperature Measurements in Human Donors During Forensic Fire-Death Scenarios

David Silveira, MS, California State University, Chico, Chico, CA; Arielle Zohara Sperber, BA, California State University, Chico, Chico, CA; Ashley Kendell, PhD, California State University, Chico, Chico, CA; Beth A.S. Shook, PhD, California State University Chico, Chico, CA*

Learning Objectives: After attending this presentation, attendees will learn about a new thermocouple-based temperature measurement system using off-the-shelf hardware and plumbing components that has produced consistently accurate data with high reliability in forensic fire-death scenarios.

Impact Statement: This presentation will impact the forensic science community by providing details of a thermocouple-based temperature measurement system that offers a unique solution to significant challenges encountered when measuring internal temperatures of human donors exposed to fire. The system has successfully been used to produce 14 separate measurements of internal donor temperatures in two experimental burns.

Abstract Text: Thermocouple measurements are conducted during forensic fire-death scenarios to correlate temperatures with the effects of fire exposure on human tissue and bone.[1-3] However, use of inadequate thermocouples can cause severe errors in temperature data. Thermocouple wire with exposed non-combustible woven-fabric insulation can exhibit severe insulation embrittlement and disintegration in response to fire exposure, which can cause movement of the location of measurement out of the donor and into the fire.[4] This type of wire is also unsuitable for direct implantation into donors because contamination with rendered fats and other bodily fluids will worsen temperature errors caused by insulation overheating and low electrical resistance.[5] Insulation failure of a thermocouple is strongly indicated when its tip remains shielded from fire by a large tissue mass, but the temperature reading shows a rapid increase by hundreds of °C nearly concurrent with fire exposure to portions of the thermocouple outside the donor. Use of mineral-insulated metal-sheathed thermocouple probes greatly reduces the chances of insulation failure, but stiffness and lack of anchoring points will cause difficulty in accommodating movements due to pugilistic posturing and pyre collapse.[6] Stainless steel loses strength at high temperatures, which makes probes more vulnerable to damage from falling debris and refueling of fires.[7]

This system is based on SCAXL-125U-120 probes from Omega Engineering which are 3 meters in length with an outside diameter (OD) of 0.3175 cm and rated to 1150 °C. Probes pass through approximately 2.4 meters of 0.635cm OD copper tubing with brass tee fittings at each end. The length of the exposed probe tip to be inserted into an incision in the donor is adjustable. The tee provides an anchor point to suture the probe assembly to the donor with 24-gauge steel wire. Each probe assembly is supplied with a continuous flow of water by a distribution manifold connected to a garden hose, and compression fittings are used to prevent water leaks. Additional tubing is used to direct discharge water away from the fire area. All components are available through thermocouple vendors and hardware supply stores, and the system can be assembled with basic tools without any need for specialized training or custom fabrication of parts from scratch.

Temperatures were successfully measured in a total of 14 different locations throughout the body during experimental burns of one male and one female donor. Probe assemblies were pre-bent to accommodate pugilistic posturing by rotating with limb movements. Donors were burned on stacks of wooden pallets (3–4 pallets high) with refueling continuing for 2–3 hours, then fires were allowed to burn out and cool undisturbed. None of the probes were dislodged by any movements or disturbances, nor did they leak water into the fire area.

Elimination of errors caused by thermocouple insulation failure has enabled observation of a consistent trend of internal donor temperatures remaining constant for extended durations after fire start before increasing, despite intense fire exposure. Distinct temperature plateaus around 100°C due to the boiling of water in tissues have also been observed. The time at which a probe tip is no longer shielded from fire due to tissue destruction can also be identified from data plots. Additional details of system construction and implementation and examples of temperature measurement results and trends will be discussed.

B1 Revisiting Guidance on Sampling of Populations for Highly Polymorphic Forensic Loci

Sanne E. Aalbers, PhD, National Institute of Standards and Technology, Gaithersburg, MD; Katherine B. Gettings, PhD, National Institute of Standards and Technology, Washington, DC*

Learning Objectives: After attending this presentation, attendees will understand the relation of several important factors to sample size, different ways of handling previously unobserved alleles, and the effect of using different formulas for evaluating the evidence.

Impact Statement: This presentation impacts the forensic science community by reviewing important concepts for determining sample sizes for population studies and demonstrating its application to modern autosomal Short Tandem Repeat (STR) data.

Abstract Text: When we find that a person of interest cannot be excluded as a potential contributor to an evidentiary DNA profile, we wish to express the strength of this observation. For autosomal STR data, population databases allow us to attach probabilities to DNA evidence by the estimation of genotype frequencies, which rely on accurate sample allele frequencies. In 1992, Chakraborty estimated that, for Variable Number Tandem Repeat (VNTR) loci with mostly rare alleles, a sample of 300 individuals would provide 95% confidence that alleles with frequency of at least 1% are represented.[1] In practice, a sample size of 200 has often been employed for forensic STR population databases, while a minimum requirement for publishing forensic STR sequence population data sets has been set at 50 samples.[2,3]

In the years since Chakraborty's seminal paper, increased knowledge of the human genome has facilitated determination of highly polymorphic STR markers and technology advancements have resulted in a higher level of STR marker multiplexing. This combination of factors has led to the development of expanded and far more discriminating kits. Sequencing techniques have further improved our ability to distinguish between alleles based on variation in underlying base-pair structure. Considering STR markers in current use have a much broader allelic range than some of the earlier characterized loci, it is important to reevaluate existing guidance on sample sizes for STR population databases. Additional important questions include: What inferences can we make when we only have a limited set of samples to work with? Beyond what point is it no longer beneficial to sample more individuals? And how do these sampling decisions or constraints affect the methods we use to account for previously unobserved alleles?

In this presentation we address these questions and discuss the implications of sample size for autosomal STR loci. We start by briefly reviewing some theory to understand the relation between heterozygosity, allele frequency, the number of alleles, and sample size. We demonstrate the effect of both length- and sequence-based STR data on sample size implications and highlight differences between lesser and more polymorphic markers. We also look at population differences and the effect of the underlying allelic distribution on the results. Furthermore, we show how increasing sample sizes by combining different data sets can be helpful in determining the point at which continued sampling may not be a worthwhile effort and what the consequences are of using limited samples.[4] Finally, we discuss different methods for accommodating previously unobserved alleles and the effect of using various evidence evaluation formulas as described in the second NRC report.[5]

Forensic DNA; STR Profiles; Next Generation Sequencing

B2 Assessing the Added Value of Non-Human DNA Analysis for Forensic Soil Analysis

Kelly A. Meiklejohn, PhD, North Carolina State University, Raleigh, NC; Melissa K. Scheible, MFS, North Carolina State University, Raleigh, NC; Tiffany Layne, PhD, National Institute of Justice Office of Justice Programs, Washington, DC; Teresa M. Tiedge, PhD, North Carolina State University, Raleigh, NC; Jodi Webb, MS, FBI Laboratory, Quantico, VA; Jack Hietpas, PhD, John Jay College of Criminal Justice, New York, NY; Libby A. Stern, PhD, FBI Laboratory, Quantico, VA*

Learning Objectives: After attending this presentation, attendees will: (1) understand the wet-laboratory steps for completing DNA metabarcoding of plants, fungi, arthropods and bacteria from surface soils; and (2) the combination(s) of biological taxa most informative for Q-to-K comparisons of surface soils.

Impact Statement: This presentation will impact the forensic science community by assessing whether biological taxa characterized using DNA metabarcoding provides added value as a supplement to traditional inorganic examinations currently performed by forensic geologists.

Abstract Text: Geologic materials, including soil and dust, are ubiquitous and often inadvertently transferred during crime events. Forensic geologists use a range of particle-based analytical approaches to characterize the inorganic fraction of soils, with resulting data primarily used to form subjective interpretations. Geological materials are also increasingly used to help address provenance questions for investigative leads and intelligence purposes. In many cases, such analyses provide sufficient information to conclude there is or is not the possibility the questioned soil originated from the same source as the known. However, there are inevitably cases where the samples being compared lack exclusionary differences or there is too little inorganic material for analysis. In these scenarios, information gleaned from new quantitative methodologies might provide valuable exclusionary differences.

In this study, two types of surface soils representing scenarios that would potentially benefit the most from new quantitative methods were collected from across the state of North Carolina, those with: (1) similar inorganic content but with distinct land use (15 locations), and (2) limited inorganic content but recognizable organic fractions
(15 locations). At each location, triplicate samples (1m apart) were collected from two sites ~100m apart to assess method reproducibility, accuracy, and small-scale variation that might be realistically observed in Q-to-K comparisons (total n, ~180). Each surface soil sample was subjected to DNA metabarcoding to characterize four broad groups of taxa: (1) bacteria via 16S, (2) fungi via ITS1, (3) plants via ITS2 and p6 loop of the *trnL*-UAA intron, and (4) arthropods via *COI*. Subsequent statistical analyses focused on assessing: (1) the appropriate level for analyzing DNA data (i.e., sequence level or family), and (2) the most appropriate combination(s) of taxa for Q-to-K comparisons. Initial findings include: (1) recovery of arthropod data was poor regardless of soil type, (2) biological communities are relatively consistent between triplicate samples, and (3) Principal Coordinates Analysis (PCoA) plots are valuable for visualizing differences in biological communities across large sample cohorts. The results of this proposed study could demonstrate the value of DNA metabarcoding for differentiating soils, providing a supplemental analysis method for samples containing too little inorganic content for conventional examination.

DNA Metabarcoding; Geologic Materials; Non-Human DNA

B3 A Small-Scale Ancestry Informative DIP-STR Marker Set for Biogeographic Ancestry Inference in United States Populations

Lauren Hoopes, MSFS, Frontage Laboratories, Inc., Glenside, PA; Nicole DeWald, Arcadia University, Birdsboro, PA; Daniele S. Podini, PhD, The George Washington University, Washington, DC; Fabio Oldoni, PhD, Arcadia University, Glenside, PA; Diana Hall, PhD, Unité de Génétique Forensique, Centre Universitaire Romand de Médecine Légale, Centre Hospitalier Universitaire Vaudois et Université de Lausanne, Lausanne, Vaud, Switzerland*

Learning Objectives: After attending this presentation, attendees will gain a better grasp of how a set of Deletion-Insertion Polymorphism-Short Tandem Repeat (DIP-STR) markers performs to infer the biogeographic ancestry of individuals.

Impact Statement: The forensic science community will benefit from this presentation since it will give investigators a different kind of intelligence tool for biogeographic ancestry inference.

Abstract Text: DIP-STRs are an alternative class of genetic markers that link high mutation STR with low mutation DIP loci.[1] DIP-STR markers were initially developed for targeting the minor DNA contributor in imbalanced two-person mixtures using specific primers that overlap the DIP (S or L) sequence providing allele-specific amplifications that include the non-shared DIP allele with the major DNA contributor. In the past, these markers have been used as ancestry informative markers [2] to determine an individual's Biogeographic Ancestry (BGA), and they have shown to be useful in differentiating between the main continental regions.[2,3] The purpose of this research was to evaluate the performance of a minimal set of 10 DIP-STR markers in inferring the BGA of individuals belonging to four main population groups from the United States.[4] This research offers researchers a different kind of intelligence tool for biogeographic ancestry inference.

A set of 100 individuals of self-reported African American (US AFR, #25), European American (US EUR, #25), Asian American (US EAS, #25), and Southwest Hispanic (US SWH, #25) origin was selected. The samples were quantified using the Quantifiler Trio Quantification kit (Thermo Fisher Scientific) on a QuantStudio Real-Time PCR system. A first round of Polymerase Chain Reaction (PCR) amplification and separation of DIP markers is necessary in the genotyping workflow to identify the target DIP allele. This is followed by a second round of PCR amplification of DIP-STRs utilizing allele-specific PCR amplifications.[1] Amplicons are separated using the SeqStudio Genetic Analyzer, and GeneMapper ID-X is used to analyze profiles. Population genetic data is evaluated and clustering analysis is performed using STRUCTURE software to characterize and visualize the genetic structure of the populations of interest.

The estimated allele frequencies were determined for each population group to highlight the distribution of the genotyping results and allow for biogeographic estimation of an unknown sample. The results obtained showed that allele diversity was observed among the four population groups across the ten DIP-STR markers. Common alleles were detected for each of the DIP-STR marker along with unique alleles observed only in some of the population groups. STRUCTURE results from ten DIP-STR loci showed that the US AFR, EUR, and EAS population groups can be clustered with AFR, EUR/CAUC, and EAS continental groups. On the other hand, the SWH group appears to be admixed, and this is expected because the US EUR and US SWH groups are genetically close populations. This study highlights how a small-scale, ancestry-informative DIP-STR marker set that combines fast-evolving and slow-evolving polymorphisms can be implemented as an intelligence tool to provide more refined resolution of biogeographic ancestry inference of major continental groups.

B5 Assessing the Viability of DNA Yields From Taphonomically Altered Bone and Teeth

Shelby R. Feirstein, MS, University of Montana, Missoula, MT; Maria J. Castagnola, MA, New Jersey Institute of Technology, New Jersey, NJ; Sara C.C. Zapico, PhD, New Jersey Institute of Technology/Smithsonian Institution, Newark, NJ; Luis L. Cabo, MS, Mercyhurst University, Erie, PA; Mayaas Hassan, BA, New Jersey Institute of Technology, Clifton, NJ; Alixs M. Pujols, BS, New Jersey Institute of Technology, Passaic, NJ; Joe Adserias-Garriga, PhD, Mercyhurst University, Erie, PA*

Learning Objectives: Attendees of this presentation will gain a better understanding of how DNA is preserved in scenarios in which human remains have been exposed to thermal alteration or corrosive chemicals contained in common household products. This is especially important in cases where no other means of identification are applicable or when different body fragments must be reassociated.

Impact Statement: This presentation will impact the forensic community by presenting a study on the efficiency of DNA analysis for identifying taphonomically altered human remains exposed to fire or common household chemicals.

Abstract Text: DNA is more resistant to degradation in hard tissues due to the protective effects conferred by the surrounding inorganic matrices of bones and dental tissue.[1] United States laboratories currently favor femora, teeth, and temporal bones as preferred samples for DNA isolation and analysis. However, the recommended elements are not always available for sampling and subsequent genetic profiling. Studies suggest that smaller bony elements, like metacarpals, carpals, and phalanges, may render similar, if not better, DNA yields.[2] These smaller bones offer ease and efficiency to the whole process and are not used in the biological profile in anthropological analyses unlike the cranium and long bones.

Circumstances, such as fatal fires, mass disasters, and exposure to corrosive substances, could hamper the possibility of DNA recovery and characterization, complicating the identification of human remains.[3] Furthermore, perpetrators may use household corrosive substances and fire as an attempt to destroy remains based on their availability and effects. Thermal alteration, sodium hydroxide (NaOH), and hydrochloric acid (HCl) are known to change both the structural integrity and composition of skeletal elements, affecting the quality and/or quantity of DNA available for extraction. Recent studies have explored whether authentic DNA profiles can be generated from human skeletal elements exposed to varying stages of fire-induced destruction. Results show that identification from DNA profiles were reliable and reproducible from both well-preserved and semi-burnt bones.[4,5] The aim of this study was to assess the possibility of DNA isolation and profiling from bones and teeth exposed to fire, sodium hydroxide, and hydrochloric acid, respectively.

Hand bones, from three donated individuals, were exposed to three separate treatments: controlled fire, sodium hydroxide, and hydrochloric acid. Eight elements (carpals, metacarpals, and phalanges) were used for each treatment, selected based on pre-alteration surface area and volume data collected using the Artec Spider hand-held 3D scanner. Additionally, 16 healthy human molars from 16 different individuals were exposed to the chemical treatments.

The fire treatment protocol consisted of elements being placed on a ceramic grill plate on top of an open-air fire pit for 1 hour, and temperatures were recorded every 5 minutes. Readings taken from above ranged from 100ºC to 500ºC.The chemical alteration protocol consisted of four intervals (total: 2 hours) with bone pairs being pulled every 30 minutes from their solutions (NaOH or HCl).

DNA was extracted using a silica-based method and quantified through a human-specific quantitative Polymerase Chain Reaction (qPCR) methodology, providing degradation and inhibitor ratios. In those samples rendering quantifiable DNA, 0.5ng of DNA was used to carry out the STR profile. These profiles were compared to the full genetic profiles taken from the control element

Our results demonstrated, as stated by previous studies, that teeth are better sources to obtain good quantity and quality of DNA compared to bone.[6] In the teeth samples, DNA yields were more affected by the NaOH treatment than HCl. Despite this, the degradation ratios as well as the inhibitors were below the threshold, and the quantity was enough to obtain full STR profiles from all teeth samples. In contrast, the degradation ratios were beyond the threshold in bone samples. Though there were no inhibitors, the quantity of DNA was low, leading to only several incomplete profiles. These differences are due to tooth anatomy. These findings indicated that teeth should be the sample of election to obtain DNA profiles in human remains exposed to fire and corrosive agents, as they may lead to a positive identification. Future research will seek to expand on these results, assessing other corrosive agents, different concentrations and durations, as well as other skeletal elements.

B6 It's Common Cents—How to Spend a Million Dollars in Five Months!

Julie Ferragut, BS, DC Department of Forensic Sciences, Fairfax, VA*

Learning Objectives: The District of Columbia Department of Forensic Sciences (DFS) lost accreditation and suspending DNA casework for approximately two-and-a-half years, accumulating a large backlog. After attending this presentation, the participants will understand a model to quickly eliminate a DNA backlog through the coordination of multiple vendors, adjusted testing strategies and turnaround times, and interagency cooperation.

Impact Statement: The impact of the presentation on the field of forensic sciences is an explanation of an innovative model to quickly reduce a DNA backlog that can be implemented in other jurisdictions with a large number of unanalyzed cases.

Abstract Text: The DFS recently obtained re-accreditation in December of 2023. Prior to the loss of accreditation, the Forensic Biology Unit had eliminated the entire casework backlog. During the span of not being accredited (approximately two-and-a-half years), a backlog of over 1,000 cases had accumulated. This presentation will demonstrate the strategic plan of how the DFS was able to effectively and swiftly reduce the backlog by 90% utilizing multiple vendor laboratories.

Through the use of previously frozen Capacity Enhancement for Backlog Reduction (CEBR) funds, multiple contracts/procurements and a muti-agency collaboration, the backlog reduction project was executed within a period of five months. Success was achieved by temporary assignments of staff to assist with evidence transfers, barcoding, and testing plans. Contracts were formulated specifically for property crimes and less complex offenses that consisted of simplistic testing strategies. Vendor laboratories coordinated with the DFS to determine numbers of cases accepted and turnaround Times (TAT). Coordination also occurred with the Evidence Control Branch, which secures and properly stores the District of Columbia's evidence.

Upon completion of testing at the vendor laboratories, strategies were implemented for the receipt and distribution of the case reports and also for the return of evidence and extracts. Each report was triaged and evaluated for possible Combined DNA Index System (CODIS) entry. Cases deemed suitable for entry were sorted and allocated for ownership reviews based on batching by the vendor laboratories.

As this was a novel project, several important lessons wre learned, including the importance of both intra-agency and inter-agency communication, the need to establish and adhere to procurement timelines, and how to assess the downstream effects of large-scale outsourcing.

Overall, the project was successful and beneficial to both the District of Columbia and to the Forensic Biology Unit. By outsourcing a majority of the backlogged cases, analysts were able to focus on CODIS ownership reviews, training, and other essential tasks. Upon resuming casework, the burden of tackling a sizeable backlog for the unit is no longer present and the agency was able to provide investigative leads in a timely manner.

Backlogs; Outsourcing; Casework

B7 The Molecular Diversity of 23 Y-STR Genetic Markers in an Endogamous Ramgharia Population of Punjab, India

Amandeep Kaur Bhambara, PhD, Galgotias University, Ludhiana, Punjab, India; Vivek Sahajpal, PhD, Directorate of Forensic Services, Junga, Himachal Pradesh, India; Shivkant Sharma, PhD*, BioZed Research and Testing Laboratories, Haryana, India*

Learning Objectives: This presentation provides a deeper understanding of how historical events, social practices, and migration patterns have shaped the genetic landscape of the population, offering valuable context for historical and anthropological studies. This presentation enhances knowledge of how genetic markers are distributed within endogamous groups, contributing to the broader field of population genetics and helping to elucidate the genetic basis of cultural and social practices. It also offers practical benefits for forensic investigations and genealogical research by providing detailed genetic profiles and understanding specific challenges in tracing paternal lineages in such communities.

Impact Statement: By presenting detailed data on Y-chromosomal Short Tandem Repeat (Y-STR) markers within a specific endogamous population, forensic scientists gain insights into the genetic diversity and uniqueness of this group. This understanding is crucial for refining databases and improving the accuracy of forensic identifications involving individuals from this population. The research can lead to the creation of more comprehensive and targeted forensic databases that include population-specific genetic profiles. Such databases help with better population coverage and more accurate forensic analysis, reducing the risk of false matches or exclusions. Sharing findings on the genetic diversity of a specific population encourages collaboration between forensic scientists, geneticists, anthropologists, and other researchers. Such interdisciplinary efforts can lead to more comprehensive solutions and advancements in forensic science.

Abstract Text: India is a diverse nation comprising about a 1.2 billion population as reported in Census of India, 2011. Perhaps this nation is famous for its culture and traditions but is also known to exhibit intra- and inter-population variations.[1,2] This is mainly due to existence of different castes, religions, and communities. Among various religions known, Sikhism accounts for the fourth-largest religion founded by Sri Guru Nanak Dev Ji in the late 15th century C.E. There are a few Sikh communities that practice the gotra (clan) system of marriage, namely Ramgharias, Khatris, Jats, and many more. However, the Ramgharia community is highly renowned for its endogamous practices and thereby holds high potential to exhibit remarkable genetic variability.[3]

In forensic investigations and population studies, Y-STR analysis has been shown to be quite useful.[4-8] The present study aimed to evaluate genetic polymorphism in the Ramgharia population of Punjab. Two hundred unrelated healthy male individuals were typed using the Powerplex Y-23 PCR amplification kit.

A total of 170 haplotypes were obtained, among which 146 were found to be unique. Multidimensional Scaling (MDS) Plot was used to study the intra-population relationship between the studied population data and other reported populations of India, which revealed that the Ramgharia population of Punjab lies in a cluster with the Bhil Population of Madhya Pradesh.[9,11] A total of 140 different alleles were reported with allelic frequency ranging from 0.006 to 0.765. The genetic diversity for 23 Y-STRs ranged from 0.375 (DYS391) to 0.836 (DYS635).

This population data may generate a significant source of information for the investigations of forensic relevance in forensic laboratories.[10,12-16] Moreover, this will strengthen the Y-STR Haplotype Reference Database (YHRD) of the Indian population, which would facilitate researches related to anthropology, population origin, evolution, and other related researches in the future. This 23 Y-STR marker data can be used as a reference for determining genetic relatedness among various Indian populations and with the other populations worldwide. Overall, the data obtained will enrich the forensic database of endogamous populations of India.

DNA; STRs; Retrospective Study

B8 A Comprehensive Drug Analysis of Vaporizer Products From Pennsylvania High Schools

Alexis D. Quinter, MASc, The Center for Forensic Science Research and Education, Horsham , PA; Joshua S. DeBord, PhD, The Center for Forensic Science Research and Education, Horsham, PA; Barry K. Logan, PhD, The Center for Forensic Science Research and Education, Horsham, PA; Alex J. Krotulski, PhD, The Center for Forensic Science Research and Education, Horsham, PA; Max T. Denn, MS, The Center for Forensic Science Research and Education, Horsham, PA*

Learning Objectives: After attending this presentation, attendees will have insight into the diverse and evolving market of vaporizer products and their respective complex chemical composition to provide awareness of the disparities between nicotine and cannabinoid-containing vaporizers.

Impact Statement: This presentation will impact the forensic community by communicating the findings of confiscated vaporizer products from high school students, emphasizing the value of timely monitoring of the evolving and unregulated vape product supply for the benefit of public health and awareness.

Abstract Text: E-cigarette, or vaporizer devices (vapes), are products that can be used to deliver nicotine, cannabinoids, flavorings, chemicals, and other substances. These products are referred to by varying names and synonyms and are manufactured in a variety of shapes, sizes, and device types. The rapid expansion of vaporizers has led to a competitive marketplace in which vape products are advertised with appealing flavors and fashionable, attractive packaging, which can appeal to younger generations despite federal laws that restrict their sale to individuals over 21. In a recent study, 43% of 15- to 20-year-old users obtained their products from retailers like vape shops, gas stations, and convenience stores.[1] Comprehensive surveillance, inventory, chemical testing, and reporting of vape contents can provide insight into composition variability and help inform future testing and regulations.

In 2019, the Center for Forensic Science Research and Education (CFSRE) established a research collaboration to evaluate vape products that were recovered from western Pennsylvania high schools, which has continued to the present. The main objective was to differentiate nicotine from cannabis vape products (or others) through comprehensive drug testing utilizing Gas Chromatography/Mass Spectrometry (GC/MS). Sampling was not random but "for cause," and the sample set may not be reflective of the larger population. In 2023, 416 vape product samples were recovered and documented, and 210 were submitted for analysis.

Of the 210 vape products, 65% of samples contained nicotine and of those, 81% contained glycerin, a common base solvent additive. Additional solvents and flavoring agents were identified based on external database matching, including methyl benzoate, benzoic acid, gamma-decalactone, vanillin, and more. Among middle and high school students reporting current e-cigarette use, 89.4% used flavored products daily. The surveying of vape use can provide insight into the popularity of specific brands and flavors as the tobacco product marketplace continues to diversify. ELFBAR was the second most frequent brand seen in the 2023 nicotine-containing vapes. There were 31 different flavor names advertised within that group (45 samples), which illustrates the versatile flavor profiles on the market. Terpenes found in cannabis vaporizers contribute to scents, flavors, and psychological effects; caryophyllene was the most abundant terpene found in both delta-8 and delta-9 vapes.

In 2023, 29% of tested vape samples contained cannabinoids, such as delta-9-THC, delta-8-THC, CBN, and CBD, and of those 43% were deemed as disposable products in which the device cannot be recharged and is designed to be prefilled and single use. Between Q1 2022 and Q1 2024, disposable products grew their share of vape dollar sales by 92%, and 56% of vape consumers cite ease of use and 44% convenience as their reasons for choosing disposable vaporizers.[2] Previously, the enclosed form of a disposable vaporizer could be an indicator that the vape contained nicotine; in the vapes tested in 2022, there was only one observed disposable vape containing cannabis. The recent market share rise of disposable cannabis-containing vapes has further led to the complexity of distinguishing between a nicotine or cannabis vaporizer device.

Rapid expansion of available products, lack of regulation, and inconsistent terminology associated with vaporizer devices have all led to a general lack of understanding at both consumer and public health levels despite a rapid increase in rate of consumption in recent years. The nuances between nicotine and cannabinoid-containing devices and products create yet another complex dynamic. Comprehensive testing of vapes and reporting of their components is vital to public health stakeholders and responsible decision making by consumers. Each vaporizer device is different, requiring an understanding of their composition and use patterns to educate, reduce harm, and provide recommended regulatory parameters.

B9 Field Testing of Drug-Incorporated Edible Jellies Using Portable Raman-Based Analyzers and Colorimetric Tests

Abid Naseer, MS, Anti-Narcotics Force, Pakistan, Sargodha, Punjab, Pakistan; Tahir Jamshaid, PharmD, MPhil, Lahore College of Pharmaceutical Sciences, Lahore, Punjab, Pakistan; Muhammad Usman, MS, University de Foggia, Foggia, Puglia; Laraib Batool, PharmD, Anti-Narcotics Force, Pakistan, Islamabad, Pakistan; Muhammad Saqib Kabir Khan, MS, Anti-Narcotics Force, Pakistan, Foggia, Italy*

Learning Objectives: Attendees will learn about the capabilities and limitations of Raman-based hand-held analyzers, including the ThermoFisher TruNarc, Rigaku Progeny ResQ, and Agilent Resolve Hand-Held Analyzer, in field drug detection. They will also explore the importance of traditional color tests and the need for advanced separation techniques and AI integration for improved identification of complex drug mixtures.

Impact Statement: The presentation will deliver a clear understanding of risks associated with the use of modern equipment in drug field testing and the management of such risks. The law enforcement agencies will think over the recent training needs of their field officers to cover the lapses and ensure more ethical, accurate, and just seizures. It will draw the attention of the scientific community and the developers to improve the technologies.

Abstract Text: The rise of technological advancements has transformed the field of forensic sciences, presenting both opportunities and challenges.[1] In this study, a cannabis-based product, known as "weed jelly," was analyzed to determine best practices in drug field testing for such products. Cannabis has a long-standing history of traditional use.[2] Recently, there has been increased interest in cannabis-based products globally, despite legal restrictions in many regions, including Pakistan.[3-5]

For the analysis, Raman-based hand-held analyzers; ThermoFisher TruNarc, Rigaku Progeny ResQ, and Agilent Resolve Hand-Held Analyzer, were used under ambient conditions. For sample excitation, the devices use 785nm, 1,064nm, and 830nm wavelength lasers, respectively.[6-8] Raman shifts displayed in the spectrum ranged from 0-3,000cm^{-1}, 0-2,450cm^{-1}, and 200-2,000cm^{-1}, respectively. Chemical spot testing using a Modified Duquenois-Levine test was conducted as a complementary method.[9] The substance was then dissolved in methanol, filtered, and subjected to Gas Chromatography/Mass Spectrometry (GC/MS) analysis using an SDP TOP GC1290 and MS8100.[10] Retention times were compared with reference standards, and MS spectra were matched with the National Institute of Standards and Technology (NIST) and cientific Working Group for the Analysis of Seized Drugs (SWGDRUG) (version 3.13) MS libraries.[11,12]

The Thermo Fisher TruNarc provided inconclusive results. Rigaku Progeny ResQ detected mixtures such as Starch Protein and DiPT with spectral component contributions of Starch Protein 62% and DiPT 28%; a mixture of Phosphorous Chloride 75% and D-Penicillamine 25%; and a mixture of Cholesterol Steroid 65% and Starch Protein 35%. The Agilent Resolve Hand-Held Analyzer showed an 82% match with milk powder; other probable results were tributyl citrate (81%), totoaba fish powder (81%), plain flour (83%), and glycerin (81%).[12] The Modified Duquenois-Levine test indicated a positive result for cannabinoids.[7] GC/MS analysis identified cannabidiol, delta-9-tetrahydrocannabinol, and cannabinol, with high match quality, alongside benzyl alcohol and phloroglucinol.

Traditional color tests remain effective for specific analytes in mixtures during field drug testing, but Raman-based hand-held analyzers showed limitations while analyzing mixtures without any separation techniques. Baseline correction and the algorithms in calculating probabilities should be revised since the match qualities above 80% are high enough to mislead a field officer, leading to the momentary apprehension of an innocent and release of criminals.[13,14] Meanwhile, for a more appropriate, ethical, and just utilization of these technologies, field officers should be educated enough to understand clearly the capabilities and limitations of these devices, that the results displayed are probabilities and the results should be counterchecked with alternative methods, the well-studied and established.[15]

Moreover, the technologies should remain developing and updating during this transformation. Improved DL & AI in machine learning can enhance data interpretation of mixtures and even synthetic analogs by developing the modules with a deep understanding of deviations in sample spectrum governed by dissolution, adulteration, and even small structural variations such as in the case of synthetic analogs. In multiple overlay spectra, spectra of concern, though challenging, may be focused. In the case of structural analogs, such features can predict the probable parent molecule and the possible differences introduced therein, with real-time data interpretation. Continuous learning and updates will further enhance the sensitivity and specificity, thereby optimizing resources at forensic labs.[16-18]

To further improve the drug field testing devices, enhancing the sensitivity and specificity and expanding libraries for broader substance detection, utilizing advanced spectroscopy techniques like SERS and hyperspectral imaging [19], implementing real-time data sharing and connectivity, developing integrated sample preparation and separation to reduce human error, and promoting collaborative development among stakeholders, can be considered.[19-22]

Recent reports of products similar to this study, being seized in various regions underscore the importance of effective detection methods.[1-3]

Raman Spectroscopy; Seized Drugs; Artificial Intelligence

B10 Source Attribution of Fentanyl Via Metals Analysis

Edward Bentil, PhD, George Mason University, Manassas, VA; Marie Taylor, BS, George Mason University, Manassas, VA; Brian Eckenrode, PhD, George Mason University, Aldie, VA*

Learning Objectives: After reading through the poster, attendees will be able to appreciate how metal data, instead of the usual organic precursors, is used to differentiate between illicitly manufactured fentanyl and pharmaceutical fentanyl using statistical applications.

Impact Statement: The overall goal of this poster will be to develop a model that uses the metal data information from the seized samples to differentiate between pharmaceutical and illicit manufactured fentanyl. This information will help law enforcement to end the illicit production of fentanyl that is killing a lot of drug users in the United States by predicting the source of these controlled substances.

Abstract Text: Fentanyl is a synthetic opioid and is a significant contributor to fatal and non-fatal overdoses in the United States. Even in small doses (2mg), it can be deadly.[1,2] There are two types of fentanyl: pharmaceutical fentanyl and Illicitly Manufactured Fentanyl (IMF), and both are considered synthetic opioids. Scientific research has primarily focused on identifying trends associated with fentanyl production, purity, synthetic impurities, and synthetic routes. Elemental impurities are now being used for source attribution since they do not break down compared to the organic components, and pharmaceutical products have tightly controlled metal contents.[3] Metals are unwanted elements that occur in drug formulations, and they can arise from active pharmaceutical ingredients, raw materials, synthetic additives, excipients, catalysts, and product processes and equipment used during manufacture. This research aimed to solve two major issues associated with fentanyl: (1) to use metals analysis data of seized fentanyl to differentiate between licit (pharmaceutical) and illicit sources via the United States pharmacopoeia-approved elemental impurities levels, and (2) profiling the metal content of seized fentanyl for same batch analysis (i.e., similar sources) using multivariate analysis and isotope ratio method.

The research was conducted in two major steps: (1) batch differentiation (i.e., inter-batch comparisons) and (2) pharmaceutical-diverted fentanyl against illicitly manufactured comparisons. The experiments analyzed 22 metals and metalloids (including some isotopes) namely C, Mo, N, Nb, Cr, Mn, Fe, Ni, T, Cu, Co, V, Si, Sr, Se, Al, Hg, Pb, Mg, Zn, Cd and As including 111Cd/ 114Cd, 111Cd/ 112Cd, 208Pb/206Pb and 207Pb/206Pb via Inductively Coupled Plasma/Optical Emission Spectrometry (ICP/OES) and Inductively Coupled Plasma/Mass Spectrometry (ICP/MS) of seized fentanyl samples.[4-5] The use of specific instruments depended on the levels of metals being analyzed. The information obtained was used to develop a metals database, including seizure metadata.

This research will help Customs and Border Protection (CBP)/ Drug Enforcement Administration (DEA)/ Department of Homeland Security (DHS)/ Law Enforcement (LE) personnel clamp down on criminal drug networks, both within our nation and internationally, including dynamic patterns of criminal activities in pharmaceutical companies.

B12 A Simple DNA Extraction Method and a Rapid PCR-Based Assay for Detecting *Ricinus Communis* L. DNA Co-Extracted With Ricin

Renato T.F. Paranaiba, PhD, Brazilian Federal Police, Brasília, Distrito Federal, Brazil*

Learning Objectives: Ricin is highly toxic and can be easily extracted, making it a potential substance for biocrime or bioterrorism. This presentation aims to discuss the problem and propose a detection approach.

Impact Statement: This presentation will introduce new analytical methods for identifying ricin and addressing the threat of biocrime and bioterrorism. The potential options for supporting traceability investigations of this substance will also be discussed.

Abstract Text: Ricin is an extremely toxic poison derived from plants, making it one of the deadliest substances known.[1] Due to its easy extraction from the seeds of the *Ricinus communis* L. plant, this species has been studied as a potential threat for bioterrorist attacks. Its abundance in Brazil has led the country's authorities to consider ricin a major concern. Advanced chemical techniques are utilized to detect ricin, but an alternative method involves analyzing the DNA extracted simultaneously with the protein fraction using the DNA barcoding technique. This technique is effective due to the abundance of nucleic acids present in the seeds of castor beans, from which ricin protein is extracted.

We will describe a rapid and efficient adaptation of an automated DNA extraction method (2) and a Polymerase Chain Reaction (PCR) -based assay to detect *Ricinus communis* L. and its plant products, such as ricin, using a fast plant DNA barcoding approach.[3] The DNA extraction is based on optimizing the buffer for incubation before running the samples in an automated DNA extraction platform. This strategy has previously been used, even for wood. In terms of the analytical approach, we analyzed DNA fragments generated by PCR from specific regions of plant DNA. These fragments vary between plant species and can be used for forensic investigations and genetic identification of plant species. Although the strategy has been theorized but not universally applied to plants, it may also be valuable for other forensic investigations and genetic identification of plant species. The International Criminal Police Organization (INTERPOL) recently hosted its inaugural biosecurity conference and unveiled the Biotracker system. The presented analytical approach also shows promise for enhancing efforts to trace ricin. The proof of concept presented here, when applied to a real case, could form the basis for a more general and simplified analytical model in the field of genetic identification of plant species.

Plant; Ricin; Genetics

B13 A Rapid Method for Identifying Source Species of Body Fluids: Implications for Wildlife Investigations

Kate Jones, Virginia Commonwealth University, Moseley, VA; Christopher Ehrhardt, PhD, Virginia Commonwealth University, Richmond, VA*

Learning Objectives: After this presentation, attendees will understand how blood cell populations from different wildlife species can be differentiated from each other and from cell populations derived from human blood. Additionally, participants will learn how methods for analyzing features of individual cells such as autofluorescence and morphology can be integrated into the workflow of a forensic laboratory.

Impact Statement: This work can impact the forensic community by providing a fast and accurate method for identifying the source species for unknown bloodstains recovered from a crime scene. This can enable laboratories to quickly screen biological evidence samples and determine which are relevant to the investigation (i.e., human vs. non-human deposits) or provide probative information for cases involving animal trafficking and/or abuse.

Abstract Text: Differentiation between human bodily fluids and body fluids derived from wildlife species is an ongoing need for caseworking laboratories. Illegal trafficking of wildlife, such as for medicinal or culinary purposes, would require use of species identification technologies to properly identify bear tissues or fluids among other animals. Additionally, killing and/or abuse of protected or domestic species would possess the same need for differentiation to ensure accurate and timely species identification. Determining the source species for evidentiary samples, particularly those containing blood deposits, can be challenging due to small amounts of sample, degradation, and the presence of cell populations from multiple tissue sources. Therefore, the goal of this research is to develop a new signature system that can be used to identify the source species for unknown blood stains and test it on a series of mock evidence samples approximating those encountered in forensic casework. This research aims to provide an efficient and effective technique that can be easily integrated into the procedures and workflows used by forensic agencies involved with wildlife investigations.

To accomplish this, blood samples from a series of wildlife species (deer, bear, rabbit, dog) were collected along with human blood samples from 20 different contributors. Blood from each source was aliquoted onto glass microscope slides in triplicate (~20ul for each spot) and allowed to dry for varying periods of time ranging between one day and two months. Samples were collected from each surface using a wet swab method and the blood cell populations were eluted from the swab using PBS buffer. Cells were then analyzed using flow cytometer equipped with an excitation laser at 488nm and detector channels for measuring emissions between 500nm and 800nm.

Results from human and canine samples showed significant differences in the intensity of autofluorescence at wavelengths between 500-600nm as well as between 600-700nm (median autofluorescence ~100 RFU and ~500 RFU for human and canine, respectively, $p < 0.001$). Additionally, differences were observed in the forward scatter and side scatter profiles that capture the overall size of the cell and its structural complexity (median FSC and SSC values).These results were consistent in samples that had been aged for up to 90 days and could be detected even in mock casework samples. Blood cell populations from other species (bear, rabbit) showed some variation in the distribution of autofluorescence values between ~200RFU and ~1500RFU compared to both human and canine samples. However, these changes showed greater intra-animal variability across replicates. Overall, these results suggest that information about the source species could be determined for samples approximating those encountered in casework, especially if the provenance is not completely unknown. Further, autofluorescence profiles can complement the information obtained from standard DNA profiling techniques, particularly in agencies that are resource limited.

Species Identification; Autofluorescence; Flow Cytometry

B14 The Mysterious Case of a Fatal Accident During Skydiving: A Fracture of the Pelvis From Parachute Opening Shock (POS)?

Julia Lazzari, MD, Institute of Legal Medicine, Department of Surgical Pathology, Medical, Molecular and Critical Area, University of Pisa, Ospedale Santa Chiara, Pisa, Toscana, Italy; Naomi Iacoponi, MD, University of Pisa, Pisa, Toscana, Italy; Alessandra Cicchini, MD, S.C. Legal Medicine, ASL Città di Torino, Turin, Piemonte, Italy; Giacomo Visi, MD, University of Pisa, Pisa, Toscana, Italy; Carla Occhipinti, MD, University of Pisa, Pisa, Toscana, Italy; Matteo Leoni, MD, University of Pisa, Cascina, Toscana, Italy; Marco Di Paolo, MD, Institute of Legal Medicine, Department of Surgical Pathology, Medical, Molecular and Critical Area, University of Pisa, Ospedale Santa Chiara, Pisa, Toscana, Italy; Giorgio Chiandussi, PEng, Politecnico di Torino, Torino, Piemonte, Italy; Roberto Testi, MD, S.C. Medicina Legale, ASL "Città di Torino", Piemonte, Italy*

Learning Objectives: This presentation will depict a case of a fatal accident during skydiving to demonstrate the importance of correctly interpreting the data collected on the scene, the subsequent postmortem examination, and the engineering report on the parachute and the flight. After attending this poster, attendees will better understand the importance of continued research and improvement in parachute design and skydiving safety protocols to prevent such incidents in the future.

Impact Statement: This presentation will significantly impact the forensic community by presenting a unique case of an open-book pelvic fracture resulting from parachute opening shock, contributing to the relevant literature.

Abstract Text: Skydiving, encompassing competitive, recreational, and military activities, is a high-risk endeavor where accidents can lead to severe injuries or death, despite technological advancements[1]

In this case, a 49-year-old military skydiver was found lifeless in a private garden, with significant blood loss evident beneath his body that had soaked into the soil. Prior to the autopsy, an X-ray revealed a fracture of the pelvis with diastasis of the pubic symphysis, a dislocated appearance and diastasis of the right sacroiliac joint, and a suspected fracture of the right iliac wing and the left sacroiliac branch. The autopsy confirmed these fractures and also revealed a laceration of the right internal iliac artery. The cause of death was determined to be acute hemorrhagic shock. A review revealed that this case is unique in the relevant literature.[2-4]

The case was investigated by a multidisciplinary team comprising a forensic pathologist, a radiologist, and engineers. The team determined that the event was accidental, and that the parachutist's death resulted from hemorrhage caused by the laceration of the internal iliac artery due to the open-book fracture of the pelvis. This fracture likely occurred during the parachute's opening phase, known as opening shock.[5]

Supporting this hypothesis, video footage showed the parachutist was alert until the parachute deployed, with a subsequent soft landing. The high-velocity blood spatter pattern on the parachute bag indicated blood leakage during free fall, confirming the pelvic injury occurred during the opening phase.

By corroborating the forensic data with the engineering report on the parachute and the flight, the dynamics of the accident were clarified, identifying the parachute opening as the critical moment for the fatal injury.

Thus, this work underscores the importance of a thorough analysis, combining precise interpretation of circumstantial and autopsy data with meticulous forensic investigation to determine the manner of death. Continued research and improvements in parachute design and skydiving safety protocols are recommended to prevent similar incidents in the future. This case highlights the need for proper training and positioning during parachute deployment. Skydivers should be educated about the risks associated with improper body positioning during the opening phase. Additionally, manufacturers may consider enhancing harness designs to better distribute forces during high-G events, potentially mitigating such injuries.

B15 A 3D-Printed Object Topography Analysis and the Viability for Forensic Examination

Cooper J. Blair, BS, Edmond, OK; Eric Law, PhD, University of Central Oklahoma, Edmond, OK*

Learning Objectives: Attendees of this presentation will learn how modern technologies like the Cadre Forensics TopMatch-GS system are being used to identify microscopic topographical signatures on 3D printed objects. Attendees will understand how these features can link objects to specific printers or determine if multiple items originated from the same printer. The presentation will cover the use of Virtual Comparison Microscopy (VCM) as well as Cadre's comparison algorithms to objectively compare and interpret these topographies for forensic analysis.

Impact Statement: This presentation will demonstrate the potential for forensic analysis of 3D printed objects using VCM, showcasing its ability to capture microscopic topographies present within 3D printed objects. This presentation aims to advance the understanding of forensic identification methodologies, offering new techniques for the identification of 3D printed objects and individuals involved in criminal activities aided by 3D printing technologies.

Abstract Text: The increasing accessibility and sophistication of 3D printing technology has led to a rise in the creation of untraceable firearms and firearm components, commonly referred to as "ghost guns." These 3D printed objects present a significant challenge to forensic investigations due to the difficulty in linking them to their original source. This study aims to address this issue by exploring the potential for same-source identification of 3D printed objects through the analysis of their microscopic surface topographies. Similar to the manufacturing process of traditional firearms, it is expected that the manufacturing processes utilized during the 3D printing process impart characteristics on the object that can be used to link the object to its original source. This study hypothesizes that the markings left from the hot end nozzle and the print surface of the 3D printer will impart characteristics on the objects that will serve as reliable identifiers of their origin. Preliminary data gathered from the study supports this hypothesis.

To further test this hypothesis with a more robust dataset, 10 hot end nozzles and 10 print bed surfaces will be used with 15 objects printed per nozzle/surface pair. These 150 objects will be inter-compared with objects from known same-nozzle/print surface origin and intra-compared with objects with known different-nozzle/print surface origin to assess the variability in markings found on the objects. To visualize these markings, the study employs the Cadre Forensics TopMatch-GS 3D scanner to capture detailed 3D scans of the 3D printed objects. The scans will be viewed using TopMatch's VCM application, which includes proprietary pattern matching algorithms to generate similarity scores, providing an objective measure of the topographical similarities between different prints. This process involves scanning multiple objects printed using the same and different hot end nozzles and print beds under controlled conditions to ensure a comprehensive analysis.

Along with visual comparison of the 3D printed objects, the system's powerful algorithms will provide similarity scores based on the topographical features that will allow for statistical analysis of the results. The study will include a thorough examination of known samples, generating box plots to visualize similarity score variability and employing Receiver Operating Characteristic (ROC) curves to evaluate the system's accuracy. In addition, confusion matrices will be used to assess the performance in distinguishing between same and different source.

In conclusion, this research advances the field of forensic science by introducing a novel method for the identification of 3D printed objects. The ability to link these objects to specific sources has important implications for criminal investigations involving 3D printed firearms. As 3D printing technology continues to evolve, the forensic techniques developed in this study will be crucial for addressing new challenges in forensic identification and maintaining public safety.

B17 A Characterization of Decomposing Human and Animal Tissue in a Micro-Scale Biotope Through Simulated Rainwater Extraction

Nicholas Iyde, BSFS, George Mason University, Manassas, VA; Edward Bentil, PhD, George Mason University, Manassas, VA; Brian Eckenrode, PhD, George Mason University, Aldie, VA; Ivory A. Krise, MSFS, George Mason University, Altoona, PA; Nana Kennedy, MSFS, George Mason University, Manassas, VA*

Learning Objectives: After attending this poster presentation, attendees will understand human and animal decomposition chemistry in soil and some principles behind the characterization of Volatile Organic Compounds (VOCs). Attendees will be shown a microbiotope used for the analysis of human and animal decomposition chemistry.

Impact Statement: This poster presentation will impact the forensic science community by contributing to the understanding of human decomposition and how the chemical "fingerprint" of human VOCs can be differentiated from animal VOCs through qualitative and quantitative analysis. This presentation will demonstrate the difference in the chemical profiles when the extraction of the VOCs is facilitated by environmental processes, such as the percolation of rainwater through soil, providing a novel methodology for the measurement of decomposition samples in suspected clandestine burial sites.

Abstract Text: The decomposition of human and animal remains produces a complex matrix of VOCs, which are released into the surrounding environment. Past research regarding this field has focused on finding human-specific makers, but due to the emission of similar VOCs in various animal tissues, there is currently a gap in the literature when it comes to a clear differentiation of these VOCs.[1-4] Further research regarding human and animal decomposition VOCs could assist forensic investigators by providing them with the ability to locate victims for suspected clandestine burial sites through soil vapor sampling and standard chemical analysis methods.[5-8] Collating more research around human-specific markers can lead to the development of more effective screening methods for clandestine burial sites, while also improving the effectiveness of Victim Recovery (VR) canine training by honing on specific chemical "fingerprints" that indicate for human decomposition.

A novel approach for studying human and animal decomposition processes will be demonstrated in this research. For this study, a micro-scale biotope has been constructed by using multiple modified soil "chromatography" columns. The research will evaluate muscle, adipose, and bone tissue samples for both human and animal remains. The tissue types will be embedded in the soil of the columns at a set depth to simulate a shallow burial. One aspect that will be evaluated alongside the soil vapors will be the effect that the movement of percolated rainwater will have on the tissue types and whether these extracted rainwater samples can be used for the sampling of human decomposition VOCs at a suspected clandestine burial site. An adjustable flow rate controller was used to maintain a consistent drip-rate in the soil columns.

For the vapor samples, headspace extraction will be performed through Solid Phase Microextraction (SPME), followed by Gas Chromatography/Mass Spectrometry (GC/MS). For the rainwater samples, chemical extraction will be performed using Solid Phase Extraction (SPE), followed by GC/MS. Upon determining the presence of VOCs and/or other organic compounds, the gathered data will be quantitatively analyzed to measure the levels of each evaluated compound in the generated VOC profiles.

Decomposition; Volatiles; Biotope

B18 Analyzing the Case of a Fatal Shooting on a Movie Set

Lexy Dejesus, BA, John Jay College of Criminal Justice, New York, NY; Peter J. Diaczuk, PhD, John Jay College, New York, NY*

Learning Objectives: Attendees will learn about how a single-action revolver functions and how it will not discharge without pulling the trigger.

Impact Statement: This work will affect the forensic science community by showing how methodical testing can reveal whether a firearm is functioning safely and according to the manufacturer's design.

Abstract Text: This research presents the findings of an experimental study conducted to analyze the tragic incident of a fatal shooting on the set of the new film "Rust" and the type of projectile that had been discharged from the firearm on the movie set. The experiment involved firing bullets at a 20-pound block of ballistic gelatine with a piece of 2"x6" wood covering the exit part of the gelatine. The ballistic gelatine acts like human tissue because it slows down the bullet as it enters.

Observations were conducted through multiple trials, photographing the entryway of the bullet trajectories and the exit after encountering the gelatine. The first four trials consisted of pulling the hammer all the way back and pulling the trigger while pointing at the target to confirm that the Pietta .45 Long Colt did shoot as designed. All four times were successful as the handgun did shoot as intended. As the shots were fired, the bullets entered the 20-pound block of gelatine and slowed down considerably as they exited, merely making an indentation in the 2"x6" backstop. Following the successful shots, another test was conducted to determine whether the gun would fire if the trigger was not pulled. Ten trials were conducted by pulling the hammer back a quarter of the way and releasing the hammer, allowing it to free fall toward a loaded chamber at the 12 o'clock position. An additional ten trials of the hammer being cocked back halfway, again with a cartridge placed into the loading gate as normal, and oriented into the 12 o'clock position. When the hammer was released, allowing it to fall toward the live cartridge without pulling the trigger, the revolver still did not result in the discharge of the cartridge. The data was collected using an original 1873 Colt Single Action Army revolver and the Italian Pietta .45 Long Colt, which is an economical replica used on the movie set. Neither the original revolver nor the modern replica revolver resulted in a discharge when the trigger was not engaged. Only when the trigger was pulled did the cartridge fire.

Movie Set; Prop Gun; .45 Caliber Revolver

B20 Forensic Intelligence Derived From Crime Scene Evidence Using Text Embeddings

Vinicius Lima, MEng, Purdue University, Lafayette, IN; Umit Karabiyik, PhD, Purdue University, West Lafayette, IN*

Learning Objectives: After attending this presentation, participants will learn how artificial intelligence can be leveraged to identify patterns in textual data, particularly with respect to crime data. Specifically, they will explore key concepts of Natural Language Processing (NLP) and its application in clustering crimes with similar characteristics. This presentation integrates research from Forensic Intelligence and Crime Linkage to uncover relationships between cases. Additionally, attendees will understand how crime scene evidence directly influences criminal modus operandi in real-world scenarios.

Impact Statement: This presentation will impact the forensic science community by showcasing the significance of Forensic Intelligence applications and their potential to enhance the efficiency of investigations. Furthermore, this work aims to demonstrate, with the support of artificial intelligence, how comprehensive intelligence can be derived by analyzing a diverse collection of vestiges, contrasting with traditional literature that typically focuses on a single type of evidence.

Abstract Text: Uncovering patterns has been a key topic across various research domains. The behavioral patterns observed in criminal activities often reflect the modus operandi of individuals or groups.[1] Crime Linkage, a field dedicated to studying crime information, aims to establish connections between potential serial crimes.[2,3] Initially explored by psychologists, sociologists, and statisticians, this area has recently garnered attention from computer scientists, leveraging artificial intelligence techniques, although this latter discipline is in its initial stages.[4-6] Also, most of the related work has been focused on proprietary crimes, leaving questions on whether crime link conclusions can be drawn with other types of crimes, especially when analyzing big data.[7]

Another related field, Forensic Intelligence, represents a shift in forensic science from individual evidence analysis to a macro-level perspective capable of deriving useful intelligent information from a collection of crime evidence data.[8] Although it is considered a general framework, most of the studies have been treating Forensic Intelligence on one particular type of seized evidence, with a scarcity of work on overall crime scene data.[9]

Both topics (Crime Linkage and Forensic Intelligence) share great similarities, but because they come from different fields, they are often unrelated. This study lies at the nexus of Crime Linkage and Forensic Intelligence, with the support of artificial intelligence, to unveil relationships among crimes utilizing real crime scene information. This research introduces a novel approach to analyzing violent crime scene data by employing advanced natural language processing techniques. In summary, the project consists of three steps: a summarization or extraction of main forensic features from crime scene reports with the support of Large Language Models (LLMs); an embedding conversion (vectorization) with the support of transformers-based models; and data clustering, visualization and analysis.[10] The objective is not merely to identify common offenders across different crime datasets (as typically observed in Crime Linkage) but rather to discern patterns or relationships abstracted from the concealed embeddings. Results demonstrated that crimes share certain commonalities that allow them to be clustered. The vectors generated from crime scene information, combined with spatiotemporal data, can thus encapsulate criminal modus operandi, providing valuable insights for investigations. Moving forward, this model will facilitate the development of a tool designed to generate intelligence for law enforcement and the forensic community.

B21 Deep Ultraviolet Raman Spectroscopy for the Forensic Analysis of Oral Fluids

Mohamed O. Amin, PhD, University at Albany, Albany, NY; Fatima Matroodi, PhD, Elettra, Sincrotrone, Trieste, Friuli-Venezia Giulia, Italy; Entesar Al-Hetlani, PhD, Kuwait Unversity, Khaldeyia, Al Farwaniyah, Kuwait; Igor K. Lednev, PhD, University at Albany, State University of New York, Albany, NY; Barbara Rossi, PhD, Elettra, Sincrotrone, Trieste, Friuli-Venezia Giulia, Italy*

Learning Objectives: This work demonstrates the application of deep Ultraviolet (UV) Raman spectroscopy and chemometrics to analyze antihistamine drugs and assess the impact of thermal conditions on Oral Fluid (OF) samples on various fabrics. The study is relevant to both analytical chemists and forensic scientists, showcasing how deep UV Raman spectroscopy can efficiently analyze OF and other forensic samples with minimal sample consumption and pretreatment. Attendees will appreciate the potential of this technique for crime scene analysis. Additionally, the use of chemometrics, including multivariate Partial Least Squares Discriminant Analysis (PLSDA), to distinguish between pure OF stains and those containing cetirizine highlights the significance of these methods for interpreting forensic evidence. The presentation will also explore the biochemical composition of OF, underscoring its importance as a source of crucial forensic evidence.

Impact Statement: This research highlights the transformative potential of deep UV Raman spectroscopy combined with chemometrics for forensic analysis, particularly in the detection of antihistamine drugs and the evaluation of OF samples exposed to extreme thermal conditions. By demonstrating the method's ability to analyze various forensic samples with minimal pretreatment and sample consumption, this work advances the field of forensic science. The integration of multivariate PLSDA further enhances the capability to differentiate between pure and drug-contaminated oral fluid stains, offering significant improvements in forensic evidence interpretation. The study's insights into the biochemical composition of OF underscore its critical role in forensic investigations, potentially influencing practices in crime scene analysis and evidence assessment.

Abstract Text: This study explores the application of Deep Ultraviolet Raman Spectroscopy (DUVRS) for analyzing OFs in forensic contexts. The application of deep UV Raman spectroscopy and chemometrics to analyze antihistamine drugs and assess the impact of thermal conditions on OF samples on various fabrics was explored. Initially, DUVRS was utilized to detect cetirizine, a common antihistamine drug, in oral fluid samples without requiring sample pretreatment. Antihistamines are a class of compounds that are used to mitigate the symptoms associated with allergic reaction by inhibiting the action of histamine. However, due to their sedative effects, this class of drugs can hinder some vital psychological functions, thereby decreasing the safety in certain common crucial tasks (i.e., driving). From a forensic viewpoint, antihistamine drugs can cause intoxication and can sometimes be fatal when co-administrated with alcohol or other sedative drugs. The method demonstrated practical sensitivity for forensic applications, detecting cetirizine at concentrations as low as 50µg/mL. Additionally, the sensitivity was assessed for analyzing dried oral fluid stains spiked with cetirizine to simulate forensic scenarios involving bodily fluid stains. Combining DUVRS with multivariate statistical analysis enabled effective differentiation between pure OF stains and those containing cetirizine, highlighting DUVRS's high sensitivity for drug detection.

In the second phase of the study, the method was adapted to analyze OFs on various fabrics subjected to extreme thermal conditions for up to 48 hours, to estimate the time since deposition. Despite some spectral changes over time, the approach successfully detected OF bands even after prolonged exposure to harsh thermal environments. This research highlights the transformative potential of deep UV Raman spectroscopy combined with chemometrics for forensic analysis, particularly in the detection of antihistamine drugs and the evaluation of OF samples exposed to extreme thermal conditions. By demonstrating the method's ability to analyze various forensic samples with minimal pretreatment and sample consumption, this work advances the field of forensic science.

Raman Spectroscopy; Drug Analysis; Age Estimation

B22 The Distribution of Retroreflective Glass Beads in Soil Samples

Shirly Montero, PhD, Arizona State University, Phoenix, AZ*

Learning Objectives: After attending this presentation, attendees will understand the value and challenges of analyzing retroreflective glass beads in soil samples.

Impact Statement: This presentation will impact the forensic community by adding an analytical strategy that could support or exclude scenarios where soil evidence is relevant.

Abstract Text: Currently, forensic laboratories do not routinely analyze anthropogenic materials found in soil samples. The primary reason is that the significance of most anthropogenic materials as evidence is not understood.[1-3] Analyses of a few specific anthropogenic materials, such as fibers and glass, have been developed as robust and useful disciplines in forensic science, and are routinely used in United States courts. However, the presence, prevalence, and persistence of anthropogenic materials are not understood in a forensic context. For example, these materials may distribute through the environment predictably such that, if they have a known point source, their concentration in soil samples could be used to infer distance from that point source.

One type of anthropogenic material found in soil is retroreflective glass beads. These beads are incorporated into pavement markings to improve nighttime driving visibility as a countermeasure for lane departures. Therefore, retroreflective glass beads found in soil adjacent to roads potentially are a new source of trace evidence for forensic investigations.

In this study, the 32-500µm fraction from 17 soil samples collected near roads from several locations in central Arizona were analyzed and compared to explore variations in spatial distribution and chemical compositions that could offer source discrimination. Bead concentrations in the soil samples ranged from 0 bead/g of soil to as much as 587 beads/g of soil. Analysis of spatial distribution of glass beads demonstrated that the bead concentration of retroreflective glass beads has a strong dependency with distance from a paved road. Soil samples taken near marked roads showed significantly higher concentrations of glass beads, averaging from 0.18 bead/g of soil sample to 587 beads/g of soil, while soil samples taken near unmarked roads had an average range of concentration of 0 bead/g of soil to 0.21 bead/g of soil. This is expected as glass beads come from pavement markings, thus soil samples near marked roads are expected to have higher concentrations of glass beads. Elemental concentrations by Inductively Coupled Plasma/Mass Spectrometry (ICP/MS) for each sample showed discriminating differences among samples, for most of the elements. An analysis of variance for elemental concentrations was conducted, and results showed statistically significant differences, beyond random chance alone for half of the elements analyzed. For forensic comparisons, these exclusionary differences would support the scenario of the samples coming from different sources. The elemental concentrations of glass beads collected from the same location, but of varying distances, was also analyzed. The results show significant differences for only one or two elements across those samples. The combined results are consistent with the potential use of retroreflective glass beads as trace evidence.

Trace Analysis; Glass; Soil Analysis

B23 Forensic Profiling of Cigarette Paper Using ATR/FTIR Spectroscopy and Machine Learning/Algorithms

Vishal Sharma, PhD, Panjab University, Chandigarh, Chandigarh, India; Akanksha Sharma, MS, Panjab University, Chandigarh, Sector 14, Chandigarh, India*

Learning Objectives: This research provides a detailed understanding of the differences between cigarette paper and other similar materials. Forensic experts and law enforcement personnel can use these insights to better assess the relevance of paper-based evidence found at crime scenes. Further, the application of Machine Learning (ML) algorithms demonstrates the growing importance of data science in forensic analysis by classifying and identifying papers based on their spectral properties. This study also emphasizes the effectiveness of the CatBoost classifier, which outperformed other algorithms. This insight is valuable for future forensic investigations that may require similar classification tasks.

Impact Statement: By demonstrating a method to accurately differentiate cigarette paper from other similar materials and identify specific brands, the study offers a novel approach to forensic evidence analysis. The ability to identify the brand of cigarette paper can offer crucial insights into the habits and social characteristics of individuals at a crime scene, potentially narrowing down suspect lists and establishing links between different pieces of evidence. The adoption of Attenuated Total Reflectance/Fourier Transform Infrared (ATR/FTIR) spectroscopy and ML in forensic investigations represents a significant advancement in the field, allowing for rapid and accurate analysis of evidence and reducing the time and resources required for traditional forensic methods.

Abstract Text: Cigarette paper, often found at crime scenes, is potentially overlooked forensic evidence in investigations ranging from burglary and theft to kidnapping and homicide. This evidence can reveal significant details about the individuals present at the crime scene, such as their brand preferences, social and economic status, and behavioral patterns. Despite its potential value, cigarette paper is frequently overlooked, primarily due to the challenge of distinguishing it from other similar-looking materials, such as tissue, newspaper, and notebook paper. This study aims to address this challenge through two primary objectives: first, to differentiate cigarette paper from other types of paper, and second, to identify the specific brand of cigarette paper from a set of nine different brands. The research employs a combination of ATR/FTIR spectroscopy and advanced Machine Learning (ML) algorithms to achieve these goals.

The spectral data underwent preprocessing, including baseline correction and normalization, to ensure consistency and reliability. Principle Component Analysis (PCA) was then applied to reduce the dimensionality of the data, facilitating more efficient and accurate analysis. The reduced data set was used as input for various machine learning algorithms to classify the paper types and identify the specific brands of cigarette paper. In this work, 15 different ML algorithms were tested to determine the most effective model for this classification task. Among these, the CatBoost classifier stood out for its exceptional performance in both objectives. CatBoost, a gradient boosting algorithm, effectively handled the complex relationships within the spectral data, achieving high accuracy in distinguishing cigarette paper from other types of paper and identifying the specific brands.

This study provides a comprehensive and reliable method for the forensic analysis of cigarette paper, emphasizing the importance of advanced technologies in modern forensic investigations. The integration of ATR/FTIR spectroscopy and ML offers a powerful tool for law enforcement agencies, enabling more precise and efficient crime scene investigations. As forensic science continues to evolve, the incorporation of such innovative methods will be crucial in enhancing the accuracy and efficiency of criminal justice processes.

B25 Cracking the Case: Toward the Development of Mass Spectral Analysis of Blow Fly Eggs for Postmortem Interval Determination

Alexa Figueroa, Louisiana State University, Baton Rouge, LA; Jennifer Y. Rosati, PhD, John Jay College of Criminal Justice, New York, NY; Rabi A. Musah, PhD, Louisiana State University, Albany, NY*

Learning Objectives: Attendees can expect to learn about the use of Direct Analysis in Real-Time High Resolution Mass Spectrometry (DART-HRMS) and its applications in forensic entomology and how statistical analysis can be applied to the metabolome profiles revealed by the aforementioned technique to enable insect species identification that can be useful for Postmortem Interval (PMI) determination, as well as geographic provenance determination.

Impact Statement: Facile generation of metabolome profiles combined with the application of statistical analysis of these profiles reveals unique chemical fingerprints that enable species differentiation and accurate identification of necrophagous blow fly eggs. Furthermore, the mass spectral data acquired from blow fly eggs within a species collected from different regions may reveal provenance with high accuracy.

Abstract Text: Medicolegal forensic entomology utilizes the patterns associated with insect colonization of remains to estimate time since death, or PMI, a critical element in criminal investigations. Blow flies (Family: Calliphoridae) are capable of detecting remains within minutes of death, often serving as the initial colonizers. A "back-calculation" method exists in which the time since death has occurred (i.e., PMI) can be estimated by correlating the insect species identity, environmental conditions, the stage of decomposition of the remains, and the species-specific insect life cycle timelines. The calculation determines the time since the laying of the eggs, based on the assumption that the eggs were laid within a time period shortly after the death occurred. Precise species identification is essential for accurate PMI estimation, as developmental rates vary significantly among blow fly species as a function of temperature and weather conditions. Retrieved entomological evidence can also reveal important information about where the death occurred through determination of whether the insects colonizing the remains are endemic to the region where the remains were found. Therefore, knowing the identity of the species is essential.

Traditional identification methods based on morphological characterization are time-consuming and susceptible to error, particularly for the immature life stages (i.e., eggs, larvae, and pupae) because of their visual similarity across multiple species. Thus, if the specimens are viable, an experienced entomologist may rear them to adulthood to accomplish species identification based on the visually apparent gross morphological features of the emergent adults.

Reported here is an alternative novel approach employing mass spectral analyses and chemometrics for rapid blow fly egg species identification, which can be used to facilitate estimation of PMI. By analyzing 70% aqueous ethanol suspensions of eggs from multiple species representing the genera *Calliphora*, *Chrysomya*, and *Lucilia* using DART-HRMS, distinct mass spectral profiles were obtained for each species. Kernel Discriminant Analyses (KDA) for each genus effectively clustered these profiles, demonstrating the potential for accurate genus identification with accuracies of 88.75%, 95%, and 92.50%, respectively. In addition, application of KDA to the mass spectral data acquired from egg specimens of *Cynomya cadaverina* from three regions (Louisiana; Manhattan, NY; and Sauble Falls, Canada) showed the potential to determine geographic provenance for samples of the same species from different regions with an accuracy of 95.56%. Future studies aim to create a database of the species-specific chemical signatures for species identification of entomological evidence that will increase the evidentiary value of juvenile life stages in the determination of PMI and assessment of whether the remains were moved from one location to another.

B26 The Contamination of Training Aid Substrates

Fernando Zaldivar Eyre, BS, Florida International University, Miami, FL*

Learning Objectives: The objectives of this poster project focus on the crucial aspects of contamination in canine training aids. First, the project aims to understand the impact of contamination on these training aids by recognizing how contamination can degrade their quality and affect detection proficiency. Second, it will evaluate non-target contamination during training by assessing the extent of contamination in different substrates under training conditions and understanding how these conditions influence contamination levels. Finally, the project will compare substrate suitability for training aids by examining contamination levels across various substrates to determine their appropriateness for use in training aids.

Impact Statement: This study significantly enhances our understanding of contamination issues in canine training aids, a critical factor in the proficiency of detection canines. By systematically comparing contamination levels across various substrate materials in training scenarios, the research identifies the key strengths and weaknesses of these materials. The findings provide crucial insights that will inform the development of improved manufacturing processes, storage protocols, and contamination mitigation strategies. This work will ultimately lead to more reliable and effective detection canines, with broad implications for security, law enforcement, and other sectors relying on these animals.

Abstract Text: The effectiveness of canine training aids is crucial for the proficiency of detection canines, but contamination can rapidly degrade their quality. This study addresses the problem of contamination in canine training aids by comparing the extent of contamination across various common substrate materials in real-world training scenarios.

The project focused on assessing non-target contamination during training. Substrate materials, including GetXent polymer tubes, cellulose-based materials, Polydimethylsiloxane (PDMS), and novel Fabric Phase Sorptive Extraction (FPSE) materials, were exposed to highly odorous environments to simulate training conditions. These odorous locations, such as open air, cars, and dog kennels, were chosen because they represent typical training environments where contamination could originate and later affect the detection canine's proficiency.

To test the substrates, triplicates were first equilibrated and sampled before being exposed to odorous locations for 4 hours. After this exposure, the substrates were sampled again to collect their headspace. The headspace above these substrates was sampled using Solid Phase Microextraction-Gas Chromatography/Mass Spectrometry (SPME-GC/MS). The collected data was then analyzed to compare the contamination profiles of the various substrates.

The results indicated significant differences in non-targeted contamination levels among the substrates, suggesting variability in the resistance of different substrates for training aids. The study also demonstrated how various methods of handling training kits affect contamination levels. This finding underscores the importance of best practices in handling and deployment to minimize contamination risks. Proper handling procedures, such as exposing the training aids using an open container and maintaining clean storage conditions, can significantly reduce the contamination of training aids, thereby enhancing the accuracy and reliability of detection canines.

Interestingly, the study showed no correlation between cost and effectiveness. This suggests that more expensive materials do not necessarily offer better resistance to contamination. Therefore, selecting cost-effective substrates that meet the required standards of contamination resistance is feasible, ensuring the sustainability of canine training programs.

Finally, while GetXent tubes and PDMS training aids are gaining popularity in the operational community, there has been limited research on their strengths, limitations, and contamination potential. This study contributes to filling that gap by providing empirical evidence on their performance under real-world training conditions. The insights gained from this research can guide trainers in making informed decisions about the selection and use of training aids, ultimately enhancing the proficiency of detection canines.

In conclusion, the study underscores the importance of selecting appropriate substrate materials and adhering to best handling practices to minimize contamination in canine training aids. By doing so, trainers can ensure the effectiveness and reliability of detection canines, which are essential for various operational applications. The findings from this study pave the way for future research and development in the field, aiming to enhance the quality and efficacy of canine training aids.

B27 A Rapid Hand-Held Detector for Drugs and Explosives and Their Signature VOCs Using Novel Nano-Porous Molecularly Imprinted Polymer Sensors

Abuzar Kabir, PhD, Florida International University, Miami, FL; Kenneth G. Furton, PhD, Florida International University, Miami, FL; Patrick Roman, PhD, Florida International University, Miami, FL*

Learning Objectives: We are presenting a new chemical detection sensor technology. We will describe how the new technology is unique and its advantages for low cost chemical detection in the field.

Impact Statement: The Nanoporous Molecularly Imprinted Polymer Sensors (NPMIPS) chemical detection sensor technology has the potential to enable new, highly selective, and sensitive, field chemical detection instruments. These new field portable instruments will be capable of detecting multiple specific compounds of interest simultaneously, based on the MIP sensor design array. A new hand-held NPMIPS portable detector will bring the next generation of rapid, safe, and reliable sensing technology to users in the field for drug, explosives, toxic chemical and materials, and chemical warfare agent applications.

Abstract Text: Novel NPMIPS exploit nanotechnology to enable new micro sensor devices for chemical sensing through nanoengineered nanoporous materials. NPMIPS sensors achieve high selectivity and sensitivity through a nanoporous polymer material that has been molecularly engineered for analyte of interest specific collection and sensing. Sol-gel molecular imprinting technology creates molecularly imprinted polymers characterized with high imprinting factor (ratio between specific and non-specific extraction), robust nanocavities complimentary to the shape, size, and functional composition of the template molecule(s), remarkably high thermal (~500°C), solvent (any solvent or solvent mixture), and chemical stability (pH 1-13). The NPMIPS sensors are designed for analyte-specific sensing using an array of capacitive sensing elements to detect compounds of interest.[5-6]

The performance superiority of novel nanoporous molecularly imprinted polymer materials has been published in several recent publications by our research group.[1-4] For example, N.P. Kalogiouri et al. utilized Bisphenol A (BPA) -imprinted NPMIP in combination with High-Performance Liquid Chromatography-Ultraviolet (HPLC-UV) to monitor BPA in walnuts and have reported 10ng/g quantitation sensitivity.[1] Similarly, V. Samanidou et al. reported application of chloramphenicol imprinted NPMIP to monitor the presence of this antibiotic in milk samples. Analytical figures of merit included an imprinting factor 9.7, Limit Of Quantitation (LOQ) in HPLC-UV 50ng/g and 0.3ng/g in Liquid Chromatography/Mass Spectrometry (LC/MS)[4] The new NPMIPS could enable rapid detection of both the analyte and its Volatile Organic Compound (VOC) (e.g., cocaine and its signature VOC methyl benzoate), giving a potential confirmatory measurement capability for a compound of interest on the same sensing device, a new and powerful method of field chemical detection without sample preparation. The new NPMIPS sensors are amenable to thick film casting on substrates, integrate well into micro sensor device and batch fabrication processes, and may be molecularly engineered and synthesized for any desired analyte. The chemical specific collection material is very stable and resistant to high temperature (500°C), allowing for temperature cycling of the sensor by resistive heating to clear the previous sample to enable new measurements. Further, it is possible for the NPMIPS to have 10 to 20 different specific sensing elements, covering a broad range of drugs, explosives, or other analyte classes of interest.

NPMIPS nanotechnology will enable the development of new low-cost portable instruments for the simultaneous detection of drugs, explosives, and other compounds, and their signature VOCs in a hand-held device for use in the field. Chemical sensing in the field demands small, lightweight, low power, cost-effective, and precise instrumentation to provide the most reliable measurement result and optimal situational awareness for end-users. The new hand-held NPMIPS device will bring the next generation of rapid, safe, and reliable sensing technology to users in the field.

B28 Exploring Alternative Solvents for Dichloromethane as an Extraction Solvent of Sexual Lubricant Components Using Gas Chromatography/Mass Spectrometry

Safiya Best, MScFS, University of Central Florida, Longwood, FL; Ashley R. Gamache, University of Central Florida, Orlando, FL; Candice Bridge, PhD, NCFS/ University of Central Florida, Orlando, FL*

Learning Objectives: Attendees will recognize the value of finding an alternative solvent for extracting sexual lubricant components that performs as efficiently as Dichloromethane (DCM).

Impact Statement: DCM-Methanol (MeOH) has been found to be proficient in extracting non-polar and polar components of sexual lubricants. However, a recent recommendation has been made by the Environmental Protection Agency (EPA) that may result in a ban of DCM usage in laboratories. Therefore, this study will provide the forensic community with an extraction solvent for sexual lubricants that results in a comparable recovery to DCM.

Abstract Text: After attending this presentation, attendees will understand the importance of finding an alternative extraction solvent in replacement to DCM that allows for an efficient recovery of sexual lubricant in comparison to DCM. The forensic community will find this information helpful due to a recent recommendation made by the EPA that suggests a ban of DCM laboratory use.

Recent research has proven that sexual lubricant may be useful as an additional form of evidence linking suspects to a sexual crime or victim.[1,2] Several extraction solvents have been evaluated for sexual lubricant extraction, particularly hexane and MeOH. However, hexane extracts the non-polar components and MeOH extracts the polar components. Thus, multiple extractions require multiple analysis, which increases turnaround. Therefore, studies have demonstrated that a DCM-MeOH (1:1) solvent system is appropriate to conduct one extraction to recover polar and non-polar components simultaneously.[3] However, recent recommendations made by the EPA to restrict the use of DCM affects the implementation of this solvent system for forensic lubricant analysis and therefore a comparable solvent must be evaluated for sexual lubricant extraction.

This study evaluates different solvents for the extraction of individual sexual lubricant components as well as manufactured lubricant samples. The extraction systems evaluated were Ethyl Acetate (EA), EA-MeOH (1:1), EA-MeOH (2:1), and 2-Methyltetrahydrofuran (2MTF). Preliminary data indicated that the EA-MeOH (1:1) solvent system was most efficient at extracting several sexual lubricant components in comparison to 2MTF and EA and thus the study was expanded to more lubricant components/samples and an additional solvent system. The EA-MeOH (2:1) solvent system was added to increase the extraction of more nonpolar components in relation to MeOH extraction of polar components. All extracts were analyzed in triplicate using gas chromatography/mass spectrometry. The resulting chromatograms from each solvent extraction were compared against the DCM-MeOH extraction chromatograms using Pearson correlations coefficients.

It is hypothesized that the EA-MeOH (2:1) solvent system will provide the most comparable results to the DCM-MeOH solvent system. Considering that the EA-MeOH (1:1) solvent system did extract some non-polar components but not in the same abundance as the DCM-MeOH (1:1) system.

B29 Time-Since-Deposition Signatures for the Analysis of Canine Body Fluids

Alysia Townsley, BS, Virginia Commonwealth University, Richmond, VA; Christopher Ehrhardt, PhD, Virginia Commonwealth University, Richmond, VA*

Learning Objectives: After this presentation, attendees will have a new understanding of how flow cytometry can be used to determine the Time Since Deposition (TSD) of canine bodily fluid samples. Attendees will also learn about biological signatures that can differentiate between human and canine bodily fluids.

Impact Statement: This presentation will impact the forensic science community by providing alternative scientific methods for animal cruelty cases and giving investigators a new method for analyzing animal bodily fluids and determining TSD. It could also assist in generating reference data and casework protocols for analysis of canine bodily fluids.

Abstract Text: Although dogfighting is a felony in all 50 states, increasing criminalization has done little to deter the estimated tens of thousands of people involved with the organization and commodification of dogfighting and related breeding in the United States. Dogfighting has grown into a substantial enterprise, which is often tied to other organized crime activities, including gambling, narcotics, and weapons trafficking.[1]

When investigating a suspected dog fighting event, canine bodily fluids such as blood or saliva are some of the primary types of physical evidence collected from the crime scene. However, one of the challenges with processing and interpreting DNA profiles generated from canine blood deposits is that DNA profiles provide identity of canines involved (through comparison with a reference sample) but cannot confirm whether the bodily fluids were deposited during the activity or at a different time under unrelated circumstances. Determining when these bodily fluids were deposited at the crime scene could add probative value to the DNA evidence, since it can be linked to both the date and location of the fight.

One proposed method of analysis uses flow cytometry to characterize changes in the autofluorescence profiles of canine blood or saliva across different TSD intervals. By comparing the changes of properties such as fluorescence intensity, forward scatter (which indicates the relative size of the cells), and side scatter (which indicates the size and density of the cell) over time, it may be possible to estimate the TSD of a canine bodily fluid after sample deposition. Therefore, the goal of this study was to develop a new set of biological signatures based on flow cytometry measurements that can be used to determine the time-since-deposition of forensically relevant canine bodily fluids, including blood and saliva.

To accomplish this, blood was taken from ten canines of different breeds and ages, then deposited onto a non-porous substrate in 15µL spots. Samples were then aged for up to 90 days and analyzed at fixed TSD timepoints (1, 2, 3, 7, 14, 30, and 90 Days). At each timepoint, blood deposits were collected from the surface using a wet swabbing method and allowed to dry prior to flow cytometry analysis. Autofluorescence profiles of individual cells were characterized using a 488nm excitation laser and detector wavelengths between 535nm-700nm. Fluorescence histograms showing the number of cells at varying fluorescence intensity were used to compare cell populations at different TSDs. Results showed that ~50% of the canine contributor samples showed high fluorescence at 523nm, 583nm, and 695nm within a week of deposition (e.g., 104 RFU at 3 days vs. 103 RFU at 7 days). After one week, fluorescence intensity continued to increase up to 30 days. However, after 90 days, all contributor cell populations showed a two-fold decrease in autofluorescence intensity (~400 RFU).

As part of this study, differences between blood cell populations of humans and canines were also investigated. Autofluorescence intensity from human samples were lower (approximately 25 RFU) compared to canine samples (approximately 100 RFU) across each TSD at 523nm for up to 30 days. Human samples also had higher median side-scatter area (SSC-ALog) at all timepoints than canine samples, though there was considerable overlap in size range between the two.

These results suggest that flow cytometry can be used to analyze an unknown blood sample and determine whether it originated from human or canine tissue as well as the sample's TSD at specific intervals up to 90 days. This indicates that it may be possible to link the relative age of canine blood samples to the known time period of a dog fighting event, leading to increased prosecution of dog fighting crimes in the United States.

B30 Implementing Y-Screen Protocols as a Tool for Sexual Assault Forensic Examination Kit Backlog Reduction

Lake A. Prescott, MSFS, Baltimore Police Department, Towson, MD*

Learning Objectives: From this presentation, attendees will learn how to implement Y-screening protocols to manage the backlog of Sexual Assault Forensic Examination (SAFE) kits more effectively. This presentation will explain the methodology for using Y-screening to identify and prioritize the most probative samples and will demonstrate the concept of autosomal-to-male DNA quantitation thresholds. Attendees will understand how these approaches can enhance forensic DNA analysis, resulting in shorter turnaround times and leading to more efficient processing of sexual assault cases.

Impact Statement: This presentation will provide the forensic science community with valuable insights into optimizing Y-screening protocols and integrating autosomal-to-male DNA quantitation thresholds. This presentation will demonstrate how the Baltimore Police Department's Forensic Biology Unit (FBU) has applied these techniques to improve efficiency, accelerate case processing, and make significant strides toward eliminating its backlog with a goal to reach real-time analysis.

Abstract Text: A prominent challenge facing many forensic DNA laboratories is a backlog of SAFE kits. Due to federal mandates, labs must now process all previously untested SAFE kits, some spanning back decades, placing a significant workload on labs that are already facing staffing shortages and budget constraints. All of this can make it difficult for labs to manage both backlogged and current cases. To help combat these challenges, many laboratories are adopting Y-screening protocols that streamline the analysis process and reduce turnaround times.

Y-screening is performed post-quantitation and is used to assess the presence of male DNA in SAFE kit samples. Using quantitation results and case circumstances, this method allows labs to prioritize the most probative samples—those most likely to produce male profiles—thereby decreasing the number of samples that require downstream analysis. By using this approach, labs can enhance efficiency and accelerate case resolution.

The Baltimore Police Department FBU first implemented its Y-screening protocol in the summer of 2021 and has since continued to refine and improve the process. In 2023, the FBU began evaluating an autosomal-to-male DNA quantitation threshold as a new criterion. In samples where the amount of female DNA is disproportionately higher than the amount of male DNA, the probability of obtaining a male profile is unlikely. This allows for even further refinement in sample selection, conserving time and reagents while optimizing the analysis workflow.

This presentation will demonstrate the successful application of Y-screening protocols in SAFE kit backlog reduction, as evidenced by the BPD's FBU. It will highlight ways to refine and improve processes, such as the use of autosomal-to-male DNA quantitation thresholds. Attendees will learn practical strategies for implementing these techniques, ultimately contributing to greater efficiency and faster turnaround times, while working toward the goal of real-time SAFE kit processing.

Backlogs; Y-Screening; Forensic DNA

B31 The Use of Quantitation Values to Infer the Possible Presence of Spermatozoa

Ashley Luther, MS, Indiana State Police Laboratory, Indianapolis, Indianapolis, IN; Kate DeHeer, MPS, Indiana State Police Laboratory, Indianapolis, IN; Joanna Johnson, MS, Indiana State Police Laboratory, Indianapolis, IN*

Learning Objectives: This presentation will introduce attendees to a novel approach to using differential extraction quantitation data as a gauge for the presence of sperm cells in a sample. Attendees will also learn how our laboratory system has implemented multiple quantitation data analysis methods as presumptive tests for the presence of spermatozoa.

Impact Statement: The presented work will impact the forensic biology community by introducing a new approach to inferring the presence of spermatozoa using quantitation results. We also provide guidance on implementing these methods into a multi-laboratory system in a way that increases the probative information obtained while following the recommended "Direct to DNA" approach to sexual assault casework.

Abstract Text: The National Institute of Justice (NIJ) recommends a "Direct to DNA" approach for the processing of sexual assault kits.[1] While effective to decrease overall processing time, the lack of traditional serology testing prevents the confirmation of spermatozoa in a sample. Research by Alderson et al. and Ridgley et al. indicates that when utilizing a differential extraction method, the average portion of male DNA in sperm fractions is high when sperm cells are present.[2,3] Both papers utilize a calculation termed the Fractionation Ratio (FR) but consider different thresholds for what percentage of male DNA is expected in a sperm fraction and the quantity of DNA in the fraction below which a sample will not be tested.

We developed an additional method using the Female-To-Male Ratio (FTMR) of both the sperm and non-sperm fractions to create a ratio we have termed the Differential Ratio (DR). It was determined that using the FR method in conjunction with the DR method captured the highest number of samples that contained spermatozoa. In particular, the DR captured samples made of dilute semen mixed with undilute body fluids from both male and female donors. There were a number of false negatives for both methods, and a false positive result was observed with the FR method using the thresholds described in Alderson et al.[2]

These results support the leading thought that these calculations should be utilized as a presumptive test for spermatozoa. Our laboratory system has implemented both the FR and DR into our processing of sexual assault kits—and any other samples subjected to a differential extraction—such that no additional sample is consumed, nor time spent by the analyst, but with a potential to retrieve additional probative case information. Using our in-house DNA analysis workbook, the FR and DR are automatically calculated and a positive result from either method is then reported to the submitting agency along with the results of DNA analysis.

B32 Seminal Fluid Identification in Different Semen Sample Types

Mercedes Aler, PhD, University of Valencia, Valencia, Comunidad Valenciana, Spain; Maria J. Castagnola, MA, New Jersey Institute of Technology, New Jersey, NJ; Francisco Medina Paz, PhD, New Jersey Institute of Technology, Newark, NJ; Scarlet Tabitha Neilson, MSFS, Arcadia University, Seattle, WA; Maik Schlieper, SERATEC Gesellschaft für Biotechnologie mbH, Goettingen, Germany; Nora Ronan-Milz, Lehigh University, Lopatcong, NJ; Sara C. C. Zapico, PhD, New Jersey Institute of Technology/Smithsonian Institution, Newark, NJ; Gabriela Roca, PhD, SERATEC GmbH, Goettingen, Niedersachsen, Germany; Mirna Ghemrawi, PhD, The Center for Forensic Science Research and Education, Horsham, PA; Amy N. Brodeur, MFS, Boston University, Boston, MA; Leah Nangeroni, MS, The Center for Forensic Science Research and Education, Horsham, PA; Maria Isabella Negretti, BS, Seratec Gesellschaft für Biotechnologie mbh, Göttingen, Niedersachsen, Germany; Polina Khalizov, New Jersey Institute of Technology, Livingston, NJ; Elizabeth Brusacoram, BS, Boston University, Boston, MA*

Learning Objectives: After attending this presentation, attendees will be informed of the differential efficiency in detecting seminal fluid in four forensic scenarios using these biomarkers: Prostate-Specific Antigen (PSA), Semenogelin (Sg), Y-chromosome profiling and microscopy.

Impact Statement: This presentation will impact the forensic science community by presenting, for the first time, an extensive study of the assessment of these four semen detection approaches, taking into consideration the characteristics of the donor.

Abstract Text: Semen detection at crime scenes is essential for sexual assault investigations. Presumptive and confirmatory tests have been developed to identify seminal fluid toward this purpose. While visual observation of sperm cells proves the presence of semen, this is not always possible. The detection of male DNA in a sexual assault sample may suggest semen is present but is not body fluid specific.

Currently, one of the main approaches to detecting seminal fluid is through the use of Lateral Flow Immunochromatographic (LFI) tests, based on antigen-antibody reactions. There are two types of LFI for the detection of semen: those based on PSA, produced in the prostatic epithelium; and those based on Sg, produced in the seminal vesicles, the vas deferens, the prostate, and the epididymis. Both proteins are secreted in semen, and to a lesser extent in some other body fluids. The question is: when to use one or another or both?

The aims of this study were: (1) to evaluate the effectiveness of PSA and Sg LFI tests to detect seminal fluid; (2) to correlate the positiveness of the tests with the presence/absence of spermatozoa; (3) to estimate the possibility of obtaining a full autosomal and Y-chromosomal Short Tandem Repeat (Y-STR) DNA profile; and (4) to assess the obtention of this profile using semen dilutions mixed with menstrual blood. To do this, PSA and Sg LFI tests were analyzed in six types of semen samples: single donor, pooled donor, vasectomized, 30-year-old frozen pooled donor (to simulate an unresolved case), low sperm count, and a reverted vasectomized donor sample. Serial dilutions of the samples were carried out from 1:2 to 1:32,000. Our results indicated that both tests were positive in all samples, ,except that Sg began to be negative from 1:2,000 in the 30-year-old pooled sample and from 1:8000 in the rest of the samples. Conversely, PSA began to be negative from 1:16,000 in the fresh frozen pool donor and from 1:32,000 in the 30-year-old group pooled sample, indicating better PSA performance than Sg, even in vasectomized samples. Cytology was done both with Christmas Tree stain and without stain, demonstrating that these results were independent of the presence of sperm cells.

LFI results for all samples were positive at the dilution 1:1,000. Previously published studies indicated that at this dilution, DNA profiling could be compromised. In regard to DNA analysis, from the dilution 1:2,000 onward, it was not possible to obtain quantifiable DNA to perform the STR analysis. In samples mixed with menstrual blood, PSA Semiquant showed positive results when tested up to 1 to 1,000. When using the sample pad of PSA immunochromatographic tests to extract DNA, it was possible to obtain both autosomal STR and Y-STR DNA profiles from positive tests, being able to produce full profiles from 1 part of semen diluted in 10 parts of menstrual blood, though profiles were not obtained from higher dilutions.

This research has demonstrated the importance of utilizing both detection of proteins (indicating possible presence of a body fluid) and DNA (identification of an individual) together as complementary techniques to detect semen when spermatozoa are not visible by microscopy or when microscopy equipment or expertise is not available. The variability of results could be related to different factors like medical conditions, age, and population affinity, among others. Future research aims to correlate the positivity of these tests at higher dilutions with DNA yield and to develop STR profiles and identify the Y chromosome for the presence/absence of male DNA to arrive at an unambiguous and powerful identification.

Bodily Fluid; PSA; Semenogelin

B33 Increased DNA Quantification Sensitivity: An Evaluation of Investigator Quantiplex Pro FLX

Julia Wang, MS, Sam Houston State University, Huntsville, TX; Ya-Chih Cheng, PhD, Sam Houston State University, Huntsville, TX; Rachel Houston, PhD, Sam Houston State University, Huntsville, TX; Joshua D. Boster, BS, Sam Houston State University, Huntsville, TX*

Learning Objectives: Upon attending this presentation, attendees will gain an understanding of DNA quantification with increased sample input through use of lyophilized reaction reagents.

Impact Statement: This presentation will impact the forensic science community by introducing support for increased sample input to increase sensitivity in DNA quantification chemistries for screening purposes.

Abstract Text: DNA quantification is crucial for successful DNA profiling and provides key information about the nature of the evidence. With advancements in DNA quantification chemistries, detection of degradation, mixtures, and inhibition has become routine, requiring only 2µL of sample input for processing. However, as human identification testing has advanced to handle challenging samples such as low-template samples and complex mixtures, the need for increased sensitivity in quantification has emerged.

The research aimed to examine the potential for increased sensitivity using the Investigator Quantiplex Pro FLX kit. This kit features a novel lyophilized chemistry, allowing for an expanded sample target input range from 2µL to 18µL. The kit was evaluated with DNA concentrations as low as 0.0000625ng/µL. Additionally, DNA mixtures with high female-to-male ratios up to 1,000,000:1 and vaginal swabs spiked with semen were tested to determine sensitivity of male DNA detection. The spiked vaginal swabs were processed with the Investigator Casework GO! kit to test the efficacy of Y-screening and compatibility between the direct lysis chemistry of Investigator Casework GO! with the Investigator Quantiplex Pro FLX kit.

The results demonstrated the successful detection of DNA at the lowest concentration of 0.000625ng/µL. In high female-to-male ratio DNA mixed samples, male DNA was detected in all of the mixtures. For the vaginal swabs, male DNA was detected from swab cuttings as small as one-eighth of a swab spiked with semen diluted to an expected 0.0064ng of total DNA. In these spiked swabs, male DNA was detected even when female DNA was present at ratios higher than 19,000:1. These findings indicate that Investigator Quantiplex Pro FLX is a highly sensitive DNA quantification kit, suitable for a variety of forensic samples and workflows, including Y-screening commonly applied to sexual assault evidence. The increased sensitivity and expanded sample input range offer greater flexibility when working with low template DNA or extreme mixtures.

B34 A Novel Method for the Identification of Source Tissue in Biological Mixtures

Nicole Dailey, MS, Virginia Commonwealth University, Henrico, VA; Christopher Ehrhardt, PhD, Virginia Commonwealth University, Richmond, VA; Gabrielle J. Wolfe, Virginia Commonwealth University Department of Forensic Science, Richmond, Virginia*

Learning Objectives: After this presentation, attendees will be introduced to a new serological test that can detect saliva in single-source samples as well as in mixtures of bodily fluids. Attendees will also learn how variations in the fluorescence and morphological profiles of cells derived from separate tissues can indicate the source of bodily fluids for biological evidence.

Impact Statement: This work can impact the forensic community by allowing analysts to rapidly screen evidentiary samples for the presence of saliva and to determine if there is enough DNA present to obtain a profile based on the population of epithelial cells present. This will help laboratories predict which samples will have probative value before processing.

Abstract Text: Current serological tests often provide little information for trace samples and are usually destructive. Recently, flow cytometry has been proposed as an alternative approach for determining the source tissue of biological deposits. This uses the excitation of fluorescent molecules within cells to characterize their biochemical composition. Imaging Flow Cytometry (IFC) has an additional advantage by including a brightfield channel displaying cellular morphology, simultaneously allowing for the distinguishment of cell populations based on size, shape, and/or structural features. Therefore, this study aimed to develop and test a new flow cytometry-based screening approach for detecting the presence of saliva epithelial cells in samples approximating those encountered in DNA casework. This approach has several advantages for forensic laboratories. The process is non-destructive and can rapidly distinguish between cell populations derived from saliva, blood, vaginal, and epidermal tissue. Thus, IFC as a serological test could allow laboratories to decrease evidence backlogs and increase the probative value of single and mixture evidentiary biological samples.

For this study, dried swabs representing both single-source and mixture samples of blood and saliva were analyzed using imaging flow cytometry with a 20x objective for magnification. A gate was applied during the acquisition of cellular events to allow single cells to be collected and remove debris that would decrease the number of true events in the raw image files. Autofluorescence and morphological features were used to identify cell signatures that either presumptively detected or confirmed the presence and amount of saliva epithelial cells within each mock evidence sample. To ensure that this technique would be compatible with a typical DNA profiling workflow, portions of each dried swab underwent DNA extraction, quantification, and Short Tandem Repeat (STR) profiling so the saliva epithelial cell signatures could be correlated to the quantity and quality of DNA within the blood and saliva mixture.

Results showed that autofluorescence and morphological signatures from saliva epithelial cells could be easily distinguished from blood cell populations. Specifically, the contrast values for the saliva epithelial cell populations in the brightfield channel showed a two-fold increase over the contrast values from the blood cell populations. This signature was consistent for single-source samples as well as the blood and saliva mixtures. Additionally, differences were observed in the intensity of the autofluorescence at wavelengths between 550–650nm when comparing saliva and blood cell populations. Within this wavelength range, there was an approximately 15% increase in the intensity of saliva cells compared to blood cells. These signatures were then used to presumptively detect the presence of saliva epithelial cells in more than 25 different mock evidence samples containing mixtures of saliva and blood in ratios ranging between 1:1 and 1:20. Last, autofluorescent signatures were used to perform a front-end separation of contributor cell populations in saliva-blood mixture samples aged between one day to two weeks. Results indicated that front-end separation successfully enriched saliva and blood cell populations from mixture samples aged less than two days with contributor ratios of 1:2, 1:1, and 2:1.

Overall, these results suggest that imaging flow cytometry can quickly screen cell populations in evidentiary samples for the presence of saliva epithelial cells in mixtures of bodily fluids. Similarly, rapid detection of epithelial cell concentrations could allow forensic scientists to determine whether a sample contains enough DNA before initiating extraction. As a result, this method could enable laboratories to increase the probative value of biological samples representing either a single source or mixtures.

B35 QIAxcel vs. qPCR: Evaluating Versatility for Forensic DNA Screening

Susana J. Garcia, BS, Sam Houston State University, Huntsville, TX; Natalia Czado, MSFS, Pearland Police Department, League City, TX; Cesar E. Cantu, Jr., PhD, Sam Houston State University, Huntsville, TX; Rachel Houston, PhD, Sam Houston State University, Huntsville, TX; Sheree R. Hughes, PhD, Sam Houston State University, Huntsville, TX; Damani Johnson, BS, Sam Houston State University, Huntsville, TX*

Learning Objectives: This presentation will compare the quantity and quality of DNA extracts predicted by the QIAxcel DNA High Sensitivity Kit and real-time Polymerase Chain Reaction (PCR) using Quantiplex Pro chemistry. The goal is to demonstrate the metrics provided by each chemistry for DNA extracts and their usefulness for downstream predictiveness.

Impact Statement: This study's findings on the QIAxcel's effectiveness in screening degraded DNA extracts prior to Capillary Electrophoresis (CE) or Next-Generation Sequencing (NGS) will help laboratories understand the added value of incorporating the QIAxcel. The data obtained from the QIAxcel could aid laboratories in their decision-making process when choosing between CE and NGS platforms. By providing valuable insights into the strengths and limitations of each technique, this research advances the ability of laboratories to streamline downstream processing of challenging casework.

Abstract Text: Real-time PCR (qPCR) has been the gold standard in forensic DNA for quantification since the 1990s, effectively predicting Short Tandem Repeat (STR) success and normalizing for STR-based methods. However, with forensic DNA capabilities evolving to include more NGS methods, such as Single Nucleotide Polymorphism (SNP) typing and mitochondrial DNA typing, qPCR may no longer consistently predict success, especially with degraded samples.

In this study, challenging samples were simulated by thermally degrading femur samples from two cadavers to four different levels of degradation. The Extra-Large Volume Bone Protocol on the EZ2 Connect Fx was used to extract DNA from the skeletal samples (n=5 replicates per degradation level). All DNA extracts were screened using standard qPCR with the Quantiplex Pro kit and fragment analysis on the QIAxcel using the QIAxcel DNA High Sensitivity kit to evaluate DNA quantity, degradation indices, and overall smear qualities. All extracts were then genotyped using the ForenSeq MainstAY Kit and Investigator 24plex QS Kit, with a subset of extracts genotyped using the ForenSeq mtDNA Whole Genome Kit and the ForenSeq Kintelligence Kit. All samples were normalized based on qPCR human target values. DNA quantity and degradation indices from both quantification chemistries were then compared with downstream success for all genotyping methods.

The data revealed that the total DNA concentration predicted by the QIAxcel correlated with the short target in qPCR. Both the QIAxcel and Quantiplex Pro were generally predictive of success with STR chemistries, MainstAY, and Investigator 24plex. However, the QIAxcel demonstrated greater predictive power for genotyping success with the mtDNA Whole Genome Kit compared to qPCR. Preliminary results with the ForenSeq Kintelligence Kit suggest that the QIAxcel may be a better screening tool for SNP genotyping success compared to qPCR.

Future studies will evaluate the sensitivity of the QIAxcel and explore additional sample types. Additionally, the QIAxcel DNA High Resolution Kit will be used to determine if it is a better predictor of downstream success than the QIAxcel DNA High Sensitivity Kit.

Forensic DNA; QIAxcel; DNA Quantification

B36 The Simultaneous Recovery of DNA, RNA, and Protein From Biological Samples for Forensic Applications Using a Novel Method

Jacob Hetzke, BS, West Virginia University, Coatesville, PA; Coral Smith, MS, West Virginia University, Kings Park, NY; Brian Davis, PhD, GE HealthCare, Niskayuna, NY; Chrystal M. Chadwick, BS, GE HealthCare, Niskayuna, NY; Michael J. Rishel, PhD, Regeneron, Mechanicville, NY; John Nelson, PhD, GE Healthcare Technology and Innovation Center, Clifton Park, NY; Arati Iyengar, PhD, West Virginia University, Morgantown, WV*

Learning Objectives: Attendees will learn the value of analyzing multiple analytes from biological samples for solving crimes.

Impact Statement: There is growing interest in recovering other analytes such as RNA from trace biological samples. We have developed a novel method for the recovery of nucleic acids from biological samples while also keeping the proteins intact. Our method uses a simple, unified workflow, is amenable to automation, and is designed to be implemented in forensic testing laboratories after full validation.

Abstract Text: Due to increased sensitivity of commercial DNA profiling kits, analysis of trace amounts of DNA from biological samples is common in forensic testing laboratories. In addition to maximizing DNA recovery from trace biological samples, there is growing interest in recovering other analytes such as RNA from trace biological samples. Using mRNA markers for identification of body fluids is superior to traditional methods which lack specificity and consume limited biological material. mRNA can also help link a body fluid to a contributor's DNA profile through coding Single Nucleotide Polymorphisms (cSNPs). This is useful in establishing the link between the DNA profile obtained, the body fluid identified, and the events that occurred. When DNA is severely compromised, proteins can be successfully analyzed for body fluid identification as well as human individualization through Genetically Variant Peptides (GVPs).

This study aims to develop a highly efficient method for extracting nucleic acids from biological samples while also keeping the proteins intact. Using mild lysis non-destructive to proteins, we bind nucleic acids to a binding vector embedded on paramagnetic beads. With the nucleic acids bound, the protein-containing supernatant is collected and used for protein identification. The bound nucleic acids are then eluted from the beads and purified. Using trace amounts of blood, semen, and saliva, our results show that using our method, DNA and RNA recovery is comparable to a commercial bead-based kit. DNA was used to generate Short Tandem Repeat (STR) profiles and RNA was used to amplify body-fluid specific mRNA markers through cDNA synthesis, PCR amplification, and Capillary Electrophoresis (CE). Work is ongoing with supernatant fractions to identify proteins using Liquid Chromatography-Tandem Mass Spectrometry (LC-MS/MS). Our method represents the first multi-analyte recovery method for forensic application. It uses a simple, unified workflow, is amenable to automation, and is designed to be implemented in forensic testing laboratories after full validation.

Nucleic Acid Extraction; Bodily Fluid; Low DNA

B37 An In-Depth Look at DNA Casework on Fired Cartridge Casings Extracted Using a Modified Swabbing and Extraction Technique

Rhonda Carter, BS, Illinois State Police Springfield Forensic Science Laboratory, Springfield, IL; Jennifer Belna, BS, Illinois State Police, Chicago, IL*

Learning Objectives: Attendees will be provided a summary of data regarding the analysis of Fired Cartridge Casings (FCCs) at the Illinois State Police (ISP). A brief description of our methods will be followed with graphs depicting submission data as well as result data from various angles that are applicable to day-to-day casework. Most importantly, we will highlight the success of our method and educate others on methods they can provide in their own labs.

Impact Statement: At many crime scenes, FCCs are the only evidence with a possible link to the offender(s). This poster presentation will show the success the ISP has achieved in obtaining DNA profiles from FCCs, a once thought near-impossible feat. We want to help educate more forensic scientists so their laboratory can also on-board this type of analysis.

Abstract Text: In 2022, the ISP validated and implemented a method for collecting cellular material from FCCs that was derived from a procedure developed by the Bureau of Alcohol, Tobacco, Firearms, and Explosives (ATFE) Laboratory.[1] Generally, FCCs have not yielded enough cellular material of quality to generate DNA profiles that can be used for comparisons using traditional collection techniques. Often, there is no DNA detected at all. In the research conducted by the ATFE, it has been learned that the detrimental effects on the DNA may have more to do with the copper that comprises many FCCs than the heat from the fired gun. Therefore, minimizing the degradation effects of the copper is imperative.

ISP validated the rinse-and-swab method, derived from that of the ATFE, while utilizing the DNA IQ chemistry run on a Promega Maxwell instrument. ISP has modified the master mix to include Bovine Albumin Serum (BSA) and Gly-Gly-His (GGH) to counteract the effects of copper in hopes of providing a higher quantity and quality of recovered DNA. The FCCs are swabbed directly with this master mix and extracted immediately. The rinse-and-swab method was also part of a comparison study conducted by the Federal Bureau of Investigation Laboratory Division.[2]

The ISP has been utilizing this method on casework for over two years. Currently, an ongoing pilot program is in place evaluating FCC collection, laboratory case acceptance, workflow, and casework results. At this time, 441 cases have been completed statewide. Of these cases, 49% have provided results suitable for comparisons. In addition, 176 cases have profiles suitable for the Combined DNA Index System (CODIS) entry, which have resulted in 101 CODIS hits. Prior to onboarding this rinse-and-swab method, ISP rarely swabbed FCCs for DNA, opting to send them for latent print analysis. Because of this, we conclude this method of cellular collection on FCCs is a success.

Please note, statistics will be updated with more information for the poster presentation.

B38 Streamlining Forensic Workflows: Field Test Results of Forensic Samples Using the HID NIMBUS Presto QNA System

Kayli N. Carrillo, BS, Sam Houston State University, Huntsville, TX; Sheree R. Hughes, PhD, Sam Houston State University, HUntsville, TX*

Learning Objectives: After attending this presentation, attendees will understand how the HID NIMBUS Presto QNA (HIDNP QNA) system increases throughput by automating purification, quantification, normalization, and amplification setup while maintaining results comparable to manual preparation methods.

Impact Statement: This presentation will impact the forensic science community by demonstrating a streamlined method for processing forensic samples from purification to amplification using the HIDNP QNA system while achieving reliable and consistent results.

Abstract Text: Incorporating automation into forensic laboratories is essential for increasing throughput and minimizing human error. While the HIDNP QNA has been previously validated for purification, its new capabilities for quantification, normalization, and amplification setup must be assessed and compared to manual methods. The software now supports the Quantifiler Trio kit for quantification and VeriFiler Plus, YFiler Plus, GlobalFiler, GlobalFiler IQC, and NGM Detect kits for amplification setup.

In this study, 29 forensic casework samples, including burned, buried, surface-decomposed bones, gum, hair, nail, blood on a cotton swab, and a dilution series were processed in duplicate (N = 58) through the HIDNP QNA system pipeline from purification to amplification setup. All samples were purified using the PrepFiler BTA Automated Protocol. Extracts processed with automation were quantified, normalized, and amplified in duplicate both on the instrument and manually to assess the reliability of the instrument. Extracts were quantified using the Quantifiler Trio kit on the ABI 7500 system and amplified with the GlobalFiler IQC kit. Amplified products were separated with a 3500 Genetic Analyzer, and data analysis was completed using Genemapper IDX v 1.6.

This study found similar DNA yields for quantification across between replicates. Additionally, all standard curve quality metrics from the instrument-prepared standards were within expected ranges, with r^2 values greater than 0.99, and slopes were within the acceptable range. The average autosomal allele recovery between automation and manual methods was consistent for most samples. Gum, hair, the dilution series, and all but one nail sample produced complete profiles for both methods. The average autosomal allele recovery from bones varied widely, from 4% to 100%, but results were comparable between automation and manual methods. Burned sampled yielded the highest recovery rates among the insult types. Blood on a cotton swab had an average autosomal allele recovery of 99% with the HIDNP QNA system versus 100% manually.

The time-saving capabilities of the HIDNP QNA system was evident: quantification took ~50 minutes manually versus ~30 minutes with automation, making the automated method 1.67 times faster. Similarly, normalization and amplification setup manually took ~1.5 hours, compared to ~35 minutes with the HIDNP QNA instrument, resulting in a 2.56-fold faster process. Overall, this study shows that the HIDNP QNA system can provide a streamlined, automated approach for purification, quantification, normalization, and amplification setup without compromising results for forensic samples.

Automation; STR Profiles; Forensic DNA

B39 The Simultaneous Determination of Time-Since-Deposition and Source Tissue for Forensic Biological Samples

Caitlin S. Lydon, BS, Virginia Commonwealth University, Ruther Glen, VA; Christopher Ehrhardt, PhD, Virginia Commonwealth University, Richmond, VA; Susan A. Greenspoon, PhD, Virginia Department of Forensic Science, Richmond, VA; Catherine Cupples Connon, PhD, Virginia Commonwealth University, Richmond, VA*

Learning Objectives: Attendees will gain an understanding of the use of morphological and autofluorescence characteristics measured by flow cytometry to provide simultaneous information for Time-Since-Deposition (TSD) and tissue source of forensically relevant biological samples.

Impact Statement: This research will impact the forensic science community by utilizing an analytical technique such as flow cytometry to provide important contextual information for DNA profiles developed from mock evidentiary samples. The ability to identify tissue source, associate that source with a DNA profile, and determine how long ago it was deposited could drastically increase the probative value of DNA profiles.

Abstract Text: Determination of tissue source and the time at which a biological material is transferred from its source to another surface, known as the time-since-deposition, would assist forensic analysts by providing crucial context for DNA profiles generated from biological evidence. Many methods for cell identification have been explored with mostly a focus on biomolecule markers such as mRNA and miRNA. Forensic laboratories have also developed methods for TSD estimation that focus on degradation of biomolecules. However, these methods have not been validated for use in a forensic science laboratory due to high false positive rates, limited application to different biological fluids, and the destructive nature of many existing methods. Flow cytometry is an analytical technique that is used to measure autofluorescence and structural properties of cells in a non-destructive and high-throughput manner. Past studies have utilized flow cytometry to identify tissue source and determine TSD; however, these signatures were always tested in separate experimental efforts and sets of samples, which may not be feasible to implement in the operational workflow of a forensic laboratory.

Therefore, the goal of this research was to develop a single laboratory technique for determining TSD and source tissue for an unknown biological sample. Initial experiments focused on blood samples that ranged in concentration from neat to 1:1,000 and varied in TSDs between 1 day and 6 months. Blood samples from three donors were deposited in quadruplicates onto microscope slides (two separate stains per slide) and air dried at ambient conditions. One set of stains was used as a reference sample. The other set of stains was used to perform Red Blood Cell (RBC) lysis to analyze White Blood Cells (WBCs). To separate the WBCs from the whole blood sample, RBCs were lysed using Ammonium-Chloride-Potassium (ACK) Lysing Buffer prior to analysis on the flow cytometer. A second method that did not utilize a WBC separation technique was also used by creating a gate based on events that were measured after running whole blood samples and data found in literature to separate WBCs from RBCs and platelets present in the whole blood sample. To test whether this technique could also be used in mixed tissue samples, blood/saliva mixtures from six donors were deposited in duplicates onto microscope slides and air dried at ambient conditions. After the designated time periods ranging from T = 0 days to T = 120 days, samples were collected using a sterile cotton swab moistened with deionized water and air-dried. Sampled were filtered through a 100µm mesh filter and analyzed using a flow cytometer equipped with 488nm excitation laser.

Results showed that autofluorescence profiles of blood cell populations showed incremental changes within the first two weeks (e.g., median autofluorescence in wavelengths between 535nm and 600nm increased from ~2,200 RFU at one day to ~2,500 RFU at 14 days). Samples that had been aged for more than two months showed a 40% decrease in median autofluorescence (~400RFU), which was consistent across each contributor tested. Results also showed that Forward Scatter (FSC) and Side Scatter (SSC) profiles collected from the same flow cytometry dataset were able to differentiate blood cells from saliva cells. Autofluorescence in wavelengths between 650nm and 700nm was capable of further discriminating between the two cell sources. These measurements were successful in detecting the presence of blood cells in a sample even when saliva was present in ratios between 1:5 and 5:1. The observed trends show promise for the development and implementation of flow cytometry as a method for TSD determination and cell identification in forensic laboratories.

Flow Cytometry; Cell Identification; Time-Since-Deposition

B40 Modified Extraction Protocols for Nuclear DNA Extraction From Human Hair Shafts

Holly Zhao, BSc, The George Washington University, Arlington, VA; Vinalon Mones, BS, The George Washington University, Washington, DC; Elaine Lewis, PhD, The George Washington University, Washington, DC; Glenn Fahrig, MS, Bureau of Alcohol, Tobacco, Firearms and Explosives, Alexandria, VA; Gregory A. Peiffer, PhD, Bureau of Alcohol, Tobacco, Firearms and Explosives, Beltsville, MD; Rebecca Sloman, MFS, Bureau of Alcohol, Tobacco, Firearms and Explosives, Beltsville, MD; Daniele S. Podini, PhD, The George Washington University, Washington, DC; Katherine Hargett, MFS, Michigan State Police-Grand Rapids Forensic Laboratory, Grand Rapids, MI; Todd Bille, MS, Bureau of Alcohol, Tobacco, Firearms, and Explosives Laboratory, Beltsville, MD*

Learning Objectives: This presentation will inform the audience about the progress made by our group in extracting nuclear DNA from hair shafts and generating a Short Tandem Repeat (STR) profile suitable for human identification.

Impact Statement: Results from this project will impact the forensic community in cases where the only evidence available are hair shafts.

Abstract Text: Hair strands are commonly collected as forensic evidence at a crime scene. Although hair shafts contain both nuclear and mitochondrial DNA, nuclear DNA markers are rarely used to genetically identify individuals. This is largely because the DNA in hair shafts is typically of low quantity and degraded, which makes generating an STR profile difficult and often unsuccessful. Therefore, developing and optimizing a method of DNA extraction that is more effective at recovering the small quantities of DNA and significantly degraded DNA present in hair shafts is critical to be able to successfully analyze hair forensic evidence. The goal of this research project was to optimize a DNA extraction method that would enable generating STR profiles from human hair shafts. To extract DNA from hair shafts, two DNA extraction methods were compared: the first one based on a modified protocol that uses the Qiagen QIAamp DNA Investigator Kit and the second one based on a modified protocol that uses the Biochain cfPure cfDNA Extraction Kit. Additional modifications were tested, such as type of lysis buffer used, altering the ethanol washes and centrifugation steps, and attempting a combined Qiagen-Biochain method. Most of the samples yielded very low amounts of DNA, less than 100pg per 5cm of hair, with high degradation indices. DNA recovered from both extraction methods did not inhibit subsequent Polymerase Chain Reaction (PCR) reactions.

The methods were tested on a variety of hair shafts from different donors and the resulting DNA quantities and STR profiles were compared. To date, hair shafts from 14 individuals have been tested, all of which were samples collected after The George Washington University-Institutional Review Board (GW-IRB) approval. Following extraction, samples were quantified with the Quantifiler HP DNA Quantification Kit (Thermo Fisher Scientific) and amplified with the GlobalFiler STR Amplification Kit (Thermo Fisher Scientific) to generate an STR profile on a 3500 Genetic Analyzer (Thermo Fisher Scientific). The DNA quantities and completeness of STR profiles varied from donor to donor, ranging from no STR profile to a profile two loci short of being a complete STR profile. However, results from the same donor were similar with regard to quality and quantity>

In our hands, both modified extraction methods are an improvement over methods that were previously tested in our lab with regard to DNA yield and quality. Thus far, the results from attempts at further optimizing these modified protocols are comparable and the modifications do not seem to greatly affect DNA quantity or STR profile quality from the same donor. There is great variation in the DNA quantity and completeness of a STR profile from donor to donor, yet 50% of the donors tested yielded STR alleles, showing the promise of generating partial profiles from hair shaft DNA. The cause of this subject-to-subject variation is yet to be determined and may be a result of differential levels of degradation in hair shaft DNA between individuals. Further efforts to optimize these protocols are ongoing with the goal of correlating morphological features of the hair to the likelihood of obtaining an STR profile of sufficient quality for identification.

Hair Shaft; STRs; Degraded DNA

B41 Direct to DNA: Revolutionizing Forensic Analysis by Streamlining the Process

Darcy Machado, MSFS, Baltimore Police Department, Baltimore, MD; Francesca Spatola, MS*, Baltimore Police Department, Parkville, MD*

Learning Objectives: In this presentation, attendees will learn about the advantages of adopting a direct-to-DNA approach in the forensic laboratory. They will also assess the implementation process and review the impact of its use in a forensic laboratory over the past few years.

Impact Statement: Exploring new advancements in the forensic field is essential to improving crime-solving techniques and transforming forensic laboratory workflows. The direct-to-DNA approach increases efficiency by accelerating the screening process. In consequence, the adoption of this approach can assist in reducing forensic laboratory backlogs.

Abstract Text: Forensic evidence analysis conventionally involves multiple steps, evidently resulting in an overall time-consuming process. The first stage in a forensic DNA laboratory is evidence screening and sample preparation, where items of evidence are visually examined, and serological testing is performed on any suspected biological material. Alternate Light Sources (ALS) can also be utilized to assist in identifying the most suitable samples for DNA testing.

Identifying specific biological materials is typically done to name the potential sources of DNA before the extraction, quantification, and amplification steps of the genetic material. Examples of some of these sources are blood, semen, and saliva. Serological testing demands a substantial amount of hands-on time from an analyst.[1] This can be attributed to the need for both presumptive and confirmatory tests for evidence staining being labeled as suspected biological fluids. Serological testing also involves consuming more of an evidentiary sample when compared to the alternative—cutting only one portion of a sample and forwarding it directly to DNA testing, also known as the direct-to-DNA approach.

In the direct-to-DNA workflow, DNA analysis is performed without testing the evidence for possible biological material during the initial screening process, thus optimizing the chances of obtaining timely Combined DNA Index System (CODIS) -eligible DNA profiles.[2] In the direct-to-DNA approach, a cutting from a substrate, whether it be a swab or a piece of material, is directly forwarded for DNA analysis without identifying the biological material or the source of the DNA. This approach streamlines the forensic evidence processing workflow while consequently offering numerous benefits, including increased efficiency and improved reliability. The direct-to-DNA approach bypasses these traditional serological testing procedures and allows evidence to be moved directly into DNA analysis.[2]

This presentation will examine how the direct-to-DNA process significantly streamlines the forensic evidence screening workflow by comparing it to the traditional methods that involve serological testing. Though the direct-to-DNA approach is most often implemented during the screening of Sexual Assault Kits (SAKs), this presentation will also explore how the workflow can be expanded to be used on evidence of various cases, increasing automation in the laboratory and ultimately reducing backlogs. The benefits of the process along with the drawbacks were recognized through implementation and will also be further discussed.

B42 Rapid DNA—Friend or Foe? Comparing Rapid DNA Analysis With Conventional Methodologies for Sexual Assault and Identification Cases

Tania M. Dominguez González, BS, Institute of Forensic Sciences of Puerto Rico, San Juan, Puerto Rico; Jenny Acevedo González, PhD, Institute of Forensic Sciences, San Juan, Puerto Rico*

Learning Objectives: This presentation will inform attendees on (1) Rapid DNA vs. Conventional Analysis; (2) Rapid DNA for Identification Cases: Improved methods for the pre-treatment for fresh, moderately degraded and highly degraded bones and teeth, including a comparison of Rapid DNA pre-treatment vs. conventional extraction method, (timeframe for fresh, moderately degraded and highly degraded bones or teeth), improved methods during Rapid DNA pre-treatment designed for a more efficient DNA recovery; (3) Rapid DNA for sexual assault cases: a validated method for evidence samples from sexual assault safe kits, a comparison of Rapid DNA pre-treatment vs. the conventional extraction method (criteria for Rapid DNA in sexual assault cases and timeframe), and a discussion of pre-treatment for separation of spermatic fraction and epithelial fraction from the evidence samples; and (4) advantages and disadvantages of Rapid DNA in sexual assault cases and identification cases

Impact Statement: Today, crime laboratories, especially DNA laboratories, have been confronting multiple challenges, including backlog of sexual assault kits, the encounter of many low-quality samples, and too many identification cases. This presentation will show some of the advancements we have made using Rapid DNA and how we can use this knowledge in the future to obtain great results in a shorter amount of time.

Abstract Text: The lack of techniques that could improve the recovery of genetic material has prevented analysts from obtaining results in a short amount of time. However, it is important to investigate alternative extraction methods and technologies that can be evaluated prior to receiving evidence in a crime laboratory, allocating time and resources to improve the analysis of evidentiary samples.

The DNA laboratory from the Institute of Forensic Sciences of Puerto Rico conducted a validation study to develop interpretation guidelines with Rapid DNA to evaluate evidence samples from sexual assault and identification cases. In this study, we compared the workflow of conventional analysis with Rapid DNA analysis for both sexual assault and identification cases. Also, we discussed the improvements we have made to the Rapid DNA pre-treatment of fresh, moderately degraded, and highly degraded bones and teeth for identification cases, and the Rapid DNA pre-treatment made to evidence samples for sexual assault cases. Finally, we reviewed the advantages and disadvantages of Rapid DNA for both identification and sexual assault cases.

For identification cases, we found that for fresh and moderately degraded bones, we obtained a full interpretable genetic profile while for degraded bones, we obtained a partial profile but for a fraction of the time compared to conventional analysis. In the case for sexual assault samples, we obtained a highly efficient separation of the spermatic fraction and epithelial fraction from the samples, but Rapid DNA has many limitations that could be considered currently a disadvantage to use for sexual assault cases. The use of Rapid DNA for the analysis of evidence samples from sexual assault cases is not yet federally approved since it lacks a quantitation step in accordance with the Quality Assurance Standards for Forensic Testing Laboratories (QAS). But once approved, it can be considered as an advantage for sexual assault cases.

Rapid DNA; Victim Identification; Sexual Crimes

B43 The Impact of Various Substrates and Deposition Time on Bacteria Associated With Saliva Samples and Its Implication on the Accuracy of a Bacterial Signature-Based Body Fluid Identification Method

Sarah Seashols-Williams, PhD, Virginia Commonwealth University, Richmond, VA; Paul P. Brooks, PhD, Virginia Commonwealth University, Richmond, VA; Denise Wohlfahrt, PhD, Worldwide Counter Threat Solutions, LLC, Richmond, VA; Baneshwar Singh, PhD, Virginia Commonwealth University, Richmond, VA; Olisdey Galano Cruz, BS, Virginia Commonwealth University Department of Forensic Science, Buffalo, NY*

Learning Objectives: This research will inform the audience about how different substrates, including fabric and non-fabric materials with smooth, rough, and porous surfaces, affect the interaction and retention of biological fluids like saliva. It will also explain how these factors influence bacterial signatures and the determination of Time since Deposition (ToD).

Impact Statement: Advancing methodologies: The findings will provide valuable information on how various materials influence bacterial signatures, leading to the development of more effective forensic methodologies and tools. Improving forensic accuracy: by examining how different substrates affect the microbial composition of saliva and tracking bacterial changes over time, this research enhances the accuracy of bacterial-signature-based body fluid identification methods. Enhancing ToD determination: insights gained from this study will refine techniques for determining the time since deposition, improving the precision of forensic analysis, and contributing to more reliable data

Abstract Text: The presence of a person's DNA at a crime scene does not necessarily indicate that the sample donor is the perpetrator; thus, establishing the time frame during which the biological stain was deposited is critical for solving a case. The type of substrate on which biological evidence is found significantly impacts the microbiome of body fluids, as substrates differ in absorbency, porosity, and chemical composition. These factors influence how biological fluids like saliva interact with and are retained by the substrate. For example, smooth, non-porous surfaces may cause fluid pooling or dispersion, while rough, porous surfaces can either trap fluids or accelerate absorption. By understanding how substrates affect the microbial composition of human saliva, we can improve bacterial signature-based body fluid identification methods. Additionally, tracking bacterial changes over time on various substrates helps in determining the ToD, which is valuable for forensic analysis.

This study aims to assess the impact of various clothing and non-clothing substrates on the microbiomes of human saliva and their implications for bacterial signature-based methods. It also evaluates how storage time and substrate type affect these microbiomes and their accuracy in determining the ToD. Saliva samples were collected at four time points (week 0 [control], week 1, week 4, and week 8) from both male (n=5) and female (n=5) donors. Fabric cuttings (denim-cotton, silk, linen, wool) and sterile cotton swabs from non-clothing substrates (wooden flooring, bathroom tiles) were used. Bacterial DNA was extracted with the Qiagen DNA Investigator kit, quantified with the Qubit 2.0 Fluorometric Quantification method, and the variable region four (V4) of the 16S rDNA was amplified via Polymerase Chain Reaction (PCR). Results were visualized on a 1.6% agarose gel, then each sample was cleaned using Agincourt AMPure XP.

Preliminary results showed consistently higher average DNA yield in control samples (Week 0) compared to Week 1 treatment samples. As expected, the substrate control and reagent blanks from control samples didn't result in any detectable DNA. Conversely, the positive controls demonstrated the highest DNA concentrations, averaging 25.95ng/uL. Following the positive controls, denim cotton, wooden tiles, bathroom tiles, and wool exhibited average DNA concentrations of 21.57ng/uL, 13.02ng/uL, 10.59ng/uL, and 9.77ng/uL, respectively. In contrast, silk and linen had lower average DNA yields, measuring 0.00525ng/uL and 4.46ng/uL, respectively. The 16S rDNA high throughput sequencing (currently in progress) will provide crucial insights into the effects of different substrates on the human saliva microbiome structure and its impact on accuracy of bacterial signature-based body fluid identification method.

In conclusion, results from this research will help forensic scientists to have a better understanding on how various substrate materials influence bacterial signature-based body fluid identification method and in the determination of ToD. Ultimately, these findings will refine forensic methodologies, leading to more accurate biological evidence interpretations and enhancing the fairness of criminal investigations.

B44 Enhancing Success Rates in Sexual Assault Investigations With the SpermX Differential Extraction System

Huma Nasir, MS, DNA Solutions, Inc., Oklahoma City, OK; Amanda Walker, MS, DNA Solutions, Inc., Oklahoma City, OK; Kelsy Lowther, MS, DNA Solutions, Inc., Oklahoma City, OK*

Learning Objectives: Attendees of this presentation will learn about new technology that significantly improves the success rates of obtaining probative DNA profiles from perpetrators when testing Sexual Assault Kits (SAKs).

Impact Statement: The presentation will make forensic DNA laboratories aware of a superior differential lysis technology that results in obtaining male profiles from a higher number of sexual assault samples.

Abstract Text: Currently, most forensic laboratories obtain a Combined DNA Index System (CODIS) -eligible DNA profile from the perpetrator in approximately 40% of SAKs tested, despite up to 70% screening positive for foreign DNA.[1] One primary cause for this gap is the inefficiency of current differential extraction methods, which recover only 5–20% of the total sperm available in SAK samples.

Differential extraction is a specialized process used in forensic science to separate sperm cells from non-sperm cells in mixed biological samples, such as those collected in SAKs. This technique is critical for isolating male DNA from female DNA in cases of sexual assault, allowing for the identification of the perpetrator. However, traditional differential extraction methods often fall short in recovering sufficient sperm cells, leading to lower success rates in obtaining usable DNA profiles.

A novel differential extraction method known as SpermX utilizes a nanofiber membrane to separate sperm from non-sperm cells by capturing the sperm cells in the nanofiber membrane while the epithelial cells are lysed and flow through the membrane.[2] This technology has demonstrated the ability to recover six times more sperm than standard differential extraction methods. This presentation will evaluate the impact of SpermX on success rates in real-world SAK cases. By increasing the success rate of male DNA profile recovery, this technology can significantly enhance the return on investment in SAK testing.

The presentation will feature compelling data comparing the performance of SpermX to laboratory's current differential extraction method. These data show a significant improvement in DNA profile recovery rates, with SpermX achieving higher yields of male DNA. This improvement is particularly noteworthy in samples with low initial quantities of sperm where traditional methods often fail to produce a usable male profile. Attendees will gain insights into how implementing SpermX could impact their laboratory operations, enhance case resolution rate, and potentially lead to more successful prosecutions and justice for victims.

Differential Extraction; Male DNA; SpermX

B45 Expanding On-Site Crime Scene Reconstruction Capabilities by Uncovering Microscopic Clues Using Mobile Laser-Induced Breakdown Spectroscopy (LIBS)

Leah D. Thomas, BS, West Virginia Universit, Morgantown, WV; Roger Jefferys, MS, West Virginia University, Morgantown, WV; Luis E. Arroyo, PhD, West Virginia University, Morgantown, WV; Tatiana Trejos, PhD, West Virginia University, Morgantown, WV*

Learning Objectives: By attending this presentation, attendees will gain an understanding of the advanced capabilities of innovative mobile LIBS technology, which uses enhanced imaging and sensitive elemental analysis for real-time results. This tool can be utilized onsite, enabling a rapid and thorough approach to trace evidence examination. It demonstrates high utility in crime scene reconstruction, case/evidence prioritization, and the improvement in investigative efficiency.

Impact Statement: This study will impact the forensic science community by demonstrating the proficiency of mobile crime scene methods and their ease of operation. With high accuracy and reliability, the full elemental characterization of a microscopic residue can be achieved onsite within two minutes. The advantages of adopting such methods promote a triage of investigative information and better prioritization of evidence collection and submission to the laboratory.

Abstract Text: Firearm-related violence encompasses a broad range of complex scenarios that each demand special investigative efforts. Trace evidence plays a crucial role as microscopic residues often transfer between surfaces during a shooting incident and other physical interactions. Identifying residue transfer helps investigators link suspects to the crime scene or to other individuals, supporting crime scene reconstruction. To fully utilize this information, the analysis and interpretation of evidence must be conducted efficiently to support subsequent investigative decision-making. Current protocols involve more time-consuming and costly methods at the laboratory, leading to longer turnaround times for evidence and decreased productivity in investigations. This study examines the effectiveness of mobile instrumentation that can be utilized at crime scenes for quick, thorough assessments of trace evidence.

Mobile LIBS technology provides novel capabilities for enhanced imaging, rapid single-particle targeted ablation, sensitive elemental analysis, and mobility to the crime scene. The instrument allows for a more comprehensive approach in a fraction of the time, making it an advantageous tool for crime scene reconstruction. Previous studies have demonstrated the utility of the mobile LIBS in identifying Gunshot Residue (GSR) with high accuracy (>98%) from hand and substrate samples through elemental and morphological characterization.[1,2] In this study, the versatility of the mobile LIBS is expanded beyond GSR to include various target materials, bullets, and cartridge case residues. Seven substrates (wood, drywall, glass, paint, concrete, and several automotive parts) were fired at using three types of bullets (Full Metal Jacket [FMJ], Jacketed Hollow Point [JHP], and Lead Round Nose [LRN]), resulting in either perforation or ricochet. Over 400 samples were collected from the shooter's hands, substrates, and recovered bullets using an adhesive collection stub, allowing for a comprehensive assessment of transfer. Composition controls from each substrate were also collected to determine the true microscopic features and elemental profiles of each substrate.

Preliminary microscopic examination revealed the transfer of residues from the substrate to the shooter's hands in many experiments. Additionally, residues from the substrates were discovered on recovered bullets and extracted for direct mobile LIBS analysis. Distinct results based on bullet type were evident as FMJ and LRN bullets held on to less trace material but exhibited a greater abundance of transfer onto the shooter's hands. In contrast, JHP bullet experiments showed less transfer to the shooter's hands but more retention in the bullet itself. Mobile LIBS analysis provided further morphological (color, size, shape) and elemental characterization of the GSR and non-GSR traces. By comparing spectral data from known composition controls to the questioned residues, the transfer of trace evidence was further confirmed. Thus, analytical confidence has been proven on hands and bullet samples for other traces that are inadvertently collected along with the GSR. This finding allows for stronger links to be made between people of interest and evidence from the crime scene.

This study demonstrates how the transfer of trace residues differs in collection surfaces, bullet types, and bullet-substrate interactions in shooting events and highlights the utility of mobile LIBS technology for fast identification of evidence. Its enhanced capabilities offer on-site convenience for assessing a wide range of microscopic traces that would otherwise go unnoticed or require lengthy laboratory analyses. The mobile LIBS enables the rapid and reliable acquisition of information, which can then be obtained and utilized to support efficient evidence prioritization and investigative decision-making processes.

Mobile Device; Trace Analysis; Gun Shot Residue

B46 Analysis of Inorganic Oxidizing Salts in Intact and Chemically Reacted Consumer Fireworks Using Microscopical and Spectroscopic Approaches

Sydney M. Hampton, Sam Houston State University, Englewood, FL; Cassidy Callaway, MS, Arkansas State Crime Laboratory, North Little Rock, AR; Patrick Buzzini, PhD, Sam Houston State University, Huntsville, TX; Geraldine Monjardez, PhD, Sam Houston State University, Huntsville, TX; Jared Estevanes, PhD, Microtrace LLC, Elgin, IL*

Learning Objectives: After attending this presentation, attendees will gain a compositional knowledge of intact and chemically reacted consumer fireworks that can be used as explosive charge in Improvised Explosive Devices (IEDs), with a focus on identifying the inorganic oxidizing salts they contain. The audience will learn about the strengths and limitations of the microscopic and spectroscopic techniques used.

Impact Statement: This presentation will impact the forensic science community with emphasis to the trace evidence community by demonstrating the efficiency of an analytical scheme that integrates light microscopy, micro-Raman spectroscopy, Attenuated Total Reflectance/Fourier Transform Infrared (ATR/FTIR) spectroscopy, and canning Electron Microscopy with Energy-Dispersive X-ray Spectroscopy (SEM/EDS) to identify the inorganic oxidizing salts present in both intact fireworks and the particles and residues resulting from the chemically reacted fireworks.

Abstract Text: Cases such as the Boston marathon bombing (2013) and the increased use of inorganic explosive mixtures, including consumer fireworks, in IEDs have led to the need to better understand their composition to assist practitioners in their rapid analysis and identification. This study aims to demonstrate an analytical scheme integrating light microscopy, micro-Raman spectroscopy, ATR/FTIR spectroscopy, and SEM/EDS that forensic investigators can utilize to identify and discriminate the inorganic oxidizing salts in the intact and chemically reacted consumer fireworks.

Twelve consumer firework samples and six inorganic oxidizers reference samples were analyzed in this study. The firework samples included artillery, firecrackers (ladyfingers), Roman candles, and fountains across three different brands for each type. For the chemically reacted samples, triplicates of each firework were ignited, and the remaining particles and residues were collected. A decantation method was used to separate the inorganic oxidizers in the intact samples before their recrystallization and a wet swabbing technique was used to collect and subsequently recrystallize inorganic oxidizers on glass slides in the chemically reacted samples. First, the intact and chemically reacted samples were investigated by microscopical means to preliminarily identify the inorganic oxidizers present, followed by micro-Raman analysis to confirm their identity. Individual crystals were located using the Raman microscope to facilitate targeted spectral acquisitions. For ATR/FTIR and SEM/EDS analyses, the intact fireworks were cut open and crushed into a fine powder. For the chemically reacted samples, residues were directly sampled or scraped from the firework remnants.

Following microscopical examinations, potassium perchlorate (KClO4) was identified as the most common inorganic oxidizer in both the recrystallized intact and chemically reacted firework material. Microscopy also allowed the identification of four types of inorganic oxidizers in the recrystallized chemically reacted samples, potassium perchlorate (KClO4), potassium nitrate (KNO3), barium nitrate (BaNO3)2, and potassium chlorate (KClO3). A lower amount of oxidizers present in the recrystallized chemically reacted samples was observed as well as unhindered growths of crystals, which rendered the identification of inorganic oxidizers difficult. Euhedral crystals with well-defined, symmetrical shapes and sharp, flat faces were first formed and identified using microscopy before being absorbed by larger anhedral crystals with no well-formed faces, preventing the localization of individual crystals to collect the Raman measurements. Using ATR/FTIR, it was determined that artillery fireworks contained nitrate salts while fountain fireworks contained mixtures with both nitrate and perchlorate salts. Using SEM/EDS, it was determined that while intact and chemically reacted fireworks shared many common elements such as magnesium, aluminum, silicon, chlorine and potassium, other elements were only found with intact fireworks. Those included fluorine and barium whereas titanium was only found in one chemically reacted fountain sample.

Microscopy; Spectroscopy; Trace Analysis

B47 An Artificial Intelligence-Based Detection of Ignitable Liquid Residues in Fire Debris Using a Deep Convolutional Neural Network

Ting-Yu Huang, PhD, Central Police University, Taiwan; Jorn Yu, PhD, Sam Houston State University, Huntsville, TX*

Learning Objectives: The attendees will understand how to develop an Artificial Intelligence (AI) workflow through a transfer learning technique to classify Gas Chromatography/Mass Spectrometry (GC/MS) data that can be applied in forensic analyses. The attendees will also learn the operability of deep Convolutional Neural Networks (CNN) to classify untrained class data, which is the practical problem of forensic evidence.

Impact Statement: AI is transforming forensic science, providing an asset to analysts. The impact of this study is to present the potential of scalogram representations to avoid retention time alignment issues that are commonly encountered in chromatographic data. The combination of scalograms and a CNN offers a promising inter-laboratory applicability to accurately detect Ignitable Liquids (ILs) residues in fire debris samples.

Abstract Text: Due to the complex chemical composition of ILs and the noteworthy matrix interferences, the interpretation of GC/MS data to detect the presence of IL residues in fire debris samples is challenging.[1] Traditionally, chemometric tools are used to process and extract analytical signals based on mathematical algorithms to assist in interpreting sample attributes.[2] The application of AI into the fields of science has been emerging and revolutionizing, and it is expected to show promise in forensic fire debris analysis. CNNs have been one of the remarkable AI algorithms for solving image classification tasks for the past few years.[3] Transfer learning is to re-train an existing CNN and leverage knowledge to another task, with noticeable performance in an efficient training fashion.[4] This work aimed to propose an AI-based workflow via transfer learning with a CNN to classify GC/MS data and detect IL residues from synthetic sample matrices. It was also hypothesized that the proposed AI workflow could be applied to analyze inter-laboratory data without retention time alignment, an unavoidable issue in chemometric analysis.

In this work, four brands of regular gasoline collected from local gas stations in Huntsville, TX, and nylon 6,6 carpet were chosen as the investigated IL and matrix, respectively. Nine levels of concentrations (0.4-100µg/20-mL headspace vial) were made from two-fold serial dilutions of stock solutions to prepare neat IL and simulated fire debris samples. All samples were analyzed by Headspace/Solid-Phase Microextraction coupling with GC/MS (HS/SPME-GC/MS). Summed Ion Mass spectra (SIM) were produced by extracting *m/z* 55–156 range and retention times between 3 and 13 minutes in each GC/MS datum, followed by a conversion procedure to generate scalograms. Finally, a pre-trained CNN, ResNet-50, was fine-tuned on 390 data for a new task (i.e., classifying the scalograms into "positive of gasoline" or "negative of gasoline")[5]

Results showed that the ResNet-50 was re-trained to detect gasoline residues with 100% validation accuracy. By being tested with new sets of intra-laboratory data, the model obtained 100% accuracy in detecting neat gasoline residues across all concentrations. The limit of detection of the model to detect simulated fire debris samples was 25µg/20-mL headspace vial with 91 ± 1 % accuracy. Regarding inter-laboratory data (collected from the National Center for Forensic Science), the model acquired 88 ± 1 % and 84 ± 1 % accuracy in correctly detecting neat gasoline and simulated fire debris samples, individually.[6-8]

In conclusion, an AI workflow was developed to yield an intelligent model for detecting gasoline residues from fire debris samples. The development of the model utilized a small training data set, enabling its application into limited data that are available in real fire case scenarios. Additionally, the model could predict samples outside of the training distribution or tested by different laboratories without aligning the retention time shift. The implication of this work was to demonstrate an AI-based, cost-effective, and reliable system to facilitate IL analysis. The proposed AI workflow can also be adopted by analyses of other types of forensic evidence.

B48 The Detection of Organic Explosive Residues From Outdoor Explosions Using Confocal Raman Microscopy

Nicholas Jernigan, Sam Houston State University, Huntsville, TX; Jared Estevanes, PhD, Microtrace LLC, Elgin, IL; Geraldine Monjardez, PhD, Sam Houston State University, Huntsville, TX*

Learning Objectives: After attending this presentation, attendees will acquire an understanding of the strengths and limitations of confocal Raman microscopy to identify organic explosive residues from controlled explosions on a variety of substrates.

Impact Statement: This presentation will impact the forensic science community by demonstrating a workflow involving a simple liquid extraction for the rapid and accurate identification of smokeless powder constituents, TNT, and RDX post-blast explosive residues using confocal Raman microscopy.

Abstract Text: Following an explosion involving an Improvised Explosive Device (IED), accurately identifying its explosive charge in post-blast debris is a crucial step that can significantly benefit subsequent investigations. In particular, IEDs utilizing smokeless powders have become more prevalent due to their ease of acquisition. Additionally, military grade explosives such as TNT or RDX bombs are often recovered from war zones by criminal elements. A majority of studies on explosive detection involve the analysis of intact explosives or post-blast debris containing partially burned grains of explosive compounds. This study aims to employ confocal Raman microscopy as a means to identify organic explosive residues recovered from post-blast debris of simulated IEDs without the presence of grains or particles.

With the help of the Montgomery County Fire Marshal's Office (MCFMO), four IEDs were constructed (two utilizing a smokeless powder and two utilizing a TNT/RDX mixture). The IEDs were placed into polypropylene toolboxes along with electrical tape, a cell phone, wooden paint sticks, copper wire, nuts and bolts, and batteries to serve as a variety of substrates suitable for sampling as well as mimic components commonly found in IEDs. The post-blast debris of the substrates were sampled with pre-wetted acetone swabs, taking care to avoid collection of any unburned particles. The swabs were then soaked in acetone for three minutes to extract the analytes. A 10µL drop of the extract was then placed onto a steel microscope slide and allowed to dry before analysis with the confocal Raman. Additionally, a standard reference mixture containing 50ppm each of ethyl centralite, dibutyl phthalate, diphenylamine, and nitroglycerin in acetone was prepared to identify characteristic bands associated with each constituent as well as assess any peak shifts in these bands when compared to the spectra obtained from the swab extracts. Raman spectra from the post-blast substrates were compared to spectra obtained from the 50ppm standard mixture. From the smokeless powder IEDs, constituents such as ethyl centralite (deterrent), dibutyl phthalate (plasticizer), diphenylamine (stabilizer), and nitroglycerin (explosive) were identified on all of the post-blast substrates sampled except for the wooden paint sticks. While detection of TNT and RDX was unsuccessful in one detonation, residues for TNT were successfully identified in the post-blast debris of the second IED. Additionally, crystals were observed in the dried extracts from the TNT/RDX swabs, which displayed characteristic peaks for RDX when analyzed with the confocal Raman microscope.

This study demonstrates the benefits and limitations of a developed methodology using a confocal Raman microscope for the analysis of organic explosive residues, as well as provides a methodological framework for practitioners for post-blast debris sampling and subsequent analysis using confocal Raman microscopy when no unburned or partially burned particles are present.

Raman Microscopy; Explosion; Trace Analysis

B49 The Application of a Hand-Held Raman Spectrometer for the Classification of Synthetic- and Petroleum-Based Hydrocarbon Fluids

Javier E. Hodges, BS, Sam Houston State University, Huntsville, TX; Kailee R. Marchand, BS, Sam Houston State University , Fairfield, TX; Jorn Yu, PhD, Sam Houston State University, Huntsville, TX*

Learning Objectives: The attendees will learn a rapid and effective analytical method to distinguish synthetic-based and petroleum-based hydrocarbon fluid products using a hand-held Raman spectrometer. The technique demonstrates the potential use of Raman spectroscopy for source tracing of physical evidence.

Impact Statement: Raman spectroscopy provides great discrimination power for chemical analysis of physical evidence. In some cases, Raman spectroscopy can be applied for sample classification and quality control. The forensic science community will benefit from this presentation by becoming aware of this recent development toward utilizing Raman spectroscopy data for the field analysis of evidence.

Abstract Text: Hand-held Raman spectrometers offer a rapid and field-deployable platform for chemical tests of physical evidence. In the case of testing pure chemicals, identification can be achieved by comparing the unknown spectrum to that collected in the Raman spectrum database. In the case of mixture analysis, the chemical signatures of major components may be detected. In this work, we investigated the capability of Raman spectroscopy for hydrocarbon fluid sample classification.

Hydrocarbon fluids are very common in our daily lives. They are used for heating, cooking, drying, transportation, and as engine fuel. These materials can be made using petroleum-based or synthetic-based manufacturing processes. While petroleum-based hydrocarbon fluids are refined, synthetic-based hydrocarbon fluids are manufactured by organic synthesis, enabling these products to achieve higher performance. Overall, synthetic-based hydrocarbon fluids are chemically engineered for a specific molecular composition with a more tailored and uniform chemical structure. To differentiate hydrocarbon fluids with different manufacturing processes, expensive and time-consuming chemical separation and identification analyses are required. This work analyzed hydrocarbon fluids with different manufacturing processes with a hand-held Raman spectrometer.

A total of six different sources of hydrocarbon fluids were tested in this study. Two of the fluids were petroleum-based, and four of them were synthetic-based. These hydrocarbon fluids are formulated and manufactured as coolants and hydraulic fluids. Each fluid was sampled into seven aliquots in 2-mL vials. Each aliquot was tested ten times using a hand-held Raman spectrometer (HandyRam). The HandyRam was equipped with a 785nm laser. Raman spectra were all collected with autointegration. No data post-treatment was performed.

After side-by-side visual comparisons of Raman spectra between two types of hydrocarbon fluids, it was found that both petroleum-based and synthetic-based hydrocarbon fluids showed a typical predominate Raman scattering peak at 1,450cm-1, likely from a CH2 bending vibration. However, the synthetic-based hydrocarbon fluids exhibit four more observable peaks at 1,310, 1,145, 1,069, and 895cm-1. The petroleum-based hydrocarbon fluids exhibit a weak Raman scattering peak at 1,610cm-1, which is not observable in the synthetic-based samples. The pattern of Raman spectra between synthetic-based and petroleum-based hydrocarbon fluids is visually distinguishable. The results demonstrate that Raman spectroscopy can detect the chemical features of hydrocarbon fluids with different manufacturing processes.

Because most field investigators are not chemists, the next step in our research is to train an AI system to interpret the results. The research team envisions an AI-powered Raman spectrometer to assist field investigators in the critical decision-making of testing unknown samples. This work is significant because the results demonstrated the capability of Raman spectroscopy in distinguishing hydrocarbon fluid samples with different manufacturing processes. We believe Raman spectroscopy is a promising technique in the forensic investigation of physical evidence, including source tracing and classification tasks.

Raman Spectroscopy; Source Tracing; Classification

B50 The Impact of Glass Vial Type in Measuring Raman Spectrum of Liquid Hydrocarbon Samples

Kailee R. Marchand, BS, Sam Houston State University , Fairfield, TX; Javier E. Hodges, BS, Sam Houston State University, Huntsville, TX; Jorn Yu, PhD, Sam Houston State University, Huntsville, TX*

Learning Objectives: The attendees will learn how the same type of glass vials purchased from the same source can result in obscure Raman scattering and the importance of vial composition for obtaining adequate quality of Raman spectra for liquid hydrocarbon samples. Attendees will become aware of how sample containers produce interference and understand a protocol to overcome this issue.

Impact Statement: Raman spectroscopy is a widely used and well-regarded test for chemical analysis. The forensic science community will benefit from this study's presentation of a vial testing method for Raman spectroscopy. The impact of glass vial selection to guarantee an interpretable spectrum will be presented. The new procedure prevents time and money from being wasted on inadequate results and, therefore, enhances the reliability of outcomes.

Abstract Text: Raman spectroscopy has been increasingly used in forensic science over the recent decades due to its myriad benefits. This method can be developed to become relatively inexpensive, rapid, non-destructive, and accepted by the scientific community, making it valuable in forensic chemical identification and classification. It also has confirmatory potential when paired with multivariate statistical methods, even when it is a portable instrument.[1] However, further use of Raman spectroscopy has been found to have difficulties with vial types. Vials labeled as the same composition of glass can lead to varying results for the same sample with this spectroscopic method. The varying results obtained from the same sample may be due to the composition of glass vials producing interfering fluorescence in the spectra.

Thus far, research on the relationship between fluorescence and Raman spectroscopy with reference to sample vials is limited. Several methods are available to overcome the obstacle of fluorescence in Raman spectroscopy. These methods include Shifted Excitation Raman Difference Spectroscopy (SERDS), adjusting laser excitation wavelength, and computational methods in postprocessing.[2] When these methods are not implemented, the detection of Raman scattering signals may be adversely impacted by the composition of the vials used to conduct experiments. By applying a protocol that detects the interference of vials, laboratories can limit the room for error and consequently save time and money.[3]

In this work, a quartz cuvette was used as the ideal sample holder that produces minimal interference for detecting Raman scattering signals. Several Type 1 borosilicate glass vials, including Amber Type 1 Borosilicate vial (B75562), Clear Vial Black Foam Lined Cap (V1526C-FM), and Clear Vial PTFE Lined Cap (V1526C-TFE), were tested using a hand-held Raman spectrometer (HandyRam). The HandyRam point-and-shoot method was used to obtain each container's spectra in two different instances. In one instance, each container held a standard neat jet fuel sample, while the other spectra were obtained with no sample in the vial. Raman scattering signals were collected with autointegration, and no post-measurement data treatment was completed on the spectra. All Raman spectra were obtained with a 785nm laser.

Although the V1526C-FM and V1526C-TFE vials are made of borosilicate, these vials produce high background signals that peak at about 1,384cm-1 in the spectra, leading to inconclusive results for liquid hydrocarbon samples. The background signal of the B75562 vial appears similar to that of the quartz cuvette. The background signals produced from the V1526C-FM and V1526C-TFE vials could be detected and noted as problematic by taking the background spectra of the vials. As a result, the spectra of the B75562 vial and quartz cuvette containing the standard neat jet fuel sample displayed a better quality of Raman spectra. In contrast, V1526C-FM and V1526C-TFE vials containing standard neat jet fuel samples produced inconclusive results. These results illustrate the importance of taking the spectra of sample containers before sample testing to guarantee adequate quality of the Raman spectra.

In summary, since glass vials are not specifically made or marked for Raman spectroscopic techniques, it is crucial to collect a background spectrum of the sample container prior to sample testing. This study demonstrates the critical role of the vial glass type in collecting acceptable Raman spectra for liquid hydrocarbon samples. This work proposes a testing protocol to ensure high-quality spectra are collected. The results of this work include an awareness of the importance of vial composition when using Raman spectroscopy.

B51 The Detection of Bio-Based Lighter Fluid and Biodiesel Residues on Wood and Fabric Debris

Mengliang Zhang, PhD, Ohio University, Athens, OH*

Learning Objectives: After attending this presentation, attendees will understand how their plant oil source and the type of substrates affect the chromatographic and mass spectral profiles of fatty acid-based Ignitable Liquids (IL).

Impact Statement: This presentation would benefit the scientific community by providing key information about the detection of commonly encountered in forensic labs but less studied IL, such asbio-based lighter fluid and biodiesels, by both Gas Chromatograph/Mass Spectrometry (GC/MS) and Direct Analysis in Real Time-Mass Spectrometry (DART-MS).

Abstract Text: The American Society for Testing and Materials (ASTM) E30.01 Criminalistics committee is currently working on a newly proposed standard, "Classification of Ignitable Liquids in Fire Debris Analysis," and the fatty acid-based products are proposed to be a new category of IL classification. Examples of fatty acid-based products include bio-based lighter fluid, torch fuel, charcoal starter fluid, and biodiesel. Biodiesel and bio-based lighter fluid, as IL are the trans-esterified products containing Fatty Acid Methyl Esters (FAME), which can be detected in fire debris by GC/MS analysis without derivatization. Compared to other petroleum-based IL, studies on biodiesels and bio-based lighter fluid in forensic settings are relatively rare, and the exploration of techniques other than GC/MS for their detection is very limited. In this study, we investigated the detection of fatty acid-based IL products on wood and fabric substrates and debris using GC/MS and DART-MS methods. In addition to the commercial bio-based lighter fluid and biofuels, we prepared biodiesels with different plant-based oils in the lab to study how the plant oil sources would impact their chemical profiles in the final products.

The IL residues on substrates and debris were extracted following the ASTM E1412 activated charcoal method, and the extracts were analyzed using both GC/MS and DART-MS.[1] The FAME standard solution, biodiesel standard solution, and biodiesel samples prepared in our laboratory with ten different plant-based oils were studied and compared. The results showed that the variety and relative distribution of FAME compound in the biodiesel products were dependent on the types of plant oils. Specifically, the main FAME compounds, such as C16:0, C18:0, C18:1, C18:2, and C18:3, were identified in the samples, and their relative quantity varied significantly based on their plant oil source. The biodiesels prepared from cooked/waste oil and straight oil gave similar FAME profiles from the GC/MS and DART-MS analysis. The results also suggested that both GC/MS and DART-MS could effectively detect FAME compounds present in the substrate and debris samples. The variation of compound ratios affected by the substrates and burning conditions was also studied in the project.

B52 Real Bullets, Plastic Guns: Evaluating the Strength of 3D-Printed Gun Parts

Maria Mayol, BA, John Jay College of Criminal Justice, NY, NY; Peter J. Diaczuk, PhD, John Jay College, New York, NY*

Learning Objectives: Attendees can learn more about the 3D design/printing process. Attendees can learn more about ghost guns, which are becoming increasing popular around the world and how they differ from privately made firearms; how they are made; what harm can be done with them; how feasible it is for someone to assemble/design a firearm; what damage can be reasonable expected from a privately made firearm; and what trace evidence is left behind after firing a plastic gun or a gun with plastic parts.

Impact Statement: 3D printing is a popular endeavor among many enthusiasts and hobbyists around the world. With easy access to 3D printers, materials, and, most importantly, the creative design of guns and gun parts, the rise of privately made firearms is an inevitability. Privately made firearms (including ghost guns) can be assembled from commercially available kits or readily available parts combined with 3D printed parts. The identification of firearms based on fired bullets is founded on the microscopic agreement of individual marks left on a fired bullet to the interior of the questioned barrel; 3D printing a functional gun barrel would successfully fire a projectile and leave no rifling on the bullet because the barrel would be printed out of plastic and lack the hardness to leave marks on a metal projectile. A 3D printed barrel that is unregulated would be difficult to trace and control, especially without advancements in forensic science and law enforcement. The language of the law needs to advance just as much as investigative techniques. Forensic investigation of privately made firearms is a complex new landscape that requires an interdisciplinary approach centered on technological advancement in order to better understand this evolving terrain.

Abstract Text: Privately made firearms, also popularly referred to as "ghost guns," are firearms created and assembled by an individual; these firearms are not manufactured or marketed by a corporation or government and, as such, many of them lack serial numbers and are unregulated. "Ghost guns" refers to guns without a serial number, which actually only comprises a small portion of the true umbrella term, privately made firearms. Privately made firearms can be entirely 3D printed, assembled from "buy build shoot" kits (can be purchased with a firearm already up to 80% assembled), or be composed of 3D printed parts retrofitted onto an existing gun. With the accessibility of 3D printing and the freely shared files of 3D printed guns and gun parts, the appearance of privately made firearms in any of the three forms has increased in the past years in several countries. 3D printing gun parts, except for the lower receiver, is legal according to the language of some state laws. Because firearm parts are designed to be interchangeable to allow for customization or repairs, it is possible to exchange an original manufactured gun part for a 3D printed part, this is a problem in a legal sense when used either for concealment or forensic evasion. The identification of firearms based on fired bullets is founded on the microscopic agreement of individual marks left on a fired bullet to the interior of the questioned barrel; 3D printing a functional gun barrel would successfully fire a projectile and leave no rifling on the bullet, being that the barrel would be printed out of plastic and lack the hardness to leave marks on a metal projectile.

The goal of the experiment was to determine if a 3D printed barrel is capable of producing a lethal projectile when retrofitted onto the original firearm. A commercially available 3D printer (Makerbot Replicator+) was used to print an exact replica of the SBS barrel (a side-by-side barrel) of a Derringer Cobray Model DD in .38 Special/.357 Magnum modified to be chambered for a .25 ACP cartridge using PLA Tough filament (the strongest filament compatible with the original extruder of the 3D printer). The modification to accommodate a smaller cartridge allows for more plastic material in an effort to maintain the integrity of the barrel when the gun is fired. The results showed that the 3D printed barrel did not have the strength to survive multiple test fires and that the bullet was not capable of penetrating ballistic gelatin deep enough to cause lethal damage. The lack of accuracy and penetrating power of the bullet can be attributed to the lack of rifling on the 3D printed barrel, which is essential for spin-stabilization of a bullet.

B54 The Characterization and Discrimination of Soil by Major Elemental Analysis Using Laser-Induced Breakdown Spectroscopy: A Case Study of Nirasaki in Central Japan

Kento Kumisaka, MD, National Research Institute of Police Science, Kashiwa, Chiba, Japan; Ritsuko Sugita, PhD, National Research Institute of Police Science, Kashiwa, Chiba, Japan*

Learning Objectives: This presentation shows the effectiveness of analyzing soils by Laser-Induced Breakdown Spectroscopy (LIBS) based on the case study in the Nirasaki area in central Japan. The spatial distribution of the major elements in soil samples reflected the geological background of sampling sites. When three elements, potassium, magnesium, and calcium, were combined, the discrimination power of the 74 surface soils was 94%. Our result demonstrated that LIBS can discriminate soils derived from similar geological backgrounds and the possibility of provenance estimation.

Impact Statement: LIBS can characterize soils based on their geological backgrounds. Despite soils derived from similar geological backgrounds, 94% of the pairs of each soil could be discriminated.

Abstract Text: In forensic soil examinations, elemental analysis is informative for discriminating and characterizing soils.[1] However, soils from similar geological backgrounds are often difficult to discriminate or estimate their provenances. This study aimed to utilize elemental analysis by LIBS to forensic soil discrimination using fine fractions in the Nirasaki area in central Japan. The study area is surrounded by different geology from place to place, such as granodiorite, accretionary prisms, volcanic debris, and lava in the neighborhood (within ca. 10km). Therefore, the soils derived from different parent materials are distributed. For this geological setting, this area was previously studied for forensic soil color examination.[2] Organic matter decomposition, iron oxide removal, and sieving in 53µm were treated on 74 surface soils and pelletized.[3] The samples were analyzed by LIBS equipped with a 266nm laser by three lines (25 laser shots per line) per sample. The emission lines of major elements were selected as follows: 288.1nm (Si), 334.9nm (Ti), 257.5nm (Mn), 518.4nm (Mg), 393.4nm (Ca), 588.9nm (Na), 766.5nm (K), 495.8nm (Fe), and 396.1nm (Al). The intensity of each LIBS emission line was normalized to the aluminum emission line, and discrimination power of the emission line ratio was evaluated. The discrimination power was calculated as the percentage of pairs that were discriminated from each other out of total number of pairs of samples. Discrimination of each sample was conducted using the three-sigma criteria.

As a result, the K/Al, Mg/Al, Ca/Al, Si/Al, and Fe/Al ratios were high in the western area, which is mainly derived from granodiorite or their fans, terrace, and river plain sediments.[4] The Mn/Al ratio was relatively high from the central to the eastern region, which originated from andesitic volcanic debris and fan deposits. These differences in geological background were considered to be reflected in the emission line ratios of each area. The discrimination powers of K/Al, Mg/Al, Ca/Al, and Fe/Al ratios were high at 76.9, 75.0, 73.8, and 67.0%, respectively. Combining K/Al, Mg/Al, and Ca/Al can discriminate 94.2% of the sample pairs. Our result demonstrated that the major elemental ratios from LIBS analysis could discriminate 94% of the samples and the possibility of estimating the provenance of unknown soil samples.

Soil Analysis; Spectroscopy; Method Development

B55 An Investigation Into Chromatographic Methods for the Preservation, Stability, and Analysis of Organic Gunshot Residue

Addio Fiordigigli, Jr., BS, West Virginia University, Morgantown, WV; Kourtney Dalzell, MS, West Virginia University, Morgantown, WV; Luis E. Arroyo, PhD, West Virginia University, Morgantown, WV; Thomas D. Ledergerber, BS, West Virginia University, Morgantown, WV; Tatiana Trejos, PhD, West Virginia University, Morgantown, WV*

Learning Objectives: After this presentation, attendees will understand how the storage conditions (temperature and length of storage) affect the detection of organic gunshot residues by various confirmatory chromatographic methods. Additionally, the attendee will gain insight into how Gas Chromatograph/Mass Spectrometer (GC/MS) micro Electron Capture Detector (μECD), Gas Chromatograph/Mass Spectrometer/Flame Ionization Detector (GC/MS/FID), and Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) can be incorporated into the current workflow of forensic laboratories for Gunshot Residue (GSR) analysis.

Impact Statement: This presentation will impact the forensic science community by providing recommendations on the best way to preserve GSR evidence for minimal loss of information of organic gunshot residues and describes the advantages and disadvantages of different chromatographic methods. This study demonstrates the results of assessing three different storage conditions and five different times from collection to analysis to assess the stability of Organic Gunshot Residues (OGSR). These results impact the forensic community by adding to the current knowledge of OGSR stability, analysis, and workflow recommendations.

Abstract Text: Following the discharge of a firearm, OGSR and Inorganic Gunshot Residues (IGSR) are produced and deposited on nearby areas, including the hands of the shooter. Most forensic laboratories analyze IGSR by scanning electron microscopy-energy dispersive x-ray spectrometry to classify particles by morphology and elemental composition.[1] Recently, OGSRs have gained traction by providing complementary information that gives extra confidence in the examiner's results due to their relatively low prevalence in the environment.[2] Due to the increase in gun violence in the United States, forensic organizations are compiling research and knowledge for the future adoption of OGSR detection and increasing the evidentiary value of GSR.[3] This study targets some of the gaps in knowledge to better understand the capabilities and limitations of analytical techniques that can be used for OGSR while exploring recommendations for the best practices to store and preserve OGSR in these analytical workflows.

In this study, two separate validations were performed for the analysis of OGSR using GC/MS coupled to an FID or μECD using a microfluidic splitter. The effect of solvent used to extract and reconstitute the samples is also investigated. Figures of merit include repeatability, reproducibility, selectivity, linear dynamic range, Limits Of Detection (LODs), and Limits Of Quantitation (LOQs). A previously validated GC/MS/FID method from our group found MS LODs to range from 40 to 120ppb and the FID LODs to range from 35 to 180ppb. ECD LODs are also in the low parts per billion range. Testing using hexane has shown an increase in sensitivity, which leads to lower LODs. GC/MS has inferior LODs and LOQs when compared to LC/MS/MS, which makes it more difficult to detect trace levels of OGSR.[2] Equipping a secondary detector to a GC/MS can increase sensitivity for certain compounds that exhibit poor response in an MS and allow for better performance. The μECD has a high sensitivity for nitro-containing compounds; however, its limitation is the lack of detection of DPA, EC, and AKII. Conversely, the FID has the ability to detect almost any compound but has similar detection windows to the MS, which does not add any increased sensitivity, just extra confidence in the results. On the other hand, LC/MS/MS showed the highest sensitivity. However, it is a more expensive instrument compared to a GC/MS, even with configurations that include extra detectors (FID or μECD).

Three analytical techniques were used in this study to assess various storage conditions and time of analysis after collection. These techniques include GC/MS/FID, GC/MS/μECD, and LC/MS/MS. The time of analysis and storage condition for an OGSR sample may vary between laboratories. To simulate this, authentic residues were recovered from hands and stored in three different conditions: room temperature, a freezer at -30°C, and an extreme heat environment to simulate if a sample were to be left in a vehicle (~80–100°F). Samples were then tested the same day of firing, 2-day, 1-week, 2-week, and 1-month time periods to determine the effect of time in each of the three conditions.

This presentation discusses recommendations on the collection, storage, and analysis of OGSR comparing the use of chromatographic methods to benefit laboratory decision-making in the future adoption of OGSR analysis.

B56 A Study of Casing Markings of Semi-Automatic Firearms Modified With a Glock Switch

Nicole Sachman, Cedar Crest College, Niles, MI; Lawrence Quarino, PhD, Cedar Crest College, Allentown, PA; Carol J. Ritter, MS, Cedar Crest College, Allentown, PA; Peter J. Diaczuk, PhD, John Jay College, New York, NY*

Learning Objectives: After attending this presentation, attendees will understand the difference between casing markings fired in the modified and unmodified fashion of semi-automatic firearms with the addition of a Glock switch. A Glock switch is an illegal modification that allows the firearm to alternate between semi-automatic and fully automatic fire.

Impact Statement: This presentation will impact the forensic science community by bringing awareness to the increased use of Glock switches on semi-automatic firearms and its potential effect on firearms examinations.

Abstract Text: This report will present research completed involving three modified firearms. The firearms used included two Glock 17's and one Glock 19. Each firearm fired three magazines (17 cartridges per magazine): one in the semi-automatic mode and two in the fully automatic mode. Standard manual examination of the 153 casings in the study was performed using a LEEDS comparison microscope at 11x magnification. Side-by-side comparisons were made of semi-automatic casings and fully automatic casings fired from the same firearm to compare striation patterns on the breech face. No discernible differences were found in the striation patterns fired from the same firearm with and without the Glock switch. Once manual comparison on casings was completed, the LEEDS comparison microscope was used in conjunction with the SPOT Imaging Solutions application to evaluate firing pin drag mark length, ejector marks, and drag mark width on each casing at 22x magnification. The increased magnification was needed to ensure sufficient detail. Statistical analysis was completed on measurements using a two-tail t-test for two dependent means at 95% confidence to compare markings made in the semi-automatic mode with markings made in fully automatic mode on casings from the same firearm.

Unlike the comparison of striations, results of the two-tail t-tests from this portion of the study showed that in two firearms, the drag mark length was significantly different between the semi-automatic and fully automatic casings fired from the same firearm. Furthermore, in one firearm involved in this portion of the study, the ejector mark location was significantly different between the two modes.

Although the chance of an incorrect conclusion reached by a trained firearms examiner is likely rare, the results of this study indicate that firearm examiners must nonetheless be aware that markings may change on casings due to the use of a Glock switch.

Firearm Examination; Modified Firearms; Glock Switch

B57 One-Step Non-Contact Sampling and Analysis of Trace Chemical Residues Using an Electrostatic Wand and Paper Spray Mass Spectrometry

Kimberly Edmunds, The University of Tampa, Tampa, FL; La'Nyah Nance, The University of Tampa, Tampa, FL; Kenyon Evans-Nguyen, PhD, The University of Tampa, Tampa, FL*

Learning Objectives: After attending this presentation, attendees will understand how electrostatic sampling can rapidly and inexpensively analyze chemical residues on surfaces while preserving underlying fingerprint and touch DNA evidence, with potential on-site use.

Impact Statement: We present a simple, portable, combined sampling and mass spectrometry ionization device for non-destructive analysis of surface evidentiary residues.

Abstract Text: When forensic chemists encounter trace powder residues, such as a baggie with cocaine residue or a fragment of an exploded pipe bomb with residual traces of explosive compounds, the residues are often analyzed using mass spectrometry. However, analysis of residues on evidentiary surfaces with mass spectrometry typically involves solvent rinses or swabbing, which destroys potential underlying fingerprint and touch DNA evidence. In previous work, we demonstrated that a simple electrostatic sampling device could be used effectively for non-contact sampling of chemical residues on surfaces.[1] The device is a hand-held Van de Graaff Generator (VDG) sold as an inexpensive children's toy. After sampling, the captured residue was analyzed offline using mass spectrometry with an electrospray ionization source. In the current work, we have changed the methodology and the sampling substrate so that the electrostatic wand can be used both for non-contact sampling of a surface and also as an ambient ionization source. In this way, the method has become a combined, online process using the same device for sampling and ionization.

In the combined method, a triangular piece of filter paper is connected to the output of a commercially available hand-held VDG. Initial experiments verified that the handheld VDG was an effective voltage source to drive ambient Paper Spray Ionization (PSI) from the paper triangle, supplying ~27 kV.[2] Drug residues were deposited directly onto the paper and allowed to dry. A spray solvent was then pipetted onto the paper, and the voltage was applied from the VDG, with the tip of the paper triangle positioned in front of the inlet to the mass spectrometer. Signals for 100pg of methamphetamine, hydrocodone, and cocaine were each obtained in Tandem Mass Spectrometry (MS/MS) mode on an ion trap mass spectrometer using the VDG to drive the PSI.

After demonstrating that the hand-held VDG could effectively drive PSI, the feasibility of non-contact sampling was tested on various surfaces. Cocaine was used as a model compound, with 1µg of cocaine deposited on rubber, stainless steel, and pine wood surfaces. For sampling, the hand-held VDG with the paper attached was held such that the tip of the paper triangle was held a few millimeters above the surface. The voltage was applied to the handheld VDG to facilitate surface charging and electrostatic evidentiary particle capture at the triangle tip. Then, the tip was moved in front of the mass spectrometer inlet, spray solvent was added, and the VDG voltage was applied to drive PSI of any captured sample. Cocaine signal was observed in each MS/MS spectra, with the signal-to-noise ratio being the lowest for the cocaine sampled from the stainless-steel surface. These preliminary experiments demonstrate non-contact capture followed by direct PSI using this device.

In follow-up experiments, the sampling and analysis of transferred residues were tested. A gloved finger was loaded with 100µg of a drug and rubbed against a rubber substrate. Drug residues transferred from the glove to the substrate were electrostatically sampled and ionized using PSI driven by hand-held VDG. Signal was obtained for both of the test compounds, atropine and procaine. Additionally, transferred residues were detected using this methodology with a fieldable ion trap mass spectrometer instrument. In this experiment, a pseudoephedrine tablet was rubbed onto a gloved finger, and that finger was rubbed on a rubber luggage handle. The luggage handle was sampled and analyzed using the VDG and PSI ionization on a fieldable instrument. This experiment extends the technique beyond benchtop equipment and has positive implications for on-site crime scene, defense, and homeland security applications beyond the laboratory.

Mass Spectrometry; Touch Sample; Seized Drugs

B58 A Quantitative Assessment of the Stability of New AR-Style Rifle Breech Face Characteristics

Eric Law, PhD, University of Central Oklahoma, Edmond, OK; Teagan Trent, University of Central Oklahoma, Yukon, OK*

Learning Objectives: Much of the research performed in forensic firearms is qualitative based on observations made using a comparison microscope. However, this study uses quantitative data from Three-Dimensional (3D) comparison algorithms to assess changes that occur to the breech face area of firearms when brand new. Attendees will learn when firearm examiners may need to be conservative in making elimination conclusions due to potential differences observed within cartridge case breech face marks over consecutive shots.

Impact Statement: The time between when a shooting incident occurs and when the suspect firearm is recovered is critical. This study will present quantitative data to inform firearm examiners about the extent to which the breech face surface of AR-style rifles changes when brand new, emphasizing the importance of newer 3D imaging systems for firearm forensics research.

Abstract Text: Firearm surfaces have been observed to change; however, previous research into this topic has been mostly qualitative in nature where a firearm examiner uses a microscope to examine a sequence of fired cartridge cases for any changes. New 3D imaging technologies have been developed to acquire high-resolution surface topographies of firearm evidence. These 3D scans can be compared using algorithms that take into account the heightmap of features present on the surface. These algorithm scores allow for the presentation of quantitative data to assess changes in firearm surfaces over consecutive shots.

Three AR-style rifles from each of two different manufacturers were acquired for this study. One hundred rounds of 5.56 x 45mm caliber Herters range ammunition were purchased and fired through each rifle for a total of 600 shots. The first ten, last ten, and every fifth cartridge case in between were collected from each rifle for a total of 36 cartridge cases per rifle. All fired cartridge cases will be assigned a unique identifier that will be engraved onto each cartridge case to track firing order and from which firearm each was fired. 3D topography scans will be acquired of all collected cartridge cases using a Cadre Forensics TopMatch-GS 3D instrument. The Cadre Forensics breech face comparison algorithm will then be used to compare the cartridge cases within and between firearms, providing an objective similarity metric. Time series analysis will be used to assess whether statistically significant decreasing trends are present. These quantitative data will be coupled with visual examination to support all conclusions.

It is hypothesized that there will be small changes, but that these changes will stabilize within the first 100 shots. Preliminary data from a 9mm Luger caliber pistol showed no statistically significant decrease in scores over the first 100 shots, indicating no significant changes were occurring to the breech face surface of the firearm. However, AR-style rifles generate double the chamber pressure when compared to 9mm Luger pistols, so some changes are expected to be observed due to this increase in pressure.

3D Technology; Firearms; Ballistics

B59 A Modified Procedure for Extracting Primer Gunshot Residue From Scanning Electron Microscopy Carbon Stubs and Trace Analysis Utilizing the Graphite Furnace-Atomic Absorption Spectrometry Technique

Khalid Sajjad Feras, MS, Naif Arab University for Security Sciences, Riyadh, Ar Riyad, Saudi Arabia*

Learning Objectives: After attending this presentation, attendees will: (1) understand the development and validation of a modified procedure for extracting primer Gunshot Residue (GSR) elements from adhesive carbon stubs collected for Scanning Electron Microscopy with Energy-Dispersive X-ray Spectroscopy (SEM/EDS) analysis; (2) gain knowledge of the Graphite furnace/Atomic Absorption Spectroscopy (GTA/AAS) technique for trace analysis of primer GSR elements; and (3) recognize the advantages of the modified extraction method, including its simplicity, high sensitivity, and potential impact on expediting forensic investigations.

Impact Statement: The development and validation of a modified procedure for extracting primer GSR elements from adhesive carbon stubs and utilizing GTA/AAS for trace analysis have significant implications for forensic investigations related to gun crimes. This alternative technique offers a practical solution, particularly in situations where SEM/EDS is unavailable or impractical. By addressing the limitations of SEM/EDS, such as cost, expertise requirements, and parts availability, implementing this modified procedure can help alleviate case backlogs and expedite the identification of shooting incidents and potential shooters. The simplicity, high sensitivity, and reproducibility of results make this method a valuable tool in forensic analysis, ultimately contributing to the effective resolution of gun-related criminal cases.

Abstract Text: **Background:** Gun crimes have become a global concern in countries with lenient firearm acquisition regulations and weak prosecution systems. The rise in homicide and suicide cases involving firearms necessitates the use of contemporary forensic techniques to identify shooting incidents and potential shooters. One such technique involves the analysis of primer GSR using SEM/EDS. In combination with SEM-EDS, the application of graphite furnace atomic absorption spectroscopy (GFA-AAS) imparts an extensive application in conducting elemental analysis of GSR from crime scene.[1,2] However, the widespread implementation of SEM/EDS is hindered by its high cost, the need for advanced expertise, and challenges related to troubleshooting and importing parts, particularly in developing countries. Consequently, the backlog of cases awaiting primer GSR analysis continues to grow. In such situations, an alternative, reliable technique that utilizes the same adhesive carbon stubs collected for SEM/EDS analysis becomes essential.[3]

Aim and Objectives: This study aimed to develop and validate a modified procedure for the extraction of primer GSR-related elements from SEM/EDS adhesive carbon stubs employing simple extraction techniques and finally analyzing by GTA/AAS.

The modified procedure involved the following steps: (1) removal of the adhesive carbon layer from the stub: The carbon layer was carefully peeled off from the stub using acetone and a scalpel; (2) digestion of the trace material on the adhesive carbon: The removed adhesive carbon material was transferred into a 15-ml plastic centrifuge tube, and the adhered material was digested in an airtight condition with 2ml of 10% nitric acid (HNO_3) for a minimum of 12 hours at 80°C ; (3) vortexing and centrifugation: after digestion, the sample tube was vortexed for at least 5 minutes at a speed of 2,000–2,500. The vortexed contents were then centrifuged at 4,000rpm for 5 minutes; and (4) analysis by GTA/AAS: The supernatant extract from the centrifuge tube was transferred to sample cuvettes and analyzed using GTA/AAS for the identification of lead (Pb), barium (Ba), and antimony (Sb) in combination.

Notably, this extraction method does not require the use of chemical modifiers to address matrix interference. The sensitivity of the method is remarkably high, enabling the successful detection of GSR-related elements (Pb, Ba, and Sb) at levels as low as parts per billion (ppb).

Results: The method demonstrated a sensitivity of ≥1ppb for Sb and ≥10ppb for Pb and Ba, which are critical detection elements present in trace amounts in positive sample stubs. The Coefficient of Variation (%CV) for Sb, Pb, and Ba ranged from 7.8% to 17.4%, 13.7% to 19%, and 5.8% to 18%, respectively. The bias for Sb, Pb, and Ba ranged from 0.6% to 13%, 4.31% to 19.12%, and 0.6% to 7.2%, respectively.

Discussion: The developed extraction method offers a simple, robust, and sensitive approach with excellent repeatability and reproducibility of results. By utilizing adhesive carbon stubs and GTA/AAS, this alternative technique provides a practical solution for primer GSR analysis, particularly in situations where SEM/EDS is unavailable or impractical. Implementing this method can help alleviate the backlog of cases and expedite forensic investigations related to gun crimes.

B60 Outpacing the Law: NPS—A Global Threat Challenging Forensic Analysis

Tahir Jamshaid, PharmD, MPhil, Lahore College of Pharmaceutical Sciences, Lahore, Punjab, Pakistan; Khalid Sajjad Feras, MS*, Naif Arab University for Security Sciences, Riyadh, Ar Riyad, Saudi Arabia*

Learning Objectives: The attendees will have a thorough knowledge of New Psychoactive Substances (NPS) emergence, their analytical strategies, and special emphasis on challenges faced by forensic scientist during their detection in seized and biological samples. The rapidly and constantly evolving nature of NPS poses a greater challenge to forensic analyst in identification. The attendee will overview the main practical challenges and their possible solutions during analysis of seized and biological samples in forensic laboratory.

Impact Statement: The presentation will give an insight and understanding of the analytical challenges and their possible solutions regarding qualitative detection and reporting of NPS using Gas Chromatograph/Mass Spectrometry (GC/MS). This will help the forensic science community in uplifting the standardization and standard operating procedures for proper identification and interpretation of NPS in forensic samples. Consequently, the content of this presentation will help in coping with the current NPS identification challenges.

Abstract Text: NPS have become a growing concern in recent years for communities and especially for forensic analytical laboratories due to their potential health risks and the difficulty in detecting them. Forensic experts face numerous challenges in the qualitative detection of NPS using GC/MS. These challenges include the rapid emergence of new substances, the lack of reference standards for identification, and the complexity of analyzing specimens with diverse compositions along with MS library matching limitations, and the chemical nature of NPS as being thermolabile.[1-3] Additionally, the interference from major constituent peaks during qualitative analysis can result in the missed detection of minor and trace constituents.[4]

This paper explores such challenges and their mitigation as well as the need for a sensitive and selective analytical approach. The qualitative identification of NPS involves presumptive and confirmatory tests. GC/MS is most common technique for confirmation of seized drugs. Various strategies like choice particular method parameters, MS libraries, derivatization techniques, extraction techniques, and data interpretation expertise are applied for correct identification of NPS in forensic samples. There is a need for thorough understanding of NPS emerging trends, their profiles, and collaborations for forensic lab with law enforcement agencies and research institutes to address these challenges so that the accuracy and reliability of qualitative detection methods can be improved as per need. The development of comprehensive databases and collaborative international efforts for data sharing are also critical, enabling the timely identification of new NPS. Alternative techniques like High-Resolution Mass Spectrometry (HRMS) and Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) may be applied if capacitated by the lab for achieving enhanced sensitivity and specificity. This technical note provides an insight into some of the key parameters that should be discussed and monitored for exact and timely identification and profiling of NPS encountered routinely.

B61 The Enhancement of Latent Fingerprints Using Waste Biomass-Derived Biocompatible Fluorescent Graphene Nanosheets

Kajol Bhati, PhD, Galgotias University, Greater Noida, Uttar Pradesh, India; Divya Tripathy, PhD, Galgotias University, Greater Noida, Uttar Pradesh, India*

Learning Objectives: Attendees will learn about green synthesis and the characterization of nanoparticles, the development of latent fingerprints on different surfaces (porous and non-porous), and toxicological studies of the synthesized nanoparticles.

Impact Statement: Green synthesis and characterization of nanoparticles aims to significantly advance the forensic science community by introducing eco-friendly and sustainable methods for nanoparticle synthesis. Using these nanoparticles, developing latent fingerprints on both porous and non-porous surfaces promise enhanced sensitivity and clarity in crime scene investigations. Comprehensive toxicological studies also ensure that the synthesized nanoparticles are safe for forensic practitioners and the environment. This multi-faceted approach not only pushes the boundaries of forensic technology but also aligns with global sustainability goals, setting a new standard for innovation in forensic science.

Abstract Text: The application of biocompatible and non-toxic nanomaterials for latent fingerprint detection is gaining significant interest in the forensic science field.[1] In this study, waste chickpea seeds, a natural resource, were bioprocessed to synthesize non-toxic Graphene Nano-Sheets (GNS) with high fluorescence. High-temperature pyrolysis was used to create the GNS, and a variety of methods were used to characterize them, including Fourier Transform Infrared (FTIR) analysis, fluorescence spectroscopy, UV-Visible (UV-Vis) spectroscopy, X-ray Photoelectron Spectroscopy (XPS), and Transmission Electron Microscopy (TEM).[2,3] The synthesized GNS exhibited excitation-independent emission at approximately 620nm with a quantum yield exceeding 10%, showing distinct blue fluorescence under a UV lamp.[4,5] Biocompatibility was assessed, revealing cell viability rates of 88.28% and 74.19% even at high concentrations (50 and 100mg/mL, respectively). Additionally, the antimicrobial properties of the synthesized GNS-based coatings were evaluated using a pathogenic strain of *Bacillus cereus* through live/dead cell counts and plate counting methods, confirming their biocompatible and antimicrobial nature. This highlights their potential use in safe fingerprint detection. The developed chickpea-originated fluorescent GNS-based spray coatings were tested on various non-porous surfaces, including plastic, glass, silicon, steel, and soft plastic. Results confirmed that GNS could effectively detect latent fingerprints on multiple non-porous surfaces, which were easily visible under a UV lamp at 395nm. The color-tunable behavior of the developed GNS-based spray coating makes it ideal for the visual enhancement of latent fingerprints.

These findings underscore the high potential of the fluorescent GNS spray coating to increase the sensitivity and stability of crime trace detection on non-porous surfaces. The prints developed showed the Level I and Level II characteristics clearly. The prints also developed on the porous surface. By utilizing sustainable and natural resources, this study offers an innovative and eco-friendly approach to forensic latent fingerprint detection, aligning with global sustainability goals while enhancing forensic technology.

Fingerprint; Accuracy; Fingerprint Identification

B62 An Assessment of the Permeability of VOCs Between Containers Housing Detection Canine Training Aids

Kayla Hogan, BA, Florida International University, Miami, FL; Lauryn DeGreeff, PhD, Florida International University, Miami, FL; Kenneth G. Furton, PhD, FIU, Miami, FL*

Learning Objectives: After attending this presentation, attendees will learn how problematic cross-contamination of volatile odorants is among co-located aids and the estimated longevity of optimal storage containment systems for canine training aids over time prior to odorant permeation and cross-contamination.

Impact Statement: This presentation will impact the forensic science community by depicting the issues of improper storage containment systems for canine training aids. Moreover, it will provide beneficial information on the selection and longevity of various storage containers in hopes of reducing cross-contamination and improving a canine's detection accuracy toward trained odorants.

Abstract Text: Canine training utilizes training aids comprised of real materials or odorants corresponding to illegal and legal materials for detection purposes. However, improper storage of aids could severely affect a canine's performance, hindering their reliability, and thus emphasizing the need for suitable containers. A recent study utilized Solid Phase Microextraction -Gas Chromatography/Mass Spectrometry (SPME-GC/MS) to assess the headspace of 11 new explosive training aids from three vendors for initial cross-contamination.[1] Though the explosives in this study were purchased new, the results depicted significant levels of cross-contamination from one of the three vendors. Evident cross-contamination could have resulted from how the samples were shipped or packaged, as it was noted that this vendor utilized plastic bags and packed aids together.[1] With possible issues of cross-contamination being caused by plastic bags and aids packaged together, ideal containment systems need to be further investigated. Therefore, this research utilized SPME-GC/MS to further explore levels of cross-contamination within old co-located drug training aids and to assess the permeation of odorants in various storage containment systems.

In this study, potential cross-contamination between previously used drug canine training aids kits containing cocaine, cocaine base, methamphetamine, 3,4-Methylenedioxymethamphetamine (MDMA), heroin, and black tar heroin from three locations was assessed using SPME-GC/MS. The main odorant evaluated for each drug was acetic acid for heroin and black tar heroin, benzaldehyde for methamphetamine, methyl benzoate for cocaine and cocaine base, and piperonal for MDMA. Small amounts of sample were collected and transferred into 20-mL vials. Following equilibration, the samples' headspace was extracted using SPME prior to thermal desorption in the GC inlet. Triplicates were performed for each drug in each location.

The co-located aids assessed from each location depicted significant amounts of cross-contamination, with acetic acid being predominantly detected in each sample. Additionally, there was no detectable limit of piperonal in MDMA or any sample; however, a high intensity of dimethyl sulfone was detected and measured.

With significant contamination being detected with these co-located aids, a further study explored the efficacy of different storage containers in preventing cross-contamination. Containment systems included glass Training Aid Delivery Devices (TADDs), canning jars, Mylar bags, Bitran bags, and Ziploc bags. Heroin and MDMA mimic training aids were formulated using dimethyl sulfone, the major odorant seen in the cross-contaminated samples by MDMA, or acetic acid, the main odorant of heroin, mixed into a cellulose substrate. The devised mimics were each stored in identical containers inside a case.

Cross-contamination in each container was evaluated by transferring small portions of the cellulose-containing no major odorant in each container into separate 20-mL vials without depleting the quantity and intensity of the heroin and MDMA training aid mimics. Samples were collected on the initial day, followed by monthly sampling to monitor cross-contamination.

The assessment of various storage containment systems depicted the odorants from heroin and MDMA mimic training aids tend to cross-contaminate earlier in some containers than others. This study provides information to individuals regarding the issues of utilizing improper training aid storage containers over time. Additionally, this research provides insight into the importance of implementing routine training aid checks for cross-contamination to ensure the odor profile remains consistent during storage.

Cross-Contamination; Permeability; Training Aids

B63 The Prevalence of GSR on Ammunition Packaging

Brittany S. Claassen, MS, Harris County Institute of Forensic Sciences, Houston, TX; Kailyn Thomas, Southern Arkansas University, Magnolia, AR; Jason L. Schroeder, MS, MBA, Harris County Institute of Forensic Sciences, Houston, TX*

Learning Objectives: This presentation will summarize the results of a Gunshot Residue (GSR) prevalence study performed on ammunition packaging in Houston, TX, area sporting goods stores. After attending this presentation, attendees will become familiar with the prevalence of GSR, the need for mitigating techniques during collection, and the need to apply the appropriate interpretation on a case-by-case basis.

Impact Statement: This presentation will impact the forensic science community by identifying the potential for elevated levels of GSR in specific environments and the importance of interpreting the results effectively in both analytical reports and subsequent testimony as well as identifying mitigating techniques to sample collection.

Abstract Text: The prevalence of GSR can be of concern in specific environments. Accordingly, specific environments with elevated levels of GSR may impact the interpretation and subsequent reporting GSR analytical results. To help build on this understanding of GSR in the surrounding area, a localized study of GSR from various sporting goods stores was conducted to determine the prevalence of GSR and identify the potential for transfer.

In this study, ammunition boxes were sampled throughout sporting goods stores in the greater Houston area. A random sampling of brands and calibers were sampled in each store. Each box of ammunition was on a public facing shelf easily accessible by customers. Sampling occurred in a similar manner from seven stores on six different dates. Each sample was collected using a commercially available GSR collection kit utilizing a carbon adhesive stub. Analysis was performed using Scanning Electron Microscopy/Energy Dispersive X-ray Spectroscopy (SEM/EDS) with an automated software to detect particles characteristic of GSR. The same standard operating Procedures (SOPs) employed for evidence analysis were followed in this study.

A total of 90 GSR stubs were collected from seven sporting goods stores from the greater Houston area. A total of 16 GSR particles were confirmed. Confirmed particles were from a variety of brands and calibers. This prevalence has the potential to lead to transfer to an individual who may not have otherwise had an association with the discharge of a firearm. The results of this study will highlight the benefit of localized prevalence studies, collection-mitigating techniques, and appropriate use of reporting statements to accurately communicate the significance of GSR analysis results.

In conclusion, this presentation will demonstrate the prevalence of GSR in sporting goods stores around the Houston area, touching on the potential for transfer of GSR, collection- mitigating techniques, and the importance of interpretation and reporting of analytical results.

Gunshot Residue (GSR); GSR Prevalence; Evidence Handling

B64 Advancing Trace Evidence Identification Through ATR/FTIR Spectroscopy and Machine Learning for Textile Fibers Analysis

Vishal Sharma, PhD, Panjab University, Chandigarh, Chandigarh, India; Akanksha Sharma, MS, Panjab University, Chandigarh, Chandigarh, India*

Learning Objectives: The integration of Attenuated Total Reflectance/Fourier Transform Infrared (ATR/FTIR) spectroscopy with machine learning offers a powerful tool for the non-destructive analysis of textile fibers in forensic investigations. The creation of an ATR/FTIR spectral database will enhance the ability of forensic experts to identify unknown or suspect fibers, thus providing critical evidence in criminal cases. The ability to quickly and accurately identify fiber types can narrow down the suspect pool in the investigations, where other forms of evidence, such as DNA or fingerprints, are unavailable or inconclusive. By providing a reliable method for linking suspects, victims, and crime scenes through fiber evidence, this study supports the purpose of ensuring justice through precise and scientifically sound forensic analysis.

Impact Statement: The development of a spectral database for textile fibers represents a significant advancement in forensic science, providing a standardized and systematic approach to fiber analysis. This resource could be continuously expanded as new fiber types are introduced into the market, ensuring that forensic capabilities keep pace with changes in textile manufacturing. Moreover, the integration of machine learning into forensic workflows reflects a broader trend toward the adoption of artificial intelligence and data-driven methods in forensic investigations. These technologies offer the potential to automate complex analytical processes, reduce human error, and improve the speed and accuracy of forensic investigations.

Abstract Text: Fibers are a ubiquitous form of trace evidence encountered in a variety of criminal investigations, particularly in cases of rape and physical assault. The analysis of these fibers can establish critical connections between crime scenes, victims, and perpetrators, often providing the only tangible link that places an individual at a scene or in contact with another person. The ability to study fiber components and assess their transferability is therefore a cornerstone of forensic science, offering insights that can corroborate testimonies or refute alibis. This study aims to explore the ability of FTIR spectroscopy in ATR sampling mode, in integration with machine learning to characterize and classify a diverse set of textile fibers.

The study focused on a comprehensive analysis of 104 fiber samples, which included natural fibers such as cotton and wool (43 samples) and synthetic fibers, including terry wool (61 samples). ATR/FTIR spectroscopy was selected for this analysis due to its non-destructive nature and ability to produce detailed spectral data that reflect the molecular composition of the fibers. The fingerprint region of the spectra (1,800–450 cm^{-1}) proved to be particularly valuable, as it contained prominent peaks that are indicative of specific chemical bonds and structures unique to different fiber types. This region of the spectrum is often the most informative for identifying materials because it captures the fundamental vibrations of molecular bonds, which are characteristic of specific substances.

Additionally, the study employed Principal Component Analysis (PCA) for data reduction to handle the complexity of the spectral data obtained from the ATR/FTIR analysis. The reduced data were then subjected to machine learning algorithms using PyCaret library of Python framework, allowing identification of the most effective approach for classifying the fiber samples. The study explored multiple algorithms, and each algorithm was evaluated based on its accuracy, Area Under the Curve (AUC) score, precision, recall, F1-value, kappa, MCC, and the ability to generalize to new data. The most effective algorithm was selected for further validation, ensuring that the chosen model was robust and reliable for practical forensic applications. The approach not only provided a rapid and non-destructive means of characterizing fibers but also showed promise for high accuracy in distinguishing between different fiber types. The creation of an ATR/FTIR spectral database, as proposed in this study, would allow for the quick identification of fibers found at crime scenes, thereby aiding in the investigation process. By comparing unknown samples to a comprehensive library of known fiber spectra, forensic experts could identify fibers with a high degree of confidence, supporting the identification of suspects or victims.

Forensic Analysis; Fibers; Machine Learning

B65 Addressing Challenges in Mineral Identification by Raman Spectroscopy

Jasmine Kaur, MFS, University of New Haven, West Haven, CT; Drew M. Kuroda, BS, University of New Haven, New Haven, CT; Peter R. De Forest, DCrim, Forensic Consultants, Ardsley, NY; Brooke W. Kammrath, PhD, University of New Haven, West Haven, CT; Marisia A. Fikiet, PhD, University of New Haven, West Haven, CT; Joshua Christensen, University of New Haven, Glastonbury, CT*

Learning Objectives: After attending this presentation, attendees will understand the challenges with mineral identification by Raman spectroscopy and the analytical techniques for overcoming them when using advanced Raman imaging techniques like Particle-Correlated Raman Spectroscopy (PCRS)

Impact Statement: This presentation will impact the forensic science community by offering practical approaches for the reliable identification of soil minerals using Raman spectroscopy.

Abstract Text: Raman spectroscopy is a valuable non-destructive tool for investigating the chemical properties of diverse samples. However, challenges with regards to mineral identification set important limits for the practical use of Raman spectroscopy for forensic soil analysis. These limitations consist of fluorescence (including for minerals that may have characteristic spectra1), orientation effects, spectral masking by substrates, sample destruction (especially regarding dark samples), and natural variations within a mineral variety, which can cause meaningful spectral differences with regard to both manual and library identifications.[1] These have additional relevant repercussions with respect to applications of new advancements in Raman spectroscopic imaging, such as hyperspectral imaging and PCRS. With Raman imaging methods, a large number of Raman spectra (thousands to tens of thousands or more, potentially) are collected so spectral acquisitions must be very rapid for each data point (on the order of 1 second), thus materials that are weak Raman scatterers are not necessarily able to be identified and methods such as photobleaching become impractical.

This presentation will feature the results and conclusions from the method development of PCRS for the forensic discrimination of soil minerals, specifically with regard to overcoming limitations to mineral identification by Raman spectroscopy with short analysis times (1second collection, 1 acquisition per spectra). Samples analyzed in this study included the standard 60 common minerals from the Cargille Comminuted Mineral Set M-4 in addition to minerals from topsoil samples collected from diverse locations in the Northeast United States, which had been prepared for traditional forensic soil microscopical analysis (undergoing washing, sieving, and heavy mineral separation).[2] The individual mineral grains were then each probed by Raman microspectroscopy using two different lasers excitations (532nm and 785nm).

Several practical solutions were discovered during the course of this research to address challenges to the Raman identification of minerals. The first, and potentially most valuable, was the creation of a large and robust spectral library of diverse minerals capable of automated searching, which was made from Raman spectra in the RRUFF mineral database containing close to 10,000 different Raman mineral spectra.[3] This ensured that the greatest number of spectral variations within a mineral were included in the analysis. Next, although many mineral species do enable characteristic identification, some minerals have indistinguishable Raman spectra. For these minerals where distinct identification is not possible, classes of minerals were identified instead. Additionally, the use of two laser excitations for the interrogation of mineral grains afforded a greater number of minerals to be identified. Another critical feature is using an appropriate sample substrate for the desired method to avoid interference. In this research, four substrates were investigated (glass, aluminum, silicon, low-E glass), each having advantages and limitations with respect to research with Raman spectroscopy. For PCRS analysis, low-e glass slides proved to be best because they have no spectral interference nor any surface features to interfere with automated imaging. Despite the limits of Raman spectroscopy for the identification or classification of minerals, it is a valuable tool for forensic soil investigations, especially when paired with automated particle imaging techniques such as PCRS.

B66 The Characterization of Residues Left by the Impact of Different Types of Firearm-Propelled Projectiles

Jesus Velho, PhD, Brazilian Federal Police, Belem, Para, Brazil; Aline Thais Bruni, PhD, University of São Paulo, Ribeirão Preto, Sao Paulo, Brazil; Michele Dos Santos, MD, PhD, Brazilian Federal Police, Belém, Brazil; Milena Souza, MD, Universidade de São Paulo, Belém, Brazil*

Learning Objectives: This report addresses the characterization of residues produced by different types of projectiles when they impact various materials. The study aims to enhance the forensic analysis of crime scenes involving firearm use by identifying the elemental composition of residues found on impacted surfaces.

Impact Statement: This study not only characterizes the elemental composition of residues left by different types of projectiles on fabric targets but also provides support for the development of more robust forensic protocols. These protocols can assist in the accurate identification of firearms and calibers used in crimes, contributing to more effective investigations and the advancement of forensic sciences.

Abstract Text: The analysis of firearm discharge residues has become very frequent in forensic activities due to the frequent use of these instruments in criminal offenses.[1] When a shot is fired, the projectile is propelled at high speed and temperature, potentially impacting different types of targets at a crime scene and leaving residual particles along its path. Thus, to respond to technical questions formulated by the justice system, instrumental analysis methods have been developed to detect and characterize these residual elements from discharges that are deposited on clothing, parts of the victim's body, and other various targets that are part of our daily lives.[2] However, Criminalistics still lacks predictive elemental characterization studies of the passage of different types of projectiles through the most common everyday targets. In this context, this work aimed to identify the most frequent residues left by different types of projectiles on fabric targets.

Samples were collected by firing different types of projectiles (jacketed, semi-jacketed, and lead alloy) using three firearms (Glock 9mm pistol, Taurus .38 Special revolver, and Taurus .357 Magnum revolver) at cotton fabric targets from a distance of two meters. The residues around the entry holes were analyzed using Scanning Electron Microscopy (SEM) and Energy Dispersive Spectroscopy (EDS). Elemental compositions were quantified in terms of weight and atomic concentration percentages. Multivariate statistical analyses, including Principal Component Analysis (PCA) and Soft Independent Modeling of Class Analogy (SIMCA), were conducted to identify patterns and classify the residues. The PCA revealed two distinct clusters: one for .38 caliber residues and another grouping 9mm and .357 residues, indicating differences in elemental compositions. The SIMCA model showed an accuracy of 84.72% in classifying the residues. The findings support the development of robust forensic protocols to identify firearms and calibers used in crimes, contributing to more effective investigations and advancements in forensic sciences.

B67 Standards Development Activities in Human Forensic Biology

Jillian Conte, PhD, National Institute of Justice, Peckville, PA; Charlotte Word, PhD, Charlotte Word, Richmond, VA; Jarrah R. Kennedy, MSFS, Kansas City Police Crime Laboratory, Kansas City, MO*

Learning Objectives: After attending this presentation, attendees will have a better understanding of the status of discipline-specific standards pertinent to the field of human forensic biology testing.

Impact Statement: The presentation will impact the forensic science community by creating greater awareness of standards development activities pertinent to human forensic biology, including serological and DNA testing. It will also increase awareness regarding training, tools, and resources that support implementation and compliance monitoring.

Abstract Text: The Organization of Scientific Area Committees for Forensic Science (OSAC) was created in 2014 to strengthen the nation's use of forensic science by promoting the use of discipline-specific standards. To this end, the OSAC drafts standards, and best practice recommendations are forwarded to Standards-Developing Organizations (SDOs), such as the Academy Standards Board (ASB). In turn, the SDO then further develops and publishes them as American National Standards Institute (ANSI) standards. The ASB approves consensus standards and best practice recommendations, including the revision, reaffirmation, or withdrawal of a document. This is done through consideration of comments, views, and objections collected during public comment periods. ASB develops standards with the ANSI framework and provides training to support those standards. The OSAC also reviews standards and recognizes them on the OSAC Registry. The OSAC Registry serves as a central repository of high-quality, consensus-based, technically sound standards. The standards go through a technical and quality review process that encourages feedback from the forensic community. Standards and best practice recommendations are then placed on the Registry following a consensus vote of both the OSAC subcommittee and the Forensic Science Standards Board.

This presentation will provide updates related to standards development in human forensic biology testing. These include:

- What's new with the ASB DNA Consensus Body
- All published ASB standards and best practices and documents on the OSAC registry
- Documents that are currently being drafted by the Human Forensic Biology Subcommittee of OSAC and those under development by the ASB

To date, ASB has 17 standards and two best practice recommendations published. The OSAC Registry has 14 published standards and 1 best practice recommendation along with 5 proposed standards and best practice recommendations within its repository. An update to these numbers will be provided during the presentation. All published standards and best practice recommendations are available for immediate download at aafs.org/academy-standards-board and from the OSAC Registry. Opportunities for supplemental training related to discipline-specific standards will be presented, as well as additional resources and tools designed to facilitate gap analysis, compliance monitoring, and outreach efforts.

Serology; Forensic DNA; Standards

B68 An Evaluation of Semen Extraction Efficiency and Recovery After Washing From Reusable Period Underwear

Caitlyn Spencer, BS, Virginia Commonwealth University, Hilliard, OH; Sarah Seashols-Williams, PhD, Virginia Commonwealth University, Richmond, VA*

Learning Objectives: The attendees of this presentation will learn about the ability to extract sufficient sperm cells from reusable period underwear in order to develop complete and quality DNA profiles. The attendees will also learn about the persistence of semen in the underwear after washing and any degradation or inhibition that may be present in the developed profiles.

Impact Statement: This presentation will impact the forensic biology community in a positive way by leading to the development of a recommended protocol for the effective analysis of period underwear.

Abstract Text: Various items of evidence for sexual assault cases are submitted to the forensic biology section of a crime laboratory to develop a DNA profile that can identify the perpetrator of the crime, including clothing items like pants, shirts, and undergarments.[1] The type of undergarments as well as the materials they are made up of can make it difficult for a DNA analyst to obtain enough DNA to generate a usable profile. Period underwear are a new class of undergarments and feminine products that women can use during their menstrual cycles or for minor urine leakage. These non-disposable feminine products with absorbance and leak-proof capabilities can be washed and re-worn multiple times.

The research began with the process of cutting open the crotch area of the three period underwear brands (Hanes, Knix, and Thinx) in order to determine the crotch area composition and sperm recovery by layer. Common materials present in the crotch area of all the brands consisted of a moisture-wicking layer, which allowed the underwear to feel dry to the touch, absorbency layers, and a leak-proof layer, which allowed the body fluid to remain in the underwear and not end up on other clothing items.[2-4] The top layers of the crotch area, which are the moisture-wicking and absorbency layers, retained the majority of the cellular material, so all the layers of the crotch area were evaluated together for each brand. Thinx had significantly reduced sperm counts compared to Hanes and Knix (35.90% vs. 82.13% and 74.75%, respectively).

Simulated post-coital samples were placed on the period underwear and evaluated as having not been washed, washed once, and washed twice. All samples were analyzed through the entire forensic workflow, including sperm counts, extraction, quantification, amplification, and capillary electrophoresis. More DNA was recovered from Hanes and Knix than from Thinx, which was congruent to sperm counts. Sperm and DNA yields were analyzed by comparing the post-coital samples to both liquid and swab controls. The ability to obtain sufficient spermatozoa and DNA from the samples were evaluated using profile completeness and peak heights as well as the evaluation of any inhibition or degradation present in the samples. No inhibition or degradation was observed in the samples. Overall, the ability to extract sufficient sperm and DNA from reusable period underwear was present but more significant in the brands Hanes and Knix than from Thinx. Based on the data, we recommend cutting strains through to the leak-proof layer for maximal sperm and DNA yields.

B69 Swab Technology Is Advancing: Are We Putting Research Evidence Into Action?

Jillian Conte, PhD, National Institute of Justice, Peckville, PA; Tracey L. Johnson, MSFS, Department of Justice/Office of Justice Programs/National Institute of Justice, Washington, DC*

Learning Objectives: After attending this presentation, attendees will understand which swab types are best to use for specific evidence types and sources of DNA. Attendees will also be aware of research gaps that exist for studying the use of different swab types for different evidence types.

Impact Statement: This presentation will impact the forensic science community by providing detailed information and graphics that are evidence-based on using different types of swabs to collect biological evidence.

Abstract Text: Forensic biology technology advances quickly: DNA typing technologies are increasing in sensitivity, resolving DNA mixtures is improving, and isolating and targeting of male-specific DNA continues to become more streamlined. However, one part of the forensic biology workflow that has remained relatively unchanged is the type of swab used to collect samples. Swab composition technology has advanced, yet cotton swabs continue to be the primary choice for biological evidence collection.

This research relates the results of a systematic review and analysis to determine which swab types are best for collecting biological evidence. We reviewed research literature and described the results below. An article was included in the review if it is an original research article, discusses more than one swab brand or material, has a forensic focus, and reports data from real-time quantitative Polymerase Chain Reaction (qPCR) or forensic DNA typing. Articles were excluded if they were not primary research (literature/systematic review) or not written in the English language or if the product was a thesis or dissertation. The literature was collected through searches in Web of Science, PubMed, and EBSCO in September 2023. Removal of duplicates and selection of articles was performed in Rayyan. Additional articles were identified through a review of the bibliographies of initially selected articles.

The analysis was organized by substrate (porous, n = 9; non-porous, n = 8) and source of DNA (n = 5). Forty-one substrate-DNA source combinations have been researched, and 13 substrate-DNA source combinations have an identified best-performing swab type. Nylon swabs were the best performing swab for glass-saliva, ammunition-saliva, skin-semen, textiles-touched surface, and leather-touched surface. Cotton swabs were the best-performing swabs for directly on swab-blood, explosive devices-blood, glass-saliva, and ammunition-touched surface. For collection of semen from the vagina and acellular DNA directly on a swab, rayon swabs have performed best. Recovering DNA from a touched drywall surface calls for using a bicomponent fiber swab and a foam swab is best for recovering saliva from wood. Polyester and microfiber swabs were studied throughout the literature and did not perform optimally.

Our study revealed multiple research gaps and trends in the current body of research. There are also several limitations in the study, including heterogeneity of data and selection bias during the literature search and study identification. The primary observations made are that DNA extraction chemistry needs to be considered with swab type, swabs made of the same material do not perform the same when compared to each other, and inter-operator swabbing is not different. This work highlights research gaps that should be addressed for substrate-DNA source combinations and can guide practitioners in making evidence-based decisions on implementing different swab types into their workflow.

Swab; Forensic DNA; Biological Evidence

B70 A Quantitative Assessment of Extraction Efficiencies Obtained From Various Methods and Sample Types

Lauren E. Mullen, MFS, National Institute of Standards & Technology, Gaithersburg, MD; Erica L. Romsos, MFS, National Institute of Standards and Technology, Gaithersburg, MD; Peter M. Vallone, PhD, National Institute of Standards and Technology, Gaithersburg, MD*

Learning Objectives: This presentation will provide attendees with an understanding of the importance of quantitatively assessing the extraction efficiency of a method starting with a known amount of DNA and through the absolute quantitation digital Polymerase Chain Reaction (PCR) offers. Additionally, it will provide information about the statistical significance, if any, that different extraction methods and DNA sample types may have on the subsequent extraction efficiency.

Impact Statement: This presentation will impact the forensic community by providing quantitative data and statistical analyses regarding the significance of an extraction method on the resulting percent yield of extracted and purified DNA. This information can be used to aid forensic laboratories in choosing the most appropriate DNA extraction method for specific sample types to maximize efficiency.

Abstract Text: In order for a forensic Short Tandem Repeat (STR) DNA profile to be obtained from biological samples, a minimum amount of extracted and purified DNA is required. In most cases, this amount ranges from 0.5 to 1.0 nanograms. Certain sample types encountered in forensic laboratories may present challenges when it comes to obtaining the minimum required amount of extracted DNA. These challenges can be compounded when an extraction results in low efficiency, meaning that a large percentage of the genetic material necessary for the downstream forensic DNA typing is lost during the extraction process, which can result in a partial DNA profile.

A variety of studies evaluating the impact of extraction methods on the ability to obtain a full DNA profile are available. In these studies, extraction efficiency is quantified by identifying the number of samples that produced full profiles divided by the total number of extracted samples.[1,2] However, this study aims to focus on the amount of DNA present pre- versus post-extraction to quantify the amount of DNA lost to each method in the hopes of identifying ways in which this can be minimized, as well as to provide a benchmark of average efficiencies attained after extraction for comparison against alternative methods used by a forensic laboratory. Additionally, the data obtained from this study was used to determine if there is a statistically significant difference between the overall recovery of two specified extraction methodologies for three different sample types.

For this study, two methods of DNA extraction were assessed: manual extraction carried out via silica spin columns and automated extraction carried out via silica-covered magnetic beads. Three sources of DNA (human fibroblast cells, whole blood, and extracted DNA) were extracted at nominal concentrations of 50, 20, 10, 5, and 1ng by the two methods. To determine the starting amount of DNA in the whole blood and cells, the method of flow cytometry was used. White blood cell counts were measured by flow cytometry and reported by the blood bank. Cultured cells were counted through flow cytometry measurements at the National Institute of Standards and Technology (NIST). The extracted DNA used was Component A of Standard Reference Material 2372a: Human DNA Quantitation Standard. These values were used to approximate the amount of total cellular DNA tested at each concentration prior to extraction. Dilutions of the starting material were performed to generate each desired concentration. The resulting extracts were quantified with the use of digital PCR with nuclear DNA assays designed and optimized in-house.[3] Preliminary results indicate extraction efficiencies across all quantities of DNA, cell types, and extraction techniques ranging from 34.9% to 99.0%. Human fibroblast cells and whole blood samples were found to have higher efficiencies on average. Further work is being explored to determine any statistical significance regarding the differences observed between cell types, sample concentration, methodologies, and kit chemistries.

B71 Innovative Lab-on-a-Disc Technology for Rapid Differential DNA Extraction in Forensic Science

Beomseok Lee, PhD, ExoDiscovery LLC, Hwasung, Kyonggi-do, Republic of Korea; Kyusang Lee, PhD, LabSpinner Inc., Ulsan-gwangyoksi, Republic of Korea; Beomhee Ahn, Labspinner, Ulsan, Republic of Korea; Hanna Kim, BS, Labspinner Co., Ltd., Ulsan-gwangyoksi, Republic of Korea; Hwanghee Ryu, MS, Labspinner, Hwaseong -Kyonggi-do, Republic of Korea; Myunghee Jang, BS, LabSpinner, Hwaseong-si, Kyonggi-do, Republic of Korea; Yoon-Kyoung Cho, PhD, UNIST, Ulsan-gwangyoksi, Republic of Korea*

Learning Objectives: This presentation will provide attendees with a comprehensive understanding of the lab-on-a-disc principle and its groundbreaking application in differentiating forensic evidence. Participants will explore the fundamental concepts of microfluidic technology in forensic science, delve into the design and operation of a lab-on-a-disc platform for automated differential extraction, and gain insights into the intricate process of separating female epithelial cell DNA and male sperm cell fractions. Moreover, attendees will examine a comparative analysis between the innovative lab-on-a-disc method and traditional manual techniques.

Impact Statement: This research promises to revolutionize the forensic science community by introducing an advanced methodology for differential DNA extraction. The automated lab-on-a-disc platform offers significant advantages, including dramatically reduced processing time, increased accuracy and reproducibility through minimized human error, potential cost savings due to reduced labor requirements, and improved efficiency in processing sexual assault evidence.

Abstract Text: Lab-on-a-disc is an innovative microfluidic technology that consolidates various laboratory functions onto a rotating disc, allowing for automated analysis of biological samples, including sexual assault evidence.[1-5] This sophisticated platform employs a series of miniaturized processes such as mixing, separation, and detection, significantly enhancing the efficiency of laboratory workflows.

In this study, a specialized lab-on-a-disc was developed for differential extraction from sexual assault samples. The disc integrates multiple processes seamlessly, including sample transfer, two-step separation, concentration, and washing. When a pre-lysed sexual assault sample, primarily containing female epithelial cells, is introduced onto the disc, it automatically separates the sample into distinct fractions: cell debris or fabric (contaminant fraction), epithelial cell DNA (female fraction), and sperm cells (male fraction). The sperm cell fraction is subjected to an additional washing step, leading to the retrieval of purified and concentrated sperm cells, which can then undergo lysis and Short Tandem Repeat (STR) analysis.

A comprehensive case study was conducted to compare the lab-on-a-disc method with traditional manual extraction techniques using both mock and actual sexual assault samples. The results indicated that the lab-on-a-disc method yielded comparable or superior quality DNA results while significantly reducing processing time to less than 10 minutes, compared to the 2–3 hours typically required for manual procedures.

This groundbreaking automated platform holds the potential to minimize human error, improve reproducibility, and reduce operational costs by decreasing labor requirements. Additionally, it opens avenues for expanding its application to encompass the entire differential DNA extraction process from raw sexual assault samples, ultimately providing both epithelial cell DNA and sperm cell DNA as final outputs. The adoption of this technology could represent a significant leap forward in forensic science, streamlining processes and enhancing the efficiency and accuracy of DNA analysis in sexual assault cases. By leveraging the capabilities of the lab-on-a-disc, forensic laboratories could improve their response times and the reliability of their analyses, ultimately contributing to more effective justice outcomes.

B72 A New DNA Collection Tool Kit: Bringing Versatility and Flexibility to Analysts

Jamie D. Fredericks, PhD, Eastern Kentucky University, Richmond, KY; Eric Wooldridge, MS, Somerset Community College, Somerset, KY*

Learning Objectives: Attendees will learn about a new novel DNA collection tool that brings flexibility and versatility to DNA analysts. The presentation will demonstrate that the new tool can: (1) increase the amount of DNA recovered from potential evidence samples, and (2) allow multiple attempts of DNA genotyping through Direct Polymerase Chain Reaction (PCR) and traditional methods.

Impact Statement: Our patent-pending novel sample collection products provide a toolkit that can provide versatility and flexibility to DNA analysts. By utilizing storage cards in a manner that can collect a wide range of samples, the tool will be able to reduce the current burdens in DNA analysis.

Abstract Text: The demand for DNA testing continues to grow and has contributed to an ever-increasing backlog of samples that require analysis. Traditional DNA typing encompasses a multi-step process that can take a considerable period of time. A significant amount of investment has been made to shorten the time it takes to generate a DNA profile. Direct DNA amplification (direct PCR) was developed to genotype samples from the source, avoiding the time-consuming extraction and quantitation processes and alleviating backlog issues. However, Direct DNA amplification can be limited by sample type, collection methods used, and regional requirements.

Storage cards, such as FTA Elute cards and Nucleic-Cards, are traditionally used to preserve blood and saliva samples that are provided for diagnostic purposes (clinical and forensics). Research has shown that when storage cards are used in more unorthodox scenarios such as collecting trace evidence, they can improve DNA recovery and analysis. However, when moistened to collect dry samples, storage cards can tear, deform, and lose their integrity.

Our toolkit is designed to provide the end-user with the flexibility to choose the appropriate collection and analysis methods (choosing from direct PCR, traditional, or both protocols) that would increase the likelihood of success. Furthermore, the use of the tool would allow repeat testing as direct PCR methods would not destroy the entire sample. The tools can utilize commercially available storage cards (e.g., Qiagen FTA Elute cards or Copan Nucleic-Cards) to collect samples so they can be analyzed using Direct PCR or traditional methods when required. The toolkit comes with interchangeable platforms that allow for collection from various surfaces (angled/trace) and maintain the structure and integrity of the card, regardless of whether it has been moistened. In addition, an internal water source is available to moisten the card when required, eliminating the potential hazards of manual pipetting and exposure to contamination.

In this study, the collection device was used to collect dry saliva, blood, and mock sexual assault evidence samples that had been deposited on various apparel materials. Our preliminary results show that in comparison to cotton and nylon swabs, the new tool can significantly increase the amount of DNA collected from the biological fluids deposited. When 10µl blood was deposited on cotton, the device was able to recover 0.85ng/µl DNA; in comparison the swab recovered 0.36ng/µl. This trend was observed regardless of whether the fluids were deposited on cotton, polyester, or jean. In addition, our study has demonstrated that analysts can choose between direct PCR or traditional methods. When 10µl of single source biological fluid was deposited, a single storage card from the device (from either FTA Elute cards or Nucleic-Cards) could be used to generate four full STR profiles. Using 1.2mm punches from the cards and direct PCR protocols, full STR profiles were observed using GlobalFiler (Applied Biosystems™) and PowerPlex Fusion 6C (Promega) STR amplification kits; full STR profiles from the STR kits were also observed using the remaining card and traditional methods.

Our patent-pending novel sample collection products provide a toolkit that can provide versatility and flexibility to DNA analysts. By utilizing storage cards in a manner that can collect a wide range of samples, the tool will be able to reduce the current burdens in DNA analysis.

B73 Differential Extractions—Defining the Problem

Robin W. Cotton, PhD, Boston University Chobanian & Avedisian School of Medicine, Boston, MA; Ashley D. Lara, MS, Boston University Chobanian & Avedisian School of Medicine, Revere, MA; Anna M. Berberoglu, MS, Boston University Chobanian & Avedisian School of Medicine, Brookline, MA; Xiaoyu Zhang, MS, Massachusetts State Police Crime Laboratory, Hudson, MA*

Learning Objectives: Attendees will gain a better understanding of why current differential extraction procedures often yield less than ideal results and how to evaluate the success of current procedures and/or apply changes to the current procedures.

Impact Statement: After attending this presentation, attendees will have an increased understanding of why current procedures used for differential extractions often provide less-than-ideal results and how to evaluate the success of current procedures and/or process changes to current procedures. This presentation will impact the forensic community by providing a detailed description of the range of outcomes observed when using differential extraction methods, increasing participants' understanding of the reasons for this variation and by providing examples of how to evaluate the procedures used in their laboratory.

Abstract Text: The original procedure for differential extraction was published in *Nature* in 1985 by Gill, Jefferys, and Werrett in one of a series of papers that introduced the possibilities of the uses of DNA identification.[1] The differential extraction procedure has undergone minor modifications over the years but, from a chemistry standpoint, remains similar to the originally published procedure. The process allows for the consecutive lysis of female epithelial cells (E-cells) and male sperm cells from a sexual assault sample. Thus, the removal of the E-cell lysate is followed by the lysis of sperm cells. Some version of this process is used by most laboratories for analysis of sexual samples. This could be hundreds to thousands of samples per year, depending on the size of the jurisdiction served by the laboratory.

In the process of exploring ways to improve current differential extraction procedures, we found that careful characterization of the samples, the process, and the outcomes was needed. All samples were dried onto cotton swabs, as this is the most common swab type used in Sexual Assault Examination Kits (SAEK). The samples used included swabs with known and unknown amounts of buccal cells, known amounts of sperm, unknown amounts of vaginal epithelial cells (from anonymous donors) ± known amounts of sperm and unknown amounts of cells on post-coital samples. Samples were extracted using the Qiagen EZ1 protocol for differential extraction, with and without modifications, and with an experimental process for differential extractions.[2] For each extraction done, the original swab was recovered from the spin basket and DNA from any cells remaining on the swab was recovered using Acrosolv from MicroGEM Bio.[3] This fraction is referred to as the Material Fraction (MF). All extracts, Epithelial Cell Fraction (EF), Sperm Fraction (SF), and Material Fraction (MF) were quantitated using Quantifiler Trio (Thermo Fisher). Total amounts of male and female DNA in each fraction were calculated based on quantitative Polymerase Chain Reaction (qPCR) results for the Y and small autosomal probes and the volume of each fraction.

The amount of total female DNA per half swab from donor swabs and mock evidence post-coital swabs showed almost a 10,000ng difference from the lowest to the highest amount. The amount of female DNA remaining on the swabs post-extraction and the amount of male DNA remaining on the swab post-extraction was substantial in some samples and maybe donor specific. Procedures to facilitate the release of sperm from the cotton were explored and chosen based on what is known about sperm surface chemistry. Additional time with a protease and higher temperatures facilitated sperm removal from the cotton while not affecting the quality of sperm profiles and reducing the amount of sperm remaining in the MF.

B74 Criminalistics Gone Wild (in the Courtroom)—Human Factors, Activity Level, and Probability, Oh My!

Agnes D. Winokur, PhD, Drug Enforcement Administration, Miami, FL; Tiffany Rodriguez, MS, Bureau of Alcohol, Tobacco, Firearms, and Explosives, Atlanta, GA

Learning Objectives: After attending this presentation, attendees will have gained insight into how forensic reporting and courtroom testimony have been impacted by innovative technologies and new machine learning tools. Specifically, attendees will hear how the different forensic disciplines have been changing and adapting to address current challenges and mitigate biases in reporting and testimony.

Impact Statement: Forensic sciences have long struggled with how to report and testify forensic results in a succinct and comprehensive manner. This panel of experts will explore the challenges in reporting and testifying in today's advanced technological environment in a manner that offers the transparency that the field and public demands.

Abstract Text: In more recent years and with the emergence of technological advances and increased media exposure of the forensic science community, the public has increased its interest and focus in the forensic sciences. As such, there has been an increasing need for practitioners to be more comprehensive in their explanation of tests and results in a court room. More specifically, forensic practitioners are expected to explain the potential for bias in their processes and be well versed in discussing other relevant topics such as how they addressed human factors concerns, the false positives and false negatives of the testing utilized, and the limitations of specific methodology and instrumental techniques.

During this interdisciplinary session, current reporting and court testimony challenges will be discussed, along with recommendations in overcoming those challenges. In addition, attendees will participate in discussions regarding technological advancements and how they are steering future approaches for presenting forensic results in court. The session will be comprised of an interactive panel of forensic experts representing different disciplines to ask and answer questions, provide feedback, and offer different perspectives in how the different disciplines are navigating through the increased public demands for clear, transparent and objective reporting and testimony. Experts from trace, DNA, and seized drugs will discuss how their disciplines have been shedding more light onto the potential limitations of applied methodology in their respective fields as well as the increased participation in collaborative research to explore better ways to objectively report forensic results. In addition, a representative from Jurisprudence will foster an environment of meaningful dialog on how the forensic science community as a whole can address current courtroom testimony challenges that are significantly impacting public perception of forensic sciences. Finally, the panel of experts will answer questions on the potential role that artificial intelligence tools play in helping practitioners meet the increasing needs of law enforcement, medical examiners, and public health agencies.

B75 A Proteomic Analysis of Semen for Human Identification and Body Fluid Classification

Zachary C. Goecker, PhD, National Institute of Standards and Technology, Gaithersburg, MD; Zheng Zhang, MD, National Institute of Standards and Technology, Gaithersburg, MD; Glendon J. Parker, PhD, University of California, Davis, Davis, CA; Stephen E. Stein, PhD, National Institute of Standards and Technology, Gaithersburg, MD; Erica L. Romsos, MFS, National Institute of Standards and Technology, Gaithersburg, MD; Meghan C. Burke, PhD, National Institute of Standards and Technology, Gaithersburg, MD; Peter M. Vallone, PhD, National Institute of Standards and Technology, Gaithersburg, MD; William E. Wallace, PhD, National Institute of Standards and Technology, Gaithersburg, MD*

Learning Objectives: During this presentation, attendees will learn about semen proteomics and the impact of environmental degradation on both forensically relevant DNA and protein markers. Attendees will also learn about mass spectrometry and its use for inferring genotype and body fluid classification.

Impact Statement: This presentation will impact the forensic science community by shifting human identification into a dual DNA-proteomics perspective and will also shed light on circumstances that may require a more proteomics-informed strategy.

Abstract Text: This research explores the prospect of a proteomics approach to semen analysis. Forensic analysis of human semen has historically been conducted under the microscope for body fluid confirmation or using Short Tandem Repeat (STR) analysis for human identification. However, these methods can prove challenging if samples are heavily degraded or if the source of the sample is vasectomized or azoospermic. Unlike DNA, protein has peptide bonds that are more resistant to cleavage, making protein markers potentially good candidates for degraded samples. Furthermore, there are hundreds of proteins in seminal plasma that can be used for human identification and body fluid classification, thereby obviating the requirement of spermatozoa in the semen sample. In terms of human identification from proteomic information, DNA markers can be passed down genetically and can be inferred in the protein sequence. These Genetically Variant Peptides (GVPs)1 offer the prospect of more discriminating analysis, with random match probabilities near 1 in 50,000 from human semen samples. For body fluid classification, there have been a number of studies demonstrating the use of Body Fluid-Specific Peptides (BFPs)2 to body fluid classes such as blood, semen, saliva, and vaginal fluid. However, their utility under degrative conditions is not well understood.

This research focuses on the ability to detect DNA information in the form of STRs and proteomic information in the form of GVPs and BFPs for pristine and degraded human semen. For sample processing, semen was diluted with DPBS buffer and aliquoted into fractions for STR typing and proteomic analysis after manual degradation. For proteomic analysis, a dialysis-based method was used instead of a detergent-based method, as this yielded the largest number of unique peptides. For DNA analysis, samples were extracted using the Qiagen EZ1 DNA investigator kit, qPCR with Quantifiler Trio, and STR typing using Powerplex Fusion 6C. Results from STR analysis of DNA material displayed no apparent degradation after seven days of incubation at 70°C, both in terms of loss of STR alleles and in qPCR degradation index, thereby illustrating how well established and robust STR typing is. For the GVP analysis, 77 GVPs have been identified from pristine seminal fluid. However, after incubation at 70°C for seven days, the number of detectable GVPs reduced to 32. Proteins most resistant to environmental degradation include proteins such as SEMG1 and SEMG2, which function as gel-forming coagulation factors whereas proteins which exhibit the most degradation include MUC5B and PIGR, which function in sperm protection and immunity. Further, BFPs declined from 58 in pristine samples to 34 after seven days of degradation. This resulted in the identification of a robust set of 34 peptides, of which three are unique to humans, that can be used for reliable body fluid classification. Results from site-specific glycosylation analysis reveal that most glycosites from semen glycoproteins consist of the same glycan structure with varying degrees of fucosylation. Further study is being conducted to explore the relationship between these glycans and epigenetic information such as age. Further work is also being explored for ancestral classification using GVPs from semen and determining peptide-specific detectability using extracted ion chromatogram abundances.

Proteomics; Semen; Degradation

B76 An Advanced Nucleic Acid Lateral Flow Assay for Rapid and Sensitive Identification of Human Vaginal Fluid Using Molecular Beacon Technology

Nidhi Subhashini, PhD, SERATEC GmbH, Göttingen, Niedersachsen, Germany*

Learning Objectives: Attendees will learn following: (1) that an alternative method of rapid test exists that is completely protein free and hence highly reproducible, with more weather resistance and shelf life; (2) that a rapid test based on lateral flow assay can be confirmatory and have multiplexing possibilities of up to six different antigens/markers within a single strip that is 6–12mm wide; (3) that with proper focus on science and research, we may utilize micro-RNAs as forensic investigators: and (4) new methods of Gold-DNA conjugation.

Impact Statement: In my presentation, the forensic science community will gain insights about: (1) how criminalistics is very important to understand "'what'" crime took place and '"how"' it was performed; (2) how body fluid identification plays an important role in all forensic investigations and that it needs a special attention for further research and advancements; (3) how we can utilize micro RNAs for development of rapid tests, Nucleic Acid-based Lateral Flow Assays (NALFAs) and that these tests will not be presumptive but confirmatory; (4) how we do not need to rely on 1 or 2 protein markers for rapid body fluid identification. Instead, we can combine up to 6 markers in a single rapid test; (5) we are the first to try and develop a nucleic acid lateral flow assay for vaginal fluid detection(6) we are also the first to reduce the limit of detection to sub picomolar levels; and (7) We also demonstrate for the first time an alternative way of Gold-DNA conjugation in a lateral flow assay.

Abstract Text: The detection of vaginal fluid poses several challenges, particularly in forensic and clinical settings. Key challenges include the lack of specific biomarkers unique to vaginal fluid, rapid sample degradation, small sample volumes, interference from other substances, complex composition, the high cost and time of traditional methods, cross-reactivity, ethical and privacy concerns, and the need for standardization and validation. To address these challenges, we present a protein-free NALFA designed to identify body fluids by leveraging DNA-based rapid tests and molecular beacon technology.

Our approach targets micro-RNAs, enabling the simultaneous testing of multiple antigens within a single assay. The system employs a spot-based rather than a line-based format, utilizing a single gold conjugate for both test and control spots. Multiple reaction zones are situated in separate lanes to prevent cross-reactions, allowing for distinct flow dynamics and reaction times in each lane. This setup ensures optimized conditions and predictable, reproducible sample flow, contributing to the assay's high sensitivity, with detection limits below 1pmol of antigen. The semi-quantitative analysis capability, combined with miniaturization, reduces sample and production material usage, leading to cost-effective and faster overall assay times.[1]

By targeting specific micro-RNAs unique to vaginal fluid, our assay overcomes the challenge of identifying reliable biomarkers. This specificity reduces the likelihood of false positives and increases the accuracy of vaginal fluid detection. The use of nucleic acid-based detection mitigates the issue of sample degradation. DNA and RNA are more stable than proteins, over wider range of temperatures ensuring reliable results even when samples degrade over time. The high sensitivity of our assay allows for accurate detection with minimal sample volumes, addressing the issue of small sample sizes commonly encountered in forensic cases. Our method's specificity for micro-RNAs reduces interference from other body fluids and environmental substances, minimizing false positives and enhancing the reliability of results. By focusing on nucleic acids rather than proteins or other complex components, our assay simplifies the detection process, making it more robust against the complex composition of vaginal fluid. Traditional methods, such as DNA methylation and sequencing, are costly and time-consuming. Our NALFA approach eliminates the need for specialized equipment and skilled personnel, significantly reducing both costs and assay time. Our assay's design allows for standardized protocols that can be easily adopted in various forensic and clinical laboratories, ensuring reproducibility and reliability across different settings.[1]

Using our advanced NALFA approach, we have demonstrated confirmed detection of seminal fluid and vaginal fluid from human samples with no cross-reactivity with blood, saliva, or other frequently tested body fluids. DNA mimics of micro-RNAs were used as antigens for assay development, which was later validated with human samples. Three to four different micro-RNA markers for each body fluid were tested and verified, ensuring robust detection. Given the challenge of vaginal fluid detection in sexual assault cases and crime investigations, our focus includes a detailed discussion on this application.

Our researched and validated approach represents a significant advancement in molecular diagnostics, offering a highly sensitive, rapid, and cost-effective solution for the identification of body fluids. Thus, we provide a streamlined, reliable alternative to current state-of-the-art methods, making it a practical choice for forensic and clinical applications.

B77 Integrating Genetic and Epigenetic Sequencing for Forensic Application in a Single Workflow

Mirna Ghemrawi, PhD, The Center for Forensic Science Research and Education, Horsham, PA; Lindsay L. Kotchey, MS, The Center for Forensic Science Research & Education, Hatfield, PA*

Learning Objectives: Attendees will learn about the advancements in simultaneous genetic and epigenetic sequencing for forensic purposes, the novel methodology developed for integrating genetic and epigenetic analysis into a single workflow, the application of this methodology in forensic profiling ,including age prediction and Body Fluid Identification (BFID), and the evaluation of the efficiency, sensitivity, and specificity of the developed approach through various fluids.

Impact Statement: This presentation will introduce a groundbreaking methodology that integrates genetic and epigenetic sequencing into a single workflow, significantly enhancing forensic profiling. By streamlining processes and combining analyses, this method promises to save time, resources, and sample consumption. This innovation has the potential to revolutionize forensic science, providing more comprehensive and efficient tools for human identification, age prediction, and body fluid identification.

Abstract Text: Epigenetic research has increasingly become crucial in forensic science, aiding in age estimation and BFID. Traditionally, molecular workflows have required separate processes for genetic and epigenetic analyses, leading to increased complexity and resource use. To overcome these inefficiencies, we have developed an innovative methodology that combines both genetic and epigenetic sequencing into a singular, cohesive workflow.

Our approach employs an enzymatic-based library preparation method integrated with hybridization capture techniques, simultaneously targeting core Short Tandem Repeat (STR) loci and CpG markers essential for BFID and age prediction. The library preparation involves multiple steps: hairpin addition, splicing, copy strand synthesis, adapter ligation, protection, deamination, and amplification. We designed 584 custom probes for effective target enrichment, followed by sequencing using the MiSeq FGx platform. A unique bioinformatics pipeline was created to resolve base pair readings (A, T, G, C, and methylated C) using a two-base coding mechanism by comparing R1 and R2 reads, with data interpretation performed via IGV and MixtureAce software.

For validation, blood, semen, buccal, and vaginal fluid samples were collected with informed consent, alongside a control sample. The DNA extracts were sheared to an average length of 250bp using the M220 focused-ultrasonicator (Covaris), enriched with methylation controls, and processed using the Duet multiomics solution +modC (Biomodal).[1] Following library preparation, samples were pooled, captured using Fast Hybridization Target Enrichment (Twist Bioscience), and sequenced on a microflow cell. Our results indicate a high conversion efficiency, with sensitivity exceeding 96% and specificity at 99.8%. We achieved average coverage of 30x for CpGs and up to 10x for most STR loci. The target enrichment process successfully demonstrated differential methylation patterns across the tested body fluids and enabled the acquisition of accurate partial STR profiles.

This groundbreaking research highlights a novel workflow that concurrently sequences STRs and CpGs, signifying a major leap forward in forensic science. By unifying genetic and epigenetic profiling into one streamlined procedure, our method provides a versatile and effective approach that aims to boost the forensic community's analytical proficiency and resource efficiency.

B79 The Identification and Optimization of MicroRNA Biomarkers for Accurate Body Weight Prediction in Forensic Samples

Kimberly L. Lettner, BS, Virginia Commonwealth University, Louisa, VA; Xiaomeng Yang, MS, Virginia Commonwealth University, Richmond, VA; Sarah Seashols-Williams, PhD, Virginia Commonwealth University, Richmond, VA*

Learning Objectives: Attendees will learn about a novel forensic DNA phenotyping approach for accurately predicting body weight class based on the Body Mass Index (BMI) using metabolism-related microRNA markers in DNA extracts from dried whole blood and saliva samples. Attendees will also gain an understanding of how the additional physical descriptive information obtained from this approach can assist in investigating cases with unknown individuals involved.

Impact Statement: This presentation will positively impact the forensic DNA community by introducing useful microRNA markers for accurately predicting the body weight class of unknown individuals, which can be easily integrated into the existing forensic DNA phenotyping panels. This research aims to acquire environmentally impacted phenotypical information from DNA evidence without increasing the sample consumption, time, and resources.

Abstract Text: Accurately profiling unknown individuals from biological samples is crucial in forensic DNA analysis. Conventional Short Tandem Repeat (STR) testing, while effective for direct identification, falls short in cases lacking suspects or database matches. Thus, an alternative method of using DNA evidence is needed to reveal more information about unknown individuals, such as their appearance traits or Externally Visible Characteristics (EVCs). Forensic DNA Phenotyping (FDP) utilizes genetic markers, such as Single Nucleotide Polymorphisms (SNPs), to predict EVCs of an unknown individual, including eye, hair, and skin colors.[1,2] However, predicting body composition, such as body height, weight, and muscularity, remains challenging due to the complex effects of environment and metabolism on genetic markers.

To enhance the capabilities of current FDP, it is critical to explore additional biomarkers like microRNAs (miRNAs), which are small, single-stranded, non-coding RNAs that mediate post-transcriptional gene regulation.[3] Their small size and protection by RNA-binding proteins give miRNAs exceptional stability, making them ideal for forensic samples subjected to long-term storage or environmental degradation.[4,5] Recent biomedical research has analyzed the mechanism of miRNA interference on mRNA and assessed their ability to control gene expression regarding the body metabolism.[6] Moreover, miRNAs responsible for regulating BMI-related genes affected the production of adipose tissue, leading to increased weight and fat percentage.[7] This responsiveness, unlike SNP markers that remain unaffected by metabolism, underscores the potential of miRNA markers for predicting EVCs influenced by environmental factors, including body weight.

This study introduces an innovative FDP approach by exploiting miRNA expression in DNA extracts from blood and saliva samples to predict an individual's body weight class. Our methodology encompasses Bioelectrical Impedance Analysis (BIA) for comprehensive body composition measurement, meticulous sample collection adhering to ethical guidelines, and DNA isolation followed by Reverse Transcription-quantitative Polymerase Chain Reaction (RT-qPCR) for miRNA analysis. Our preliminary studies on dried whole blood DNA extracts showed that the expression of specific miRNA markers, including miR-486-5p, miR-885-5p, and let-7i-5p, demonstrated a positive or negative correlation with body weight. Using statistical models built upon the miRNA data, a 100% accuracy was achieved in predicting body weight categories (underweight, normal, overweight, obese), regardless of ethnicity or biological sex. Saliva, another commonly encountered body fluid type in forensic casework, was collected and analyzed in addition to blood to identify predictive miRNA markers for body weight. An expansion in the size and diversity of the donor population, including various ages, heights, weights, and ethnicities, was conducted to develop and maximize the confidence of our miRNA body weight prediction panel.

In conclusion, our study has shown the close association between body weight and miRNA expression in blood and saliva DNA extracts, highlighting the usefulness of miRNAs in predicting environmentally impacted EVCs beyond traditional FDP markers. This project not only aims to enhance current FDP by incorporating body weight prediction as a ready RT-qPCR miRNA analysis assay, but also seeks to set the stage for adding these validated markers into a commercial forensic high-throughput sequencing panel that is already employed in many forensic laboratories. The ability to detect miRNAs from DNA extracts can also eliminate the need for additional sample consumption and processing time, allowing for easy integration into the current forensic case workflow and more subject identity information for investigators in less time, especially in cold cases, missing-person searches, and victim identification in mass disasters.

B80 Dead or Alive? Biomarker Identification for Postmortem Blood Detection

Amy N. Brodeur, MFS, Boston University, Boston, MA; Tai-Hua Tsai, MS, Lotus Pharmaceuticals, Taipei, Taiwan, Republic of China; Sara C.C. Zapico, PhD, New Jersey Institute of Technology/Smithsonian Institution, Newark, NJ; Gulnaz T. Javan, PhD, Alabama State University, Montgomery, AL; Gabriela Roca, PhD, Seratec GmbH, Goettingen, Niedersachsen, Germany; Christian Stadler, PhD, Seratec GmbH, Goettingen, Niedersachsen, Germany;*

Learning Objectives: After attending this presentation, attendees will consider the possibility of using D-dimer as a biomarker to detect postmortem blood at crimes scenes.

Impact Statement: This presentation will impact the forensic science community by presenting a broad study of the applicability of D-dimer and immunochromatographic tests to identify postmortem blood.

Abstract Text: The detection of hemoglobin and glycophorin A through immunochromatographic tests is currently used to identify blood at crime scenes. However, depending on the forensic scenario, it may be important to determine whether a person was alive at the time of blood deposition. Based on the rapid onset of fibrinolysis after death, this pathway could be considered to identify potential biomarkers for postmortem blood. Fibrinolysis is the natural process that breaks down blood clots after healing a vascular injury. Among the fragments produced in fibrinolysis are soluble fibrin monomers crosslinked between two adjacent outer D domains detectable in plasma, known as D-dimers. Thus, D-dimer could be a potential biomarker for postmortem blood.

SERATEC has developed the PMB immunochromatographic assay to simultaneously detect human hemoglobin and D-dimer. The main goal of this study was to assess the possibility of using the PMB test to detect postmortem blood. Additionally, evaluation of D-dimer levels in peripheral, menstrual, and postmortem blood was carried out, and the ability to obtain Short Tandem Repeat (STR) profiles from postmortem blood was assessed. All postmortem blood samples reacted positively for the presence of hemoglobin using the SERATEC PMB tests, and all but one degraded sample showed a positive result for D-dimer. All peripheral blood samples from living individuals showed positive results for hemoglobin and negative results for D-dimer detection, except for one liquid sample with a weak positive, probably due to a previous blood condition. Menstrual blood samples gave positive results for hemoglobin but variable results for D-dimer. The DIMERTEST Latex assay was used for semi-quantitative measurement of D-dimer concentrations, with postmortem and menstrual blood yielding higher D-dimer concentrations compared to living peripheral blood. Full STR profiles were developed for all postmortem samples tested except for one degraded sample, pointing to the possibility of not only detecting postmortem blood at the crime scene but also the potential identification of the victim.

B82 The Recovery of Probative aSTR and Y-STR Profiles From Single or a Few Micromanipulated Sperm Cells

Morgan S. Peters, MS, University of Central Florida, Orlando, FL; Kaitlin Huffman, PhD, Department of Justice/FBI, Fredericksburg, VA; Erin Hanson, PhD, University of Central Florida, Orlando, FL; John Ballantyne, PhD, University of Central Florida, Orlando, FL*

Learning Objectives: This presentation will provide attendees with an understanding of our sperm cell micromanipulation and genotyping methodology. This includes single sperm cell collection, direct sperm cell lysis, genetic analysis methods suitable for the low template DNA in sperm cells, and the application of probabilistic genotyping to both single source and mixture sperm samples.

Impact Statement: Potential impact on the forensic science community by sperm micromanipulation prior to DNA analysis would be to improve the recovery of probative genetic information from the male perpetrator(s) in challenging multiple semen donor sexual assaults. By isolating individual sperm cells for direct lysis and amplification, this approach avoids the loss of valuable sperm DNA while simultaneously avoiding mixtures of the multiple male semen donors and victim DNA. This approach for single sperm genetic analysis could also be applied to late-reported sexual assault, historic and remnant samples, as well as those from multiple sperm contributors.

Abstract Text: The ability to recover an autosomal STR (aSTR) profile of a semen contributor relies on the separation of sperm DNA from epithelial DNA. However, the sperm cells present in samples from delayed reported assaults can be weakened by prolonged exposure to the cervico-vaginal environment, which can result in premature sperm cell lysis to produce a sperm-epithelial DNA admixture. Because of this, it is typically not possible to recover aSTR profiles from samples collected 48–72 hours after a sexual assault using standard extraction and analysis methods, as the sperm DNA may be masked by the abundance of victim DNA.[1-3] For these samples, Y-chromosome STR (Y-STR) analysis is often used subsequent to aSTR analysis, as this approach preferentially amplifies the Y-chromosome. Y-STR profiles can provide useful investigatory leads, but unfortunately do not hold the same statistical weight as aSTR profiles.

We hypothesize that some of the limitations of standard sexual assault sample analysis can be overcome by using simplified micromanipulation to preferentially select rare individual or few sperm cells for direct lysis and amplification. We have previously demonstrated the successful application of our micromanipulation approach to epithelial cells.[4-12] In this study, we optimized and applied our micromanipulation methodology to sperm. This simplified approach utilities a water-soluble adhesive on the tip of a needle to collect individual sperm cells for direct transfer into a lysis solution. Following direct lysis, samples undergo a modified STR amplification, suitable for low template DNA samples.

Y-STR and aSTR analysis was performed on subsamples containing 1–5, 10, and 25 sperm cells collected from five semen donors. Each cell subsample was evaluated using five replicates, with a consensus profile generated from the replicates. For single cell aSTR analysis, the maximum allele recovery was 50% due to the haploid nature of sperm cells. For single cell replicates an average of ~20% recovery was achieved with a maximum recovery of 47%. Average allele recoveries for 2–5 cell replicates ranged from ~47–73% (with increasing percentages observed with increasing cell number). For 10 and 25 sperm cells, recoveries of 86.7%, and 99.0% were observed, respectively. Additionally, this method was applied to simulated sperm-epithelial cell (buccal and vaginal) admixtures with single source aSTR profiles obtained from collected sperm cells.

A similar trend was obtained for Y-STRs with average percent recoveries of ~13–65% for 1–5 cell subsamples, 78% for 10 cells, and 94% for 25 cells. A maximum of 92% recovery was achieved from a single sperm, with all other cell inputs having replicates resulting in full profiles. Compared to aSTR samples, greater variability in recovery was observed for Y-STR analysis, which can be attributed to only 50% of sperm cells containing a Y-chromosome. In addition to standard Y-STR analysis, Y-Targeted Pre-Amplification (Y-TPA), an in-house-developed nested Polymerase Chain Reaction (PCR) approach, was used for enhanced Y-STR analysis of single sperm cells. This resulted in an improved average allele recovery of ~25% and a maximum recovery of 100%. When applied to simulated sperm-epithelial cell admixtures, probative partial Y-STR profiles were recovered through use of Y-TPA.

Probabilistic genotyping was employed to further improve the recovery of aSTR DNA profiles from single sperm. The database matching and sample-to-sample matching features of FaSTR were used to successfully cluster single sperm aSTR profiles to specific donors. Once clustered, probabilistic genotyping replicate analysis (STRmix) was conducted, resulting in highly probative LRs and diploid STR profiles from each of the donors, potentially suitable for reference database searching. This PG approach was used to recover single source aSTR DNA profiles from complex 2–4-person semen mixtures.

Forensic DNA; Single Cell; Probabilistic Genotyping

B83 The Humanitarian DNA Database (HDD): An Update

Michael D. Coble, PhD, University of North Texas Health Science Center, Ft. Worth, TX; Melody Josserand, MS, Center for Human Identification, University of North Texas Health Science Center, Fort Worth, TX; Erika Ziemak, MS, Center for Human Identification, University of North Texas Health Science Center, Fort Worth, TX*

Learning Objectives: Attendees of this presentation will learn about the HDD, a resource at the Center for Human Identification (CHI) at the University of North Texas Health Science Center at Fort Worth for associating missing and unidentified human remains in the United States (Texas) with families living outside of the United States.

Impact Statement: This presentation will discuss the potential to increase the identification of missing and unidentified remains using a collaborative effort to associate family references outside of the United States to DNA profiles discovered and genotyped in Texas by the Center for Human Identification.

Abstract Text: Due to the increase of global migration, Missing Person (MP) and Unidentified Human Remains (UHR) deceased person cases can have a cross-border impact. Often these cases are difficult to resolve in a national DNA database system. CHI at the University of North Texas Health Science Center at Fort Worth in collaboration with the Federal Bureau of Investigation (FBI) have developed the HDD to assist with the identification of deceased non-United States citizens recovered in the United States.

Conceptualized in 2018 in response to the challenges encountered by international agencies and non-governmental organizations in identifying deceased individuals recovered along migration routes in the Southwestern region of the United States, the building of the database was initially slowed due to the COVID-19 global pandemic.

Operated by CHI and supported by the FBI's Combined DNA Index System (CODIS) software, the HDD enables family references voluntarily contributed by foreign nationals to be compared to genetic information from unidentified, deceased individuals. The HDD database is air-gapped (an information technology term referring to isolation of a computer from any form of the internet) and contains DNA profiles from UHRs in Texas processed at CHI. With permission from the FBI, CHI can accept reference profiles that were generated by non-CODIS laboratories, including those from outside of the United States and search them in the HDD. The laboratories providing these profiles must meet certain quality criteria established by CHI and the DNA data must be reviewed by CHI prior to searching.

Allowing for the searching of DNA profiles generated by other laboratories in the HDD allows for potential associations to be made that would have not otherwise occurred and is being done in a humanitarian effort to provide closure to the families of missing persons. This is of particular interest with regard to unidentified human remains found along the Mexico-United States border.

In addition to the outreach and collaboration with international and non-governmental agencies for this effort, CHI is also the recipient of a grant from the United States State Department entitled *Reducing Human Trafficking Through Forensics in Central America* that involves the provision of technical and legislative support to countries in Central America. Countries in Central America have been significantly impacted by human trafficking and forensic DNA is an investigative tool that can assist the laboratories and governments within these countries to help combat it. While forensic DNA has not traditionally been viewed as a means of combatting human trafficking, the ability to properly develop, expand, and maintain DNA databases will add tremendous value in Central America, specifically Guatemala, El Salvador, Honduras, Panama, Costa Rica, and Belize. As a result of this grant, family reference profiles that were developed at the Instituto Nacional de Ciencias Forenses, which is the national DNA laboratory in Guatemala, are being shared with UNTCHI for searching in the HDD.

We will present an overview of the process to establish the HDD and present metrics on the successes of searches from the inception. We will also discuss future possibilities for the HDD.

Forensic DNA; Missing Persons; Unidentified Persons

B84 When You Come to a Fork in the Road, Recognize It: Mapping the FIGG Decision-Making Landscape

Colleen M. Fitzpatrick, PhD, Identifinders International LLC, Fountain Valley, CA; Valerie Mattimore Fuller, PhD, Identifinders International LLC, Sapulpa, OH*

Learning Objectives: Upon attending this presentation, attendees will come to recognize the decisional complexities involved with Forensic Investigative Genetic Genealogy (FIGG). Case studies will illustrate lessons learned, while others will prompt discussion by leaving open questions. Attendees will be guided through the FIGG process map of exactly where data-driven decision-making ends and data-absent gaps and risks begin.

Impact Statement: This presentation will impact the forensic science community by raising awareness of the need for responsible and ethical development of a standardized FIGG laboratory pipeline, while at the same time allowing for innovation and exception.

Abstract Text: FIGG has revolutionized the world of human identification but, with the revolution, has come the responsibility to recognize where data-driven decision-making ends and data-absent risks begin.

Standardization of FIGG is in its infancy. Policy is advancing. The majority of FIGG cases can and do follow a more or less defined path, but certain types of cases still challenge our decision-making efforts along that path toward a best outcome. Is a case a violent offence, an Unidentified Human Remains (UHR), or a threat to public safety? What if none of the above, but maybe? Can it still comply with the FIGG database terms of service? Also consider those tough cases that have precious little evidence remaining. Because blind spots exist in the FIGG pipeline, we must still rely on technologies designed for use with Short Tandem Repeat (STR) systems, so that we may find ourselves without the data required to take informed risks. A sample that is judged useless for STR analysis may actually be the best sample for FIGG, but how can we know? Suppose that sample is the last hope of solving a case? How do we weigh the risks of consuming the sample versus waiting for technology to improve? Once the decision is made to proceed, how do we determine which Single Nucleotide Polymorphism (SNP) processing method, if any, is best without data that characterizes the full range of outcomes? And how do we regulate the decision-making path without excluding innovation and exception? In this talk, we present case studies that illustrate the decisional complexities involved with FIGG. Some case studies represent lessons learned, while others leave us with open questions. The focus of this talk is to describe the current FIGG landscape to reveal where data-driven decision-making ends and data-absent risks begin.

Forensic DNA; Pipeline; Method Development

B85 Building Branches: Navigating Practical and Ethical Considerations for the Responsible Use of Forensic Investigative Genetic Genealogy (FIGG)

Claire L. Glynn, PhD, University of New Haven, West Haven, CT*

Learning Objectives: After attending this presentation, attendees will gain insight into the key steps in the FIGG workflow and how existing policies, guidance documents, and state legislation form responsible and ethical frameworks for conducting FIGG investigations.

Impact Statement: This presentation will impact the forensic science community by serving as guidance for those either beginning to implement FIGG or already conducting FIGG within their agencies/departments.

Abstract Text: FIGG combines the fields of forensic genetics with genetic genealogy and traditional genealogical research to generate investigative leads in criminal investigations, namely violent crimes (homicide and sexual assault) and the identification of Unidentified Human Remains (UHRs). It is estimated that FIGG has helped generate investigative leads in at least 1,000 case investigations in the United States in recent years.

FIGG traverses both the public sector and the private sector, with federal and state agencies and local departments developing in-house FIGG units/programs, and private companies offering FIGG services. Robust training and education in FIGG should equip analysts/practitioners with the core competencies necessary to interpret complex genetic data, understand genealogical methodologies, and navigate the ethical and legal implications involved. As this novel tool makes use of consumer DNA databases and goes beyond routine Short Tandem Repeat (STR) analysis of evidence samples, appropriate precautions, policies, and procedures must be developed and followed to safeguard individual privacy and uphold ethical standards when FIGG is implemented in forensic workflows. The intersection of privacy, ethics, and legal boundaries demands rigorous scrutiny, particularly as the field of FIGG continually evolves rapidly. A balance between leveraging genetic data to advance criminal investigations and respecting the privacy rights of all parties is attainable if all stakeholders make a commitment to adhering to best practices for maintaining transparency and accountability in FIGG investigations.

This presentation will address key steps in the FIGG workflow to include, but are not limited to, case qualification and triaging, use of public genetic genealogy databases, third-party DNA testing, privacy and protection of data, case reporting, and oversight. This presentation will highlight the importance of comprehensive training and education, continuous professional development, and interdisciplinary collaboration to enhance the accuracy and integrity of FIGG investigations. In addition, existing policy (e.g., the United States Department Of Justice [DOJ] interim policy), guidance documents (e.g., from the National Technology Validation and Implementation Collaborative [NTVIC] FIGG working group), and state legislation (e.g., Maryland, etc.) will be discussed. Attendees will gain insights into developing policies and procedures that protect both individual privacy and the integrity of the investigative process, ensuring that the application of FIGG adheres to sound science, legal requirements, and ethical principles.

Forensic DNA; Genealogy; Ethics

B86 Down the Rabbit Hole—Now Up a Tree: Solving Cold Cases Using Forensic Investigative Genetic Genealogy at the New York City Office of Chief Medical Examiner and the Queens District Attorney's Office

Lisa Mertz, MS, Office of Chief Medical Examiner, New York, NY; Karen L. Ross, JD*, Queens District Attorney's Office, Kew Gardens, NY*

Learning Objectives: In this presentation, attendees will gain a broader understanding of the importance of technological advancements, such as Familial Searching (FS) and Forensic Investigative Genetic Genealogy (FIGG), in solving cold cases. The lack of a hit of an unknown evidence profile to an individual or a suspect in the Combined DNA Index System (CODIS) is no longer the end of the road for a cold case but is rather another step along the path to justice.

Impact Statement: Attendees will learn the importance of collaborative efforts among law enforcement agencies to successfully solve cold cases. These collaborations are especially important for DNA laboratories, such as the New York City Office of Chief Medical Examiner (OCME), that do not currently perform FIGG testing due to limited resources. They will come to understand the challenges faced when subjecting older evidence to FIGG and FS testing and be taught strategies to overcome these obstacles.

Abstract Text: This presentation will highlight how, within the past 15–20 years, successful technological advances in forensic science have resulted in solved cold cases. Testing of crime scene evidence was once limited to serological testing. Today, however, we can associate these biological fluids with an individual through the development of a DNA profile and provide evidence to a jury that can positively associate someone to crime scene evidence or exonerate the innocent. This presentation will also demonstrate how FS and FIGG testing can be used to identify previously unidentifiable DNA profiles and enhance a prosecutor's ability to investigate and prosecute a cold case.

FIGG and FS testing requests by police departments and District Attorney's offices have steadily increased over the years, due to the volume of successful resolutions of cold cases. Many law enforcement agencies have obtained cold case grants and funding that has enabled them to seek FIGG and FS testing, even if their forensic laboratory does not have such monetary resources. The presenters will discuss the successful partnership between the Queens District Attorney's Office and the OCME that has enabled the testing to be effective. We will discuss the difficulties and complexities that arise when dealing with old cases. We will discuss the workflow and teamwork that is needed to prepare cold cases for FIGG and FS testing, both at the DAs office and in the forensic laboratory. Last, we will highlight a cold case solved using FIGG testing. This solved cold case is the first arrest and prosecution of a FIGG case in New York City and came to pass 45 years after the crime was committed. Despite what many people believe, cold cases aren't too cold or too old to investigate and prosecute.

This presentation will inspire the forensic community to continue its efforts to bring much needed answers to families and loved ones whose lives remain forever impacted by the senselessness of crime. The successful processing of cold cases illustrates how forensic science can, through the development and deployment of new technologies, continue to serve the criminal justice system and our society.

Genealogy; Forensic DNA; Collaboration

B87 The Development of Artificial Single Nucleotide Polymorphism (SNP) Data for Investigative Genetic Genealogy (IGG) Research and Training: A Preliminary Study

Jessica E. Whitney, MS, West Virginia University, Morgantown, WV; Keith B. Morris, PhD, West Virginia University, Morgantown, WV; Aldo Romero, PhD, West Virginia University, Morgantown, WV*

Learning Objectives: After attending this presentation, attendees will understand how high-quality human SNP data, specifically concerning those markers analyzed in IGG databases, can be synthesized using artificial intelligence methods, in particular deep neural networks. Attendees will also be introduced to an alternative to human data for practitioner training as well as optimization of Identical-By-Descent (IBD) detection and matching algorithms across varying population structures.

Impact Statement: This presentation will provide the forensic community with a Convolutional Neural Network (CNN) architecture that can learn the haplotypic structure of human SNP data efficiently to generate high-quality artificial samples. With synthetic SNP profiles, IGG practitioners have a surrogate for protected human data that is flexible and can be used as a training resource, contributing to the need for the development training materials for forensic genealogical familial matching statistics identified by the Organization of Scientific Area Committees (OSAC) Human Biology subcommittee as of October 2021.

Abstract Text: IGG is a relatively new technique for identifying suspects of violent crime and unidentified human remains.[1] It employs a combination of traditional genealogical research strategies with genetic testing of SNP markers. Such markers are used to capture the genetic variation between individuals and trace familial lineages by means of IBD detection and matching algorithms.[1-3] The longer segments of shared DNA-IBD that are present, the more closely related two individuals are, following the rules of genetic inheritance.[2,3]

Our central hypothesis is that when inbreeding is found within a family tree (e.g., multiple relationships and pedigree collapse) or a population (e.g., endogamy), it will artificially elevate the background levels of IBD segments, resulting in relationship misclassification between two or more individuals.[1,4] This hypothesized effect was observed in 2020 by Thomson et al., and the measure of coancestry was the subject of numerous statistical computations described as early as the 1920s.[4,5]

Given the increase in the number of cold cases resolved with the aid of IGG, it is necessary that the methods applied accurately classify relationship states and clearly report the significance of those relationship predictions.[6-9] As far as can be determined, there is little, if any, existing literature that provides a comprehensive assessment on the effect of inbreeding on background IBD in IGG searches. To achieve such an aim, IBD detection and matching algorithms will be trained on known, non-inbred individuals. Data from an inbred population will be subsequently analyzed and the relationship classification performance assessed for different degrees of inbreeding. However, each of these objectives necessitates extensive sampling of human subjects and accurate genealogical records. Therefore, our strategy was to develop a dataset of realistic, yet artificial, human SNP data, allowing greater flexibility in downstream experimental design.

For this presentation, artificial SNP profiles were simulated in RStudio® for the length of SNPs in an Ancestry® DNA profile and used to assemble an outbred family tree spanning four generations. The family tree included twelve individual profiles categorized into two groups, viz., the two founders and the spouses of their descendants, as well as all the direct descendants of the two founders. For all union couples, direct descendants were generated by programming for genetic recombination in RStudio®. To assess a relative recombination rate for realistic fragmentation of inherited SNPs, pairwise comparisons of the proportion of shared DNA were performed for all relationship states through analysis in GEDmatch® . For all pairwise comparisons of the individuals, the measured centimorgan values were observed to fall within predicted shared IBD ranges for all relationship states. To produce realistic profiles, a dataset of up to 100 artificial human SNP profiles for a single chromosome was produced using a convolutional variational autoencoder (VAE) programmed in Python® by using PyTorch.[10, 11] The network was trained on publicly available data from the 1000 Genomes Phase 3 dataset which includes 2,504 individuals spanning 26 populations.[11-13] For each generated profile, the SNPs were pruned to include only those markers present within both the 1000 Genomes Phase 3 dataset and an Ancestry® DNA profile, preserving SNP

B88 The Coldest Cold Case in Croatia: The Body in the Chest Freezer

Tina Smoljanović, BASc, Forensic Science Centre "Ivan Vučetić," Zagreb, Bjelovarsko-Bilogorska, Croatia; Hrvoje Senješ, MAS, Ministry of the Interior Croatia, Zagreb, Grad Zagreb, Croatia; Jerković Ivan, PhD, University Department of Forensic Sciences, University of Split, Split, Splitsko-Dalmatinska, Croatia*

Learning Objectives: After attending this presentation, the participants will gain insight into circumstances that hamper further progress in investigation, leading to a case becoming cold. They will also understand the complexity when the case is opened with new leads and the importance of comprehensive recovery, collection, and forensic examination of sensitive evidence that may have degraded over time.

Impact Statement: This presentation will impact the forensic science community by demonstrating investigative actions in the case reopened after 14 years, particularly regarding the successful recovery and identification of a fingermark from a frozen storage environment and DNA mixtures analysis. The consideration of the case specifics and approach demonstrated this case may improve professionals' methods for managing cold cases and handling and analyzing evidence recovered many years after a crime has been committed.

Abstract Text: Cold cases are considered those cases where further progress could not be made due to a lack of evidence, leads, and/or omissions in the initial investigations, resulting in long-time inactivity.[1] As time goes by, the probability that the case will be solved decreases as evidence degrades, witnesses' memories fade, and suspects become more challenging to locate.[2] However, turnarounds, like new clues or evidence, can sometimes reopen the investigation.

This presentation will demonstrate investigative actions and forensic examinations in a case reopened with new evidence after 14 years, emphasizing the successful recovery and identification of a fingermark frozen for at least 19 years and the crucial role of mixed DNA profiling.

The case study begins in the summer of 2005, when a mother reported her daughter missing, with no contact since 2000, except for her sister, who claimed she was abroad and out of touch. Police found the missing person's mobile phone and outdated documents at the family home, casting doubt on the sister's story. Despite multiple interrogations, the case remained unsolved for years.

In February 2019, the daughter of the suspect and her partner decided to remove an old freezer in the family home that had remained unopened for years. When they opened the freezer and began emptying it, the partner cut open a black bag inside and discovered human remains, specifically legs and female genitalia, and called the police.

Upon scene examination on February 16, 2019, it was determined that the freezer had been sealed with a cyanoacrylate-based adhesive, which was confirmed by chemical and physical examination. Inside the freezer, the body was found unclothed, wrapped in a colorful sheet, along with black plastic garbage bags. Continuing the investigation at the pathology department where the freezer and the body were transported, it was found that the body was wrapped in various materials, including black nylon bags and stockings, with blood stains on the coverings and around the neck. The autopsy revealed 5–6 blunt force injuries on the left side of the face and forehead, with no defensive wounds.

In the Forensic Science Center, the victim's identity was confirmed through a fingerprint match from the right index finger of the unidentified body and the fingerprint collected to issue an ID card. Three fingermarks were developed by cyanoacrylate fuming on PVC bags and rubber glove fragments, out of which only one, found on the black plastic bag wrapped around the victim's head, was suitable for identification. Upon examination, it was proved that fingermark originated from the suspect's (victim's sister's) right thumb. DNA analysis of swab samples from the nylon stockings used to tie the plastic garbage bag around the legs revealed a mixed DNA profile that could be attributed to the deceased and her sister.

After considering all the evidence and establishing the facts, the court found the accused guilty of murder and sentenced her to 15 years in prison. In the presented case, the fingermark was recognized as the oldest one identified in Croatia and, globally, one of the rare instances where a fingermark was successfully recovered from a frozen storage environment after many years.

Cold Case; Fingerprint Identification; Forensic DNA

B89 A 2025 Update From the Scientific Working Group for the Analysis of Seized Drugs (SWGDRUG)

Jaclyn Iera, PhD, Drug Enforcement Administration, Springfield, VA*

Learning Objectives: The goal of this presentation is to provide a summary of the most recent activities and work products developed by SWGDRUG.

Impact Statement: SWGDRUG supports the development of internationally accepted minimum standards for forensic examination of seized drugs, identifies best practices within the international community, and provides resources to help laboratories meet these standards.

Abstract Text: SWGDRUG was formed in 1997 in a joint effort between the United States Drug Enforcement Administration (DEA) Office of Forensic Sciences and the Office of National Drug Control Policy (ONDCP). SWGDRUG works to improve the quality of the forensic examination of seized drugs and to respond to the needs of the forensic community by supporting the development of internationally accepted minimum standards, identifying best practices within the international community, and providing resources to help laboratories meet these standards. This presentation will provide attendees with information on SWGDRUG activities during the past year.

The SWGDRUG core committee members met in the summer of 2024 and approved the most recent version of the SWGDRUG Recommendations, version 8.2, which includes minor revisions to PART II (*Education and Training*), PART IIIA (*Methods of Analysis/Sampling Seized Drugs for Qualitative Analysis*), and PART IIIB (*Methods of Analysis/Analytical Scheme for Identification of Drugs or Chemicals*). Revisions in these sections address virtual training, options for sampling when negatives are encountered, and the use of validated methods in an analytical scheme. The most significant revision in version 8.2 of the core recommendations occurs in PART IVB (*Quality Assurance/Validation of Analytical Methods*) and associated definitions in the Annex. Revisions include information on the performance characteristics to be evaluated during the validation of both qualitative and quantitative methods. In addition, revisions to Supplemental Document SD-7 (*Methods of Analysis/Analytical Scheme for Identification of Drugs or Chemicals - Construction of an Analytical Scheme*) to include examples of analytical schemes for clandestine laboratory evidence were also completed. SWGDRUG also hosted its first webinar at the start of 2024.

Future work for the committee will involve the revision of the currently existing Supplemental Document SD-2 (*Validation of Analytical Methods*), revisions to SD-2 to incorporate sampling scenarios when negatives results are encountered, guidance on policies for cease testing and reporting procedures, structural elucidation procedures, and additional webinars and presentations.

This presentation will also summarize recent updates on multiple SWGDRUG resources such as the MS library, IR library, and Drug Monographs.

The SWGDRUG core committee includes representatives from regional, national, and international forensic organizations; educators, practitioner and scientists from the United States; and representatives from the European Network of Forensic Science Institutes (ENFSI), the Iberoamerican Academy of Criminalistics and Forensic Studies (AICEF), the Asian Forensic Science Network (AFSN), the Australia New Zealand Forensic Science Society (ANZFSS), the Canada Border Services Agency (CBSA), and the United Nations Office on Drugs and Crime (UNODC).

B90 Reference-Free Identification of Fentanyl Analogs

Tom Metz, PhD, Biological Sciences Division, Pacific Northwest National Laboratory, Richland, WA; Katherine Schultz, MS, Pacific Northwest National Laboratory, Richland, WA; Adam Hollerbach, PhD, Pacific Northwest National Laboratory, Richland, WA; Christopher Harrilal, PhD, Pacific Northwest National Laboratory, Richland, WA; Dylan Ross, PhD, Pacific Northwest National Laboratory, Seattle, WA; Danielle Ciesielski, PhD, Pacific Northwest National Laboratory, Richland, WA; Yehia Ibrahim, PhD, Pacific Northwest National Laboratory, Richland, WA; Simone Raugei, PhD, Pacific Northwest National Laboratory, Richland, WA; Bobbie-Jo Webb-Robertson, PhD, Pacific Northwest National Laboratory, Richland, WA; Robert Ewing, PhD, Pacific Northwest National Laboratory, Richland, WA*

Learning Objectives: In this presentation, the audience will learn details on the following: (1) limitations of the current analytical paradigm for Mass Spectrometry (MS) -based identification and quantification of small molecules (<1,000 Da): (2) a new MS-based workflow for identifying small molecules without reliance on reference materials and including advanced multi-dimensional analyses coupled with computational predictions of measured molecular properties; and (3) demonstration of the new workflow in reference-free identification of fentanyl analogs.

Impact Statement: This presentation will introduce new MS-based experimental and computational capabilities for reference-free identification of small molecules. The integrated workflow is demonstrated in reference-free identification of fentanyl analogs within a chemical space of two billion possible analogs.

Abstract Text: Fentanyl and other synthetic opioid-related deaths have outpaced all other overdose-related deaths in the United States. This situation is exacerbated by the continuous development of new compounds by clandestine manufacturers to avoid detection. Conventional MS-based methods used in forensic toxicology and criminalistics laboratories require comparing experimental data from sample analysis to similar data obtained from the analysis of pure reference compounds. With the potential for ~1,012 analogs, the reliance on authentic reference compounds is not realistic for efficient interdiction of novel fentanyl analogs.

The *m/q* Initiative at Pacific Northwest National Laboratory is developing capabilities for MS-based reference-free identification of existing and emerging fentanyl analogs, including: (1) prediction and prioritization of novel fentanyl analog structures, (2) prediction of experimental observables such as ultra-high precision molecular Collision Cross Sections (CCS), fragmentation spectra and infrared ion spectra, and (3) new multi-dimensional experimental capabilities, such as Structures for Lossless Ion Manipulations (SLIM) coupled with Orbitrap MS and SLIM coupled with cryogenic infrared ion spectroscopy and MS.[1-3] Through combinatoric analysis, we generated ~two billion fentanyl analogs that were prioritized based on predicted risk and ease of synthesis, with validation performed on a hold-out set of molecules. For these, ultra-high precision CCS calculations were performed using the HP-Ω tool, and Tandem Mass Spectrometry (MS/MS) spectra predicted using the graph neural network tool QC-GN2oMS2.[2] A mixture of the validation molecules was analyzed using the novel SLIM-Orbitrap, with experimental values compared to predicted values. Calculated CCS values showed errors ≤2% compared to measured values, and the average cosine similarity for predicted high-resolution MS/MS spectra was 0.82 when using fentanyl-focused training data. From SLIM-Orbitrap analyses, we report multi-dimensional signatures correlated to gas-phase molecular conformations diagnostic of fentanyl analogs.[3] All nine fentanyls in the mixture exhibited two IMS peaks that fragment differently, and the intensities of the two IMS peaks changed as a function of water concentration.

Together, these experimental results strongly suggest that all the fentanyls we studied exhibit two gas-phase protomers, and it seems likely all fentanyls will exhibit two protomers. Further, these multi-dimensional signatures can all be computationally predicted with high accuracy and serve as a pattern of features for confident identification of true fentanyls. Finally, to evaluate the integrated experimental and computational capabilities in a blinded analysis of fentanyl analogs, we measured a fentanyl mixture using SLIM-Orbitrap and SLIM-cryoIR-MS and compared the experimental data to predicted data for the two billion fentanyl analog chemical space. A workflow was developed to down-select the fentanyl analog chemical space based on matching predicted data to experimental data, resulting in an average of five candidate fentanyl structures per experimentally measured analog.

This work was funded by the *m/q* Initiative, under the Laboratory Directed Research and Development (LDRD) Program at Pacific Northwest National Laboratory (PNNL).

Mass Spectrometry; Reference-Free Identification; Fentanyl

B91 Using Chemical Profiling and Chemometrics for Predictive Fentanyl Geographic Associations

Agnes D. Winokur, PhD, Drug Enforcement Administration, Miami, FL*

Learning Objectives: After attending this workshop, attendees will: (1) be able to better understand the challenges associated with associating fentanyl cases to each other and to geographic locations in seized drug analysis; (2) be able to describe the advantages and limitations of three chemometrics algorithms; and (3) be able to explain how chemical profiling and chemometrics can be used in support of forensic science intelligence investigations.

Impact Statement: This workshop will benefit the forensic science community by highlighting how algorithms can be applied to chemical profiles of fentanyl seized drug samples and build predictive models to associate and classify samples and determine potential geographic origins.

Abstract Text: Qualitative and quantitative data from Gas Chromatograph/Mass Spectrometry (GC/MS), Gas Chromatography/Flame Ionization Detection (GC/FID), and Fourier Transform Infrared (FTIR) spectrophotometry from chemical analysis of seized fentanyl samples (n=439) was used to evaluate the potential of developing chemical profiles to associate the fentanyl samples to specific geographic locations. Data from chemical compounds within these fentanyl samples (additives, excipients, contaminants, etc.) were normalized and clustered by location. The combinations of reported compounds and their relative concentrations resulting in chemical profiles for each of the fentanyl samples were insufficient to associate samples to a given geographic location for the purpose of creating a predictive model. However, the data show that chemometric models offer an approach to the classification of fentanyl samples, including limited geographic clusters, based on their chemical profiles.

An evaluation of the raw chemical data using three chemometric algorithms: the linear Partial Least Squares Discriminant Analysis (PLSDA) method, Artificial Neural Networks Discriminant Analysis (ANNDA), and Support Vector Machines Discriminant Analysis (SVMDA) were used to classify fentanyl samples to a specific geographic location. The objective of this study was to demonstrate the potential of using chemical data of fentanyl samples to build algorithms to predict geographic origin. The performance of the three algorithms were evaluated and presented for fentanyl samples (n=198). SVMDA was found to be better at dealing with non-linear relationships when compared to PLSDA. SVMDA generated the best predictive model by correctly associating 95% of the samples to the geographic location of the seizure. While the best results were for Class "C" as expected, it was surprising to see good predictive results for Class "A," which only had 13% of the data points. The best results overall were provided by the SVMDA model, not only for the calibration and cross-validation, but also for the independent prediction sample data set. For Class "C," 20 out of 22 samples were predicted correctly for a 90% accuracy using ANNDA and 21 out of 22 were predicted accurately using SVMDA (for a 95.45% accuracy). It was surprising to find good predictions for the other classes. For Class "A," there was an accuracy of 85% prediction (6 out of 7) using ANNDA and SVMDA. The samples from Class "B" were also correctly predicted using ANNDA and SVMDA. Samples for Class "G" were accurately predicted using ANNDA (100%). The results also demonstrated that chemical profile data composed of 55 different compounds found in fentanyl samples can be combined and used to associate fentanyl samples and provide intelligence about potential geographic sources.

Fentanyl; Chemometrics; Chemical Profiling

B92 Profiling Fentanyl in a Local Drug Market and Characterizing Variability Through Quantitative Chemical Analysis

Joshua S. DeBord, PhD, The Center for Forensic Science Research and Education, Horsham, PA; Alexis D. Quinter, MASc, The Center for Forensic Science Research and Education, Horsham , PA; Barry K. Logan, PhD, Center for Forensic Science Research and Education, Horsham, PA; Alex J. Krotulski, PhD, Center for Forensic Science Research and Education, Horsham, PA; Max T. Denn, MS, Center for Forensic Science Research and Education, Horsham, PA*

Learning Objectives: After attending this presentation, attendees will gain an understanding of the analytical and chemometric methodologies used to investigate the homogeneity and consistency of recreational drug materials sold as powdered fentanyl. The presentation will explore similarities and dissimilarities among samples, based on their branded markings and chemical compositions, providing insights into the complexity of drug adulteration and distribution within the Philadelphia, PA, fentanyl market.

Impact Statement: This presentation will enhance the forensic science community's understanding of the uniformity and variability of drug products. It will also demonstrate how inter-sample variability can be leveraged for forensic investigations and public health interventions through quantitative chemical analysis and sophisticated data processing.

Abstract Text: Understanding the consistency and homogeneity of recreational drug products is crucial for both public health and forensic investigations. Pairing Gas Chromatography/Mass Spectrometry (GC/MS) with an automated data processing algorithm allowed our laboratory to assess the homogeneity of fentanyl samples representative of Philadelphia's drug market during 2021 and 2022. Beyond simple identification, this study focused on the quantification of controlled and non-controlled substances, producing profiles of samples used for multivariate comparisons. Test groups of fentanyl samples were created for association and discrimination based upon having similar packaging and branded markings (a.k.a. logos, stamps, or labels).

At the Center for Forensic Science Research and Education, our laboratory conducts applied research and performs drug market trend surveillance and confirmatory quantitative analysis for public health and safety agencies, aiming to assess drug safety, monitor market changes, and guide harm-reduction strategies. Our current workflow includes qualitative analysis using GC/MS and externally calibrated quantitative analysis using GC/MS for fentanyl, xylazine, 4-anilino-N-phenethylpiperidine (4-ANPP), fluorofentanyl, lidocaine, cocaine, caffeine, and methamphetamine. Quantitative ranges for analytes are from ~0.5% (dependent on the amount of the prepared sample) to 100% by mass.

Quantitative data were processed using a custom algorithm, automating the processes of defining and testing pairwise equivalence among samples. The algorithm determines equivalence based on standard deviation of replicate preparation, a relative factor of the mean, and/or the absolute deviation from the mean. Our findings reveal interesting patterns of both similarity and dissimilarity among drug samples branded as a common product (i.e., identical packaging and stamp). In a case of association, two test groups of fentanyl powder, each group with a different packaging stamp, showed noteworthy inter-group similarities. Their intra-group quantitative results were: (1) 10.29 ± 0.25% and (2) 10.15 ± 0.31% for fentanyl; (1) 1.44 ± 0.05% and (2) 1.43 ± 0.07% for 4-ANPP; (1) 15.11 ± 0.68% and (2) 14.64 ± 0.51% for xylazine; and (1) 2.32 ± 0.11% and (2) 2.24 ± 0.08% for caffeine, demonstrating marked consistency in both qualitative and quantitative findings. In a case of discrimination, several samples of fentanyl powder branded with the same stamp (presumably sold as the same product) were divided into two distinct sub-populations based on the chemical differences of their contents: the first sub-group had quantitative results of 2.71 ± 0.17% for fentanyl, 0.15 ± 0.03% for 4-ANPP, 7.78 ± 0.57% for xylazine, and 21.07 ± 0.83% for caffeine; the second sub-group contained only fentanyl and 4-ANPP, with concentrations of 17.57 ± 0.58% and 0.63 ± 0.05%, respectively. Samples for each group were prepared separately and analyzed across different days.

These results demonstrate that while many similarly branded fentanyl batches exhibit consistency, other batches can vary significantly in their composition. This is especially concerning when samples are sold with consistent packaging and stamps. The potential for overdose is elevated when there is an expectation of consistency among common sample types, but the actual fentanyl content varies more than five-fold, as demonstrated by identically stamped samples ranging from 2.71% to 17.57% fentanyl by mass. The observations from this study highlight the need for comprehensive chemical analysis and refined data processing to monitor trends and uncover these variabilities. The traditional role of forensic drug chemistry in identifying controlled substances is extended here to include detailed quantitative analysis, which when coupled to the presented data processing methods, have the potential for linking and distinguishing drug samples. Such associations/discriminations would also lend vital capabilities to public health efforts to curtail the distribution of particularly harmful batches of street drugs as well as furthering strategic intelligence and public safety investigations pertaining to drug distribution.

Overdose; Fentanyl; Drug Analysis

B93 Longitudinal Insights Into the United States' Illicit Fentanyl Supply From the Characterization of Counterfeit Fentanyl Tablets

Barry K. Logan, PhD, Center for Forensic Science Research and Education, Horsham, PA; Sarah A. Shuda, MS, National Institute of Standards and Technology, Horsham, PA; Amanda L.A. Mohr, MS, Center for Forensic Science Research and Education, Horsham, PA; Thom Browne, Jr., MA, Colombo Plan, Huachuca City, AZ; M.J. Menendez, JD, Center for Forensic Science Research and Education, Horsham, PA; Mia Borrelli, MS, Center for Forensic Science and Research and Education, Horsham, PA*

Learning Objectives: After attending this presentation, attendees will be able to describe findings of applying various means of characterizing counterfeit illicitly manufactured fentanyl tablets and what they tell you about trends in tablet composition over a three-year period.

Impact Statement: This presentation will impact the forensic science community by raising awareness of the utility of illicit drug profiling in understanding the illicit drug threat.

Abstract Text: Illicit drug profiling of illicitly manufactured fentanyl, especially in the form of counterfeit oxycodone tablets, involves the application of a comprehensive set of analytical techniques aimed at identifying the chemical composition, origin, and distribution patterns of these exhibits. Given the significant public health threat posed by these drugs, the profiling process is an important tool for informing both law enforcement and public health initiatives about changes in the drug supply, from manufacturing and precursor supply to drug potency and harm reduction efforts.

Fentanyl, a potent synthetic opioid, and counterfeit oxycodone tablets are often clandestinely produced with varying degrees of purity and potency, containing potent principal component drugs such as fentanyl and fluorofentanyl, adulterants, reaction by-products, and unreacted precursors. This can lead to increased risks of overdose and death. Profiling these drugs involves both qualitative and quantitative analyses. Using previously described and validated workflows, we present the results of three years of monitoring the composition and signature of counterfeit oxycodone tablets seized adjacent to the Southwest border between the United States and Mexico.

Tablet exhibits were grouped based on their physical appearance, color, dimensions, and monogramming. Subsamples of each exhibit were selected and subjected to qualitative Gas Chromatography/Mass Spectrometry (GC/MS), Liquid Chromatography quadrupole Time-Of-Flight/Mass Spectrometry (LC-qTOF/MS), and quantitative Liquid Chromatography Tandem Mass Spectrometry (LC-MS/MS) analysis. These methods enable the identification of active ingredients, cutting agents, and impurities, which can provide insights into the manufacturing process and origin.

For this report, we describe the analysis of data from 262 counterfeit drug exhibits consisting of 2,058 tablets seized between Q3 2020 and Q1 2024, which were tested qualitatively to identify drugs and adulterants, and of which 1,684 pills were also tested quantitatively for fentanyl. Across seven different sites, with numbers of tablets ranging from 15 to 1,167, the fentanyl content of the tablets was in aggregate consistent but ranged from 1.0±0.3mg to 1.9±0.3mg. However, in terms of individual tablet variability, there were significant outliers, with some tablets containing as little as 0.012mg of fentanyl and as much as 6.6mg. There were also seasonal fluctuations in the fentanyl content of the tablets, with the most recent quantitative trend being a decline in fentanyl purity from a high of 2.4mg/tablet in Q4 2022 to 1.1mg in Q3 2023. Overall, the potency of fentanyl in 2023 was slightly higher than in 2022. This unpredictable variability in potency, especially at the higher end, is a likely contributor to accidental overdose and other adverse events. The other constituents of the tablets were also consistent, irrespective of their origin of seizure, consisting of fentanyl, 4-ANPP, acetaminophen, metamizole, and mannitol. Only 2% of the tablets contained other opioids, principally para-fluorofentanyl. By and large, tablets containing both fentanyl and para-fluorofentanyl contained more of the latter than the former. Para-fluorofentanyl has a potency estimated to be 2.5 times less potent than fentanyl, while other studies suggest that the two drugs are equipotent. Unreacted precursors and reaction by-products (e.g., para-fluorophenethyl-4-ANPP, N-BOC-norfentanyl, N-BOC-4-ANPP, and others) were also identified, as were other adulterants, including tramadol, xylazine, methamphetamine, lidocaine, levamisole, and pentobarbital.

Illicit drug profiling not only aids in law enforcement efforts to dismantle trafficking networks but also supports public health initiatives by providing data that can inform prevention and intervention strategies. By understanding the specific characteristics of illicitly manufactured fentanyl and counterfeit oxycodone tablets, agencies can better predict and respond to emerging threats, ultimately aiming to reduce the prevalence and impact of these dangerous substances. The data above demonstrate that greater insights into the nature of the illicit drug threat can be achieved through more comprehensive testing.

Drug Analysis; Signature Identification; Mass Spectrometry

B94 The Optimization of Soft Ionization by Chemical Reaction in Transfer Coupled to a Time-of-Flight Mass Spectrometer for Rapid Seized Drug Screening

Joanna Eldon-Edington, BASc, The George Washington University, Washington, DC; Elizabeth L. Robinson, MS, National Institute of Standards and Technology, Gaithersburg, MD; Edward Sisco, PhD, National Institute of Standards and Technology, Gaithersburg, MD; Ira S. Lurie, PhD, The George Washington University, Washington, DC; Thomas P. Forbes, PhD, National Institute of Standards and Technology, Gaithersburg, MD*

Learning Objectives: After attending this presentation, attendees will better understand the analysis of seized drugs via Soft Ionization by Chemical Reaction in Transfer (SICRIT) Mass Spectrometry (MS). In addition, attendees will discover the optimization of the above system for the application of general seized drug screening.

Impact Statement: This presentation will impact the forensic science community by discussing a recently developed Dielectric Barrier Discharge Ionization (DBDI) source, SICRIT, and its optimization for the general screening of seized drugs. This rapid analysis requires no auxiliary gases and provides an alternative to other gas-dependent Ambient Ionization (AI) sources like Direct Analysis in Real Time (DART).

Abstract Text: Increasingly, AIMS is being employed for forensic applications, including seized drug analysis. Given the increased presence of emerging drugs and novel psychoactive substances amidst backlogs, AI sources, such as DART, provide a rapid analysis. SICRIT allows for further minimization of reliance on auxiliary gases while maintaining this rapid analysis, holding the potential to be fieldable and more accessible.

This research employed a JEOL AccuTOF LC-Express connected to a recently developed in-line DBDI source (Plasmion SICRIT) operated in positive polarity mode.[1] A Gas Chromatography (GC) inlet heating attachment was coupled to the SICRIT for sample introduction. Samples were introduced using a stainless-steel Swagelok holder for glass microcapillaries. An aerodynamic-assist interface (IonSense Vapor Interface) was used to help entrain the sample through the heater and source. Optimization of the method focused on identifying the Vapor Flow Rate (VFR) (rate at which ambient air enters the SICRIT source), the temperature of the heater, the plasma generation voltage, and the plasma generation frequency. The MS method parameters, including the In-Source Collision Induced Dissociation (IS-CID) voltages, were replicated from previous work.[2]

Various common seized drugs, adulterants, and diluents of interest were included within this optimization: fentanyl, heroin, cocaine, N-N-Dimethylpentylone (DMP), methamphetamine, and alprazolam. Increasing the VFR increased the peak area of compounds, with the exception of heroin that showed no general trend. This increase was substantial from 1.5L/min to 1.75L/min with a significant reduction in background due to the improved transport of the compounds through the heater, SICRIT, and AccuTOF inlet. Increasing the temperature of the heater increased peak areas for fentanyl and alprazolam while that of methamphetamine decreased. Cocaine and heroin plateaued after 220ºC and DMP showed no general trend. Increases in the plasma generation voltage increased peak area up to 1,800V. Methamphetamine, alprazolam, and DMP peak areas remained consistent after 1,800V while those of heroin and fentanyl decreased. With increased voltage, a greater charge for ionization is present, which must be compromised with increased fragmentation of present compounds and the stability of the plasma. Increasing SICRIT frequency increased peak areas until 15MHz, after which values plateaued. Optimized values for this general seized drug screening method were found to be a VFR of 1.75L/min, an introduction temperature of 240ºC, a SICRIT voltage of 1600V, and a SICRIT frequency of 15MHz. These parameters were chosen to maximize peak areas while minimizing fragmentation and the presence of dimerization within spectra, notably for alprazolam, heroin, and fentanyl. Similar to DART and other AI sources, the spectra primarily feature that of the protonated molecular ion peak with limited fragmentation. While many compounds have similar spectra to that of DART-MS, some show a difference in observed fragmentation and dimerization of compounds is observed at lower concentrations. Notably, fentanyl observes a fragment at *m/z* 150 in SICRIT-MS as opposed to *m/z* 189 that is seen in DART-MS.

After method optimization, a validation was conducted using a panel of single component solutions of common seized drugs at IS-CID of 30V, 60V, and 90V. This focused on obtaining a greater understanding of the potential challenges and limitations for the implementation of SICRIT-MS for qualitative seized drug analysis. This presentation will address the proposed methodology accuracy, precision, reproducibility, specificity, limits of detection, environmental factors, robustness, and potential for use in casework. Additionally, this research compares obtained SICRIT-MS spectra to that of DART-MS to increase understanding of this AI source and its fragmentation. To investigate the applicability to seized drug analysis, realistic samples were obtained and analyzed following the optimized method. Results were compared to those obtained by GC/MS.

B95 The Development of an Analytical Scheme for the Identification of Nitazene Compounds

Sarah Caceres, MS, Drug Enforcement Administration, Chicago, IL; Russell L. Ford, PhD*, Drug Enforcement Administration, Chicago, IL; Sherri L. Tupik, BS*, Drug Enforcement Administration/Department Of Justice, Dulles, VA*

Learning Objectives: An analytical scheme to qualitatively identify nitazene compounds using various types of instrumentation, including Gas Chromatography/Flame Ionization Detection (GC/FID), Gas Chromatograph/Mass Spectrometry (GC/MS), Infrared (IR), Gas Chromatography coupled with Vapor Phase Infrared Detection (GC-IRD), Direct Analysis in Real-Time Mass Spectrometry (DART-MS), and Direct Analysis in Real-Time-Tandem Mass Spectrometry (DART-MS/MS), with each compound and also identify any method limitations.

Impact Statement: Nitazenes have entered the illicit drug market and have raised public health concerns. Due to their structural similarities, forensic identification has proven to be a challenge. In this study, we will identify an appropriate analytical scheme using various instrumentation to support the identification of these nitazene compounds.

Abstract Text: Nitazene compounds (2-benzylbenzimidazole) are a class of synthetic opioids that have recently emerged as a significant public health concern due to their potency compared to other opioids. The development of an analytical scheme for identifying nitazene compounds is crucial to law enforcement and their forensic counterparts. This study aimed to determine an appropriate qualitative analytical scheme to differentiate and identify nitazene compounds. As with any emerging substance, it is critical for forensic analysts to know the limitations associated with the instrumentation used and the minimum number of methods required for an appropriate analytical scheme to support the differentiation and identification of each substance.

A series of nitazene reference materials were analyzed using various types of instrumentation, including GC/FID, GC/MS, IR, GC-IRD, DART-MS, and DART-MS/MS. For each compound, we were able to identify method limitations associated with each technique and determine a final analytical scheme to support the identification. Most forensic laboratories analyzing seized drug evidence use GC/MS with Electron Ionization (EI) to identify nitazenes, but many of these compounds have very similar EI spectral patterns due to their structural similarities. Since additional confirmatory data was needed, the reference materials were analyzed using GC-IRD to determine if the vapor phase infrared spectra could provide structural confirmatory data for isomers. Although not part of this study, this technique would also provide adequate separation from the complex matrices these nitazene compounds tend to accompany in seized drug evidence. GC/FID data was also obtained; although it lacks confirmatory data, it did provide variations in retention time, which is critical when trying to differentiate compounds that have similar EI spectral data. The presumptive data provided the required information for a proper qualitative identification. DART-MS and DART-MS/MS provided soft ionization mass spectral data that allows for both mass separation and confirmatory identification. With these techniques, the soft ionization, extremely low limits of detection, and speed of analysis posed valuable additions to the analytical scheme. Finally, due to the high purity of the materials and the accessibility of IR for forensic laboratories, IR data was also collected. The IR data that was collected provided structural information for these compounds; however, the practicality of using this technique while analyzing seized drugs in casework may pose an issue due to the low purity and complex combinations of substances found in samples containing nitazenes. A combination of these techniques is required to provide complimentary data to make an accurate identification.

B96 Novel Approaches to Increase Specificity for Difficult Isomeric Separations With Ultra-High Performance Liquid Chromatography (UHPLC) for the Analysis of Seized Drugs

Jerimiah J. Seba, The George Washington University, Saltsburg, PA; Ira S. Lurie, PhD, The George Washington University, Washington, DC*

Learning Objectives: After attending this presentation, attendees will understand different approaches to achieve UHPLC separations for complex isomeric compounds as evidenced by JWH-018 positional isomers. In addition, attendees will understand novel approaches of enhancing specificity when compared to more traditional drug analysis separation techniques such as Gas Chromatography (GC).

Impact Statement: This presentation will impact the forensic science community by displaying evidence of enhanced separation specificity of positional isomers using UHPLC. These methods aim to demonstrate alternative approaches to methods currently used within the field for resolving complex isomeric mixtures.

Abstract Text: GC, the standard separation technique for forensic drug analysis, is problematic for thermally degradable, polar, and non-volatile analytes, which can require sample preparation steps such as derivatization and/or liquid-liquid extraction. Conversely, UHPLC, which affords separations complementary to GC, is amenable to the dilute-and-shoot analysis of seized drugs. For both GC and UHPLC, extensive overlap exists for the separation of positional isomers, which are highly prevalent for Novel Psychoactive Substances (NPS). In this vein, various reverse phase chromatographic approaches were investigated to increase retention time specificity for UHPLC for 11 JWH-018 positional isomers, including the use of serial columns, use of different organic modifiers, or employing separate runs using different stationary phases with either acetonitrile or methanol modifiers. For all chromatographic runs, formic acid was used as the mobile phase additive with single quadrupole mass spectrometric and/or diode array Ultraviolet (UV) detection. Columns investigated included classical silica and silica hydride phases (C18, C30, Bidentate C8, UDC Cholesterol, PFP-Pentafluorophenyl, Phenyl Hexyl, and Diamond Hydride).

For the UHPLC separation of 11 positional isomers of JWH-018 extensive co-elution was obtained for both classical silica and Silica-Hydride (SiH) columns under Reverse Phase (RP) conditions using an acetonitrile modifier, with at best only 3 out of 11 satisfactorily resolved. Utilizing serial columns with an acetonitrile modifier at best provided satisfactory resolution for 5 out of 11 positional isomers. However, 9 positional isomers were satisfactorily resolved using a Cogent RP PFP column with a methanol modifier. The additional two positional isomers were resolved using a Cogent RP C18 column with a methanol modifier.

The range of stationary phases using both acetonitrile and methanol modifiers demonstrated considerable differences in selectivity in both single and serially coupled column trials, thus indicating the ability of both mobile phase and combined orthogonal columns to increase specificity of chromatographic separations, improving the separation of synthetic cannabinoid positional isomers.

UHPLC Separations; Emerging Drugs; Positional Isomers

B97 Determining the Utility of Gas Chromatography/Derivative Vacuum Ultraviolet Spectroscopy for Seized Drug Analysis Through a Comparison to Gas Chromatography/Mass Spectrometry Capabilities

Alexa Mehlman, BS, The George Washington University, Westwood, MA; Ira S. Lurie, PhD, The George Washington University, Washington, DC*

Learning Objectives: This presentation will demonstrate the utility of a Gas Chromatography-Vacuum Ultraviolet Spectroscopy (GC-VUV) method for seized drug analysis. After attending this presentation, attendees will know the capabilities of the GC-VUV method, the value of second derivative analysis of VUV spectra, and how this method compares to the favored Gas Chromatography/Mass Spectrometry (GC/MS) for forensic drug analysis in terms of specificity.

Impact Statement: This presentation will impact the forensic science community by providing a method framework using an emerging technology in forensic drug analysis, Gas Chromatography-Derivative Vacuum Ultraviolet (GC-DVUV) spectroscopy, to identify 14 different commonly seen illicit compounds from all major drug classes that is comparable to, if not better than, GC/MS capabilities. Forensic scientists will learn the value of GC-DVUV application to general drug screening that may exceed the current capabilities of the commonly employed workflow in forensic drug analysis laboratories.

Abstract Text: GC/MS has long been praised as the gold standard in forensic drug analysis due to its accuracy and precision in identifying and differentiating between illicit substances. However, GC/MS has inherent limitations, such as the lack of a molecular ion and difficulties in distinguishing between positional isomers and diastereomers. Our study aims to compare the specificity and repeatability of GC-VUV, GC-DVUV, and GC-MS drug identification.

GC-VUV is an emerging technology that shows great promise in drug detection. GC-VUV excels in the areas in which GC/MS falls short with its ability to deconvolute spectra and its potential to distinguish between positional isomers and diastereomers. Our study aims to demonstrate that GC-VUV provides more specificity in drug identification as compared to GC/MS by employing a derivative analysis of VUV spectra.

Fourteen illicit drugs from various major drug classes, including opiates, opioids, stimulants, cannabinoids, hallucinogens, depressants, and anabolic steroids, were analyzed using GC-VUV. Spectral data were processed to determine the first and second mathematical derivatives of the spectra to increase identification specificity. Principal Component Analysis (PCA) was used to analyze raw data, first derivative, and second derivative spectra from five repeats, and the results were compared to those obtained from GC/MS data.

PCA demonstrates that increasing the derivative of the VUV spectra enhances the distance between clusters, leading to better identification specificity. PCA comparisons between GC-MS and second derivative GC-VUV data revealed that GC-VUV identification was more repeatable. Points representing runs of the same compounds were clustered closer to each other in the VUV data, whereas in the MS data, there was more spreading, showing more variability between runs. Run-to-run repeatability was also evaluated by comparing each run to an in-house spectral library, resulting in an R2 value representing match probabilities. Our study shows that higher derivatives of the VUV spectra significantly decrease the likelihood of misidentifications by increasing the difference between the most likely probable match R2 value and the second and third closest matches, resulting in a more definitive identity of the compound.

Overall, increased specificity in identification is attained by using both DVUV and MS data in analysis, and repeatability is greatly improved in VUV analysis compared to MS. The use of GC-DVUV could be particularly advantageous for the more accurate identification of current and emerging psychoactive substances, better equipping forensic drug laboratories to analyze novel substances.

B98 Chemometrics as a Tool for Transformation: Addressing the Limitations of Gas Chromatography/Infrared Spectroscopy for Synthetic Cathinone Analysis

Jennifer Bonetti, PhD, Virginia Department of Forensic Science/University of Amsterdam, Norfolk, VA; Ruben Kranenburg, PhD, Netherlands Police, AC Driebergen, The Netherlands; Stephen P. Hokanson, BS, Virginia Department of Forensic Science, Western Laboratory, Roanoke, VA; Arian van Asten, PhD, University of Amsterdam, Amsterdam, Noord-Holland, Netherlands; Matthew Pothier, MS, Virginia Department of Forensic Science, Roanoke, VA; Saer Samanipour, DSc, University of Amsterdam, Amsterdam, The Netherlands*

Learning Objectives: After attending this presentation, attendees will understand the limitations associated with using Gas Chromatography solid deposition Infrared Spectroscopy (GC/IR) for the analysis of synthetic cathinones and how chemometrics may be the key to addressing these challenges.

Impact Statement: This presentation will impact the forensic science community by showcasing situations in which the expert visual assessment of spectra in combination with a typical library searching algorithm may not be sufficient for confident compound identification. In these instances, chemometric analysis may be better suited to assist the forensic scientist in reaching a sound conclusion.

Abstract Text: Novel psychoactive substances pose a significant analytical challenge for forensic laboratories. Many structurally similar compounds produce visually indistinguishable mass spectra, thus leading forensic scientists to investigate other methods of analysis. One commonly proposed instrumental technique is the combination of GC/IR. Typically, this alternative is presented as producing distinct spectra that can be easily differentiated with the combination of a library search and an expert visual examination. However, it is important to acknowledge that this is not the case for all compounds. In this study, we showcase three synthetic cathinone analogs (methylone, N-ethylpentylone, and pentylone) that produce extremely visually similar solid state IR spectra to one another.

A primary dataset of these three cathinone analogs was generated at the Amsterdam Police Laboratory over the course of three weeks. Libraries were created in tandem using two different sample preparation methods. In addition, the same compounds were analyzed at the Virginia Department of Forensic Science (DFS) using the same sample preparation methods. It was observed that changes in either instrument or sample preparation were enough to pose challenges to both the visual assessment and the library matching algorithm. Additionally, week-to-week variation was observed within the primary dataset. Using Principal Component Analysis (PCA), the efficacy of a chemometric model in combination with Mahalanobis distances for objective comparison was assessed. Optimization of preprocessing methods and wavenumber selection showed that the second derivative of the full spectrum resulted in the best separation of the three compounds in principal component space. This method successfully identified three replicates of two real case samples as well as validations samples not utilized in the training of the PCA model.

Chemometrics showed particular improvement over the library-searching algorithm for samples analyzed at an alternative laboratory from that which prepared the library. In addition to producing higher match scores (suggesting lower similarity) for all samples, the pentylone samples analyzed at DFS were mis-identified as N-ethylpentylone when using the library matching algorithm. However, they were successfully identified using the chemometric method.

This study showed how the application of chemometrics to spectral GC/IR data can improve and substantiate the differentiation capabilities of the instrument and provide valuable objective support to the expert when making a compound identification. In addition, limitations in the consistency of GC/IR spectra over time and across instrumental conditions were observed, which could affect how the forensic community utilizes these techniques in the future.

Drug Analysis; Machine Learning; Spectroscopy

B99 An Additional Analysis of Drug Test Strips by Mass Spectrometry for Rapid Comprehensive Drug Checking

Meghan G. Appley, PhD, National Institute of Standards and Technology, Gaithersburg, MD; Edward Sisco, PhD, National Institute of Standards and Technology, Gaithersburg, MD*

Learning Objectives: After attending this presentation, attendees will be introduced to a method for extracting compounds from used Lateral-Flow Immunoassays (LFIs) that can then be analyzed by mass spectral techniques to provide complementary comprehensive information for rapid drug checking.

Impact Statement: This presentation will impact the forensic science community by providing information on a rapid drug screening method that takes advantage of an existing technique. This method would allow for rapid onsite testing using LFIs followed by additional laboratory-based analysis resulting in complementary information that can be used by forensic science laboratories and public health agencies to triage samples, monitor drug trends, and identify emerging threats.

Abstract Text: Over the past five years, there has been a 70 % increase in opioid-involved drug overdose deaths.[1] Many of these overdoses occur because People Who Use Drugs (PWUD) are often unaware of what is in their drug products. To help combat the opioid epidemic, public health agencies provide point-of-care testing using a range of techniques including LFIs (herein referred to as test strips) as well as comprehensive laboratory-based testing (e.g., direct analysis in real time – mass Spectrometry (DART-MS) through programs such as the Rapid Drug Analysis and Research (RaDAR) program at the National Institute of Standards and Technology (NIST).[2]

Test strips were initially designed for urine analysis, but studies have shown their effectiveness in testing drug material.[3] Public health agencies provide these tests to PWUD to test their drugs prior to consumption, but they are also used by forensic science agencies as part of their standardized analytical scheme to conduct presumptive testing. These tests are cheap and highly sensitive but are highly selective, resulting in rapid non-comprehensive information. In addition to onsite testing, there are programs, such as RaDAR, which provide rapid laboratory-based drug checking through the analysis of trace drug residues collected from used paraphernalia by DART-MS. The information provided through laboratory-based techniques is more comprehensive than onsite testing but has longer turnaround times and requires programs to be in place that can sample used paraphernalia.

This project hypothesized that the methods used for point-of-care/presumptive testing (test strips) and laboratory-based testing (DART-MS) could be combined to provide rapid comprehensive information for drug checking programs and forensic science laboratories. For this to be possible, an optimized extraction process needed to be developed to remove the compounds from the used test strips to then be analyzed by DART-MS. This study presents an optimized method that evaluated several variables, including test strip type, target compound, and extraction solvent, time, and volume as well as identified limits of detection for a range of compounds (fentanyl, xylazine, cocaine, carfentanil, methamphetamine, heroin, and isotonitazene). Following optimization of the extraction method, real-world samples were tested using the developed method. Test strip samples were submitted alongside 100 traditional RaDAR samples. Compounds were extracted from the test strips then analyzed using the same method used to analyze traditional RaDAR samples. The results were then compared to the traditional samples and showed 95% agreement between the test strip and traditional samples. These results show that test strips can be used to rapidly test samples onsite by PWUD or law enforcement, then be submitted to a laboratory for analysis by mass spectral techniques providing rapid comprehensive information. This information can then be used to triage samples for forensic science laboratories or help track drug trends and emerging threats across the United States.

B103 The Evolution of VOC Profiles During Early Human and Animal Decomposition in Application for Canine Detection

Fantasia Whaley, MSFS, Florida International University, Miami, FL; Valerie Albizu, BS, Florida International University, Miami, FL; Lauryn DeGreeff, PhD, Florida International University, Miami, FL; Jordi Cruz, PhD, EUSS School of Engineering, Barcelona, Catalonia, Spain; Joel L. Fuentes Carrasco, BS, Florida International University, Hialeah, FL; Emily Millan, BS, Florida International University, Miami, FL*

Learning Objectives: This presentation will examine and advise attendees on the changes in odor profiles during early decomposition using varying analogs for human remains—human blood, pig skin, and mouse carcasses. The transition from the odor profile of fresh remains to decomposed will be demonstrated both chemically, by examining the Volatile Organic Compounds (VOCs), and via canine trials to display how this shift in the odor profile may impact canine detection in the field.

Impact Statement: The results in the presentation will differentiate distinct odor profiles of the various analogs, with a focus on the first 48 hours after death/collection, utilizing chemometric analysis and canine detection. This has applications to Search And Rescue (SAR) and Human Remains Detection (HRD) detection canines and their abilities to discover crucial evidence in fresh crime scenes or disaster scenarios.

Abstract Text: HRD canines provide a crucial role in locating missing persons and in revealing valuable evidence for criminal investigation. Previous research has demonstrated that the odor profiles of remains, whether human or animal, change significantly over time. This evolution of VOC profiles can affect canine detection accuracy, requiring that handlers train their dogs on a variety of materials of different ages.[1-4] This study aims to address the gap in understanding the changes in decomposition within the first 48 hours after death—a critical timeframe in SAR operations. Anecdotal findings from HRD canine handlers suggest a perceptible change in odor to canines about two to four hours after death, highlighting a need for frequently sampling in the first 24 hours, a task not previously applied to human remains research. Due to difficulties in obtaining human remains immediately postmortem, this work aims to begin with a simpler human remains matrix and full animal carcasses: human blood, pig skin samples, and then on to full mouse carcasses.

Odor analyses of blood, skin, and carcasses were conducted using Headspace/Solid Phase Microextraction (HS/SPME) for sample collection and Gas Chromatography/Mass Spectrometry (GC/MS) for VOC separation and detection. This allowed for detection of the compounds in the odor profiles and tracked their changes over time. Chemometrics techniques, including Principal Component Analysis (PCA), hierarchical cluster analysis, and Multivariate Curve Resolution using constrained Alternating Least Squares algorithm (MCR-ALS), were applied to reveal statistically significant changes in the odor profiles. Results indicate an early change in the VOC profiles of all samples between Hour 4 and Hour 8, with a fresh odor profile present from Hours 1–4. After Hour 8, there was a decrease in compounds characteristic of the fresh profile and an increase in those of a later odor profile, with a notable a shift to an aged odor profile between Hours 24 and 40. HRD canine trials with blood of varying ages support these findings, with minimal detection of blood one to two hours old and the optimal detection at 34–36 hours old. These results implied that early changes in odor profiles of numerous remains samples impact canine detection, providing valuable insights to the training of HRD canines.

Headspace Analysis; Human Remains; Search and Recovery

B104 Assessing the Accuracy and Reliability of Canine Explosives Detection Using OSAC Training and Certification Standards

Adele Quigley-McBride, PhD, Simon Fraser University, Burnaby, BC, Canada; Haylie A. Browning, BS*, Texas Tech University, Lubbock, TX; Lauryn DeGreeff, PhD, Florida International University, Miami, FL; Paola A. Prada-Tiedemann, PhD, Texas Tech University, Lubbock, TX*

Learning Objectives: Attendees will learn the level of knowledge and general awareness that operational canine-handler teams have of the existing training and certification standards produced by the Dogs and Sensors subcommittee at the Organization of Scientific Area Committees (OSAC). In addition, attendees will receive information about the recommended training and certification protocols specified in the American National Standards Institute/Academy Standards Board (ANSI/ASB) Standard 092, which outlines a training program to develop the necessary skills and provides guidance for testing, explosive detection canine-handler teams performance on baggage/parcel, vehicle, and building searches that mimic operational contexts. Attendees will learn about current efforts that are underway to validate the protocols outlined in ANSI/ASB Standard 092 and the performance data collected to date.

Impact Statement: This presentation will impact the forensic science community by demonstrating the reach of OSAC standards among operational canine handler teams. The presentation will also detail the practical and scientific challenges associated with validating standard protocols and can serve as an example for other groups of researchers or practitioners seeking ways to develop empirical support for their procedures. Finally, this presentation will include a first look at important data demonstrating canine handler team performance in classic testing scenarios and circumstances designed to mimic operational contexts.

Abstract Text: Canines have played a formal role in criminal investigations, emergency response, security, and other important fields in the United States for decades. There is no question that canines have superior abilities when it comes to detecting, tracking, and identifying odors, and that humans can train canines to perform myriad useful tasks. That said, as is the case for most forensic disciplines, there is a lack of empirical data to support protocol, procedures, and programs that canine handler teams know to be effective through experience.

The development of dog detection training and certification standards by the OSAC Dogs and Sensors Subcommittee has made a significant contribution in this area by developing and publishing detailed protocols with the goal of improving consistency in the field. However, consistency of methods—*method conformance*—is only one piece of the puzzle. To provide empirical evidence that a discipline is reliable, the performance that results from the use of a particular method also must be demonstrated empirically, under conditions that are controlled and for which ground truth is known—*method performance*.[1] The canine will exhibit normal variations in behavior and skill, and a person is responsible for subjectively interpreting the canine's behavior using their experience and expertise. Hence, there will be some variation in both method conformance and performance, but variation can be measured using empirical methods and accounted for in real cases.[2]

Although canine detection practitioners worldwide are actively working on disseminating, developing, and promoting canine detection standards in both training and operational contexts, the utility of the standards has not yet been evaluated. Thus, the extent to which canine handler teams are training and certifying their canines according to OSAC standards remains an open research question. In addition, the OSAC standards have consensus support among experienced canine handlers and researchers, but the protocols have not yet been assessed in terms of the resulting performance that can be expected if a canine handler team trains and certifies in line with this method. This presentation will describe a recent effort to assess how widespread knowledge and use of OSAC standards are among the canine-detection community. In addition, the same research team is conducting a proof-of-concept black box study that seeks to objectively assess the OSAC National Registry Standard 092, *Standard for Training and Certification of Canine Detection of Explosives* (ANSI/ASB Standard 092).

In this presentation, we will present survey results demonstrating how far-reaching the Standards produced by the OSAC Dogs and Sensors subcommittee have been in the canine-detection community. We will also present a first look at the data from operational canine assessments that align with the certification testing paradigms developed in Standard 092. This is the first black box study to assess canine detection and has followed a similar approach to black box studies conducted to validate other forensic disciplines. Future directions will be discussed as well as a discussion about the challenges that have been overcome to get this research project underway.

B105 Developing a Universal Smokeless Powder Training Aid

Rushali Dargan, PhD, Florida International University, Miami, FL; Lauryn DeGreeff, PhD, Florida International University, Miami, FL*

Learning Objectives: Participants will gain insights into the development of a universal Smokeless Powder (SP) training aid. Attendees will learn about the challenges posed by the diverse chemical compositions of SPs and the strategies used to overcome these obstacles.

Impact Statement: This research addresses the challenges posed by the diverse chemical compositions of SPs by developing a universal training aid for detection dogs. By overcoming these obstacles, the study aims to standardize SP training aids, potentially enhancing security measures by improving the reliability and effectiveness of canine detection teams, improving security measures.

Abstract Text: SPs, extensively utilized as propellants in firearms and artillery ammunition, are readily accessible and hence frequently exploited for illicit purposes. Given their involvement in firearm and explosive-related criminal activities, the analysis of SPs is of forensic significance. The detection of trace levels of SPs is challenging due to the extensive diversity in their chemical compositions and the plethora of available brands. Previous headspace analyses of pre-blast SPs have indicated volatiles such as 2,4-Dinitrotoluene (2,4-DNT), Diphenylamine (DPA), ethyl centralite, and nitroglycerin, among other compounds, as compounds of interest in the vapor phase pertinent to the trace-level detection of SPs.[1]

Addressing the complexities associated with the SPs, this study aimed to develop a universal SP training aid intended for the training of detection canines. During the current study, comprehensive analysis of SPs was conducted to quantify the abundance of 2,4-DNT, DPA, ethyl centralite, and nitroglycerin in the headspace, utilizing Solid-Phase Microextraction-Gas Chromatography/Mass Spectrometry (SPME-GC/MS). Subsequent to the headspace analysis, training aids were formulated to represent the average abundance of these volatile compounds prevalent in commonly available SPs.

The formulated SP training aid underwent a rigorous evaluation employing an innovative approach involving murine models to monitor brain receptor activity. This phase of the study was conducted in collaboration with Canaery, an organization pioneering the development of the world's first Nose-Computer Interface (NCI).[2] The empirical data derived from this investigation demonstrated that the SP training aid developed in this study is proficiently generalized across diverse SP variants. The brain receptor activity tracked in the murine models furnished compelling evidence corroborating the efficacy of the training aid in emulating the olfactory profile of a broad spectrum of SPs.

The results of this study indicate that the developed SP training aid holds significant promise for enhancing the capabilities of detection dogs. This advancement has the potential to improve the accuracy and reliability of forensic investigations involving SPs. The universal SP training aid offers a practical solution to the complex challenge of detecting trace levels of SPs across various compositions and brands.

B106 OSAC/ASB Standards Development Activities in Firearm and Toolmark Examination

Xiaoyu A. Zheng, MS, National Institute of Standards and Technology, Gaithersburg, MD; Robert M. Sanger*, Sanger Dunkle Law, P.C., Santa Barbara, CA*

Learning Objectives: After attending this presentation, attendees will have a better understanding of the work of the National Institute of Standards and Technology (NIST) Organization of Scientific Area Committees (OSAC) Subcommittee and the American Academy of Forensic Sciences (AAFS) Academy Standards Board (ASB) Consensus Body (CB) for Firearms and Toolmarks and to update the status of those discipline-specific standards.

Impact Statement: The presentation will impact the forensic science community by creating greater awareness of standards development activities pertinent to firearms and toolmarks focusing on the collaborative efforts of the NIST OSAC and the AAFS ASB on those standards.

Abstract Text: The OSAC for Forensic Science was created by NIST to strengthen the nation's use of forensic science by promoting the use of discipline-specific forensic science standards. To this end, the OSAC drafts standards that are forwarded to Standards Developing Organizations (SDOs) that further develop and publish them. The OSAC also reviews standards and recognizes them on the OSAC Registry, which serves as a central repository of high quality, consensus-based, technically sound standards. The OSAC Firearms and Toolmarks Subcommittee is comprised of over 20 experts in the field from crime laboratories, academia, and government agencies. Its work includes the comparison of microscopic toolmarks on bullets, cartridge cases, and other ammunition components as well as firearm function testing, serial number restoration, muzzle-to-object distance determination, and forensic examination of tools, and toolmarks.

The ASB was formed by the AAFS and is recognized as an SDO to accomplish the task of completing and publishing Standards, Best Practice Recommendations, and Technical Notes. The Firearms and Toolmarks CB was created by the ASB. The Firearms and Toolmarks CB is comprised of representatives of the various stakeholders in the firearms and toolmarks forensic discipline. It includes analysts, academics, prosecution and defense lawyers, industry representatives, and related forensic scientists. The Firearms and Toolmarks CB meets regularly and has done so over the past several years. The CB does most of its work through committees that meet on specific work proposals. Those proposals generally originate from the Firearms OSAC, which promulgates draft standards. The CB reviews the proposed draft standards, submits them for rigorous discussion and review by the relevant committee members and by the CB itself. The proposed standards are then circulated for public comment and often return for several rounds of discussion and revision.

During this presentation, updates related to firearms and toolmark evidence will be discussed. These include: (1) recent standards that have been added to the OSAC Registry; (2) OSAC-proposed standards; (3) published standards from the ASB that have yet to go through the Registry approval process; (4) documents currently in development at the OSAC or by the ASB; and (5) priorities for new documents or work proposals and other highlights.

Firearms; Standards; Toolmarks

B107 A Quantitative Topography Comparison of Toolmarks Made by Tongue-and-Groove Pliers

Eunah NMN Joo, MS, National Institute of Standards and Technology, Gaithersburg, MD; Thomas B. Renegar, AA, National Institute of Standards and Technology, Gaithersburg, MD; Robert M. Thompson, MFS, National Institute of Standards and Technology, Reno, MD; Xiaoyu A. Zheng, MS, National Institute of Standards and Technology, Gaithersburg, MD; Johannes Soons, PhD, National Institute of Standards and Technology, Gaithersburg, MD; Michael T. Stocker, BS, National Institute of Standards and Technology, Gaithersburg, MD*

Learning Objectives: Attendees will learn about measuring the three-dimensional (3D) surface topography of impressed toolmarks made by tongue and groove pliers and the application of algorithms for objective quantitative comparison. Experimental results characterize similarity scores of toolmarks obtained under different conditions and the effects of possible subclass characteristics.

Impact Statement: This presentation provides foundational support for the objective identification of impressed toolmarks made by hand tools.

Abstract Text: Toolmarks made by hand tools are encountered in various crime scenes (e.g., murder, burglary, theft, arson, and bombings). The forensic comparison of these toolmarks can help solve criminal cases by linking a suspect tool to a crime scene or by connecting related crime scenes. In this study, we evaluated the application of objective comparison methods developed for forensic firearm identification to impressed marks made by tongue-and-groove pliers.

We made toolmarks under different conditions relevant to casework using 12 consecutively manufactured pliers and 15 non-consecutively manufactured pliers. The pliers were made from drop forged steel, and the teeth were machined using a milling process. Each jaw of the pliers has a flat tooth at the front and back, and 10 teeth in between that have a triangular cross-section. After several heat treatment operations, including laser hardening of the teeth, the pliers were bead blasted and coated with a transparent lacquer for rust protection. Impressed toolmarks were generated on metal strips of different materials (lead, tin, aluminum, copper, galvanized steel, and brass).

The 3D surface topography of the tools' working surfaces and toolmarks were measured using focus variation microscopy. The analyzed regions of interest were toolmarks generated by the front flat tooth and the triangular teeth. After trimming the topography images of toolmarks to the region of interest, we applied a bandpass filter to attenuate noise and highlight individualizing features. The images were then compared algorithmically to obtain two similarity scores: the maximum value of the normalized Areal Cross Correlation Function (ACCF) and the number of Congruent Matching Cells (CMCs). Experimental distributions of the toolmark similarity scores were generated for Known Matching (KM) and Known Non-Matching (KNM) comparisons to evaluate individuality and reproducibility. To investigate possible subclass characteristics, we compared similarity score distributions for toolmarks made by consecutively and non-consecutively manufactured tools. We also characterized the effects of potential influence factors on similarity scores, including substrate material, change of the tool's working surface after use, and contact angle.

The KM and KNM score distributions for both ACCF and CMC showed complete and large separation for all conditions. No significant effects of subclass characteristics were observed. Variations due to differences in substrate material and contact angle were reduced by automatically limiting the compared topography to the bottom area of the tool mark. Persistence tests showed changes in the similarity of KM marks, mainly due to the accumulation of debris.

The results indicate that the two algorithmic comparison methods of topography data (3D images) have utility in the identification of impressed marks made by tongue-and-groove pliers.

3D Technology; Toolmarks; Quantitative Evidence

B108 The Interoperability of 3D Firearm Toolmark Measurements

Xiaoyu A. Zheng, MS, National Institute of Standards and Technology, Gaithersburg, MD; Johannes Soons, PhD, National Institute of Standards and Technology, Gaithersburg, MD; James Yen, PhD, National Institute of Standards and Technology, Gaithersburg, MD*

Learning Objectives: A set of 120 cartridge cases originating from four different sets of consecutively manufactured firearms were used in a round robin style interoperability study. The research goal was to evaluate the effect of different measurements methodologies and laboratory protocols on the National Institute of Standards and Technology (NIST) similarity metrics Areal Cross Correlation Function (ACCF) and Congruent Matching Cells (CMC).

Impact Statement: 3D surface topography measurements can be generated by different measurement methodologies, each of which results in slightly different reconstructions of the surface. In order for the interoperability and exchange of 3D measurement data between different agencies, there is a critical need to understand the measurements limitations. The research demonstrates that there were significant differences observed when applying the NIST similarity algorithms. However, once these differences are documented, correction factors and uncertainty estimates can be generated to account for these differences. The research can help facilitate interoperability between different laboratories and instruments in the future.

Abstract Text: There has been a major paradigm shift in firearm and toolmark analysis toward the use of 3D topography measurements. The new approach bolsters objectivity through the International System of Units (SI) traceable measurements. Several manufacturers are now offering specialized 3D microscopes for toolmark measurement that rely on differing measurement principles that each has advantages and challenges. These instruments are currently being used in laboratories for Virtual Comparison Microscopy (VCM). The future goal for these instruments is to generate measurements used to report on the statistical weight of evidence of comparison in casework.

For impressed toolmarks, there is no comprehensive study that characterizes the resulting differences in 3D data obtained using different instrument types and their effect on objective similarity scores. This is an important gap in the quest for objective comparison results and quantitative weight of evidence reporting. This gap needs to be addressed to ensure consistency in results among labs and provide associated foundational data for future *Daubert* hearings.

The research evaluated the effect of measurement source variations on similarity metrics. This was accomplished through a round-robin study where each lab/instrument measures the same set of 120 cartridge cases fired from four sets of consecutively manufactured firearms. Twelve laboratories participated in this study to generate a total of 18 datasets across 9 different 3D instruments.

To quantify the differences between labs and technologies, each lab's measurements were analyzed using two well-established similarity scores: the normalized Areal Cross Correlation Function (ACCFMAX) and the number of Congruent Matching Cells (CMC).[1,2] The results were used to generate Known Matching (KM) and Known Non-Matching (KNM) score distributions, which were used to statistically analyze for differences between labs and systems. Results will facilitate improvements in the consistency of measurement results while providing the foundational research data required to defend the future use and interoperability of 3D measurements in casework.

3D Technology; Interpretation; Firearms

B109 The Generation and Interpretation of the Similarity Score Distribution for Matched and Non-Matched Bullets and Cartridge Cases

Neal Schrode, BSBME, Leeds Forensic Systems, Minneapolis, MN*

Learning Objectives: After this presentation, attendees will understand: (1) how Automatic Ballistic Identification Software (ABIS) is used to identify possible matches in database correlations; (2) the basis of histogram generation for matched and non-matched similarity scores; and (3) how correlation results can be interpreted. This will include reviewing how sample types included in correlations can have a bearing on the interpretation of correlation results.

Impact Statement: This presentation will impact the performance of examiners using ABIS by increasing the efficacy in interpreting correlation results by better understanding the relationship between matched and non-matched samples, in addition to factors that can contribute to software presenting possible matches that are not matched or class exclusions (false positives).

Abstract Text: ABIS systems use computer algorithms to derive a similarity score that represents how alike two bullets or cartridge cases are as a numerical result—falling into one of two categories: matched samples or non-matched samples. This presentation reviews how matched and non-matched similarity scores are represented in histograms; how these histograms are related to each other; how sample features can affect the correlation scores generated by algorithms; and how datasets can create bias in correlation results.

By providing a fundamental understanding of how sample features relate to generated similarity scores, including class characteristics, examiners will better be able to interpret ABIS system results to reduce the number of possible matches that need to be compared, or the number of samples that are on the top rankings of their correlation results, to ensure that matched samples do not get missed in addition to understanding how class characteristics can be used to prevent false positives (the indication of possible match for class exclusions).

Comparison tools, such as Leeds Evofinder, are designed with an advanced, automated identification system to automatically correlate sample images to other images stored in your database, providing a numerical similarity value between two representative images. These similarities can then be compared to each other using Virtual Comparison Microscopy tools in the Evofinder or under a comparison microscope to identify possible matches. The Leeds Evofinder System compares land engraved areas/land engravings, groove engraved areas/groove engravings, and slippage marks on bullets and breech face impression and striker mark/firing on cartridge cases. Total process time from receipt of sample to correlation result on a 9mm bullet or cartridge case face is approximately 4 minutes. It scans cartridge case, bullets, and bullet fragments; performs VCM gun sorting correlations, and requires no annual licensing. Your lab owns the image files and there are no consumables, no critical cleaning is needed, and is portable for field use.

Firearms; Accuracy; Forensic Imaging

B110 Quantitative Assessment of Barrel Wear From Solid Copper Bullets

Natali Hassett, MS, Oklahoma State Bureau of Investigation, Edmond, OK; Eric Law, PhD, University of Central Oklahoma, Edmond, OK*

Learning Objectives: This presentation will utilize algorithm comparisons to demonstrate the effect of solid copper bullets on the persistence of barrel rifling characteristics. By attending this presentation, attendees will also learn about three-dimensional bullet scans and how they can be used in comparisons.

Impact Statement: This presentation will impact forensic science because it highlights the use of three-dimensional scans and algorithms to conduct bullet comparisons. Furthermore, this research shows the effect of solid copper bullets on the enhanced polygonal rifling of Glock Marksman Barrels, which are present in some of the most common pistols in the United States.

Abstract Text: The persistence and wear of barrel individual characteristics is a common research topic in forensic firearm analysis; however, most studies are conducted on conventional ammunition such as full metal jacket. While solid copper bullets are not yet as common, calls for lead-free ammunition are leading to a rise in the use of solid copper bullets. As they become more widespread, crime laboratories will see an increase in the number of solid copper bullets submitted as evidence. For firearm examiners to better understand the effects of solid copper bullets on barrel wear, more research is needed.

This study included the successive firing of 500 solid copper bullets through a new Glock 19 Gen 5 with a Glock Marksman Barrel. To profile the barrel at the beginning and end of the study, the first ten and last ten bullets were collected. Every tenth bullet was collected to track any changes in the features. The Cadre Forensics Versa Scanner was used to scan the land engraved areas on each collected bullet. These scans were used to compare the individual characteristics left on the bullets by the barrel rifling.

Compared to similar studies that involved qualitative comparison methods, this study focused on quantitative data. The Cadre Forensics system includes a built-in algorithm that compares the bullet scans and generates a similarity score for each comparison. The algorithm is Cadre Forensics' implementation of the Congruent Matching Profile Segments algorithm developed at the National Institute of Standards and Technology. The data were analyzed using the Kwiatkowski-Phillips-Schmidt-Shin time series test to determine the statistical significance of differences observed in the similarity scores. Results from the algorithm comparisons were supported by visual examinations of the depth profiles generated from the bullet scans.

The results from this study demonstrate that solid copper bullets have a statistically significant effect on the individual characteristics of firearm barrels. This conclusion is supported by the algorithm results and the visual examinations. There is a decreasing trend in the similarity scores, and the depth profiles of later bullets are less detailed than those of bullets fired earlier in the sequence. These results will inform firearm examiners that they may need to be more conservative when using individual characteristics to reach an elimination.

Solid Copper Bullets; Three-Dimensional Scanning; Algorithm Comparison

B111 A Quantitative Determination of Muzzle-to-Target Distance in Shooting Cases

Taqiyah Chernesky, MScFS, Virginia Commonwealth University, Montpelier, VA; Sophie Knier, MFS, Virginia Commonwealth University, Richmond, VA; Emanuele Alves, PhD, Virginia Commonwealth University, Richmond, VA; Stephanie Walcott, MScFS, Virginia Commonwealth University, Richmond, VA*

Learning Objectives: This presentation demonstrates a method to quantitatively determine muzzle-to-target distance using Inductively Coupled Plasma/Optical Emission Spectroscopy (ICP/OES) by the Inorganic Gunshot Residue (IGSR) profile of common ammunition. The main outcome of this study works to create a reliable mathematical relationship between elemental composition and shooting distance to be applied in shooting cases.

Impact Statement: This presentation will expand the scope of both the firearms and trace evidence sections in the forensic science community by utilizing instrumental analyses that focus on the target material rather than the shooter-end of firearm-related evidence. By developing this technique, we would also be able to improve current techniques by creating quantitative, less subjective, and more specific conclusions to be used in court.

Abstract Text: In the years between 2014 and 2022 alone, firearm-related deaths in the United States nearly doubled, increasing conversations among the public surrounding gun control. Gun regulations vary between states; several states, including Mississippi, not only have relaxed gun control laws but also have the highest overall firearm-related deaths. Currently, some gun-control laws are related to the type of firearm a person can purchase, concealed carry laws and processes, registration laws, and other aspects. However, many Americans believe these laws are still not enough to reduce and prevent gun violence, calling for more research surrounding the analysis of firearm-related evidence in shooting cases.

Research involving IGSR typically focuses on the shooter end rather than the target material. This work seeks to create a mathematical relationship between the concentration of well-known elements, namely lead, barium, and antimony, on target materials and muzzle-to-target distance with an attempt to estimate shooting distance quantitatively. Cloth samples containing IGSRs were obtained by shooting Remington UMC 9mm Luger ammunition from a Smith & Wesson M&P9 Shield semi-automatic pistol in a controlled indoor environment at varying distances. The IGSR was extracted from samples using an acid digestion procedure and analyzed using ICP/OES to quantify barium, lead, and antimony. A mathematical model was developed for the interpretation of barium, lead, and antimony concentrations in both ammunitions analyzed. Each inorganic metal produced a unique polynomial function with statistical value at an R2 of 0.9886, 0.9748, and 0.992, respectively. This research provides evidence that a relationship between muzzle-to-target distance and the concentration of metal on the target material not only exists but is a polynomial relationship. This relationship can be used to create mathematical models for varying metals in specific ammunition types and provides a quantitative method for distance determination in shooting cases.

Ballistics; Firearms; Gun Shot Residue

B112 Close Non-Matches and Database Searches: How Often Can We Expect to See a True Match Among the K Highest Correlations?

Blanca I. Parker, BA, Iowa State University, Schenectady, NY; Heike Hofmann, PhD, University of Nebraska-Lincoln, Ames, IA; Alicia L. Carriquiry, PhD, Iowa State University, Ames, IA*

Learning Objectives: This presentation will explore close non-matches and the probability of a true match appearing in the top *k* search results in database searches involving bullets and cartridge cases. Participants will gain insight into the reliability of database searches when close non-matches may be present.

Impact Statement: This presentation will have an impact on the forensic science community by raising awareness about the challenges inherent when conducting searches of large databases and the potential for increased contextual bias that may result from those searches. Forensic practitioners should be aware of the interplay between database size, size of largest candidate correlations, the presence of close non-matches, and the number of true matches in the database.

Abstract Text: A crime has been committed and firearms examiners have recovered spent bullets and cartridge cases from the scene. To generate investigative leads, examiners often rely on proprietary systems such as the National Integrated Ballistics Information Network (NIBIN) to correlate a piece of evidence to potentially similar bullets or cartridge cases recovered from other crime scenes. Investigators upload images of the crime scene item(s) onto the system, request a list of the top *k* most similar items from the database and then decide whether any of the *k* candidates are similar enough to the questioned items to warrant a physical comparison.

But how reliable are NIBIN searches? Suppose that one or more true matches to a questioned piece of evidence is in the NIBIN database. How likely are those true matches to be included in the list of the top *k* correlations identified by the system? Because NIBIN is proprietary, there is no straightforward way to estimate how frequently a search may fail to include a true match among the *k* most promising candidates. One reason this is important has to do with contextual bias. If among the *k* items that are most similar to the questioned item there is one or more that are close non-matches, the investigator may be persuaded to detect similarities that are not really there. This is not an unreasonable concern; after a database search that included a close non-matching print, three senior latent print examiners from the Federal Bureau of Investigation (FBI) incorrectly identified Mr. Mayfield as the perpetrator of a 2004 train bombing in Madrid that resulted in over 200 casualties.

To explore this question, we carried out a simulation where we varied the potential number of correlations (*N*), the size of the list of candidates (*k*) when the number of true matches in the database (t) is exactly one. In a small state such as Iowa, the size of the local NIBIN database is likely to be small, perhaps with *N* around 500 potential correlations. In large states, the potential number of correlations might be in the order of a few hundred thousand. We have reported on earlier findings that relied on the use of beta probability models to represent the distributions of same and different source (SS, DS) similarity scores, with parameter values that closely reproduced scores obtained by Fadul and Weller (Song et al.) after scaling.[1]

We have extended the study to the more realistic cases where the number of actual true matches t among the *N* possible correlations is larger than 1. We have also investigated the use of alternative probability models for the distributions of scores. How does the probability that the top *k* correlations include 0, 1,…,t true matches vary when *N*, *k*, and t vary? What if t = 0 but *N* includes close matches to the questioned item? We explore the similarity scores that may be obtained for the *k* most similar candidates and discuss how this may affect the chances of a false positive lead.

Bullet; Probability; Data

B113 Deep Ocean Recovery and DNA Identification of Human Remains From the Titan Submersible

Nancy A. Stokes, MSFS, Armed Forces Medical Examiner System/Armed Forces DNA Identification Laboratory/Amentum, Dover Air Force Base, DE; Taylor M. Dickerson III, MSFS, Armed Forces Medical Examiner System/Armed Forces DNA Identification Laboratory/SNA, Dover Air Force Base, DE; Timothy P. McMahon, PhD, Armed Forces Medical Examiner System/Armed Forces DNA Identification Laboratory, Dover Air Force Base, DE; John C. Walsh, MD, Armed Forces Medical Examiner System/Forensic Pathology Investigations, Dover , DE*

Learning Objectives: After attending this presentation, attendees will be informed of the DNA identification of human remains from the Titan submersible implosion and of environmental factors of the deep ocean that may help preserve DNA for forensic examination.

Impact Statement: This presentation will impact the forensic science community by providing an overview of oceanic environmental factors affecting DNA identification of recovered human remains and demonstrating the impact of those factors in the context of the Titan submersible implosion event in the deep ocean.

Abstract Text: There is a great deal of practical experience in the forensic biology community with obtaining DNA from human remains recovered from the ocean at relatively shallow depths. Analysts are familiar with considering how the remains, and ultimately the DNA, have been affected by predation, salt water, light, and other factors at these depths. There is very little experience, however, in the forensic community with DNA recovery and analysis from human remains recovered from ocean depths greater than approximately 650 feet (200 meters).

The OceanGate Expeditions submersible vessel, Titan, had five men aboard for a deep-sea dive in the North Atlantic Ocean to the wreckage of the Titanic when it imploded on June 18, 2023. Missions to recover vessel debris from approximately 12,500 feet (3,800 meters) were conducted in late June 2023 and early October 2023. Possible human remains were discovered among the vessel debris and delivered to the Armed Forces Medical Examiner System (AFMES) for examination and sorting. Selected samples were then delivered to the Armed Forces DNA Identification Laboratory's–Current Day Operations section (AFDIL-CDO) for DNA processing. Sixteen bone and tissue samples from the June recovery and fifty bone, teeth, nail, and tissue samples from the October recovery were tested and yielded five distinct autosomal Short Tandem Repeat (STR) DNA profiles and four Y-chromosomal Short Tandem Repeat (Y-STR) haplotypes. Family reference samples for each decedent were also collected and processed. DNA profiles generated from the Titan evidence samples and the family references were compared and subjected to multiple kinship analyses, resulting in identification of all five decedents from the Titan submersible.

Deep ocean recovery of disaster victims and forensic DNA identification of human remains will be compared from the Titan submersible implosion and the Air France 447 crash of June 1, 2009, in the South Atlantic Ocean. Factors that may contribute to preservation of human remains at ocean depths of approximately 12,500 feet will be presented.

Identification; Search and Recovery; Ocean

B114 An Evaluation of DNA Recovery From Chemically Treated Human Remains

Jennifer Snedeker, PhD, Sam Houston State University, Onalaska, TX; Rachel Houston, PhD, Sam Houston State University, Huntsville, TX; Sheree R. Hughes, PhD, Sam Houston State University, Huntsville, TX*

Learning Objectives: This presentation will offer foundational insights into the quantity and quality of DNA recovered from human remains treated with household chemicals, highlighting the potential for successful human identification from these compromised remains.

Impact Statement: This study is the first of its kind to expose intact large segments of human cadavers to common household chemicals, providing realistic samples for examining DNA recovery. The alterations in the samples' appearance, integrity, and recovered DNA will be assessed, offering guidelines for sampling these challenging remains. Our findings emphasize the need for authentic samples when studying chemically damaged remains.

Abstract Text: The identification of human remains has always been a complex task but can be further complicated when extreme methods of disposal are implemented. Offenders may resort to household chemicals to dissolve human remains, aiming to completely dispose of them or prevent identification. Once primarily associated with large criminal organizations, these practices have become more common, influenced by popular television shows like *Breaking Bad*.'

Despite the growing frequency of such cases, research on DNA recovery from chemically treated human remains is limited. Most studies focus on the visual effects these chemicals have on tissues, while the few that examine DNA recovery rely on animal proxies or focus solely on DNA recovery from human teeth, leaving a gap in research using realistic samples.[1-6] Our study addresses this issue by recreating the most authentic case scenarios, exposing intact segments of human cadavers to readily accessible household chemicals available at local hardware stores.

Whole heads, forearms, and hands were obtained from five cadavers provided by the Southeast Texas Applied Forensic Science (STAFS) facility at Sam Houston State University. These body segments were exposed to one of five chemicals: bleach, Rid-X septic treatment, lye drain cleaner, sulfuric acid drain opener, and hydrochloric acid pool cleaner. Tissue samples, including bone, teeth, muscle, fingernails, and hair, were collected at days 0, 1, 3, 5, 7, and 28. Subsequent DNA analysis included traditional Short Tandem Repeat (STR) typing and mitochondrial DNA analysis.

Although full STR profiles were recovered from remains after exposure to all five chemicals, hydrochloric acid was the fastest acting chemical, limiting identifications to only 3 days of exposure. In contrast, full STR profiles were recovered after 21 days of exposure to sulfuric acid and 28 days of exposure to bleach, Rid-X, and lye. Furthermore, comparisons to a pilot study using porcine rib samples highlight the need for authentic samples when examining these compromised remains, as the effects of certain chemicals varied drastically.

Chemical Damage; Skeletal Remains; Human Identification

B115 The Use of Mitochondrial DNA to Provide Ancestry of Skeletal Remains Discovered in the East Marshall Street Well (EMSW)

Martin W. MacStudy, BS, Virginia Commonwealth University, Richmond, VA; Filipa Simao, PhD, Virginia Commonwealth University, Richmond, VA; Baneshwar Singh, PhD, Virginia Commonwealth University, Richmond, VA; Tal Simmons, PhD, Virginia Commonwealth University, Richmond, VA*

Learning Objectives: This presentation will demonstrate how ancestry markers are used to gather information on human remains when there are limited avenues of DNA analysis and show the importance of mitochondrial DNA in predicting ancestry in samples that are severely degraded.

Impact Statement: This presentation will demonstrate how phenotypic and ancestral data can be obtained and used to provide life histories for severely degraded samples.

Abstract Text: During the construction of a building on the Medical College of Virginia campus of Virginia Commonwealth University in Richmond, VA, the East Marshall Street Well was discovered. The contents of the well included a commingled assemblage of human remains for upward of 50 individuals dating back to the mid-19th century. Of these individuals, anthropologists estimated there were at least nine juveniles.[1] These individuals were victims of grave robbing and were utilized for both dissection and amputation practice by the medical school before ultimately being disposed of in the well.[2]

With the exception of one juvenile, previous nuclear genetic research failed to re-associate the subadult remains into discrete individuals. In an effort to deepen understanding of the life history of the juveniles found in the well, mitochondrial-DNA analysis was performed to obtain mitochondrial haplotypes from targeted regions of the genome. Select samples were chosen to be sequenced on the MiSeq FGx to obtain autosomal Short Tandem Repeat (STR), Y-chromosomal Short Tandem Repeat (Y-STR), X-chromosomal Short Tandem Repeat (X-STR), and ancestral and phenotypic Single Nucleotide Polymorphism (SNP) information. The ForenSeq DNA Signature Prep Kit was used to prepare the library and sequence.

Of the remains sequenced thus far, African ancestry has been demonstrated for most of the juveniles. Two femora, one fibula, and one humerus were predicted as Sub-Saharan African haplogroup L1c2b1c through the sequencing of HVI; results from other remains are pending. The MiSeq FGx sequencing showed two more femora and one tibia clustering toward African ancestry, and another femur exhibited mixed ancestry. Phenotypic expression of hair and eye color was obtained for two femurs through the MiSeq FGx sequencing. One femur contained markers indicating the individual had black hair and brown eyes; the other had brown eyes and dark hair, with no hair color able to be predicted.

The results are consistent with the data obtained from the adult nuclear DNA sequencing, adult mitochondrial DNA sequencing, and anthropological work that has been done on the skeletal remains recovered from the well since its discovery. The majority of the remains in the well were assumed to be of African origin, due to a dark history of grave robbers targeting the burial sites of enslaved people, although DNA also demonstrated that several adult individuals of European ancestry were also present. Mitochondrial analysis of the juveniles has, thus far, narrowed the maternal line origin point to West-Central Africa, which echoes historical accounts of the origin of the enslaved in Richmond, VA.

Ongoing analysis of the ancestry of the juvenile remains will continue to broaden our knowledge of the life histories of these young individuals.

Mitochondrial DNA; Ancestral; Human Remains

B116 An Optimized Demineralization Method Using Bone Slices for Improved DNA Recovery of 19th-Century Human Skeletal Remains

Ciara Rhodes, BS, Virginia Commonwealth University, Richmond, VA; Reilly Elizabeth Price, MS, South Carolina Law Enforcement Division, Irmo, SC; Sarah Seashols-Williams, PhD, Virginia Commonwealth University, Richmond, VA; Tal Simmons, PhD, Virginia Commonwealth University, Richmond, VA; Celeste Willetts, BS, Department of Forensic Science, Richmond, VA*

Learning Objectives: This presentation will introduce a novel processing method for obtaining endogenous DNA from compromised skeletal samples and describe how it can improve Short Tandem Repeat (STR) profile quality from challenging biological samples. Attendees will understand how to integrate this modified approach into the standard forensic DNA workflow and the applications of powder-free processing methods of skeletonized remains for human identification.

Impact Statement: This presentation will positively impact the forensic community by providing a unique approach to recovering endogenous DNA from degraded skeletal remains. This research aims to improve front-end processing methods for isolating genomic material from compromised skeletal samples, which will have broad applications across numerous fields of study.

Abstract Text: Current processing techniques for harvesting DNA from osseous elements are destructive of potentially limited samples, and success rates vary widely. Few studies have explored whether the pulverization of bone contributes to DNA damage observed in STR profiles obtained from skeletal remains for human identification. Grinding the hard tissue into a fine powder exposes a greater surface area of the bone matrix to the various chemicals utilized in the extraction process and is suggested to release DNA molecules from the hydroxyapatite mineral matrix.[1,2] However, such homogenization of skeletal elements can introduce inhibiting components and exogenous DNA to the sample, competing with endogenous DNA during amplification.

In this work, we have developed and optimized an alternative front-end processing method using aged, weathered bovine cortical bone as a model for aged and degraded human skeletal remains. Given its dimensions, collagen composition, and comparatively reduced ethical restrictions, bovine bone was used as an experimental model for normal human bone.[3] After sample preparation, complete demineralization of small cortical bone fragments was performed, and samples were sliced manually with a razor blade before isolation with silica-based DNA extraction chemistry. For comparison, an organic extraction method was performed on a subset of pulverized samples following the protocol described by Edson and McMahon.[4] Bovine mitochondrial DNA quantification data and STR profile quality were assessed for powdered bone samples and demineralized slices. Analysis of Variance (ANOVA) was used to determine significant means differences for total bovine mitochondrial DNA yields across the treatment types. Bovine profiles generated from demineralized slices yielded a higher average percentage of alleles detected ($p < 0.05$) and had greater retention of larger STR loci than pulverized samples. In conclusion, using demineralized slices resulted in more complete, balanced STR profiles, higher peak heights, and less degradation than powdered samples.

Using 19th-century human cortical skeletal samples, the efficacy of the developed methodology was assessed to investigate the concordance of genetic markers through traditional and emerging genotyping applications, including length-based and targeted sequencing technologies with Capillary Electrophoresis (CE) and High-Throughput Sequencing (HTS) to maximize the recovery of degraded DNA for human identification. Total endogenous DNA yields and degradation indices of powdered samples and demineralized slices were evaluated. The average total DNA yields for pulverized and demineralized slices were 0.1391ng and 0.9043ng, respectively. The Internal Positive Control (IPC) Cycle threshold (Ct) values were assessed for each processing method, and 52% of pulverized samples and 73% of demineralized slices samples had IPC Ct values within the acceptable range (27–31). The average degradation index for pulverized samples could not be calculated due to failed large autosomal amplification. Demineralized slices ultimately resulted in greater recovery of amplifiable DNA than traditional homogenization methods of skeletal remains for DNA analysis.

By eliminating the powdering step of bone and utilizing modified silica-based extraction chemistry, the susceptibility to inhibitory and competitive effects from native and foreign components often found in degraded human skeletal remains can be minimized when prolonged demineralization of small cortical bone fragments and subsequent slicing is performed before lysis.

B117 Biparental and Uniparental Ancestry of the Unidentified Human Remains From the East Marshall Street Well

Christopher Twene, MS, Virginia Commonwealth University, Richmond, VA; Filipa Simao, PhD, Virginia Commonwealth University, Richmond, VA; Baneshwar Singh, PhD, Virginia Commonwealth University, Richmond, VA; Tal Simmons, PhD, Virginia Commonwealth University, Richmond, VA*

Learning Objectives: Attendees will learn about advanced genetic techniques for analyzing historical human remains, including the use of Insertion/Nulls (INNULS), Short Tandem Repeat (STR) markers, and sequencing technologies to determine ancestry and phenotypic traits. They will also gain insights into the ethical considerations and community involvement necessary for handling ancestral remains and how these methodologies can be applied to contemporary forensic casework.

Impact Statement: This presentation will impact the forensic science community by demonstrating the successful application of advanced genetic analysis techniques to historical human remains, thereby setting a precedent for similar future investigations. It will highlight the importance of integrating historical context with modern forensic methods to uncover ancestry and phenotypic traits, which can enhance the accuracy of identification efforts in forensic casework. Additionally, the research underscores the ethical considerations and community involvement necessary for handling ancestral remains, promoting a more inclusive and respectful approach in forensic practice.

Abstract Text: In April 1994, during the construction of the Kontos Building at the Medical College of Virginia on East Marshall Street, a well was discovered to contain artifacts and human remains, mainly of African American descent. Archaeologists were given a limited time to recover the remains and artifacts discarded over numerous years. The improper excavation of the well resulted in a commingled assemblage of skeletal remains and material. Later anthropological analysis indicated that remains from at least 44 adults and 9 children were in the well. The well was dated back to the mid-19th century when grave robbing and the use of cadavers of African descent in medical schools were common practices.

Addressing one of the recommendations of the Family Representative Committee (a committee of community individuals representative of the descendant family of the ancestral remains), genetic reassociation of the human bones recovered from the East Marshall Street Well have been performed using INNULS and STR markers. A total of 15 individuals were assembled.

Aiming to obtain biparental and uniparental ancestry information on the individual groups, one or two samples each from 15 adult individual groups were genotyped using Primer B of ForenSeq DNA Signature Prep Kit on the MiSeq FGx sequencing system. Universal analysis software was used to predict the biological sex, hair color, eye color, and ancestral origin of the 15 individuals. Ancestry proportions were calculated using STRUCTURE software, for K=3 (African, European, and Native American continental contributions). Paternal haplogroups were predicted with NevGen software using data for 24 Y-chromosomal Short Tandem Repeats (Y-STRs), for those samples typed with Primer B of ForenSeq DNA Signature Prep Kit. Mitochondrial DNA haplotypes were obtained for the HV1 segment, through Sanger sequencing.

Most individuals exhibited primarily African autosomal ancestry. Nonetheless, European and admixed ancestry was also detected for other individuals. Brown eye color was observed in all the individuals typed, with predominantly black hair color and dark brown observed in some samples. Three of the four Y-STR profiles obtained were predicted as African haplogroups, while the other one was predicted to be European. Maternal haplogroups obtained were of African origin, except for the individual with autosomal European ancestry that exhibited a European lineage. The findings complement the historical records regarding the slave trade and human trafficking, to Richmond, VA. Information obtained on the ancestry and phenotypic traits will enable the family representative committee, and the African American community in Richmond, VA, to know about their ancestors and to ensure a proper burial ceremony for the ancestral remains. This research will also provide insights into future genetic identification of human remains.

B118 Non-Destructive Brand Classification From Automobile Tire Rubber Traces Using ATR/FTIR Spectroscopy and Machine Learning for Forensic Investigations

Vishal Sharma, PhD, Panjab University, Chandigarh, Chandigarh, India; Akanksha Sharma, MS, Panjab University, Chandigarh, Sector 14, Chandigarh, India*

Learning Objectives: This study presents a novel approach for the classification of tire rubber samples using Attenuated Total Reflectance/Fourier Transform Infrared (ATR/FTIR) spectroscopy and machine learning. By combining these advanced techniques, the study offers a powerful tool for the non-destructive identification of tire traces in forensic investigations. The findings demonstrate the potential of this method to accurately and efficiently determine the brand of tires from rubber evidence, thereby providing critical information that can link suspects to crime scenes. As forensic science continues to evolve, the integration of machine learning and spectroscopic techniques will play an increasingly important role in ensuring that justice is served swiftly and accurately.

Impact Statement: The non-destructive nature of ATR/FTIR spectroscopy ensures that valuable evidence is preserved, allowing for further analysis if needed. By providing a systematic, rapid, and accurate method for identifying tire brands from trace evidence with the efficiency of machine learning, this study enhances the capability of forensic experts to quickly and confidently narrow down the range of suspects. This is particularly important in cases where time is of the essence, such as in hit-and-run incidents or abductions. Furthermore, the integration of advanced spectroscopic techniques with machine learning represents a growing trend in forensic science toward more sophisticated and automated methods of analysis that could lead to significant improvements in the efficiency of forensic laboratories, reducing backlogs and enabling faster turnaround times for evidence processing.

Abstract Text: The identification of tire rubber traces is a crucial aspect of forensic investigations, particularly in cases involving traffic accidents, hit-and-run incidents, abductions, hostage situations, and the unauthorized transit of prohibited items. These traces can appear as skid marks on road surfaces, imprints on clothing, or residues left on victims or other objects after sudden stops or abrupt movements. Such evidence plays a vital role in narrowing down suspects by establishing a connection between the crime scene, the getaway vehicle, and the perpetrator through the through the identification of the brand, manufacturer, or origin of automobile tire. There is a growing need for efficient, non-destructive, and accurate methods to examine these traces, as traditional approaches can be both time-consuming and destructive. This study proposes an innovative approach that utilizes ATR/FTIR spectroscopy, combined with machine learning algorithms to classify tire rubber samples from various brands sold in India and throughout the world.

ATR/FTIR spectroscopy is a non-destructive analytical technique that provides detailed spectral information on the molecular composition of tire materials, making it ideal for forensic applications. Its rapid analysis and minimal sample preparation requirements further enhance its applicability. The study involves the classification of 220 tire rubber samples from multiple brands, creating a comprehensive database for forensic comparisons. The main focus of this study is to evaluate the accuracy of classifying tire rubber samples from Light Motor Vehicles (LMVs) and Heavy Motor Vehicles (HMVs) and to identify the most effective machine learning algorithm for discriminating various rubber tires in accordance with brands. The spectral information obtained from ATR/FTIR is subjected to several preprocessing steps, including baseline correction, smoothing, derivatization, and normalization, to reduce noise and enhance reliability of the subsequent machine learning analysis by minimizing the effects of noise and other inconsistencies in the data.

Further, several machine learning models were evaluated, with the Extra Tree (ET) classifier emerging as the best-performing algorithm, achieving over 90% classification accuracy in distinguishing between LMV and HMV automobiles. After fine-tuning, it provided 73% accuracy in identifying three specific tire brands, namely JK Tires, Apollo Tires, and MRF Tires. The ability of machine learning algorithms to handle large datasets and identify complex patterns within the data makes it an ideal tool for forensic applications by providing valuable evidence that can link a suspect to a specific vehicle.

Tire Rubber; Trace Evidence; FTIR

B119 The Development of a Protocol for the Elemental Analysis of Tire Marks in Road Crime Forensics

Matthieu Baudelet, PhD, University of Central Florida, Orlando, FL; John G. Lucchi, PhD, University of Central Florida, Orlando, FL; Micaela S. Hernandez, BS, University of Central Florida, Sanford, FL; Alex N. Curto, BA, National Center for Forensic Science, Riverview, FL*

Learning Objectives: Attendee's will learn about different methods of skid mark particle lifting and analysis, with their comparison to known tires. They will also learn about its application to Inductively Coupled Plasma/Mass Spectrometry (ICP/MS) analysis for forensic association of tire skid marks.

Impact Statement: This presentation will impact the forensic science community by providing another form of trace evidence analysis, especially helpful in traffic accidents and hit-and-run accidents.

Abstract Text: With nearly 33,000 hit-and-run fatalities occurring in the United States between 2004 and 2022, extracting detailed information from accident scenes is crucial. Identifying who is at fault is essential for delivering justice to the victims. Traditionally, tire mark analysis relies on physical reconstruction of the accident, but analyzing the rubber left from braking events can provide additional evidence. By examining tire particles and linking them to their specific tire source, crucial evidence can be gathered to perhaps identify the perpetrator to the hit-and-run accident.

Tires vary by model and brand, each with a unique chemical composition designed for specific characteristics. Additionally, tires have trace elemental contaminants introduced through manufacturing that help in the association with their source. While some studies have shown the use of rubber analysis for the classification of tires, elemental analysis can be a very sensitive approach to use the contaminants as signatures of manufacturers and models of tires. To that end, ICP/MS has been explored in this study, and we show its success to classify tires with over 90% accuracy based on their elemental profile, distinguishing among 39 different tire models.

While the unicity of tire models is a necessary demonstration, the association of tire particles from skid marks to the tire itself is the goal of such application. Effective sampling of tire marks from the road is then essential for capturing as many tire particles as possible while minimizing contamination from road surfaces and the sampling method itself. Various techniques were explored for sampling and extracting tire rubber from road surfaces while being optimized for ICP/MS analysis. Statistical analysis shows that the association between skid marks and their source tires can be confirmed or reveal no connection to unrelated tires.

The results presented in this work will show how tire particles and tire rubber can be analyzed quantitatively with minimal to null contamination from the road materials, and we will discuss how this novel analysis could help road crime forensics practitioners.

Trace Analysis; Tire Marks; Accident

B120 The National Institute of Standards and Technology (NIST) Mass Spectral Reference Libraries

Edward Erisman, MS, National Institute of Science and Technology, Gaithersburg, MD*

Learning Objectives: During this presentation, attendees will learn about the types of mass spectral libraries available from NIST and how they are made (how compounds are chosen, how spectra are evaluated, etc.). Attendees will also learn about the software tools freely available from NIST.

Impact Statement: This presentation will impact the forensic community by informing them of how high-quality mass spectral libraries are made and how to use the tools available to them. This talk will also demonstrate the utility of using retention indices in coming to the correct identification.

Abstract Text: The NIST Mass Spectrometry Data Center (MSDC) maintains several mass spectral libraries. These libraries include the Electron Ionization (EI) library (collected at 70eV), the tandem (electrospray) spectral library, and the Direct Analysis in Real Time (DART) library. The EI and tandem libraries are commercial products distributed through vendors and are on a three-year update cycle, with 2026 being the next release. The MSDC has an extensive compound selection process to ensure new additions to the library are relevant. The libraries are carefully curated by a professional staff to ensure the spectra are of the highest quality. The MSDC has developed data processing software tools to aid the extraction, search, and evaluation of spectra, and the tools are freely available. The software available includes Automated Mass Spectral Deconvolution and Identification System (AMDIS) for mass spectral deconvolution, MS Search for spectral searching, and MS Interpreter (to aid in interpretation).

The NIST23 EI mass spectral library contains 394,000 spectra of which 347,100 are unique compounds.[1] The library has 492,000 experimentally determined retention index values for a variety of column polarities. Each library entry also has an artificial intelligence-predicted as well as a group additivity model-predicted retention index value for a semi-standard non-polar column. Each library entry contains meta data that includes common name, molecular formula, molecular mass, chemical structure, InChIkey, Chemical Abstract Service registration number (when available), and a link to search the internet for more information. The EI library contains compounds of interest for the forensic community, including, but not limited to, over 250 fentanyl-related compounds, over 125 tryptamine-related compounds, over 125 benzodiazepine-related compounds, and over 500 synthetic cannabinoid-related compounds.

The 2023 tandem mass spectral library contains 2.4 million spectra from 51,501 compounds. The library contains ESI high resolution accurate mass spectra for 49,590 compounds, ESI low resolution spectra for 49,865 compounds, and high resolution APCI spectra for 561 compounds. The tandem library has low resolution spectra for over 220 fentanyl compounds, over 50 tryptamines, over 75 benzodiazepines, and over 350 synthetic cannabinoids. The library also has high resolution spectra for over 225 fentanyl compounds, over 50 tryptamines, over 65 benzodiazepines, and over 350 synthetic cannabinoids.

The DART mass spectral library is a freely available library tailored to compounds of forensic interest. Each of the 1,371 compounds in the library consists of a set of three different in-source collision-induced dissociation mass spectra. The DART Data Interpretation Tool (DIT) utilizes an Inverted Library Search Algorithm (ILSA) to look for confirmation in higher fragmentation energy spectra of a component found in low fragmentation energy spectra.[2]

B121 The Development and Evaluation of a Contrastive Learning Framework for Source Identification: Technology for Transformation in the Interpretation of Forensic Data

Danica M. Ommen, PhD, Iowa State University, Ames, IA; Christopher P. Saunders, PhD, South Dakota State University, Brookings, SD; JoAnn Buscaglia, PhD, FBI Laboratory, Quantico, VA*

Learning Objectives: Participants will learn about the contrastive learning strategies from artificial intelligence and a specific framework applicable for using these algorithms to assist examiners in interpreting data for source identification.

Impact Statement: The forensic science community will be impacted through the understanding of the proper usage of machine learning methods, which examiners can apply to comparative analyses.

Abstract Text: To interpret the value of forensic evidence that results in data from a pair of items, the common source identification framework asks the question: do the items share a common unknown source or come from two different unknown sources?[1] This question can be addressed using a variety of forensic statistics techniques, including the usual Two-Stage, Likelihood Ratio, and Bayes Factor approaches.[2,3] Contrastive learning methods address the question using two major components: a method for quantifying the similarity (or dissimilarity) of pairs of evidential items and a method for determining the best separation between within-source or between-source comparisons.[4] Contrastive learning methods are particularly useful when the data derived from the evidence is high-dimensional or complex. In this case, the contrastive learning algorithms take advantage of high-performing artificial intelligence and machine learning tools to avoid specifying complicated probability models for the usual forensic statistics approaches. In this presentation, a contrastive learning algorithm framework is developed for complex evidence and applied to data from aluminum (Al) powders.

In comparing Al powder particles recovered from two pre-blast Improvised Explosive Devices (IEDs), the goal is to determine whether the powder sources are associated, potentially providing investigative between-case linkages. Unfortunately, the complex nature of the resulting data creates difficulties in applying the usual statistical approaches in a straightforward manner. For characterizing features of the Al powder, we take several subsamples from the bulk Al powder, several aliquots from each subsample, several fields of view are imaged on each aliquot, and then multiple micromorphometric parameters are measured for each particle in a field of view. This means that the multiple measurements on each single object can be aggregated at different substructure levels when applying statistical techniques for interpreting the evidential value.

During this presentation, we apply contrastive learning techniques with the ultimate aim of assigning an interpretable value of evidence, and we explore different methods of summarizing the data, quantifying pairwise similarity, and classifying pairs as within- or between-source comparisons. The contrastive learning methods in this presentation can also be applied to other complex data encountered in the analysis of trace and pattern evidence.

B122 The Curious Case of the Elusive Generalist

Sheila Willis, DSc, Leverhulme Research Centre for Forensic Science, Dundee, Scotland; Michelle D. Miranda, PhD, Farmingdale State College, State University of New York, Farmingdale, NY*

Learning Objectives: After attending this presentation, attendees will have a better understanding of the need to establish a structured and universal generalist course of study to serve as the foundation of forensic science education in order to enforce a shared understanding of forensic science, regardless of individual discipline or specialization.

Impact Statement: This presentation will impact the forensic science community by challenging individuals to rethink existing forensic science education with the goal of viewing the generalist approach as a foundation on which to build one's knowledge as a forensic scientist. This approach focuses on principles outlined in the Sydney Declaration and includes content such as understanding the nature of traces within the event scene; logic and reasoning; meaningful evaluation and interpretation of findings in context; and communicating scientific information. It is this fundamental generalist education on which later specializations should be built, and it is the properly educated and trained generalist that can serve as advisor as traces move from the scene to the court.

Abstract Text: Forensic science has advanced considerably with technology. Many scientists have welcomed this development but bemoaned the lack of guiding principles from which scientific problem-solving should proceed. This presentation will focus on the need for the generalist to support the specialist role.[1] Some technologies will be explored to illustrate the risk of technology becoming the master and the scientist its subordinate. An obvious difficulty arises when we are not in a position to interpret and explain the output of technology applied to forensic science problems. How to manage this will be explored.

Different jurisdictions have addressed the application of new and emerging technology in different ways, primarily relying on Standard Operating Procedures (SOPs) and (traceable) standards. This can be rendered more complex when statistical methods are arbitrarily applied to forensic science problems. This presentation suggests that SOPs, standards, and "statistics" alone are insufficient, and a meaningful, structured education in forensic science principles and philosophies is essential to ensure the correct use and application of science within the criminal justice system.

Within myriad fields, the specialist employs a narrow but deep focus, while the generalist has a wider, more shallow focus. As reflected in the medical model, these two should be complimentary. The specialist in the laboratory has no material to examine unless it is recovered from the scene. This statement is obvious but not enough attention is devoted to the need for a generalist to facilitate this process. More is needed beyond blindly utilizing technology without applying reasoning to ensure the right questions are being asked in the context of the case. The assumption may be that the crime scene examiner is knowledgeable about the technology employed and thus will be well-versed in how and what to collect in order to maximize the "evidential potential" within the laboratory. In extreme situations, this can lead to overlooking other traces that could meaningfully address the questions that need to be answered in an investigation and reconstruction—*who, what, where, when, why,* and *how*. As such, the authors argue that the generalist role is needed to support forensic science within the broader criminal justice system.

Once laboratory results become available, someone is needed to interpret them within the context of the case. This has been left primarily to the specialist in which their views have been developed according to different norms for different evidence types, leaving decision makers to differentiate between the values of various outcomes. The inclination is to focus on the specialist field to define the problem. The growing tendency is to assume that digital forensic science will be the answer to all forensic science problems, as human nature seeks to find a simple answer or silver bullet to address issues that may arise during an investigation. Forensic scientists are no different in seeking useful outcomes with minimal effort and faster turnaround times.

Would the situation be better if an educated generalist was present at the starting point for all forensic science problems and if all forensic science was built on foundational principles regardless of trace type or technology? We argue, yes. The key is a generalist program serving as the foundation of forensic science education, enforcing a shared understanding of forensic science—one that extends beyond forensic science history and terminology provided in introductory textbooks. The generalist education requires: knowledge of traces and how they behave (e.g., creation, transfer, persistence); logic and reasoning; the proper application of statistics; meaningful evaluation of findings; and the ability to clearly communicate findings.[2] The Sydney Declaration defines forensic science and the fundamental principles that underpin it, thus establishing a foundational knowledge for all forensic scientists regardless of discipline or specialization.[3,4]

B123 The Implementation of a Uniform Approach to Determine Measurement Uncertainty in Routine Chemical Forensic Casework

Ivo Alberink, PhD, Netherlands Forensic Institute, The Hague, Zuid-Holland, Netherlands; Ingrid Bosman, PhD, Netherlands Forensic Institute, The Hague, Zuid-Holland, Netherlands; Dick-Paul Kloos, PhD, Netherlands Forensic Institute, The Hague, Zuid-Holland, Netherlands; Marzena Glama, MS, University of Amsterdam, Zaandam, Zuid-Holland, Netherlands; Annette Sprong, BS, Netherlands Forensic Institute, The Hague, Zuid-Holland, Netherlands; Camille van Dijk, MS, Netherlands Forensic Institute, Zuid-Holland, Zuid-Holland, Netherlands*

Learning Objectives: After attending this presentation, attendees will have knowledge of a new uniform approach to determine Measurement Uncertainty (MU) in routine chemical forensic casework.

Impact Statement: This presentation will impact the forensic community by illustrating how reliable and uniform results may be obtained when determining MU in routine chemical forensic casework.

Abstract Text: Results obtained from quantitative research inherently involve uncertainty. At every step of the analytical process, from sampling to the final measurement, deviations from the true value in question will occur. The concept of MU is used to represent this imperfection. Without information on MU, measurement results may be misinterpreted, leading to incorrect conclusions. Determination of the MU basically entails describing how to convert an observed measurement into an interval that, with a certain level of confidence, contains the true value.

MU determination is a common issue in routine chemical forensic casework, where measurements are taken on, for example, seized drugs or whole blood samples. In these cases, quality control measurements are routinely performed and recorded on control charts to monitor and quantify measurement process variation. Control measurements are often performed on either Certified Reference Material (CRM), uncertified reference material (prepared in-house), or in Proficiency Tests (PTs).

Principles of the methodology for determining MU are laid down in guidelines.[1-4] Typically, the statistical model assumes that any measurement equals a real value plus a systematic bias, plus a random error. In forensic chemistry measurements, this model is often applied in a relative manner, meaning relative to the true value.

The approaches for MU found in the literature may have some drawbacks. For example, the formulas used to quantify MU involve implicit double counting of variance components, and the formulas vary considerably depending on the type of reference material used. Moreover, compensation terms for bias may be quite conservative.

A method was developed to determine MU in a uniform manner, for any type of reference material, based on formal statistical analysis. The system corrects measurements for observed bias, after which the combined MU is only determined by two factors: the relative standard deviations under reproducibility conditions within the lab and of the assumed true value of the reference material. Estimations of these factors are based on a top-down approach because of the complexity of the chemical analysis. This method has been implemented at our institute.

In conclusion, MU that was determined in guidelines could be quite conservative, differed heavily on the type of reference material used, and was not always exact as to calculation rules. Therefore, we see the new approach as a step forward in these respects. It may also be useful in a broader area than forensic casework.

B124 A Study of Standards Implementation Across the Forensic Sciences: Notes, Trends, and Future Directions

Vincent J. Desiderio, MS, National Institute of Standards and Technology, Gaithersburg, MD; John Paul Jones II, MBA, National Institute of Standards and Technology, Gaithersburg, MD; Allison Getz, MS, National Institute of Standards and Technology/Organization of Scientific Area Committees, Monrovia, MD; Steven L. Johnson, BS, Ideal Innovations, Inc., Arlington, VA; Mark D. Stolorow, MS, MBA, National Institute of Standards and Technology, Frederick, MD; Crystal E. DeGrange, MS, National Institute of Standards and Technology, Gaithersburg, MD*

Learning Objectives: Attendees will learn about efforts to standardize forensic practices from the national point of view, how standards are created and published, and the extent to which these standards are being deployed in forensic units throughout the United States. The manner in which implementation data is being used to improve the standards development process will also be emphasized.

Impact Statement: This presentation will impact the forensic community by demonstrating the extent to which standards are being used throughout the forensic sciences. It is expected that additional forensic science service providers will be encouraged to implement standards, provide data on that implementation, and further support the efforts to increase and improve forensic standardization across the forensic landscape.

Abstract Text: In 2009, after much anticipation by the forensic science community, the National Academy of Sciences' National Research Council released their Report, *Strengthening Forensic Science in the United States: A Path Forward*.[1] The Report outlined 13 recommendations to strengthen scientific rigor across the forensic landscape. Among these recommendations was a call to increase standardization throughout forensic practice with particular emphasis on the scientific analysis of evidence and the reporting of results. To address this need, the National Institute of Standards and Technology (NIST) in conjunction with the United States Department of Justice established the Organization of Scientific Area Committees (OSAC) for Forensic Science in 2014.

Over the past ten years, OSAC has built processes to evaluate, review, draft, and improve forensic standards with the goal of placing them on a highly vetted repository known as the OSAC Registry. Through the diligent efforts of hundreds of forensic practitioners, laboratory managers, scientific academicians, defense attorneys, prosecutors, judges, statisticians, and human factors experts, the Registry has grown to include almost 200 published and proposed standards.

The growth of the Registry over this period is certainly a significant accomplishment. However, without data to demonstrate the extent of implementation of these standards, it is difficult to evaluate the impact of these efforts. To this end, the National Institute of Standards and Technology's (NIST's) Special Programs Office has been collecting standards implementation data from forensic science service providers willing to voluntarily provide this information since 2021. With the initiation of an "open enrollment" concept in 2023, in conjunction with the launch of a new electronic survey tool in 2024, NIST has gained greater ability to look more critically at implementation data to better evaluate and improve the state of forensic science standards implementation.

This presentation will provide a brief overview of NIST's initiative to collect standards implementation data and discuss the importance of these efforts. Through various illustrations, this presentation will also reveal the current extent of standardization in the forensic sciences, highlight implementation related trends, and outline how these data can be used to improve the national forensic science standards landscape.

Standards; OSAC; Data

B125 Problematic Exclusionary Differences: The Tyranny of Universal Standards for Determining Exclusionary Differences

Janean Hanka, MS, South Dakota State University, Brookings, SD; JoAnn Buscaglia, PhD*, FBI Laboratory, Quantico, VA; Danica M. Ommen, PhD, Iowa State University, Ames, IA; Christopher P. Saunders, PhD, South Dakota State University, Brookings, SD; Jack Hietpas, PhD, John Jay College of Criminal Justice, New York, NY*

Learning Objectives: Attendees of this presentation will gain an understanding of the statistical issues with the use of the American Society for Testing and Materials (ASTM) -style comparison methods for trace element profiles when source-dependent thresholds for declaring an exclusionary difference exist. Attendees will learn about novel developments for testing if multiple thresholds are warranted.

Impact Statement: The use of statistically rigorous methods for characterizing the applicability of standards for identifying exclusionary differences will be explored. The implications of differing rates of false exclusions among sources (resulting from the inappropriate use of a single threshold) will be discussed relative to the concept of algorithmic fairness and the fidelity of evidence interpretation to assist in the administration of justice.

Abstract Text: Within the forensic science community, there is a need for a statistically rigorous determination of whether an exclusionary difference exists. With respect to the ASTM glass interpretation standards, this difference is determined to have occurred if any one of the standardized differences between the measured trace element concentrations is greater than four.[1-3] In this work, we will present strategies for assessing the validity of using a common threshold for all sources when determining if an exclusionary difference exists.

The determination of when an exclusionary difference exists is integral to the Kirkian Two-Stage approach to evidence interpretation.[4] If an exclusionary difference is observed when comparing questioned v.s known source objects, then the known source is excluded as having given rise to the questioned object at the first stage of the approach; however, if the known source is not excluded as the source of the questioned object, then the examiner must determine the rate at which competing alternative sources would be excluded. These methods/algorithms are typically constructed to ensure that the false exclusion rate for each source is equal. However, if the underlying score function that the algorithm is based on has a distribution that varies by source, then the corresponding thresholds for determining an exclusionary difference will need to vary as well.

In this work, we will review various strategies for identifying when the within-source distribution of scores varies between sources; methods for estimating the thresholds; remedial approaches such as pooling subsets of the sources together; and implications of this type of variability among the sources to the classical Kirkian approach to evidence interpretation. Although we will focus on the Kirkian approach, these issues are even more problematic for Likelihood Ratio (LR) -based methods due to the need to estimate a likelihood function from just a few observations from a specified source; the discussed remedial methods will apply equally to the LR paradigm for evidence interpretation.

We will illustrate these methods with trace element concentrations in glass and Aluminum (Al) foil as well as micromorphometric data from small arms propellants.

Exclusionary Difference; Algorithmic Fairness; Evidence Interpretation

B126 Standards Development Activities Related to Friction Ridge Examination

Heidi Eldridge, PhD, The George Washington University, Washington, DC*

Learning Objectives: After attending this presentation, attendees will have a better understanding of the status of discipline-specific standards related to the examination of friction ridge detail from the hands and feet.

Impact Statement: This presentation will impact the forensic science community by creating greater awareness of standards development activities pertinent to the examination of friction ridge detail.

Abstract Text: The Organization of Scientific Area Committees (OSAC) for Forensic Science was initially created in 2014 through a cooperative agreement between the National Institute of Standards and Technology (NIST) and the Department of Justice (DOJ) to address the lack of discipline-specific standards guiding forensic science practices. To this end, the OSAC facilitates the development of discipline-specific forensic science standards and guidelines that can be further developed and published by Standards Developing Organizations (SDOs). The OSAC also evaluates standards for placement on the OSAC Registry, which serves as a central repository of consensus-based standards that have been deemed high quality and technically sound. The Academy Standards Board (ASB) was established by the American Academy of Forensic Sciences (AAFS) in 2015 as an ANSI-Accredited SDO. Both organizations are comprised of volunteer practitioners and other stakeholders, and they have a collaborative relationship in which documents created by the OSAC Friction Ridge Subcommittee (FRS) are passed to the ASB Friction Ridge Consensus Body (FRCB) for the standards development process, after which they are considered for inclusion on the OSAC Registry.

During this presentation, updates related to friction ridge standards development activities will be presented. These include: (1) standards and guidelines that have been proposed by the OSAC FRS and are currently being evaluated and further developed through the ASB FRCB, (2) standards and guidelines that have been published by the ASB and are being considered for the OSAC Registry, (3) standards and guidelines published by the ASB that have been placed on the OSAC Registry, (4) documents currently in development by the OSAC or by the ASB, and (5) priorities for new documents or work products by the OSAC FRS or by the ASB FRCB. This presentation will also highlight how the process of moving documents back and forth between the OSAC and ASB works for the friction ridge discipline, challenges and successes that process has encountered, and what the near future looks like for the promulgation of friction ridge standards and guidelines.

Standards; Latent Prints; Professional Responsibility

B127 Forensic Lab's Phoenix Rise: The Remarkable Redemption of a Lost Latent Fingerprint Unit

Angelic M. Rountree, BS, DC Department of Forensic Sciences, Washington, DC; Alice White, BS, Evolve Forensics, Partlow, VA*

Learning Objectives: Attendees will learn about the comprehensive strategies and methodologies employed to restore the accreditation of the Latent Fingerprint Unit (LFU), including the overhaul of Standard Operating Procedures (SOPs) and the implementation of a specialized training program. They will gain actionable insights into quality control measures and continuous improvement practices that can be applied to elevate standards and achieve excellence in forensic identification.

Impact Statement: The loss of accreditation and quality issues within the LFU had significantly impacted the credibility and reliability of our forensic processes, eroding trust within the community and among stakeholders. Implementing robust SOPs and specialized training programs is essential to restoring our accreditation and elevating our operational standards. These measures will ensure accuracy and integrity in our analyses, helping to rebuild our reputation and regain confidence in our forensic capabilities.

Abstract Text: In recent years, the Department of Forensic Sciences (DFS) faced a significant setback with the loss of accreditation and quality issues within its LFU. This adversity prompted a critical evaluation of existing practices and a call for comprehensive reforms. In response, Alice White, a renowned expert from Evolve Forensics, conducted a thorough gap assessment and specialized training sessions for LFU personnel. This initiative aimed to address deficiencies and equip the LFU team with the latest techniques and methodologies in latent print examination.

The challenges faced by the LFU were multifaceted, including outdated procedures, lack of standardized training, and gaps in quality control measures. The loss of accreditation served as a wake-up call, highlighting the urgent need for systemic changes. The collaboration with Evolve Forensics marked the beginning of a transformative journey. Alice White's expertise was instrumental in identifying critical gaps and areas for improvement, setting the stage for a comprehensive overhaul of the unit's operations.

The gap assessment revealed issues in the foundational skills (minutiae mark-up, distortion, latent isolation, and suitability) that required immediate attention. These included the need for updated SOPs, enhanced training programs, and the implementation of rigorous quality control measures. The specialized training sessions conducted by Alice White were designed to address these deficiencies, providing LFU personnel with the skills and knowledge necessary to perform their duties to the highest standards. The training covered various aspects of latent print examinations, from incorporating an explicit suitability criterion to expanding the conclusion scale, ensuring that the team was well-equipped to handle the demands of their work.

Following the completion of the training, the LFU Manager played a pivotal role in implementing the recommended changes. This included the overhaul of SOPs to align with best practices in the field, as well as the development of a robust training manual tailored to the specific needs of LFU personnel. The new SOPs provided clear guidelines for applying the suitability criteria appropriately and consistently, ensuring consistency and accuracy in the unit's work. The training manual served as a valuable resource for both new and experienced team members, offering comprehensive guidance on all aspects of latent print examination.

The proactive measures taken by the LFU Manager also included the establishment of a continuous improvement program, aimed at maintaining high standards of quality and efficiency. Regular audits and reviews were instituted to monitor compliance with the new procedures and identify areas for further enhancement. These efforts have been instrumental in restoring the unit's reputation and regaining accreditation.

Through these concerted efforts, the LFU has not only elevated its standards but also positioned itself as a beacon of excellence in forensic identification. The journey of the LFU serves as a testament to the power of collaboration, expertise, and unwavering commitment to quality. The LFU's experience provides valuable lessons for other forensic units facing similar challenges, highlighting the importance of continuous improvement and the pursuit of excellence in the field of forensic science.

Accreditation; Quality Assurance; Latent Prints

B128 Assessing the Performance of Fingerprint Laboratories Through Collaborative Exercises: The ENFSI Fingerprint Working Group Experience

Aldo Mattei, PhD, RIS Carabinieri, Messina, Sicily, Italy*

Learning Objectives: By attending this presentation, attendees will learn how to design an interlaboratory testing scheme (i.e., collaborative exercise), including (1) how to define the aim of the test; (2) how to design the test in its phases (selection of the type(s) of item, preparation of the pilot test, evaluation of the pilot test); (3) how to prepare and distribute the test; and (4) how to collect and evaluate the information collected.[1] Moreover, attendees will benefit from a series of examples of collaborative exercises run between 2004 to 2024.[2-6]

Impact Statement: This presentation will impact the forensic science community by setting practical rules on how to organize an interlaboratory comparison in the fingerprint domain, in conformance to the published regulatory literature (European Network of Forensic Science Institutes [ENFSI], National Institute of Standards and Technology-Organization of Scientific Area Committees [NIST-OSAC]). Additionally, major outcomes and lesson learned from the organization of interlaboratory testing schemes in the past 20 years will be highlighted, thus demonstrating their use in the assessment of the performance of forensic science providers.

Abstract Text: According to the document "Council conclusions on the Action Plan for the European Forensic Science Area 2.0," there is a need to "ensure continuous development of key forensic science capabilities in order to secure and strengthen its current and future relevance within the judicial system."

Friction ridges are still the most used biometric used in the criminal justice system. To guarantee the validity of the friction ridge examination, since the end of 2015, all European fingerprint services laboratories have to be International Organization for Standardization **(**ISO) 17025 accredited to be able to exchange the results of their expertise within European Union (EU) countries. Therefore, the conduct of proficiency tests and collaborative exercises at the international level has to be seen as a mandatory activity for the forensic fingerprint laboratories. The availability and use of proficiency tests is limited in the friction ridge domain. There are only a few companies providing proficiency tests in the field of friction ridge visualization, imaging, and comparison, and these tests show a modest level of difficulty, according to practitioners.

"Demonstrating reliability in forensic results" imposes a robust quality and competence assurance, which can be achieved not only by measuring the outcomes through proficiency testing, but also by collecting all the information needed to ensure a root cause analysis in case of failure, which is granted only by means of collaborative exercises. Interlaboratory exercises are aimed to: (1) provide a clear picture of the performance of fingerprint laboratories participating in the scheme; (2) identify shortcomings or failures in the practice; (3) suggest remedies to the measured errors;(4) detect the needs for specific training related to the application of the current forensic methods; (5) disseminate the results, facilitating educational sessions through ad hoc workshops; (6) contribute to the standardization of the methods and of the evaluative reporting, through the benchmarking of laboratories' performance; (7) provide with the European Conformity (CE) organizers (i.e., ENFSI ATACH Working Group on Financing [FIN-WG]) a robust procedure to design, validate, realize, and evaluate CEs in the friction ridge field to assess the performance of the member laboratories.1

ENFSI FIN-WG started in 2004 to provide free-of-charge CEs to the WG members both in the visualization of friction ridge marks and in the comparison of marks with a known source.[2-6] The outcomes of these CEs showed a heterogeneous situation across Europe: failures in CEs are not strictly related to the accreditation status of laboratories.

As stated by European Food Safety Authority (EFSA) 2.0, "The ability to extract, use and exchange biometric data is one of the cornerstones of forensic science. Securing the current and future use of biometric procedures, including final human verification of results, within forensic science is essential for the ability to support forensic science at large". The data collected through CEs in the past 20 years, and only partially made available to general public via scientific publications, demonstrates that there is a consistent gap to reach this objective.[2-6] The use of commercially available PTs does not provide the assurance of a reliable performance since such tests are not sufficiently representative of the average difficulty of routine examinations. Moreover, the collected results show a relevant inconsistency in the examination and in the interpretation of the data, thus reducing the reliability of the friction ridge evidence. The main objective of the action is to highlight the impact of the different examination methods and evaluation on a homogeneous (or identical) testing sample, thus highlighting the limits of local procedures. A robust quality and competence assurance is the only path to ensure the reliability of forensic results. By constantly demonstrating with factual data the limits of some of the current procedures, a standardized approach to friction ridge examination will be reached in the long term.

Fingerprint; Interlaboratory Comparison; FSPs Performance

B129 An Investigation of Fingermark Residue Components and Differentiation From Contaminants

Emma Macturk, BS, William & Mary, Williamsburg, VA; Katelynn A. Perrault Uptmor, PhD, William & Mary, Williamsburg, VA*

Learning Objectives: After attending this presentation, attendees will be able to identify exogenous cosmetic contaminants and key endogenous volatile compounds present in fingermark residue.

Impact Statement: This topic will impact the forensic community by providing a proof-of-concept method study for the non-targeted analysis of fingermark residue using new instrumentation. Baseline fingermark residue analysis will provide a foundation for the analysis of trace contaminants found in fingerprint residue.

Abstract Text: The ridge characteristics from a deposited fingerprint are routinely used by forensic specialists to individualize a pattern to a suspect. Partial fingerprints that lack a complete ridge pattern are often not fit to undergo the identification process, although their residue may still contain valuable chemical information about a suspect or a crime scene. These incomplete prints, called fingermarks, consist of sweat and oil originating from the sebaceous glands of their donor. There have been initial studies analyzing fingermarks using Gas Chromatography (GC) that have demonstrated their residue contains biomarkers, including alcohols and lipids, that can distinguish between sex and age of donors. However, there has been little research in the full, non-targeted characterization of fingermark residue using advanced chromatographic methods to allow: (1) full comprehensive profiling of all fingermark residue components simultaneously without derivatization, and (2) simultaneous differentiation of fingermark components from external contaminants. This is largely due to the fact that the number of components can be extremely high when considering both endogenous fingermark components and other residues present through contact, and, therefore, traditional methods for component analysis can be limited in their ability to separate, identify, and visualize all analytes within a single method.

The goal of this study was to develop a method for the collection and non-targeted analysis of fingermark residue using comprehensive Two-Dimensional Gas Chromatography/Time-Of-Flight/Mass Spectrometry (GC×GC/TOF/MS). Fingermarks were collected on a microscope slide after hand washing and regeneration of residue. The residue was dissolved in solvent and analyzed using GC×GC/TOF/MS. Peaks for common fingermark compounds such as cholesterol and squalene were identified and exhibited peak areas with Relative Standard Deviation (%RSD) of approximately 56.53 % and 33.21 %, respectively, over a sample set of 18 fingermarks. Fatty alcohols such as palmityl alcohol (C16) and stearyl alcohol (C18) were identified as well as various saturated fatty acids from C_8-C_{34} such as octanoic acid (C8:0), myristic acid (C14:0), and palmitic acid (C16:0).

Several cosmetic contaminants were resolved from fingerprint residue. Octocrylene and avobenzone, common sunscreen ingredients, were respectively present in 44 % and 28 % of samples analyzed. In addition, α-tocopheryl acetate, the cosmetic form of Vitamin E, was resolved from fingermark compounds. The use of GC×GC subtraction plots yielded effective visualization of endogenous and exogenous components that may yield value for presentation in expert witness testimony. The presence and identification of analytes outside of expected fingermark compounds provide a baseline for future probing of residue with additional external contaminants such as explosives, gunshot residue, drugs, or other personal care products that may be relevant in forensic casework.

Fingerprint Residue; Trace Analysis; Chromatography

B130 Developing Reproducible Protocols and Definitions for Selecting Combined Minutiae: Applications in Research and Practice

Adele Quigley-McBride, PhD, Simon Fraser University, Burnaby, BC, Canada; Heidi Eldridge, PhD*, The George Washington University, Washington, DC; Brett O. Gardner, PhD, University of Virginia, Charlottesville, VA*

Learning Objectives: Attendees will learn about the protocols developed to assess the content of latent print examiners' responses to questions about use of minutiae frequencies in case work as well as the process through which a repeatable and reproducible protocol was created for standardizing the collection of data about combined minutia types. Attendees will see new data regarding the way in which latent print examiners use minutiae rarity in their Analysis and Comparison judgments and what sources of information informed their estimates of minutiae rarity. Attendees will see new information about objective minutiae frequencies and the protocol developed to establish objective frequencies for combined minutiae in research.

Impact Statement: This presentation will impact the forensic science community by providing fingerprint examiners with information about how latent print examiners weigh the presence of minutiae according to the perceived rarity of those minutiae and their placement as well as the sources of the information used to make these judgments. The presenters will also give an update regarding the collection of objective frequencies for combined minutiae. This presentation will also include a description of the development of the repeatable and reproducible protocol created for standardizing the collection of data about combined minutia types and the benefits of using this protocol in future research.

Abstract Text: Forensic science literature has increasingly emphasized the importance of consistency and reliability across forensic disciplines in recent years. Latent fingerprint comparison, in particular, has received a high level of scrutiny given that research on some of the core aspects of these analyses remains lacking. Assessing the appearance and placement of fingerprint minutiae (the shapes and features within friction ridge patterns) is central to the task of a fingerprint examiner, as is their ability to communicate their analytic process and the reasons for their expert opinion.

Although we know that some minutiae are rarer than others, there exists very little systematic research about minutia base rates and latent print examiners' perceptions of minutiae rarity.[1] Research on judgment and decision-making shows, though, that people generally struggle with the task of estimating how often events or features occur, and that different contexts can alter how data are perceived, interpreted and evaluated.[2] Thus, we can expect variation in latent print examiners' estimates of minutia frequency and their classification of friction ridge events within minutia types. We can also expect that latent print examiners' beliefs about minutia rareness or commonness will affect how much weight is given to each feature during analyses.[3]

Last year, we presented data on latent print examiners' perceptions of minutia frequency.[4] With these data, we were able to provide consensus-based evidence of minutia frequency in general, within different friction ridge patterns (loop, arch, whorl), and by location within the fingerprint impression (i.e., center versus periphery). In addition to consensus data on minutia rarity, we also presented research-based suggestions for appropriate, popular minutia labels to help standardize communication in the field.[5]

This year, there are two recent, significant data updates to share. First, we will present the results of a content analysis that involved extracting themes from latent print examiners' explanations of how they use their perceptions and knowledge of minutia frequency in their casework. We will present information about the most common ways minutia frequency is factored into latent print examiners' Analysis and Comparison judgments, as well as their reports concerning the origin of their knowledge about minutia base rates (e.g., experience, formal training, scientific articles).

The second major update concerns the creation and implementation of a repeatable and reproducible protocol created for standardizing the collection of data about combined minutia types. As was the case for other phases of this research project, the development of this protocol was an interdisciplinary endeavor, and relied on an iterative process to achieve the goal of a useable, practical protocol that could be adopted with ease by other research groups and in casework. We will present some updates on the objective minutia frequency database and discuss the benefits of using a rigorous, research-based protocol like the one developed for this project in future research.

Taken together, these data provide new insights into latent fingerprint examiners' use of perceived minutia frequency in their casework. Our data provide significant advances in the standardization of latent print examiners' use of minutiae in casework and will help to standardize future research so that data across studies can be synthesized. These studies can also serve as a model to other forensic disciplines seeking to increase consistency and reliability.

Latent Prints; Standards; Human Factors

B131 Likelihood Ratios for Fingerprint and Palm Impressions

Thomas Busey, PhD, Indiana University, Bloomington, Bloomington, IN; Meredith Coon, MS, Aver, LLC, Columbia, MD*

Learning Objectives: Attendees will learn how likelihood ratios can be calculated from human examiner data from error rate studies. They should be able to describe the limitations of source conclusions and the advantages of likelihood ratios. Finally, they should be able to communicate how current practice overstates the strength of the evidence by wide margins in some cases, which can lead to clear miscarriages of justice.

Impact Statement: Articulation language must be calibrated against the strength of the evidence or fact finders will overinterpret the results of forensic comparisons. We find that in many cases the likelihood ratios for image pairs are much lower than what would be expected based on published verbal equivalency scales. This demonstrates that the terms Identification or Source Identification as currently defined are inappropriate, and the present work provides the data to allow for community-approved changes that bring the terms in line with the actual strength of the evidence.

Abstract Text: The results of fingerprint and palm comparisons are communicated using posterior language such as "Identification" and "Source Identification." Recent efforts have recast these to strength-of-support statements such as "extremely strong support for common source."[1] However, none of these terms have been calibrated against the actual strength of the evidence, except indirectly in error rate studies.

In this talk we use an ordered probit model to reanalyze error rate study data to compute likelihood ratios for each image pair in an error rate study.[2-4] The distribution of subjects who made conclusions on each pair are converted to an underlying latent scale that expresses the support for the same source proposition as determined by the distribution of responses. For example, if 12 examiners say Identification and 4 say Inconclusive, this offers more support for the same source proposition than an image pair where 3 examiners say Identification and 13 say Inconclusive. The ordered probit model is an extension of signal detection theory to individual image pairs, and, when combined with additional assumptions of independence between the examiners and image pairs, can be used to compute the probability of the observation (the latent value), given the same source and different sources propositions. The ratio of these two probabilities is the likelihood ratio.

We find that in many same source pairs the likelihood ratios are less than 100. Likelihood ratios are less than 10 for some comparisons for which a majority of examiners reached an Identification decision. Given that phrases such as "extremely strong support" are typically associated with likelihood ratios of 10,000 or a million, we find that current articulation language overestimates the strength of the conclusion by up to five orders of magnitude.[5]

The results help calibrate the existing source conclusion articulation scale. Likelihood ratios have additional benefits: They explicitly acknowledge the support for both the same-source and different-sources propositions, do not require knowledge of priors or the costs of errors, and are readily integrated with other likelihood ratios through Bayesian updating. We explore possible extensions to active casework and discuss the potential problems with moving to a strength-of-support reporting style.

Score Likelihood Ratios; Accuracy; Fingerprint Identification

B132 One Size Does Not Fit All: Variations in Documenting the ACE-V Process Among Latent Print Examiners

Ivy A. Walker, MS, RTI International, Raleigh, NC; John H. Grassel, MA, RTI International, Apex, NC; Micaela A. Ascolese, MS, RTI International, Cary, NC; Rebecca L. Shute, MS, RTI International, Research Triangle Park, NC*

Learning Objectives: Attendees will gain an understanding of the range of current technological tools and approaches utilized by latent print examiners to document the Analysis, Comparison, Evaluation, and Verification (ACE-V) methodology within the examination process and how these strategies have progressed over time. Examples of agency circumstances, associated workflows, and practical insights will be discussed, and attendees will be able to identify factors that latent print units must consider prior to updating procedures or implementing new technological solutions.

Impact Statement: Based on the need for transparent and comprehensive documentation during the latent print examination process, it is important to understand what technological tools (e.g., commercial and forensic software products) are utilized to achieve this goal. It is also necessary to understand how these tools are effectively integrated into case workflows based on diverse agency circumstances. Research has been conducted on what latent print examiners document during the examination process, but there are limited resources describing how the information is documented.

Abstract Text: Latent print examination is commonly conducted using the ACE-V methodology. A variety of manual and digital tools, such as magnifying equipment and software, are routinely utilized by examiners in the examination process to better visualize and annotate observed features in latent and known prints. For example, documentation in the Analysis phase may include details of image acquisition and processing (e.g., color enhancement, calibration, magnification, and annotation of observed friction ridge features), as well as written notes (e.g., free text and dropdown entries) to describe various attributes of a latent print such as the depositing matrix or receiving substrate, clarity, anatomical source, and pattern type. The Comparison, Evaluation, and Verification phases of the examination may include side-by-side depictions of annotated latent and known prints, along with written notes.

Latent print examination notes have historically been criticized as being deficient in reflecting observations from this process. The 2009 National Academy of Sciences (NAS) Report, 2016 President's Council of Advisors on Science and Technology (PCAST) Report, and various emerging best practice documents set forth by the Friction Ridge Subcommittee of the Organization of Scientific Area Committees (OSAC) have called for more transparent and comprehensive latent print examination documentation.[1,2] To accomplish this, examiners and agencies have attempted to provide more thorough written observations and visual aids utilizing varied approaches based on their capacity and organizational infrastructure.

This study will inform the forensic community and provide an overview of the technological tools and strategies currently in use by latent print examiners to document the latent print examination process, with emphasis on the ACE-V methodology. Approaches used by agencies will be categorized into three high-level areas: agency-specific (homegrown) approaches, which include software not specific to forensic applications, such as Adobe Photoshop or Microsoft Office products; customizable laboratory information management systems; and forensic software specifically designed for latent print examination and documentation. Of note, some agencies use a combination of these approaches, which will also be discussed. Based on data collected through end-user experience, details on current agency latent print documentation workflow processes will be elucidated. This study will also cover other current challenges and considerations when implementing a certain documentation approach.

Overall, this study will provide a timely update on the strategies and technology latent print examiners are utilizing, considerations for technology implementation, and recommendations for improving workflow efficiency.

B134 Enhanced Genetically Variant Peptide Profiling From Human Hair Using Keratinase and Trypsin

Zheng Zhang, MD, National Institute of Standards and Technology, Gaithersburg, MD; William E. Wallace, PhD, National Institute of Standards and Technology, Gaithersburg, MD; Stephen E. Stein, PhD, National Institute of Standards and Technology, Gaithersburg, MD*

Learning Objectives: The goal of this presentation is to increase the confidence of Genetically Variant Peptide (GVP) identification using the National Institute of Standards and Technology (NIST) -developed hair protein extraction, sample preparation, and data analysis pipeline—at present only traditional, non-targeted, error-prone proteomics methods are available. A freely available, comprehensive hair peptide library covering GVPs will be made available to the forensics community. This work will be of direct use to forensic colleagues for making confident GVP identifications.

Impact Statement: Our long-term goals are to: (1) build a comprehensive and in-depth hair/skin peptide mass spectral library, including all identifiable peptides, a diverse array of experimental, introduced artifacts, and all known hair/skin GVPs; and (2) build a pipeline to generate a useful report of GVPs regarding quality control.

Abstract Text: **Introduction:** Trypsin is usually the default digestion enzyme in proteomic experiments. GVPs derived from human hair proteins have been studied as evidence for human identification in forensics.[1,2] We hypothesized that the use of different proteases can expand sequence coverage in the hair proteome and therefore increase the chance of a variant peptide being identified as well as confirm the findings from tryptic digests. Since keratins and keratin-associated proteins are the main components of hair proteome, we examined keratinase alone and combined with trypsin to explore their ability to generate additional identifiable regular or variant peptides, and this led to both an increase in number of identified GVPs and their confidence of identification.

Methods: Human hair proteins were extracted from individual 5cm-long hair shafts of a male donor, reduced, and alkylated, followed by an optimized SP3 method.[3,4] Keratinase (K, repeated 3 times) was tested alone with enzyme-to-protein ratio 1:20 for 2 hours at 50°C or followed by trypsin (KT, repeated 3 times) with enzyme-to-protein ratio 1:20 for 18 hours at 37°C. K or KT was compared to trypsin (T, repeated 3 times). Peptides were cleaned up with MonoSpin C18 columns for Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) on an Orbitrap Fusion Lumos mass spectrometer. The FASTA file was expanded by adding mutations reported by BioMuta5 for 54 keratins with 7,554 proposed mutations and 92 keratin-associated proteins with 4,534 proposed mutations. We used Sequest (Proteome Discoverer) for database searching.

Preliminary Data: Preliminary analyses led to the following findings: (1) using keratinase alone, the average number of GVPs identified was 31; (2) using trypsin alone, the average number of GVPs identified was 106; (3) using keratinase combined with trypsin, the average number of GVPs was 140; (4) the significant increase of numbers of GVPs found in the combined group (140 vs. 31, $p = 0.0002$; 140 vs. 106, $p = 0.02$) suggests that (a) the addition of keratinase pretreatment facilitated downstream trypsin digestion by making it more efficient, and (b) the combination performed slightly better than by summing results of independent digestions; (5) we identified approximately two times as many peptides in the combined group when compared to trypsin or keratinase alone (average peptides/spectral counts for K, T, and KT: 696/2,034, 680/7,942, and 1,962/16,066); (6) the observation that a variant site was identified in different GVP sequences generated by different enzyme digestions increases the confidence of identification of a single variant site; (7) keratinase led to unique sequence coverage in some hair keratins and keratin-associated proteins compared to trypsin, demonstrating the complementary nature of keratinase and trypsin; and (8) each enzyme resulted in the identification of unique variant sites, suggesting improved GVP discovery. In addition, we are in the process of testing the effect of combining trypsin and other enzymes on protein identification and GVP profiling from human hair.

Novel Aspect: Improved variant peptide identification and confidence by combining keratinase with trypsin for digestion of human hair.

B135 Developing Digital Polymerase Chain-Based Assays for the Detection and Speciation of Foodborne Illness

Sylvia S. Etim, MS, Florida International University, Miami, FL; Bruce R. McCord, PhD, Florida International University, Miami, FL*

Learning Objectives: After attending this presentation, attendees will be informed about a novel digital Polymerase Chain Reaction (dPCR) multiplex analysis for detection of contaminated agricultural products using Bacteroides DNA detection and the use of vertebrate mitochondria DNA (mtDNA) for sourcing the contamination. The results of this work should prove valuable for border protection (Homeland Security) and tracking of foodborne illness.

Impact Statement: This research will impact the forensic science community by informing attendees on the use of nanoplate digital PCR for rapid detection and sourcing of fecal contamination in casework involving foodborne illnesses.

Abstract Text: It has been estimated by the United States Center for Disease Control and Prevention (CDC) that consumption of foods, especially fruits and vegetables, contaminated with feces can lead to about 48 million cases of foodborne illness in the United States yearly, which causes 128,000 hospitalizations and 3,000 deaths.[1] Fruits and vegetables have a significant risk of microbial contamination due to an array of environmental factors that might affect their growth, harvest, and distribution. The bacteriological quality of farm products is commonly affected by fecal contamination.

The routes of fecal contamination of agricultural produce include human excreta on land run off and sewage contamination of oceans, rivers, lakes, and groundwater.[2] Criminal activity or neglect may also be a factor. For example, absence of sanitation barriers and contamination of water sources used on farmlands can lead to enteric bacteria infections. Similarly, contamination from livestock, wild animals, and birds as well as food industry wastes can result in illness or death.

Conventional methods such as the use of enrichment-plating-based detection are considered the most reliable method for the detection of fecal contamination; however, it is time consuming, expensive, and difficult to automate. More recent techniques utilize real-time or quantitative PCR-based primers and probes to detect specific bacteria; however, the complex matrices of these samples can sometimes limit precision, sensitivity, and specificity. A potential alternative to these methods is nanoplate dPCR. This procedure is a more rapid, precise, and sensitive method that partitions the samples into thousands of individual wells (8.5K or 26K), improving specificity and limiting problems with PCR inhibition. The results obtained are then quantified using a Poisson distribution that is based on the target gene's presence or absence in each discrete well.

The goal of this study is to develop a method for use by homeland security using dPCR to detect fecal (Bacteroides) contamination on agricultural produce (i.e., strawberries) at border crossings and to compare these results with standard real-time PCR-based methods.[3] Fecal samples from cattle, rodents, poultry, and other animals were collected and bacterial DNA (Bacteroides) from these samples was collected and analyzed. To determine the origin of the fecal contamination, mitochondria DNA (mtDNA) primers and probes were also developed to detect individual vertebrate species. Multiplex amplifications were developed and validated, and the resultant procedures were tested on inoculated and unwashed fruit. The results indicated the procedure was capable of detecting femtogram levels of bacteria in a sample and the mtDNA probes were species specific and useful in determining the origin of the contamination.

B136 Statistical Analysis of Fairness in Forensic Source Identification Problems

Semhar Michael, PhD, South Dakota State University, Brookings, SD; Christopher P. Saunders, PhD, South Dakota State University, Brookings, SD*

WITHDRAWN

Fairness; Likelihood Ratio; Algorithmic Bias

B137 Enhancing the Number of Contributor Inference Using mtDNA Haplotypes for Mixture Deconvolution

Zack Beyerl, BS, The George Washington University, Washington, DC; Nicole Mischak, BS*, The George Washington University, Palos Park, IL; Daniele S. Podini, PhD, The George Washington University, Washington, DC; Helene D. Douglas, BS, The George Washington University, Washington, DC; Regan Fenske, BA, The George Washington University, Arlington, VA; Robert Lagace, BA, ThermoFisher Scientific, Waltham, MA*

Learning Objectives: By attending this presentation, participants will learn about using the control region of the mitochondria to complement STR analysis in determining the number of contributors (NoC) to a DNA mixture.

Impact Statement: One of the biggest challenges in forensic DNA analysis is accurately determining the number of contributors in a complex mixture. Although probabilistic genotyping tools have improved mixture analysis, they still rely on the correct NoC input, which is determined by the analyst. This study demonstrates how mtDNA sequencing can support DNA analysts when evaluating STR mixtures for NoC determination.

Abstract Text: With the advent of probabilistic genotyping, more complex DNA mixtures with a greater NoC have become easier to deconvolute and interpret. Despite this, determining the NoC present in a mixture remains a significant concern to accurate mixture deconvolution, as this still requires manual interpretation by the analyst. Entering the wrong NoC into probabilistic genotyping software can drastically alter the accuracy of the deconvolution.[1,2] NoC is usually inferred with STRs by using the Maximum Allele Count (MAC) method, where the locus with the greatest number of alleles is counted to determine the minimum NoC and infer the actual NoC, along with considerations from the rest of the profile. When using MAC with STRs, it can be difficult to accurately infer the NoC in mixtures with four or more contributors due to allele masking. Allele masking occurs when an allele of one contributor is obscured by the allele of another (more abundant) contributor.[3] Preferential amplification, sister allele peak height imbalance, and allele dropout represent additional challenges that may result in underestimating the NoC of a mixture. MtDNA is less affected by this masking when sequencing the hypervariable regions, which are the most polymorphic regions of its genome. Given its abundance and greater resistance to degradation, it is not affected by preferential amplification in the same way STR alleles are.[4] Additionally, there is usually only one haplotype per contributor, rather than one or two STR alleles, reducing the uncertainty around how many markers should be present in a mixture of a given NoC and making the evaluation of allele balance to determine whether two alleles are from the same contributor mute. These factors make mtDNA a promising tool to aid analysts in accurately inferring NoC, complementing the information provided by the STR profile. Despite these potential advantages, mtDNA mixture interpretation has not received much attention due to the difficulties of mtDNA mixture interpretation using Sanger Sequencing; however, the popularization of Massively Parallel Sequencing (MPS) has placed renewed focus on mtDNA mixtures.[5]

In this study, the Precision ID mtDNA Control Region Panel was used to target the mtDNA hypervariable regions, followed by library preparation with the Precision ID Library Kit, sequencing on the Ion GeneStudio™ S5, and analysis using Integrated Genomics Viewer, Qiagen CLC Workbench, and Converge™ Software. Twenty-three individuals were typed to determine the amplicon from the Control Region Panel with the highest discrimination power between the tested individuals. Individuals were then selected that could be differentiated at the region of this amplicon, and 19 mixtures were created between them, representing from 2 to 14 different haplotypes. Contributors were differentiated in the mixture by examining the haplotypes at the chosen region in phase, and the NoC was inferred by counting the number of different haplotypes present. In the mixture with 14 different haplotypes, 12 were successfully identified, and all haplotypes were successfully differentiated in the mixtures with individuals with 9 and 12 different haplotypes. A set of extremely imbalanced mixtures was also tested, and the lowest contributor was detected down to a 1:77 ratio.

Heteroplasmic individuals and maternally related contributors present in a mixture represent limitations to this assay as they could appear as more or fewer contributors, respectively. Determining the extent of these limitations, as well as developing an assay targeting a larger amplicon for increased discrimination, represent the next steps of this research.

B138 Different TrueAllele Users, Same DNA Answer: A Multi-Center Proficiency Study

William P. Allan, MASc, Cybergenetics, Pittsburgh, PA; Jennifer M. Bracamontes, MS, Cybergenetics, Pittsburgh, PA; Mark W. Perlin, MD, PhD, Cybergenetics, Pittsburgh, PA; Matthew Legler, BS, Cybergenetics, Pittsburgh, PA; Jonathan Perlin, MS, Cybergenetics, Chicago, IL*

Learning Objectives: After attending this presentation, attendees will understand how TrueAllele results are independent of source, laboratory, or analyst.

Impact Statement: This presentation will impact the forensic science community by evaluating TrueAllele software across multiple DNA Short Tandem Repeat (STR) data types, DNA laboratories, and forensic analysts. It also shows how analyst software proficiency can be demonstrated within the forensic community.

Abstract Text: For two decades, interlaboratory studies have highlighted considerable variation in DNA mixture interpretation outcomes.[1-3] The same DNA evidence can produce widely different results—one laboratory may calculate a match statistic that connects a suspect to the mixture, another lab may exclude him, while a third can't reach any conclusions. This variability diminishes confidence in forensic DNA science.

Cybergenetics conducted a study of crime laboratories that use its TrueAllele technology. A TrueAllele computer applies Bayesian inference and statistical search to derive genotypes from DNA mixture data. Each "probabilistic" genotype corresponds to one contributor to the mixture. These single-contributor genotypes are compared with reference profiles to calculate a Likelihood Ratio (LR) match statistic. The LR quantifies the statistical support for a person having left their DNA (or not) in the evidence.

Our study had two goals: assessing the TrueAllele proficiency of participating analysts, and examining the concordance of their reported results. Each TrueAllele laboratory sent us electronic data from one mixture item, along with a matching reference profile. The labs produced data using five different Polymerase Chain Reaction (PCR) kits and four different genetic analyzers. The DNA mixtures contained three to five contributors; 70% were four-contributor mixtures. The comparison person comprised 18% to 90% of the mixture.

We sent anonymized data from ten mixtures to 32 analysts across ten participating laboratories. Each TrueAllele analyst processed every item. Once an analyst had completed their TrueAllele processing, we sent them reference profiles for LR comparison. This two-stage data distribution assured objectivity—TrueAllele did not need or use reference information to interpret mixture data.

The lab analysts used TrueAllele comparisons to first determine which reference was associated with which mixture sample. They then calculated LR match statistics for the DNA associations. The analysts returned their match statistics to Cybergenetics, who collated their results and conducted Analysis of Variance (ANOVA) statistical tests. The ANOVA grouped the LR results by mixture item, laboratory, and analyst.

The study showed analyst proficiency in using TrueAllele—all were able to process DNA mixture data and produce match statistics. The ANOVA results demonstrated no statistical difference in LR outcomes between laboratories (p-value = 0.273 > 0.05) nor between analysts (p-value = 0.856 > 0.05).

The TrueAllele laboratories derived reliable results using STR data from other laboratories. No PCR kit or genetic analyzer calibration was needed, since TrueAllele learns this information directly from evidence data. It made no difference where the DNA data came from, nor what lab technology was employed to generate the data.

The study showed that TrueAllele results do not depend on where, when, who, how, why, or what DNA mixture data is generated and interpreted. The LR results are invariant across person and laboratory, DNA complexity and analysis procedure, motivation and bias, or time and space. The answers are the same regardless.

With TrueAllele mixture analysis, all laboratories and analysts get the same output LR answer from the same input DNA data. All qualified experts will report the same answer.[4] This cross-laboratory consistency improves on other approaches that showed high inter-laboratory reporting variation. Reporting concordant LR results increases confidence in forensic DNA science and human identification.

Proficiency Testing; Validation; Crime Laboratory

B139 The Advancement and Practical Application of a Kinship Identification System Through the Exploration of Genetically Shared Chromosomal Regions Using High-Density SNP Data

Sohee Cho, PhD, Institute of Forensic and Anthropological Science, Seoul, Seoul-t'ukpyolsi; Eunsoon Shin, PhD, DNA Link, Seoul, Seoul-t'ukpyolsi; Soong Deok Lee, MD, PhD, Institute of Forensic and Anthropological Science/Department of Forensic Medicine, Seoul, Seoul-t'ukpyolsi; Yong-Seok Kim, PhD, DNA Link, Anseong, Korea*

Learning Objectives: After attending this presentation, attendees will understand a novel approach in kinship determination that extends beyond conventional methods by measuring genetically shared regions of chromosomes using high-density Single Nucleotide Polymorphisms (SNPs). Additionally, they will gain insights into the potential applications of this approach in identifying kinship among distant relatives and complex familial relationships.

Impact Statement: This presentation will impact the forensic science community by presenting a promising kinship approach validated through SNP analysis using DNA samples from Korean families. We explored various influencing factors crucial for practical forensic application and demonstrated the effectiveness in resolving real kinship cases across diverse scenarios.

Abstract Text: Relatives share wider regions of chromosomes compared to non-relatives, with closer relatives sharing more regions. While previously theoretical, recent advancements in high-throughput SNP genotyping technologies have facilitated their practical implementation. We have developed a novel kinship determination method that measures shared chromosomal regions between individuals using approximately 250K SNP data generated from the Axiom Korean Biobank Array (Affymetrix Axiom KORV1.1-96 Array). The measurement is quantified in centimorgan (cM) and is referred to as the "GD-ICS" value in the study. This method has been validated on independent SNP datasets generated using real DNA samples from Korean families, providing robust evidence of its effectiveness.[1] Our findings demonstrated the efficacy of this method in distinguishing distant relationships up to the fifth degree of kinships.[2] It has proven effective in distinguishing unrelated pairs from true relatives. Additionally, we examined several factors influencing forensic applications, including the quality of samples and DNA for the array, and the number of SNPs analyzed in the GD-ICS calculation. We also considered the performance of various SNP microarray platforms and ethnic differences beyond the Korean population.

Furthermore, we have successfully applied this method in actual kinship cases where traditional STR and lineage marker testing proved inconclusive. This method provided clarity not only in cases involving distant or complex relationships but also in scenarios where multiple STR mutations posed challenges, even in close relationships. It also firmly supported the absence of genetic relatedness between individuals, proving its applicability in various types of practical casework.

To enhance the practical usability of this method, we are developing a Next Generation System (NGS) -based SNP sequencing panel and calculation system specialized for efficient GD-ICS value analysis. This NGS panel is expected to streamline the process, making it more time and labor efficient. We anticipate this customized panel analysis will provide more practical and efficient solutions for the forensic and broader scientific communities.

B140 DNA Metabarcoding: Can It Reliably Be Used to Characterize Pollen From Surface Soils?

Kelly A. Meiklejohn, PhD, North Carolina State University, Raleigh, NC; Ozge Kuddar, MS, North Carolina State University, Raleigh, NC; Benjamin Callahan, PhD, North Carolina State University, Raleigh, NC; Christopher Bernhardt, PhD, Florence Bascom Geoscience Center, United States Geological Survey, Reston, VA*

Learning Objectives: After attending this presentation, attendees will understand: (1) the wet-laboratory steps for completing DNA metabarcoding of pollen, and (2) reproducibility between morphology and DNA metabarcoding for qualitative and quantitative characterization of pollen.

Impact Statement: This presentation will impact the forensic science community by demonstrating of the value of DNA metabarcoding for the characterization of pollen. This method, if implemented into casework, could provide useful information in criminal and intelligence cases.

Abstract Text: Geologic materials such as surface soils are important types of trace evidence as they are transferred during criminal acts, possess unique characteristics, and are often overlooked by perpetrators. Pollen grains are ubiquitous in the environment year-round and are nearly always present in surface soils. In casework, pollen can provide valuable probative information on sample origin and assist in sample-to-sample comparisons. Despite the utility, pollen analysis is not routinely completed on evidence, as it is time consuming, requires specialized expertise, and the quantity of material needed varies on sample type. High throughput DNA sequencing approaches, such as DNA metabarcoding, have been successfully applied to characterize pollen in bulk environmental samples, but have yet to be applied in a forensic context.

Before DNA metabarcoding could be implemented into casework, a side-by-side comparison with results generated using traditional morphological approaches is needed. This study focused on completing this comparison using 250 diverse surface soils with respect to pH, sand/silt/clay composition, surficial material, and location within the contiguous United States. For each sample, pollen was characterized two ways: (1) sequencing two commonly used plant DNA metabarcoding regions (ITS2 and p6 loop of the *trnL*-UAA intron), and (2) using traditional morphological techniques.

We will present the results we have generated to date, focusing on assessing whether DNA metabarcoding is comparable to morphological results at two levels: (1) *qualitative*, whether the same plant taxa are identified using both methods (i.e., taxa presence or absence), and (2) *quantitative*, whether the relative abundance of identified plant taxa is comparable between methods (i.e., proportion of pollen grains compared to proportion of sequencing reads). Additionally, we will outline a cost- and time-effective protocol to purify pollen grains from archived herbarium material, which provides a straight-forward approach to creating mock standards for proficiency testing or inclusion as positive controls in casework.

Pollen; Morphology; DNA Metabarcoding

B141 An Analysis of DNA Preservation in Human Remains Embedded in Solid Building Materials

Hayle Boechler, BS, Sam Houston State University, Huntsville, TX; Mayra Mayr-Eduardoff, PhD, Sam Houston State University, Huntsville, TX; Sheree R. Hughes, PhD, Sam Houston State University, Huntsville, TX*

Learning Objectives: This presentation will compare the quantity and quality of DNA extracts from human remains that have been embedded in solid building materials such as concrete. The goal is to assess tissue preservation and DNA conservation levels over different timepoints.

Impact Statement: Embedding human remains into solid building structures is a documented practice of body disposal by criminal and narcotic trafficking organizations. This study's findings will help laboratories understand challenges in the recovery process of human remains embedded in solid building materials, preservation differences of different tissue, as well as DNA conservation levels in those tissues over differing timepoints.

Abstract Text: Embedding human remains into building structures, such as concrete foundations, wells, walls, and other construction filled with concrete has been documented as one means of body disposal used by criminal and narcotic trafficking organizations. The recovery of DNA from hard and soft tissue of remains embedded in these materials for human identification has not been well documented. Components of concrete are sand, silica, quartz, cement, and other potentially DNA-damaging substances. The aim of this experiment was to assess tissue and DNA preservation levels over different time points and selected body parts embedded in standard commercially available concrete mix and other building materials such as alternative concrete mixes, lime, asphalt, and mortar. Replicate sections of right forearms submerged in commercial concrete mix were sampled for skin swabs, hard and soft tissue, and surrounding concrete once a month for the period of six months. Furthermore, to assess the effect of different building materials (concrete mix, lime, asphalt, and mortar), replicate fingers were embedded separately and recovered at two three-month intervals to take skin swabs and soft and hard tissue samples as well as samples from the surrounding material. Sections of left forearms and replicate fingers decomposing on the ground surface were sampled over the same time period to serve as controls. DNA was extracted, quantified, and analyzed for Short Tandem Repeats (STRs) using standard forensic methods and kits.

Phase one of the experiment was to analyze decomposition and DNA content of humans remains embedded in concrete using forearms submerged in commercial concrete mix for up to six months. The samples taken consisted of a skin swabs, tissue, bone, and surrounding concrete. Phase two analyzed decomposition and DNA content of whole fingers embedded in other solid building materials and alternative concrete mixes, lime, asphalt, and mortar over six months. The samples taken at each time period will consist of a skin swab, nail, tissue, bone, and surrounding concrete. Two methods of extraction (Investigator chemistry automated on the EZ2 platform and the manual Dabney method) were used to evaluate any differences in the DNA yield.

Human Remains; Forensic DNA; Concrete

WITHDRAWN

B143 Microhaplotypes: A Double-Edged Sword in Forensic Genetics

Pegah Farhadi, PhD, LMO, Kermanshah, Iran; Arash Alipourtabrizi, MD, LMO, Mashhad, Iran*

Learning Objectives: This presentation focuses on the complex implications of this technology, with an emphasis on evaluating both its advantages and disadvantages in the context of technological advancement.

Impact Statement: This presentation will shed light on the scientific basis of microhaplotypes, their practical applications in forensic genetics, and challenges associated with their routine implementation.

Abstract Text: Microhaplotypes, defined as short DNA sequences with high variation, hold immense potential for revolutionizing forensic identification. This presentation will focus on the complex implications of this technology, emphasizing the evaluation of both its advantages and disadvantages and the promises and perils in the context of technological advancement. Using multiple microhaplotypes could yield superior discrimination power over traditional methods, such as Short Tandem Repeat (STR) typing or Y-chromosomal Short Tandem Repeat (Y-STR) typing, which could aid in resolving complex caseworks and forensic individualization. Due to their high resistance to postmortem degradation, they are an invaluable tool for challenging forensic samples consisting of highly degraded tissues and bruised bone samples in mass disaster identification. Specialized expertise, resources, and software are necessary for analyzing them, but they may not be available in all situations or at local laboratories in every country. Additionally, it is important to carefully consider the privacy and ethical concerns that come with using them.

This presentation will shed light on the scientific basis of microhaplotypes, their practical applications in forensic genetics, and challenges associated with their routine implementation. Not only will it address ethical issues, how to prevent violation of the personal privacy along with national securities, but also propose frameworks for proper applications and more equitable use. This presentation aims to promote a comprehensive discussion about the importance of this methodology in case work analysis and shaping the future of forensic genetics, taking into account its diverse aspects. National/international guidelines must be approved for clarification of the use and misuse of micro-haplotypes in forensic genetic case works analysis and for which category of caseworks it must not to be used due to ethical considerations.

Forensic DNA; Genetics; Microhaplotype

B144 Investigating a Different Forensic Workflow for DNA Paternity Testing

Franzoni Anna, MSc, Copan Italia Spa, Serle, Lombardia, Italy; Michele Rosso, PhD, Copan Italia Spa, Brescia, Lombardia, Italy*

Learning Objectives: Attendees will learn about a novel forensic workflow for DNA paternity testing that employs microFLOQ direct (MF) subsampling from buccal swabs that were stored long-term at Room Temperature (RT). The study explores how this method, which bypasses traditional DNA extraction and quantification steps, can streamline the testing process and preserve original samples for future use. Key insights include the effectiveness of the MF subsampling approach in generating full and consistent DNA profiles from buccal swabs stored at RT for extended periods as well as the potential for this method to simplify and enhance forensic workflows.

Impact Statement: This study will impact the forensic science community by offering a streamlined alternative to traditional paternity testing workflows. By demonstrating that the MF subsampling method can successfully generate complete DNA profiles without the need for preliminary DNA extraction and quantification, it introduces a more efficient and cost-effective approach for forensic analysis. This innovation not only accelerates the testing process but also preserves valuable samples for potential future use.

Abstract Text: **Introduction:** In legal contexts, establishing paternity hinges on obtaining full DNA profiles from all parties involved, which are crucial for providing definitive genetic evidence necessary for judicial decisions. Copan buccal 4N6FLOQSwabs (4N6FS) are extensively utilized in the forensic field for collecting buccal DNA due to their non-invasive nature and high efficiency. This study investigated an alternative method using MF for subsampling from buccal 4N6FS that had been stored at RT for over five years, across five simulated paternity cases. The study aimed to streamline the paternity testing process by eliminating the steps of DNA extraction and quantification, thus preserving the primary 4N6FS samples for potential future use. Additionally, the study evaluated whether complete DNA profiles could be successfully obtained through this subsampling approach from buccal samples that were stored long-term at RT.

Materials and Methods: Starting in 2018, five simulated paternity cases were set up. For all cases, two buccal 4N6FS were collected from each person of interest; one was analyzed shortly after collection (T_0), and the second was subsampled using two pre-wet MFs at the Time To Subsampling (TTS) interval as described below:

- Case 1 (T_0: 07/2018 – TTS: 5 years and 8 months): Daughter, Presumptive Mother
- Case 2 (T_0: 01/2020 – TTS: 4 years and 2 months): Son, Mother, Presumptive Father
- Case 3 (T_0: 09/2020 – TTS: 3 years and 6 months): Son, Mother, Presumptive Father
- Case 4 (T_0: 07/2021 – TTS: 2 years and 8 months): Daughter, Presumptive Father
- Case 5 (T_0: 10/2021 – TTS: 2 years and 4 months): Son, Presumptive Father

The first MF was processed immediately following the subsampling procedure and the second after four weeks of storage at RT. Each MF was directly amplified according to a workflow, which included: profiling with GlobalFiler Express kit on Veriti 96-well thermal cycler; capillary electrophoresis using AB 3500 Genetic Analyzer and GeneMapper ID-X v1.6 software. The profiles obtained with the two MFs were compared to those obtained at T_0 from 4N6FS.

Results: Compared to the results obtained at T_0 from 4N6FS, the MF alternative workflow provided full and matching profiles for the majority of individuals, whether the MF was analyzed right after subsampling or after being stored at RT for four weeks prior to analysis. Although there was some variability in average peak heights, peak height ratios, and intralocus balances, obtained profiles for most of the individuals were complete and consistent. However, partial profiles were observed from the MFs of one individual in Case 4. These partial profiles may result from low sample quantity on the initial 4N6FS or from subsampling with the MF from areas of the swab with little sample content.

Conclusion: This study supports the effectiveness of the MF approach in accelerating the paternity testing process, regardless of whether the samples are analyzed right after subsampling or after being stored at RT for four weeks. By eliminating the need for traditional DNA extraction and quantification, this method not only simplifies the workflow but also keeps the original 4N6FS samples available for subsequent analysis. Remarkably, complete profiles were generated for the majority of individuals from subsampled 4N6FS that had been collected several years earlier and stored at RT.

B145 Enhancing Rapid DNA Programs: Implementing a Metrics Tracker to Improve Performance and Measure Success

Emily G. Strelka, MFS, RTI International, Alexandria, VA; Erin P. Forry, MS, RTI International, Research Triangle Park, MA; Mikalaa M. Martin, BS, RTI International, Cincinnati, OH; Jason M. Chute, MSFS, RTI International, Research Triangle Park, NC; Patricia Melton, PhD, RTI International, Research Triangle Park, NC; Misty Marra, MSFS, RTI International, Huntington, WV; Shannon Krauss, PhD, RTI International, Research Triangle Park, NC*

Learning Objectives: Understand the Functionality of the Rapid DNA Metrics Tracker: Attendees will learn how to utilize the Excel-based Rapid DNA Metrics Tracker to monitor and evaluate the effectiveness and outcomes of Rapid DNA technology.

Evaluate Performance Metrics: Attendees will gain insights into how to assess sample success rates, identify optimal techniques for resource allocation, and enhance operational efficiency through the tool.

Analyze Operational Efficiency: Attendees will learn how to monitor individual operations to pinpoint training needs, ensure quality, and maintain consistency in processing.

Assess Program Impact: Attendees will be equipped with methods to compile and analyze data on case outcomes to evaluate the impact of Rapid DNA technology on the criminal justice system.

Utilize Data Management Features: Attendees will explore the tool's data management capabilities, including menu selections and visualization options for effective data entry and reporting.

Apply Strategic Planning Techniques: Attendees will learn how to use the metrics tracker to compare data with broader crime statistics, aiding in strategic decision-making and policy development.

Impact Statement: This presentation will advance the forensic science community by introducing a practical, data-driven tool designed to optimize Rapid DNA technology usage. The Rapid DNA Metrics Tracker enables Law Enforcement Agencies (LEA) and Forensic Science Service Providers (FSSPs) to systematically monitor and enhance their Rapid DNA programs, leading to increased operational efficiency and more informed decision-making. By offering detailed insights into performance metrics, operational workflows, and program impact, this tool supports evidence-based strategies and strategic planning. As a result, the forensic science community will benefit from more effective integration of Rapid DNA technology into forensic practices, ultimately strengthening the overall effectiveness of forensic operations.

Abstract Text: This poster presentation will showcase a Rapid DNA Metrics Tracker. an Excel-based tool developed to help LEAs and fFSSPs monitor the effectiveness and outcomes of Rapid DNA technology. By providing a data-driven approach to both the implementation and continuous improvement of Rapid DNA programs, this no-cost tool offers tangible benefits to LEAs and FSSPs looking to optimize use of this technology. Drawing from experience assisting multiple Bureau of Justice Assistance Byrne Discretionary Grants Program grantees in developing Rapid DNA programs, this poster presentation will detail how this tool is currently applied and highlights how a strategic, data-driven approach can enhance the value of Rapid DNA technology.
As the use of Rapid DNA technology by LEAs and FSSPs expands, effective metrics tracking is critical for evaluating program performance, assessing impact, and supporting decision-making. The Scientific Working Group on DNA Analysis Methods is developing standards to facilitate the future integration of Rapid DNA data into the Combined DNA Index System (CODIS). As these standards are implemented, the applications of Rapid DNA will broaden, making comprehensive metrics tracking even more important for optimizing its use. The Federal Bureau of Investigation's document, Non-CODIS Rapid DNA Considerations and Best Practices for Law Enforcement Use, emphasizes the value of tracking key metrics such as the volume and types of cases submitted, the number and types of samples processed, the types of profiles generated (e.g., partial, complete), and the impact on case outcomes (e.g., arrests, prosecutions, convictions, exonerations). [1]By collating these key metrics, the Rapid DNA Metrics Tracker will assist LEAs and FSSPs with:

- Performance Evaluation: Provides insights into sample success rates and techniques, optimizing resource allocation and improving workflows, policies, and procedures.
- Operational Efficiency: Monitors individual instrument usage to identify training needs and ensure quality and consistency.
- Outcome Analysis: Compiles data on case outcomes to assess the impact of Rapid DNA on the criminal justice system.
- Data Management: Provides customizable menu selections and visualization tools for consistent data entry and reporting.
- Program Impact and Strategic Planning: Analyzes program metrics against broader crime statistics to inform strategic decision-making, resource allocation, and policy development.

As part of this poster presentation, attendees will be able to download the no-cost, Excel-based Rapid DNA Metrics Tracker, which can be further customized to meet their agency's specific policies and needs.

Rapid DNA; DNA; Metrics

B146 Upgrading to STRmix v2.11: A Chance to Do It All Again

Alicia M. Cadenas, MS, Signature Science LLC, Austin, FL; Ut Dinh, MS, Signature Science LLC, Austin, TX*

Learning Objectives: This presentation will highlight additional validation studies incorporated into the version upgrade of STRmix and the reasons why the additional studies were considered.

Impact Statement: This presentation will impact the forensic science community through the evaluation of additional validation studies meant to test the limits of STRmix and the impact it can have on interpretation.

Abstract Text: In life, second chances may not always come along but in the field of forensics, where new or improved technology continues to expand the limits of DNA testing, that is routinely not the case. One such technology is probabilistic genotyping, specifically STRmix, which has undergone various version upgrades since its original introduction to forensic DNA testing laboratories. With each new version release, laboratories must consider which additional validation studies should be undertaken prior to implementation in casework. Standards and guidelines are in place for the validation of new methodology in the laboratory to assist in forming a basis for establishing reliable methods, but it is ultimately up to the laboratory to determine which studies are relevant for a given method and to identify additional studies that can further assist in defining method limitations/parameters.

Signature Science (SigSci), a private Forensic DNA Laboratory based in Austin, TX, initially validated STRmix v2.5 in 2018; however, validation efforts have been ongoing. Several validation addendums have been completed as well as an upgrade to STRmix v2.11. A thorough validation was initially performed prior to casework implementation to include the examination of known and non-probative evidence samples and investigations into reproducibility and precision, sensitivity, and stochastic effects, and mixture data. As is often the case with newly implemented methodology, SigSci identified a need to explore and characterize additional parameters of the STRmix software functionality prior to any version upgrades. Interpretation guidelines were updated to evaluate unintuitive comparisons as a result of potential familial relationships in casework mixture data. A validation addendum was also performed to evaluate drop-in and stutter modeling.

In addition to the original and addendum studies that were performed when validating v2.5, the v2.11 validation studies included the characterization of additional parameters. Familial relationships, specifically relationship likelihood ratios generated, were explored to establish a familial diagnostic range for use in casework. Additional challenging samples affected by degradation and/or inhibition were included to further assess features within STRmix modeling. Finally, a wider range of mixture samples were prepared and analyzed for the integration of interpretation thresholds in the laboratory. These validation efforts ultimately establish more robust and definitive guidelines for DNA profile interpretation, specifically regarding samples and/or contributors not suitable for comparison.

B147 The Application of Deep Learning in Latent Fingerprint Enhancement

Daye Kim, MS, Sam Houston State University, Huntsville, TX; Ming-Sie Pan, Department of Industrial Management, I-Shou University, Kaohsiung, Kaohsiung, Taiwan; Jorn Yu, PhD, Sam Houston State University, Huntsville, TX; Chao-Hsing Fan, PhD, Tainan City Police Department, Tainan City, Taiwan, Republic of China*

Learning Objectives: The presentation will demonstrate the application of deep learning for latent fingerprint development and enhancement. The attendees will understand the use of Artificial Intelligence (AI) tools to assist in latent fingerprint visualization and comparison. The attendees will also understand the general process of developing AI tools for latent fingerprint examination.

Impact Statement: This study will impact the forensic science community by introducing an AI agent to improve the efficiency and quality of latent fingerprint examination and comparison. The AI agent can also shorten the training time to improve the quality of young and experienced fingerprint examiners. The application of AI to fingerprint comparison and development can support crime scene investigators and fingerprint examiners in enhancing the overall efficiency of the workflow.

Abstract Text: Deep learning is a subfield of AI that utilizes Multilayer Neural Networks (MLNN) to learn from data. A MLNN can learn complex patterns that simple linear models cannot solve, and it is a type of model that can classify the given input based on what has already been learned. Among the models of MLNN, the Fully Convolutional Network (FCN) and U-net are used in this research work because both are technologies commonly used for medical image processing and image segmentation. Segmentation technology detects changes in pixel values to find boundaries and then divides the image based on those boundaries to extract meaningful data.

Visualizing latent fingerprints at crime scenes is considered one of the most important tasks in obtaining crucial pieces of physical evidence, just like detecting and collecting DNA evidence. However, latent fingerprint development requires highly skilled investigators with forensic expertise and experience. In the case of partial fingerprints, an additional single minutia can lead to the determination of whether the fingerprint can be identified or not. Various optical technologies are used to complement this, but most of them still rely on analysts' proficiency. Due to this limitation, using AI-enhanced fingerprinting techniques for assisting determination are worth attempting. Information invisible to the human eye but detectable by optical devices can be enhanced through AI. AI trained on data similar to that of experienced professionals could process images captured by optical devices in place of human eyes. Using AI technology could lead to savings in time and resource.

In this work, latent fingerprints were visualized by ethyl cyanoacrylate fuming method on red envelopes made of glossy film materials that are water resistance. The vitalized latent fingerprints were enhanced with fluorescent powder and photographed for subsequent analysis and comparison. Moreover, synthesized fingerprint images were used to simulate the red envelope fingerprints collected at the crime scene. A qualified latent fingerprint examiner was engaged to annotate the simulated images and assess their accuracy in comparison to collected fingerprints.

The experimental outcomes demonstrated the possibility that AI technology can correct distorted and blurring fingerprint images. When this technology was used to correct distorted friction ridges in fingerprints, it resulted in more valuable images for analysis and comparison. With the advancement of AI recognition technology alongside other techniques, a significant portion of fingerprints that cannot be identified using current methods may become valuable as investigative leads. In summary, when compared FCN and U-net as a tool for comparison of incomplete fingerprints, U-net shows higher performance in every performance benchmark, including accuracy, Jaccard Index (JI), Dice Similarity Coefficient (DSC), sensitivity, and specificity.

Artificial Intelligence; Latent Prints; Crime Scene Investigation

B148 Elucidating the Mechanism of Unwanted and Uncontrolled Water Adducts in the Tandem Mass Spectra of Synthetic Cannabinoids

McKenna R. Oaks, West Virginia University, Morgantown, WV; Christopher S. Poulos, MS, Oak Ridge Institute for Science and Education, Cincinnati, OH; Glen P. Jackson, PhD, West Virginia University, Morgantown, WV; Emmanuel I. Ubana, BS, West Virginia University, Morgantown, WV; Fabien Goulay, PhD, West Virginia University, Morgantown, WV*

Learning Objectives: After attending this presentation, attendees will understand how uncontrolled ion molecule reactions can interfere with the mass spectrometric analysis of synthetic drugs. Audience members will leave with the knowledge of how common molecules, like water and methanol, can adduct to certain Synthetic Cannabinoid (SC) fragments when stored for extended periods of time, such as in Orbitrap mass spectrometers.

Impact Statement: This research will help drug analysts and forensic toxicologists identify novel SCs in seized drugs and body fluids, respectively.

Abstract Text: SCs are modeled after cannabis, which is a Schedule I drug in the United States that has recreational and medicinal uses. SCs have recently been identified as Novel Psychoactive Substances (NPS), meaning that certain new analogs have not yet been scheduled or controlled under United States federal law. Since 2008, the European Monitoring Centre for Drugs and Drug Addiction (EMCDDA) has reported 224 new SCs.[1]

When SCs are analyzed on different types of mass spectrometers, some subtle differences are expected in the resulting tandem mass spectra. However, when SCs with an indazole core—like the FUBINACA and PINACA families of SCs—are analyzed on certain tandem mass spectrometers, the fragmentation patterns can be dramatically different. This presentation focuses on elucidating the fragmentation mechanisms that lead to the major fragments observed in several types of indazole and indole SCs. This presentation also provides an explanation for the occurrence of certain fragments that have so-far defied explanation.

Ten different SCs, including three isotopically labelled versions, containing indole and indazole-cores were analyzed using an LTQ Velos Pro linear ion trap mass spectrometer with a Heated Electrospray Ionization (HESI) ion source in positive mode. When particular fragment ions from indazole-containing SCs were isolated and stored for tens of milliseconds, fragments containing an acylium or ketene group on the indazole ring gained +18 Da and +32 Da with rates following first order kinetics. These two gains in mass correlate to the uncontrolled adduction of water and methanol to the fragments. When this same procedure was applied to indole-containing SCs, no such adduction was observed. Therefore, the indazole core adjacent to the acylium group is crucial for the adduction of these background reagents. The adduct product ions could be isolated at MS3 level, and the adducts were easily reversed with low-energy CID, which is indicative of a non-covalent reaction. These findings are supported by high-level Density Functional Theory (DFT) calculations conducted using Gaussian 16 and GaussView, which showed large free energies of formation for the water adducts. The proclivity for water adduction of certain ions in the tandem mass spectra of SCs helps explain why spectra collected on certain ion trap instruments—that store ions for prolonged periods before mass analysis—are more likely to contain these unusual "fragments." In addition to helping drug analysts identify novel cannabinoids in seized drugs, this project could also help forensic toxicologists identify emerging SCs in the emergency room or during autopsies.

Novel Psychoactive Substances; Cannabinoids; Mass Spectrometry

B149 Utilizing a Field-Deployable, High-Resolution Mass Spectrometry System for Screening of Seized Drugs by DART-MS Analysis

Elizabeth L. Robinson, MS, National Institute of Standards and Technology, Gaithersburg, MD; Edward Sisco, PhD, National Institute of Standards and Technology, Gaithersburg, MD; Thomas P. Forbes, PhD, National Institute of Standards and Technology, Gaithersburg, MD*

Learning Objectives: After attending this presentation, attendees will understand how an existing workflow for the screening of seized drugs by Direct Analysis in Real Time (DART) Mass Spectrometry (MS) can be adapted for a field deployable, High-Resolution Time-Of-Flight/Mass Spectrometry (TOF/MS) system.[1] Attendees will be presented with optimization and validation results for seized drug analysis by DART-TOF/MS.

Impact Statement: This poster will impact the forensic science community by providing the foundational work for the utility of a recently developed, mobile, high-resolution TOF/MS system. The optimization and validation of this MS system will allow for field-deployable analytical screening with the ability to obtain rapid, high-quality mass spectral measurements.

Abstract Text: The ever-changing drug landscape continues to highlight the need for rapid, on-site analytical techniques to assist public health, public safety, and customs personnel to accurately identify compounds in the drug supply. Existing on-site techniques (Raman, Fourier transform infrared spectroscopy, ion mobility, lateral flow immunoassays, etc.), benefit from portability and/or low cost, but often suffer from lack of sensitivity and selectivity. TOF mass spectrometers have the necessary sensitivity and selectivity but are limited by extensive laboratory requirements. However, a high-resolution TOF mass spectrometer that is mobile, and therefore deployable to sites of interest, has recently been developed. The ability to obtain rapid, high-quality mass spectral measurements is realized when this TOF mass spectrometer is coupled with a widely utilized ion source, such as DART.

This work investigated the adaptation of a laboratory-based seized drug analysis DART-TOF/MS workflow to a field-deployable, high-resolution mass spectrometer.[1]
A Tofwerk Vocus TOF/MS was coupled with a Bruker DART-SVP ion source. Initial studies investigated optimal instrument parameters to maximize the mass spectral response. Specifically, the depth of the ceramic tube, distance between the ceramic tube and DART ceramic cone, flow rate of the external Vapur pump, and SSQ pressure were investigated. Fragmentation spectra from in source-Collision-Induced Dissociation (is-CID) voltages ranging from 10V to 50V were then compared to existing spectral libraries.[2] Once the instrument parameters were optimized, the field-deployable, high-resolution mass spectrometer was then validated for the screening of seized drugs. Single- as well as multi-component standard solutions of compounds across multiple drug classes were used to investigate mass accuracy, fragmentation pattern precision (for mid-voltage spectra), specificity, reproducibility, carryover, limits of detection, solvent effects, and robustness.

The performance of the field-deployable, high-resolution DART-TOF/MS system was determined to be appropriate for the screening of seized drugs. The protonated molecular ions for a 15-component solution were used to determine a mass accuracy within ±0.020 Da. Single-component solutions were analyzed across multiple is-CID voltages to ensure correct and repeatable responses for mid-voltage spectra, as compared to an existing DART-TOF/MS library. Both the low- and mid-voltage library spectra were found to have comparable fragmentation patterns when using 15V and 30V for is-CID for this DART-TOF/MS system. The mass accuracy of the mid-voltage spectra, as determined by the major fragment ion, was within ±0.020 Da. The DART-MS Data Interpretation Tool was used to determine scores for reverse match factor and fraction of peak intensity explained for the 15V spectra as compared to a down-selected DART-MS low-voltage library, and the 30V as compared to a down-selected DART-MS mid-voltage library.[2] Reproducibility was then investigated for ten replicates for seven analyses across a 21-day period, and the mass assignments for the 15V (low-voltage) were monitored to test the mass tolerance of ±0.020 Da. Carryover was monitored through methanol blanks that were analyzed between replicate samples. The limits of detection for most compounds, as investigated by the protonated molecular ion for single-component solutions, were determined to be in the single nanogram range. A second analyst, familiar with the system, also completed the reproducibility study, to determine the robustness of the system. Current work is focused on determining additional limits of detection and investigating solvent effects for common organic solvents. The ability for the system to identify compounds in complex, real-world mixtures will also be investigated.

Once validated, this system will be deployed in a mobile laboratory for on-site analysis at public safety and public health venues.

Field Deployable; Seized Drug Analysis; Mass Spectrometry

B150 The Effect of Mass Spectral Selection on Discrimination of Fentanyl Analog Positional Isomers

Alexandra Rahn, BS, Michigan State University, East Lansing, MI; Ruth Waddell Smith, PhD, Michigan State University, East Lansing, MI; Victoria L. McGuffin, PhD, Michigan State University, East Lansing, MI*

Learning Objectives: After attending this presentation, attendees will be familiar with a statistical method to compare mass spectra and understand the effect of mass spectral selection on the ability to discriminate spectra of positional isomers.

Impact Statement: This presentation will impact the forensic science community by providing further evaluation of a statistical method to compare mass spectra of seized drug samples and demonstrate the ability to distinguish positional isomers.

Abstract Text: The number of new *novel psychoactive substances* (NPS), specifically novel synthetic opioids, has increased over the past decade, increasing from 450 new substances reported in 2013 to 618 in 2021.[1] Submitted samples are typically analyzed by Gas Chromatography/Electron Ionization/Mass Spectrometry (GC/EI/MS) for identification. However, with the emergence of structural and positional isomers, definitive identification based on the EI mass spectra is challenging due to the high spectral similarity.

In our previous work, a method was developed to compare two mass spectra in an objective, statistical manner. The method uses an unequal variance t-test to compare ion intensity at all m/z values of two mass spectra.[2] The null hypothesis (H0) states that the difference in ion intensity is equal to zero while the alternative hypothesis (Ha) states that the difference is not equal to zero. If H0 is accepted at all m/z values, the two mass spectra are statistically indistinguishable, and the association of the spectra is confirmed. In contrast, if Ha is accepted for at least one m/z value, the two mass spectra are statistically distinguishable, and the m/z values responsible are defined as discriminating ions.

In our ongoing work, the robustness and ruggedness of the statistical comparison method are being evaluated. To this point, the effects of concentration and inherent instrument variation on the ability to associate and discriminate spectra of positional isomers have been evaluated.[3] The focus of the current work is to evaluate the effect of mass spectral selection on the ability to discriminate spectra of positional isomers.

The ortho (o-), meta (m-), and para (p-) positional isomers of sets of fentanyl analogs, including methyl fentanyl, fluorobutyryl fentanyl, fluoroisobutyryl fentanyl, and fluoro methoxyacetyl fentanyl, were used in this work. Each isomer was analyzed in triplicate by GC/EI/MS and spectra were selected in two ways. First, spectra were collected from the apex of the chromatographic peak, and second, spectra were averaged across the peak width at half height. For each fentanyl analog, spectra of the positional isomer were statistically compared, based on both the peak apex spectra and the average spectra.

Discrimination of positional isomers was achieved at the 99.9% confidence level for both the apex and average spectra, albeit with some differences in the number of discriminating ions. For example, m-methyl fentanyl and p-methyl fentanyl were distinguished with seven discriminating ions. Many of these ions (e.g., m/z 107, 164, 176, 236, and 280) were present in the spectra at low intensity, which is defined in this work as less than 5% of the base peak intensity. Based on the average spectra, discrimination of m-methyl fentanyl and p-methyl fentanyl was also achieved although with four ions responsible for discrimination. Further, all ions identified as discriminating in the average mass spectra were also identified as discriminating in the apex mass spectra.

Similar trends were observed for positional isomer comparisons of the other fentanyl analogs considered, all of which were distinguished at the 99.9% confidence level. In this presentation, these trends will be presented in more detail and the chemical relevance of discriminating ions will be discussed.

Fentanyl Analogs; Mass Spectrometry; Statistical Comparison

B151 Structural Characterization of Nitazene Analogs Using Electrospray Ionization-Tandem Mass Spectrometry (ESI-MS/MS)

Emma Hardwick, BA, Sam Houston State University, Huntsville, TX; J. Tyler Davidson, PhD, Sam Houston State University, Huntsville, TX*

Learning Objectives: After attending this presentation, attendees will have learned about Collision-Induced Dissociation (CID) fragmentation trends and characteristic product ions observed for 38 nitazene analogs using ESI-MS/MS. The audience will learn about conserved fragmentation pathways between analogs as well as the impact of different types and locations of substitutions to the core nitazene structure on the resulting fragmentation behavior. This information will provide attendees with additional tools to help identify novel nitazene analogs.

Impact Statement: This presentation will impact the forensic science community by providing a comprehensive fundamental understanding of nitazene analog fragmentation behavior under ESI-MS/MS conditions. The identification of characteristic product ions as well as trends in the CID fragmentation behavior for different substitutions will aid with the development of screening and targeted Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) methods for nitazene analogs. The identified trends in fragmentation behavior will also assist the toxicology and seized drug communities in identifying novel nitazene analogs using ESI-MS/MS methods.

Abstract Text: Nitazene analogs are a class of Novel Synthetic Opioids (NSOs) that have become prevalent on the illicit drug market in recent years due to increasing legislation of fentanyl analogs in both the United States and China. Although several nitazene analogs have been categorized under Schedule I of the Controlled Substances Act, novel analogs continue to emerge to circumvent legislation. This novelty provides a challenge for forensic scientists when it comes to identifying nitazene analogs. Therefore, there is a need to understand the behavior of nitazene analogs under various analytical conditions. ESI-MS/MS is often utilized with liquid chromatography instrumentation, which is routinely applied in toxicology, and is an emerging technique for seized drug analysis. This research provides a comprehensive understanding of nitazene analog behavior under ESI-MS/MS conditions. The central hypothesis of this research is that the type and location of substitution to the core nitazene structure will impact the resulting ESI-MS/MS fragmentation behavior and thus, enable the differentiation of nitazene analog subclasses.

This research utilized 38 representative nitazene analogs, including compounds with various substitutions at the amine moiety, the benzyl ring, and the benzimidazole core. This selection of analogs includes every type and location of substitution that has been observed on the illicit drug market to date, as well as several novel substitutions that have not yet been observed in drugs of abuse. All nitazene standards were prepared at a concentration of 10ppm and analyzed using an Agilent 6530 quadrupole Time-Of-Flight (qTOF) mass spectrometer, using direct injection. CID activation was achieved using collision energies of 15, 25, 35, and 45eV. All standards were analyzed individually, and three replicates of each compound were collected to understand the natural variability in the observed CID fragmentation behavior.

The results indicate that there are many similarities between the product ion spectra of most nitazene analogs, with a few key differences that enable the identification of certain substitutions. For example, nitazene analogs with a diethyl substitution at the amine moiety have a base peak of *m/z* 100, analogs with a desethyl substitution have a base peak of *m/z* 72, analogs with a pyrrolidine ring have a base peak of *m/z* 98, and analogs with a piperidine ring have a base peak of *m/z* 112. These fragments are all formed through an even-electron cleavage involving the nitrogen of the amine group, but the observed *m/z* value shifts based on the substitution present. Another indication of a diethyl substitution is a product ion 73 Da less than the protonated molecule. Additionally, desethyl compounds produce a product ion that is 71 Da less than the protonated molecule, which is likely formed through a 4-center elimination at the β-hydrogen of the nitrogen in the benzimidazole core. This information will be helpful for the identification of novel desethyl nitazene analogs. Additionally, the length of the alkoxy chain attached to the benzyl ring can be determined based on the presence of product ions, such as those observed at *m/z* 121 for methoxy substitutions and *m/z* 135 for ethoxy substitutions. Interestingly, desnitazene analogs displayed the unique formation of doubly charged precursor ions. This behavior is extremely helpful for identifying desnitazene compounds, which otherwise have very similar, if not identical, product ion spectra to nitazene analogs with a nitro group at the benzimidazole core. The comprehensive CID fragmentation behavior and characteristic product ions identified in this study enhance our understanding of the behavior of nitazene analogs using ESI-MS/MS and equip the toxicology and seized drug communities with knowledge that can help to differentiate existing nitazene analogs and identify novel nitazene analogs.

Novel Synthetic Opioids; Analogs; Tandem Mass Spectrometry

B152 Fingerprint Evidence Analysis of Fraudulent Receipts in Taichung City, Taiwan

Yu-Chih Lin, PhD, Taichung City Police Department, Taichung City, Taiwan, Republic of China; Pei-Yi Hua, MS, Taichung City Police Department, Taichung City, Taiwan, Republic of China; Chi-I Wu, MS, Taichung City Police Department, Taiwan, Republic of China; Kuo-Lan Liu, MD, PhD, Taichung City Police Department, Taichung City, Taiwan, Republic of China; Chia-Chen Weng, MAS, Taichung City Police Government, Taiwan, Republic of China*

Learning Objectives: Through this field study, fingerprint examiners will gain insights into where criminals are likely to leave fingerprints on fraudulent documents and recognize that the 1,2-IND method is significantly more sensitive and effective than the ninhydrin method in real cases. Additionally, the study highlights how the time elapsed between the crime and evidence collection impacts the likelihood of obtaining usable fingerprints. This information enables fingerprint examiners to evaluate and choose the best methods for processing such evidence in their own laboratories.

Impact Statement: This study, viewed from the perspective of Taichung City, Taiwan, analyzes fraud schemes involving fake receipts used by criminal organizations. It summarizes various aspects of fingerprint evidence collection and provides valuable insights for forensic laboratories worldwide to effectively assess and improve their methods for handling such evidence.

Abstract Text: Taiwan has experienced a significant increase in online fraud cases in recent years. Since 2023, fraud rings have frequently collected cash from victims in person to make financial flows harder to trace. To build trust with their victims, these fraudsters provide paper receipts as proof of payment. When victims eventually realize they have been scammed and report the incident, these receipts become crucial evidence, potentially containing fingerprints of the criminals involved.

This study, conducted with the Taichung City Police Department in Taiwan, analyzed 122 fraudulent receipts to examine fingerprint evidence.[1] The results revealed that the IND-Zn method detected an average of 2.97 fingerprints per receipt, with 2.03 matching suspects in the criminal database, 0.34 matching victims, and 0.60 with no matches to either. In comparison, the ninhydrin method detected an average of 2.13 fingerprints per receipt, with 1.37 matches in the database, 0.31 matching victims, and 0.44 with no matches to either. Remarkably, fingerprints from suspects were detected more frequently than those from victims. The IND-Zn method proved to be significantly more sensitive than ninhydrin, providing a higher probability of matching fingerprints to suspects.[2,3]

This study also examined the effect of the time between the crime and evidence collection on fingerprint recovery. The likelihood of obtaining usable fingerprints diminished as the interval increased.[4] For collections within 30 days of the crime, an average of 2.97 matching fingerprints per receipt was found. This number dropped to 1.36 for collections between 31 and 60 days, 1.67 for 61 to 90 days, and only 0.22 for periods exceeding 91 days. Further analysis of fingerprint locations showed distinct patterns: suspects were more likely to leave fingerprints on the document's front edges (46.3%) and corners (19.05%), while victims were more likely to leave fingerprints on the back edges (38.46%) and central areas (23.08%). This study provides valuable insights for forensic examiners dealing with fingerprints on fraudulent documents, thereby enhancing the ability to identify potential suspects.

Fingerprint; Fraud; Paper

B153 The Development and Validation of a New GC/MS Decision-Point Method for Marijuana and Hemp Differentiation Using Hydrogen as Carrier Gas

Agatha B. Villegas, BS, Drug Enforcement Administration, Dulles, VA; Sandra E. Rodriguez-Cruz, PhD, Drug Enforcement Administration, Dulles, VA; Michael L. Weaver, BS, Drug Enforcement Administration, Sterling, VA*

Learning Objectives: After attending this presentation, attendees will understand the process undertaken to develop, optimize, standardize, and validate a new Gas Chromatography/Mass Spectrometry (GC/MS) method for the analysis of cannabis materials. This new 1% decision-point method utilizes hydrogen as the carrier gas, a narrow-bore column, and a new Internal Standard (IS) compound.

Impact Statement: This presentation will impact the forensic science community by providing a deep dive into the processes used for evaluating and selecting the new IS, the preparation of a new positive control solution, and the performance characteristics evaluated during validation.

Abstract Text: During 2020, the Drug Enforcement Administration (DEA) laboratories started conversion of their GC/MS systems from using helium to hydrogen as a carrier gas in an effort to transition to a more sustainable and environmentally friendly alternative while also reducing maintenance costs and dependence on helium. In the years since, the move to using hydrogen along with parallel standardization efforts have resulted in the development and validation of various targeted and non-targeted qualitative analysis methods, including the more recent Global Uniform Analysis and Reporting of Drug-Related Substances (GUARDS) method, which combines the use of hydrogen with a narrow-bore (35%-phenyl-methylpolysiloxane) column for enhanced sensitivity. In order to further standardization efforts, the original DEA 1% decision-point method used for hemp and marijuana discrimination has now been adapted and validated to use the same GC/MS instrumental conditions as the GUARDS method. This adaptation allows for harmonization across DEA laboratories by allowing use of the same analytical instrumentation for cannabis testing and other (non-cannabis) routine screening analyses.

Past limitations encountered when using 4-androsten-3,17-dione and testosterone led to the search for alternative compounds and ultimately the selection of dextromethorphan as a new IS due to its comparable size and structure. Short- and long-term (18 weeks) experiments demonstrated not only similar instrument response as that recorded for previous IS compounds, but also stability of the prepared solutions under different storage conditions. This presentation will describe these evaluation tests and provide details about the new positive control solution used to easily visualize the abundance of the target analyte (delta-9-Tetrahydrocannabinol [THC]) and establish the THC:IS peak height ratio used as part of the DEA cannabis analytical scheme to discriminate between hemp and marijuana.

This report will also discuss the steps and performance characteristics evaluated during the validation of this new method at the DEA Special Testing and Research Laboratory, including selectivity, repeatability (short-term precision), and the linear response (around the critical decision-point region) of not only THC but also Cannabidiol (CBD). The validity (accuracy) of the decision-point method was also evaluated by testing cannabis materials with THC levels below, at, and above the 1% level (w/w). To demonstrate fitness for purpose, this presentation will also summarize results from the various method verification experiments performed and documented after transferring of the new method to additional DEA laboratories, a step required to demonstrate the ruggedness of the method prior to system-wide implementation and casework use.

Marijuana; Hemp; Hydrogen

B154 Evaluating the Performance of DEA's New GUARDS Method Via an Interlaboratory Study

Mark Frisch, PhD, Drug Enforcement Administration, Dulles, VA; Sandra E. Rodriguez-Cruz, PhD, Drug Enforcement Administration, Dulles, VA*

Learning Objectives: After attending this presentation, attendees will know about the Global Uniform Analysis and Reporting of Drug-Related Substances (GUARDS) method recently implemented throughout the Drug Enforcement Administration (DEA) laboratories, United States Customs and Board Protection (CBP), and other state/local laboratories. This non-targeted Gas Chromatography/Mass Spectrometry (GC/MS) method was established to better standardize drug analysis and reporting across the seized-drug community and to enhance the reliability and accuracy of the information being reported through the National Forensic Laboratory Information System (NFLIS).

Impact Statement: This presentation will impact the forensic science community by informing the audience of the advantages and disadvantages of the GUARDS method and by presenting and discussing data collected during a system-wide Interlaboratory Study (ILS).

Abstract Text: In response to the continual emergence of novel psychoactive substances and the ongoing opioid epidemic, GUARDS was designed to offer a GC/MS method that allows for standardized analysis of both commonly encountered drugs as well as emergent compounds. The ILS presented here involved the analysis of three sets of solutions containing a total of 14 compounds at different concentration levels. Fentanyl was evaluated at two different concentrations to mimic levels routinely encountered in lab submissions. An internal standard (octacosane; C_{28}), added at the 1% concentration level, was also included. Solutions were sent out to DEA field laboratories and analysts were instructed to analyze the solutions using the GUARDS method. Each ILS solution was divided into ten different autosampler vials (30 vials total) and each vial was analyzed once. If available, analysts were to transfer the vials to a different instrument and repeat the analyses. All raw data files were transferred to the DEA Special Testing and Research Laboratory for processing. In total, the ILS involved 21 different instruments across nine laboratories.

This presentation will summarize the ILS results and the final figures of merits determined for the GUARDS method. These will include assessment of Retention Time (RT) data collected for each compound tested. After compiling data across 21 instruments, results demonstrate high within- and between-instrument RT repeatability, with calculated standard deviations ranging from 0.053 to 0.172 minutes (0.72% - 3.7% RSD) and early eluting compounds showing higher variability.

Additionally, the precision and accuracy of the experimentally determined Relative Levels (RL = compound peak area/C_{28} peak area) were investigated in order to assess if the values across compounds, instruments, and laboratories were: (1) reproducible, and (2) could provide an estimated purity range. Data from three replicate injections (injections 1, 5, and 10) from each compound were evaluated in accordance to American Society for Testing and Materials (ASTM) E691 and results demonstrated good within-instrument precision.[1] However, consistency statistics highlighted various outliers and trends across the 21 instruments evaluated. The high instrument-to-instrument variability was demonstrated to be the most significant factor influencing the method's overall reproducibility standard deviation.

The accuracy associated with RL was evaluated using all 210 injections collected for each compound (10 injections across 21 instruments). Correction Factors (CF) were calculated by comparing each compound's concentration (as originally prepared) against the RL measured for each individual injection. The final 210 RLs and 210 CFs produced for each compound were statistically evaluated using box plots, histograms, and normality tests. Overall, results show that a significant portion of the RL measured underestimate the compounds' concentration in solution; CFs varied from compound to compound and from instrument to instrument; dimethyl sulfone and noscapine were significant outliers; and distributions were found not to be normal. Compilation of the 25th and 75th percentile CFs for all compounds resulted in two "global" correction factors (1.439 and 1.992) that could hypothetically be applied to generate an Inter-Quartile Purity Range (IQPR) for any compound tested using the GUARDS method under standardized sample preparation conditions.

Applying the "global" correction factors, a total of 210 IQPR were generated for each compound investigated. When evaluating those purity ranges against the compound concentrations (as prepared), it was found that, on average, only about 40% of the IQPR generated captured the true purity of the compound. In other words, the probability of producing an estimated purity range that does not capture the true purity of the substance being tested is about 60% (on average). These results are not surprising and highlight the natural variability of responses across GC/MS systems, even when using standardized acquisition conditions.

B155 Exploring Natural Aging and Depletion Processes of Latent Fingermarks With 2D and 3D Imaging

Alexzandrea N. Buscarello, BS, University of New Haven, East Haven, CT; Josep De Alcaraz-Fossoul, PhD, University of New Haven, West Haven, CT*

Learning Objectives: After attending this poster presentation, attendees will have a better understanding of the complex Three-Dimensional (3D) structure of fingermarks and how different temporal mechanisms of degradation affect their topography as examined by 2D and 3D imaging.

Impact Statement: This presentation will impact the forensic science community by serving as an observation and comparison of the microscopic 2D and 3D topographical changes that simultaneously may occur during the (1) natural aging of latent fingermarks and (2) chronological order of sequential depositions (depletions). This preliminary study will have future implications for crime scene investigations as it provides useful data toward determining the chronological order of fingermark depositions.

Abstract Text: Latent fingermark age estimation remains a complex and unresolved challenge in forensic science.[1-3] Fingermarks are dynamic matrices that undergo time-dependent changes of topography, a process referred to as fingermark aging. These can be measured with 2D and 3D "chronomorphometrics," such as loss of color contrast between ridges and furrows and loss of ridge height and volume over time.[3-5] Physical, biological, and environmental factors each play a role in the severity and rate of degradation patterns of fingermarks. Early methods to estimate fingermark age focused on analyzing changes in chemical composition, while recent studies have shifted toward non-destructive, faster, and portable visual quantitative measurements. Currently, there are no standardized optical approaches to determine not only the natural age of latent fingermarks, but also the chronological order of depletions post-deposition. Investigating how these two temporal mechanisms affect the topography of ridges over time is important as they may play a role in fingermark aging patterns, simultaneously. Furthermore, establishing these patterns has the potential to identify both the suspect and the time at which a crime was committed.

This study aims to assess and record fingermark physical changes occurring over time on a glass substrate in complete darkness at four time points, days 0, 5, 13, and 27, utilizing a 2D imaging method with black magnetic powder and with a 3D imaging technique, an optical profilometer. With approval from the Institutional Review Board, triplicate sebaceous-rich fingermarks of the index finger and thumb of the dominant hands of four healthy male individuals were collected in sets of 15 depletions for each time point. A total of 1,440 fingermarks were deposited on glass microscope slides with medium pressure and examined under controlled environmental and lighting conditions. The 2D examinations provided morphometrical data: Color Contrast (CC), color-coded maps of ridge clarity (BlueGreen, BG), and fingermark visual Quality Scores (QS). The 3D approach collected microscopic measurements on the x, y, and z axes, and provided ridge height (S_a), and volume (Volume up, V_{up}) data.[6,7] It was hypothesized that 2D and 3D topographical changes occur in the two temporal degradation mechanisms, in which 3D measurements will be more sensitive in the detection of time-dependent changes.

Exploratory analysis included data cleaning, normalization of data, and regression analysis on Microsoft Excel. Further examinations included Grubb's tests for the detection of outliers, Boxplots for data distribution, and univariate and multivariate Analysis of Variance (ANOVA) analyses for each metric with IBM SPSS Statistics 25. Additionally, Principal Component Analysis (PCA) was utilized to reduce the dataset dimensionality and find correlations between variables.

Preliminary regression data for the depletion mechanism revealed the S_a and V_{up} metrics follow a power model, in which a significant initial decrease in ridge height and ridge volume, respectively, was observed for each time point. The CC metric, which represents the ratio of the average color (Mean Intensity [MI]) and the spread of color intensities (Intensity Amplitude [IA]), follows a positive linear model, in which the MI/IA ratio increased over 27 days. The BG metric, a color-coded measure of areas of high (blue and green) and low (red and yellow) ridge clarity, data revealed a linear decrease over time. Preliminary regression data for the natural aging mechanism revealed both the V_{up} and CC metrics follow a second-order polynomial model, both with an initial steady increase in ridge volume and MI/IA ratio, respectively. A positive linear trend was noted for S_a, while a negative linear trend was observed for the BG metric. This preliminary cross-analysis reveals there are differences in which the topographical changes of fingermarks occur over time when comparing the two temporal mechanisms.

Latent Prints; Age Estimation; Imaging

B156 Utilizing Low Energy Ionization to Differentiate and Identify Fentanyl and Nitazene Analogs

Kirk E. Lokits, PhD, Agilent Technology, Churchville, VA*

Learning Objectives: Many fentanyl and nitazene analogs generate similar or non-characteristic spectra when ionized at the conventional 70eV. This presentation will illustrate the ability to generate a molecular ion to provide confirmational and structural information by using isotopic fidelity and High-Resolution Mass Spectrometry (HRMS). Attendees will learn how low energy ionization works and how it can be applied to generate molecular ions that may not be produced under standard 70eV electron ionization. In addition, attendees will learn how to generate and interpret isotopic fidelity based on their masses and abundance ratios.

Impact Statement: Utilizing low energy ionization techniques could reduce or eliminate the difficulty of identifying compounds with similar EI spectra resulting in an enhanced level of confidence during the identification process and improve spectral certainty based on isotopic ratios and ion fragment stability in a low energy environment.

Abstract Text: Historically abused opiates such as heroin, are being "cut" with and/or replaced with many New Synthetic Opioids (NSO), such as the fentanyls and non-fentanyl-derived synthetic opioids (i.e., nitazenes).[1] Keeping up with the ever-evolving synthetic illicit drugs, precursors, and their metabolites is increasingly difficult and the need for retrospective data mining is invaluable. This research describes the workflow for employing a high-resolution accurate mass Gas Chromatograph/Mass Spectrometry (GC/MS), in combination with low energy ionization, to generate differentiating structural information on synthetic fentanyl analogs, including 4-ANPP, a scheduled precursor along with nitazene analogs from seized street drug case samples. This work compiles high resolution mass spectrometry low energy ionization spectra, the formation of an analyte's molecular ion, and the molecular ion's elemental isotopic ratios to assist in the identification of isobaric spectra generated under conventional nominal mass GC/MS 70eV ionization energy. Low energy ionization spectra were produced at 10, 12, 15, and 17eV ionization energies to assist in the formation of a molecular ion enabling the measurement of the isotopic abundances based on the elemental composition of the molecular ion. Comparisons of the exact masses and ratios (calculated) to the accurate masses and ratios (measured experimentally) are illustrated in this work. Low energy spectral patterns of known of nitazene and fentanyl analog standards were compared to seized drug case samples and used to identify nitazene analogs and other controlled substances based on the creation of their respective accurate mass molecular ion and isotopic ratios and patterns.

The data demonstrates the power and ability of low energy ionization and high-resolution MS to produce molecular ions of many illicit drugs that would normally be difficult to identify due to their similar or isobaric spectra when generated under the conventional 70eV ionization energies. This comprehensive analytical technique would be useful in identifying and differentiating NSOs that continually flood the illicit drug market, contributing to the increasing caseloads for seized drug analysis across the country.

Mass Spectrometry; Low Energy Ionization; Novel Psychoactive Substances

B157 The Development and Validation of a Combined Selected Ion Monitoring-Scan GC/MS Method for Nitazene Analogs

Alleigh N. Couch, BS, Sam Houston State University, Huntsville, TX; Emma Hardwick, BA, Sam Houston State University, Huntsville, TX; J. Tyler Davidson, PhD, Sam Houston State University, Huntsville, TX; Claire Phelps, MSFS, Sam Houston State University, Inver Grove Heights, MN*

Learning Objectives: After attending this presentation, attendees will have learned about a validated Selected Ion Monitoring (SIM) -scan Gas Chromatography/Mass Spectrometry (GC/MS) method for the identification of 20 representative nitazene analogs. The audience will learn about the concept of SIM data acquisition, including the use of retention time windows and ion ratios to increase method specificity. Finally, the audience will learn about the benefits of a combined SIM-scan acquisition method to identify low concentration nitazene analogs, even in the presence of commonly encountered controlled substances, adulterants, and diluents.

Impact Statement: This presentation will impact the forensic science community by providing a validated SIM-scan acquisition GC/MS method to identify 20 representative nitazene analogs. The validated method enables the detection of low concentration nitazene analogs using SIM acquisition, as well as the identification of other controlled substances and cutting agents using mass spectral library searching and scan acquisition. The developed SIM-scan GC/MS method provides a potential solution for seized drug laboratories to address the increasing presence of nitazene analogs in seized drug casework, which could easily be missed by routine scan data acquisition given the potency of nitazene analogs.

Abstract Text: The third wave of the opioid epidemic is characterized by overdoses due to synthetic opioids, such as fentanyl and fentanyl analogs. However, changing legislation in the United States and China has led to the emergence of a new class of synthetic opioids, known as 2-benzylbenzimidazoles, or nitazene analogs. These compounds are very potent and have grown in popularity within the United States since 2019. Given the potency of nitazene analogs and their increasing prevalence in seized drug casework, it is imperative that seized drug laboratories have sufficient methods to identify nitazene analogs. The central hypothesis of this research is that a combined SIM-scan acquisition GC/MS method will enable the necessary sensitivity and selectivity to identify nitazene analogs, even in the presence of higher-concentration controlled substances and cutting agents. The developed method was also validated in terms of the Limit Of Detection (LOD), carryover, selectivity, repeatability, reproducibility, and processed sample stability.

An Agilent GC/MS was used to develop the combined SIM-scan acquisition method. The 20 representative nitazene analogs analyzed in this study were: isotodesnitazene, 3'-methoxy metodesnitazene, protodesnitazene, 5-methyl etodesnitazene, nitazene, menitazene, 5-aminoisotonitazene, N-desethyl etonitazene, propylnitazene, N-desethyl isotonitazene, 4'-hydroxy nitazene, N-pyrrolidino metonitazene, ethyleneoxynitazene, iso-butonitazene, N-pyrrolidino isotonitazene, N-pyrrolidino 4'-hydroxy nitazene, N-piperidinyl etonitazene, N-piperidinyl 4'-hydroxy nitazene, N-piperidinyl protonitazene, and metodesnitazene. A mixture of the 20 nitazene analogs and a PCP internal standard was prepared at 50ppm in methanol for the Quality Control (QC) mixture used for the validation studies.

The LOD was determined based on the lowest concentration that provided a Signal-to-Noise (S/N) ratio of at least 3:1, a retention time within 1% of the QC, and ion ratios within ±20% of the QC. Carryover was monitored by analyzing each nitazene analog individually at 100ppm and assessing the subsequent methanol blanks. Selectivity was assessed by monitoring the ability to identify each nitazene analog in the presence of common interferences. The interference compounds included cocaine, caffeine, methamphetamine, xylazine, diphenhydramine, quinine, levamisole, phenacetin, alprazolam, diazepam, bromazolam, clonazepam, fentanyl, tramadol, and heroin. Interferences were prepared at various concentrations ranging from 25ppm to 250ppm. Repeatability was determined using ten injections within one day and reproducibility was determined using one injection per day for ten days. Processed sample stability was assessed in methanol at room temperature for up to four days.

All 20 targeted nitazene analogs had an LOD between 5ppm and 10ppm due to the enhanced sensitivity provided through SIM acquisition. No carryover was observed for any of the nitazene analogs. The 20 nitazene analogs were differentiated from each other and the common interference compounds that were included in this study. The retention times demonstrated acceptable repeatability and reproducibility, although there were inconsistent relative peak areas for several of the nitazene analogs. The processed sample stability study revealed that the majority of nitazene analogs in this study were stable in methanol at room temperature for up to 48 hours. The validated method was then applied to analyze 35 blind simulant samples. The ground truth nitazene analog composition was identified in 34 out of 35 simulant samples. The lone incorrectly reported sample was due to ion ratios outside of tolerance, likely because of a concentration below the limit of detection. Finally, two blind authentic samples were analyzed using the validated method. The identified controlled substances were consistent with those reported by the laboratory that provided the authentic samples. Thus, the validated SIM-scan GC/MS method is suitable for seized drug casework and should help provide an additional resource for seized drug analysts to combat the ongoing opioid epidemic.

Novel Synthetic Opioids; Analogs; Chromatography

B158 The Differentiation of Isobaric Methyl-Substituted Fentanyl Analogs Using Direct Analysis in Real-Time Mass Spectrometry (DART-MS) and All-Ion Fragmentation (AIF)

Christany Liggins, BS, Sam Houston State University, Huntsville, TX; Alleigh N. Couch, BS, Sam Houston State University, Huntsville, TX; J. Tyler Davidson, PhD, Sam Houston State University, Huntsville, TX*

Learning Objectives: After attending this presentation, attendees will have learned about the differentiation of isobaric methyl-substituted fentanyl analogs using DART-MS and AIF. The audience will learn about the fundamentals of AIF, characteristic differences in the AIF data of isobaric methyl-substituted fentanyl analogs, and how the location of the methyl substitution impacts the formation of characteristic fragment ions under AIF conditions.

Impact Statement: This presentation will impact the forensic science community by demonstrating the effectiveness of AIF combined with DART-MS for the differentiation of isobaric methyl-substituted fentanyl analogs. Without the incorporation of AIF, the DART mass spectra of the isobaric methyl-substituted fentanyl analogs are indistinguishable. The application of AIF with soft ionization sources such as DART provides a potential solution for the differentiation of isobaric analogs that are becoming increasingly present in seized drug casework.

Abstract Text: As the number of seized drug casework submissions continues to rise, forensic laboratories need more rapid screening techniques to address their growing backlogs. One potential solution is the incorporation of rapid seized drug screening using DART-MS, which is an ambient ionization technique that enables the analysis of samples with only minimal sample preparation. Unfortunately, because DART is a soft ionization technique that produces predominantly protonated/deprotonated molecules, DART-MS cannot readily distinguish between isomers. Tandem Mass Spectrometry (MS/MS) can be used to generate fragment ions through Collision-Induced Dissociation (CID) that may help differentiate isomers; however, targeted MS/MS analysis requires knowledge about potential compounds of interest. In comparison, AIF enables CID activation of all precursor ions present without prior knowledge regarding the sample composition. Given the abundance of fentanyl analogs in seized drugs casework, the reliable identification of fentanyl analogs is critical for forensic laboratories. However, the differentiation of isobaric methyl-substituted fentanyl analogs is quite challenging, especially when present in mixtures. The central hypothesis of this research is that the combination of AIF with DART-MS will enable the differentiation of isobaric methyl-substituted fentanyl analogs, even when present in mixtures, based on differences in fragmentation derived from the location of the methyl substitution to the core fentanyl structure.

A DART JumpShot ionization source coupled to an Agilent 6530 quadrupole Time-Of-Flight (qTOF) mass spectrometer was used to analyze a series of isobaric methyl-substituted fentanyl analogs. Samples were introduced to the DART ionization source by depositing 5µL of sample onto a QuickStrip, which was allowed to dry before analysis. All analyses were completed in positive ionization mode using helium as the source gas heated to 350°C. The isobaric methyl-substituted fentanyl analogs included 4-methyl fentanyl, 4'-methyl fentanyl, butyryl fentanyl, isobutyryl fentanyl, ortho-methyl fentanyl, trans-3-methyl fentanyl, α-methyl fentanyl, and β-methyl fentanyl, which only differ in the location of the methyl substitution to the core fentanyl structure. All standards were prepared at a concentration of 10ppm in methanol. Two-component mixtures of methyl-substituted fentanyl analogs were also prepared at a total concentration of 20ppm in methanol. AIF was used to obtain low (i.e., 0 eV), medium (i.e., 30 eV), and high (i.e., 60 eV) activation energy spectra.

Except for butyryl fentanyl and isobutyryl fentanyl, all methyl-substituted fentanyl analogs produced either a unique combination of fragment ions or distinct differences in ion abundance ratios that enabled successful differentiation. For example, ortho-methyl fentanyl produced fragment ions at m/z 230 and m/z 188 without the presence of a fragment ion at m/z 281 that enabled differentiation from amide-substituted fentanyl analogs, such as butyryl fentanyl and isobutyryl fentanyl. Trans-3-methyl fentanyl and 4-methyl fentanyl produced a fragment ion at m/z 202 without the presence of fragment ions at m/z 119 and m/z 91 that are present for analogs such as α-methyl fentanyl, β-methyl fentanyl, and 4'-methyl fentanyl. The presence of a fragment ion at m/z 230 enabled the differentiation of trans-3-methyl fentanyl and 4-methyl fentanyl. Likewise, α-methyl fentanyl can be differentiated from β-methyl fentanyl and 4'-methyl fentanyl based on the presence of a characteristic fragment ion at m/z 233. Finally, β-methyl fentanyl and 4'-methyl fentanyl can be differentiated based on the abundance of the fragment ions at m/z 119 and m/z 91, with β-methyl fentanyl favoring the formation of the tropylium ion at m/z 91. Unfortunately, due to the location of the methyl substitution on the amide moiety for butyryl fentanyl and isobutyryl fentanyl, these compounds remained indistinguishable even under AIF conditions. However, this study demonstrates the potential benefits of combining AIF with DART-MS for differentiating isomeric species, such as isobaric methyl-substituted fentanyl analogs.

Fentanyl; Analogs; Direct Analysis in Real Time (DART)

B159 Thermal Desorption-Direct Analysis in Real-Time Mass Spectrometry (TD-DART-MS) of Seized Drug Mixtures

Keshonna Towns, BS, Sam Houston State University, Huntsville, TX; Alleigh N. Couch, BS, Sam Houston State University, Huntsville, TX; J. Tyler Davidson, PhD, Sam Houston State University, Huntsville, TX*

Learning Objectives: After attending this presentation, attendees will have learned about a TD-DART-MS screening method that provides a temperature-based separation of seized drug mixture components before DART-MS analysis. The audience will learn about the benefits of the developed TD-DART-MS method, including reduced competitive ionization and the ability to acquire DART-MS spectra for individual components of seized drug mixtures, reducing the challenges associated with mixture interpretation.

Impact Statement: This presentation will impact the forensic science community by providing an alternative rapid screening method for seized drug mixtures using TD-DART-MS. The developed TD-DART-MS method enables the separation of mixture components, reducing concerns with competitive ionization and mixture interpretation. The demonstration of similar performance using either helium or nitrogen as the source gas supports using more affordable nitrogen as an alternative source gas for the developed TD-DART-MS method.

Abstract Text: Seized drug mixtures are analyzed daily in forensic laboratories across the United States. Presumptive testing, such as color tests, is typically used to rapidly gain information about an unknown substance without extensive sample preparation or lengthy analyses. However, color tests struggle with the presence of multiple components in seized drug mixtures, which can lead to unpredictable or inconclusive results. Recently, DART-MS has gained popularity as an alternative seized drug screening method. DART-MS enables the rapid analysis of seized drug mixtures with little-to-no sample preparation; however, the presence of multiple components can lead to issues with sensitivity due to competitive ionization and it requires complex mixture interpretation. The central hypothesis of this research is that incorporating thermal desorption before DART-MS analysis will provide a temperature-based separation to improve analyte detection and the ease of identification due to reduced competitive ionization and the production of single-component mass spectra.

An Agilent 6530 quadrupole Time-Of-Flight (qTOF) mass spectrometer was coupled with an IonSense DART JumpShot ionization source and a BioChromato ionRocket thermal desorption unit for analysis of the seized drug mixtures. The thermal desorption temperature program included a 0.8-minute hold at 40 °C followed by a 30°C/minute ramp rate to 200°C with an additional 0.5 minute hold for a total analysis time of 6.6 minutes. All TD-DART-MS data was collected in positive ionization mode with a scan range of m/z 50-450. The analyses were completed using helium and nitrogen as the source gas to assess the impact on the resulting analysis. The seized drug mixtures analyzed in this study included controlled substances such as methamphetamine, cocaine, heroin, fentanyl, and oxycodone, and cutting agents such as dimethyl sulfone, aniline, procaine, caffeine, and xylazine. Pure samples and mixtures were prepared in methanol at concentrations ranging from 5ppm to 50ppm to assess the sensitivity of the developed TD-DART-MS method.

The analysis of each substance individually enabled the development of a temperature program to maximize the temperature-based separation of the individual components before mixture preparation. As expected, components with similar vapor pressures could not be readily separated. However, components with more drastic differences in vapor pressure can be readily separated before DART-MS analysis. For example, aniline/fentanyl and methamphetamine/fentanyl can be easily separated, whereas mixtures such as dimethyl sulfone/methamphetamine, cocaine/caffeine, and fentanyl/oxycodone cannot be readily separated. Several mixtures exhibited separation between several components, but not all components within the mixture. For example, xylazine can be readily separated from heroin/fentanyl and fentanyl can be readily separated from procaine/cocaine, but the remaining components cannot be readily separated.

The limit of detection for separated mixture components was slightly lower than when the components were unable to be separated, likely due to competitive ionization. Likewise, the separated components could be identified without complex mixture interpretation typically required for DART-MS analysis of seized drug mixtures. Even with the presence of competitive ionization in the non-separated mixtures, the limit of detection was still on the order of 5ppm for all mixture samples. Finally, similar TD-DART-MS results were acquired when using either helium or nitrogen as the source gas, which supports using the more affordable nitrogen compared to traditional helium as the source gas. The helium source gas provided slightly more sensitivity; however, sufficient performance was still achievable with the more affordable nitrogen source gas. The developed TD-DART-MS method improves upon existing DART-MS analysis by reducing concerns with competitive ionization and mixture interpretation, especially for components with disparate vapor pressures.

Rapid Drug Screening; Drug Analysis; Direct Analysis in Real Time (DART)

B160 An Evaluation of a Transportable Linear Ion Trap Mass Spectrometer for Rapid Seized Drug Screening

Fiza Tajdin, BS, Sam Houston State University, Huntsville, TX; Christina Chang, MS, Sam Houston State University, Huntsville, TX; J. Tyler Davidson, PhD, Sam Houston State University, Huntsville, TX; Alleigh N. Couch, BS, Sam Houston State University, Huntsville, TX*

Learning Objectives: After attending this presentation, attendees will have learned about the advantages and limitations of rapid seized drug screening using a transportable linear ion trap mass spectrometer. The audience will learn about the capabilities of direct tandem mass spectrometry analysis, including the development of an internal library and associated alarm system for the automated identification of individual compounds within commonly encountered seized drug mixtures.

Impact Statement: This presentation will impact the forensic science community by evaluating the use of a transportable linear ion trap mass spectrometer for rapid seized drug screening of commonly encountered seized drug mixtures. Assessing the performance of this instrumentation to enable automated seized drug identification will inform the community about the potential utilization of transportable linear ion trap mass spectrometers as an alternative rapid seized drug screening method.

Abstract Text: The increasing number of seized drug casework submissions is creating a significant problem for seized drug analysts. Not only are analysts having to examine more items of evidence per submission, but the backlogs of seized drug casework are continuing to grow. The implementation of field-portable or transportable instrumentation is one potential solution that could ease the current casework burden; however, extensive testing is required before these instruments can be reliably applied within the field. Ideally, law enforcement or forensic practitioners will be able to rapidly and accurately screen seized drug evidence on-site to reduce the number of casework submissions and improve the allocation of resources within forensic laboratories. The central hypothesis of this research is that the direct tandem mass spectrometry capabilities of a transportable linear ion trap mass spectrometer will enable rapid and reliable screening of seized drug mixtures, even by non-trained personnel, using an automated alarm system for compound identification.

In this study, a BaySpec Continuity transportable mass spectrometer coupled with a Thermal Desorption-Atmospheric Pressure Chemical Ionization (TD-APCI) source was used for the analysis of seized drug mixtures. The following controlled substances and cutting agents were analyzed to represent compounds commonly found within seized drug mixtures: cocaine, methamphetamine, heroin, fentanyl, caffeine, acetaminophen, pseudoephedrine, phenacetin, phentermine, and levamisole. Both full scan and product ion spectra were collected for all individual compounds. The parameters required for Collision-Induced Dissociation (CID) activation and characteristic product ions for each compound of interest were imported into the internal library. A library-based alarm system was implemented to enable the automated identification of unknown compounds by even non-trained personnel. Any precursor ion and corresponding product ion abundance above the optimized library alarm threshold resulted in compound identification and a corresponding system alarm. The following two- and three-component mixtures were analyzed to demonstrate the ability to identify each component within the mixture using the developed alarm system: (1) heroin and fentanyl, (2) cocaine and levamisole, (3) methamphetamine and pseudoephedrine, (4) methamphetamine and phentermine, (5) methamphetamine, caffeine, and acetaminophen, and (6) cocaine, caffeine, and phenacetin. Validation studies consisting of selectivity, reproducibility, repeatability, and Limit Of Detection (LOD) were performed to assess instrumental performance. Five blind simulant mixture samples and ten authentic adjudicated casework samples were analyzed to establish the efficacy of the developed approach for real-world casework samples.

The results indicate that the controlled substances and cutting agents analyzed in this study were reliably identified as both pure samples and mixtures. Implementation of a library-based alarm system enabled the rapid identification of each component in the analyzed seized drug mixtures. In addition, even isobaric species such as methamphetamine and phentermine were differentiated based on distinguishable Tandem Mass Spectrometry (MS/MS) fragmentation behavior. The LOD was established on a per-compound basis, with most compounds detected at a concentration of 15ppm or less. The correct controlled substance was identified in 100% of two- and three-component mixtures, blind simulant mixtures, and authentic adjudicate casework samples. One potential limitation of the library-based alarm system is the requirement for the compound to be in the internal library, highlighting the need for continued expansion of the current internal library. However, this limitation did not impede correct compound identification for the authentic adjudicated casework samples used in this study. The developed library-based alarm system implemented with a transportable linear ion trap mass spectrometer coupled to TD-APCI sample introduction enabled individual compound identification in seized drug mixtures, providing a potential solution for rapid on-site seized drug screening, even by non-trained personnel.

Rapid Drug Screening; Drug Analysis; Tandem Mass Spectrometry

B161 The Differentiation of CBD and Δ9-THC Isomers Using Copper Ion Complexation and Electrospray Ionization Tandem Mass Spectrometry

Alleigh N. Couch, BS, Sam Houston State University, Huntsville, TX; Christopher M. Zall, PhD, Sam Houston State University, Huntsville, TX; J. Tyler Davidson, PhD, Sam Houston State University, Huntsville, TX*

Learning Objectives: After attending this presentation, attendees will have learned about the differentiation of Cannabidiol (CBD) and Δ9-Tetrahydrocannabinol (Δ9-THC) isomers using copper ion (Cu+) complexation and Electrospray Ionization-Tandem Mass Spectrometry (ESI-MS/MS). The audience will learn about subtle differences in the preferential binding affinity of Cu+ to CBD and Δ9-THC isomers and how these differences enable the formation of unique product ions or product ions ratios enabling cannabinoid differentiation.

Impact Statement: This presentation will impact the forensic science community by providing the first application of copper ion complexation for CBD and Δ9-THC isomer differentiation. The characterization of Cu-cannabinoid adducts for each isomer reveals the presence of unique MS/MS product ions or unique product ion ratios enabling their differentiation using a rapid direct mass spectrometry approach.

Abstract Text: After the enactment of the 2018 Farm Bill, marijuana was redefined as *Cannabis sativa* L. or any derivative thereof that contains greater than 0.3% Δ9-THC, whereas hemp contains no more than 0.3% Δ9-THC on a dry weight basis. The Controlled Substances Act classifies marijuana as a Schedule I controlled substance, prohibiting marijuana at the federal level. Therefore, the ability to differentiate between legal hemp and controlled marijuana is critical within the seized drug community. CBD and Δ9-THC are the main cannabinoids present in hemp and marijuana, respectively. However, there are additional cannabinoids present within cannabis, many of which have identical chemical formulas yet slightly differ in their structural arrangements, resulting in nearly identical product ion spectra under ESI-MS/MS analysis. Likewise, there are concerns with thermal degradation and interconversion between cannabinoid isomers with gas chromatography/mass spectrometry analysis. The central hypothesis of this research is that the application of copper ion complexation and ESI-MS/MS will enable the differentiation of CBD and Δ9-THC isomers based on the formation of unique MS/MS product ions due to subtle differences in the binding affinity between cannabinoid isomers.

An Agilent 6530 quadrupole Time-Of-Flight (qTOF) mass spectrometer coupled to direct injection ESI was used to analyze Cu adducts of the targeted cannabinoids. The following compounds were analyzed in this study: Δ9-THC, CBD, Δ8-tetrahydrocannabinol (Δ8-THC), exo-tetrahydrocannabinol (exo-THC), Δ6a, 10a-tetrahydrocannabinol (Δ6a,10a-THC), cannabicitran (CBT), cannabichromene (CBC), tetrahydrocannabinolic acid (THCA), cannabidiolic acid (CBDA), cannabigerol (CBG), and cannabinol (CBN). These cannabinoids included Δ9-THC isomers, as well as other common cannabinoid interferences found in cannabis. Product ion spectra were collected for the precursor ions of the Cu adducts formed as [Cu(cannabinoid)*n*]+ adducts (*n* = 1, 2, or 3) observed at *m/z* 377, *m/z* 691, and *m/z* 1003, respectively. Product ion spectra were collected using a 4 Da isolation width and collision energies of 15-55eV. Spectral comparisons were utilized to characterize the Cu-cannabinoid adducts and to identify unique MS/MS product ions or unique product ion ratios that enable differentiation between CBD and Δ9-THC isomers. The efficacy and robustness of the developed approach were assessed by analyzing known mixtures of Δ9-THC isomers and methanolic extracts of cannabis plant material to identify the impact of matrix effects and potential overlapping product ions from isobaric cannabinoids.

The results indicate that CBD and Δ9-THC isomers can be differentiated using copper ion complexation and direct injection ESI-MS/MS. The differentiation of isomers is based on differences in the binding affinity between the Cu+ and alkene functionalities within the cannabinoids; therefore, small differences in structure between each isomer enable subtle differences in the formation of MS/MS product ions. Three variations of the Cu adducts were formed, including [Cu(cannabinoid)*n*]+ adducts (*n* = 1, 2, or 3), and when fragmented under optimal activation energies, unique product ions were observed enabling isomer differentiation. For example, when fragmenting the precursor ion at *m/z* 691 under 45eV activation energies, the presence of the product ion at *m/z* 313 and the absence of the product ion at *m/z* 254 enables the differentiation of Δ9-THC from CBD. Likewise, the presence of a product ion at *m/z* 245 indicates the presence of Δ8-THC rather than exo-THC. Known cannabinoid mixtures and authentic cannabis plant material extracts were analyzed and Δ9-THC and CBD isomers were able to be identified, even in the presence of common cannabinoid interferences. The results of this study highlight the potential for the combination of copper ion complexation and ESI-MS/MS as an alternative method for the forensic science community to differentiate CBD and Δ9-THC isomers, which is necessary for the differentiation of hemp and marijuana.

Marijuana; Hemp; Tandem Mass Spectrometry

B162 Enhancing Latent Print Development With Lanconide Powder

Lydia J. Buxa, Liberty University, Oconomowoc, WI; Chad A. Snyder, PhD, Liberty University, Lynchburg, VA*

Learning Objectives: From this poster presentation, attendees will learn: (1) the importance of white fingerprinting powders, (2) safety concerns with the current lanconide powder, (3) the method for altering lanconide to make it more effective as well as the results of those compositions, and (4) possible chemical properties that explain why TiO2 inhibits print development.

Impact Statement: While more complex technologies for latent print development are being created, powders are always a valuable tool to keep in the toolbox of crime scene techs and forensic investigators. Continuing to improve on old techniques, specifically powders, is incredibly valuable in the field of forensics. White fingerprinting powders are drastically under-researched, so the study described in this poster presents enhanced latent print development using lanconide, which could be applied to crime scene and trace evidence scenarios.

Abstract Text: Latent fingerprints found on crime scenes cannot be seen with the naked eye and require development techniques for visualization and analysis.[1] Because fingerprints are composed of oily sebaceous secretions, powders used in dusting adhere to the fingerprint oils.[2] The fine powder particles help visualize the print increasing contrast of the ridges and minutiae. The most common fingerprint powder is a black powder made of carbon black or powdered acacia. The composition of black powder is far more researched, but the limitation of this powder comes when the latent prints are found on dark surfaces.[3] Since black powders would not provide the necessary contrast for photo documentation in this situation, a white-colored powder must be used. However, there are very few literature compositions of white powders developed.

The current study then focuses on altering the composition of lanconide, a white powder composed of zinc sulfide (ZnS), zinc oxide (ZnO), barium sulfate (BaSO4), titanium (IV) oxide (TiO2), bismuth oxychloride (BiOCl), and calcium carbonate (CaCO3). The purpose was to improve the standard composition for lanconide powders to enhance latent print development. By removing one of the inorganic salts per trial, seven total powder compositions were tested to see if specific compounds had inhibitory or enhancing effects in the powder. The resulting prints and minutiae were analyzed for clarity to determine which powder provides the best contrast for print photography and analysis. A grading scale for analyzing prints was developed to standardize the process and quantify the data. While all powders developed prints, the highest quality resulted from removing TiO2 or BaSO4. More research needs to be done to confirm why these results occurred, but qualities such as acidity, hygroscopicity, solubility, and density were explored. The current hypothesis is that non-hygroscopic compounds (such as TiO2 or BaSO4) inhibit print development. This study posits that removing TiO2 from the powder recipe produces a more effective and safe lanconide powder.

Fingerprint; Latent Prints; Trace Analysis

B163 A Modified and Optimized Duquenois Test for Classical and Designer Cannabis Products

Marie E. Lemay, Hofstra University, Jamestown, New York; Ryan A. Smith, BS, Hofstra University, SWANSEA, MA;Ling Huang, PhD, Hofstra University, Hempstead, NY; Nanetter Wachter, PhD, Hofstra University, Hempstead, NY*

Learning Objectives: After attending this presentation, attendees will better understand the routinely used Duquenois-Levine test for cannabis products. They will have the opportunity to hear about modifications made to this presumptive color test to make it safer, simpler, and quicker. The removal of chlorinated solvents in this test makes it much safer for scientists and others, such as police officers, to utilize it in-field. This modified test can screen various popular designer formulations, such as gummies, oils, and plant material, and it has the potential to screen others as well for the presence of cannabinoids such as delta-9 THC, delta-8 THC, CBD, HHC, and other similar compounds.

Impact Statement: The results of this project can have long-lasting effects on forensic practitioners and law enforcement, as the removal of harmful solvents makes the work significantly safer. The modifications made on Duquenois-Levine, which has been the gold standard of cannabis color tests for over 50 years, not only increase the stability of the test result but also make it quicker, simpler, and a completely different color from the classical blue/purple extracted into the organic layer. This research also utilizes squeeze droplet Ultraviolet/Visible (UV/Vis) spectroscopy and is semi-quantitative.

Abstract Text: The classical Duquenois-Levine test is the primary presumptive color test used for cannabis products. This has been the preferred test for cannabis for over 50 years, and little changes have been made in that time. This test involves various harmful chemicals, including chloroform, a suspected human carcinogen. The substitution or elimination of this solvent would make the test significantly safer and was one of our major research goals. Another goal was improving results interpretation and exploring the possibility of differentiating color results for different cannabinoids and matrices using droplet UV/Vis spectroscopy and Red/Green/Blue (RGB) values. However, this was deemed not plausible using the classical or modified Duquenois-Levine as this test primarily confirms or denies that a sample contains cannabinoids.

A modified Duquenois reagent was prepared using the same reagent ratios as in the classical Duquenois reagent but replacing vanillin with 4-Hydroxy-3-Methoxycinnamaldehyde (HMC). Combining this three-component reagent (acetaldehyde and HMC in 95% ethanol) with hydrochloric acid and a cannabinoid-containing sample produced a deep green color. In addition to chloroform, cyclohexane, heptane, and hexane were all tested as solvents for this test result, and it was found that the addition of an organic solvent (Levine's modification) did not have a significant effect on the results. Using the modified Duquenois reagent, the chloroform step in Duquenois-Levine could be eliminated without altering the end color. It was discovered that the ethanol solvent used in the preparation of the chromophore was adequate at turning out the positive colors for both vanillin-based classical Duqunois tests and modified tests that were based on HMC.

Small amounts of each reagent (~0.3mL) were added to spot plates containing small quantities of each sample (10–20mg for plant material, around 100mg of gummy, and 100µL of oils). Photographs of the color results were collected with a smart phone camera, and UV/Vis spectra were collected for each sample using an NP80 Nanophotomer. 0.3µL aliquots of the colored matrix in the spot plates were transferred directly onto the instrument and analyzed using a squeeze droplet design that minimizes the sample's contact with the environment during analysis to prevent evaporation. A λ_{max} of between 655 and 657nm was observed for cannabinoid-containing gummies, 662 and 663nm for marijuana and hemp plant material (respectively), and between 652 and 658nm for oils.

Using HMC as a replacement for vanillin in the Duquenois reagent, the chemistry of the reaction was successfully altered to produce a different color (green) so that it was easier to identify a positive test result, and the absorption band separated more clearly from the other bands in the UV/Vis spectrum. The elimination of chloroform in the test also makes it safer and simpler. The resultant chromophore solution appears to be more stable and less volatile compared to classical Duquenois-Levine test solutions.

UV/Vis Spectroscopy; Duquenois Test; Color Test

B164 Discriminating Between the Tandem Mass Spectra of Isomeric Synthetic Cannabinoids Using the Expert Algorithm for Substance Identification (EASI)

Alexandra I. Adeoye, MS, West Virginia University, Morgantown, WV; Alleigh N. Couch, BS, Sam Houston State University, Huntsville, TX; Glen P. Jackson, PhD, West Virginia University, Morgantown, WV; J. Tyler Davidson, PhD, Sam Houston State University, Huntsville, TX*

Learning Objectives: In this presentation, attendees will learn how the abundances of fragment ions in replicate tandem mass spectra display correlations that can be used to discriminate between spectrally similar synthetic cannabinoids.

Impact Statement: This presentation will provide the forensic community with a robust algorithm capable of identifying substances from their tandem mass spectra, even when collected under different activation conditions. EASI aims to minimize false identifications and improve forensic analysts' confidence in their identifications and testimony.

Abstract Text: The identification of isomers is one of the greatest challenges currently facing the seized drug community. Whether through traditional techniques, such as Gas Chromatography/Electron Ionization/Mass Spectrometry (GC/EI/MS), or emerging techniques, such as Liquid Chromatography/Electrospray Ionization/Tandem Mass Spectrometry (LC/ESI/MS/MS), seized drug analysts are faced with the difficult task of correctly identifying compounds that may contain numerous structural isomers. For example, the synthetic cannabinoid class of novel psychoactive substances contains multiple controlled substances, such as AB-PINACA, that have several known isomeric species that must be differentiated for an analyst to reach the correct conclusion. Previously, we have demonstrated the application of EASI to the differentiation of isomeric fentanyl analogs, synthetic cathinones, and cannabinoids using GC/EI/MS instrumentation. This study expands our work with EASI to LC/ESI/MS/MS instrumentation. Our central hypothesis is that relative ion abundances of replicate tandem mass spectra are not independently variable but highly correlated and anticorrelated. We use the measured correlations (confirmed by Pearson correlation matrices) between abundances in replicate spectra in a series of general linear models to make accurate predictions of ion abundances within the spectra. This hypothesis is supported by unimolecular fragmentation theories like Rice–Ramsperger–Kassel–Marcus (RRKM).

More than 60 replicate spectra were collected for each synthetic cannabinoid analyzed in this study. These chosen synthetic cannabinoids were isobaric or spectrally similar to AB-PINACA and included AEP-PINACA and ADB-BUTINACA. Tandem mass spectra were collected on an Agilent 6530 Q-TOF mass spectrometer at four collision energies. The replicate spectra were randomized and distributed so that 80% of the data was in a training set, and the remaining 20% was in the test sets for General Linear Modeling (GLM). Since the fragment abundances vary at different collision energies, the 30 most abundant fragments across all collision energies were selected as variables for the linear models and entered in a stepwise addition method. The models from each training set were used to predict each compound's fragment abundance. The measured and EASI-predicted abundances were evaluated using similarity and dissimilarity metrics, including the weighted dot-product and the mean absolute residual. Each metric was then used as a binary classifier to generate Receiver Operating Characteristic (ROC) curves and to determine the true and false positive rates over a range of threshold values. The Area Under the Curve (AUC) was then calculated to assess the performance of each metric and its supporting model.

The residuals from the EASI models were generally four times smaller than those from the consensus-based approach. Using all the modeled fragment abundances as input variables for classification, the consensus-based approach discriminated between selected compounds with an average of ~80% accuracy. However, EASI distinguished between the analogs with an average of >90% accuracy. Abundance predictions were more accurate for both EASI and the consensus approach when the training set and query spectra were kept at a fixed collision energy. Demonstrating an extension of EASI to tandem mass spectra generated using multiple collision energies with LC/ESI/MS/MS instrumentation further highlights the utility of EASI for compound identification regardless of the instrumental configuration.

Novel Psychoactive Substances; Tandem Mass Spectrometry; Modeling

B165 An Analysis of *Mitragyna Hirsuta* and *Mitragyna Diversifolia* Being Offered as Legal Alternatives to Kratom

Megan Joos, BS, University of Alabama at Birmingham, Hoover, AL; Elizabeth Gardner, PhD, University of Alabama at Birmingham, Birmingham, AL*

Learning Objectives: While not controlled at the federal level, kratom is regulated or controlled in 13 states and is considered a drug and chemical of concern by the Drug Enforcement Administration (DEA). This poster provides attendees with understanding of the current state of the kratom, *Mitragyna speciosa*, alternatives being sold in the United States. The primary focus is on the sale and analysis of two *mitragyna (M.)* species, *M. hirsuta* and *M. diversifolia* which do not contain mitragynine, the psychoactive substance used to identify kratom. *M. hirsuta* and *M. diversifolia* are sold online and in head shops as a legal alternative to kratom as neither contains the psychoactive alkaloid.

Impact Statement: This presentation aims to add to analysts' and law enforcement's understanding of the different species of mitragynine being sold as legal alternatives to kratom. The knowledge gained from this presentation can also be applied to future regulations regarding kratom.

Abstract Text: *Mitragyna (M.) speciosa* is a tree native to Southeast Asia, where its leaves have traditionally been consumed for medicinal purposes through smoking or ingestion in teas, capsules, or with food. The plant is typically reported as having both stimulant effects in low doses and sedative effects when taken in high dosage. The effects are caused by the active alkaloids, mitragynine and hydroxymitragynine or 7-hydroxymitragynine.[1] Different strains of *M. speciosa* have characteristic levels of the active alkaloids.[2]

In 2016, the DEA published a notice of intent to list mitragynine and 7-hydroxymitragynine as a Schedule 1 substance under the Controlled Substances Act's emergency scheduling provisions. Following public backlash from kratom organizations and lobbyists, the DEA withdrew its expedited scheduling and, eventually, the attempt at scheduling entirely. It remains a DEA drug or chemical of concern.[3] Although there are no federal regulations regarding kratom, the possession and sale of kratom has been regulated in 13 states, with complete bans on the active alkaloid put in place in six states, including Alabama.[1] Since the scheduling of kratom in Alabama, head shops and gas stations have begun selling other mitragyna species, including *M. hirsuta* and *M. diversifolia* ,which do not contain the mitragynine alkaloid but are known to provide similar effects as *M. speciosa*.[4]

Samples of *M. hirsuta*, and *M. diversifolia* in capsule form were purchased from a head shop in Birmingham, AL. Products labeled as "Kratom," including Red Malay and Red Bali strains, were purchased from gas stations in Alabama and Georgia. Approximately 0.15g of each capsule's contents were dissolved in 7.5mL of methanol to create a 20mg/mL solution of the product. Nine hundred µL of the sample solution was added to a gas chromatography vial, along with 100µL of 1mg/mL dibucaine internal standard. The samples were run on an Agilent 8890 GC System 5977B Gas Chromatography/Mass Selective Detector (GC/MSD) with an external standard of mitragynine. All labeled kratom samples were positive for mitragynine, as expected for *M. speciosa*. The *M. hirsuta* and *M. diversifolia* samples were also positive for mitragynine, despite previous studies documenting these species lack the alkaloid. Due to the presence of mitragynine in the sample, it is possible that companies may be selling *M. speciosa* as the uncontrolled *M. hirsuta and M. diversifolia* in order to circumvent regulation.

Kratom; Mitragyna hirsuta; Mitragyna diversifolia

B166 The Development of a Virtual Liquid Chromatography Method Development Tool

Haley Berkland, MS, Restek Corporation, Bellefonte, PA*

Learning Objectives: By attending this presentation, attendees will understand the background and development process of a virtual Liquid Chromatography (LC) method development tool. The validation of this tool will be explained in depth to emphasize the accuracy of the modeler when compared to experimental, in-lab results.

Impact Statement: This presentation will impact the forensic science community by exploring the use of a novel technology being used to improve the analytical method development process.

Abstract Text: The development and optimization of LC separations can be time consuming and costly, often requiring several steps, including literature research, column selection, method scouting, method development, and method optimization. In an effort to eliminate these steps, an instrument-free, software modeling tool that gives users the ability to select compounds from a database and instantly model a separation on different column stationary phases was developed. Optimization of the model can be performed while maintaining critical pair separations by adjusting for instrument/system effects (e.g., dwell volume and extra column volume), mobile phase preferences, number of gradient steps, and more. The initial database consists of a Drugs of Abuse (DoA) library containing approximately 250 compounds with plans to continually expand the utility.

To build the chromatogram modeler, a DoA library containing approximately 250 compounds was created. Data was collected using a standard High-Performance Liquid Chromatography (HPLC) system coupled to a triple quadruple mass spectrometer (LC/MS/MS). Retention times were first collected using a fast/slow gradient, 30°C/60°C column temperature points, and ACN/MeOH mobile phases on a single column dimension (50 x 2.1mm, 2.7µm). Some additional data points outside of these runs were also collected for the development of a semi-empirical correction factor that was used to improve modeling accuracy. To assess the accuracy of the modeler, experiments comparing compound retention time values between wet-lab and modeled data were conducted. After the initial DoA library was built, the modeler was evaluated over four increasingly more complex stages of verification. In the final, most complex stage, new compounds not previously part of the initial DoA library were added and then compared by testing two different column dimensions, two different columns lengths, two different mobile phases, two different stationary phases, three different gradients programs, and three different temperatures against modeled retention time values. Because the semi-empirical correction factor was developed using only the original library compounds, this stage assessed the viability of adding future compounds to existing libraries.

During software development, the acceptance criteria for retention time agreement between wet-lab and modeled values was set at +/- 15 seconds. This range was chosen because it represents a typical Multiple Reaction Monitoring (MRM) window. In the most complex portion of the verification, 704 retention time data points were collected in total for the 25 compounds used in the evaluation. Only 13 data points exceeded the +/- 15 second window, with no compounds missing acceptance criteria by more than five seconds, giving an overall pass rate of 98.2%.

An online chromatographic modeling tool was successfully developed that allows users to select columns and compounds for separation. A modeled chromatogram and instrument-ready conditions are automatically generated and can be further optimized by users.

Method Development; Liquid Chromatography; Drugs of Abuse

B167 The Drug Enforcement Administration's Basic Forensic Chemist Training Program Becomes the First Forensic Training Program Accredited by the Federal Law Enforcement Training Accreditation Board

Jessica M. Rasmussen, MS, United States Drug Enforcement Administration, Stafford, VA*

Learning Objectives: This poster will enable attendees to understand the requirements, process, and importance of becoming an accredited forensic science entry-level training program. It will outline the structure of Drug Enforcement Administration's (DEA's) Basic Forensic Chemist Training Program (BFCTP) as a model to better equip attendees to create or re-organize their respective training programs should accreditation be desired.

Impact Statement: This poster will impact the forensic science community by highlighting the importance of maintaining a comprehensive, structured training program. As the forensic science community faces increased scrutiny in the criminal justice system, it is of the utmost importance that the public maintains a high level of confidence in the competency, proficiency, and professionalism of forensic examiners. Achieving and maintaining accreditation demonstrates a training program's effectiveness in producing forensic examiners able to meet these standards and expectations of the criminal justice system.

Abstract Text: On May 9, 2024, the DEA BFCTP became the first forensic training program to be accredited by the Federal Law Enforcement Training Accreditation (FLETA) Board.[1] The centralized program is located at the DEA Training Academy in Quantico, VA. It is a rigorous 18-week program that trains incoming Basic Forensic Chemists (BFCs) on DEA policy and procedures; methods and techniques used in seized drug analysis; and quality management, law, ethics, and courtroom testimony. Additionally, elements of professionalism, such as demeanor, integrity, and judgement are evaluated.

The accreditation process includes applying and preparing for the assessment, an onsite inspection, and an interview panel at the Federal Law Enforcement Training Center (FLETC) in Glynco, GA. This process confirms that the program meets several standards and ensures it has sufficient organization and oversight for accreditation. Specifically, the program must maintain records on curriculum content, such as lesson plans, training materials, practical and written evaluations, and respective answer keys. Ethics training as it relates to the forensic science profession is also required. For each class, the roster, the inclusive course dates, the dates each lesson was taught, and the instructors that taught each lesson must be recorded.[2]

The DEA BFCTP uses a federal agency training software to store most of the documentation regarding training dates, instructors, and completed practical assessment rubrics. Formal lesson plans and test questions are maintained by the DEA Training Academy's Policy and Learning Development Section. Each lesson includes one or a combination of PowerPoint presentations, written classroom exercises, hands-on laboratory exercises, verbal assessments, laboratory practical skills assessments, and written exams.

In addition to program content, the following information must be maintained on each trainee: course prerequisites met by each trainee (degree requirements, medical clearances, etc.), evaluation and examination scores, waivers or reasonable accommodations granted, and transcripts documenting the successful completion of the course.[2] The training software used by the BFCTP collects and retains much of this information for each BFC, including their educational background and work experience and progress through the course.

Finally, the program must adhere to its organizational policies, such as equipment maintenance, student misconduct, and security of controlled substances, hazardous substances, practical lesson samples, classrooms, and training laboratories.[2] The BFCTP is inspected on a routine basis by the DEA's Office of Forensic Sciences to ensure these organizational requirements are being met.

The FLETA accreditation validates the high quality, standards, and professionalism of the BFCTP, ensuring that DEA forensic chemists are fully prepared to analyze complex seized drug evidence. It further establishes credibility to the program, its curriculum, and ultimately, its graduates as competent, professional forensic chemists.

Training; Accreditation; Drug Analysis

B168 The Development and Testing of a Novel Sorbent Material for Headspace Analysis With Application to Illicit Drugs

Sadie Olrogg, BS, Florida International University, Miami, FL; Lauryn DeGreeff, PhD, Florida International University, Miami, FL; Joongho Moon, PhD, Florida International University, Miami, FL*

Learning Objectives: The audience will learn about a novel method of Volatile Organic Compound (VOC) collection for use in drug analysis and the distinct VOCs present in illicit drugs such as xylazine and nitazenes.

Impact Statement: The results will show the novel sorbent material's ability to be used as a headspace sampling technique in comparison to Solid-Phase Microextraction (SPME) fibers for illicit drug sampling. This technique offers a cost-effective and more rugged approach to headspace sampling methods in the field.

Abstract Text: SPME is an extraction technique used with Gas Chromatography/Mass Spectroscopy (GC/MS) that uses a polymer-coated fused silica rod to extract compounds from the liquid or gaseous phases. This technique is highly versatile, with uses in many different fields such as environmental, pharmaceutical, toxicology, and forensics. For this research, VOCs from pharmaceutical-grade and seized drug samples are identified to better understand the headspace profile of illicit drugs for use in development of canine training aids. SPME fibers are available with different polymer chemistries and thus varying fiber affinities for application to many targets, matrices, and applications. The most common polymer for SPME fibers is Polydimethylsiloxane (PDMS). The polymer coating acts to adsorb VOCs in the vapor profile of a sample, prior to desorption and analysis. The main drawback to SPME is the fragility of the fiber and cost, making sampling in the field challenging.

As an alternative to the SPME fiber, a novel headspace sampling material that is both rugged and inexpensive was designed using a functionalized glass surface for use in seized drug detection. The glass surface was functionalized with various amino silanes to improve vapor collection. Silanes are often used in functionalizing GC columns and SPME fibers; amino silanes have been previously used for small molecule/ volatile capture and drug delivery.[1] Amino silanes have an advantage on PDMS as a chemical modifier; since it includes a polar amine group, it allows for a greater ability to adsorb polar compounds allowing for broad selectivity. These functionalized glass surfaces were tested for their efficacy using a case study of various illicit drug samples such as nitazenes and xylazine and compared to the headspace analysis using SPME fibers. This sampling method is comparable to the SPME fiber for collection of VOCs in the headspace of illicit drug samples and more cost effective. During analysis of the samples, several target VOCs were found, and the most abundant targets were focused for each drug. The targets were found with similar abundances in the SPME fiber as well as the functionalized glass surface, showing a comparable technique to SPME and were more cost effective.

B169 The Optimization of Fast Blue B Test for Cannabis Products

Ryan A. Smith, BS, Hofstra University, Swansea, MA; Ling Huang, PhD, Hofstra University, Hempstead, NY; Marie E. Lemay*, Hofstra University, Jamestown, New York*

Learning Objectives: After attending this presentation, attendees will understand the capabilities and shortcomings of the current Fast Blue B Test for cannabis products, and how to optimize the test by avoiding hazardous solvents and differentiate THC, CBD, and HHC using droplet Ultraviolet/Visible (UV/Vis) spectroscopy across multiple sample matrices such as plant material, oil, and gummy, with only 0.3-µL test solution. In addition to the optimization of the Fast Blue B Test, this presentation will demonstrate the capabilities of the Nanophotometer NP80's squeeze droplet design and the benefits of this setup over conventional UV/Vis spectrometers and other types of droplet spectrometers.

Impact Statement: The results of this experiment can have long-lasting benefits for law enforcement, harm reduction, and consumer safety as a quick and improved presumptive test can be utilized to differentiate cannabinoids in different designer formulations without the use of hazardous solvents. This research will also help to improve presumptive drug tests.

Abstract Text: The Fast Blue B test is a common colorimetric test used for the presumptive screening of cannabis products, which is commonly found in the form of a KN-S Nik Kit. It is composed of a color agent, a base, and the hazardous solvent trichloroethylene. This test would yield a dark red color change as a positive for the THC-containing samples and an orange color for CBD. The current test has its limitations as it was originally designed solely for a sample matrix which is plant material, but there has since been an emergence of designer cannabinoids such as HHC, THC-O, and THC-P found in various matrices such as oils and gummies.

In our investigation, the color change that is observed after cannabinoids react with Fast Blue B agent was quantified as an absorbance maximum wavelength using the Nanophotometer NP80 and UV/Vis spectroscopy as its squeeze droplet design prevented the evaporation of a small sample liquid droplet with more reliability than other droplet spectrometers. This allowed the analysis of the cannabinoid samples to only require 0.3µL, using a greener solvent than the chlorinated solvent used in the current Nik Kits.

To begin the test, approximately 0.05 grams of the Fast Blue B salt was dissolved in 10mL of solvent (either dimethylsulfoxide, DMSO, or deionized water which were found to be the best solvents). From here 100µL of the newly produced FBB reagent was mixed with 100µL 0.1 M NaOH and the cannabinoid-containing sample in a well plate and the color change was photographed and recorded. These cannabinoid samples ranged from marijuana leaf and hemp cigarettes to CBD oils to cannabinoid-containing gummies. Using only 0.3µL of each test solution from each well, it was discovered that THC consistently had an absorbance peak at 490nm, CBD consistently had an absorbance peak of 505nm, and HHC consistently had an absorbance of 495nm. These results provide evidence that the cannabinoid present in the samples of various forms can be differentiated using this optimized Fast Blue B test and UV/Vis spectroscopy.

To conclude, the end goal of being able to differentiate between cannabinoids across various sample matrices through their absorbance maximums using UVVis spectroscopy was achieved, with the added benefit of the test being quick to use and portable due to the Nanophotometer NP80's small size. In addition to the goal of the experiment being achieved, great strides in the field of public health have been made, as trichloroethylene has been shown to be unnecessary for the test to proceed, making the test safer to perform. Our improvements have also benefited law enforcement, as this presumptive test is minimally destructive since it required only 0.3µL of a sample to reliably produce results.

Cannabinoids; Color Tests; UV/Vis Spectroscopy

B170 The Detection and Quantitation of Xylazine, Medetomidine, and Detomidine as Adulterants to Heroin or Illicitly Manufactured Fentanyl Using NanoLC With Various Mass Spectrometers

Mehdi Moini, PhD, George Mason University, Manassas, VA; Brian Eckenrode, PhD, George Mason University, Aldie, VA*

Learning Objectives: After attending this presentation, attendees will understand the dangerous role of xylazine, medetomidine, and detomidine as adulterants to heroin or illicitly manufactured fentanyl to produce a mixture which in the United States is known as FAAX, "tranq," or "tranq dope," on the individuals using it, and the importance of the quantitative analysis of this mixture with nano Liquid Chromatography in conjunction with Mass Spectrometry (nLC/MS).[1]

Impact Statement: This presentation will impact the forensic science community by discussing the key advantages of nLC/MS in the quantitative analysis of xylazine, its derivatives as adulterants to heroin or illicitly manufactured fentanyl, and alert the forensic community concerning the increased prevalence of illicit drug overdose deaths involving xylazine.[2]

Abstract Text: In November 2022, the United States Food and Drug Administration (FDA) issued an alert concerning the increased prevalence ofxylazine and medetomidine in illicit drug overdose deaths involving xylazine.[3] As such, quantifying these compounds using LC/MS has become an important task. NLC/MS, with its high sensitivity, high separation efficiency, economy of sample size, solvent and gas consumption, and virtually no liquid waste production has become the instrument of choice in sample-limited applications such as proteomics. However, the application of nLC/MS to the forensic analysis of illicit drugs remains elusive. This report will present a case study in the analysis of illicit drugs containing xylazine and its derivatives as a practical application of nLC/MS to seized drugs. It is recommended that analysts become familiar with the principles of nLC/MS in seized drugs containing xylazine, medetomidine, and detomidine.

In this study, an nLC was used in conjunction with three mass spectrometers: (1) a Linear Trap Quadrupole (LTQ), (2) an orbitrap, and (3) a triple-quadrupole. These systems were used for the analysis of complex illicit drugs that included xylazine, heroin, fentanyl, and their derivatives. Analytical figures of merit, including detection limit and dynamic range, were studied and compared. Under the conditions used here, baseline resolved peaks were obtained for almost all compounds. Preliminary results indicated detection limits in the pg/uL range under positive ionization mode. Experiments were also conducted under negative ionization mode; however, the detection sensitivity for most compounds was lower than positive mode. Overall, Oribtrap, with its high resolution and high mass accuracy, provided the best performance since there were many overlapping peaks with the same nominal mass but different accurate mass, and a high resolution, high mass accuracy mass spectrometer was needed to identify the drug of interest with better quantitation.

Phytocannabinoids show a strong memory effect on our C18 column. Once a sample with a concentration above one ng/uL was used, removing the background peaks related to these compounds was difficult. Because of this, we could not find a thorough detection limit since our background was about ½ of the lowest (50 picograms on column injection) levels. Also, we noticed that xylazine ionization efficiency was much lower than most other compounds, such as phytocannabinoids. It is important to note that these comparisons were performed under full-scan mode for all instruments. The results obtained under full-scan mode will be compared with those from multiple ion monitoring modes.

B171 The Development of an LC/MS/MS Method for the Identification of Psilocybin and Psilocin From Seized Drugs

Alexia Cassman, BS, Sam Houston State University, Huntsville, TX; Kristen J. Head, MS, Harris County Institute of Forensic Sciences Houston, TX*

Learning Objectives: After attending this presentation, attendees will have learned about the benefits of incorporating Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) instrumentation into seized drug analysis for the detection of challenging substances such as psilocybin and psilocin. The audience will learn about the necessary method optimization required to chromatographically separate and identify psilocybin and psilocin using Multiple Reaction Monitoring (MRM).

Impact Statement: This presentation will impact the forensic science community by serving as a model for the development of LC/MS/MS methods for the analysis of difficult seized drug casework samples. Unlike traditional GC/MS methods, LC/MS/MS methods can accommodate non-volatile, thermally unstable, and otherwise hard-to-detect analytes using GC/MS instrumentation. Informing the seized drug community about the capabilities of LC/MS/MS instrumentation and providing an example of a developed method for the identification of psilocybin and psilocin will assist with the adoption of LC/MS/MS instrumentation for the analysis of seized drug evidence.

Abstract Text: The analysis of suspected mushroom samples or samples suspected of containing psilocybin (i.e., edibles) requires derivatization before analysis using traditional GC/MS instrumentation due to the elevated temperature of the inlet and oven. In comparison, LC/MS/MS instrumentation eliminates the need to derivatize thermally unstable compounds, making this technique more suitable for suspected mushrooms or edibles suspected of containing psilocybin. In addition, LC/MS/MS instrumentation is more compatible with edible matrices. The central hypothesis of this study is that an LC/MS/MS method can be developed to separate and identify psilocybin and psilocin for application to seized drug casework samples including suspected mushrooms or edible samples.

An Agilent 1200 LC coupled to a Sciex QTRAP ABI 3200 mass spectrometer using Electrospray Ionization (ESI) and MRM was utilized for the analysis of psilocybin and psilocin. An Ascentis Express biphenyl column and an Ascentis Express biphenyl guard column were chosen for analysis due to the high polarity of both analytes. Two MRM transitions were optimized for each analyte as follows: psilocybin m/z 285.4/240.1 and m/z 285.4/58.1, and psilocin m/z 205.2/58.1, m/z 205.2/160.1. The optimized collision energy for psilocybin was determined to be 23V and psilocybin was 25V. A gradient elution was used with 0.1% formic acid in water and 0.1% formic acid in acetonitrile as the mobile phases as previously demonstrated by Goff et al.[1] The gradient starts at 6% B from 0-1 minutes and is increased to 25% B from 1 minute to 3 minutes, increased to 95% from 3.0 to 3.1 minutes, held at 95% until 3.2 minutes. From 3.2 to 3.3 minutes, B is decreased to 6% B and held until 4.5 minutes, when the method runs to completion.

Using the developed method, psilocybin and psilocin had retention times of 1.08min and 1.73min, respectively. The optimized MRM transitions led to consistent signal for samples analyzed as low as 25ng/mL of psilocybin and 2.5ng/mL of psilocin. Performance characteristics of the method were assessed consistent with the Scientific Working Group for the Analysis of Seized Drugs (SWGDRUG) recommendations.[2] Baseline separation, acceptable chromatographic peak shape, signal-to-noise ratio, and ion ratios were assessed across analyses of each analyte and their corresponding internal standard to statistically assess significant differences in retention time and ion ratios.

The selectivity of this method was tested by using ten compounds related to casework samples or compounds similar in structure to psilocybin and psilocin. Three replicates of each compound were diluted to 100ng/mL and analyzed. The only potential interference observed was 4-acetoxy-DMT, which had the same retention time as psilocin, but did not produce any signal for psilocybin. Matrix effects were tested by running 20 samples of blank matrices mimicking edible matrices. These samples were extracted using HCIFS Drug Chemistry protocol and then sampled for the LC/MS/MS method to confirm the absence of analytical signal for psilocybin and psilocin. Selectivity was also tested by running five replicates of each analyte and internal standard ten times total to confirm no signal was observed from any of the other analytes or internal standard. The LOD was determined through creation of five calibrators for each analyte ranging from 50ng/mL to 1ng/mL. Each calibrator was analyzed three times across three days and monitored for acceptance criteria. The determined Limit Of Detection (LOD) for psilocybin was 25ng/mL. The LOD of psilocin was determined to be 2.5ng/mL. Ion suppression was studied by running the same ten compounds as mentioned above in mixture with psilocybin and psilocin, with their corresponding internal standards, at their LOD.

In conclusion, a method for the separation and detection of psilocin and psilocybin has been developed and produced qualitative results.

Liquid Chromatography; Method Development; Seized Drugs

B172 DSI-GC/MS Analysis of Designer Cannabis Gummies

Hannah LaVena, Hofstra University, Barrington, RI; Kevin Bisceglia, PhD, Hofstra University, Hempstead, NY; Ling Huang, PhD, Hofstra University, Hempstead, NY*

Learning Objectives: After attending this presentation, participants will better understand the operational principles of Direct Sample Introduction (DSI) Gas Chromatograph/Mass Spectrometry (GC/MS) and how it can be applied to the analysis of designer cannabis gummies.

Impact Statement: This presentation will impact the forensic science community by demonstrating the utility of DSI-GC/MS as an effective and efficient tool to differentiate, identify, and quantify cannabinoids and their isomers with minimal sample preparation, and it can identify inactive components within the sample matrix, allowing for the linkage of samples to specific manufacturers or distributors.

Abstract Text: After attending this presentation, participants will better understand the operational principles of DIS-GC/MS and how it can be applied to the analysis of designer cannabis gummies.

This presentation will impact the forensic science community by demonstrating the utility of DIS-GC/MS as an effective and efficient tool to differentiate, identify, and quantify cannabinoids and their isomers with minimal sample preparation, and it can identify inactive components within the sample matrix, allowing for the linkage of samples to specific manufacturers or distributors.

DIS-GC/MS has the ability to separate and detect target analytes in the presence of a complex, viscous, and often "dirty" sample matrix. It also allows for a smaller sample size to be analyzed and the elucidation of the sample matrix composition. It employs a Programmable-Temperature Vaporization (PTV) injector in combination with a ChromatoProbe accessory, in which a solid or liquid sample in a disposable glass vial can be heated to create vapor or aerosol prior to GC separation and MS detection.

Designer cannabis gummies can be found in various forms and configurations (e.g., hard, soft, cube-shaped, or bear-shaped). Additionally, they can be deliberately enhanced by distributors by combining currently available strains in order to generate a product that is both higher in quality and potency, containing a vast array of cannabinoids such as delta-8 THC, CBD, THC-A, and HHC. These products are then sold through private sellers, online retailers, and delivery services, often maintaining a low profile to avoid attention from law enforcement.

In our investigation, gummies were cut into smaller pieces (8 to 16), dissolved in solvent, and treated with manual agitation prior to analysis. Each GC run was completed in approximately 15 minutes, and the resulting mass spectra contained m/z signatures characteristic to cannabis-containing compounds.

Once identified, each cannabis-containing compound was quantified utilizing a CBD external standard calibration curve, resulting in a CBD range of 2.9%-76.8%. With library searches, additional components such as food dyes and sucrose were also detected. Additionally, the small sample volume (around 1–2µL) allows for repetitive sample analysis and additional testing.

The complexities and irregularities contained within these products pose serious threats to consumers. As there is only partial regulation by states within the cannabis industry and no systemic federal regulation on the contents of these designer products, users do not always know exactly what they are consuming.

After consumption, the delayed onset of the active cannabinoids also allows the potential for inadvertent overconsumption and extreme side effects, including psychotic episodes, impaired motor ability, and paranoia. Children and adolescents were reportedly the victims of these designer cannabis products with poor quality control and unknown pharmacology.

The DIS-GC/MS method allows for the rapid analysis and identification of cannabinoids in designer products with minimal sample preparation and identification in real time of designer cannabinoids and other components. Cannabinoids not listed as ingredients were identified, indicating this method can be used for quality assurance and the identification of contaminants in samples, thus informing consumers of the actual components of these popular designer gummies.

Further improvement of the scope and accuracy of designer gummy analysis can result from the evaluation of sugar, oil, and flavor matrix components, taking into account the unique and custom formulations across products as well as their manufacturers and suppliers. DIS-GC/MS is presented as an analytical technique that uses temperature programming, rapid analysis times, and smaller sample sizes as an adjunct to the investigation of seized designer cannabis products.

This report will present a thorough analysis of designer cannabis gummies utilizing DIS-GC/MS.

Cannabinoids; Gas Chromatography/Mass Spectrometry (GC/MS); Direct Sample Introduction (DSI)

B173 GC/VIR Technology in Seized Drug Analysis

Sherri L. Tupik, BS, Drug Enforcement Administration/Department of Justice, Dulles, VA*

Learning Objectives: The poster will show the power of Gas Chromatography/Vapor Phase Infrared Spectroscopy (GC/VIR) in identification and differentiation of nitazene compounds in seized drug analyses.

Impact Statement: The use of GC/VIR as an alternative technology in seized drug analysis combats challenges in identification of chemically and structurally similar substances when using traditional instrumental techniques such as Gas Chromatography/Mass Spectrometry (GC/MS).

Abstract Text: The ongoing emergence of Novel Psychoactive Substances (NPS), synthetic opioids, nitazenes, xylazine, and analog compounds creates challenges in identification of chemically and structurally similar substances using traditional instrumental techniques such as GC/MS. Often in forensic samples, analogs or isomers are present and possess similar chemical and physical properties. Multi-component mixtures are also a challenge. GC retention times can overlap, be difficult to differentiate, and are limited by the separation capabilities of the instrumentation. GC/MS fragmentation patterns can be very similar.

This has led to the introduction and use of alternative technologies in seized drug analysis. GC/VIR is a separatory and confirmatory technology capable of distinguishing the smallest of chemical structure subtleties in a compound enabling identification of drug substances within specific chemical classifications. GC/VIR is capable of chromatographically separating a mixture of compounds and obtaining singular infrared spectra as each compound elutes from a capillary column. GC/VIR can distinguish between different ring and side chain regioisomers, substituted aromatics, functional groups, and analogs. Confirmatory VIR spectroscopy can distinguish differences in spectra based on the arrangement of substituents in a molecule and provides identification with exclusion of all other isomers. GC/VIR use in forensic laboratories eliminates the need to purchase costly reference materials of all possible isomers to use for identification. There is ease in sample preparation, small amount of sample needed, and ability to resolve compounds of interest away from complex matrices. Using the data analysis software, spectra can be overlaid or stacked assisting in identification of specific analytes in structurally similar compounds.

The increased presence of synthetic opioids, specifically the nitazene compounds, in seized drug evidence has enabled GC/VIR to be a valuable tool in identification and analysis of such compounds. This poster shows the power of GC/VIR in identifying and differentiating nitazene compounds.

Chromatography; Spectroscopy; Forensic Science

B174 Inconvenient Truths in the Friction Ridge Discipline

Alice White, BS, Evolve Forensics, Partlow, VA*

WITHDRAWN

B175 The Development and Optimization of a Method for the Quantitation of Seized Drugs Using Rapid Gas Chromatography/Mass Spectrometry

Marissa Ho, BS, The George Washington University, Washington, DC; Briana A. Capistran, PhD, National Institute of Standards and Technology, Gaithersburg, MD; Edward Sisco, PhD, National Institute of Standards and Technology, Gaithersburg, MD; Ira S. Lurie, PhD, The George Washington University, Washington, DC*

Learning Objectives: After attending this presentation, attendees will be able to understand a newly developed method for the quantitation of seized drugs using rapid Gas Chromatography/Mass Spectrometry (GC/MS). In addition, attendees will also be informed on the use of Selected Ion Monitoring (SIM) with rapid GC/MS technology.

Impact Statement: The presentation will have an impact on the forensic science community by providing insight into the use of rapid GC/MS for quantitation of seized drugs. The method presented will demonstrate how rapid GC/MS can be used to reduce overall analysis times for forensic drug samples and ultimately help in decreasing the backlog of seized drug samples.

Abstract Text: With the increasing prevalence of seized drug mixtures in the United States in addition to the growing backlog of forensic seized drug samples, leveraging highly sensitive and selective screening techniques can be a useful complement to traditional confirmatory techniques. Rapid GC/MS has previously been demonstrated as a successful screening technique for seized drugs, providing chromatographic separation in under two minutes with limits of detection comparable to traditional GC/MS methods (e.g., low µg/mL range). Previous work focused on validating an analytical method for representative drug classes, such as opiates/opioids and synthetic cathinones.[1] From these results, rapid GC/MS has been shown to be a viable preliminary screening method to current GC/MS methods in situations where fast analysis is required.

Another recent concern in the forensic drug landscape is the need for quantitation of seized drugs. The implementation of the 2018 Farm Bill, which requires quantitation of Tetrahydrocannabinol (THC) in cannabis, has set the precedent for the imminent possibility of required quantitation of other seized drugs. In anticipation of potential legislation, it is important to begin researching new methods for quantitation now. Using rapid GC/MS for initial quantitation would provide forensic analysts with an understanding of the amount of a drug present during the preliminary screening stage, therefore allowing them to better determine which confirmatory method to use for further analysis. This project aims to explore the quantitative capabilities of rapid GC/MS for seized drugs.

In this study, a quantitative rapid GC/MS method was developed for a 14-compound test mixture consisting of seized drugs, adulterants, and diluents. The method was optimized for maximum separation, applying deconvolution to identify coeluting compounds. The use of SIM for rapid GC/MS analysis was studied for the first time in comparison with full scan MS data in order to determine which data collection method resulted in the most repeatable peak areas. Investigations into a suitable internal standard for quantitation as well as a determination of the best method for incorporation of the internal standard were also completed. Three methods for incorporation were tested: incorporation into the calibration curve solution (Method 1), external addition to the calibration curve solution (Method 2), and reconstitution of the calibration curve solution in solvent spiked with the internal standard (Method 3). The method was validated by determining the concentrations of compounds with known amounts using calibration curves. Lastly, mock and adjudicated case samples were analyzed to determine the real-world applicability of the method in a practical environment.

The developed method had a final run time of 1.63 minutes (97.8 seconds) and resulted in maximum separation for all compounds in the mixture. SIM was utilized to improve specificity and eliminate background noise, resulting in an overall decrease in variation for normalized peak areas. Ethylparaben was selected as the internal standard due to its symmetrical, narrow peak shape and early elution time. Preliminary results demonstrate the highest degree of calibration curve linearity using Method 1 for the incorporation of the internal standard, which resulted in coefficients of determination (R2) for single analytes as high as 0.9998. Initial quantitation results indicate acceptable performance of the calibration curve and internal standard incorporation method. For example, a known 20µg/mL heroin solution was determined to contain 14µg/mL ± 1 µg/mL heroin using the corresponding calibration curve, which is adequate for obtaining a good estimate of purity to satisfy sample analysis requirements. Overall, this method demonstrates a rapid workflow allowing for semi-quantitation of seized drugs and can potentially be utilized in forensic laboratories in order to reduce the backlog, decrease analysis times for seized drug samples, and provide fast feedback to law enforcement.

B177 A Needle in a Haystack: Are Those "Rare" Minutiae in Palms Really as Uncommon as You Think?

Heidi Eldridge, PhD, The George Washington University, Washington, DC*

WITHDRAWN

B178 The Proliferation of Nitazenes in the United States Drug Market: Examining Powders and Counterfeit Tablets

Mia Borrelli, MS, Center for Forensic Science Research and Education, Horsham, PA; Sarah A. Shuda, MS, National Institute of Standards and Technology, Horsham, PA; Barry K. Logan, PhD, Center for Forensic Science Research and Education, Horsham, PA; Amanda L.A Mohr, MS, Center for Forensic Science Research and Education, Horsham, PA; Thom Browne, Jr., MA, Colombo Plan, Huachuca City, AZ*

Learning Objectives: After attending this presentation, attendees will be able to describe the range of benzimadazoles ("nitazenes"), potent novel synthetics, in contraband powders and counterfeit pills.

Impact Statement: This presentation will impact the forensic science community by raising awareness of the presence of highly potent Novel Synthetic Opioids (NSOs) in the United States drug supply, allowing forensic chemists to identify these in their casework, especially counterfeit pills.

Abstract Text: A class of benzimidazole opioid agonists, the "nitazenes", are non-fentanyl synthetic opioids that were discovered by a Swiss drug company in the 1950s. They were known to activate the mu opioid receptor, producing opioid-like effects, but were never approved for use due to their high potency and low therapeutic index.

Nitazenes were identified in the United States drug supply both on their own as novel psychoactive substances and combined with illicitly manufactured fentanyl. These combinations are especially dangerous to People Who Use Drugs (PWUD) and have increased overdose rates throughout the United States. In 2021, the Drug Enforcement Administration enacted emergency scheduling to control a subset of the known nitazene compounds; however, other analogs have emerged on the illicit market. This makes testing difficult because new variations manufactured in clandestine labs continue to enter the drug supply. In addition to analytical challenges associated with identifying the drugs when they first appear, these drugs pose a public health challenge as the effects of nitazenes in combination with other drugs can be extremely detrimental to PWUD. Comprehensive testing of seized materials is necessary for laboratories to be able to track the emergence of nitazenes and analogs, as this knowledge will enhance harm reduction strategies and ultimately impact the treatment and outcomes of acutely intoxicated patients.

Illicit powders (n=3) and pills (n=60), collected during November and December 2023 were received at the Center for Forensic Science Research and Education (CFSRE) in April 2024. Both tablet types were collected on the same date. Powder Types 2 and 3 were collected on the same date, and Powder Type 1 was collected on a different date. Both types of tablets were round, green tablets monogrammed "OC 80" meant to resemble pharmaceutical 80mg oxycodone tablets but were different in appearance to pharmaceutical "OC 80" tablets. The tablets were assigned to two separate groupings based on differing characteristics. All powders and 30 of the tablets underwent comprehensive drug testing. The samples were analyzed using a workflow that included microscopic imaging of tablets using the MiScope Megapixel MP3, color measurement, and qualitative analysis of drugs, adulterants, precursors and reaction byproducts using Gas Chromatography/Mass Spectrometry (GC/MS) and Liquid Chromatography/quadrupole Time-Of-Flight/Mass Spectrometry (LC/qTOF/MS). Quantitative estimates were made by measuring relative peak areas to most intense peak (relative parts). Nitazenes were identified in all samples tested (n=33). The main component in the tablets was metonitazene. Tablet Type 2 had three nitazenes present in addition to ketamine related compounds, and synthetic cathinones. The three powders had different nitazenes as the largest peak as outlined in Table 1.

Table 1. Drugs Identified in powder and tablet exhibits.

Material	Date of Seizure	Drugs Identified (Relative Parts Calculation, Main Component = 1p)
Tablet Type 1 (n=15)	11/2023	N-desethyl Metonitazene (trace) Metonitazene (1 p)
Tablet Type 2 (n=15)	11/2023	Phenyl-2-propananone (P2P) (trace) Amphetamine (trace) O-PCE (trace) 2-fluoro-2-oxo-PCE (0.56 p) Pentylone (0.02 p) N,N-Dimethylpentylone (0.26 p) N-desethyl Metonitazene (0.04 p) Metonitazene (1 p) N-pyrrolidino Protonitazene (trace)
Powder Type 1 (n=1)	12/2023	Protonitazene (1 p)
Powder Type 2 (n=1	12/2023	N-pyrrolidino Metonitazene (1 p)
Powder Type 3 (n=1)	12/2023	N-pyrrolidino Protonitazene (1 p)

The continued emergence of nitazenes in the illicit drug supply is concerning due to their relatively high potency. Studies evaluating the potency of nitazenes suggest that metonitazene, N-desethyl-etonitazene, and protonitazene are 1.5-10X more potent relative to fentanyl.[1] Furthermore, in Tablet Type 2, the combination of several NPS (stimulants, hallucinogens, and opioids) presents additional concerns about the potential for adverse polydrug toxicity for PWUD. These cases also reinforce the need for crime laboratories to have updated scopes that include new and emerging substances.

Nitazenes; Drug Chemistry; Surveillance

B179 A Discovery of False Positive Illicit Drug Identification With Portable Surface-Enhanced Raman Spectroscopy (SERS)

Ella M. Galvan, University of New Haven, Albany, OR; Desmond A. Brown, University of New Haven, Bridgeport, CT; Brooke W. Kammrath, PhD, University of New Haven, West Haven, CT; Pauline E. Leary, PhD, Noble, Stanfordville, NY; Richard A. Crocombe, PhD, Crocombe Spectroscopic Consulting, Winchester, MA; Don Ostrowski, APM, Noble, Cape Coral, FL*

Learning Objectives: The goal of this presentation is to share the findings of a reproducible false-positive identification of cocaine from a mixture of fentanyl and acetaminophen when using a portable Raman spectrometer equipped with a 785nm laser paired with a SERS field test kit.

Impact Statement: This presentation will impact the forensic science community by sharing the first reproducible false positive identifications of an illicit drug using portable SERS.

Abstract Text: For several decades, the standard procedure for testing suspected controlled substances in the field involved the use of color-based or colorimetric presumptive tests. Although color tests are quite sensitive with low limits of detection, they have several recorded limitations, including a lack of specificity which means they suffer from false positives. A recent publication by the Quattrone Institute reported:

"Each year approximately 773,000 drug-related arrests involve the use of presumptive tests. Although the true error rate of these tests remains unknown, estimates based on the imperfect data that are available suggest that around 30,000 arrests each year involve people who do not possess illegal substances but who are nonetheless falsely implicated by color-based presumptive tests."[1]

The availability of robust portable spectrometers has great promise for addressing some of the limitations of field color tests. The majority of instrumental methods used in the forensic analysis of illicit drugs in the laboratory have field portable versions, which includes the Scientific Working Group for the Analysis of Seized Drugs (SWGDRUG) and the American Society for Testing and Materials (ASTM) identified confirmatory methods of Raman spectroscopy, infrared spectroscopy, and mass spectrometry.[2,3] However, portable spectrometers may have meaningful differences in their performance characteristics when compared to their benchtop counterparts, which must be evaluated and understood prior to deployment of these instruments in the forensic field.

The major advantages of Raman spectroscopy for the identification of illicit drugs are its rapid, non-destructive, non-contact (e.g., through glass and plastic containers) analysis, which generates a reviewable record (i.e., a spectrum) with very high discriminating capabilities. When paired with SERS, a technique which enhances Raman scattering through molecular interactions with rough metal surfaces or nanostructures, there can be a meaningful improvement in the limits of detection for illicit drugs to include trace-level detection for analytes of interest like fentanyl, heroin and cocaine.

During the course of evaluating a commercially available hand-held narcotics analyzer (a Raman spectrometer equipped with a 785-nm laser) in SERS mode for the detection and identification of low dose fentanyl mixtures, a false positive for cocaine was identified when the fentanyl was dispersed in an acetaminophen matrix at low concentrations. Other matrices evaluated in the same manner did not generate this false identification. The SERS kit uses a gold nanoparticle-infused substrate in a polycarbonate holder and a solvent for dissolving a sample of interest. It is critical for police officers and other first responders who are using this commercially available technique for the field identification of suspected controlled substances to be aware of this reproducible false positive identification of cocaine and its potentially hazardous repercussions. This resulting false positive for cocaine and absence of identification for fentanyl will inevitably complicate subsequent laboratory testing, has implications for safety, and may have important legal ramifications

Raman Spectroscopy; SERS; Illicit Drugs

B180 Illicit Drug Analysis in the Field With a Portable Instrument "Toolkit"

Brooke W. Kammrath, PhD, University of New Haven, West Haven, CT; Desmond A. Brown, University of New Haven, Bridgeport, CT; Samuel R. Friday, BS, University of New Haven, West Haven, CT; Drew M. Kuroda, BS, University of New Haven, New Haven, CT; Ella M. Galvan, University of New Haven, Albany, OR; Alexander Klein, BS, Henr, Westhaven, CT; Pauline E. Leary, PhD, Noble, Stanfordville, NY; Jon Naples, CT State Police, Meriden, CT; Richard A. Crocombe, PhD, Crocombe Spectroscopic Consulting, Winchester, MA; Jessica Persechino, MA, University of New Haven, Torrington, CT; Jessica R. Behn, BS, University of New Haven, Woodbridge, CT; Debbie Fuller, Refana Inc, Devon, United Kingdom; Isabelle Radgen-Morvant, MS, NIRLAB, Lausanne, Switzerland;*

Learning Objectives: After attending this presentation, attendees will learn the capabilities and limitations of a portable instrument "toolkit" for the field detection and identification of illicit drugs.

Impact Statement: This presentation will impact the forensic science community by directly comparing seven different portable technologies for the detection and identification of seized illicit drugs and providing recommendations for a "toolkit" approach for their successful implementation in the field.

Abstract Text: Portable instruments offer numerous advantages for combatting the illicit drug market in the field. Portable spectrometers have detection, identification, and analysis capabilities that provide valuable investigative and adjudicative information about a sample that can be used on its own or to inform further evidence selection, preservation, and collection. The real-time data provided by portable instruments, which have the ability to identify both bulk and trace components of a mixture, can be of particular value to first responders given the modern dynamic illicit drug landscape that contains highly dangerous and New Psychoactive Substances (NPS), including fentanyl-related substances. Still, given the diversity of commercially available portable instruments for illicit drug identification, there remains questions regarding which portable technologies are best and what are the best practices for their implementation in the field.

This research evaluated seven different field portable methods for the analysis of 38 adjudicated seized illicit drug samples. The 38 samples represented a range of illicit drug products, including, but not limited to, cocaine, heroin, methamphetamine, MDMA, PCP, and NPSs. The technologies included in this study included: (1) field color tests, (2) a portable Fourier Transform Infrared (FTIR) spectrometer, (3) a hand-held Raman spectrometer equipped with a 1,064nm laser, (4) a hand-held Near Infrared (NIR) spectrometer; (5) a portable Gas Chromatograph/Mass Spectrometer (GC/MS) equipped with a quadrupole mass analyzer, (6) a portable GC/MS equipped with an ion-trap mass analyzer, and (7) a portable High Pressure Mass Spectrometer (HPMS). Samples were also analyzed using traditional laboratory benchtop GC/MS and FTIR instrumentation for comparison. In agreement with the work by Lanzarotta et al., this research concluded that a toolbox or "toolkit" approach is best when working with field portable instrumentation.[1] Lanzarotta et al. proposed using a three-instrument toolkit for detection and identification of the Active Pharmaceutical Ingredients (APIs) in illicit medications and foreign unapproved pharmaceutical products. With their three-instrument toolkit, consisting of a portable FTIR spectrometer, a hand-held Raman spectrometer equipped with a 1,064nm laser, and a portable Direct Analysis in Real-Time Mass Spectrometer (DART-MS), 81 of 82 (92.0 %) of the APIs were detected by at least one technique. The current research demonstrated the reliable detection and identification of both bulk and trace components of seized illicit drugs when at least two field deployable devices are employed. Since multiple instruments can be used in combination to achieve these results, a "toolkit" approach is recommended, which provides flexibility for use by agencies with a range of resources and is consistent with recommendations by the Scientific Working Group for the Analysis of Seized Drugs (SWGDRUG) and *ASTM E2329: Standard Practice for the Identification of Seized Drugs*.[2,3]

Drug Analysis; Scene Investigation; Seized Drugs

B181 Optimizing Extraction Methods for Cannabinoid Quantitation in Cannabis Gummies: A Comparative Study Using LC-PDA

Ya-Chih Cheng, PhD, Sam Houston State University, Huntsville, TX; Walter B. Wilson, PhD, National Institute of Standards and Technology, Gaithersburg, MD*

Learning Objectives: Attendees will gain insight into the challenges and solutions associated with extracting and quantifying cannabinoids, specifically delta-9-Tetrahydrocannabinol (Δ9-THC) and Cannabidiol (CBD), in cannabis gummies.

Impact Statement: This presentation impacts the forensic community by providing a thorough evaluation of diverse extraction methods for cannabis gummy products for cannabinoid quantification. By optimized protocols compatible with Liquid Chromatography-Photodiode Array (LC-PDA), this study supports forensic laboratories in adapting to the evolving legal requirements and improving their analytical capabilities, thereby enhancing the reliability of forensic evidence related to hemp and cannabis products.

Abstract Text: The Agriculture Improvement Act of 2018 (Farm Bill) legalized hemp plants containing 0.3% or less Δ9-THC as hemp, removing them from the list of controlled substances. The change of legal landscape necessitates that forensic laboratories shift from just qualitative to quantitative cannabinoid analysis. Various methods have been proposed for this purpose, but the diverse range of sample matrices in gummy products complicates the extraction of the regulated substance Δ9-THC. Gas Chromatography/Mass Spectrometry (GC/MS) and LC-PDA are widely used techniques for cannabis analysis. However, the extraction process for GC/MS is typically lengthy and involves multiple steps to prevent matrix-related issues like syringe clogging or column damage. LC-PDA, on the other hand, may be more compatible with simpler extraction protocols, which are preferable in forensic laboratories.

This study offers a comprehensive comparison of various extraction methods and the factors influencing cannabinoid extraction for the efficient quantitation of Δ9-THC and CBD in gummies using liquid chromatography coupled with a LC-PDA. More than ten extraction methods were evaluated, incorporating various solvent combinations such as two types of basic water (NaOH or NH4OH), acetonitrile, basic acetonitrile, methanol, basic methanol, and hexane. Additionally, enzymatic methods (lipase and amylase) and the use of QuEChERS and lipid filtration were also compared. The study also examined the effects of incubation temperature and duration on extraction efficiency. A simple combination of water and basic acetonitrile provided optimal recovery. Although lipid filter and QuEChERS might slightly increase extraction efficiency, the effects were not significant. The incubation temperature and duration also impacted Δ9-THC and CBD quantitation.

Gummies, being very sticky and hard to grind mechanically, often require cryo-milling, which is effective but limits sample throughput and is not accessible to most crime labs. Sampling a single gummy may result in biased results due to potential variations in cannabinoid content, especially in homemade THC gummies. Therefore, the sampling procedure was assessed to address sample homogenization issues. Overall, this study provides insights into optimizing extraction protocols for accurate cannabinoid quantitation in edible gummy products, meeting the needs of forensic laboratories, and ensuring compliance with regulatory standards.

Cannabinoids; Gummies; Extraction

B182 The Presumptive Identification of Psilocybin and Psilocyn in Mushrooms and Food Products Using Matrix-Assisted Ionization Vacuum (MAIV) and Time-of-Flight/Mass Spectrometry (TOF/MS)

Maci D. Koester, BS, Virginia Department of Forensic Science, Richmond, VA; Deborah Brimijoin, MS, Virginia Department of Forensic Science, Richmond, VA; Jennifer Clary, MS, Virginia Department of Forensic Science, Richmond, VA*

Learning Objectives: The information in this presentation discusses the challenges of analyzing psilocybin and psilocyn in mushrooms and food products. Attendees will learn how MAIV can be used with TOF/MS to screen for both compounds under conditions that will not initiate conversion.

Impact Statement: This presentation will impact the forensic science community by providing a fast and efficient instrumental screening technique for both psilocybin and psilocyn in mushroom material as well as edible products.

Abstract Text: Psilocybin is readily dephosphorylated to psilocyn under various conditions, such as heating and hydrolysis in solution.[1,2] Thus, the identification of psilocybin can be difficult and time-consuming. Further complicating this is the complex matrix of edible products available today that contain one or both hallucinogenic compounds. Psilocybin identification may be accomplished by Liquid Chromatography/Mass spectrometry (LC/MS) or Gas Chromatography/Mass Spectrometry (GC/MS) with derivatization. If these methods are not available, determining whether psilocybin was present before analysis or if it was converted to psilocyn during analysis is difficult.

The Virginia Department of Forensic Science (VA-DFS) uses Direct Analysis in Real Time-Time of Flight Mass Spectrometry (DART-TOF/MS) for presumptive screening of general unknown samples and for confirmation of pharmaceutical preparations.[3-5] The DART ionization source is paired with a TOF/MS to measure each ion's exact mass.[4] Function switching mode on the DART-TOF utilizes an in-source collision induced dissociation (CID) to switch the orifice 1 voltages between 20, 30, 60, and 90V.[6,7] Under these conditions psilocybin is converted into psilocyn. This study focuses on the use of 3-nitrobenzonitrile (3-NBN) crystals instead of the DART ionization source to facilitate matrix assisted ionization vacuum (MAIV).[7-9] This matrix ionizes the sample while keeping the psilocybin intact.

Samples are prepared by a solvent extraction and combined with a 3-NBN solution. This is dried with air to create a crystallized 3-NBN:sample matrix. The DART is turned off to remove the instrumental ionization source. The crystallized 3-NBN:sample matrix is scraped from the test tube using a spatula which is then placed in front of orifice 1 of the TOF-MS. Various orifice 1 temperatures and 3-NBN solutions were evaluated for psilocybin and psilocyn ionization. In addition, the occurrence of dephosphorylation was evaluated. The ideal conditions were found to be 60˚C and a 3-NBN solution made with DI water:ACN with 0.1% formic acid, respectively. The developed method showed 77.8% rate of ionization for psilocybin and 2.8% rate of psilocybin to psilocyn conversion.

The 3-NBN is the ideal matrix to facilitate MAIV due to its low thermal energy requirement to produce ions from atmospheric pressure.[7] Further testing is required to fully optimize and streamline the Matrix-Assisted Ionization Vacuum-Time of Flight (MAIV-TOF)for psilocybin and psilocyn screening and to understand how 3-NBN is facilitating the ionization at low temperatures. This method has the potential to be applied to other compounds relevant to drug chemistry, especially those with thermal instability. The implementation of this screening method will provide verification of psilocybin and/or psilocyn's presence in food products prior to dephosphorylation during routine analysis.

B183 A Green Method for Seized Drug Analysis Using a Portable Liquid Chromatograph

Jayda R. Barber, BS, The George Washington University, Alexandria, VA; Ira S. Lurie, PhD, The George Washington University, Washington, DC*

Learning Objectives: After attending this presentation, attendees will understand how seized drug analysis may be performed using a portable Liquid Chromatograph (LC) employing dual capillaries with dual wavelength detection, and how it can provide a greener and relatively low-cost method for seized drug analysis.

Impact Statement: The use of a portable LC, as presented in this presentation, will impact the forensic science community by providing a green and relatively low-cost option for seized drug analysis, all the while likely adhering to the guidelines outlined by the Scientific Working Group for the Analysis of Seized Drugs (SWGDRUG).

Abstract Text: Like other chromatographic methods, the portable LC described in this presentation is amenable to mixtures in contrast to other portable instrumentation, such as Raman and Fourier transform infrared spectroscopy. The portable LC can either be kept in a laboratory setting or brought into the field. Unlike traditional, full-sized chromatographs, this relatively inexpensive, small-footprint LC only weighs 17.6 pounds, uses a fraction of the materials and solvents normally used, and generates considerably less waste. These features would be of interest to developing countries and jurisdictions with limited resources and present for these entities a possible low-cost alternative to gas chromatography Mass Spectrometry (MS) and LC/MS instrumentation. This study employed a 3µm, 0.15 × 100mm capillary column in series with a 3µm, 0.15 × 50mm biphenyl capillary column with dual on-column Ultraviolet Light Emitting Diode (UV LED) detection at either 235nm and 275nm or 255nm and 275nm using acetonitrile as the organic modifier and trifluoracetic acid as mobile phase additive. For representative compounds from different drug classes, including stimulants, depressants, opioids, opiates, hallucinogens, anabolic steroids, cannabinoids, synthetic cannabinoids, synthetic cathinones and phenethylamine analogs, UV LED detection at 255nm and 275nm was found to be more universal and was utilized for further investigation. Analytes of interest were identified based on relative retention times for both capillaries and UV absorbance ratios obtained from dual UV LED detection.1

The proposed methodology could satisfy SWGDRUG requirements which, in the absence of a category A method of analysis, allow for two category B methods and a category C method of analysis.[2] The use of dual capillaries with different stationary phases (C8 and phenyl) would exploit different chemical or physical properties of the analytes and thus qualify as two category B techniques. In addition, dual wavelength detection, which imparts selectivity through general or class information, would appear to qualify as a category C technique.

The LC instrumentation presented for seized drug analysis is applicable to both field and laboratory use, being lightweight, portable, green, and economical. The dual capillary on-column UV detection could satisfy SWGDRUG requirements, which would be particularly useful for developing countries.

Seized Drugs; Liquid Chromatography; Green Chemistry

B184 Drug Detection in Complex Materials Using Confocal Raman Microspectroscopy

Natasha Wheatley, MPA, Ada County Sheriff's Office, Boise, ID; Kenzie Ballinger, BS*, Boise State University, Boise, ID*

Learning Objectives: Attendees will review current difficulties associated with seized drug analysis, which includes analysis of counterfeit drugs. The application of Confocal Raman Microspectroscopy (CRM) in the forensic field is examined to address the current difficulties experienced with illicit drug detection.

Impact Statement: Law enforcement currently relies upon scientific techniques for illicit drug analysis, which have some challenges that hinder the detection of some drugs. This presentation will look at the use of CRM as a possible type of analytical technique that is not presently used widely in forensic analysis, which includes the detection of illicit drugs.

Abstract Text: Counterfeit drugs and food items are a global problem, and the World Health Organization estimates that roughly 10% of medical products in low- and middle-income countries are substandard or falsified.[1] Often, counterfeit drugs contain unknown substances that are difficult to detect without destroying the sample. Moreover, in 2023, over 80 million fentanyl-laced fake pills were seized in the United States, according to the Drug Enforcement Administration, making the analysis of counterfeit drugs an urgent topic.[2]

Here, we report on the use of CRM to identify drugs such as counterfeit pills. CRM is a powerful analytical tool that provides information about the molecular composition of various samples. CRM works by giving a microscopic image where scientists can pinpoint specific areas to measure the molecular structure of compounds. This is a useful tool to microscopically examine mixtures and chemically analyze the different components. It offers non-destructive analysis at the molecular scale that can be automated, making it valuable for counterfeit pills or other mixtures received for forensic analysis because it maintains the integrity of the evidence for future testing if needed. CRM also reduces the scientist's interaction with hazardous samples, such as fentanyl.

Our research, conducted in collaboration with the Ada County Forensic Lab, leverages CRM to address the detection challenges posed by complex matrices in counterfeit pills and food items. Our research improves the methodologies for detecting different mixtures of illicit drugs that are difficult to analyze using standard techniques. One of the most common methods in seized drug detection is sample extraction followed by analysis using Gas Chromatography/Mass Spectroscopy (GC/MS). Various drugs and matrices have shown to be challenging to detect the illicit substance using GC/MS, which leads to possible incorrect reporting of no controlled substance detected. By integrating CRM into routine forensic workflows, we enhance the capabilities of law enforcement agencies and forensic scientists. Our findings underscore the importance of innovative technologies in forensic science, contributing to more effective drug enforcement through a chemical analysis that has not been typically used in forensics.

WITHDRAWN

B186 Back to the Future: Applying Decades-Old Probabilistic Models to Today's DNA Results When Activities Are of Interest

Simone Gittelson, PhD, DC Department of Forensic Sciences and The George Washington University, Washington, DC; Franco Taroni, PhD, University of Lausanne, Lausanne, Vaud, Switzerland; Tim Kalafut, PhD, Sam Houston State University, Huntsville, TX; John S. Buckleton, DSc, ESR, Auckland, New Zealand*

Learning Objectives: After attending this presentation, attendees will understand that there is a robust, foundational, probabilistic framework for the evaluation of biological results given activity level propositions.

Impact Statement: This presentation will impact the forensic science community by explaining this probabilistic model for assigning the value of evidence to biological findings given each of the three different categories of activity level proposition pairs (i.e., no alternative activity, different alternative activity with the same person of interest, same alternative activity with an unknown person) and typical case scenarios encountered by DNA analysts.

Abstract Text: Evaluating scientific results given activity level propositions is nothing new. A robust probabilistic framework exists for this evaluation, with the original model published in the *Journal of the Royal Statistical Society* over 40 years ago.[1] This model introduced the concept of material being transferred during an alleged activity and the concept of material being present by chance as part of background noise, both of which are model parameters required for a probabilistic evaluation of the results given activity level propositions. This model provides a foundational basis for the evaluation of findings given activity level propositions, regardless of the forensic science discipline these findings fall into.

We have taken this foundational basis and adapted it to the evaluation of the DNA typing results seen today to create a forensic biology specific framework. This model has been validated for the presence of DNA showing the same alleles as the person of interest's profile, alleles different from the person of interest's profile, and the absence of DNA. In addition, it includes the case's specific circumstances, such as cohabitation of a defendant and complainant, which impact the evaluation of the results. The translation of this framework into Bayesian networks for each of the three categories of proposition pairs (i.e., no alternative activity, different alternative activity with the same person of interest, same alternative activity with an unknown person) and specific case circumstances is straightforward and provides us with the fundamental Bayesian network structures for each type of proposition pair and case scenario. The underlying mathematical equations for the value of evidence highlight which parameters are the most crucial for establishing the order of magnitude of the value of evidence.

This presentation provides valuable insight into a way forward toward a robust, structured, fundamental, and overarching model for the evaluation of DNA results given activity level propositions.

Activity Level; Likelihood Ratio; Bayesian Network

B187 The Construction of a Microhaplotype Panel for Complex Mixture Deconvolution Using Next-Gen Sequencing

Regan Fenske, BA, The George Washington University, Arlington, VA; Sarah Cavanaugh, MSFS, Bode Technology, Lorton, VA; Helene D. Douglas, BS, The George Washington University, Washington, DC; Robert Lagace, BA, Thermo Fisher Scientific, San Francisco, CA; Andrew B. Feldman, PhD, NexGen Forensic Sciences, Inc., Columbia, MD; Daniel S. Standage, PhD, National Bioforensic Analysis Center, National Biodefense Analysis and Countermeasures Center, Frederick, MD; Daniele S. Podini, PhD, The George Washington University, Washington, DC; Kenneth K. Kidd, PhD, Yale University School of Medicine, Hamden, CT; Jeffrey S. Lin, MS, Johns Hopkins University Applied Physics Laboratory, Laurel, MD*

Learning Objectives: By attending this presentation, attendees will learn about a novel microhaplotype panel in development specifically for analysis of complex mixtures. Attendees will learn about locus selection, sequencing platform agnostic assay development, and overall assay sensitivity to minor contributor detection.

Impact Statement: This presentation will impact the forensic science community by demonstrating that a microhaplotype panel, specifically constructed for the analysis of complex mixtures, can complement Short Tandem Repeats (STRs) when inconclusive results are obtained. Overall, this presentation will further demonstrate the usefulness of implementing current sequencing technologies to improve DNA typing results.

Abstract Text: Microhaplotypes (MHs) are short DNA regions (< 300 nucleotides) containing two or more Single Nucleotide Polymorphisms (SNPs) with multiple allelic combinations.[1] Current sequencing technologies reveal that MHs offer significant advantages over STRs in analyzing complex and imbalanced mixtures. Key benefits include the absence of stutter artifacts and uniform allele size, which makes preferential amplification of smaller alleles a non-issue.[2] Moreover, loci with a high effective number of alleles (Ae) also provide substantial ancestry information (In), much more so than conventional forensic STRs, potentially allowing biogeographical ancestry inference even for minor contributors to a DNA mixture.[3]

Large genome sequencing projects, including, but not limited to, 1000 Genomes, Genomes Asia, and gnomAD, have provided databases of whole genome sequence information. These resources have allowed researchers to explore SNP variation across populations using advancements in bioinformatic tools and identify numerous MH loci with an Ae comparable to, or exceeding, forensic STRs.[4] The comprehensive repository of MH loci, MicrohapDB, includes over 3,000 loci detailing marker locations, Ae, In, and specific allele-defining SNPs5. Aiming to develop a sequencing-platform agnostic multiplex MH assay for complex mixtures, 43 MHs were selected for primer design with the Ampliseq system. Using MicrohapDB, loci were sorted based on their Ae focusing on markers with lengths less than 270 base pairs and an Ae > 5. This narrowed-down pool was further assessed based on the following set of parameters: ranges and standard deviation of Ae values from the different populations, presence and frequency of indels, the occurrence of homopolymers longer than five nucleotides, and the BLAST search results for each marker. Initially, approximately 250 markers were identified, some of which had been included in a panel by Bode Technology and in the Kidd 24-locus panel. Markers that demonstrated a high Ae value, but were too long, were evaluated for length reduction and Ae values were re-calculated. Any marker that showed a significant reduction in allelic diversity was further eliminated.

Ten individuals from diverse ancestries were chosen from an Institutional Review Board (IRB) -approved GW collection. Various mixtures, ranging from two to five contributors with different ratios, were sequenced on a Gene Studio S5. Sequence alignment was conducted with the Torrent Suite Server by TMAP to produce mapped bam files. The bam files were then processed with the JAVA-based application mh.jar, available from Thermo Fisher Scientific, which generates allele calls based on relative coverage. Although primer concentration can be optimized, the preliminary data shows a read coverage ratio of sister alleles, averaged across loci and samples, of 77%, with random match probabilities less than one in 10^50 for single-source samples. The sensitivity to detecting minor contributors is equal or greater to that of STRs, detecting 58% and 43% of unique minor contributor alleles in a 1:40 and 1:60 mixture, respectively. The multiplex is also being tested on the MiSeq sequencing platform and next steps include: (1) generating allele frequencies both empirically by testing ~250 GW samples from individuals across the major United States populations and *in silico* by utilizing data from large sequencing projects such as 1000 Genomes and gnomAD, (2) optimizing inter-locus balance by adjusting primer concentrations, and (3) adapting probabilistic genotyping tools to incorporate MH data for mixture deconvolution and analysis.

B188 DNA Evidence Analysis Using the Same Number of Contributors for Prosecution and Defense Will Often Frame a Non-Contributing Suspect

Charles H. Brenner, PhD, Oakland, CA*

Learning Objectives: Prosecution and defense are each entitled to choose whatever hypothesis they prefer. In particular, a prosecution DNA mixture analyst cannot assume that the best choice of number of contributors for the prosecution will also be fair for the defense.

Impact Statement: I hope the audience will come to a better understanding that "number of contributors" in mixture analysis is not a fixed number like "ground truth," but rather is dependent on context and hypothesis.

Abstract Text: If there is a low-level contributor who shares some alleles with a non-contributing suspect S, there is a lively chance to frame the suspect. ("Frame" here means reporting that the evidence is against S when a correct understanding of the data would be in S's favor.) The error consists in failing to realize that the prosecutor's choice of number of mixture contributors must not be foisted on the defense.

Suppose DNA mixture evidence for a particular case is analyzed using a leading edge, fully continuous, a.k.a. "probabilistic," model program. For this case, we have an electropherogram that includes some low-level signals, signals not much above a standard rfu detection threshold. It is not particularly unusual for about half of suspect's genotype to overlap with alleles of the epg's.

Then we have two possibilities for the unseen suspect alleles. It may be that the suspect is a contributor and the remaining but missing suspect alleles dropped out (whether visible below threshold or completely absent). That's the prosecution's hypothesis, Hp. Or it may be that the suspect is a non-contributor, maybe wrongly arrested, and the alleles that are tempting evidence against suspect are purely coincidence—defense's hypothesis Hd.

Then it is common that prosecution and defense should not agree on number of contributors to assume for analysis. Instead, it is likely that the phantom contribution that S comprises under Hp, disappears as a contributor under Hd leaving a contributor count one fewer. (The discussion of discrepant numbers of contributors by [Taylor et al] is similar.)[1] The simple way to assign the appropriate choice of number of contributors for each of Hp and Hd is to accept, for each, the number which maximizes the likelihood, independently, under each H. For further simplicity just to explain the idea, let's suppose that the mixture consists of the alleles/peaks that cover half of the suspect's genotype, plus one more peak, and there is not much peak height variation. Then under Hp we need at least two contributors—the suspect, plus an "unknown" second contributor (and a lot of allelic stacking) to cover the extra allele. But under Hd it is easy to imagine that one contributor is enough. Further, the likelihood of one random genotype covering that contributor is obviously much more than the likelihood of two contributors covering the same set of peaks and staying within bounds as well. Hence, it is quite intuitive that, when about half of the suspect's genotype is observed in a mixture, the appropriate number of contributors to assume for likelihood ratio calculation is one fewer contributor for Hd. Moreover, it is common that wrongly applying the prosecution's larger number of contributors to the defense's calculation results in evidence against suspect S, while correctly allowing each of Hp and Hd its own preference results in evaporating away any evidence against suspect S.

There are additional analysis improvements for a future presentation. One is, given the assumption that S did *not* contribute, to the extent that we can find a legitimate way to take advantage of sub-threshold data, expect not merely neutral but positive support of the innocence of suspect S.

Forensic DNA; Mixture Analysis; Justice

B189 The Development of Universal STRmix Parameters for Legacy Kits

Tim Kalafut, PhD, Sam Houston State University, Huntsville, TX*

Learning Objectives: Attendees will learn about community-sourced Probabilistic Genotyping (PG) parameters for legacy Short Tandem Repeat (STR) kits. The purpose of these parameters is to allow for the application of modern PG software, specifically for laboratories that have adopted STRmix, to old cases that require interpretation due to ongoing investigation, Forensic Investigative Genetic Genealogy (FIGG) results, or other post-conviction activities.

Impact Statement: This presentation will impact the forensic DNA community by presenting parameters that will allow legacy samples to be interpreted using updated methods. This can have an impact on the outcome of on-going court activities by allowing for modern methods to be applied to old cases. The use of a fully continuous likelihood ratio can take advantage of all the information in a sample and may provide exculpatory weights of evidence that are not possible to obtain using Combined Probability of Inclusion (CPI) and Random Match Probability (RMP) methods.

Abstract Text: PG is quickly approaching ubiquity in the United States forensic DNA community. The most commonly used PG software in the United States is STRmix. As of the beginning of 2021, over 50% of certified laboratories were using this software with another 30% moving toward implementation. Each laboratory does their own independent validation prior to use to generate required parameters from known single source samples, which then get applied to unknown case work samples. In casework, the stochastic modelling parameters and evidence profiles generate weightings for allowable genotypes.

There is a disconnect from current best practices involving PG software when data using legacy STR kits is evaluated. Old cases are revisited from time to time, such as an unsolved case that has recently generated a suspect, or post-conviction activities as part of an ongoing appellate process. When this happens, laboratories essentially roll the clock back to the status of mixture interpretation and statistical analysis to that of the time the analysis was performed. This means that modern PG analysis is not used for STRmix laboratories. Laboratories are limited to the use of CPI or RMP, which have limited utility at best, and may be considered to having been inappropriately calculated by some critics at worst. One of the most striking differences between the CPI and RMP calculations compared to STRmix is that the legacy methods cannot return a numerical weight in favor of the defense.

This concept of only using what was available at the time of the original analysis contrasts with many other areas of science, such as medicine and engineering. Newer tools, such as cancer-fighting drugs and powerful mathematical software, are used on cases that may pre-date the current need for additional attention by decades. This is generally considered beneficial, whether for someone diagnosed with cancer in their 20s whose illness has returned in retirement or for stress analysis of a crumbling bridge or building constructed long ago.

A recent paper has been published that shows STRmix is remarkably tolerant of a wide range of stochastic parameter (stutter ratios and variance parameters).[1] In this study, eight laboratories provided validated stutter data and variance parameters along with 20 mixtures of 2- to 4-contributors. This included both GlobalFiler and Investigator 24plex laboratories, and both 28- and 29-cycle PCR amplifications for each kit. The results of this paper suggest that STRmix should perform well using community-derived universal parameters for older kits, such as Profiler/Cofiler, Identifiler, PowerPlex 16, and others.

This presentation will present a grassroots, community-driven set of parameters suitable for use with legacy STR kits for STRmix. One of the challenges of creating parameters for these older kits is that any one individual laboratory may not have a sufficient set of samples to generate the needed allele specific stutter models or the 100 samples of varying quality to generate their own variance parameters. However, as these are to be considered universal parameters, collecting a few samples from many labs can both generate the samples needed and ensure that the parameters developed consider a wide range of laboratory data. These parameters will be publicly available and shared without constraint. It is expected that internal testing will need to be conducted by any laboratory that may be interested in using these parameters on legacy kits.

Probabilistic Genotyping; Interpretation; Legacy Data

B190 Touch/Trace DNA in Activity-Level Propositions: Anatomy of a DNA Transfer

Ashley Hall, PhD, University of California Davis, Davis, CA; Ray A. Wickenheiser, DPS, New York State Crime Laboratory System, Youngsville, LA; Aldrin Alviar, MS, University of California Davis, Davis, CA*

Learning Objectives: In this presentation, we will describe a quantitative evaluation of DNA transfer at a crime scene supported by our extensive experimental touch DNA data. Attendees will learn about the vagaries of primary vs. secondary DNA transfer events, DNA recovery, and how they impact activity-level questions at a crime scene.

Impact Statement: The impact to the forensic science community is rooted in the empirical evaluation of the fundamental events of DNA transfer and recovery and the metrics we can use to describe them. This expression of transfer events could contribute to a Bayesian evaluation of a crime scene, adding value to the forensic scientists' interpretation to assist the trier of fact.

Abstract Text: Consider this scenario: your DNA is found on a spent bullet casing at a death scene. The prosecution presents this as evidence that you deposited your DNA as you loaded the gun and committed the crime. Your defense, however, argues that you shook hands with the actual perpetrator earlier in the day, and they transferred your DNA to the casing as they loaded the gun and did the shooting. Each of the scenarios is possible; your DNA could be transferred along both pathways. The critical question becomes not "whose DNA is it," but, rather "how did the DNA get there?"

Evaluations of the evidence given the donor's activities inform such activity-level propositions; such assessments of alternate scenarios can provide tremendous value when they are backed by empirical data.[1] The forensic scientist is uniquely qualified to interpret data to inform activity-level questions and present them to the trier-of-fact. However, there is a dearth of empirical data available in the literature.

The goal of this project was to generate empirical data in support of activity-level evidence interpretation. We asked the question: Can we tell a difference between primary and secondary transfers using DNA recovery values? To address the question, we used a well-established protocol—the domesticated fingerprint, a ground truth sample containing a known quantity of DNA.[2] We mocked three crime scenes, tracking DNA transfer through a primary versus a secondary pathway. Using the domesticated fingerprint and its transfer device, the domesticated hand, we transferred DNA across pathways that involved three commonly occurring surfaces in criminal casework—a subway pole, a drug baggie, and a knife. Samples were collected from each surface and from the domesticated hand. Quantifying the DNA recovered from each surface allowed us to track DNA across the pathway and compare the results of primary and secondary transfers.

By repeating each pathway 20 times independently, we were able to generate mean recovery values, measure the standard deviation, and run an analysis of variance. We found that the difference in recovery after a primary vs. secondary transfer pathway is statistically significant difference for all three crime scenes. Therefore, we suggest that assessments of alternate scenarios provide tremendous value when they are backed by empirical data and may aid the trier-of-fact in a determination of which scenario is most probable.

B191 Evaluating the Consistency of a DNA Mixture Interpretation Protocol

Joseph Truppi, BS, Harris County Institute of Forensic Sciences, Houston, TX; Mario Galioto, MS, Harris County Institute of Forensic Sciences, Houston, TX; Katie Welch, MS, Harris County Institute of Forensic Sciences, Houston, TX; Michael Donley, MS, Harris County Institute of Forensic Sciences, Houston, TX*

Learning Objectives: After this presentation, attendees will understand the requirements of a DNA mixture interpretation protocol verification as defined by Standard 4.4 of American National Standards Institute/Academy Standards Board (ANSI/ASB) Standard 020, Standard for Validation Studies of DNA Mixtures and Development and Verification of a Laboratory's Mixture Interpretation Protocol. Attendees will learn how to design and administer a mixture interpretation protocol verification that demonstrates the consistency and reliability of the laboratory's procedures for interpretation of DNA mixtures.

Impact Statement: This presentation will encourage other forensic DNA testing laboratories to evaluate the effectiveness of their procedures for DNA mixture interpretation by performing a protocol verification. The protocol verification discussed in the presentation will be offered as a template for other laboratories interested in strengthening the quality of their DNA interpretation procedures by measuring consistency and reliability in a controlled study. The results from the most challenging samples will demonstrate for the forensic DNA testing community that protocol verification can illuminate gaps in an existing or new DNA interpretation procedure, thereby offering opportunities for improvement.

Abstract Text: To comply with ANSI/ASB Standard 020, Standard for Validation Studies of DNA Mixtures and Development and Verification of a Laboratory's Mixture Interpretation Protocol, a laboratory must perform a mixture interpretation protocol verification to demonstrate consistency and reliability in its conclusions.[1] In May 2023, the Harris County Institute of Forensic Sciences revised the laboratory's DNA interpretation procedure and later that same year endeavored to evaluate the performance of the procedure and its application by performing a protocol verification planned to coincide with the training program for a newly implemented capillary electrophoresis platform.

A wide range of DNA samples was prepared from previously extracted saliva samples of nine known donors. The breadth of samples, as required by Standard 020, was intended to reflect the range of DNA mixtures routinely encountered in casework, with consideration given to Number Of Contributor (NOC) range, mixture ratios, DNA template amounts, and donor combinations. DNA mixtures with more than one acceptable interpretation were intentionally included in the study to challenge the participants with genuinely ambiguous data. In total, 21 DNA samples were prepared and administered in a blind format to 19 qualified DNA Analysts and two trainees. Participants in the study were provided with three references for comparisons against the 21 test samples. Comparison results were expressed as likelihood ratios or visual exclusions. A total of 441 NOC interpretations were made in the protocol verification, and 436 of 441 (98.9%) were deemed to be within the predefined acceptable range of variation for each sample. Four of the five interpretation errors were attributed to a misreading of peak height imbalance in the stochastic range for the Polymerase Chain Reaction (PCR) typing kit and detection platform. Considering ground truth NOC, 73 of 441 NOC interpretations (16.6%) did not agree with the true NOC by addition or subtraction of one contributor. Fifty-seven interpretations were N-1 relative to the true NOC, while 17 interpretations were N+1 relative to the true NOC. Conclusions omitting one true donor were considered acceptable in select samples where alleles from trace-level contributors failed to amplify or were masked by higher-template contributors. Insertion of a phantom contributor was deemed acceptable in select samples if multiple peak height imbalances or spuriously elevated stutter gave justification for an additional contributor.

Participants evaluated a total of 63 comparisons in the study. Fifty-eight of 63 (92.1%) comparisons provided likelihood ratio support or visual exclusions concordant with the ground truth. Among comparisons discordant with ground truth, four provided false exclusionary support and one false support for inclusion. In each case, the relevant samples were amplified at suboptimal DNA template less than 0.5ng. The incidence of false exclusionary results was driven by the incorporation of trace-level contributors in several test samples. The laboratory's own internal validation and published studies predict this risk.[2-4] The one result incorrectly supporting inclusion of a non-contributor was an instance of coincidental allele sharing. The magnitude of the average likelihood ratio (=9), however, appropriately weights the false inclusion within the "limited support" category of the Scientific Working Group on DNA Analysis Methods (SWGDAM) -recommended verbal scale.[5]

An unexpected outcome of the protocol verification allowed the laboratory to identify an opportunity to improve the interpretation of four-person mixtures. Three such DNA mixtures were included in the study, and each provoked inconsistent decisions on suitability for comparisons. Most participants deemed these DNA mixtures unsuitable for comparisons. The minority who decided that these complex DNA mixtures were suitable for comparisons obtained likelihood ratios that mostly supported ground truth. Based on these findings, the laboratory intends to supplement its internal validation with more complex mixtures and update the DNA interpretation protocol to promote consistency with this sample type.

Protocol Verification; Mixture Analysis; Probabilistic Genotyping

B192 A Perspective on More Than 30 Years of Forensic DNA Research and Technology Development

Bruce R. McCord, PhD, Florida International University, Miami, FL*

Learning Objectives: After attending this presentation, attendees will understand the history of the development of methodology for DNA typing including Capillary Electrophoresis (CE), mini Short Tandem Repeats (miniSTRs), DNA extraction, Polymerase Chain Reaction (PCR) inhibition, body fluid analysis, and Rapid DNA. Projections for future technology such as body fluid detection and microbial forensics will also be discussed.

Impact Statement: This presentation will assist the forensic science community in understanding the background research involved in the development of current methodology for forensic DNA typing. The presentation will discuss history as well as project future technology as well as technology transfer from research to validation to implementation.

Abstract Text: This presentation will discuss the various approaches taken by the McCord research group in developing methods for genetic typing and body fluid analysis from 1989 to the present, a span of 35 years. Among the items covered will be the initial development of CE and STRs for use in forensic DNA typing. Here, the author will discuss the transition from gel electrophoresis to CE and key factors such as the optimization of soluble polymer buffers. Experiments to determine the interesting effects of electrokinetic injection on DNA separations in which slight changes in conductivity affect signal intensity and resolution will also be discussed. Other topics will include the application of CE-based analysis for mixture determination and how signal-to-noise differences and variations in PCR efficiency can affect overall results.[1,2]

A second portion of the presentation will discuss experimental studies of PCR inhibition and DNA degradation. This includes early work on the application of real-time PCR for the detection of PCR inhibition and the development of miniSTRs. Here experimental data demonstrated the multiple ways inhibitors can alter peak intensity and peak dropout.[3] Portions of this work led to interesting experiments involving the development of miniSTRS and microfluidic systems for DNA typing.[4] This work demonstrated the improvement in recovery and inhibition resistance when CE and PCR are used with smaller amplicons. An interesting side result was that smaller amplicons also permitted the development of ultra-high-speed PCR, ultimately resulting in devices capable of multiplex PCR amplifications as fast as seven minutes with 80-second genotypes.[5]

The presentation will end with a discussion of non-traditional applications for forensic DNA analysis, including epigenetic body fluid detection with sensitivity and specificity that is fully compatible with STR typing.[6] DNA methylation can also be used for phenotyping, and we have examined its use for age determination and smoking status.[7] More recently, our laboratory has been examining microbial DNA. Here we show how microbial transfer can be used to detect sexual assault and also to examine contamination of agricultural produce.[8,9] The discussion will end with the author's comments on technology transfer and the potential topics for future research in forensic analysis.

Forensic DNA; Body Fluid Analysis; Microbial Forensics

B193 From Planning to Practice: Navigating the Implementation of Rapid DNA Technology and Tracking Success Metrics

Jason M. Chute, MSFS, RTI International, Research Triangle Park, NC; Patricia Melton, PhD, RTI International, Research Triangle Park, NC; Mikalaa M. Martin, BS, RTI International, Cincinnati, OH; Erin P. Forry, MS, RTI International, Research Triangle Park, MA; Emily G. Strelka, MFS, RTI International, Alexandria, VA; Misty Marra, MSFS, RTI International, Huntington, WV; Shannon Krauss, PhD, RTI International, Research Triangle Park, NC*

Learning Objectives: Attendees will: (1) gain detailed knowledge of the four key stages of implementing Rapid DNA technology, from pre-purchasing concerns to pre-implementation considerations; (2) understand the details and resources available to cover the tasks outlined in each of the key stages; and (3) learn how to utilize the implementation checklist and metric tracker to ensure a thorough and successful integration of Rapid DNA technology within their agencies.

Impact Statement: This presentation will provide a comprehensive roadmap for law enforcement agencies considering or in the process of integrating Rapid DNA technology. Attendees will gain critical awareness into the implementation process from procurement to practical application and will be equipped with two valuable tools: an Interactive Implementation Checklist and a Metric Success Tracker. These resources will enable agencies to effectively manage and develop their Rapid DNA programs, ensuring robust and successful integration.

Abstract Text: In this presentation, attendees will gain insights into a comprehensive approach that has been utilized by law enforcement agencies currently integrating Rapid DNA technology. Experiences from 18 months of supporting multiple Byrne Discretionary Grants Program grantees adopting Rapid technology, the presenter will expand upon several critical considerations for implementation—from procurement to practical application of the Rapid DNA technology.

Rapid DNA technology is gaining prominence among law enforcement agencies across the United States. Agencies may choose to implement it for various reasons, including disaster victim identification, booking stations, and crime scene analysis. While current regulations restrict entry of forensic samples into the Federal Bureau of Investigation's (FBI's) Combined DNA Index System (CODIS), some jurisdictions have developed or utilize local databases for these types of samples. Additionally, the Scientific Working Group on DNA Analysis Methods (SWGDAM) is developing new standards for forensic sample data generated from a Rapid DNA instrument to be uploaded into CODIS, which are anticipated to be in place by mid-2025. Agencies must carefully consider the steps required to implement Rapid DNA technology, and this presentation will provide a roadmap for planning accordingly.

Specifically, the implementation process is separated into four key stages: Prior to Instrument Procurement, Prior to Receiving Instrumentation, After Receiving Instrumentation, and Prior to Implementation. Pre-procurement will cover key considerations such as establishing partnerships and consultants and determining fit-for-purpose given agency needs. Pre-receiving will cover key considerations such as security, staffing, and training. Post-receiving will cover strategies for Quality Assurance/Quality Control, sample types, and validation. Last, Pre-Implementation will cover approaches associated with sample assessment and acceptance, comparisons, reporting, and metrics tracking.

As part of the presentation, attendees will be given a preview and have access to two downloadable tools at no cost that have been met with a positive response:

1. Interactive Implementation Checklist: This comprehensive checklist covers all stages and aspects of the implementation process. The tool offers interactive features with key information and associated resources that will allow for a thorough and robust implementation process.
2. Metric Success Tracker: An Excel-based metrics tracker that agencies can customize to monitor the success of rapid DNA technology after implementation. Tracking of critical information will allow agencies to effectively manage or develop their program.

Attendees can bring both tools back to their agency for practical application and sharing.

Rapid DNA; Forensic Investigation; Forensic DNA

B194 A Sensitivity Evaluation of the Applied Biosystems RapidHIT ID System v2.0 and RapidINTEL Plus Sample Cartridge

Emily Yen H. Dang, BS, Virginia Commonwealth University, Richmond, VA; Morgan E. Eaton, MS, Colorado Bureau of Investigation, Richmond, VA; Tracey Dawson Green, PhD, Virginia Commonwealth University, Richmond, VA; Raygan Harrington, BS, Virginia Commonwealth University, Midlothian, VA*

Learning Objectives: This presentation provides a better understanding of the sensitivity and performance of the newly released RapidHIT ID system v2.0 and RapidINTEL Plus sample cartridge via experiment and analysis

Impact Statement: By providing better understanding of the performance and sensitivity limitation of RapidHIT ID system v2.0 and RapidINTEL Plus sample cartridge, this presentation demonstrates the potential implementation of this system in casework, thus eliminating the lengthy process in obtaining Short Tandem Repeat (STR) profiles and alleviating the backlog issue in many laboratories.

Abstract Text: The RapidHIT ID is a fully automated system that is designed to perform cell lysis, DNA isolation, Polymerase Chain Reaction (PCR) amplification, electrophoretic separation, and data analysis from saliva or blood sample swabs.[1-4] The RapidHIT ID systems require less than one minute of hands-on preparation and 90 minutes of processing time.[1,2,5-8] Currently, the most recent RapidHIT ID firmware released by the manufacturer is the RapidHIT ID System v2.0, which works in conjunction with the new RapidINTEL Plus Sample Cartridge, the RapidLINK Software v2.0, and utilizes GeneMapper ID-XR Software for profile analysis.[5-8] Samples processed with this cartridge and the accompanying upgraded software are automatically analyzed utilizing validated locus-specific stochastic thresholds, which are much lower than those previously recommended.[5] Additionally, the RapidHIT ID System v2.0 has a minimum peak height ratio of 0.2 or 0.4 (depending on the locus), whereas the previous version used the minimum peak height ratio threshold of 0.4 across all autosomal markers. Furthermore, the RapidINTEL Plus sample cartridge is equipped with small and large quantification markers (QTS and QTL), which allows the estimation of the DNA quantity of the template DNA analyzed. Given the firmware, software, and cartridge updates associated with the recently released RapidHIT ID System v2.0, the new, more specific analytical settings, and the desire to use this platform for more complex evidence-type samples, it is critical that the sensitivity and other operational limitations be carefully evaluated. In this study, the range of detection and performance of the updated instrument and software were experimentally evaluated using buccal swab samples from four different donors with total DNA inputs of 5ng, 7ng, 10ng, 20ng, and 50ng. Each swab was processed using the RapidHIT ID and analyzed with the GeneMapper ID-XR Software, following the general protocol with lysis volume of 500uL. The resulting STR profiles were compared to the corresponding reference STR profiles to confirm accuracy and concordance. Each experimental concentration tested was compared to the values generated from the on-board quantification markers and the sensitivity of the platform determined.

Across the five tested DNA input groups, all STR profiles observed were fully concordant with the profile from the traditionally tested reference buccal swabs. Interestingly, the QTL quantification values indicated that only ~1.15% of the total input of each sample was metered for amplification. Accordingly, the average percentage of expected alleles detected for the DNA inputs of 5ng, 7ng, 10ng, 20ng, and 50ng were 59.41%, 72.78%, 86.11%, 98.17%, 100.00%, respectively. From all sample sets, the average peak heights of all DNA input groups were below the internally validated optimal peak height range used by the RapidLINK Software v2.0. However, the average intralocus heterozygous peak height ratio of the STR profiles across all testing inputs ranged from 0.67 to 0.79, which is above the minimum peak height ratio of 0.2 or 0.4 (marker-specific) recommended by the manufacturer.5

Overall, the results show that the updated system provides several improvements to the rapid DNA process, including valuable quantification data. However, with such a small volume of the DNA extract moved into amplification chamber of the cartridge, it will be important for examiners to carefully consider the specific nature of evidence items being tested. For very challenged DNA samples or for those expected to yield low template DNA, it may be beneficial to increase the amount of substrate loaded into the cartridge or use the specialized protocol that has a lower lysis volume (100ul). Future studies may include experimental evaluation of the sensitivity of the lower volume specialized protocol of RapidHIT ID System v2.0 when coupled with RapidINTEL Plus Sample Cartridge.

B195 An Assessment of the RapidHIT ID System V2.0 for Use on Evidentiary Samples and Its Suitability for Implementation Into Law Enforcement

Trupti Sriram, BS, Bode Technology, Arlington, VA; Jamia Mealy, MFS, Bode Technology, Lorton, VA; Kristen Naughton, BS, Bode Technology, Lorton, VA*

Learning Objectives: After attending this presentation, attendees will have a better understanding of how the Applied Biosystems RapidHIT ID System v2.0 is evolving Rapid DNA technology to be more suitable for law enforcement in terms of processing evidentiary samples and will understand the capabilities of this system compared to standard laboratory processing. Specifically, attendees will learn about the new RapidINTEL Plus chemistry and how to determine the correct protocol option based on sample type.

Impact Statement: This presentation will impact the forensic science community by providing insight on the potential benefits and limitations of the RapidHIT ID System v2.0 for processing crime scene samples and how implementation of this new system is facilitating the advancement of Rapid DNA technology to ensure that it is reliable, responsible, and appropriate for obtaining evidentiary DNA profiles to upload to DNA databases.

Abstract Text: The rise of Rapid DNA technology in the field of forensic science has been fueled by the desire for faster processing times of biological samples, the expansion of DNA typing to include non-traditional operators, and the ability to process samples from remote locations. As a fully automated "sample in-answer out" system that obtains a DNA profile in under 90 minutes, Rapid DNA has shown to be a viable option for obtaining arrestee profiles at booking stations and producing investigative leads. Currently, the only sample type approved for enrollment and/or search in the Combined DNA Index System (CODIS) following Rapid DNA processing is reference samples since crime scene evidence can vary in quality and quantity of DNA.[1] However, there has been significant interest from law enforcement to extend the capabilities of this technology to approve Rapid DNA analysis on evidentiary samples for database upload in addition to reference-type samples. In response, manufacturers have made efforts to improve the ability of Rapid DNA instruments to process more challenging samples. This study assessed the performance of the Applied Biosystems RapidHIT ID (RHID) System v2.0 and the RapidLINK Software v2.0 with a focus on the new RapidINTEL Plus Sample Cartridge for evidentiary samples. This cartridge provides a specialized protocol to increase sensitivity with the goal of improving first-pass success rates for a range of crime scene samples. Additionally, it includes internal quality control and quantification markers to assist with identification of low quantity, degraded, and inhibited samples.[2] These markers allow sample processing with the RapidINTEL Plus cartridge to be in line with the required enhancements needed for Rapid DNA crime scene evidence processing as outlined by the Federal Bureau of Investigation's (FBI's) Rapid DNA Technology Advancement Task Group.[1]

Various studies were conducted to assess the performance of the RHID System v2.0 with the RapidINTEL Plus cartridge and evaluate the first-pass success rate for a variety of evidentiary-type samples in comparison to standard laboratory processing. The sensitivity of the RapidINTEL Plus cartridge was determined by comparison against processing with the original RapidHIT ID ACE GlobalFiler Express (GFE) cartridge as well as standard laboratory processing.

Overall, the RHID System v2.0 with the RapidINTEL Plus and ACE GFE cartridges produced accurate, reproducible, precise, and sensitive results that were free of contamination. The RapidINTEL Plus specialized protocol provided the highest level of sensitivity as shown by obtaining a searchable DNA profile from even a 1:1,000 blood dilution sample. In most cases, evidentiary items from blood or mouth contact samples run using the specialized protocol obtained full DNA profiles comparable to standard processing. High-quality bone samples also obtained full profiles with the RapidINTEL Plus sample cartridge. Touch samples, specifically handled items and fingerprints, did not consistently obtain searchable DNA profiles due to low-level DNA or presence of a mixture that is not suitable for Rapid DNA analysis. The quantity and quality markers in the RapidINTEL Plus cartridge accurately depicted sample quantity, inhibition, and degradation.

These results indicate that the RHID System v2.0 is a suitable tool for processing most evidentiary sample types and obtaining database-ready DNA profiles. The RapidINTEL Plus cartridge advances Rapid DNA technology toward being eligible to analyze crime scene samples for search and/or upload to DNA databases. Additionally, the implementation of this system into law enforcement allows Rapid DNA to maximize the potential of crime scene samples by generating more reliable investigative leads.

Rapid DNA; Crime Scene Samples; Law Enforcement

B196 An Analysis of Pre- and Post-Coital Microbial Transfer Using Deep Shotgun Metagenomic Studies

Andrea Ramirez Torres, Florida International University, Miami, FL; Mirna Ghemrawi, PhD, The Center for Forensic Science Research and Education, Horsham, PA; Bruce R. McCord, PhD, Florida International University, Miami, FL; George Duncan, PhD, Nova Southeastern University, Fort Lauderdale, FL*

Learning Objectives: After attending this presentation, attendees will understand how the genital microbiome can be observed pre- and post-sexual intercourse. They will also be informed on how to perform sample collection to increase bacterial DNA yields.

Impact Statement: This presentation will assist the forensic science community in understanding the potential of the genital microbiome as an aid in forensic investigations by describing a sample collection method and demonstrating bacterial transfer.

Abstract Text: The microbiome is becoming an emerging field of interest within forensic science with high potential for individualization; however, little is known about signature bacterial species within the genital area or their ability to transfer between individuals during sexual contact. There have been some forensic-focused studies suggesting that metagenomic analysis of human pubic hair could be a useful tool to trace sexual contact when traditional forensic methods are inconclusive.[1] As per Locard's Principle of Exchange, the genital microbiome may indicate proof of sexual contact between two individuals, each of male and female sex. Our goal was twofold: first, to examine the effects on vaginal, labial, and penile microbiome before and after sexual intercourse, and second, to determine what types of bacteria were transferred and to assess whether the specificity of recovered microbial genotypes is sufficient to trace individual bacterial origins.

In this study, we investigated microbial transfer dynamics in seven monogamous, heterosexual couples by collecting pre- and post-sexual intercourse samples from their genital areas, including penile, vaginal, and labial locations. The samples were extracted and the microbial DNA in the samples were then quantified using Real Time Polymerase Chain Reaction (qPCR), an intercalating dye, and universal bacterial primers. Utilizing shotgun metagenomic sequencing, we sequenced the microbial profiles of these samples. To determine the number of microbial species (richness and evenness of bacterial species distribution) associated with these biological specimens, alpha diversity analysis was carried out. Next, to measure the differences in the microbiome composition among different species studied, beta diversity was examined, and a principal coordinate analysis was performed to assess and visualize the compositional similarities of the microbial communities associated with these specimens. Subsequently, we used a couple-wise comparison among pre- and post-coital microbiomes to determine shared taxa and possible transfer of microbiota after sexual contact. Finally, when shared bacterial species were evident, we utilized the evolutionary analysis method using Single Nucleotide Polymorphism (SNP), which helps determine the genetic variations at a single base position in the DNA, thereby, offering a high-resolution assessment of the genetic similarity of two candidate bacterial strains in order determine a potential transfer of strain through sexual contact.

Our findings reveal significant transfer from the vaginal microbiome onto the penile microbiome, predominantly originating from the labial genitalia. For example, *Lactobacillus crispatus* abundance level increased by 70% in penile samples for two couples. Moreover, strain analysis unveiled distinct differentiation between the same species of bacteria across individuals, underscoring the potential for microbial forensics to distinguish individuals. This study contributes to our understanding of microbial transfer during sexual contact and highlights the forensic implications of the genital microbiome.

B197 Exploring the World of "Touch DNA" and "Touch Microbiome": One-Shot DNA Collection and Extraction

Michele Di Nunzio, PhD, University of Barcelona, Barcelona, Catalonia, Spain; Sarah Gino, MD, University of Eastern Piedmont, Novara, Piemonte, Italy; Andrea Bonicelli, PhD, University of Central Lancashire, Preston, England, United Kingdom; Noemi Procopio, PhD, University of Central Lancashire, Preston, England, United Kingdom*

Learning Objectives: After attending this discussion, participants will have an improved understanding of the precise method for extracting human and microbial DNA from a fingermark and the information that the microbial signature can reveal in association with the donor of the fingermark.

Impact Statement: This presentation will impact the forensic science community by providing a new methodology to co-extract from a standardized fingermark surface extension to obtain successful DNA genotyping and microbial sequencing.

Abstract Text: Microorganisms are present on both the interior and exterior surfaces of the human body, outnumbering human cells at a 3:1 ratio.[1] Like human DNA shed from skin cells, microbes are also transferred to the surrounding environment.[2,3] Due to the robust structure of bacterial DNA, it withstands degradation more effectively than human DNA. Given the increasing role of microbiome analyses in forensics, and the presence of enough microbial DNA in a fingerprint to generate a reliable profile, this presentation examines the transfer and recovery of touch DNA and microbiomes using 4N6FLOQSwabs.[2]

At a crime scene, the simultaneous collection of fingermark ridge patterns and related evidence can be challenging. When a fingermark is compromised, investigators are often advised to prioritize DNA recovery over dactyloscopy. Fingermarks frequently contain low quantities of DNA, sometimes below the 0.002ng/µL threshold for obtaining a meaningful Short Tandem Repeat (STR) profile.[4] Despite this, forensic DNA analyses can still yield high-quality profiles.[5-7] Additionally, a person's microbial signature can reveal more about their lifestyle and health than human DNA alone. By analyzing both nuclear DNA (nDNA) and microbial DNA from the same swab, investigators can gain further insights, using established forensic genetics methods while maintaining the accuracy of human identification profiles.

A total of 40 participants provided fingermarks of their Dominant Hand's Index (DHI) on a standardized and sterilized glass surface. Prior to deposition, participants washed their hands and allowed natural "recharge" for one hour. Fingermarks were deposited using a cutout mold, applying 500g pressure for 60s. DNA was collected by swabbing the entire fingermark with dried flocked 4N6FLOQSwabs. NDNA extraction was done using the Qiagen QIAamp DNA Blood and Tissue kit.[8] DNA quantitation was conducted using the Human Quantifiler kit on a 7500 Real-Time PCR System. Human DNA was amplified by AmpFLSTR Identifiler Plus PCR Amplification Kit on a 9700 GeneAmp PCR System. The amplified samples were processed by capillary electrophoresis and STRs analyzed by GeneMapper ID 3.2 software. Using the same extracts, the V4 region of the 16s rRNA gene was amplified and sequenced using the Illumina MiSeq System. FASTq files were analyzed in QIIME2 (ver. 2024.5.0), were quality filtered using DADA2, and trimmed accordingly. Taxonomic assignments were made using silva-138-99. Data were further analyzed in R (version 4.2.3) with the "Phyloseq" packages.

Results showed that the co-extraction of touch DNA and touch microbiome is possible, and the use of standardized conditions for the deposition and collection of the fingermark significantly improves the success of the analysis when compared with previous studies conducted in less ideal and optimized conditions.[3] The microbial profiles obtained from the various fingers from the same donor are distinct one from another one but still more similar than between individuals in terms of bacterial composition, bacterial relative abundance, alpha and beta diversity. Specific taxa (ASVs) unique to specific donors were found in the deposited finger marks after excluding the environmental signature found on the glass slide, highlighting the potential use of touch microbiome as an additional tool to identify the donor of the trace found on touched objects on the crime scene.

On the basis of our preliminary results, it is possible to affirm that the obtention of human DNA and microbial DNA with standardized approaches may help forensic analysts in performing a more appropriate personal identification and simultaneously obtain information about habits of a suspect.

B198 Size-Selective Purification to Separate High and Low Molecular Weight DNA

Vinalon Mones, BS, The George Washington University, Washington, DC; Helene D. Douglas, BS, The George Washington University, Washington, DC; Glenn Fahrig, MS, Bureau of Alcohol, Tobacco, Firearms and Explosives, Alexandria, VA; Gregory A. Peiffer, PhD, Bureau of Alcohol, Tobacco, Firearms and Explosives, Beltsville, MD; Rebecca Sloman, MFS, Bureau of Alcohol, Tobacco, Firearms and Explosives, Beltsville, MD; Katherine Hargett, MFS, Michigan State Police- Grand Rapids Forensic Laboratory, Grand Rapids, MI; Daniele S. Podini, PhD, The George Washington University, Washington, DC; Michael D. Coble, PhD, University of North Texas Health Science Center, Ft. Worth, TX; Elaine Lewis, PhD, The George Washington University, Washington, DC; Jessica Broner, MS, University of North Texas Health Science Center, Fort Worth, TX; Jonathan King, MS, University of North Texas Health Science Center, Fort Worth, TX; Todd Bille, MS, Bureau of Alcohol, Tobacco, Firearms, and Explosives Laboratory, Beltsville, MD*

Learning Objectives: Attendees of this presentation will learn about a modification to the Qiagen Investigator Kit protocol for DNA extraction that can allow for the selective isolation of low and high molecular weight DNA.

Impact Statement: Forensic DNA samples can be mixtures with contributors differing in DNA quality. This simple modification to an already-known extraction method can be used to separate the degraded DNA from higher-quality DNA, which can benefit mixture deconvolution of casework samples.

Abstract Text: When working with DNA evidence containing multiple contributors, separating and identifying contributors with varying levels of DNA integrity can be challenging. Solid phase extraction methods utilize chaotropic salts and the affinity of DNA for silica in the presence of ethanol to isolate DNA from cell lysates. However, commercial forensic kits are not always optimized to purify highly degraded DNA, leading to potential loss during the initial post-lysis purification step.

We optimized a straightforward modification to the QIAmp Investigator Kit protocol to recover degraded DNA that might otherwise be lost. This allows for the separation and potential differentiation of contributors with different DNA qualities within the same sample. The Size Selective Purification (SSP) method involves adding extra ethanol to the first flow-through of the lysate through the silica-based column and then passing it through a second column. The additional ethanol enhances the binding of degraded DNA that was not captured by the first column to the second one. Both columns are then processed in parallel following the standard protocol. The amount of ethanol added to a lysate before spinning through the column affects binding efficiency and the size of the DNA fragments recovered.

Although there is a potential to co-elute other undesired or inhibitory substances, modern amplification methods are better equipped to overcome Polymerase Chain Reaction (PCR) inhibitors. We tested 12 pairs of high-quality DNA samples (extracted from whole blood) from different individuals, enzymatically fragmenting one sample in each pair. The paired samples were mixed and processed using both the regular protocol and the SSP method. Results demonstrated that the SSP method enabled the separation of fragmented samples from non-fragmented ones in a mixture, allowing for the recovery of approximately 20% more alleles from the degraded DNA samples, otherwise undetectable with the regular protocol. In some cases, the separation was so effective that it enabled us to conclusively attribute alleles to the degraded contributor, which were masked by the non-degraded individual and unidentifiable in the regular extraction.

The SSP method can enhance mixture deconvolution and could potentially be applied to DNA mixtures involving a source of degraded DNA and another of higher quality, such as ancient DNA with recent contamination or criminal evidence involving firearm handlers (degraded source) and victim blood (higher quality).

Low DNA; Forensic DNA; STRs

B199 Probabilistic Clustering of Single-Cell Investigative Evaluations

Qhawe A. Bhembe, MSFS, Rutgers University, Camden, NJ; Nidhi Sheth, PhD, Legal Aid Society, Philadelphia, PA; Ken R. Duffy, PhD, Northeastern University, Boston, MA; Catherine M. Grgicak, PhDf, Rutgers University, Camden, NJ; Desmond S. Lun, PhD, Rutgers University Camden, Camden, NJ; Leah M. O'Donnell, MS, Grgical lab at Rutgers University, Camden, Cannonvale, Queensland, Australia*

Learning Objectives: After attending this presentation, attendees will learn how peak-height-based probabilistic clustering of single-cell data enhances forensic investigations when there is no suspect. This presentation will showcase the effects of accurate clustering, an essential step in single-cell interpretation. By comparing two probabilistic clustering methods—a Peak-Height-Based model and the previously published Model-Based Clustering (MBC)—we highlight the merits of faithful clustering when determining the posterior probability distribution of a genotype at a locus in non-suspect casework.

Impact Statement: This presentation will impact the forensic science community by demonstrating a significant improvement in clustering accuracy for single-cell Electropherograms (scEPGs), narrowing the estimated number of contributors explaining the evidence which, in turn, leads to a concentration in the credible set of genotypes that explain it. We will show that the concentration is persistent, even when the evidence is complex or the donor contributed as little as two cells.

Abstract Text: In forensic DNA analysis, one of the primary goals of the analyst is to generate data that will discriminate candidate hypotheses. Traditionally, these data are obtained through bulk treatments, where DNA of all contributors is extracted in a single vessel, resulting in DNA fragments that are equally distributed in solution. If the concentration of any one contributor is low, then allele drop-out can result. If there are many donors, allele overlap will result. With all contributors' DNA being sampled together, the result is that evidence (i.e., the likelihood ratio) approaches one as allele drop-out or the Number of Contributors (NoC) to a mixture increases. These issues mean that there is scope to improve the robustness of mixture interpretation.

One path forward is by way of single-cell analysis, which is defined as a system of laboratory procedures that:(1) isolate each cell; and (2) extracts and directly amplifies the DNA within the same vessel. By applying single-cell treatments, alleles of each contributor remain coupled and variability due to extract fractionation is circumvented, leading to *m* single-cell, single-source contributor electropherograms (scEPGs). The interpretation of these highly resolved data, therefore, changes from one of determining the weights given multifarious genotype combinations to one that relies on clustering the scEPGs by similarity. With this modification, the NoC to the admixture is an output, no longer relying on human interventions. For non-suspect casework, a multi-hypothesis evaluation that estimates the probability of genotype *g* given the cluster can, therefore, provide significant gains in investigative genetics.

Previously, we used MBC to group scEPGs, based on a Gaussian mixture model.[1,2] Though fruitful, MBC resulted in some instances of over-clustering, where scEPGs from the same genotype were split into multiple clusters, which inflated the estimated NoC. We extend this previous work by introducing a model that uses conditional probabilities based on peak heights, allele positions, and allele frequencies to assess the universe of possible partitions, resulting in more accurate clustering.

To test the new clustering approach, we analyzed the same 630 admixtures used to test MBC. These mixtures contained 17 to 75 scEPGs from 2 to 5 contributors. We applied the Peak-Height-Based model, implemented in Evidentiary Evaluation of Single Cells (EESCIt), and compared its performance to MBC. We then use EESCIt to estimate the probability of the scEPGs in a cluster, *C*, given *g*, the given genotype within the set of all common genotypes according to background frequencies. In summary, EESCIt assigns P(G=g|C) for each locus allowing a decision threshold, such as 0.998, to define the credible set of genotypes explaining the cluster of cells.

To evaluate the performance of each clustering method, we determined the proportion of admixtures that gave correct and incorrect number of clusters (i.e., NoC). The Peak-Height-Based model outperformed MBC, eliminating over-clustering. Specifically, while MBC over-clustered 86 (13%) of the 630 admixtures and mis-clustered one sample (< 0.1%), the Peak-Height-Based model achieved perfect clustering, recovering the over-clustered samples from MBC.

We also report the proportion of loci for which only one genotype is in the credible set and that genotype is the true genotype. When using the Peak-Height-Based model, 90% of the time the credible contained one genotype and it was the correct one, compared to 84% for MBC. Furthermore, the Peak-Height model showed improved posterior distributions, resulting in a higher percentage of loci (94%) with only one or two candidate alleles in the credible set, compared to 89% for MBC. With the peak height model demonstrating improved clustering results, it is the investigative evaluation process that is improved, narrowing the number of investigative leads to one or two genotypes.

B200 The Comparison and Evaluation of Predictors on Single-Cell Weights of Evidence

Catherine M. Grgicak, PhDf, Rutgers University, Camden, NJ; Desmond S. Lun, PhD, Rutgers University Camden, Camden, NJ*

Learning Objectives: After attending this presentation, attendees will know what single-cell Likelihood Ratio (LR) features to assess and learn how to query the calibration of single-cell Weights of Evidence (WoE). They will hear about what procedures support the efficient construction and validation of single-cell assessments and will become aware of models that effectively predict single-cell WoE.

Impact Statement: This presentation will impact the forensic science community by demonstrating that at the boundary of one cell and as the information in a single-cell signature increases, LRs approach the inverse of the random match probability when H1 is true and approach 0 when H2 is true. We discuss the effects of extreme, though rare, stutter events that occur when amplifying single copies of DNA and proffer model adaptations describing ways in which these rare, impactful events can be addressed. These findings, therefore, not only show how single-cell forensics can be used in casework but demonstrate the value of single-cell data as a research tool able to illumine fundamental forensic problems.

Abstract Text: Recent developments in single-cell analysis have revolutionized basic research and have garnered the attention of the forensic domain. Though single-cell analysis is not new to forensics, the ways in which these data can be generated and interpreted are. Modern interpretation strategies report LRs that rely on a model of the world that is a simplification of it. It is, therefore, plausible that different reasonable models will assign impactfully different WoEs to some of these data. With one goal of research being to identify and understand sources of inconsistencies during early stages, we undertake a study that evaluates WoE at the limit of one single-cell Electropherogram (scEPG) across three architecturally distinct models.

To do this, we performance test three models on a set of 996 individual scEPGs and conduct one H1-true and 201 H2-true tests per scEPG. With these results, we confirm that scEPGs can well resolve between *source* hypotheses, regardless of what model was applied. We also observe that the WoE increases, on average, by 1 for every 1,000RFU of total intensity added until a plateau near the logarithm of the inverse of the random match probability is reached at ca. 22,000RFU.

By querying WoE calibration for each model, we determine if the evidence is over- or under-stated. We find that for WoE $\geq$ -1 hardly any calibration discrepancy is observed. There are rare instances, however, for which WoEs too strongly point in the negative direction, though H1 was true. This is the result of five scEPGs that not only exhibit extreme signal in stutter positions, but also carried little information in other loci. These findings show that all three models appropriately state WoEs for scEPGs when reporting positive WoE, and the two continuous model's WoE reasonably represent the findings when WoE < -1 for most loci. To further explore, we continue with paired analyses that evaluate the consistency in WoE, per scEPG, across models. Unlike unpaired analyses, this evaluation determines if similarly, well performing models return equivalent results for the same scEPG. With Pearson correlations of at least 0.98, and with 975 of 996 WoEs being within a range of 3, we conclude that the models, generally, perform equivalently. For the 21 scEPGs that did not return equivalent results and for the five scEPGs returning too strong negative WoE for true contributors, we proffer interpretive adaptions that extend beyond manually addressing the phenomena and maintain the locus independence assumption.

Single-Cell; Forensic DNA; Probabilistic Genotyping

B201 Low-Level DNA Recovery From Fired Cartridge Casings, Firearms, and Explosive Devices: Comparing Conventional Methods and Sequencing-Based DNA Typing

Leah Nangeroni, MS, The Center for Forensic Science Research and Education, Horsham, PA; Mirna Ghemrawi, PhD, The Center for Forensic Science Research and Education, Horsham, PA*

Learning Objectives: After attending this presentation, attendees will gain insight into a modified purification procedure that can be utilized on low template DNA samples, to include Fired Cartridge Casings (FCCs), Firearms (FAs), and swabbing from material recovered from Improvised Explosive Devices (IEDs). Attendees will also learn about both conventional and novel approaches to processing low-level DNA type samples.

Impact Statement: This presentation will benefit the forensic science community by presenting a modified automated extraction method to aid in the recovery of DNA from evidence items known to contain low levels and quality of DNA, such as FCCs, FAs, and IEDs. Additionally, the results will showcase the effectiveness of both conventional and novel downstream processing approaches for handling low-level DNA sample types.

Abstract Text: Low-level DNA samples often pose challenges for forensic laboratories in their successful profile recovery. However, these evidence samples remain crucial in forensic cases due to their impact on public safety within communities. Between 2017 and 2021, the National Integrated Ballistic Information Network reported a 103% increase in cases, reaching a total of 843,719 casings.[1] This rise in FA-related crimes in the United States highlights the critical need for laboratories to efficiently process FCCs and FA swabs. Another sample type, IEDs, made from various materials, including explosive materials and shrapnel, have shown DNA recovery even after exposure to explosive charges and fingerprinting recovery techniques in previous studies.[2-4] However, DNA recovery can be challenging for all these sample types due to the presence of metal in materials, heat exposure, and the inherently low quality of DNA present.

To successfully obtain DNA profiles, it is crucial to focus on two key steps: efficient upstream collection and extraction followed by downstream DNA typing. Various collection techniques are employed in DNA recovery, including the traditional method of using a wet swab followed by a dry swab. Recent developments in novel methods, such as Massively Parallel Sequencing (MPS), can provide an additional tool for laboratories to process these low-level DNA sample types.

This study focuses on processing these samples utilizing a modified automated extraction procedure, followed by splitting the extract into two parts: one for conventional DNA methods using Capillary Electrophoresis (CE) and the other for MPS. The study involved the following sample types (extracts) from participants: 90 FCCs, 24 FA swabs, and 20 IED swabs. For the IED collection, galvanized steel pipe bombs were constructed and handled prior to the Render Safe Procedure (RDS). Wet and dry nylon swabs were collected at five locations from the IEDs (end cap, blown end cap, pipe-blown end, pipe middle, and the pipe closed-end). For the FA collection, the trigger and the handle were tested, and FCCs were collected after test firing rounds. All samples were processed using a customized extra-large volume method on QIAGEN's EZ2 Connect instrument. This automated DNA purification technique facilitates substantial lysate volumes from either two swabs or two FCCs (2,000µL) and allows for low elution volumes (20µL), enhancing DNA fragment recovery with ethanol. Quantification was conducted using the Quantiplex Pro RGQ Kit, with average quantification values and degradation indices (DI) calculated.

From the IEDs, the DNA yields from the combined swabs reached up to 1,376pg, with a maximum Degradation Index (DI) of 15.07. For the FCCs, DNA yields reached up to 568pg, with a maximum DI of 37.9. The FAs yielded DNA up to 2,750pg, with a maximum DI of 28.68.

Samples were then processed using the Investigator 24plex QS Kit on the 3500 Genetic Analyzer for CE and the ForenSeq MainstAY kit on the MiSeq FGX for MPS. Data analysis was performed using GeneMapper ID-X (CE) and Universal Analysis Software (UAS). Based on quantitation results, successful outcomes are anticipated from samples using both downstream kits. This will result in DNA profiles, along with their corresponding quantitation results, that can be used to identify the best approach for processing these sample types.

Overall, this study demonstrates the successful recovery of DNA from these challenging samples, offering laboratories a valuable automated tool for handling this challenging sample type. Additionally, a decision tree for downstream processing will be developed, guided by both the quality and quantitative results obtained. Future work will include additional donors, test explosive procedures, and various types of explosive materials to further validate these methods.

Low DNA; MPS; Extraction

B202 Getting More From Less: Low-Level DNA Mixtures on Cartridges

Kari Danser, MS, Cybergenetics, Pittsburgh, PA; Jennifer M. Bracamontes, MS, Cybergenetics, Pittsburgh, PA; Mark W. Perlin, MD, PhD, Cybergenetics, Pittsburgh, PA; Matthew Legler, BS, Cybergenetics, Pittsburgh, PA*

Learning Objectives: TrueAllele Casework technology was able to use more DNA information than manual interpretation from cartridge casings, especially low-level and mixture data, providing more informative results.

Impact Statement: Cartridges are common pieces of evidence at crime scenes, and DNA information from cartridges is hard to obtain. TrueAllele technology can find information from this challenging data while also providing match information quickly.

Abstract Text: Cartridge casings are the empty shells left behind after a gun was fired and they are typically made of different metals and have different calibers. Nearly 200,000 cartridge cases are recovered annually at United States crime scenes.[1] The crime scenes where cartridges can be collected can range from homicides, aggravated assaults, robberies, and gang-related crimes. It has been shown that cartridges that were fired degrade any DNA that was left and have significantly less DNA.[2] Items with less DNA make it harder for crime labs to interpret the data and for crime scene investigators to collect DNA.

The cartridge study was designed to determine how much single-source identification information can be recovered from firearm cartridges as well as the best collection method and most informative cartridge type. Our study examined DNA data from seven different casing materials for a total of 910 cartridge samples. The cartridge samples were then collected using five different DNA collection methods. Once the DNA was collected, both manual interpretation and a probabilistic genotyping software, TrueAllele Casework, were used to analyze the cartridge data.

Once the single source cartridge samples were created, the George Washington University lab manually interpreted the DNA data. The lab used a threshold and an allele counting method. The laboratory counted how many alleles matched the reference that was expected to be present in the sample. The laboratory found the reference sample was present in 205 of the cartridge samples.

A TrueAllele trained analyst set up single-source requests for the program to solve. Upon review of the data, it was determined that the cartridge data was low-level mixtures. There was a total of 202 samples that were low level. There was a total of 431 mixtures present, which made up 47% of the total samples.

The presence of additional contributors was an unexpected result, so a TrueAllele analyst did further processing considering multiple contributors, with the number of contributors that was observed in the data. The total number of contributors for these mixtures ranged from two to five.

TrueAllele measured more information by looking at the lower-level data and mixtures and found a previously unidentified contributor. The unknown profile was informative with an expected genotype statistic of 30.36 ban. The unknown contributor was also found in 138 of the samples, ranging across the seven different cartridge types. Manual interpretation did not consider this unknown person as the method focused on the reference's allele pair only, limiting their interpretation of the data.

Based on the results of the study, the known reference was found in 351 cartridge samples using TrueAllele, compared to 251 samples using manual interpretation. The unknown person was found in 138 samples using TrueAllele where manual interpretation ignored the unknown person.

The most informative collection methods based on high genotype statistics were wet:wet or wet:dry. The least informative collection methods were scraping and soak and sonicate. The most informative cartridge types based on high genotype and inclusionary statistics were aluminum and steel. The least informative cartridge type was 45 fired.

Overall, TrueAllele was able to use more DNA information than manual interpretation from cartridge casings, especially low-level and mixture data.

Probabilistic Genotyping; Cartridge Casings; Mixture Analysis

B203 Integrated On-Chip PCR-Capture-Sizing-CE Microsystems for Ultrasensitive Forensic DNA Typing

Xiujun James Li, PhD, University of Texas at El Paso, El Paso, TX*

Learning Objectives: Conventional forensic Short Tandem Repeat (STR)) typing suffers from the challenges posed by: (1) mixture samples from several contributors, and (2) Low-Copy Number (LCN) DNA samples. Hence, a fully integrated microdevice for ultrasensitive forensic STR analysis has been developed that includes Polymerase Chain Reaction (PCR), post-PCR cleanup and inline injection, and Capillary Electrophoresis (CE).

Impact Statement: The high sensitivity of this on-chip forensic STR analysis can help solve challenges from LCN DNA samples and it has potential for single-cell forensic STR analysis, thus providing an ultimate solution for forensic DNA typing of mixture samples. Given high potability of this fully integrated microsystem, this portable forensic STR analysis microsystem with sample-in-answer-out capability is a significant advance in the development of rapid, sensitive, and reliable micro-total analysis systems for on-site human identification.

Abstract Text: Forensic scientists are always seeking techniques that can improve STR analysis for better throughput, cost, sensitivity, and reliability. Conventional Forensic STR typing suffers from the challenges posed by: (1) mixture samples from several contributors, and (2) LCN DNA samples. Microfabricated bioanalysis devices have the potential to address these challenges by providing lower reagent consumption, the ability to integrate multiple analytical steps on a single device, and facile scaling capability. Hence, a fully integrated microdevice for ultrasensitive forensic STR analysis has been developed that includes PCR, post-PCR cleanup and inline injection, and CE. After on-chip cell lysis, DNA was amplified in the PCR chamber with an integrated heater. The resulting biotin-labeled PCR products are electrophoretically injected through a streptavidin-modified capture gel where they are captured to form a concentrated and purified injection plug. The thermally released sample plug was injected into a 14-cm-long CE column for fragment separation and detection. We used DNA male sample 9948 as a model system to optimize DNA capture process and on-chip PCR-capture-sizing-CE. Since K562 cell line (instead of Jurkat cell) was reported to exhibit stable STR profiles over time, we applied the approach to test samples of K562 cells for multiplex STR typing. This system can produce full 9-plex STR profiles from oral swabs in about 3 hours. During the multiplex STR typing, this on-chip microsystem exhibited a limit of detection of close to single cells. The high sensitivity of this on-chip forensic STR analysis can help solve challenges from LCN DNA samples and it has potential for single-cell forensic STR analysis thus providing an ultimate solution for forensic DNA typing of mixture samples. Given high potability of this fully integrated microsystem, this portable forensic STR analysis microsystem with sample-in-answer-out capability is a significant advance in the development of rapid, sensitive, and reliable micro-total analysis systems for on-site human identification.

DNA; Criminalistics; Forensic Analysis

B204 So, You Want a Job in Forensic Science? Getting Hired as a Forensic Scientist From the Hiring Manager's Perspective

Matthew Gamette, MS, Idaho State Police Forensic Services, Meridian, ID; Rylene Nowlin, BS*, Idaho State Police Forensic Services, Meridian, ID*

Learning Objectives: Attendees will learn how to be effective in obtaining employment at a forensic science laboratory. Attendees will learn about errors, pitfalls, and things to avoid doing that will stifle an application to work in a desired lab or field.

Impact Statement: Hundreds of students and student affiliates attend the American Academy of Forensic Sciences (AAFS) meeting every year. There is a hiring session for labs to interact with potential employers. However, there has never been a presentation for students about what employers are looking for, how they go about the hiring process, and what things will lead you to not get a job with a publicly funded agency. This presentation will be a huge benefit for these students by helping them to avoid pitfalls they will encounter as they apply for full-time work. The presentation will also help colleges and universities that are preparing their students for these interviews and jobs. Further, the impact to other forensic hiring managers in tools that will be discussed to help them make better hires will lead to a better forensic science workforce.

Abstract Text: Forensic science service providers advertise openings for positions every year and hope to find qualified candidates to fill those positions. Often, candidates for these positions do not understand what is behind the hiring curtain at state and local agencies making these hiring decisions. Programs like the Forensic Science Education Programs Accreditation Commission (FEPAC) -accredited organizations and other colleges and universities try to prepare their students to qualify for and secure these positions. However, there are certain applicant knowledge and experience gaps that have been identified by forensic science service providers that are blind spots to the applicants and even educational institutions. Examples include preparation for technical- and situational-based interview questions, appropriate attire and demeanor for government employment interviews, working with government agency Human Resource (HR) representatives, providing accurate and complete documentation, and what interview panels are looking for in an excellent candidate. Often, very qualified candidates on paper are not successful in obtaining employment in a forensic lab because of background or polygraph issues, inappropriate social media postings, or poor references from former employers or internships. Something as simple as not knowing anything about the local area, the organization, or the organization website, mission, vision, values, size, forensic disciplines, etc. may completely derail an otherwise qualified applicant interview.

This presentation by current forensic science service provider hiring managers will focus on skills, tools, abilities, and knowledge that will help applicants obtain gainful employment in a forensic science laboratory. The presenters have extensive experience hiring new trainees and are currently writing minimum qualification documents, evaluating applicants, participating in candidate interviews, and offering positions at forensic science laboratories. Presenters have also attended many focus groups on this topic with national organizations interested in improving the hiring and onboarding processes. While this topic will be focused on individuals looking for their first job in forensics, some focus will be directed to those scientists looking to move from one laboratory to another, and what laboratory leaders and managers are looking for in experienced scientist applicants. Information will also be presented about new standards and state laws regarding minimum qualifications for positions that are changing the way employers are hiring. In addition, presenters will discuss tools that hiring managers could be using to evaluate and select candidates. These tools include artificial intelligence, cognitive tests, and deception detection testing. Employers are looking to hire and retain exceptional employees, and the vetting process for new employees is a critical part of the selection. Attendees will take away new ideas and thoughts about obtaining employment or hiring in a more effective way.

Job; Interview; Education

B205 The Role of the National Technology Validation Implementation Collaborative (NTVIC) in Forensic Technology Implementation

Matthew Gamette, MS, Idaho State Police Forensic Services, Meridian, ID*

Learning Objectives: Attendees will learn about the new National Technology Validation and Implementation Collaborative (NTVIC) and the mission, vision, and values of the organization. They will also learn about a new collaborative model to implement new and emerging technologies in a more expeditious and comprehensive way. Attendees will be provided with information about data publication and sharing. A major learning objective is how to leverage partnerships between researchers, instrument manufacturers and representatives, forensic science practitioners, and others to develop best practices and excellent work practices. The final learning objective is for the attendees to understand how collaboration will lead to established publish policy, procedures, validation plans, validation studies, and implementation plans for Forensic Investigative Genetic Genealogy (FIGG), Rapid DNA, 3D Firearms Analysis, and Single-Cell DNA instruments and technologies in public forensic laboratories.

Impact Statement: The NTVIC is a revolutionary organization that is changing the way that forensic science technology implementation and advancement is happening in the United States. Attendees will gain a new appreciation of the need to publish validation data in a collaborative way to aid the expedited implementation of technology. Attendees will understand how practitioners are leading the implementation of FIGG technology into publicly funded laboratories in the United States and understand more about the path for this implementation to happen in their laboratory. Attendees will also understand more about other emerging technologies and potential timelines for those to be implemented in laboratories. The goal is to help the forensic science community understand that the lift to implement new technology is easier when we are all pulling toward the same goal and leveraging the resources that we have to get to that goal.

Abstract Text: The NTVIC was established in 2022 with a vision to collaborate nationally on forensic science validation, method development, and implementation in the public sector.[1] The NTVIC has expanded to include the state public forensic laboratories in over 30 states (and growing). Efforts of the NTVIC to collaborate validations between public laboratories, instrument manufacturers, public and private researchers, and other industry experts has proven to increase the speed of implementation, quality, and scientific nature of these technologies. This presentation will discuss plans to establish and publish policy, procedures, validation plans, validation studies, and implementation plans for Forensic Investigative Genetic Genealogy (FIGG), Rapid DNA, 3D Firearms Analysis, and Single-Cell DNA instruments and technologies in public forensic laboratories. NTVIC publications will be discussed, plans for future growth will be outlined, and the vision of the organization to collaborate on forensic science validations will be presented. The NTVIC strategic vision of open, transparent, and scientific publication of validation data will advance forensic science by ensuring that new technologies implemented in forensic science laboratories have been scientifically evaluated, peer reviewed, and transparently published for use in legal settings.

Specifically, this presentation will discuss the implementation of FIGG technology in the United States by the NTVIC setting forth robust policy and procedure guidelines. These NTVIC publications include model state legislation and recommended best policies and procedures for responsible use of the technology and the investigative technique.[2-4] The process of collaboration employed by NTVIC to achieve consensus recommendations along with the adjudication process the NTVIC applies to vet and respond to public criticisms and comments will be presented. In addition, efforts to develop model FIGG training programs for DNA staff, genealogy researchers, and law enforcement investigators will be discussed. Further, NTVIC publications regarding validation of various FIGG technologies and validation plans for Whole Genome Sequencing in public laboratories in the United States will be summarized. Finally, other considerations, such as cost benefit analysis evaluation for implementation strategies, will demonstrate the value represented by the NTVIC collaborative approach.

Validation; Technology Transition; Quality Assurance

B206 A National Survey and Interviews on Training in Forensic Science Service Laboratories in the United States Evaluative Report

Kelly M. Elkins, PhD, Towson University, Towson, MD*

Learning Objectives: By attending this presentation, attendees will gain insights into the content and emphasis of forensic DNA training onboarding programs at public and private Forensic Science Service Providers (FSSPs) in the United States through survey responses and development of a standardized curriculum for forensic DNA training and education.

Impact Statement: This presentation will impact the forensic science community by providing an opportunity to learn the results of a national survey and interviews conducted in 2024 on the content and emphasis of DNA training programs at public and private FSSPs in the United States funded by the National Institute of Standards and Technology (NIST) through a cooperative agreement to Towson University.[1] New hires in forensic laboratories undergo training that may last from six months to two years. The time commitment (six month minimum) is dictated by the Federal Bureau of Investigation (FBI) Quality Assurance Standards (QAS) for Forensic DNA Testing Laboratories for a DNA analyst who "conducts and/or directs the analysis of forensic samples, interprets data and reaches conclusions."[2] Additionally, there are consensus-based standards for lab testing and reporting, and new hires need to be aware of these standards and how they impact their work. Standards are a means to strengthen forensic science and promote scientifically supported methods and analysis approaches.

Abstract Text: To gather information and opinions from forensic science practitioner leaders about training activities, consent and 20-question multiple-response survey and paired semi-structured set of interview questions were created, and Institutional Review Board (IRB) approval was obtained. The survey and interview requests were sent to forensic lab directors, assistant directors, and/or DNA technical leaders across the United States to public contacts or those obtained through social media. Thirty-two survey responses were collected, and 12 interviews were conducted. The qualitative interviews were developed to learn about the characteristics or values that are sought in new analysts, the focus and timeline of the training program, training materials used, concepts new hires learn, how learning is assessed, the passing threshold score, ideas, needs or plans for improvement, and near-future modification plans. The top three focuses of the training are lab techniques (extraction, quantitation, amplification, and capillary electrophoresis), Short Tandem Repeat (STR) typing, and mixture analysis. The top items respondents would like to spend more time offering training on are troubleshooting, validation, and root cause analysis. Ethics violations and failure to pass the competency tests and mock trial, even after remediation, are the top reasons new hires fail training. Interviewees reported that they valued critical thinking, decision-making, ethics, willingness to admit mistakes, and strong pipetting skills and shared that they use a variety of materials, including books, recorded presentations, slides, manuals, and Standard Operating Procedures (SOPs) for training. Labs employ different training program models, including modular, start-to-finish, individual trainee, and cohort. Training is individualized and remediation on components is offered, if necessary. Interviewees communicated that they would like more off-the-shelf training materials and commercial options of training samples and mock cases.

Insights from this study were used to guide the preparation of a forensic DNA training and education curriculum that aligns to American National Standards Institute/Academy Standards Board (ANSI/ASB) Standard 1153 that is being uploaded to a public website and accessible by the forensic community and beyond at no cost. The study provides insight into processes and pathways that can be implemented to more rapidly train new hires so they can contribute to casework processing and reducing or eliminating backloads. Additionally, this project can serve as a model for other disciplines seeking to understand training content and emphasis in their specialties through mapping training documents to standards, creating surveys and interviews to understand training goals and priorities, and standardizing training curriculum to published standards.[1-3]

Training; Standards; Survey

B207 Planning for and Executing a Disaster Response: The Rapid DNA Mass Disaster Emergency Response and Preparedness Toolkit

Mikalaa M. Martin, BS, RTI International, Cincinnati, OH; Taylor L. Koepfler, MSFS, Wisconsin Department of Justice-Division of Forensic Science, Verona, WI; Jason M. Chute, MSFS, RTI International, Research Triangle Park, NC; Shannon Krauss, PhD, RTI International, Research Triangle Park, NC; Laura J. Kuyper, MFS, Marshall University Forensic Science Center, Huntington, WV; Katie Scott, MSFS, Marshall University, Huntington, WV; Jeri D. Ropero-Miller, PhD, RTI International, Research Triangle Park, NC*

Learning Objectives: Attendees will learn the following from this presentation:

- A background on how the Rapid DNA Mass Disaster Emergency Response and Preparedness Toolkit was developed, including key collaborations with agencies who have previously deployed to mass disaster events through virtual questionnaires and discussions and completion of virtual mock exercise scenarios.
- An overview of all 30+ materials contained within the Rapid DNA Mass Disaster Emergency Response and Preparedness Toolkit as well all additional resources that have been collated into an easy-access repository to support agency's emergency response preparedness.
- An explanation of the intended usage of materials contained within the Rapid DNA Mass Disaster Emergency Response and Preparedness Toolkit, including demonstrations of how to access the toolkit; download materials; use the interactive features; and adapt them to fit their agency's needs and existing frameworks, policies, and standard operating procedures.
- How to get in contact with the team that developed the Rapid DNA Mass Disaster Emergency Response and Preparedness Toolkit with any questions, suggestions for improvement, or development of additional materials to integrate within the toolkit for further benefit to the forensic community.

Impact Statement: Mass disaster events by nature are unpredictable events that are unique in nature and are coupled with their own particular challenges. When an agency receives notification that a mass disaster event has occurred and response is needed, time is of the essence. This presentation of the Rapid DNA Mass Disaster Emergency Response and Preparedness Toolkit will provide valuable no-cost, adaptable resources to support immediate deployment response to mass disaster events of any kind (e.g., building collapses, wildfires, aviation accidents). The entirety of the forensic community from law enforcement, DNA laboratory personnel, crime scene investigators, medical examiner/coroner personnel, and other first responders and emergency response personnel will benefit from having access to these resources. Within the forensic community, due to the nature of the work and ever-prevalent resource barriers, many agencies do not have the time, funding, personnel, or other resources to devote to building a robust emergency response plan. These resources will equip agencies with a foundation of over 30 materials to alleviate the resources required for developing an emergency response plan that can be further adapted to meet any agency's specific needs and fit within their existing frameworks, policies, and standard operating procedures. When it comes to mass disaster events, every second counts, and this toolkit aims to alleviate the burden faced by the agency when that unpredictable and unfortunate response call is received.

Abstract Text: The National Institute of Justice (NIJ's) Forensic Technology Center of Excellence (FTCOE) is dedicated to elevating the status of forensic science through advancing technology, sharing knowledge and addressing challenges encountered within the field. Through engagement with early adopters, the FTCOE develops no-cost, evidence-based resources that support technology adoption and knowledge transfer that aid Forensic Science Service Providers (FSSPs) in addressing and overcoming emerging challenges.

During this presentation, attendees will learn about the FTCOE's partnership with Marshall University Forensic Science Center (MUFSC) and other FSSPs to develop a no-cost emergency response toolkit to support the immediate deployment of rapid DNA instrumentation for mass disaster events. This toolkit aims to furnish FSSPs with adaptable, essential resources for the preparation and deployment of rapid DNA instrumentation to identify unidentified human remains.

This toolkit is the product of four key development phases. First, material was exchanged with agencies experienced in mass disaster response planning (e.g., Palm Beach Sheriff's Office) to establish a foundation for the toolkit. Second, a gap analysis was conducted through questionnaires and interviews with past deploying agencies (e.g., Miami Dade Police Department, Butte County Sheriff's Office). Third, mock scenarios were developed to identify disaster-specific resources (e.g., Kentucky State Police, Lee County Sheriff's Office) necessary for a comprehensive toolkit. Finally, the development team participated in a mass disaster exercise conducted by the Kentucky State Police, utilizing the mock scenario developed via this study.

Through the development of this toolkit, engagement with early adopters assisted with identifying five key deficiencies and areas for improvement: Strategy, Infrastructure, Database (e.g., Laboratory Information Management System) Integration, Collaboration, and Training. These gaps were specifically addressed in the development of this toolkit, enhanced with disaster-specific resources for versatile deployment. Validation of the toolkit's efficacy was demonstrated during a mock mass disaster exercise, showcasing its practical implementation in disaster response.

By the end of this presentation, attendees will gain foundational resources for adopting or enhancing an emergency response plan that is compatible with their agencies' current infrastructure, offering valuable insights and tools for agencies at any stage of their emergency response preparedness process.

Rapid DNA; Mass Disaster; Unidentified Persons

B208 Standards Development Activities in Trace Materials

Sandra Koch, PhD, National Institute of Standards and Technology, Gaithersburg, MD; Celeste M. Grover, MSFS, Oregon State Police, Forensic Services Division, Clackamas, OR*

Learning Objectives: After attending this presentation, attendees will have a better understanding of the status of discipline-specific standards pertinent to the examination and interpretation of trace materials.

Impact Statement: The presentation will impact the forensic science community by creating greater awareness of standards development activities related to trace material examination and interpretation. It will also increase awareness regarding training, tools and resources that support implementation, compliance monitoring, and broader understanding.

Abstract Text: The Organization of Scientific Area Committees (OSAC) for Forensic Science was created to strengthen the nation's use of forensic science by promoting the use of discipline-specific forensic science standards. To this end, the OSAC drafts standards that are forwarded to Standards Development Organizations (SDOs) that ballot and publish them. The OSAC also reviews standards and recognizes them on the OSAC Registry, which serves as a central repository of high-quality, consensus-based, technically sound standards.

As of July 2024, the Trace Materials Subcommittee has 24 published and 6 proposed standards on the OSAC Registry. Work is on-going for additional documents making their way through the subcommittee, OSAC Registry, and ANSI/ASTM processes.

The following (new or updated) standards were added to the OSAC Registry in the past year:

Fibers:
Standard Guide for Forensic Analysis of Fibers by Infrared Spectroscopy
Standard Guide for Forensic Examination of Fabrics and Cordage
Standard Guide for Forensic Examination of Dyes in Textile Fibers by Thin-Layer Chromatography
Standard Guide for Microscopical Examination of Textile Fibers

Geology:
Standard Practice for Use of Color in the Visual Examination and Forensic Comparison of Soil Samples
Standard Guide for Collection of Soils and Other Geological Evidence for Criminal Forensic Applications
Standard Guide for Forensic Analysis of Geological Materials by Powder X-Ray Diffraction

Hair:
Standard Practice for Training in the Forensic Examination of Hair by Microscopy
Standard Guide for Forensic Examination of Hair by Microscopy

Physical Fit:
Standard Guide for Forensic Physical Fit Examination

Polymer:
Guide for Using Micro X-Ray Fluorescence (μ-XRF) in Forensic Polymer Examinations.

Published standards that have been reapproved and remain on the OSAC Registry while going through the ASTM 5-year review process or waiting for OSAC Registry approval include:
Standard Guide for Forensic Paint Analysis and Comparison
Standard Test Method for Forensic Comparison of Glass Using Micro X-ray Fluorescence (μ-XRF) Spectrometry
Standard Guide for Using Infrared Spectroscopy in Forensic Paint Examinations
Standard Guide for Fourier Transform Infrared Spectroscopy in Forensic Tape Examinations

Published standard eligible for the OSAC Registry:
Test Method for Determination of Trace Elements in Soda-Lime Glass Samples Using Laser Ablation Inductively Coupled Plasma Mass Spectrometry for Forensic Comparisons (revised).

Proposed standards added to the OSAC Registry:
OSAC 2022-S-0017, Standard Guide for Microspectrophotometry in Forensic Fiber Analysis
OSAC 2022-N-0018, Standard Practice for a Forensic Fiber Training Program
OSAC 2022-S-0019, Standard Guide for Forensic Examination of Fibers
OSAC 2023-N-0005, Standard Practice for Training a Forensic Glass Practitioner
OSAC 2023-N-0011, Standard Practice for a Physical Fit Analysis Training Program
OSAC 2024-S-0015, Standard Guide for Evaluating Physical and Optical Characteristics in Forensic Tape Examination and Comparison.
OSAC 2023-N-0027, Standard Guide for Forensic Trace Evidence Recovery

Documents going through the ASTM process:
WK72932 Standard Guide for Forensic Glass Analysis and Comparison

Documents under development:
Standard Guide for Interpretation and Reporting in Forensic Comparisons of Trace Materials.
Standard Practice for the Forensic Analysis of Geological Materials by Scanning Electron Microscopy (SEM) and Energy Dispersive X-Ray Spectrometry.
Standard Guide for Polarized Light Microscopy of Soils and Geological Materials for Forensic Applications.
Standard Guide for Forensic Examination of Textile Damage
Standard Guide for Forensic Examination of Fibers and Textiles Using Fluorescence
Standard Terminology Relating to Forensic Analysis of Trace Evidence Materials
Standard Guide to Raman Spectroscopy in Forensic Polymer Examinations
Standard Guide for Using X-ray Diffraction in Forensic Polymer Examinations

Subcommittee priorities for new documents and research needs for the community to address will be discussed during the presentation.

B209 Differentiating Soil by Color and Mineralogy for Soil Comparisons: An Experiment Using Soil From North Carolina

Hannah Dickson, MS, Tetra Tech, Ponte Vedra Beach, FL; Libby A. Stern, PhD, Federal Bureau of Investigation Laboratory, Quantico, VA; Ian Saginor, PhD, Federal Bureau of Investigation, Quantico, VA; Kelly A. Meiklejohn, PhD, North Carolina State University, Raleigh, NC; Jodi Webb, MS, Federal Bureau of Investigation Laboratory, Quantico, VA; Jack Hietpas, PhD, John Jay College of Criminal Justice, New York, NY; Michael Smith, PhD, Federal Bureau of Investigation Laboratory, Quantico, VA*

Learning Objectives: This presentation will summarize the use of soil color, mineral grain identification, and X-ray diffraction in forensic soil examinations and test the spatial variability of the properties at a range of spatial scales in effort to document what differences may be expected and those that may be used to exclude a common source of material.

Impact Statement: This presentation could inform the forensic science community about the unique qualities of soil trace evidence and the interpretation of results within soil comparison examinations.

Abstract Text: **Goal of Study:** To test the potential application of novel examination methodology in forensic soil comparisons, surface soils were collected in triplicate (1m apart) from 30 locations in North Carolina with paired sites with distinct vegetation cover (n=180). The experimental design is primarily aimed at assessing the potential use of E-DNA in soil comparison (presented in companion presentation), organic rich soils present at half the sites. However, this presentation assesses the similarities and differences observed among these samples using methods commonly used in soil examinations (color, mineral identification by Polarized Light Microscopy [PLM]).

COLOR: Soil color was measured in CIE L*a*b* space, both of the bulk soil and a fine-grained fraction to allow quantification of color difference. The derived metric, ΔE00, corresponds to perceptible color difference, where a color difference value < 1 will be imperceptible, and a value of > 10 is similar to exceeding the faint soil color contrast category used the United States Department of Agriculture (USDA) Soil Survey.[1,2] Approximately 3% of triplicate soil samples showed color differences of ΔE00>10 in the fine fraction (6% in bulk), meaning that on small spatial scales soil color is relatively similar (few false exclusions), and these errors could be further mitigated by thorough collection of known exemplars, whereas soil color differences between paired sites (collected 12 to 490 m apart) exceed this ΔE00 >10 threshold 21.8%, 18,1 % and 27.8 % of the time for bulk color, fine fraction color or the combination, respectively. Comparing all 180 soils, 41.9% (bulk) and 56.2 % (fine fraction) have ΔE00 >10. This indicates that color alone can differentiate among many soil samples and is useful as an initial screening method.

MICROSCOPY: Soil (1.6–6.6g) was washed to mount mineral for examination by PLM. Most mineral types present at >~1 % modal abundances not helpful at differentiation among locations as all samples included, feldspar, and opaque grains (two locations had other minerals >1% abundance). The trace grains on slides containing ~13,000 grains were assessed for "drop out" of low abundance mineral types among triplicate soils. The maximum number of grain-types observed in 1 slide with zero observed in from soil 1m away was 14 (biotite). The three mineral types with the highest grain count with dropout from an adjacent soil were biotite, chlorite and kyanite, all which have perfect cleavage. This high grain count with "drop out" could result from grain fracture along cleavage planes during sample preparation. The mean and median of grain counts with dropout are two and three respectively, suggesting caution should be given for the absence of a single mineral type observed in trace amount in one sample and absent in another. The presence of at least one unique grain type in all three samples at one site absent from all three samples at its paired sites occurred in 14 of 30 locations, whereas these mineral differences occur in 81% of comparisons when including all 60 sites.

The combination of color and mineral grain presence improves the capacity to differentiate soils. In this study, 92 percent of the sites could be differentiated by comparing average color with the unique presence/absence of a mineral type among all three sub site samples. There may be other notable characteristics allowing the differentiation of soils from these sites, for example, biological components, morphological features (grain size distribution, grain shape, grain surface texture, zoning, inclusions), or minerals in the clay-sized fraction of the soil.

Soil Analysis; Microscopy; Minerals

B210 Soil Discrimination by Particle-Correlated Raman Spectroscopy

Drew M. Kuroda, BS, University of New Haven, New Haven, CT; Jasmine Kaur, MFS, University of New Haven, West Haven, CT; Peter R. De Forest, DCrim, Forensic Consultants, Ardsley, NY; Marisia A. Fikiet, PhD, University of New Haven, West Haven, CT; Joshua Christensen, University of New Haven, Glastonbury, CT; Peter D.B. Harrington, PhD, Ohio University, Athens, OH; Brooke W. Kammrath, PhD, University of New Haven, West Haven, CT*

Learning Objectives: After attending this presentation, attendees will learn about the discrimination capability of Particle-Correlated Raman Spectroscopy (PCRS) for soil samples.

Impact Statement: This presentation will impact the forensic science community by evaluating the discriminating potential of PCRS for the differentiation of soil samples using varied statistical approaches, including hypothesis testing and chemometric methods.

Abstract Text: Forensic soil analysis has had a rich history of providing valuable information for investigating criminal events. However, many modern forensic laboratories have stopped performing this analysis due to the perception that it is either too time consuming or labor intensive. Further complicating the issue is the view that many forensic soil analytical methods are subjective due to their reliance on feature comparisons. PCRS is a new method that may address both of these concerns by providing automated and objective analysis and comparison of sample mixtures. PCRS is an integrated technique that combines automated image analysis with Raman spectroscopy. Particle imaging determines particle size and shape distributions for each component in a sample, yielding detailed morphological information (e.g., circularity, area). At the same time, Raman spectroscopy can probe the molecular chemistry of specific particles of interest. In forensic soil analysis, PCRS is therefore able to non-destructively identify the types of minerals present and provide morphological information about individual mineral grains. Particle size distributions can be generated for the entire sample or for each mineral present, along with quantitative information on the relative amount of each type of particle.

Mineral counts and morphological properties are used as the basis for classification and comparison of Raman-identified particles. The discrimination potential of PCRS was explored using a variety of statistical methods from data collected from topsoil samples collected in triplicate from 30 different locations in the northeast United States. First, error rates were investigated using traditional comparative statistics (i.e., hypothesis testing) with eight match criteria. The match criteria tested consisted of confidence intervals based on range, range +0.00005 , mean +1 standard deviation, mean +2 standard deviations, t-test at 95% confidence, t-test at 99% confidence, mean +0.0001, and mean +0.0002 (Miller criterion). The resulting match criteria were evaluated based on their Type 1 (false negative) and Type 2 (false positive) error rates, with the preferred criteria being one that minimizes both. The particle size and other morphological property distribution comparisons were evaluated using a two-sample Kolmogorov–Smirnov test, due to its sensitivity to differences in both location and shape of the empirical cumulative distribution functions of the two samples. Multivariate statistical methods were explored for the discrimination of PCRS mineral data, which included creating and testing models with Partial Least Squares-Discriminant Analysis (PLSDA), Support Vector Classification (SVC), and Hierarchical Cluster Analysis (HCA). Ultimately, this research provides statistical evidence for the discriminatory power of minerals and their morphologies for the classification and source identification of soil samples.

PCRS; Raman Spectroscopy; Discrimination

B211 An Elemental Analysis of Glass Powder on Spent Projectiles

Shirly Montero, PhD, Arizona State University, Phoenix, AZ; Summer Garcia, Arizona State University, Glendale, AZ*

Learning Objectives: The attendee will be able to explain how to implement a method to analyze the elemental composition of glass in powder form.

Impact Statement: This presentation will impact the forensic community by adding an analytical method that could support or exclude scenarios proposed during the reconstruction of a shooting incident.

Abstract Text: In forensic investigations of cases involving shootings, the reconstruction of the trajectory of a bullet is of relevance ,particularly when considering the transfer of material from intermediate targets.[1,2] Glass fragments are among the traces that can be useful to analyze on recovered bullets. Glass fragments have been long recognized as useful trace evidence; they are easily transferable, and broken glass can give a timing and location of an event (the moment the glass was broken, and which glass was broken). The glass evidence embedded in a spent projectile, usually in powder form, can be associated with potential sources or exclude other sources, testing the proposed trajectory of the projectile.

Work previously presented provided independent evidence for shooting reconstructions through comparative analysis of glass evidence using the elemental composition and optical properties of the glass. However, the sample size and complex matrix excluded the direct use of the gold standard for float glass Laser Ablation-Inductively Coupled Plasma/Mass Spectrometry (LA-ICP/MS). This study explored the robustness of a shorter modified method to analyze glass powder by LA-ICP/MS based on American Society for Testing and Materials (ASTM) 2927-23. This modified method also included the use of a simple signal integration algorithm for the automated processing of the shorter time resolved signal, minimizing operator bias. The advantages and disadvantages of the analysis using these modifications will be discussed.

The set of samples consisted of simulated casework samples from vehicle glass (float soda-lime) prepared by shooting through different glass panes at typical angles found in vehicles. The spent projectiles were recovered from a loose Kevlar receiver box. The proposed source glasses were then compared to the glass powder embedded on recovered spent projectiles. Because of the ablation cell configuration, it was possible to mount the spent projectiles directly in the cell for ablation. Standard reference materials included CFGS2 for calibration and NIST SRM 1831, and National Institute of Standards and Technology (NIST) Standard Reference Material (SRM) 612 as verification standards. All the elemental profiles were compared using the criteria in ASTM standard methods E2927-23. In our limited universe situation, where the number of sources were few, known, and distinguishable by chemical composition, we were able to accurately associate the recovered traces to the corresponding source.

Trace Analysis; Glass; Python

B212 Data Fusion From Infrared, Elemental, MSP, and Raman Analysis Techniques to the Maximization of the Efficiency of the Analytical Sequence for the Forensic Examination of Paint Evidence

Patrick Buzzini, PhD, Sam Houston State University, Huntsville, TX; Morgan N. Carpenter, BS, Sam Houston State University, Conroe, TX; Swathi Murali, MS, Sam Houston State University, Huntsville, TX; James Curran, PhD, University of Auckland, Auckland, Auckland, New Zealand*

Learning Objectives: After attending this presentation, attendees will gain knowledge about the advantages of combining analytical data from different spectroscopic methods when applied in the context of automotive paint examinations for interpretation purposes.

Impact Statement: This presentation will impact the forensic science community, with emphasis for trace evidence examiners, by exploring various data fusion methods to obtain a data sets of discriminating features in the light of addressing interpretive aspects (i.e., source attribution questions) following comparative examinations of paint specimens.

Abstract Text: Forensic paint examinations are conducted following an analytical sequence that typically starts with microscopical methods followed by methods of instrumental analysis. The type and number of methods utilized during analyses primarily depends on the quality and quantity of unknown specimens recovered in each case (i.e., multilayered fragments yield more analytical information than abrasive smears resulting from abrasions).

While comparing sets of recovered specimens and reference samples, data obtained from the various techniques are usually evaluated sequentially by technique, in the sense that when exclusionary differences are noted between compared sets for a given technique, then there is no need to proceed with further testing and the examiner typically reports an exclusion. In cases where the analyst cannot differentiate the compared sets with a method, a subsequent one is applied until all relevant and available methods have been applied. When the compared sets cannot be distinguished at the end of an analytical sequence, an overall evaluation of the data is made to typically address the question of a common source between them.

While evaluating the question of a common source, a critical facet is the estimation of the chance to randomly observe another coated object in a population of interest that exhibits the same properties as those observed within the questioned specimens as a function, for example, of the observed microscopic features *and* infrared profile *and* elemental profile. Currently this process is carried out subjectively and to date any effort made to assist practitioners with the implementation of objective statistical or probabilistic approaches has been limited to the consideration of data from methods taken in isolation. Hence, this project aimed to maximize the efficiency of analytical schemes for forensic paint examinations by evaluating various data fusion approaches applied to infrared, elemental, Microspectrophotometric (MSP), and Raman analysis techniques.

The study focused on the definition of the features of interest detected with the proposed techniques, the evaluation of each technique to reliably detect minor components resulting from a heterogenous paint formulations, and the identification of dependencies or redundancies of analytical information collected from the different analytical techniques. Different sample sets were used to study different aspects of the contribution of the utilized techniques (e.g., sensitivity, selectivity, or redundancy), including different brands of spray paint samples of commonly encountered colors, binary mixtures of refinishing automotive basecoat paints, and binary mixtures of interior architectural paints featuring color desaturation with white and black components. Different low-level and mid-level data fusion approaches were applied including sparse Linear Discriminant Analysis (sLDA) and Random Forests within each instrument and combined the classification results with majority voting. It was observed that the "fused" or combined results gave high levels of performance—in terms of classification accuracy compared with the individual classification results—thus demonstrating the effectiveness of data fusion. Functional Data Analysis (FDA) was also investigated as a means of reducing the data dimensionality before applying classification methods.

This approach proved to be remarkably efficient and offers a novel approach to both analyzing spectral data and performing data fusion. These methods appeared to perform better than the typical data fusion methods consisting of Multiblock classification by means of Common Components and Specific Weight Analysis (CCSWA) and Sequential and Orthogonalized Partial Least Squares (SO-PLS) regression.

Trace Analysis; Paint; Criminalistics

B213 Wait, Hot Cooking Oil Turned Your Shirt From Green to Orange?

Tiffany Rodriguez, MS, Bureau of Alcohol, Tobacco, Firearms, and Explosives, Atlanta, GA; William Perdue, MPA*, Bureau of Alcohol, Tobacco, Firearms, and Explosives, Atlanta, GA*

Learning Objectives: After attending this presentation, attendees will learn and see the effect heat, cooking oil, and solvents can cause on colored fabric. They will also learn different tests to determine what could cause the color damage.

Impact Statement: This presentation will impact the forensic science community by presenting methods to determine the effects that heat, cooking oils, and solvents can have on the dye of a garment.

Abstract Text: In June 2023, a Bureau of Alcohol, Tobacco, Firearms, and Explosives (ATF) Special Agent Certified Fire Investigator (CFI) received a request for assistance from a local district attorney's office. They were preparing to prosecute a case where the defendant was accused of intentionally burning his girlfriend. At the time of arrest, the defendant stated to police that his girlfriend burned herself during an altercation that occurred between the two of them while she was cooking at their stove with "hot oil." The victim stated at the time that the suspect poured Isopropyl Alcohol (IPA) over her and lit her on fire using a cigarette lighter. However, in the months since the incident, she recanted her statement, even writing a letter to the judge stating that she had in fact, burned herself with "grease." Investigators and prosecutors were now left with competing hypotheses as to what occurred.

The available evidence included digital images of the victim, her garments, and the scene after the altercation. As seen from the images, the victim had discernable skin burns on her right shoulder, right side of her neck, and her right wrist. The images of the damaged clothing (a bra and a tunic) appeared to correspond to the same areas. The remaining images did not reveal any signs of heat damage to the apartment. In addition, ATF investigators could not conduct a fire scene examination, since they were not notified from the onset and several months had elapsed since the incident.

The CFI reached out to the ATF Forensic Science Laboratory-Atlanta (FSL-A) for assistance. Traditional fire debris testing was not a viable option as the suspected accelerant would no longer be present on the garments. Examination of the damage to the tunic would require a non-traditional examination. The tunic appeared to have dye discoloration and possible thermal deterioration of the green cotton. Ultimately, the fact in question was whether the damage to the clothing was caused by hot cooking oil or ignited isopropyl alcohol. A series of examinations were conducted on the fabric to determine if the question could be answered.
The following findings were noted:

- Visual examination of the clothing revealed no grease/oil stains.
- Testing revealed neither IPA nor cooking oil at room temperature discolored the garment from green to various shades of orange as was observed in the original damaged area. The cooking oil does leave a greasy patch that is slightly darker than the surrounding area.
- When the tunic is subjected to hot vegetable or canola cooking oil (up to 235°C), the fabric does not discolor like the original damaged area. Nor does it deteriorate or char. References cite a range of 177-232°C as preferred to fry most foods.[1,2]
- In controlled temperature dry heat examinations, fabric discoloration began to appear when subjected to 275°C for 90 seconds; however, the intensity of discoloring was not consistent with the thermal damage that was observed on the tunic. At 300°C, the fabric completely discolored in two minutes time; however, no charring or total deterioration was present.
- When 91% IPA is splashed on the garment and ignited with a disposable lighter, the garment immediately burns, discolors, and deteriorates. When cooking oil is splashed on the garment and ignited with the same lighter, the garment is slow to burn and chars heavily with minimal discoloration.

The results of this testing support the premise that the damage observed on the shirt is consistent with originating from an ignited solvent such as IPA and inconsistent with a hot or ignited cooking oil source. The presentation will deep dive into the process that was used to reach these conclusions.

Trace Analysis; Textiles; Fabric Damage

B214 Skeleton in the Stream: Unraveling the Murder Mystery of the River's Silent Witness

Akhilesh Pathak, MD, All India Institute of Medical Sciences, Bathinda, Punjab, India*

Learning Objectives: The attendees will learn about the various challenges a forensic examiner faces during the autopsy of the dead bodies recovered from the water. They will also learn about the multiple factors that can hinder the determination of the cause of death, time since death, and identification of the deceased in similar cases. Overall, attendees will have a deeper understanding of the complexities of examining skeletal remains recovered from water environments. They will be equipped with practical skills, updated knowledge, and a comprehensive approach to conducting thorough and accurate forensic examinations in such cases.

Impact Statement: The presentation will enhance the community's understanding of drowning deaths and the complexities associated with it. The presentation will also emphasize recognizing and interpreting postmortem changes due to prolonged water exposure. This will assist forensic pathologists in making accurate time-of-death estimations and understanding the decomposition process in aquatic environments. By elucidating the forensic challenges and potential pitfalls in water-related autopsies, the presentation will aid forensic pathologists and legal professionals in understanding the complexities involved. This can help them make more informed decisions in legal proceedings and criminal investigations. The presentation will serve as an educational resource for forensic science students and professionals, providing them with updated knowledge and best practices during the examination of the dead bodies recovered from the water. This can contribute to the overall advancement of forensic education and training programs.

Abstract Text: Disposing of a dead body to conceal a crime involves various illegal and unethical methods, including throwing the body in water, burial, cremation, chemical dissolution, dismemberment, and concealment in structures or vehicles. Water disposal is a common method in India due to the widespread availability of water resources. Examining dead bodies recovered from water poses several challenges for forensic examiners, complicating the determination of the cause of death, time since death, and identification of the deceased.

In the case presented, divers accidentally recovered a skeleton from a riverbed while searching for the body of a relative involved in another case. The divers left the skeletonized body on the riverbank, where it was discovered by a villager, who then alerted the police.

An autopsy examination revealed the remains to be those of an elderly female who had been murdered by ligature strangulation. Her body was disposed of in the river, with her hands tied, likely to conceal the crime. Efforts are ongoing to identify the victim through DNA profiling and by cross-referencing the details with missing person reports of a similar age and sex in the state.

This case illustrates the forensic challenges and potential pitfalls in water-related autopsies. It aims to help forensic pathologists and legal professionals understand the complexities of such cases, aiding in more informed decision making in legal proceedings and criminal investigations. Additionally, it will serve as an educational resource for forensic science students and professionals, providing them with updated knowledge and best practices for examining bodies recovered from water. This can contribute to the overall advancement of forensic education and training programs.

This case also highlights the importance of meticulous forensic examination and the need for standardized protocols when dealing with water-recovered bodies. The ongoing efforts to identify the victim underscore the critical role of DNA profiling and collaboration between forensic and law enforcement agencies. This knowledge can improve the accuracy and efficiency of investigations, ultimately aiding in the pursuit of justice.

Drowning; Death Investigation; Forensic Analysis

B215 Chemometric Approaches for Investigating Multiblock Hyperspectral Data in Forensic Biological Evidence Analysis

Alberto Mazzoleni, MS, University of Turin, Torino, Italy; Carolina Scagliarini, MS, University of Turin, Torino, Italy; Paolo Garofano, MD, PhD, Centro Regionale Antidoping "A. Bertinaria" di Orbassano, Torino, Italy; Eugenio Alladio, PhD, University of Turin, Department of Chemistry, Torino, Italy*

Learning Objectives: In this presentation, attendees will gain insights into the advanced application of multiblock hyperspectral imaging techniques for forensic analysis of biological fluids. Specifically, they will learn how these techniques, utilizing X-Ray Fluorescence (XRF) data alongside Visible and Near-Infrared (VNIR) and Short-Wave Infrared Reflectance spectra (SWIR), enable selective and non-destructive detection of dehydrated biological traces. The study focuses on two primary objectives: first, to effectively identify and spatially localize various biological fluids on substrates such as wood; and second, to distinguish between specific fluids like blood, urine, semen, and saliva deposited along different times. Through the implementation of chemometric methods, including Principal Component Analysis (PCA) and Multivariate Curve Resolution-Alternating Least Squares (MCR-ALS), the presentation demonstrates how these tools enhance the recognition and differentiation of biological fluids based on their unique chemical signatures. This approach not only highlights the practical application of hyperspectral imaging in forensic investigations but also underscores the critical role of data fusion strategies in overcoming challenges posed by complex sample matrices and degradation effects commonly encountered in forensic scenarios.

Impact Statement: This presentation will significantly impact the forensic science community by showcasing the transformative potential of multiblock hyperspectral imaging techniques in the analysis of biological fluids at crime scenes. By demonstrating the efficacy of integrating XRF data with VNIR as well as SWIR, the study offers a novel approach to detecting and differentiating dehydrated biological traces non-destructively and with high selectivity. The application of advanced chemometric methods further enhances the accuracy and reliability of identifying specific fluids like blood, urine, semen, and saliva, crucial for forensic investigations. This innovative methodology not only expands the forensic toolkit but also sets a precedent for future research and practical applications in crime scene investigation, ultimately advancing the field's capabilities in solving complex cases involving biological evidence.

Abstract Text: In the field of forensic science, traditional techniques face significant obstacles when analyzing and identifying biological fluids, such as complex sample matrices and potential degradation effects.[1,2] As a result, there is an urgent requirement for novel methods capable of identifying hidden biological evidence specifically and without causing damage during forensic investigations. This research investigates the features of a modern multiblock platform (IRIS, XGLab SRL – Bruker Nano Analytics) that acquires XRF data in addition to VNIR (380–1,100nm) and SWIR, (1,100–2,500nm) simultaneously. This platform, when used together with advanced chemometric techniques, seeks to accurately recognize dehydrated biological fluids. Different biological fluids such as blood, urine, semen, and saliva from various donors were placed on wood samples and examined at different time intervals for two main purposes: identifying the location of the fluids on surfaces and distinguishing between different types of fluids. Utilizing the diverse hyperspectral data blocks, a multivariate approach using PCA and MCR-ALS was used to process each block and the combined fused arrays, leveraging their complementary information. The chemometric strategies employed proved highly effective in generating detailed chemical maps that facilitated the recognition and discrimination of various biological fluids. By integrating XRF, VNIR, and SWIR spectra with sophisticated algorithms like PCA and MCR-ALS, the study achieved a comprehensive understanding of the spectral signatures unique to each fluid type. A critical aspect of the study was the utilization of a low-level data fusion approach, which synergistically combined information from multiple spectral domains to enhance differentiation accuracy. This approach was particularly pivotal in scenarios where similarities in vibrational bands and elemental compositions posed challenges, such as distinguishing between urine and saliva samples. This research not only underscores the potential of advanced hyperspectral imaging and chemometric techniques in forensic investigations but also provides novel insights and methodologies to enhance the field's capabilities in the analysis of biological evidence. Moving forward, these findings hold promise for refining forensic protocols, improving evidence processing efficiency, and ultimately strengthening the forensic community's ability to provide accurate and scientifically robust conclusions in criminal investigations involving biological fluids.

B216 A Layered Analytical Method for Detecting Clandestine Human Burials

Brian Eckenrode, PhD, George Mason University, Aldie, VA; Edward Bentil, PhD, George Mason University, Manassas, VA*

Learning Objectives: After attending this presentation, attendees will understand how using Light Detection And Ranging (LiDAR) and a Soil Vapor Probe (SVP) sampling-layered analytical method can be deployed prior to excavations during clandestine human burial investigations.

Impact Statement: This presentation will impact the forensic science community by providing a methodology that uses LiDAR and SVP technologies to facilitate the process of excavation and is based on the qualitative and quantitative nature of the Volatile Organic Compounds (VOCs) that can be detected in soil resulting from human decomposition. This new methodology will enable Law Enforcement (LE) to use another "tool" in their arsenal when faced with these investigations.

Abstract Text: The use of "tools" such as Ground Penetrating Radar (GPR) and canines has provided inconsistent success rates over the years and as such LE is always looking to scientists for assistance to improve their investigative abilities and build support for search warrants.[1-4] Given the LE quandary, the use of soil vapor probes for sampling the VOCs in the vicinity of a suspected clandestine burial related to a missing persons cold case out of Washington in 2023 will be discussed. In this case, there was a requirement to search 71 acres and to locate buried victims. This research will show results from this wide search area case using LiDAR and a non-invasive SVP VOCs collection strategy followed by an Environmental Protection Agency (EPA) number 15 Total Organic (TO15) Gas Chromatography/Mass Spectrometry (GC/MS) analysis.

VOCs were collected using a non-invasive SVP sampling strategy along with a layered scheme to cover a wide search area. A drone with LiDAR capability was used to reveal potential SVP locations for the 71-acre search area. Several SVPs were strategically placed based on the LiDAR data. Each SVP consists of a 1" by 0.5"-diameter fine mesh screen located near the tip of a 0.5"-diameter steel rod that is positioned several feet underground and connected to the surface via an inner Teflon tube. Evacuated canisters connected at the surface to the Teflon tube extract collected VOCs through a flow controller while reaching atmospheric pressure. Each canister was then subjected to a TO15 GC/MS VOCs analysis protocol that is based on trapping and thermal desorption. The TO15 EPA methodology employs a VOC concentrator for vapor phase trapping. The concentrator is desorbed to the GC via a 60-meter fused silica capillary column directly connected to the source of a quadrupole mass spectrometer. The system is calibrated using a modified direct dynamic calibration system with a fixed volume sample loop to meter in the internal standard to the air stream for quantitation.

For this wide search area scene, the LiDAR indicated 11 potential SVP locations. Over three days, 33 samples were acquired along with a few scattered SVPs and other samples that appeared on the surface as interesting. All samples were analyzed via quantitative GC/MS TO15 via the JMP multivariate statistical analysis software. The results indicated a highly unusual soil VOCs pattern relative to what would be expected in a control soil sample and therefore provided credence to a source of human decomposition. The analysis indicated that only 2 of the 11 locations yielded VOC data indicative of human decomposition. There were several compound classes detected, including: alkenes, alkanes, aldehydes, aromatics, sulfides, chlorinated compounds, and ketones. The classes of compounds were grouped and compared across the samples and controls. Sites were identified from the compound comparisons and were investigated resulting in the successful location and subsequent recovery of the homicide victims.

Field execution of SVP sampling and analysis of the VOCs detected for the successful recovery of homicide victims in a one-year cold case will be presented.

Human Decomposition; Soil Vapor; VOCs

B217 Standards Development Activities Related to Ignitable Liquids, Explosives, and Gunshot Residue

Brenda B. Christy, MS, Virginia Department of Forensic Science, Norfolk, VA*

Learning Objectives: After attending this presentation, attendees will have a better understanding of the status of discipline-specific standards related to Ignitable Liquids (IL), Explosives (E), and Gunshot Residue (GSR).

Impact Statement: The presentation will impact the forensic science community by creating greater awareness of standards development activities related to IL, E, and GSR.

Abstract Text: The Organization of Scientific Area Committees (OSAC) for Forensic Science was created to strengthen the nation's use of forensic science by promoting the use of discipline-specific standards. To this end, the OSAC drafts standards that are forwarded to Standards Developing Organizations (SDOs) that further develop and publish them. The OSAC also reviews standards and recognizes them on the OSAC Registry, which serves as a central repository of high quality, consensus-based, technically sound standards. During this presentation, IL, E, and GSR standards development activities will be discussed. These include:

1. Recent standards that have been added to the OSAC Registry:

- ASTM E2451-21 Standard Practice for Preserving Ignitable Liquids and Ignitable Liquid Residue Extracts from Fire Debris Samples
- ASTM E3196-21, Standard Terminology Relating to the Examination of Explosives
- ASTM E3253-21, Standard Practice for Establishing an Examination Scheme for Intact Explosives
- ASTM E3329-21ε1, Standard Practice for Establishing an Examination Scheme for Explosive Residues
- ASTM E3309-21, Standard Guide for Reporting of Forensic Primer Gunshot Residue (pGSR) Analysis by Scanning Electron Microscopy/Energy Dispersive X-Ray Spectrometry (SEM/EDS)

2. OSAC proposed standards:

- OSAC 2021-N-0009, Standard Practice for the Collection and Preservation of Organic Gunshot Residue
- OSAC 2022-S-0002, Standard Practice for the Identification of Compounds Related to Organic Gunshot Residue (oGSR) by Gas Chromatography/Mass Spectrometry (GS/MS)
- OSAC 2022-S-0003, Standard Practice for the Identification of Compounds Related to Organic Gunshot Residue (oGSR) by Liquid Chromatography/Mass Spectrometry (LC/MS)
- OSAC 2022-S-0023, Standard Practice for the Forensic Analysis of Explosives by Polarized Light Microscope
- OSAC 2023-N-0010, Standard Practice for the Collection of Primer Gunshot Residue (pGSR) Particles from Clothing, Vehicles, and Other Inanimate Objects using Scanning Electron Microscopy (SEM) Stubs

3. Published standards from ASTM that have yet to go through the Registry approval process:

- ASTM E2881-18 Standard Test Method for Extraction and Derivatization of Vegetable Oils and Fats from Fire Debris and Liquid Samples with Analysis by Gas Chromatography/Mass Spectrometry
- ASTM E1386-23 Standard Practice for Separation of Ignitable Liquid Residues from Fire Debris Samples by Solvent Extraction
- ASTM E3197-23 Standard Terminology Relating to the Examination of Fire Debris
- ASTM E3391-24 Standard Terminology Relating to Gunshot Residue Analysis (GSR)
- ASTM E3284-23 Standard Practice for Training in the Forensic Examination of Primer Gunshot Residue (pGSR) Using Scanning Electron Microscopy/Energy Dispersive X-Ray Spectrometry (SEM/EDS)
- ASTM E1388-24 Standard Practice for Static Headspace Sampling of Vapors from Fire Debris Samples

4. Documents currently in development at the OSAC or by the SDO:

- REVISION to ASTM E2997-16 Standard Test Method for Analysis of Biodiesel Products by Gas Chromatography/Mass Spectrometry (under revision as WK78732)
- REVISION to ASTM E2998-16 Standard Practice for Characterization and Classification of Smokeless Powder
- REVISION to ASTM E2999-17 Test Method for Analysis of Smokeless Powder by Gas Chromatography-Mass Spectrometry and Fourier-Transform Infrared Spectroscopy
- REVISION to ASTM E3255-21 Standard Practice for Quality Assurance of Laboratories Performing Chemical Analysis of Ignitable Liquids and Ignitable Liquid Residues (Annex)
- REVISION to ASTM E1588-20 Standard Test Method for Primer Gunshot Residue Analysis by Scanning Electron Microscopy/Energy Dispersive X-Ray Spectrometry
- Standard Practice for Training in the Forensic Examination of Fire Debris
- Standard Practice for the Characterization of Solid Oxidizer/Fuel Explosive

- Standard Practice for Expert Opinions on the Interpretation of Primer Gunshot Residue (pGSR) Analysis by Scanning Electron Microscopy/Energy Dispersive X-Ray Spectrometry (SEM/EDS)
- Standard Practice for Forensic Explosives Analysis Training Program
- Standard Practice for Reporting Results and Opinions of Ignitable Liquids Analysis
- Standard Practice for Reporting Results and Opinions of Explosives Analysis

Standards; Fire Debris Analysis; Gun Shot Residue

B218 The Validation of a Rapid GC/MS Method for Forensic Fire Debris Screening Applications

Briana A. Capistran, PhD, National Institute of Standards and Technology, Gaithersburg, MD; Elizabeth L. Robinson, MS, National Institute of Standards and Technology, Gaithersburg, MD; Edward Sisco, PhD, National Institute of Standards and Technology, Gaithersburg, MD*

Learning Objectives: After attending this presentation, attendees will learn about a validated method for rapid Gas Chromatography/Mass Spectrometry (GC/MS) screening of fire debris samples. Capabilities and limitations of rapid GC/MS will be presented as they relate to each validation component. Attendees will also learn about an associated validation package developed for forensic applications of rapid GC/MS that is available for use when adopting the technique.

Impact Statement: This presentation will impact the forensic science community by demonstrating a fully validated rapid GC/MS method available for forensic fire debris screening, consisting of nine validation studies to evaluate the performance of the analytical system. The work is part of a larger validation template developed for forensic applications of rapid GC/MS. The template is available for use as written or can be modified to fit a laboratory's needs, ultimately intended to reduce the barrier of implementation of rapid GC/MS in practicing forensic laboratories.

Abstract Text: The detection of ignitable liquids in fire debris samples is most commonly achieved through GC/MS analysis to identify compounds consistent with a reference liquid. Due to lengthy GC/MS analysis times required for these complex samples, the utility of screening techniques can be beneficial to preliminarily determine sample contents prior to confirmatory analysis. Rapid GC/MS is a screening technique gaining interest due to its fast separation capabilities, high sensitivities, and MS detection.[1,2] Its utility has been demonstrated for several areas of forensic analysis, including ignitable liquid applications.[3,4] However, for it to be adopted in practicing forensic laboratories, validation is required to demonstrate its suitability for the intended purpose(s). Currently, standardized validation protocols do not exist across the forensic chemistry community, especially for trace evidence analysis. Validations themselves can be time-consuming to perform, and the process of developing new protocols can serve as a barrier to implementing new techniques. Thus, demonstrated validations according to pre-defined plans can help ease this burden.

This work presents the complete validation of rapid GC/MS for ignitable liquids according to a template developed specifically for the system. Nine components were studied to gauge analytical performance (i.e., selectivity, matrix effects, precision, accuracy, range, carryover/contamination, robustness, ruggedness, and stability), and results were compared to established acceptance criteria. Single- and multi-compound test solutions were utilized, consisting of compounds present in common ignitable liquids. Based on the results from each study, a comprehensive determination of system performance specifically for ignitable liquids was achieved.

Results for seven of the nine validation components met the associated acceptance criteria. For example, precision, robustness, and stability were evaluated by assessing variation in retention times and mass spectral search scores for each test compound. In all cases, percent Relative Standard Deviations (% RSDs) were below the 10 % acceptance criteria for both metrics. Limits Of Detection (LODs) were determined, ranging from 0.0630µg to 0.138µg across seven compounds, comparable to LODs determined for similar compounds using traditional GC/MS. Ruggedness was evaluated by assessing instrument performance after varying parameters external to the instrumental method. While the greatest variability was observed when analyses were performed by a different analyst, only 3% RSD was observed, which was still well below the 10 % acceptance criteria.

Limitations to the system were identified when evaluating selectivity and accuracy. Isomer differentiation for three isomer series was assessed to measure selectivity. Differentiation was achieved for some, but not all, isomer species studied, and was particularly difficult for early-eluting compounds. Accuracy was assessed by comparing compounds identified in mock burn samples analyzed by rapid GC/MS and traditional GC/MS. Due to the complexity of such samples, complete agreement of compounds detected between the two techniques was unable to be obtained. However, these results were expected due to the timescale of the rapid (1.63min) versus traditional (31min) temperature programs and are important for understanding the extent of the system's capabilities.

In total, rapid GC/MS was successfully validated for ignitable liquid applications. Additional studies have focused on verification using solid phase microextraction as an alternative sampling and injection technique. This work is part of a full validation package developed for forensic applications of rapid GC/MS. The package includes plans with developed procedures, materials, and acceptance criteria for all components and is designed for use as written or can be modified to fit a laboratory's analytical needs. Overall, this work demonstrates the utility of rapid GC/MS for forensic fire debris analysis to provide an informed analytical approach and highlights the utility of the developed validation package to ultimately reduce the barrier of implementation of such technology.

GC/MS; Ignitable Liquids; Validation

B219 An Application of the Expert Algorithm for Substance Identification (EASI) to Predict ASTM E1618-19 Ignitable Liquid Classes From Gas Chromatography/Mass Spectrometry Data of Ignitable Liquid Residues

Hannah McMillen, MS, West Virginia University, Morgantown, West Virginia; Glen P. Jackson, PhD, West Virginia University, Morgantown, WV*

Learning Objectives: After attending this presentation, attendees will understand the benefits of using a statistical modeling method for the classification of ignitable liquids into their American Society for Testing and Materials (ASTM) E1618-19 classes. Attendees will also gain an understanding of how ions from volatile compounds in ignitable liquids correlate during weathering and permit effective prediction of ignitable liquids.

Impact Statement: This presentation will impact the forensic science community by discussing the benefits of the statistical model and how it works. Understanding this model and its foundations will aid analysts to make more informed decisions on the presence of ignitable liquids in casework samples.

Abstract Text: Arson investigators require reliable and objective methods to interrogate fire debris for the presence of ignitable liquid residues. Although standard methods like ASTM E1618-19 exist for such procedures, these methods typically do not rely on quantitative measures but instead rely on the subjective judgment of fire debris analysts.[1] To provide a more objective means to interpret fire debris evidence, we examined the ability of the EASI to identify ignitable liquid classes from the Total Ion Spectrum (TIS) of Gas Chromatography/Mass Spectrometry (GC/MS) data files.[2,3] TISs have been promoted by others to help remove variability caused by the GC dimension.[4] This work focused on modeling and identifying gasoline samples from the other ignitable liquid classes.

EASI first assumes that there must be correlations and anticorrelations between variables (*m/z* abundances) in the TIS of a gasoline sample as it evaporates. For example, abundances of fragments like *m/z* 91 and 105 from volatile aromatic should correlate strongly with one another and should both decrease with the extent of weathering. EASI determines the correlation matrix between all the covariates, then uses mixed stepwise selection to build multivariate general linear models of each of the 15 most abundant ions in the TIS. Each dependent ion is sequentially modeled using the remaining ions as covariates.

The TISs of 64 gasoline samples in the training set were first preprocessed using two different methods and two different methods of normalization. The accuracy of the 15 spectral predictions per sample were evaluated using both Pearson Product Moment Correlations (PPMCs) and the Mean Absolute Residual (MAR). These measures were then used for binary classification (e.g., gasoline present or not present) and assessed using Receiver Operating Characteristic (ROC) curves. MARs produced the most accurate spectral predictions, as determined by evaluating the Area Under the ROC curves (AUROC). More specifically, the greatest AUROC of 0.937 was observed for MAR using ions selected according to fragments in ASTM E1618-19 and normalized by summing TISs to one. Most of the false positives were caused by samples from the aromatic class, which is understandable given the chemical similarity between aromatic liquids and gasoline. EASI was also compared to the Mahalanobis distance as a binary classifier. The AUROC of the Mahalanobis distance using ions selected according to fragments in ASTM E1618-19 and normalized by summing TISs to one was 0.571—slightly above the useless "guessing" threshold AUROC value of 0.50. The lower AUROC for Mahalanobis distance indicates that EASI is a more effective means to model and classify ignitable liquids into their ASTM E1618-19 classifications than more naïve statistical approaches that depend on clustering.

B220 Revealing Gunshot Residue Flow and Deposition Behaviors Using Laser Sheet Scattering, High-Speed Videography, Atmospheric Particle Analysis, and Spectrometric Analytical Techniques

Thomas D. Ledergerber, BS, West Virginia University, Morgantown, WV; Matthew Staymates, MS, National Institute of Standards and Technology, Gaithersburg, MD; Luis E. Arroyo, PhD, West Virginia University, Morgantown, WV; Tatiana Trejos, PhD, West Virginia University, Morgantown, WV; Roger Jefferys, MS, West Virginia University, Morgantown, WV; Kourtney Dalzell, MS, West Virginia University, Morgantown, WV*

Learning Objectives: By attending this presentation, attendees will understand the flow and deposition patterns of Gunshot Residue (GSR), the effects of firing conditions on the GSR plume and resulting deposition, and the differences in GSR exposure risk to a shooter, bystander, or passerby.

Impact Statement: This study will impact the forensic community by demonstrating the behavior of GSR under different environmental conditions associated with activity-level hypotheses that can become relevant in assessing the evidence in the courtroom. This study utilizes a comprehensive and modern analytical approach that includes laser sheet scattering and videography, two real-time atmospheric sampling methods, and two analytical techniques for the visualization and analysis of GSR. The results from this study are expected to expand our understanding of the movement and deposition mechanics of GSR when considering various firing conditions and in different scenarios involving a shooter, bystander, or passerby individual.

Abstract Text: During the discharge of a firearm, GSR is released in highly variable patterns and directions, which are heavily dependent on the environmental conditions of the firing event. Because these residues are prone to deposit in the vicinity of the firing, information surrounding the generation and dispersion of the chemical components and resulting GSR are of interest to forensic investigations. However, the complexity of GSR production and variable diffusion factors make the interpretation of GSR evidence challenging. For instance, it can be hypothesized that the presence of GSR on the hands of a person of interest indicates the person fired a gun, was in contact with a gun but did not fire it, or was in the vicinity of the shooting during or after the firing. From a criminal justice perspective, elucidating which of these hypotheses is more likely is paramount for the fact finder, yet it is complex for a forensic scientist to evaluate the probability of observing the GSR evidence under some of these competing propositions. The main reason for this challenge is the lack of knowledge-base and technology to distinguish the processes of transfer and deposition of GSR under various circumstances. This study employs a novel multi-sensor and multi-instrument approach to enhance the current understanding of GSR flow, deposition, and airborne persistence.

In this study, particle sizing systems and custom-made atmospheric samplers with the ability to determine in real-time the density of airborne particles were employed in indoor, outdoor, and vehicular environments to simulate shooting events in enclosed residential areas, open outdoor settings, and drive-by shootings. Particulate matter < 2.5µm (PM2.5) was measured simultaneously by nine custom-made sensors to evaluate the GSR plume's dynamic flow after discharging the firearm. Concurrently, color and high-speed videography combined with laser sheet scattering were used to reveal the flow of GSR to the naked eye under various controlled experimental conditions. The combination of visual techniques has brought forth novel advances to aid in the visualization and interpretation of GSR deposition mechanics and evaluate the effects of different firing procedures (i.e., make and caliber of firearm, airflow, number of shots fired, slide position, enclosed and open spaces, relative locations from the firing point).

Scanning Electron Microscopy with Energy-Dispersive X-ray Spectroscopy (SEM/EDS) and Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) were used as complementary tools to confirm the elemental (Pb, Ba, Sb) and chemical (2-nitrodiphenylamine, 4-nitrodiphenylamine, Akardite II, diphenylamine, and ethyl centralite) makeup of residues detected by or in proximity to the sensors. This study compared different behaviors and risks of exposure of organic and inorganic residues (OGSR and IGSR). GSR was found to diffuse rapidly to fill an enclosed space, and settling can take up to three hours in enclosed rooms with limited airflow. However, in an open (outdoor) environment, the resulting GSR cloud was found to be easily and quickly (< 60s) swept away by even a light breeze (< 0.5mph). From a forensic perspective, LC/MS/MS allowed differentiation of OGSR present on a shooter's hand from those on a bystander or passerby, while SEM/EDS revealed a bystander or even passerby following a shooting event is more prone to receive exposure to IGSR and offered critical information regarding the flow and properties of the IGSR particles. Exposure to IGSR on the skin of a vehicle passenger and deposition of vehicle surfaces was also more likely than OGSR. The combination of these sampling and visualization tools provides breakthrough knowledge on the movement and redistribution of inorganic and organic compounds during shooting that can lead to recommendations for safety regulations, sampling, collection, and evidence interpretation, while the videography performed in this study offers a never-before-seen look into the movement and deposition dynamics of GSR.

Gun Shot Residue; Laser Sheet Scattering; Video Analysis

B221 An Assessment of the Transfer and Persistence of Gunshot Residue in Simulated Arrest Scenarios Analyzed by Screening and Confirmatory Methods

Kourtney Dalzell, MS, West Virginia University, Morgantown, WV; Thomas D. Ledergerber, BS, West Virginia University, Morgantown, WV; Luis E. Arroyo, PhD, West Virginia University, Morgantown, WV; Tatiana Trejos, PhD, West Virginia University, Morgantown, WV; Leah D. Thomas, BS, West Virginia University, Morgantown, WV; Addio Fiordigigli, Jr., BS, West Virginia University, Morgantown, WV*

Learning Objectives: After attending this presentation, attendees will understand the risks of exposure to Gunshot Residue (GSR) in mock arrest scenarios under firearm handling and firing situations with different levels of contact between the arresting personnel and the arrestee.

Impact Statement: This presentation will impact the forensic community by demonstrating how screening and confirmatory methods can be combined for a more encompassing understanding of GSR transfer and persistence in arrest situations. The study provides three levels of contact and different transfer situations to assess the transfer and persistence from arresting personnel to the arrestee and vice versa. These results help with understanding GSR and its behavior in these situations, which can lead to recommendations to minimize risks of unintended contamination.

Abstract Text: GSR evidence interpretation can be difficult due to the complex nature of their generation and depositions, which can be further compounded by post-shooting transfer and persistence factors. With over 50,000 deaths and injuries occurring due to firearm violence in the United States, there is a need for information on how GSR can help answer investigative questions and provide relevant information to other parts of the criminal justice system.[1] The GSR discipline has identified the need to understand these mechanisms for both Inorganic and Organic Gunshot Residue (IGSR and OGSR) as per the Organization of Scientific Areas Committee (OSAC) Research Needs.[2-4] IGSR is typically studied with the standardized method using Scanning Electron Microscopy Energy Dispersive X-ray Spectroscopy (SEM/EDS) due to its inherent capabilities of classifying particles by morphology and elemental composition.[5] Other confirmatory methods like Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) have been proposed to include OGSR in the analytical workflow, and standard practices are being drafted to assist forensic agencies with future adoption. Additionally, recent research has investigated employing screening methods for mobile GSR analysis to help with triage from the crime scene to the laboratory and improve turnaround times. The benefits of OGSR analysis and screening technology are to enhance understanding of the entirety of GSR and its interpretation in situations where exposure to GSR may be challenged.

Our research group has developed and transitioned to mobile screening methods for IGSR and OGSR analysis by Electrochemical Detection (ECD) and Laser-Induced Breakdown Spectroscopy (LIBS).[6-8] The goal of this study is to help fill the gaps in general knowledge of GSR transfer and persistence in arrest scenarios. For this study, three degrees of activity were investigated to simulate real-case situations where a low, medium, or high contact arrest was performed between the officer and the Person Of Interest (POI). For each arrest, three different transfer scenarios were performed where the POI had recently fired and then been arrested, the officer have recently fired then arrested the POI, and the officer have recently handled their firearm and then arrested the POI. The POI and officer were sampled before and post-arrest. Each combination of arrests and transfer scenarios was replicated five times for a total of 180 samples collected during the study. To gain a comprehensive picture of IGSR and OGSR in these scenarios, screening by ECD and LIBS was followed by confirmatory analysis by SEM/EDS and LC/MS/MS.

The results demonstrate that IGSR and OGSR behave differently, and their transfer and persistence vary with the level of contact, activities, and exposure to GSR before the arrest. In general, OGSR was less likely to secondary transfer than IGSR, and there was a decrease in GSR detected with increased activity during the arrests. In low-contact situations, IGSR and OGSR are more likely to persist after the arrest of the person who had recently fired a gun than in medium and high-resistance arrests. While performing the same low-contact arrest, IGSR persisted more than OGSR on the individual who had recently handled or fired their weapon. These findings can help the decision-making process in future OGSR analysis adoption to inform which screening and confirmatory methods to prioritize to save time and cost. Recommendations during arrest protocols and post-arrest collections are discussed in this presentation.

Gun Shot Residue; Simulated Arrests; Interpretation

B222 Standard Development Activities in Seized Drug Analysis: The Current Status and Challenges

Agnes D. Winokur, PhD, Drug Enforcement Administration, Miami, FL*

Learning Objectives: After attending this presentation, attendees will have a better understanding of the current status and future path of discipline-specific standards and activities pertinent to the analysis of seized drugs. Attendees will gain awareness of what challenges and obstacles are encountered in the development of standards for seized drugs.

Impact Statement: This presentation will impact the forensic science community by increasing awareness of current efforts in standard development activities pertinent to the examination of seized drugs. This presentation will also increase understanding of current and evolving training, tools, and resources that support implementation and compliance monitoring.

Abstract Text: The Organization of Scientific Area Committees (OSAC) for Forensic Science was created to strengthen the nation's use of forensic science by promoting the use of discipline-specific forensic science standards. The OSAC Seized Drugs Subcommittee has been drafting standards and forwarding them to the standards developing organization, ASTM International, to further develop and publish. Once published, the OSAC reviews the standard documents for inclusion in the OSAC Registry, which serves as a central repository of high-quality, consensus-based, technically sound standards.

During this presentation, updates related to the standards being developed at both the OSAC Seized Drugs Subcommittee and the American Society for Testing and Materials (ASTM) E30 Forensic Sciences Committee/Criminalistics Subcommittee will be discussed. These include: (1) newest standards added or in the process of being added to the OSAC Registry; (2) documents currently at ASTM E30 for further development; (3) new and on-going documents currently at the OSAC Seized Drugs Subcommittee or ASTM E30; and (4) other highlights of activities related to standards and the analysis of seized drugs.

In particular, the status and updates for standard documents regarding the identification of marijuana, reporting drug analysis results and opinions, evidence handling practices, the use of color tests, structural similarity assessments, and others. Highlights of how standards progress through the ASTM process after they move from the OSAC Seized Drugs Subcommittee will also be shown, with specific emphasis on the challenges and successes encountered this past year. In addition, the changes being implemented to assist in the efficiency of the standard balloting process will be discussed.

A brief look at some of the other activities related to seized drug standards will also be discussed. Furthermore, the process for the revisions of standards once they are added to the OSAC Registry and how those revisions are balanced with the need to draft new standards is handled by the Seized Drugs Subcommittee.

Seized Drugs; Standards; Forensic Analysis

B223 Tracking the Emergence of Medetomidine, Tetracaine, and Other Substances as Adulterants in Philadelphia, Pennsylvania, Recreational Opioid Markets

Joshua S. DeBord, PhD, The Center for Forensic Science Research and Education, Horsham, PA; Alexis D. Quinter, MASc, The Center for Forensic Science Research and Education, Horsham , PA; Barry K. Logan, PhD, The Center for Forensic Science Research and Education, Horsham, PA; Alex J. Krotulski, PhD, The Center for Forensic Science Research and Education, Horsham, PA; Max T. Denn, MS, The Center for Forensic Science Research and Education, Horsham, PA*

Learning Objectives: Through attending this presentation, attendees will examine the evolving landscape of recreational drug adulteration in Philadelphia, with a focus on the decrease in xylazine prevalence and the emergence of new adulterants in the opioid market. The audience will be able to assess changes in adulteration as evidence of the adaptability of drug markets in response to legislation, with significant implications for public health and safety.

Impact Statement: This presentation will impact the forensic science community by describing a timeline of changes in a recreational drug market, emphasizing the need for surveillance programs that can rapidly identify emerging substances of concern.

Abstract Text: In 2020, the recreational drug market in Philadelphia, PA, became the epicenter of an outbreak of overdoses attributed to fentanyl adulterated with xylazine. Xylazine, an animal tranquilizer not approved for use in humans, acts as a central nervous system depressant. Xylazine is now frequently sold in combination with fentanyl and intended to enhance or prolong the effects of the opioid; however, its use has been associated with necrotic wounds and other health risks. Despite this risk, xylazine has proliferated through various recreational opioid markets. By 2021, xylazine was present in over 90% of recreational opioids from Philadelphia.

Xylazine-adulterated opioids have proliferated in recreational drug markets across the United States. In response, the United States Congress introduced the Combating Illicit Xylazine Act in March 2023, which would classify xylazine as a Schedule III drug at the federal level. In May 2024, Pennsylvania passed legislation classifying xylazine as a Schedule III drug, joining several other states in criminalizing the possession and use of the drug.

Soon afterward, the Novel Psychoactive Substance (NPS) Discovery program at the Center for Forensic Science Research and Education (CFSRE) began recording a decrease in the percent composition of xylazine in fentanyl products and a decrease in the percentage of xylazine-positive recreational opioid samples from the state of Pennsylvania. The percentage of fentanyl samples containing xylazine dropped from 98% in Q1 2024 to 85% in Q2 2024. This marked the first quarter in which the percent positivity dropped below 98% since Q1 2023. Q2 2024 also marked the Pennsylvania when we began detecting two new adulterants previously not observed by our laboratory in the PA recreational opioid supply: medetomidine and tetracaine. These adulterants were detected in 25% and 27%, respectively, of the opioid samples from Pennsylvania tested at the CFSRE in Q2 2024. This sudden rise in new adulterants, coinciding with the decrease in positivity for xylazine, suggests that one or both may evolve into a potential replacement for xylazine as an adulterant in recreational opioids in Pennsylvania.

Medetomidine is a more potent alpha-2 agonist than xylazine and exists as a mixture of the pharmacologically active dexmedetomidine enantiomer and the inactive levomedetomidine enantiomer. Dexmedetomidine is approved for both human and veterinary use, while levomedetomidine only appears in veterinary use. Its emergence in the Philadelphia drug supply as a fentanyl adulterant corresponded with a large-scale overdose outbreak, marked by increased sedation and severe bradycardia, as noted by clinical colleagues. Surprisingly, medetomidine was present in larger amounts relative to fentanyl and xylazine in some samples tested; however, overall ratios of the drugs varied.

Tetracaine is a local anesthetic like lidocaine but has rarely been observed with recreational drugs. Like xylazine and medetomidine, it is also a veterinary drug. Lidocaine is used as an adulterant in cocaine and less commonly in fentanyl to add bulk weight. Lidocaine and tetracaine intoxication have been associated with bradycardia and other negative cardiovascular effects. In our experience, the combined use of tetracaine and cocaine is rare and its combined use with opioids has not previously been reported. Currently, neither medetomidine nor tetracaine are explicitly scheduled in the United States.

Real-time surveillance findings of medetomidine and tetracaine represent the kind of information that can be provided by drug-checking programs. The decreasing abundance of xylazine and the simultaneous emergence of previously unreported adulterants shows that recreational drug markets respond quickly to legislation and remain versatile, dynamic, and increasingly toxic.

Medetomidine; Drug Checking; Adulterants

B224 A Systematic Study of Liquid Chromatography in Search of the Best Separation of Cannabinoids for Potency Testing of Hemp-Based Products

Liguo Song, PhD, Western Illinois University, Macomb, IL*

Learning Objectives: After attending this presentation, attendees will gain knowledge in achieving the best separation of cannabinoids for potency testing of hemp-based products by either Liquid Chromatography/Diode Array Detector (LC/DAD) or Liquid Chromatography/Electrospray Ionization/Tandem Mass Spectrometry (LC/ESI/MS/MS).

Impact Statement: This presentation will first impact the forensic science community by enabling crime labs to effortlessly select an appropriate LC separation for potency testing of hemp-based products by either LC/DAD or LC/ESI/MS/MS. It will further impact the forensic science community by allowing the regulatory agencies to easily create a standard method for potency testing of hemp-based products.

Abstract Text: Since the 2018 Farm Bill legalized hemp products with a Delta 9-Tetrahydrocannabinol (D9-THC) concentration of not more than 0.3% on a dry weight basis, a variety of hemp-based products, including plant materials, concentrates, vape cartridges, tinctures, edibles, topicals, and pet treats, entered the United States market. Potency testing of hemp-based products is meant to quantify all the major cannabinoids in a sample, so that its quality and safety can be determined. So far, the maximum number of cannabinoids that were quantified in hemp-based products for the purpose of potency testing was 18.[1] Although many methods have been published for potency testing of hemp-based products, only five LC/DAD, four LC/ESI/MS/MS, and two LC/ESI/MS methods were developed for 14 and more cannabinoids.[1-11]

For potency testing of hemp-based products by LC/DAD, baseline separation of 18 cannabinoids, (i.e., CBC, CBCA, CBD, CBDA, CBDV, CBDVA, CBG, CBGA, CBL, CBLA, CBN, CBNA, CBT, D9-THC, D9-THCA, D8-THC, THCV, and THCVA) was successfully achieved using two sequential Poroshell 120 EC-C18 columns (stationary phase: dimethyl-octadecyl (-OSi(CH3)2C18H37); A solvent: 0.03% HCO2H + 0.5 mM NH4HCO2 (pH 2.97); B solvent: acetonitrile; mobile phase: 77.5% (v/v) B; flow rate: 0.45mL/min) within 18.0-min. Baseline separation of 18 cannabinoids was also achieved using two consecutive Raptor ARC-18 columns (stationary phase: diisobutyl-octadecyl (-OSi(*i*Bu)2C18H37); A solvent: 0.03% HCO2H + 0.5 mM NH4HCO2 (pH 2.97); B solvent: acetonitrile; mobile phase: 75.0% (v/v) B; flow rate: 0.5mL/min) within 15.0-min. Baseline separation of 18 cannabinoids, except for the CBCA/CBLA pair, was also achieved using a Cortecs Shield RP-18 column (stationary phase: RP-carbamate (-OSi(CH3)2C3H6O(CO)NHC12H25); A solvent: 0.02% HCO2H + 1 mM NH4HCO2 (pH 3.15); B solvent: acetonitrile; mobile phase: 65.0% (v/v) B; flow rate: 03 mL/min) within 20.0-min. For potency testing of hemp-based products by LC/ESI/MS/MS, baseline separation of all isomers of the 18 cannabinoids was successfully achieved using the same Cortecs Shield RP-18 column (A solvent: 0.01% HCO2H + 1 mM NH4HCO2 (pH 3.38); B solvent: acetonitrile; mobile phase: 70.0% (v/v) B; flow rate: 0.5mL/min) within 7.0-min. The two separations by the Cortecs Shield RP-18 column can be used together for potency testing of hemp-based products by LC/DAD. Baseline separation of 18 cannabinoids was further achieved using an Ascentis Express RP-Amide column (stationary phase: RP-amide (-OSi(CH3)2C3H6NH(CO)C15H31); A solvent: 0.01% (v/v) HCO2H + 4 mM NH4HCO2 (pH 3.80); B solvent: acetonitrile; mobile phase: 65.0% (v/v) B; flow rate: 0.5mL/min) within 24.5-min.

For potency testing of hemp-based products by LC/DAD, the two RP stationary phases were better choices due to shorter run times. Between Poroshell 120 EC-C18 and Restek Raptor ARC-18, the longer run time by Poroshell 120 EC-C18 was due to higher backpressure and consequently lower flow rate, which would not be a problem for Ultra High-Pressure Liquid Chromatography (UHPLC) systems. Other similar columns with either dimethyl-octadecyl or diisobutyl-octadecyl stationary phase are likely to achieve similar separation under optimized LC conditions. For potency testing of hemp-based products by LC/ESI/MS/MS, the RP-carbamate stationary phase was the best choice. However, when columns with RP-carbamate stationary phase other than Cortecs Shield RP-18 are considered, the short chain length of Cortecs Shield RP-18 should be taken into account. The RP-Amide stationary phase was the least preferred for potency testing of hemp-based products by either LC/DAD or LC/ESI/MS/MS because some acidic cannabinoids had high retention factors and imperfect peak shapes.

B225 Sample Preparation Procedures at NIST for the Determination of Δ9-THC and Its Isomers in Commercial and Seized Cannabis Vape Products by GC/MS

Walter B. Wilson, PhD, National Institute of Standards and Technology, Gaithersburg, MD; Ya-Chih Cheng, PhD, Sam Houston State University, Huntsville, TX*

Learning Objectives: After attending this presentation, attendees will learn about the Gas Chromatograph/Mass Spectrometry (GC/MS) method at the National Institute of Standards and Technology (NIST), the differences in sample preparation for both methods, and comparisons of Δ9-Tetrahydrocannabinol (Δ9-THC) isomer levels between commercial and seized cannabis vape products.

Impact Statement: This presentation will impact the forensic science community by providing a summary of sample preparation procedures used at NIST for GC/MS measurements of THC isomers in commercial and seized cannabis vape products. This presentation will help inform the forensic science community of challenges encountered by the sample matrix for the determination of Δ9-THC and its isomers. NIST has developed these procedures with forensic laboratories in mind to help them distinguish seized cannabis vapes as legal or illegal products in the future.

Abstract Text: Hemp was removed from the United States Drug Enforcement Administration controlled substance list with the passage of the Agriculture Improvement Act of 2018 (Farm Bill), which defined hemp as *Cannabis sativa* containing 0.3 % or less of Δ9-THC. The passage of new legislation resulted in a significant increase in hemp farms in the United States, bringing forth an explosion of different *Cannabis*-derived finished products. One of the more common products in various forms is *Cannabis* vapes such as e-liquid solutions, oil additives, and disposable cartridges. Additionally, hemp manufacturers started to convert Cannabidiol (CBD) -rich hemp flower into other cannabinoids such as Δ8-tetrahydrocannabinol (Δ8-THC) and other THC isomers. Forensic laboratories have primarily been measuring only Δ9-THC in seized *Cannabis* flowers/buds by GC/MS. Some forensic laboratories have started to express interest in having access to reliable sample preparation and analytical methods for seized *Cannabis* products.

This presentation will expand on previous studies optimizing a sample preparation procedure that was originally developed for the determination of 11 cannabinoids (e.g., Δ9-THC) in hemp oil samples by Liquid Chromatography-Photodiode Array (LC-PDA).[1,2] The revised procedure for LC-PDA uses approximately 0.1g of vape sample mixed with 25mL of methanol and shaken for 1min. The methanolic sample is filtered and further diluted with methanol through a 10-fold and 100-fold sample dilution prior to analysis. The goal of the new research presented here was to adapt a similar approach for GC/MS measurements of Δ9-THC while also expanding to include other THC isomer vape products, including Δ7-THC, Δ8-THC, four stereoisomers of Δ10-THC and *exo*-THC. The new sample preparation procedure included varying the mass of the sample and dilution factors. This procedure was validated for GC/MS by a single laboratory at NIST for 10 commercial oil products, 25 commercial vape products, and 25 seized vape products. Approximately 50 % of the commercial oil products contained levels of Δ9-THC too low to measure by GC/MS because of the necessary dilution factors of 100 times to minimize the oil matrix being injected in the GC/MS instrument. All the commercial and seized vape products could be analyzed by GC/MS because the sample matrix is primarily comprised of components generally measured in tobacco e-cigarettes. Comparisons will be presented for the mass fractions of Δ9-THC in the *Cannabis* products by both LC-PDA and GC/MS methods. Distinct advantages will be highlighted for each of the methods in response to chromatographic co-elution with Δ9-THC from other THC isomers.

Cannabis; Tetrahydrocannabinol; Vape

B226 The Development of a Δ9-THC Colorimetric Breathalyzer Using 3D Printing Manufacture

Savanah Allinson, BS, Virginia Commonwealth University, Richmond, VA; Taqiyah Chernesky, MScFS, Virginia Commonwealth University, Montpelier, VA; Emanuele Alves, PhD, Virginia Commonwealth University, Richmond, VA; Aron Jaffe, MS, Virginia Commonwealth University, Richmond, VA; Stephanie Walcott, MScFS, Virginia Commonwealth University, Richmond, VA*

Learning Objectives: This presentation will demonstrate the development of a Δ9-Tetrahydrocannabinol (Δ9-THC) breathalyzer for the detection of recent cannabis use on the site. After attending this presentation, attendees will better understand the mechanism of the colorimetric reaction applied to detect Δ9-THC and the application of this reaction to a support base that works as a prototype for a colorimetric-based Δ 9-THC breathalyzer.

Impact Statement: This presentation will impact the forensic science community by showing the development of the foundational mechanism for the development of a portable colorimetric device to detect Δ9-THC in breath for the early detection of driving under the influence of marijuana.

Abstract Text: According to the 2021 World Drug Report, cannabis continues to be one of the most widely used drugs worldwide. Currently, in the United States, 31 states and the District of Columbia have legalized non-medical cannabis. The 2018 Farm Bill defines hemp as a cannabis plant or finished product containing 0.3% or less decarboxylated Δ9-THC and removed hemp from the controlled substances list. As more and more products containing Δ9-THC are becoming available, concerns about the public health consequences of cannabis use have increased.

As a result of Δ9-THC ability to impair performance and decrease the ability of drivers, and the current lack of correlation between driving impairment and Δ9-THC concentrations in blood, the necessity of a quick and portable detection method to identify Δ9-THC in non-invasive samples from drivers is imperative. Due to the popularity of alcohol breathalyzers, breath was chosen as the matrix for the Δ9-THC detection. The concentration of Δ9-THC in breath is estimated to be 250 parts per trillion (ppt), a challenging detection limit. However, the Δ9-THC concentration in the breath may be higher since some of the generated Δ9-THC during smoking will be carried by aerosolized particles and deposited on the lung tissues. These particles can be removed by exhalation and be detected in breath. The goal of this project was to develop a cartridge based on a colorimetric reaction for the creation of a breathalyzer for the detection of Δ9-THC in breath samples.

The development of the Δ9-THC breathalyzer was based on the application of an additive manufacturing solid device made by 3D printing. Five different 3D polymerizable resins and three different cannabinoid-specific dyes were analyzed. Resins were treated with varying concentrations of Fast Blue B, Fast Blue BB, and Fast Blue RR dyes, followed by treatment with 10µg of Δ9-THC for the optimization of best resin/dye/dye concentration (1, 2, 4, and 6% w/w) set. Cartridges were printed using an Anycubic 3D printer. Color formation was captured using a ballistic microscope coupled to a high-resolution camera and the intensity of the color was analyzed using the software ImageJ. The solubility of the dye in the resin, the analytical signal obtained, the stability of the dye, and the influence of the shape of the cartridge were evaluated.

Five resins commercially available were tested, including the AnyCubic 3D resin suggested by the printer vendors. The white Creality 3D resin showed the best signal for the same concentration of Δ9-THC among all resins. The solubility of the dyes also showed to be better in the Creality resin when compared to the other four resins tested. Among the dyes, Fast Blue B and BB at 1% (w/v) showed the best results with higher signals than the signals given by Fast Blue RR. The cartridge shape was shown to be relevant to the stability of the reaction. A circular shape is the target shape due to the air collection system that will be attached to the cartridge to form the breathalyzer prototype. A current validation of the parameters is being performed and preliminary results showed the capacity of the cartridge to react positively to a concentration of 0.01µg of Δ9-THC. Achieving lower concentrations is extremely important as the concentration of Δ9-THC in exhaled air is described to be in the range of 1ng/30 L of exhaled air.

The results obtained in this work are the initial foundation needed to construct a reliable semi-quantitative breathalyzer device to be applied in Driving Under the Influence of Drugs (DUID) monitoring in the United States.

B227 Psilocin Derivatives in Edibles: Issues, Extraction Tips, and Case Studies

H. Ross Ehmann, MSFS, Texas Department of Public Safety, Houston, TX; Oriana C. Ovide, MSFS, Texas Department of Public Safety, Houston, TX*

Learning Objectives: After attending this presentation, attendees will have learned about the emerging trend of psilocin derivatives in counterfeit mushroom edibles. Attendees will also learn of extraction techniques to avoid false psilocin positives and see examples from real casework.

Impact Statement: This presentation will provide a unique perspective through case studies into the real-time complications that occur in drug analysis. Analysts will receive information and tips for extracting psilocin derivatives from complex matrices.

Abstract Text: Proper identification of chemical substances is the crux of the controlled substance discipline. Identification of illegal substances often requires the analyst to have an understanding of laws that govern their jurisdiction. Statutes can be worded in ways such that a particular drug is illegal, but analogs and derivatives are de facto legal. It is also possible that the process of testing for a substance can have the unintended consequence of converting a compound leading to erroneous results.[1]

Psilocybe "magic mushrooms" are popular hallucinogens due to the activity of psilocin. While directly ingesting the basidiocarps is the common route of administration, mixing mushrooms into edible matrices such as chocolate is a popular means.[2] Online searches lead to a plethora of retailers claiming to sell confectionaries containing these or sometimes other hallucinogenic mushrooms like fly agaric.

Derivatives of psilocin, such as o-acetylpsilocin, have increasingly appeared in edibles advertised to contain *psilocybe* throughout the country.[3,4] These items have made their way to the Texas Department of Public Safety (DPS) as well. Our analysis of these cases showed large peaks for psilocin derivatives accompanied by minor peaks attributed to psilocin. The issue presented is two-fold. Many of the submitted retail edibles specifically listed legal or non-psilocin compounds as their active ingredients. Therefore, the presence of either psilocin or its derivatives demonstrate the existence of counterfeits that can further complicate the judicial process.

The second, more pressing issue is conversion. Literature has shown strong base extractions used to isolate drugs of interest can unintentionally convert psilocin derivative into psilocin.[5] Further, the Weber exam, a color test to detect psilocin, was found to give false positives when only o-acetylpsilocin was present. Combined, the conversion phenomena and false Weber results can lead to erroneous reporting of psilocin where only a derivative is present. This is especially salient if jurisdictions only charge for psilocin and not related derivatives.

The Texas DPS lab system allows flexibility to analysts when choosing extraction techniques. These range from complex and time-consuming to simple and efficient. For this study, cases with confirmed psilocin or psilocin derivative from the past decade were examined. The majority of cases had a positive Weber exam. The case review found that simple extractions produced the lowest-quality TICs with many coeluting compounds obscuring analytes of interest. Conversely, complex extractions showed very clean TICs. None of the DPS utilized techniques, fortunately, demonstrated conversion as seen in literature. Our use of moderate acid and base solutions as opposed to extreme pH solutions may account for this.

To verify this assertion, DPS extraction techniques were compared to a strong acid technique on o-acetylpsilocin standard. Strong base extraction was not tested as literature already demonstrated conversion. For the first DPS technique, standard was dissolved in 1 M sodium carbonate base solution (pH ~10.1) and extracted into chloroform. For the second, standard was extracted into 0.1 N HCl acid solution (pH ~1), sat overnight, then pH shifted with the base solution and extracted into chloroform. Neither technique showed conversion of o-acetylpsilocin into psilocin. For the strong acid technique, standard was dissolved in 2 N HCl solution (pH ~0.1), sat overnight, then pH shifted with the base solution and extracted into chloroform. This technique showed almost 100% conversion of o-acetylpsilocin into psilocin. Conversion via deacylation at the Gas Chromatograph/Mass Spectrometry (GC/MS) inlet was ruled out as the temperature was too low. Acylated compounds are more thermally stable in general, hence the use of acylating derivatizing agents for thermally sensitive compounds. Regarding the Weber exams, it is hypothesized that the HCl acid step is converting derivative into psilocin leading to false positives.

Psilocin; Mushroom; Chocolate

B228 The Application of the Expert Algorithm for Substance Identification (EASI) to Differentiate Tandem Mass Spectra of 2,3-MDMA and 3,4-MDMA

Glen P. Jackson, PhD, West Virginia University, Morgantown, WV; Alexandra I. Adeoye, MS, West Virginia University, Morgantown, WV; Sandra E. Rodriguez-Cruz, PhD, Drug Enforcement Administration, Dulles, VA*

Learning Objectives: In this presentation, attendees will learn that variance that exists in the branching patterns of replicate mass spectra is not random, but highly correlated, and can be modeled and used to effectively discriminate between compounds of notoriously high spectral and structural similarity, such as 2,3-MDMA and 3,4-MDMA.

Impact Statement: This presentation will provide the forensic community with an algorithm that, in theory, can cope with the variance that exists within and between mass spectrometers. The flexible algorithm is capable of extrapolating from data collected on one instrument to assess the spectral behavior of compounds collected under different conditions or on different instruments. EASI aims to minimize false identifications and improve forensic analysts' confidence in their identifications and testimonies in the absence of reference spectra on the same instrument.

Abstract Text: In most existing library search algorithms, a query spectrum is compared to a library of discrete exemplar spectra of standards. In our discussions, the average spectrum of hundreds of replicate spectra of a substance is considered to be the consensus or exemplar spectrum to which the individual replicates or any query spectra can be compared. One problem with this consensus approach is that even when conditions are kept as constant as possible, inter-day spectral abundances can vary by up to ±20%. This variance is even more pronounced when collecting tandem mass spectra at different collision energies or on a different instrument. Such variance increases the difficulty in differentiating between compounds with similar mass spectra. EASI takes an informed approach that accounts for the different sources of variance by modeling the correlations within replicate spectra.[1,2] Our central hypothesis is that the relative abundances of mass spectra fragments are not independent but highly correlated. This hypothesis is supported by unimolecular fragmentation theories like Rice–Ramsperger–Kassel–Marcus (RRKM) and confirmed by Pearson correlation matrices of replicate spectra for each compound.

For this presentation, 300 replicate spectra were collected each for 2,3-MDMA and 3,4-MDMA at eight different collision energies on a triple-quadrupole mass spectrometer equipped with a Direct Analysis in Real Time (DART) ionization source. The total number of spectra was 4,800. The replicate spectra were randomly distributed to create a training set for General Linear Modeling (GLM) and an equal-sized test set for unbiased assessment. Since the branching patterns vary at different collision energies, the 30 most abundant mass fragments across all collision energies were selected as variables for the linear models. The variables were entered in a stepwise addition method to produce the simplest models that explained the most possible variance in each fragment ion abundance. Typically, the amount of explainable variance in each ion's abundance at a fixed collision energy was greater than 90%. The models from each training set were used to predict each compound's fragment abundance. The measured and EASI-predicted abundances are evaluated using similarity and dissimilarity metrics, such as the weighted dot-product and mean absolute residual. Each metric is then used as a binary classifier to generate a Receiver Operating Characteristic (ROC) curve to determine the true positive rate and false positive rate over a range of threshold values. The Area Under the Curve (AUC) is then calculated to assess the performance of each metric and its supporting model.

In line with previous work, the residuals from the EASI models were typically four times smaller than those from the consensus-based approach at each collision energy, and EASI had a significantly higher overall accuracy than the consensus-based approach.[1,2]

This presentation will discuss more details on data processing, model building, evaluation, and accuracy performance.

B229 Standardizing and Implementing Direct Analysis in Real Time-Mass Spectrometry Methods Throughout DEA Laboratories

Sandra E. Rodriguez-Cruz, PhD, Drug Enforcement Administration, Dulles, VA*

Learning Objectives: After attending this presentation, attendees will have a better understanding of the multi-phase and multi-year process undertaken to standardize and implement the rapid analysis technique of Direct Analysis in Real Time-Mass Spectrometry (DART-MS) throughout the Drug Enforcement Administration (DEA) laboratory system.

Impact Statement: This presentation will impact the forensic science community by providing a comprehensive overview of the necessary steps completed in order to: (1) select the appropriate instrument, (2) standardize and validate fit-for-purpose analysis methods, (3) transfer the technology and methods to multiple laboratories, and (4) successfully train the forensic analysts who will use the methods during active casework.

Abstract Text: Since its introduction to the scientific community back in 2005, the ambient ionization technique of DART-MS has been successfully applied across a variety of forensic fields, including analysis of drugs, inks, gunshot residue, paints, explosives, etc.[1,2] One of the most common commercially available systems combines a DART ionization source with a high-resolution time-of-flight MS system. The main advantage of such a configuration is its ability to achieve fast analysis while also facilitating the preliminary identification of New Psychoactive Substances (NPS) via determination of their elemental chemical formulae. However, adoption of the technique by forensic laboratories has been hindered by factors such as its high cost and maintenance, the need for knowledgeable operators, the inability to perform formal tandem MS analyses, and difficulties analyzing mixtures, among others.

This presentation will describe a dual-configuration liquid chromatography/DART triple quadrupole MS system and the advantages of implementing this simpler and more affordable configuration within routine seized-drug analytical schemes. Adoption of this technology included the creation of 12-second analysis methods for both non-targeted full-scan spectral acquisition and targeted tandem (MS/MS) analyses. Method variations included automated use of sampling cards and glass capillaries as well as the use of manual sampling. The accuracy of the spectra generated was successfully evaluated using the National Institute of Standards and Technology (NIST) 2020 MS/MS libraries.

After validation and standardization at the original laboratory in Virginia, eight additional dual-configuration systems were procured and installed throughout DEA laboratories in New York, Maryland, Florida, Illinois, Texas, California (two laboratories), and the DEA Training Academy. A 3-day training program was designed and delivered to forensic chemists at each of these locations. The training included a two-hour lecture covering background on soft ionization techniques and tandem mass spectrometry. This also provided opportunities for open discussions regarding the analytical information that can be obtained from using these techniques in comparison to the more routine GC/MS systems. The main part of the training consisted of hands-on exercises that covered: how to perform a non-targeted analysis; how to customize and execute a targeted MS/MS analysis at the optimized collision energy; how to evaluate and process data using standardized instrument reporting templates; and how to perform library searches. Dedicated technical/quality personnel at each of the laboratories were trained on how to switch ionization sources from Electrospray Ionization (ESI) to DART, how to develop in-house spectral libraries, and how to complete and document routine performance verification procedures. This latter group of analysts were also responsible for performing and documenting the verification of the methods at each of the receiving laboratories. During the last day of training, at least two DART-MS "champions" were competency tested at each of the laboratories and these analysts (along with the Quality Assurance supervisors) were then responsible for testing and documenting the competency of their colleagues during the weeks following the training.

This report will present an overview of the method validation, verification, implementation, and training activities completed (including illustrations of some of the training materials used), and the lessons learned throughout this multi-year process.

Seized Drugs; Direct Analysis in Real Time (DART); Validation

B230 The Development and Validation of the Global Uniform Analysis and Reporting of Drug-Related Substances (GUARDS) Method

Sandra E. Rodriguez-Cruz, PhD, Drug Enforcement Administration, Dulles, VA; Mark Frisch, PhD, Drug Enforcement Administration, Dulles, VA; Michael L. Weaver, BS, Drug Enforcement Administration, Sterling, VA; Corey Nida, PhD, Drug Enforcement Administration, Ashburn, VA*

Learning Objectives: After attending this presentation, attendees will know how the Global Uniform Analysis and Reporting for Drug-Related Substances (GUARDS) method was developed, validated, and implemented throughout Drug Enforcement Administration (DEA) laboratories. This qualitative non-targeted Gas Chromatography/Mass Spectrometry (GC/MS) method, designed to standardize drug analysis within DEA laboratories, is now available for implementation throughout the seized drug community at large.

Impact Statement: The forensic science community will benefit from this presentation by learning about the various method parameters optimized during development, the challenges faced, the performance characteristics evaluated, and the chromatographic advantages that GUARDS offers. Using hydrogen as a carrier gas to combat the global shortage of helium, the method was developed to also produce increased sensitivity by using a narrow-bore capillary column and modified tune parameters.

Abstract Text: In response to the continual emergence of Novel Psychoactive Substances (NPS) and the ongoing opioid epidemic, GUARDS was designed to offer a GC/MS screening method that would allow for consistent analysis and reporting of both commonly encountered drugs as well as emergent compounds. With each DEA laboratory using GUARDS, data can be compared nationwide and also allow the early reporting of regionally detected NPS and trends. Under current jurisdictional requirements, reporting of analysis findings varies throughout municipal, county, state, and federal laboratories. This disparity in reporting requirements sometimes results in some laboratories not reporting lower-scheduled or non-controlled drugs such as fentanyl or xylazine when found in mixtures containing a higher scheduled drug,like heroin. GUARDS was envisioned to address these and other national reporting discrepancies by providing laboratories with a single, uniform method that would also facilitate interlaboratory comparisons.

This presentation will describe the aspects of qualitative method validation used by the DEA lab system as well as explain the development of the method which consisted of evaluation of three different narrow-bore column phases (DB-1, DB-5, and DB-35), numerous column lengths, and temperature ramp programs. Over 90 method iterations were assessed and compared and system suitability was monitored using numerous sets of forensically relevant close-eluting compounds, including fentanyl analogs and their positional isomers. The initial method validation process involved evaluation of selectivity, repeatability (short-term precision), and reproducibility (long-term precision). Results from these tests—and additional testing focused on critical-resolution compound pairs—also provided the basis for revising the acceptance criterion used throughout DEA laboratories for retention time comparisons during routine casework. After validation was completed, the method was transferred to two regional laboratories (ruggedness partners) for additional verifications. As of this writing, the method has been successfully transferred, verified, and implemented on over 25 additional instruments across ten regional and satellite laboratories. Furthermore, the method was recently shared with another federal agency, where it has been successfully verified and adopted. This presentation will include a summary and discussion of the data collected during the validation process as well as the data obtained beyond validation and across the other instruments' verifications, highlighting the figures of merit, such as a less than 3% Relative Standard Deviation (RSD) among tested compounds across multiple instruments, that this new screening method offers to the seized-drug community.

Seized Drugs; GC/MS; Method Development

C1 A Framework for Systematic Error Mitigation for Digital Evidence

Eoghan Casey, PhD, University of Lausanne, Lausanne, Vaud*

Learning Objectives: Participants in this session will learn about the Digital Evidence Weakness Taxonomy (DEWT), which organizes potential sources of error in the digital forensic process and provides a systematic support for error mitigation analysis as defined in the American Society for Testing and Materials (ASTM) E3016-18.[1] The DEWT provides a common language to discuss effective approaches to reducing weaknesses in digital evidence and increasing reliability of forensic results and expert opinions.

The DEWT knowledge base will be freely available to everyone, helping practitioners, attorneys, developers, and researchers improve their understanding of problems in digital investigations.

- Practitioners can use the DEWT to help avoid potential problems in their work.
- Attorneys can use the DEWT to assess their cases for weaknesses.
- Agencies can use the DEWT to determine the most common sources of error and implement mitigations.
- Developers can use the DEWT to test their solutions for bugs and other issues.
- Researchers can use the DEWT to find gaps that require further study.

The objective of the DEWT is to increase trust and transparency in digital investigations and resulting digital evidence and expert opinions.

Impact Statement: This presentation will inform the forensic community of the range and scope of potential errors in digital forensic science and provide a systematic approach to prioritizing and mitigating these errors.

Abstract Text: The increasing complexity and diversity of computer technology and forensic methods make it difficult for practitioners, attorneys, developers, and researchers to know about every potential problem that can weaken digital evidence. Furthermore, criminals are exhibiting a variety of concealment behaviors that make it more difficult to find digital evidence of their activities. These challenges increase the risk of failures, errors, mistakes, and misinterpretations, undermining the primary purpose of forensic science to produce trustworthy understanding of digital evidence to support decision making in legal contexts. There is a pressing need for a knowledge base that describes potential weaknesses at each phase of the digital forensic process. The weaknesses include errors in digital forensic tools, incompleteness, misinterpretation, and inaccuracy related to the existence, alteration, association, or corruption of digital evidence.

This session presents the DEWT, a digital forensic community initiative to organize potential sources of error in the digital forensic process and to support error mitigation analysis. Specifically, the DEWT provides a systematic support for ASTM E3016-18, Standard Guide for Establishing Confidence in Digital and Multimedia Evidence Forensic Results by Error Mitigation Analysis.[1] The DEWT provides a common language to discuss effective approaches to reducing weaknesses in digital evidence and increasing reliability of forensic results and expert opinions. For each category of weakness, the DEWT outlines associated subcategories, mitigations, detection methods, and references to related resources. The DEWT can be used to highlight and mitigate weaknesses in a given item of digital evidence in a repeatable and transparent manner.

This session demonstrates how practitioners, attorneys, developers, and researchers can use the knowledge base, and developers will learn how to reference specific errors they have mitigated in their tools. Planned work will be discussed, including operationalizing the knowledge base and creating test datasets to increase visibility and understanding of errors at each abstraction layer.

Digital Evidence; Error; Mitigation

C2 NoSQL Database Forensics: An Analysis of Redis Logs

Oluwasola Mary Adedayo, PhD, The University of Winnipeg, Winnipeg, MB, Canada; Muhammad Abdul Moiz Zia, BCS*, The University of Winnipeg, Winnipeg, MB, Canada*

Learning Objectives: This presentation focuses on advancing the field of database forensics, with a specific emphasis on NoSQL databases where there is currently less research.

Impact Statement: This presentation will significantly impact the forensic science community by providing insights into NoSQL database forensics using the Redis server as an example. The presentation highlights potential sources of information in the database logs and the potential challenges in the analysis process.

Abstract Text: Many of the advances in database forensics have focused on relational database systems. However, with the changing landscape of data management, non-relational (NoSQL) database systems, particularly key-value stores, are increasingly essential for managing large amounts of data due to their simplicity and efficiency. This study utilized Redis, an in-memory key-value store, as a case study to demonstrate some of the challenges in database forensics examinations, with a focus on NoSQL systems. Drawing from many of the existing works in database forensics, logs play a critical role in database examinations, providing essential information about database operations and security incidents.[1,2] From a forensics standpoint, insights from these logs are vital for identifying security breaches, unauthorized access, and other suspicious activities that help piece together data and event reconstruction.

We hypothesize that while Redis provides basic logging and supports Access Control Lists (ACLs) for managing user permissions, there is a limited understanding of its logging behavior, particularly about how much information can be gathered about unauthorized command executions. To better understand this limitation, we conducted a detailed examination of Redis's default logging capabilities, focusing on different log levels debug, verbose, notice, and warning, and the events they record. We designed and executed a series of experiments to observe Redis' logging behavior under various scenarios, including both authorized and unauthorized command executions. By utilizing Redis' ACLs, we simulated unauthorized command attempts to evaluate Redis' ability to detect and log these events. Through these experiments, we also aimed to gain insights into Redis' operations and how it can serve as a potential source of information for forensic investigations, given the increasing use of key-value stores in application areas such as caching, session, user profile management, messaging queues, and publisher/subscriber systems.

Our evaluation uncovered several key findings. Debug-level logs provide detailed insights into the database's contents, such as the number of keys and their structure, which are crucial for debugging but lack context about ongoing operations. Verbose logs offer periodic snapshots of the database's status without additional context, while notice-level logs give critical information about the server's configuration and operational status but not detailed data changes. Warning logs highlight potential issues, such as memory overcommitment, without offering detailed diagnostic information or resolution steps. The ACL logs record user activities and the context of command executions but do not specify the outcomes or any errors. The MONITOR command logs real-time command execution along with client information but lacks user identification, command outcomes, error messages, performance data, and details about session durations or security incidents.

These findings advance knowledge on the forensics analysis of Redis databases and build on current works, which have focused on high-level experimentation to understand the data file structures in Redis.[3] Our experiments draw insights from the structures of the Redis data files in analyzing the logs for artifacts and limitations. The study provides a basis for identifying and acquiring artifacts from forensic analysis from Redis.

NoSQL Database Forensics; Reconstruction; Key-Value Stores

C3 Reimagining the Forensic Pipeline Out of Necessity

Mark D. Guido, MS, The MITRE Corporation, McLean, VA; Justin N. Grover, MS*, The MITRE Corporation, Mclean, VA*

Learning Objectives: The learning objective of this presentation is to introduce and describe a large-scale case study of the aftermath beyond triage and recovery from an incident in a large corporate setting. When presented with a large number of projects with potentially tainted data, the team constructed innovative and practical forensic workflow and file sanitization procedures.

Impact Statement: This presentation will impact the forensics community by discussing the aftermath of incident discovery and response. How does an organization protect the clean portions of its enterprise from data that was potentially exploited as part of a cyber incident? How can this be extended to help investigators that may need to deal with potentially tainted or malicious files from a forensic image?

Abstract Text: In April 2024, The MITRE Corporation discovered they were subject to an intrusion into one of its research and prototyping networks. MITRE's security team immediately began an investigation, cut off known access vectors to/from the threat actor, and brought in third-party Digital Forensics Incident Response teams to perform an analysis alongside the company's in-house experts. Prior to the incident, the impacted networks contained a significant number of actively used projects. While investigative activities may have yielded indicators of unauthorized accesses to projects and files, it was determined that it would be impossible to gain a full understanding of the actor's actions on the network to exfiltrate or impact files due to the potential for undiscovered capabilities and malware. MITRE faced the question: What can be done to get projects back online with a high assurance that any restored data was not compromised?

MITRE has a long history of developing solutions for cross-domain challenges, but usually these types of solutions deal with a limited number of file types and are designed, developed, and tested with customer requirements provided in advance.[1-3] This incident was treated as a novel cross-domain challenge involving hundreds of known and unknown file types, each of which could be compromised through unknown adversary malware. The team could not rely solely on traditional Anti-Virus (AV) solutions, given that AV products are not 100% effective in identifying malware.

During the presentation, the team will unveil a new forensic pipeline that was built, tested, and used to aid in the aftermath of MITRE's cyber intrusion event. The team will provide strategies, recommendations, and lessons learned for others that may be similarly impacted. Topics will cover forensic file type handling, data transfer, automated analysis, and reporting. For example, text files (e.g., configs, code, free text, etc.) proved to be a complex challenge when ensuring that no executable data would traverse from our "dirty" to "clean" networks. We will also describe procedures used for other popular file types to ensure that malware could not be embedded in those formats.

We will also discuss a custom physical one-way transfer solution that was developed to confine undiscovered malware that may be attempting to break out of our "dirty" network. As Stuxnet has demonstrated, removable media can be exploited to jump air gapped networks.[4] The solution kept all data on-net, which became paramount for speed and reliability during automated workflow processes. The capability also mitigated the potential for malicious processes to laterally move across boundaries using most modern internet protocols. We will discuss, in practical terms, these added innovations that enabled MITRE to migrate projects to "clean" environments and reestablish trust in our data in a relatively short amount of time.

C4 Bias in Bytes: Practitioner Awareness in Digital Forensics

Chris Shennan, MSc, Liverpool John Moores University, Liverpool, England, United Kingdom*

WITHDRAWN

C5 A Forensics Investigation of the Social Networking Application: Tencent QQ on iOS and Android

Yufeng Gong, MS, Purdue University, West Lafayette, IN; Umit Karabiyik, PhD*, Purdue University, West Lafayette, IN*

Learning Objectives: This presentation will reveal the forensically recoverable artifacts from a popular social networking application, Tencent QQ, with a variety of functions, including device connection, file editing and transferring, built-in camera, shared documents, payment and service, real-time location sharing, contacts, QQ group activities, messages withdrawal, conversation history, QQ zone, payment, private information preserving and protecting.

Impact Statement: This presentation can aid digital forensic investigators in a thorough analysis in their cases where QQ application is used. What's more, it can serve as a foundational reference for other researchers. They can build on our findings to further explore Tencent QQ and apply similar techniques to other applications. Recovered artifacts can inform the enhancement of existing forensic tools that can automatically extract and analyze Tencent QQ artifacts, thereby improving investigations' efficiency. Researchers and educators can use your findings as case studies or training materials, which can assist new forensic analysts to handle data from social networking applications.

Abstract Text: Tencent QQ, founded in 1999, stands as one of the world's most widely used instant messaging applications, with a peak user base of around 900 million in 2016.[1] Despite the rise of similar applications like Instagram, Discord, and WeChat, QQ continues to hold its ground, particularly among young adults in China. As of December 2023, QQ still boasts nearly 600 million users, with the majority under 25 and only 0.9% between the ages of 26 and 35.[2,3] According to a report by QuestMobile, QQ remains the most popular instant messaging app among young people in China.[4] Given its extensive user base and features, mobile forensics on QQ is crucial. One representative issue concerning QQ is that it includes a payment feature called CAIFUTONG, used for personal and business transactions, which has unfortunately attracted scammers, particularly in Southeast Asia. These fraudsters exploit QQ to contact victims and extort money, leading to significant and often irrecoverable losses. This ongoing issue underscores the need for comprehensive forensic research into QQ's functions to enhance security measures and protect users from fraud.

While there have been numerous forensic studies on QQ since 2009 focusing on its memory functions, instant messaging capabilities, and PC version, many of its newer features have not been fully explored. To address this gap, we conducted a comprehensive forensic analysis of QQ's latest functions on Android and iOS devices. This includes an examination of device detection, file editing and transferring, the built-in camera, shared documents, payment and service functions, message withdrawal, real-time location sharing, contacts, QQ group activities, conversation history, QQ Zone, and private information preservation. This study has uncovered security-critical evidence related to payment functions, location data, identity information, chat histories, multimedia files, and contact information.

This presentation will delve into the recovered artifacts from Tencent QQ by examining its features carefully. The research is designed to assist investigators in fully harnessing the forensic recoverability of QQ's updated functionalities. Gaining insight into the types of evidence that can be retrieved and understanding the scope of recoverable data is crucial for addressing current knowledge gaps. These artifacts are crucial for uncovering evidence in criminal investigations and tackling issues related to cybercrime as well as safeguarding personal and corporate security. By preserving and analyzing digital evidence, mobile forensics are essential for protecting individuals and organizations from various security threats.

Mobile Forensics; Social Networking; Tencent QQ

C6 A Story of Obsession: Data Analysis of a Stalker's Mobile Phone Device

Nicole R. Odom, MSFS, University of Wisconsin-Madison Police Department, Medex Forensics, Richmond, VA*

Learning Objectives: Through this presentation, attendees will learn about the immense amount of data stored in a wide variety of applications on mobile phones and how this information provided detectives at the University of Wisconsin-Madison's Police Department (UWPD) substantial documentation of a stalker's mental state and resulting actions.

Impact Statement: This presentation will impact the forensic science community by providing a detailed breakdown of phone usage and explaining how, through in-depth analysis, several independent data points can be connected to relay an individual's mindset and behavior both via actions performed directly by the user or those passively recorded by a digital device.

Abstract Text: In early 2024, a resident of Madison, WI, was repeatedly contacted and physically approached by a former partner, leading them to file an incident report of stalking with the UWPD. Through the resulting investigation, the offending party's mobile phone device was acquired via consent. A thorough review of the suspect's device revealed that the claims of stalking were well-founded and were, in fact, much more in-depth than originally anticipated.

In this technological day and age, it is commonplace for much of the public to not only own a mobile phone device, but to also carry it on their person at all times. Given all the various applications running on these devices, and the fact that software developers often strive to collect and categorize as much data as possible about their users, there is a vast amount of data being created and stored about an individual on any given day. This only continues to increase exponentially as smart phones advance, adding a variety of hardware sensors and robust operating systems capable of all sorts of communication methods, search utilities, location capabilities, and multimedia functionalities.

Due to this overwhelming amount of content potentially obtained from each device, it can be easy to extract and produce everything in a report without providing any context to the data; however, this case study will highlight the importance of our responsibility as digital forensic examiners to thoroughly review and correlate the information presented to us and to transform vast quantities of data into evidence that has solid probative value. By breaking the data down into small chunks of relational information, it is possible to effectively tell the story of a stalker solely through their digital footprint, outlining their thought process from the initial breakup to breaking point to arrest in a way that is irrefutable.

Mobile Device; Digital Evidence; Psychological Behavior

C7 ImageRec: A Tool for Android In-Memory Code Reconstruction

Aisha Ali-Gombe, PhD, Louisiana State University, Baton Rouge, LA*

Learning Objectives: The audience will learn about Android runtime design and how that can aid the recovery and reconstruction of in-memory code. Additionally, the presentation will provide a detailed comparison between the in-memory structures used for Code management from Android 8-14, which is invaluable to the field of mobile memory forensics. Finally, the presentation will provide a case study of how the proposed tool was used to recover code that was not available at installation and had no footprint on the disk.

Impact Statement: From a digital forensics standpoint, this tool can impact the community in code recovery, which can then be used to identify the underlying structure of application logic and, thus, facilitate data and user activity recovery.

Abstract Text: Android application developers generally withhold loading their complete code from Google Play to protect against reverse engineering and IP theft, opting instead for a skeletal version that is replaced or updated upon installation. Moreover, apps may load dynamic classes at runtime that only leave a footprint in the transient memory. This challenge of the potential lack of a complete code base in secondary storage and/or marketplace can significantly negatively impact mobile forensics and malware analysis. Addressing these challenges, we propose ImageRec—a tool designed to recover and reconstruct an Android-loaded code base from a target process's memory image. ImageRec works by navigating the runtime object to locate the OAT File Manager pointer, which leads to a set structure containing addresses of OAT Files associated with the process. By traversing each OATFile structure, ImageRec focuses on retrieving the file name and the embedded OAT dex files' storage locations in memory, enabling the recovery of all developer's loaded dex files and any boot images used by the runtime environment.

Our evaluation of the recovery path for Android Dex files from Android 8-14 showed that the same structures are maintained for this purpose. However, we observe a notable shift in the recovery offsets for some internal structures. We also assessed ImageRec by analyzing the Facebook process memory, successfully recovering the entire app code base, including the Instant Game code. This enabled a detailed examination of the design and operation of these games within Facebook. Our analysis revealed that the games are hosted within a WebView object, with settings like setAllowFileAccess, setMixedContentMode, setJavaScriptEnabled, addJavaScriptInterface, and setAcceptThirdPartyCookies enabled by default. Notably, these settings cannot be disabled by users, raising potential concerns regarding user control and security. From a digital forensics standpoint, this tool is instrumental in recovering code, which can then be used to identify the underlying structure of application logic and thus facilitate data and user activity recovery.

Android; Cyber Forensics; Code

C8 The Reliability of Confidence Factors in iPhone GPS Data for Forensic Applications

Jeff Rutherford, BS, Magnet Forensics, Roswell, GA; Romy Haas, BA, Los Angeles County Sheriff's Department, Los Angeles, California; Danielle Ponce de Leon, BS, Los Angeles County Sheriff's Department/Homicide Bureau, Los Angeles, California*

Learning Objectives: From this presentation, participants will learn how to rigorously validate the accuracy of geolocation data extracted from iPhones, focusing on the reliability of Apple's confidence factors. By applying statistical analysis and comparing Global Positioning System (GPS) points to a known reference point, participants will gain measurable skills in assessing the precision of geolocation data, which is essential for forensic investigations and legal proceedings.

Impact Statement: This presentation enhances the forensic science community's competence by providing methodologies to validate the accuracy of geolocation data extracted from iPhones. It translates this competence into action by offering practical steps for forensic examiners to assess and verify the precision of GPS data in real-world scenarios. Stakeholder outcomes are positively impacted as legal professionals and investigators gain reliable data to support or challenge evidence in court, ensuring accurate and just judicial decisions.

Abstract Text: In modern digital forensics, the ability to accurately validate geolocation data extracted from smart phones is paramount, particularly in legal proceedings where the integrity of evidence is scrutinized. This study focuses on the analysis of geolocation accuracy of digital forensic data extracted from an iPhone. Specifically, it examines the reliability of the confidence factor assigned by Apple to each GPS point by comparing the recorded locations to a known reference point. The necessity for precise validation of GPS data in legal context arises from the critical role this information can play in establishing alibis, tracking movements, and corroborating or refuting testimonies. Inaccurate geolocation data could lead to wrongful conclusions, affecting the outcomes of investigations and judicial decisions.

Geolocation data extracted from iPhones includes latitude, longitude, timestamps, and confidence factors, all of which are stored in various databases within the device. A key database utilized in this study includes Cache.sqlite, which stores detailed records of a device's location history. This database provides a wealth of information but also necessitates rigorous validation methods to ensure the data's accuracy and reliability.

This study establishes and validates an accuracy factor by measuring the distance between the extracted GPS points and a pre-determined reference point and then comparing these distances to the expected values indicated by the confidence factors. This factor quantifies the precision of the geolocation data, providing insights into the effectiveness and reliability of Apple's location services in digital forensic applications. Such validation is crucial for forensic examiners and legal professionals who must rely on this data to construct or dismantle narratives in court. The study aims to enhance the forensic community's understanding of geolocation data accuracy and provide methodologies to ensure its reliability in legal contexts.

Per the Apple developer website, the data variable horizontalAccuracy (referred as confidence factor in this report) is: the latitude and longitude specified by the coordinate property identify the center of the circle, and this value (horizonalAccuracy) indicates the radius of that circle.[1]

Additionally, this study focuses not on the accuracy of the individual GPS data points relative to the actual known GPS location but rather on assessing the reliability of Apple's "horizontalAccuracy" confidence factor in representing the precision of the collected GPS data points. This will be defined by examining whether collected data points fall within each individually reported confidence factor.

Digital Evidence; Forensic Science; Forensic Investigation

C9 Using TikTok Around the World: A Comparison and Updated Forensic Analysis of TikTok on Android and Ios

Xiao Hu, Purdue University, West Lafayette, IN; Umit Karabiyik, PhD*, Purdue University, West Lafayette, IN*

Learning Objectives: By attending this presentation, attendees will be able to understand the main content and storage path of key data in a TikTok application installed on both Android and iOS; learn the updated parts of artifacts compared to previous studies; recognize the characteristics and differences in the information stored in TikTok between different APK versions; and distinguish the performance of commercial and open-source digital forensic tools for parsing TikTok.

Impact Statement: This presentation will impact the forensic science community to further explore the forensic value of TikTok by identifying the types, locations, and analysis methods of artifacts related to TikTok's main features and the new feature, TikTok store. The results of this work cover TikTok versions used in different parts of the world, raising awareness on a larger scale that digital forensics research should evolve more aggressively to keep up with the rapid technological advances in social media platforms.

Abstract Text: TikTok, the online video-sharing social media network, has made a significant impact worldwide. With over 37 million active users in the United States alone, it has become a dominant force in the social media landscape. Dedicated to creating and sharing short videos, TikTok has gained immense popularity.[1] Recently, the platform introduced the TikTok store feature, which collects sensitive data related to users' orders, addresses, and payments. The forensic analysis of TikTok can provide valuable insights into user behavior, data transactions, and potential security vulnerabilities. However, despite its massive user base, TikTok's forensic research capabilities still have room for improvement.

This presentation will illustrate the analysis of TikTok's general information, media, and new shopping features, updating previous research on this app. In the general information section, we will present data about user accounts and apps. In the media section, we will explain how to discover the video content uploaded and watched by users and suggest possible ways to differentiate what users watched. The research methodology used in our study follows the approach described by Fahad E. Salamh et al. in and is further guided by the National Institute of Standards and Technology (NIST), which consists of five phases: data population, data acquisition, analysis and examination, validation, and reporting.[2,3] Since TikTok uses different APKs in different regions, this presentation will also contrast TikTok applications using different APK versions. In our forensic images that will be presented, scenarios include account registration, keyword searches, user conversations, follower additions, video uploading and favoriting, card registration, purchases, etc. In terms of the use of digital forensic tools, we will also report on the results of analyzing our images using both commercial tools such as Magnet AXIOM and open-source tools such as iLEAPP, thus further comparing their effectiveness. This work further refines the forensic analysis of TikTok by providing investigators with information about TikTok-related folder structures and important data paths, offering valuable insights into digital forensic investigations, which are crucial for keeping up with the rapid technological advancements and overall development of social media platforms.

Forensics; Mobile Device; Data

C10 A Forensic Analysis of Google Fit App on WearOS

Chen Shi, MS, Iowa State University, Ames, IA; Yong Guan, PhD, Iowa State University, Ames, IA*

Learning Objectives: Attendees will gain insights into the fundamental challenges and limitations in extracting forensic artifacts from the Google Fit app on WearOS. They will learn how to utilize a novel forensic analysis toolkit specifically tailored for WearOS to automatically detect and analyze forensic artifacts stored on smart watches and data transmitted to paired phones. The presentation will cover the types of data stored and transmitted by the Google Fit app, including health data, location data, and device data, as well as the mechanisms of data transmission between Google Fit and other connected apps, highlighting potential exposure of sensitive information. Additionally, attendees will understand the importance of data storage and transmission for forensic investigations, focusing on the identification and preservation of evidence. The presentation will include a comparative analysis with existing mobile forensic toolkits, demonstrating the effectiveness and efficiency of the new methodology through experimental evaluations. The broader implications for forensic science, application security, and the development of robust forensic analysis procedures will also be discussed.

Impact Statement: This presentation will significantly impact the forensic science community by introducing innovative methodologies for analyzing data from wearable devices, specifically the Google Fit app on WearOS. By providing a comprehensive forensic analysis toolkit tailored for WearOS, the presentation will enhance the ability of forensic investigators to automatically detect and analyze forensic artifacts stored on smart watches and data transmitted to paired phones. This will improve the efficiency and accuracy of forensic investigations, particularly in cases involving data breaches, unauthorized data access, or personal injury claims where health data is critical. Additionally, the insights gained from this analysis will aid in the development of more secure wearable technologies, ensuring better protection of user data. Ultimately, this presentation will contribute to the advancement of forensic science by offering new approaches to uncovering crucial evidence and promoting the development of robust forensic analysis procedures.

Abstract Text: Our detailed analysis uncovers various types of data from the Google Fit app, including health data (such as heart rate and activity levels), location data (Global Positioning System [GPS] coordinates), and device data (sensor readings).[1] Additionally, we examine the data transmission between Google Fit and other connected apps, shedding light on how these interactions can potentially expose sensitive information.

The forensic toolkit identifies and analyzes how data is stored locally on the smart watch and how it is synchronized with paired devices. Health and activity data are frequently transmitted to the user's phone and backed up on Google's servers, facilitating seamless synchronization across devices. This transmission process involves various data types, including user activity logs, health metrics, and sensor data, which are critical for providing personalized fitness insights and recommendations.

Understanding the storage and transmission mechanisms is crucial for forensic investigations as it allows for the identification and preservation of evidence. This kind of analysis is important in the cases involving data breaches, unauthorized data access, or even in personal injury claims where health data can serve as evidence.

Our methodology includes a comparative analysis with existing mobile forensic toolkits and demonstrates the effectiveness of our approach through extensive experimental evaluations. The toolkit significantly expedites the investigation process and enhances the ability of forensic investigators to locate and analyze forensic artifacts with high precision.

The implications of this study extend to the broader forensic science community, developers, and researchers. By understanding the forensic artifacts generated by the Google Fit app on WearOS, stakeholders can better protect user data, improve application security, and develop more robust forensic analysis procedures.[2]

Overall, our findings provide valuable insights into the types of data stored and transmitted by the Google Fit app on WearOS. This analysis not only underscores the importance of securing wearable devices but also highlights the potential forensic implications, given the sensitive nature of the data involved.

C11 Unveiling Sleep Patterns: Insights From Garmin FIT Protocol Data

Nina Matulis, MS, Purdue University Lafayette Police Dept., West Lafayette, IN; Jenna Rockhold, BS*, Purdue University, Lafayette, Indiana; Umit Karabiyik, PhD*, Purdue University, West Lafayette, IN; Marcus K. Rogers, PhD*, Purdue, West Lafayette, IN*

Learning Objectives: After attending this presentation, attendees will have a comprehensive understanding of Flexible and Interoperable Data Transfer (FIT) Protocol files designed by Garmin developers, specifically, the forensically relevant data contained in these files. The FIT files collected and analyzed in this study focus specifically on the sleep activity collected by a Garmin smart watch, although these files also keep location, activity, workout, and wellness data. Such data can be used as digital evidence in a law enforcement investigation, for instance, corroborating the alibi that a person of interest was asleep during the time a crime was committed.

Impact Statement: Due to the lack of previous research on the FIT Protocol and its related files, this presentation will be of great interest to the Digital and Multimedia Sciences community, as a deeper understanding of such files obtained from Garmin devices will be discussed.

Abstract Text: The everyday use of smart watches to track health and fitness information has become a common practice among adults in the United States. This is further supported by a study that indicated 25.8% (n = 2,368) of the total United States adults (n = 9,193) wore a smart watch to monitor their health and activity within the past 12 months.[1] Garmin, a popular smart watch brand, has devices that are most commonly used in tandem with a smart phone and the Garmin Connect app. Together, these devices and application collect a plethora of user health-related information, including but not limited to: number of steps, number of flights of stairs climbed, active energy, weight, body fat percentage, Body Mass Index (BMI), heart rate, resting energy, walking and running distance, workouts, and sleep analysis.[2] To effectively store and share such data, Garmin developers designed the FIT protocol, which "defines a set of data storage templates (FIT messages) that can be used to store information such as user profiles and activity data in files."[3] As the health and activity data potentially stored in FIT files could prove to be valuable evidence in a law enforcement investigation, understanding these files is of great importance to the forensic and law enforcement community. Due to the lack of previous research specifically focused on the sleep activity data in these files, this study aims to close the gap and gain further insight by forensically analyzing the sleep activity collected by a Garmin smart watch.

For this study, a Garmin vívoactive4 smart watch was utilized and synced with a Google Pixel 7a smart phone via the Garmin Connect App. Sleep data was populated by wearing the Garmin vívoactive4 while sleeping. As data population is completed, forensic images of the two devices used in this study are being collected. Thus far, two full file system images of the Google Pixel 7a using Magnet GrayKey and Cellebrite Premium have been acquired. In the near future, the researchers aim to collect the following forensic images: a Google Pixel 7a image using Android Logs Events and Protobuf Parser (ALEAPP), a Garmin vívoactive4 smart watch image using MOBILedit Smartwatch Kit, and Garmin Connect App images using Magnet AXIOM Cloud and an Application Programming Interface (API) developed for collecting smart watch cloud data. Upon analysis of the forensic images, the researchers will present the findings during this presentation.

Garmin Flexible and Interoperable Data Transfer (FIT) Protocol Files; Smart Watch Forensics; Sleep Activity Artifacts

C12 Utilizing Smart Watches in Forensic Science: A Case Study on Verifying Witness Statements and Tracking Drug Ingestion

Ashraf Mozayani, PhD, Texas Southern University, Houston, TX*

Learning Objectives: By the end of this presentation, attendees will gain insight into the value and potential of utilizing smart watch data in forensic science investigations. They will explore how this data can be integrated with witness statements to establish accurate timelines in drug-related cases. Additionally, attendees will become aware of the limitations and ethical considerations of using smart watch data in forensic investigations. This presentation aims to equip attendees with the knowledge and awareness to effectively incorporate smart watch data into forensic practices, ensuring responsible and informed decision-making.

Impact Statement: This presentation will empower the forensic science community to embrace and leverage the potential of smart watch data, leading to advancements in forensic science practices and the enhancement of investigative outcomes.

Abstract Text: The case history revolves around an individual suspected of drug abuse, with suspicions that her non-physician boyfriend injected her with ketamine and attempted resuscitation with multiple epinephrine injections before her death. The investigation team acquired a smart watch worn by the individual during the alleged incident. This smart watch, equipped with sensors measuring heart rate, motion, and other relevant parameters, provided critical data. Through meticulous analysis, investigators aimed to identify the probable time of drug injection. Additionally, witness statements from those present during the incident were collected, detailing the sequence of events, the presence of drug paraphernalia, and the individual's behavior. The goal was to compare the smart watch data with witness statements to establish a consistent and accurate timeline.

The findings of this case study underscored the utility of smart watch data in forensic toxicology investigations. The smart watch data revealed an increase in heart rate and expected motion patterns during the suspected time of drug injections. These findings were further validated by witness statements, which described the individual's behavior and the presence of drug paraphernalia during the same timeframe.

The collaborative approach of integrating smart watch data with witness statements proved instrumental in establishing a more precise timeline of the drug injection. This method not only strengthened the reliability of forensic investigations but also enhanced the admissibility of evidence in legal proceedings.

Despite the promising results, this study has several limitations. The accuracy of smart watch data can be influenced by factors such as device quality, placement on the body, and user activity levels. Witness statements are inherently subjective and may be affected by memory recall biases or personal perceptions. The reliance on a single case study limits the generalizability of the findings. Further research with larger sample sizes and multiple cases is essential to validate this approach. Ethical concerns regarding privacy and data security must also be addressed to ensure the responsible use of personal technology in forensic investigations.

This case study highlights the immense potential of utilizing smart watch data in forensic toxicology to determine the time of drug injection. The collaboration between smart watch data and witness statements offers a comprehensive and corroborative approach for establishing accurate timelines in drug-related cases. This research underscores the importance of integrating emerging technologies, such as smart watches, into forensic investigations to enhance evidence collection and analysis efficiency and accuracy. As technology evolves, its role in forensic science may oscillate between being a tool for transformation or tyranny, emphasizing the need for ethical considerations and rigorous standards in its application.

Scene Investigation; Mobile Device; Forensic Analysis

C13 DarkWeb Investigations Using Offensive Security Techniques

Gabriel Nunes, BS, Brazilian Federal Police, Curitiba, Parana, Brazil*

Learning Objectives: After attending this presentation, attendees will better understand the DarkWeb inner workings and implement several advanced cyber investigation techniques in this environment to identify malicious servers and users and de-anonymize services.

Impact Statement: This presentation will impact the forensic science community by providing extensive detail about DarkWeb investigations, enabling forensic analysts to uncover information that would not be possible through traditional techniques.

Abstract Text: The DarkWeb is a network environment, within the internet, that implements different protocols and massive encryption to protect its users data and provide extreme privacy. The access to these networks requires special software and their content is very difficult to index.

Several kinds of DarkWeb exist; the best known and most popular is The Onion Route, known as Tor.[1] This network uses multiple nodes before packets reach the final destination. Each of these nodes implements a level of cryptography in the application layer of the OSI Model and only knows the previous and next node, thus keeping the anonymity of this traffic. In this way, it also acts as a Virtual Private Network (VPN), protecting this data and hiding the source of these connections. The use of traditional investigation techniques for discovering information such as IP addresses, geolocalization of services, and user tracking are completely ineffective in these environments.

Despite this type of technology having been developed to assist with privacy and security, aimed at protecting freedom of expression in repressive regimes, for instance, what we are witnessing in reality is an increase in illegal activities on these networks. Currently, with technological advancements and the ease of using these tools, criminals are migrating to the DarkWeb. Ransomware groups, child pornography, drug trafficking, arms trade, and terrorism are examples of how these networks are being utilized.

Due to the encryption techniques implemented, new forms of cyber investigation must be applied by law enforcement agencies to collect and identify these malicious services.

Advanced offensive security techniques (hacking) can usher in a new era in the field of cyber intelligence and digital forensics. The use of social engineering can be employed for the de-anonymization of users in these environments. Vulnerabilities in web applications are a means for identifying the real IP address of a malicious server or for the remote collection of relevant cyber evidence, such as databases and internal operating system files.

Indexing services for devices such as Shodan and Censys can be used as means to de-anonymize servers on the Dark Web.[2,3]

This presentation will showcase practical case studies demonstrating how these techniques and tools are crucial for the discovery of information and identification of criminals in the most hostile environments on the internet.

DarkWeb; Offensive Security; Investigation

C14 The Combination of Non-Obvious Links in Online Fraud Investigations

Timothy Bollé, MS, Université du Québec à Trois-Rivières, Trois-Rivières, QC, Canada; Eoghan Casey, PhD, University of Lausanne, Lausanne, Vaud; Thomas Souvignet, PhD, University of Lausanne, Lausanne, Vaud, Switzerland*

Learning Objectives: Attendees will learn how to detect non-obvious links between fraud investigations using approximate matching of pseudonyms and how to combine multiple non-obvious links to help analysts work with big data. We will discuss the decision-making process of working with many investigations and dealing with an important number of links between them.

Impact Statement: This presentation demonstrates how digital traces can contribute to forensic intelligence and discusses the challenges of working with a large quantity of linked data. Based on real-world data, this research aims to provide actionable methods to assist field investigators and engage the research community in discussions about the relevance of detected links.

Abstract Text: This research concentrates on finding and combining non-obvious links between high-volume internet crimes to produce forensic intelligence. Non-obvious links are drawn using approximate matching of pseudonyms created by criminals. Perpetrators can easily switch to different online accounts or platforms, effectively changing their digital identity and the traces of their activities. As a result, unique and exact comparisons of digital traces is a limitation for link discovery in online fraud investigations. To overcome this limitation and avoid linkage blindness, it is necessary to use near similarity comparison of distinctive digital traces. Investigations usually involve many digital traces in each case, drawing multiple non-obvious links between them. Combining those weak links enables the detection of related investigations. With thousands of reported online frauds each year, this approach helps analysts prioritize important investigations involving many linked offences.

The first aspect of this work is focused on the detection of non-obvious links, using non-exact matching between pseudonyms. Various algorithms can be used to compute string similarity and a first step was to examine how these methods perform on short strings and how they can be used to produce sound and actionable intelligence in online fraud investigations. Preliminary results showed good performance on detecting similar pseudonyms but that a significant number of new links were detected.

The second part of this study examines the need for better and more transparent methods to combine and prioritize multiple non-obvious, or weaker, links. When faced with many investigations and thousands of kinks, it may be difficult for an analyst to decide where resources should be dedicated. The decision-making process of evaluating the combination of links found using near-similarity computation is an integral part of this work. Understanding the process leading to the detected links and their ranking is essential to manage investigative resources.

Methods to compute pseudonym similarity, the combination of non-obvious links, and the decision-making process surrounding these methods in the investigation of online frauds will be discussed in this presentation. The targeted audience is practitioners and academics of any level.

Forensic Intelligence; Approximate Matching; Cyber Forensics

C15 Principles of Locality of Reference: A Proposal to Reduce the Scope of Forensic Analysis in Cases Occurring in the Cyber Environment

Gustavo P. Vilar, MS, Polícia Federal Brasileira, João Pessoa-PB, Brazil*

C16 Is It a Transformation? Is It Tyranny? Is It Even Cost Effective? The Value of Independent Software Testing Your Technology

Marc Canellas, JD, PhD, Maryland Office of the Public Defender, Alexandria, VA*

Learning Objectives: The objectives of this presentation are to: (1) understand why independent software testing is valuable to forensic laboratories when purchasing and implementing new technologies; (2) understand what independent software means, the processes, and the documentation; and (3) understand how the results of independent software testing can inform their testimony in courts and the admissibility of evidence generated by software.

Impact Statement: From this presentation, attendees will better understand what to ask of developers when purchasing technology, what to do when they are making sure the technology works for them, and how to leverage these methods to ensure results of reliable technology are admissible in court.

Abstract Text: Forensic science is now a software-based discipline. DNA now has probabilistic genotyping. Fingerprints have the Automated Fingerprint Identification System (AFIS). Ballistics have the National Integrated Ballistic Information Network (NIBIN). Cell phone analysis and Global Positioning System (GPS) location are awash in readers and analyzers. As this conference asks: Are these technologies tools for transformation or tyranny? And as labs spending the money may ask: Are these technologies cost effective? This presentation answers that the only way to answer these questions is through independent software testing—the universal method that is used to ensure the effectiveness and safety of everything from our medical systems and nuclear power plants to mobile apps and games.1-3 Given the rise of software in forensic science, the community has increasingly interacted with software testing: testing prior to acquisition or implementation (e.g., before labs adopt STRmix) and responding to calls for testing by the White House, proposed federal legislation, and defense attorneys.4,5 Despite the rise in discussions of software testing, and the interest by forensic labs, this presentation will answer fundamental questions that have been left unanswered: (1) What is independent software testing? (2) What are the documents that labs should require before purchase from the developer and produce after their testing? (3) What are its implications for the questions of reliability?

First, software testing involves the processes of Verification and Validation (V&V), which are intended to show that a system both conforms to its specification (verification) and that it meets the expectations of the system customer (validation). This V&V process is foundational for any software system, including things as big as nuclear systems and as small as mobile games. Then, depending on how much risk is acceptable, there may be additional steps or required independence of the testers in order to prevent conflicts of interest. We know this from our daily lives: We don't trust students to grade their own homework, where all that is at stake is a GPA. This presentation will synthesize this understanding through a review of the industry standard documents like Institute of Electrical and Electronics Engineers (IEEE) 1012 Standard for System, Software, and Hardware Verification and Validation, the International Organization for Standardization/International Electrotechnical Commission (ISO/IEC)/IEEE 12207 Software Lifecycle Processes and Activities, and National Aeronautics and Space Administration (NASA) Procedural Requirement 7150.2D Software Engineering Requirements, and software engineering textbooks and handbooks.6-10

Second, prior to labs purchasing or relying on software, they should require documents to show that proper software testing was done. This includes the requirements document that provides complete details on how the system should behave. The verification in V&V is the process of making sure that the final system meets these requirements. The goal is that if the requirements are met, then the customer should be satisfied. There is also the V&V (or test) plan, which documents the steps the tester plans to take to ensure that the requirements (including what level of independence is necessary) and the customer are satisfied. One of the final documents is the acceptance test documentation that describes the final testing, making sure that the customer is satisfied with the software.

Third, when software-generated evidence is used in court, these documents are essential for understanding the evidence's reliability. Under Frye, independent software testing is the generally accepted method of determining any piece of software. Under Daubert, documented independent software testing will, by definition, address questions of standards and testing, while the results of the testing will generate meaningful error rates.

Ultimately, independent software testing is a long-established method that can assure the forensic science community that they are purchasing and implementing reliable software to transform the criminal legal system in positive way towards justice and away from tyranny.

C17 The Limitations of Digital Forensics Tools for Database System Examination

Bhavye Malhotra, BTech, Groww, New Delhi, Delhi, India; Oluwasola Mary Adedayo, PhD*, The University of Winnipeg, Winnipeg, MB, Canada*

Learning Objectives: The goal of this presentation is to highlight some of the yet-existing limitations of digital forensics tools in database systems examinations. The presentation focuses on a selected set of tools and compares their capabilities for database forensics analysis.

Impact Statement: This presentation will impact the forensic science community by focusing attention on the challenges in database forensics and highlighting the limitations of existing tools as well as how the capabilities of the tools can be improved.

Abstract Text: Over the past decade, there have been advances in the definition of processes for database forensics and data reconstruction methods.[1,2] Many have also highlighted several challenges relating to the use of digital forensics tools for database analysis. However, it is important to focus on each challenge in relation to the goals of database forensics analysis to better understand the limitations of the existing tools and changes that may be necessary to address these challenges.

In this work, we focus mainly on some of the common tools that can be used in the database forensics process, such as Autopsy, ILEAPP, ALEAPP, and FTK imager. We evaluated the usability of these tools for some of the processes in database forensics by conducting several experiments, involving custom database setups and using dumps from different devices, including mobile phones.

Our analysis shows that when examining database files, many tools are unable to extract Binary Large Objects (BLOBs) such as images, videos, and other multimedia objects from the data file. Also, in many cases, it was impossible to view database files based on their associated applications. Although most tools support searching within an overall file system, the ability to search or sort within records and fields in data files was absent in many tools. For mobile devices, the use of location information stored in databases on the devices as well as the ability to parse common database file type into a viewer was incorporated into many tools. In terms of reconstructing data deleted from a database, only a subset of the tools could recover the information from the disk. In some cases where data is recovered, that data can no longer be associated with the database. In other cases, only the unallocated memory space was identified and the data had to be manually recreated. In addition, dependent database files such as Write-Ahead Log (WAL) files and Shared Memory (SHM) files could not be extracted at all or in a way that preserved their dependency in many cases.

Our experiments also considered some of the known challenges of database forensics with respect to tools to evaluate how well some of the challenges have been addressed. The complexity of database systems and the interconnection of different database objects are some of the major challenges discussed in the literature. We note that while the retrieval of database files, especially in relational databases, can be done with some existing tools, complex structures such as indexes, schemas, and triggers still require a manual process to retrieve them. Also, processes such as handling database file formats that are not commonly used, capturing database memory, and handling encrypted information are all still particularly challenging when using existing tools for database systems. Although our experiments did not explore all possible digital forensics tools, these findings provide insights into many aspects of tool development that are still required for database forensics examinations.

C20 An Update on the Status of a Facial Identification Certification Program

Steven L. Johnson, BS, Ideal Innovations, Inc., Arlington, VA*

Learning Objectives: To update attendees regarding the status of a Facial Identification (FI) Certification Program and the challenges/hurdles the developers face throughout the process. The presentation will cover, at a high-level: (1) requirements necessary for creation of a new certification program, (2) challenges to achieve "accreditation level" approval, (3) events and incidents that have heightened interest in a certification program, (4) stakeholders in the forensic community that are tracking the program's progress, and (5) anticipated launch window and expected initial participation.

Additional elements include: (1) a better comprehension of FI as a forensics discipline, (2) more insight into the certification program development process, (3) understanding the increasing need for highly qualified facial examiners and reviewers, and (4) seeing the growing interest in FI from the stakeholder community.

Impact Statement: Despite the fact that FI as a forensic discipline has a relatively short history (the Facial Identification Scientific Working Group [FISWG] was founded in 2009), the increased accuracy of Facial Recognition (FR) algorithms has increased the spotlight on the practice as well as the demand for law enforcement use. Professional courses of instruction and a valid, accredited certification program are a logical next step for this discipline.

Abstract Text: Law enforcement use of FR technology remains a controversial subject, but there is growing support for use of FR as part of an investigative enterprise pursuant to assisting in the identification (and potential apprehension) of perpetrators of criminal activity. In order to ensure the highest level of accuracy and mitigate potential misuse of this technology, training, proficiency, and certification of FR system end-users will be essential for acceptance from the legal community, the media and the general public.

This "Update on the Status of a Facial Identification Certification Program" is intended to further inform the forensic science community and other stakeholders regarding how and when a program of testing will be made available to facial identification professionals. Interest in the status of this effort reaches the highest levels of state and federal government organizations as there is general consensus that by establishing competency and proficiency assessments through vetted and valid testing programs, there will be significant improvement in the effectiveness of the overall FR system enterprise. As FR algorithms improve, the accuracy tends toward more challenging comparisons of possible source exclusions and inclusions. Just as Automated Fingerprint Identification Systems (AFIS) require a well-trained and experienced fingerprint examiner to adjudicate the algorithmic results of a search, an automated face identification system (or a multimodal biometric system that includes a facial algorithm) requires similarly trained and skilled facial examiners and facial reviewers to assess and compare resulting face image probe searches against a controlled capture known face database. Additionally, like latent print examiners, facial examiners are expected to work with extremely challenging comparisons. Often these unknown images are results of closed-circuit and/or surveillance camera stills with poor lighting, less than optimal pose, and often exhibit other image quality artifacts. Properly training and tested practitioners will understand how these challenges to comparison can be addressed and overcome. The presentation will include: (1) a summary of training and experience requirements to be eligible for certification testing, (2) a list of the reference materials necessary to prepare for testing, (3) a description of the practical and written tests, and (4) a breakdown of the two levels of certification (Reviewer and Examiner).

Facial Identification; Certification; Law Enforcement

C21 Distinguishing Head Poses From Camera Angles in Non-Frontal Images for Automated Face Identification

Petra Urbanova, PhD, Masaryk University/Faculty of Science, Brno, Jihomoravsky Kraj, Czech Republic; Tomas Goldmann, PhD, Brno University of Technology, Faculty of Information Technology, Brno, Jihomoravsky Kraj, Czech Republic*

Learning Objectives: After attending this presentation, attendees will understand the challenges encountered by state-of-the-art face processing algorithms. They will become familiar with performance results obtained from images taken with varying head poses and camera angles.

Impact Statement: This presentation will impact the forensic science community by illustrating how variations in head pose. caused by the subject's head movement and camera angle, resulting from changes in the camera's position, affect automated face identification.

Abstract Text: Changes in view have been identified as key factors that influence a person's physical appearance captured in images, consequently diminishing the performance of automated identification systems.1 The angle of view is a result of two distinct positions: head pose and camera angle. Head pose is intrinsic to the subject, referring to the orientation of a person's head relative to their body. It can be described in three main directions: roll (motion toward the right/left shoulder), yaw (right to left), and pitch (up and down), although any combination of these directions is possible, limited only by the subject's range of motion. Camera angle, by contrast, is extrinsic to the subject, referring to the position and orientation of the camera relative to the subject. It includes the height, distance, and angle at which the camera is positioned when capturing an image, often dictated by the camera's purpose (surveillance, communication) and the circumstances while in use (visibility). Both factors change the appearance of the face but in different ways. Head pose alters the alignment, visibility, and appearance of facial features. In contrast, camera angle changes the perspective and proportions. In studies of automated face identification, the effects of head and camera orientation have typically been considered together without further distinctions. However, with the rise of surveillance using drone-mounted cameras, where non-stationary camera angles collide with the subject's behavior, it has become crucial to properly distinguish between their separate effects on automated identification. Additionally, distinguishing between head pose and camera angle is essential when comparing 2D and 3D images, where the angle of view is simulated by rotating a 3D face.

This study tests the influence of view angle, separated into head pose and camera angle, on automated face processing, which includes face detection, view estimation, and face identification. The sample consisted of 145 participants, 74 males and 71 females of European descent, aged between 19 and 87 years. For each participant, an array of 75 photographs varying in head poses, camera height (from 0.87m to 2.24m), and angles (from 0° to ±145°) at a constant camera-to-subject distance of 0.83m was collected. In total, the dataset comprises 10,955 images with a resolution of 4208x3120 pixels. Additionally, each subject's 3D facial appearance was captured using the Vectra 3D imaging system. Head poses were determined according to a 3-point plane constructed using the right and left tragion and the intersection between the assumed line connecting the right and left infraorbital margins and the mid-sagittal plane.

The study tested selected algorithms for face detection (OpenCV, RetinaFace, YOLOv8 Face) and view angle estimation (MediaPipe, SPIGA, FLAME). For face identification, the performance of two open-source algorithms, ArcFace and MagFace, was explored.2,3 Dissimilarity scores were recorded for each pair-wise intra-/inter-person comparison. Additionally, facial typicality/uniqueness scores were computed as standardized Procrustes distances between a subject's 3D face and the mean. The performance was evaluated using Receiver Operator Curve (ROC) curves and likelihood ratios. To explore the effects of head and camera views, angles were expressed as sine and cosine values and treated as covariates.

The results revealed significant variation in the performance of face detection and angle view estimation algorithms when subjected to different head poses and camera angles. They also validated the need to address head poses and camera angles separately. ArcFace consistently underperformed compared to MagFace. Furthermore, the algorithms varied in how they handled intra-person and inter-person comparisons, which notably impacted their overall performance. Our study underscores the importance of thoroughly understanding algorithms and their performance under various real-world conditions to enhance the transparency of automated face identification in forensic settings and address the black-box problem.

Scheible, MFS, North Carolina State University, Raleigh, NC; Jane C. Harris, PhD, Northern Michigan University, Marquette, MI; Christina A. Malone, MSFS, USACIL, Atlanta, GA; Lora Sims, AS, Ideal Innovations, Inc, Bridgeport, West Virginia*

Learning Objectives: After attending this presentation, attendees will: (1) understand the source opinion categories provided in Organization of Scientific Area Committees (OSAC) Proposed Standard 2022-S-0001; (2) consistency of source opinions for face, hands, and clothing image pairs among both forensic practitioners and laypersons; and (3) considerations when conducting a global interlaboratory study.

Impact Statement: This presentation will impact the forensic science community by demonstrating of the value of OSAC developed standards for practical use in digital and multimedia forensics. This is the first verbal opinion document for comparisons to come out of OSAC and provides a framework for numerous digital/multimedia disciplines. Thus, it is imperative that practitioners who complete image comparisons have a standard that is straightforward, applicable to diverse subjects, and, when followed, permits reproducible results.

Abstract Text: Forensic image comparison is an assessment of the correspondence between features in questioned items depicted in images and either questioned or known objects or images for the purpose of rendering an expert opinion regarding identification or elimination. Images that are sent to forensic laboratories for comparison include but are not limited to faces (and other body parts/areas), vehicles, weapons, clothing, luggage, furniture, landscapes, and buildings. Trained forensic practitioners are tasked with determining whether there is sufficient support to conclude either common source or different source.

To harmonize the opinion categories used across the digital multimedia forensic disciplines for image comparisons, a task group consisting of individuals from the Digital/Multimedia Scientific Area Committee (DMSAC) of the OSAC for Forensic Science developed OSAC Proposed Standard 2022-S-0001, Standard Guide for Image Comparison Opinions. While this proposed standard was extensively developed with input from a broad range of United States-based forensic practitioners, the practical utility to reproducibly apply the opinion categories in 2022-S-0001 has not been assessed. To ensure this standard meets the OSAC program goal of developing technically sound standards and promoting their adoption through the forensic community, an interlaboratory study focused on 2022-S-0001 was conducted using face, hands, and clothing images. Two cohorts of individuals were recruited to participate: (1) forensic practitioners who have been determined to be competent by their respective agency, organization, or other entity, and currently conduct forensic casework on face, hands, or clothing image comparisons; and (2) laypersons composed of individuals trained in forensic science but not image comparisons, undergraduate/graduate forensic science students, and the general public.

Machine learning approaches were used to identify 100 face, hands, and clothing image pairs from over 125,000 images licensed to the North Carolina State from the University of Notre Dame Computer Vision Research Laboratory. Subject matter experts subsequently selected a total of 20 image pairs for each image category that included varying source (i.e., same or different) and difficulty (i.e., easy or hard comparison). Qualtrics was used to disseminate a survey to over 60 forensic practitioners and 100 laypersons and collect participants responses. This presentation will present the results on the distribution, reproducibility and accuracy of source opinion categories (as specified in 2022-S-0001) selected when completing image comparisons. Additionally, we will assess whether results are correlated to the participant cohort (e.g., forensic practitioner, laypersons), image subject (face, hands, or clothing), and the level of relevant expertise/training.

OSAC Proposed Standard; Image Comparisons; Digital and Multimedia Forensics

C23 An Evaluation of Interpolation Methods and Their Impact on Resizing Images: Is the Nearest Neighbor Algorithm the Best Solution in All Situations?

Jason Latham, MS, Complete Digital Forensic Solutions, Wheat Ridge, CO; Douglas S. Lacey, MS, BEK TEK LLC, Stafford, VA*

Learning Objectives: Many video and image forensics training organizations have taught and currently teach when resampling images/videos (enlargement, line duplication, correcting pixel dimensions and aspect ratios, etc.) that the nearest neighbor algorithm may be the most accurate and reliable method to "forensically" conduct this process in certain circumstances. Many forensic practitioners in the Digital and Multimedia Evidence (DME) field contend this resampling algorithm is the only "valid" approach to produce accurate and reliable data for use in forensics when the resampling algorithms are applied to preserve the original image pixel details and identify small and/or discrete objects (e.g., weapons in hands, tattoos, license plate characters, etc.). Although this method is being taught and recommended for specific forensic purposes, very little if any independent and objective scientific research has been conducted to evaluate these statements and this approach. This research was conducted to start this scientific discussion and to evaluate these claims using carefully designed experiments and a novel approach to resampling test images. Various statistical techniques were used to evaluate the results.

Impact Statement: This work used a novel scientific method to generate various known test images containing specific content (down-sampling). These test images were generated in a very careful and specific process such that the resampling algorithm used to resize (up-sample) the test images to the original pixel dimensions (size) could be compared to the original starting test image in a statistical manner (quantitative analysis) to assess any difference the algorithm had introduced in the process. We compared the interpolated image to the original image to assess the statistical differences between the images and which algorithm was most similar and dissimilar to the original unaltered test image.

Abstract Text: Digital forensic laboratories receive video and image data in a wide variety of formats, pixel dimensions, and levels of compression. Many of these files are from Digital Video Recorders (DVRs), body-worn cameras, mobile devices, and other surveillance systems. Many of these recording systems generate data in a proprietary format or do not conform to standard video and/or image pixel dimensions (height x width) and aspect ratios (width divided by height). Many times, this data is in a non-standard aspect ratio, and this must be corrected to accurately represent the real-world scene as it was captured. This involves resampling the data in the image/video typically into larger standard dimensions and aspect ratios. This resampling is accomplished by interpolation algorithms.

For many years, forensic practitioners have been taught that the nearest neighbor algorithm may be the most accurate and accepted method to accomplish this task. In this research, we reviewed the common and generally accepted interpolation algorithms available to forensic practitioners and tested them on known data to evaluate the pros and cons of each approach. Several difference statistics were used to evaluate the changes to the base image through the interpolation process to assess how similar the resampled data is to the original. Several methods of evaluating the effect of the interpolation algorithms on the resized data were used to assess the mathematical similarities of each interpolation approach. The final analysis involved applying these techniques to real-world image data to determine if there are situations where one resampling algorithm is more or less appropriate based on the statistical analysis of these differences. Various statistical models were applied to attempt to determine the meaning and interpretation of these differences and what variable(s) may be at play, if any. This is the first step in scientifically evaluating the various resampling approaches to see if there are any differences and potential impacts.

Digital Evidence; Forensic Imaging; Forensic Science

C24 Identifying Social Media Video Provenance Through Forensic Structural Analysis

Clarissa YJ Tan, MSc, Liverpool John Moores University, Liverpool, England, United Kingdom; Brandon Epstein, MS*, Medex Forensics, Freehold, NJ; Bertram Lyons, MA*, Medex Forensics, Madison, WI*

Learning Objectives: Attendees will gain a clear understanding of how social media platforms alter video files upon upload, leaving unique digital "signatures" that can be used to verify the provenance and authenticity of video evidence. This knowledge will enhance their ability to investigate the provenance of video files.

Impact Statement: This presentation will equip the forensic science community with advanced methods for identifying the provenance of video files altered by social media platforms. Practitioners will have a more informed approach to authenticating digital evidence, ultimately leading to more accurate and reliable investigative processes.

Abstract Text: This study explores the hypothesis that Social Media Platforms (SMPs) introduce unique, detectable alterations to video files, which can be utilized to verify their provenance. As digital media increasingly plays a critical role in forensic investigations and legal proceedings, understanding how SMPs modify video files is crucial for maintaining the integrity of digital evidence. This research aims to identify and analyze these alterations to enhance forensic methodologies.

The study employed in-depth forensic structural analysis to examine video files before and after their upload to various SMPs. The primary objectives were to determine whether video files undergo structural changes upon upload, to identify and catalog these changes, and to assess the consistency of these alterations across different devices and operating systems. Additionally, the research sought to discover whether these changes could be used to establish a unique, repeatable "signature" for each SMP.[1]

A diverse dataset of video files was collected from several SMPs, including TikTok, Facebook ,and Instagram, using various devices and operating systems. Forensic analysis focused on metadata changes, such as file size and codec information, as well as patterns in structural alterations, including processing and conversion artefacts. Metadata parsers, such as ExifTool, were used to extract the relevant metadata for collation and comparison.

The results revealed that SMPs impose distinct and consistent modifications on video files. These modifications include metadata removal, varying degrees of compression, and specific encoding practices. These findings confirm the hypothesis that each SMP introduces unique digital "fingerprints" that can be detected and used to trace the video's origin. This aligns with previous research, which have similarly found and utilized these "fingerprints" in their investigations.[2-4]

This research addresses significant challenges in digital forensics by providing a methodological framework for identifying SMP-specific alterations. The unique markers identified for each platform enable forensic experts to more accurately determine the provenance of video evidence, even when traditional metadata is missing or manipulated. This capability is critical in verifying the authenticity of video evidence, a growing concern given the proliferation of manipulated media online.[5,6]

In conclusion, this study contributes to the field of digital forensics by enhancing the tools available for video provenance verification. By establishing a database of identifiable SMP-induced artifacts, forensic analysts can improve their ability to authenticate video evidence and support the integrity of judicial processes. This advancement not only strengthens forensic methodologies but also provides a foundation for future research in social media forensics, addressing the growing challenges posed by digital media manipulation.

Digital Evidence; Social Media; Video Analysis

C25 The Application of Likelihood Ratios to Audio Authentications: Selected Preliminary Results

James Zjalic, MS, Verden Forensics, Birmingham, England, United Kingdom*

Learning Objectives: Attendees will learn the following:

- What likelihood ratios are
- Why they are considered the most logical form of evaluation of evidence within forensic science
- A proposed method for the evaluation of audio authentication examinations using likelihood ratios
- Some selected results pertaining to the within-source variability of a selection of parameters
- Some selected results pertaining to the between-source variability of a selection of parameters
- Some selected evaluations using likelihood ratios based on the within and between source variability

Impact Statement: The purpose of an audio authentication examination is for the examiner to opine on the authenticity of a recording. The current method recommended within guidance published by the Scientific Working Group on Digital Evidence (SWGDE) is to conclude whether a recording is consistent or inconsistent with an original recording. The research presented will provide a method and some preliminary results using likelihood ratios rather than the currently recommended method. The motivation behind the study is to push the audio authentication discipline forward by using a format that is widely accepted as the most logical method for evaluation of evidence within forensic science

Abstract Text: Although there are various methods for reporting when addressing the question of source problem within forensics, for example, verbal levels of support, categorical match/non-match, numerical scores and likelihood ratios, it is the latter that is considered by some to be the most logical method.[1-3] This is evidenced by its widespread use and success when opining on the source DNA trace evidence.

The reporting method currently recommended for audio authentications is the use of 'consistent with,' inconsistent with,' or no conclusion, based on the premise that if an audio recording is observed to be consistent with an original, the possibility of editing having occurred can be refuted.[4,5] This method only considers a single proposition and does not, therefore, communicate the significance of the observations. In order to do so, an alternative proposition would need to be introduced to inform the trier of fact how consistent or inconsistent the observations are within a relevant population. This is an element that likelihood ratios resolve, as two propositions are fundamental to their use.[6]

After attending the presentation, attendees will learn the motivation for the study, the overarching method and the methods to consider the three segments into which the research has been broken down, namely: within (or intra) source variability, between (or inter) source variability, and the evaluation of results using likelihood ratios. They will also learn of difficulties in applying likelihood ratios when inferring the source of an item that is mass-manufactured and a proposed definition of source that inherently reduces within-sample variability while increasing between-sample variability.

The research forms part of a PhD study relating to the use of likelihood ratios for audio authentication evaluation, which is currently at its halfway stage.

C26 Keeping Up With the Times: Are Standards Meeting the Needs of Rapidly Expanding Technology in Forensic Multimedia Analysis?

Christina A. Malone, MSFS, United States Army Criminal Investigation Laboratory, Atlanta, GA; Wendy A. Dinova-Wimmer, BS*, Adobe, Gaithersburg, MD*

Learning Objectives: After this presentation, attendees will have an understanding of the challenges and capabilities that technological advances have created within forensic multimedia examinations. Additionally, attendees will learn how the work being conducted on standards and best practices within the Video/Imaging Technology & Analysis (VITAL) Subcommittee at the Organization of Scientific Area Committees (OSAC) and at the Scientific Working Group on Digital Evidence (SGWDE) is being used to address the changing forensic multimedia needs arising from technological developments.

Impact Statement: This presentation will impact the forensic science community by offering information on the ongoing efforts that support and address the ever-expanding technological developments within multimedia forensics. Information on the current work efforts within the OSAC VITAL Subcommittee and SWGDE will be highlighted.

Abstract Text: Forensic multimedia analysis has long been impacted by and intertwined with technological advancements. From the invention of the digital camera in the 1970s to the expansion of synthetically generated media today, challenges are presented to the forensic multimedia community on how to incorporate and efficiently address the rapid evolution of multimedia technology. Such developments have expanded this field through the creation of new tools and capabilities available to examiners; however, when such technology is analyzed and employed in a forensic setting, boundaries must be established to ensure high-quality, technically sound standards and best practices are employed.

Advancements in image capture and video recording have improved the quality and accessibility of multimedia evidence and enhanced the capabilities available to forensic multimedia examiners. The prevalence of high-resolution cameras, the increased reliance on smart phones, the widespread use of surveillance systems, and the pervasiveness of social media have led to an exponential increase in the volume and complexity of multimedia data available. Furthermore, significant impacts to digital and multimedia analysis have been introduced through the use of tools powered by Artificial Intelligence (AI) and Machine Learning (ML). The acceptance and use of such tools has blurred the lines between what is possible with imagery and what should be done to ensure imagery is not deceptive. The expansion of the capabilities and work volume, as well as ambiguity in the application of new technology, present new questions and challenges demonstrating the need for up-to-date standards and best practices for handling multimedia evidence in forensic settings.

Organizations, such as the OSAC VITAL Subcommittee and the Scientific Working Group on Digital Evidence (SWGDE), both focus on developing and prompting standards and best practices to support examiners in their analysis of multimedia evidence. As the development of new technologies will continue, such standards related organizations must be continually prepared to update their documents while simultaneously emphasizing the importance of validation, reproducibility, and transparency in forensic processes. These organizations must address the challenges for defining standards and best practices that quickly adapt to the changing needs of the forensic multimedia community.

Up-to-date standards and their implementation are essential to ensuring the sound practice of forensic science across all disciplines, including digital and multimedia sciences. However, rapidly expanding technology presents a challenge to both examiners conducting multimedia analysis as well as the organizations developing standards and best practices. Ensuring the reliability, validity, and admissibility of multimedia evidence in this dynamic environment requires continuous adaptation and adherence to current, relevant standards and best practices.

Multimedia; Standards; Imagery

C27 Detecting Generative AI Through the Structural Analysis of Multimedia Files

Nicole R. Odom, MSFS, University of Wisconsin-Madison Police Department, Medex Forensics, Richmond, VA*

Learning Objectives: After attending this presentation, attendees will understand how file structural analysis can be utilized to detect multimedia files created or modified through use of generative Artificial Intelligence (AI). As a result, attendees will also develop an understanding of possible limitations when it comes to the identification of synthetic media and the associated ethical responsibility of industry leaders.

Impact Statement: This presentation will impact the forensic science community by exploring novel techniques for the authentication of multimedia files. Specifically, this presentation will compare the output of a variety of popular generative AI software at the structural level.

Abstract Text: There has been a mass influx of synthetic media generation and multimedia modification utilizing AI, making it more important than ever to be able to reliably and effectively identify and apply context to media files. AI is an extremely useful tool for a wide number and variety of industries but can present strong ethical concerns when it comes to engendering trust in a multimedia file, especially in an era where generative AI is becoming much more readily available to the general public. Although many market leaders in multimedia production are taking measures to show AI-generated or modified content, current approaches are not reliable since they lack any independent authenticity analysis.[1,2] Many current methods utilized to identify or label AI media online require the user to self-identify their AI-assisted content, which places a lot of trust in content creators to self-identify generative AI.

Many detection and analysis tools, forensic and open-source alike, claim to be able to detect generative AI through probability analysis. While this may initially appear helpful, these "black box" methods are unable to be validated by digital forensic examiners or consumers and often provide percentages of probability for a given observation with little to no explainability. This study aims to provide a reliable and reproducible method for identifying synthetic or manipulated media produced from generative AI.

For this work, several of the most popular generative AI software were utilized to both create multimedia files and modify existing content. The produced multimedia files were analyzed at the structural level utilizing a file format forensic approach to apply context[3], both through provenance and generational history, to allow for a transparent method for evaluating synthetic media that is both repeatable and meets legal admissibility standards.[3,4]. Additionally, ethical concerns and considerations regarding possible multi-generational implications (i.e., structural normalization) will be discussed.

C28 Artificial Intelligence for Image and Video Forensics: Mine of Information or Minefield?

Marco Fontani, PhD, Amped Software, Trieste, Friuli-Venezia Giulia, Italy; Martino Jerian, MSc, Amped Software, Trieste, Friuli-Venezia Giulia, Italy; Blake Sawyer, BBA, Amped Software, Brooklyn, NY*

Learning Objectives: Attending this presentation will help attendees understand the difference between AI, machine learning, and deep learning. Through simple examples, they will see the impact of training data bias on forensic applications. Finally, they will discover the opportunities and pitfalls of deep learning-based techniques for video forensics.

Impact Statement: The presentation aims to increase awareness of the pitfalls of using deep learning techniques for video enhancement and analysis. Attendees will learn to weigh the explainability of an AI method and will learn the importance of implementing bias-mitigation techniques in the use of AI systems. Correct handling of AI techniques can significantly impact justice and security.

Abstract Text: This presentation consists of three parts and discusses the opportunities and challenges of using AI-based technologies for image and video forensics, specifically focusing on modern deep-learning solutions.

The first part introduces some terminology related to machine learning and distinguishes investigative use from evidentiary use and image enhancement from image analysis. It then discusses how typical deep-learning techniques compare against the accuracy, reproducibility, and explainability requirements, showing with a simple yet insightful example that training data can dramatically impact the result of a super-resolution system based on AI. Finally, it proposes some general guidelines for using AI for video forensics to foster discussion at the end of the presentation and during the conference.

The second part shows the results of research conducted by the authors on using AI for three common tasks:

1. AI-based image super-resolution to aid humans with face identification.[1] The experiment compares the performance of humans when presented with AI-scaled faces with those obtained using bicubic-scaled faces. Results show that the improvements brought by AI super-resolution in recognition rate are not significantly different from those brought by bicubic interpolation. The results of a similar study focusing on fully automated face recognition will also be mentioned.[2]
2. AI-based reading of severely degraded license plates. The experiment evaluates the ability of a neural network trained on synthetic license plates to decipher real license plates, showing results obtained from an extensive dataset of 2,400 real plate images of varying difficulties.[3]
3. AI-based detection of deepfakes, specifically Generative Adversarial Network (GAN) -generated images. The developed method ranked second in an international challenge.[4] The presentation will also highlight some interesting properties of diffusion-model deepfakes that can help their detection even with traditional analysis tools.

The third and final part mentions some cases presented in the news in which the jaunty use of AI-driven methods led to mistakenly arrested people and discusses a recent court case that has challenged the suitability of AI for video enhancement.

After attending the presentation, attendees will better understand the opportunities and pitfalls of using deep learning-based methods for forensic and investigative applications.

C29 Deepfake Detection: Technology as a Tool for Transformation or Tyranny

Zeno J. Geradts, PhD, Netherlands Forensic Institute and University of Amsterdam, Den Haag, Zuid-Holland, Netherlands*

Learning Objectives: Attendees will gain insights into the technical, legal, and ethical dimensions of deepfake detection, empowering forensic professionals to navigate the complexities of this evolving landscape.

Impact Statement: The session will underscore the necessity of a multi-disciplinary approach, combining technological expertise with robust ethical standards to ensure that deepfake detection serves as a tool for transformation, safeguarding truth and justice in the digital age.

Abstract Text: The proliferation of deepfake technology, fueled by advances in generative AI, poses significant challenges and opportunities for forensic science. This presentation at the 2025 American Academy of Forensic Sciences conference explores the dual role of deepfake detection technology as both a transformative tool and a potential instrument of tyranny. Deepfakes, which leverage advanced AI to create highly realistic but fake media, threaten to undermine trust in visual and auditory evidence, complicate legal proceedings, and enable new forms of cybercrime.

This session will delve into the latest advancements in deepfake detection methods, with a particular focus on Photo Response Non-Uniformity (PRNU) analysis, Electrical Network Frequency (ENF) analysis, and other state-of-the-art algorithms and machine learning techniques designed to identify manipulated content with high precision. PRNU, a technique used to trace the unique sensor pattern noise of digital cameras, has emerged as a critical tool in forensic investigations, enabling the detection of synthetic images and videos generated by AI (Informatics Institute) (Netherlands Forensic Institute). Similarly, ENF analysis leverages the fluctuating frequency of electrical grids captured inadvertently by recording devices to timestamp and geolocate video recordings, adding another layer of verification to digital evidence (Netherlands Forensic Institute).

We will discuss the implementation of these technologies in forensic investigations, emphasizing their potential to uphold the integrity of evidence and support justice. The integration of generative AI with forensic methods, such as PRNU and ENF, allows for a comprehensive approach to deepfake detection. For instance, ENF analysis can reveal inconsistencies in the time and location of recordings, thereby identifying discrepancies that suggest tampering (Netherlands Forensic Institute). When combined with PRNU, which identifies the specific device used to capture an image or video, these techniques provide a robust framework for authenticating digital media (Universiteit van Amsterdam) (Netherlands Forensic Institute).

Conversely, the presentation will address ethical concerns and the risk of misuse of deepfake detection technology. Topics include the implications for privacy, the potential for overreach by authorities, and the danger of false positives leading to wrongful accusations. The ethical use of these technologies requires a careful balance between the need for security and the protection of individual rights. By examining case studies and current legal frameworks, we aim to provoke a critical discussion on the balance between technological innovation and ethical responsibility.

Attendees will gain insights into the technical, legal, and ethical dimensions of deepfake detection, empowering forensic professionals to navigate the complexities of this evolving landscape. The session will underscore the necessity of a multi-disciplinary approach, combining technological expertise with robust ethical standards to ensure that deepfake detection serves as a tool for transformation, safeguarding truth and justice in the digital age.

Multimedia; Video Analysis; Deepfakes

C30 Leveraging Artificial Intelligence for Advancements in Forensic Science: The AI4Forensic Lab

Zeno J. Geradts, PhD, Netherlands Forensic Institute and University of Amsterdam, Den Haag, Zuid-Holland, Netherlands*

Learning Objectives: The goals of this presentation are to help attendees:

- Understand the impact of AI on forensic science: Attendees will gain insight into how AI technologies are revolutionizing forensic methodologies, enhancing accuracy, and improving the efficiency of forensic investigations.
- Explore key AI applications in forensics: Participants will learn about specific AI applications such as image and video analysis, digital forensics, biometric facial comparison, and predictive modeling, and how these applications are implemented in real-world scenarios.
- Recognize the importance of ethical compliance: The session will highlight the importance of adhering to regulatory frameworks like the AI Act, ensuring that AI technologies are used responsibly and ethically in forensic science.
- Enhance knowledge of man-machine interaction: Attendees will understand strategies to improve collaboration between forensic experts and AI systems, ensuring effective integration and utilization of AI in forensic workflows.

Impact Statement: Attendees will learn how to:

- Identify Bias and Ensure Fairness: The presentation will cover methods to detect and mitigate biases in AI algorithms, ensuring that forensic analyses are fair and unbiased.
- Emphasize Transparency and Explainability: Participants will learn about the critical role of transparency and explainability in AI systems, ensuring that AI-driven conclusions are understandable, trustworthy, and legally defensible.

Abstract Text: The application of AI in forensic science holds transformative potential, promising unprecedented advancements in accuracy, efficiency, and scope of forensic investigations. The AI4Forensic Lab is at the forefront of this evolution, dedicated to integrating cutting-edge AI technologies into forensic methodologies. This abstract outlines the Lab's pioneering research, key projects, and the profound implications of AI in forensic science, with a specific focus on the AI Act, biometric facial comparison, man-machine interaction, bias prevention, transparency, and explainability. Forensic science has long been reliant on meticulous manual analysis, often constrained by human error and time-intensive processes. The AI4Forensic Lab aims to revolutionize this field by leveraging AI to enhance various aspects of forensic analysis. Our multidisciplinary team, comprising experts in AI, computer science, and forensic science, is working on developing and implementing AI-driven solutions that address critical challenges in forensic investigations, while adhering to regulatory frameworks such as the AI Act.

The primary objectives of the AI4Forensic Lab are to develop AI algorithms capable of analyzing forensic data with high accuracy, automate forensic processes to reduce the time and effort required for investigations, and improve the interpretation of complex forensic data using advanced AI techniques. Additionally, we aim to facilitate real-time decision-making in forensic scenarios and ensure ethical compliance by aligning our AI developments with the AI Act.[1] Central to these efforts are transparency and explainability, ensuring that AI-driven conclusions are understandable and trustworthy. Performance evaluation is conducted thoroughly to ensure the reliability, accuracy, and applicability of AI models in real-world forensic scenarios. We collaborate closely with law enforcement agencies, legal experts, and forensic practitioners to ensure the practical integration of AI solutions into forensic workflows. Enhancing man-machine interaction is a key focus, ensuring seamless collaboration and effective use of technology in investigations. Additionally, we implement strategies to identify and mitigate biases in AI algorithms, ensuring fair and unbiased forensic analyses. Ensuring transparency and explainability in our AI systems is paramount, as it builds trust and facilitates the understanding of AI-driven conclusions by forensic experts, legal professionals, and the public.

The integration of AI into forensic science offers numerous benefits, including enhanced accuracy, reduced workload for forensic experts, and faster resolution of cases. As the AI4Forensic Lab continues to advance its research, we anticipate significant breakthroughs that will shape the future of forensic science. Our ongoing efforts aim to make AI an indispensable tool in forensic investigations, ultimately contributing to the improvement of the criminal justice system. By adhering to the AI Act and focusing on ethical AI usage, we ensure responsible and transparent application of AI technologies. Transparency and explainability will remain central to our research, ensuring that AI-driven forensic methods are clear, interpretable, and legally defensible.

The presentation will cover several key topics, including the development and implementation of the AI4Forensic Lab's research agenda, the impact of AI on various forensic disciplines such as image and video analysis, digital forensics, biometric facial comparison, and predictive modeling. Additionally, we will discuss the ethical considerations and regulatory compliance, particularly in relation to the AI Act, strategies for enhancing man-machine interaction, and efforts to prevent biases in AI algorithms. Furthermore, we will showcase our current projects and funding initiatives, including work on deepfakes, data hiding, speech analysis, and financial data analysis. The broader context of our collaboration with national and international institutions will also be highlighted, along with future funding possibilities and research directions. Special attention will be given to the topics of transparency and explainability, illustrating how our AI systems ensure clear, interpretable, and justifiable outcomes.

C31 The Development of a Responsible AI Framework Suitable for Forensic Science Needs

Janet K. Stacey, MS, The Institute of Environmental Science and Research Ltd, Auckland, Auckland, New Zealand; Deepak Karunakaran, PhD, The Institute of Environmental Science and Research Ltd, Porirua, Wellington, New Zealand; Rachel Fleming, PhD, The Institute of Environmental Science and Research Ltd, Auckland, Auckland, New Zealand; Dion Sheppard, MS, The Institute of Environmental Science and Research Ltd, Auckland, New Zealand*

WITHDRAWN

C32 Attitudes Toward and Barriers to Mental Health Support for Digital & Multimedia Forensic Examiners

Sonali Tyagi, Purdue University, West Lafayette, IN; Kathryn C. Seigfried-Spellar, PhD*, Purdue University, West Lafayette, IN*

Learning Objectives: After attending this session, attendees will have a better understanding of digital and multimedia forensic examiners' attitudes toward counseling and barriers to receiving mental health support from being exposed to disturbing media as part of their job.

Impact Statement: The presentation will impact the forensic science community by explaining the mental health stigma perceived by digital & multimedia forensic examiners, impacting their decision to receive counseling/treatment. It will also explain their attitude toward mental health support

Abstract Text: Digital evidence is estimated to be a factor in about 90% of criminal cases.[1] Digital & multimedia forensic examiners work on a variety of criminal cases, such as burglary, child sexual exploitation, school shootings, police-involved shootings, rape, fraud, and drug-related offenses.[2] These investigations usually involve more than one type of digital device (e.g., mobile phone, computer, Global Positioning System [GPS], video surveillance) and mobile phones are the most-seized device in criminal investigations.[3]

We now have more audio, video, and image evidence of the actual crime itself than ever before. As a result, digital & multimedia forensic examiners are often requested to review or enhance probative media to identify the actors or clarify the context of the situation, all of which may involve repeatedly viewing or hearing heinous acts (e.g., homicide, child sex abuse, torture).[4] Research shows that digital forensic examiners experience high levels of stress due to the nature of their jobs involving exposure to disturbing media, including anxiety, poor psychological well-being, secondary traumatic stress, and emotional burnout.[5-9] This study aimed to understand digital & multimedia forensic examiners' attitudes toward and experiences with barriers to counseling and mental health support.

Ninety-four digital and multimedia forensic examiners from the United States completed an anonymous, internet-based survey assessing a needs analysis for mental health support. Participants self-reported their current primary role as either an image, audio, or video forensic examiner. In addition, participants reported whether they currently worked as an investigator or detective. Most digital forensic examiners reported multiple primary roles: image (n = 50), audio (n = 27), or video forensic examiner (n = 56). In addition, 53 worked only as a Digital Forensic Examiner (DFE), whereas 41 were both digital forensic examiners and investigators (DFE + DET). Results compared their attitudes toward and experiences with barriers toward mental health support based on their self-reported primary roles. Of the 94 digital forensic examiners, 36% personally sought counseling due to work-related stress. Mental health support was required for only 28% of respondents. However, 50% of participants believed counseling should be required.

Several barriers toward mental health support were reported by the digital & multimedia forensic examiners. Image analysts were more likely to report: "I don't know where to get help" (r = .27), "There would be difficulty getting time off work for treatment" (r = .24), "I find it difficult to talk about" (r = .37) compared to non-image analysts. Audio forensic examiners were more likely to report: "It is difficult to get an appointment" (r = .19) and "I find it difficult to talk about" (r = .19) compared to non-audio analysts. Video forensic examiners were also more likely to report that they have difficulty getting an appointment (r = .19) compared to non-video examiners. Finally, there was a small effect size in that individuals working both as DFE + DET were more likely to report that "It might affect my promotion" (r = .15) compared to individuals who only worked as DFEs.

Additional findings and suggestions for future research and policy implications regarding mental health services for digital and multimedia forensic examiners will be discussed.

C33 Emerging Ethical and Technical Challenges in Digital Profiling

Chad M. Steel, PhD, George Mason University, Springfield, VA; Angel D. Morningstar, MS*, Steampunk, Alexandria, VA*

Learning Objectives: Attendees will learn how new technologies can both enhance and complicate digital behavioral analysis. Using victimology, case linkages, and the interpretation of digital artifacts, the use of these technologies will be examined through an ethical lens. Attendees will learn techniques directly applicable to these areas in addition to being provided ethical considerations for applying behavioral analysis to traditional digital forensics work.

Impact Statement: This presentation will bring together evidence-based concepts from psychology and digital forensics and will present challenges from recent criminal cases in these areas. Because digital profiling is a relatively new topic area, this presentation will provide an introduction to the field for many attendees through the coverage of selected real-world technical challenges and solutions in addition to the ethical considerations in applying them.

Abstract Text: After attending this session, attendees will have a better understanding of the risks and limitations associated with behavioral analysis based on digital forensics and data analytics. This will be presented by examining both human and technology factors using current digital investigative case trends within the context of an ethical framework.

This session will review the intersection of digital forensics and data science based on current and emerging tools and techniques, including Artificial Intelligence (AI) and big-data-based approaches. The ethical considerations when using these tools and techniques and the limitations present as a result of examiner bias as well as issues with the underlying technologies will be examined through a behavioral analytical lens.

While digital forensics has matured as a discipline, new challenges have arisen that were not present even a few years prior. AI has provided new opportunities to conduct rapid reviews and assessments, but many of the implementations have poorly understood technical limitations and lack traceability. Additionally, AI tools may exacerbate examiner confirmation bias if used improperly. Finally, generative AI deepfakes and inpainted images and videos may hinder victim identification or mislead investigators if identified as “ground truth” in examinations.

Similar to the challenges presented at an individual device or case level, linkages between cases can be inappropriately made or overstated, leading to inefficient deterrence or even improper attribution. Digital artifacts used in link analysis, including IP address and phone numbers, need to be understood in the context of Voice over IP (VoIP) recycling, carrier grade network address translation, Virtual Private Networks (VPNs), and other technological countermeasures. Similarly, an understanding of current trends in cybercriminology, including the outsourcing of expertise for functions such as botnets and money laundering, can lead to improper conclusions that disparate criminal networks are co-conspirators if not taken into account when utilizing graph databases. Finally, the blending of subjects and victims (e.g., a romance scam victim that becomes a money mule) needs to be incorporated into these analyses when performing targeting.

In addition to the technological challenges, human bias remains present and can be exacerbated through an overreliance, improper use, or misunderstanding of the limitations of digital tools and data analytic approaches. Ways of ensuring that personnel understand the limitations of digital forensics approaches, particularly those using data science and AI (including concepts such as base rates, sensitivity, and specificity) will be covered. Accountability and oversight of digital investigative personnel, and training of those personnel to recognize bias in themselves and their work, are equally essential and systemic improvements that can be operationalized and will be presented.

Artificial Intelligence; Digital Evidence; Behavioral Science

C34 Exploring Fantasy Enactment and Self-Disclosure Themes in Offender-to-Offender Communication: A Comparative Study of Adult and Peer-to-Peer Groomer Digital Evidence

Reeya M. Ramasamy, Purdue University, West Lafayette, IN; Tatiana Ringenberg, PhD*, Purdue University, West Lafayette, IN; Kathryn C. Seigfried-Spellar, PhD*, Purdue University, West Lafayette, IN*

Learning Objectives: In this session, attendees will learn about the dynamics of offender-to-offender communication in peer-to-peer grooming, a growing form of child sexual exploitation and abuse globally. Additionally, they will learn about the distinctions in communication patterns between adult groomers and minor groomers in these scenarios.

Impact Statement: This presentation will impact the forensic community by providing an in-detail case study involving peer-to-peer grooming cases. There are many aspects of peer-to-peer grooming that are yet to be studied, and this presentation will aid forensic professionals to better understand and identify peer-to-peer grooming from a psychological, technological, and forensic standpoint.

Abstract Text: According to a study published in the Journal of the American Medical Association Network Open, one in six United States children experience online sexual abuse.[1] With a growing number of cases, the concept of Harmful Sexual Behavior (HSB) is becoming more prevalent. HSB is considered any sexual action that is outside of what is safe for a young person's stage of development. HSB contributes to the growing number of peer-to-peer grooming cases, and the level of aggression and violence can be seen in these peer-to-peer grooming cases. Research suggests aggression and glorification of rape can be tied to the prevalence of rape and aggressive sex that is shown in media.[2]

While prior work has examined online sexual abuse processes occurring between an adult and a minor, peer-to-peer grooming between minors has recently garnered attention. This case study compares the differences in fantasy enactment and negotiation in offender-to-offender communication in both minor peer-to-peer grooming and adult online sexual grooming scenarios, which have yet to be studied. This case study covers two separate cases: one in which adult offenders discuss online sexual abuse and one in which minor offenders discuss online sexual abuse. The adult offender cases include two chats between two adults regarding child online sexual grooming, while the peer-to-peer grooming covers ten chats between two minors. This case study analyzes the differences in fantasy enactment and self-disclosure themes between adult offenders and peer-to-peer groomers to gain a deeper understanding of these dynamics in offender-to-offender chats involving child sexual abuse. By understanding these dynamics, researchers and law enforcement can develop more effective intervention and prevention strategies tailored to the specific communication patterns and motivations of different offender groups. With more than 33% of sexual offenses against children being committed by other children, it is important to further understand the fantasy enactment and discussions that take place in peer-to-peer grooming to reduce this statistic.[3]

Peer-to-Peer Grooming; Online Sexual Grooming; Cyber Crime

C35 Proactive Detection of Child Sexual Abuse Material: Predicting Victim Risk From App Usage, Media Content, and Messaging Behaviors

Nina Matulis, MS, Purdue University Lafayette Police Dept., West Lafayette, IN; Kathryn C. Seigfried-Spellar, PhD*, Purdue University, West Lafayette, IN; Marcus K. Rogers, PhD*, Purdue, West Lafayette, IN*

Learning Objectives: Attendees of this presentation will have a better understanding of how digital artifacts from a victim's smart phone relating to app usage, media content, and messaging can be of use in a Child Sexual Abuse Material (CSAM) investigation. Further, attendees will gain knowledge on whether such artifacts collected from a minor's (i.e., an individual under the age of 18) smart phone can be used to predict offender risk and victim vulnerabilities in this type of case.

Impact Statement: This presentation will be of great interest to not only the Digital & Multimedia Sciences forensic community but also the entire forensic science community, as information relating to both digital artifacts and CSAM cases will be discussed. Because this study specifically delves into how social networking digital artifacts can play an important evidential role in a CSAM investigation, Law Enforcement (LE) officials who investigate such cases will gain an understanding of the specific information they can obtain from analyzing these artifacts in a CSAM investigation.

Abstract Text: Smart phone usage by the youth community has continued to increase, and minors are using such devices as their main source of communication. A 2018 survey indicated that 89% of teenagers ages 13–17 years had a smart phone, an amount which had doubled since 2012.[1] With the growth in the amount of young people using messaging, social networking, and media-sharing apps by means of their smart phones, the risk of child sexual offenders using such apps to contact, groom, and inquire for CSAM also increases.

In LE investigations, social networking digital artifacts such as the use of social networking websites/apps, the sharing of media content, and messaging behaviors, can offer valuable insight regarding the communication between a child sex offender and their victim. Previous research has indicated the importance of analyzing networking artifacts from the offender's smart phone to better understand child sex offender motivation.[2] Therefore, this study is a continuation of previous research and aims to determine whether such digital artifacts collected from a victim's smart phone can aid in predicting offender risk and victim vulnerabilities in CSAM cases.[2]

For this study, LE investigators from the Tippecanoe County High Tech Crime Unit (HTCU) randomly selected several closed CSAM cases where a forensic image of the victim's phone was present. The research team was then provided with only statistical information (f, %) for various social networking digital artifacts (e.g., list of apps, number of messages) and pornography collection (e.g., % of CSAM, pornography content type), obtained from the forensic image of the victim's device; Investigation details were not disclosed. A comprehensive analysis of the provided data was completed by the research team to predict details about the case (e.g., type of child sex offense, method of contact by the offender), offender risk, and victim vulnerability. Results from the research team's analysis were shared with the HTCU and scored for accuracy by LE.

The results and future implications of the study's findings will be discussed in the future, as the research team is awaiting additional data from the HTCU. Our team aims to receive data from at least 30 CSAM cases.
