After critically appraising each method, a gap in the literature was identified: the use of micro-CT to assist fracture aging. Specifically, 2D radiography benefits from being non-destructive, quick, and applicable both clinically and postmortem. However, it is limited by low image resolution, resulting in the publication of several descriptive methods which have received little secondary validation. As such, high levels of interobserver subjectivity elicit caution in using these methods for forensic fracture ageing. Histology instead visualizes healing at the cellular level, providing a more robust estimate of fracture age at the expense of time, destruction of the bone sample, and its exclusively postmortem application. Micro-CT, with its strong reputation for research purposes and applications to forensic fracture detection, draws on the strengths of each.[4-6] With the addition of 3D visualization, it therefore represents an ideal modality to complement histological fracture ageing.

Forming the second part of this project, the presentation will demonstrate the potential of micro-CT for fracture ageing using a forensic case worked at the University of Warwick. Correlation of micro-CT findings to the histopathological examination found that micro-CT supported the histopathologist by serving as a screening tool to identify subtle fractures not otherwise detected using 2D radiography. The 3D micro-CT data then assisted in targeting the cross-sectional location of fractures during histological sectioning to ensure the trauma was visualized. Further, micro-CT imaging can support presentation of the histopathological evidence in court to enhance jury understanding. Owing to the high-resolution, non-destructive, and 3D nature of micro-CT, such cases demonstrate micro-CT's potential to enhance the visualization and interpretation of bone healing and advance more robust radiographic methods for fracture aging.

I144 Using Micro-CT Scanning for Criminal Investigations of Suspicious Child Deaths: A Decade of Experience From the United Kingdom

Charlotte Primeau, PhD, University of Warwick, Coventry, England, United Kingdom; Sofia Goia, PhD, Warwick Manufacturing Group (WMG), The University of Warwick, Coventry, England, United Kingdom; Mark A. Williams, PhD, University of Warwick, Coventry, England, United Kingdom; Charlotte G. Lawrence, MSc, Warwick Manufacturing Group, University of Warwick, Coventry, England, United Kingdom*

Learning Objectives: This presentation will provide an insight into how micro-Computed Tomography (micro-CT) imaging technology is being used for investigating suspicious child deaths in the United Kingdom, highlighting a decade of experience within the Forensic Centre for Digital Scanning and 3D printing at the University of Warwick.

Impact Statement: This presentation will impact the forensic community through an enhanced understanding of how micro-CT as a non-invasive imaging modality can contribute by making such complex investigations more time efficient. Further, it will be illustrated how micro-CT imaging can be used for court presentations in communicating complex medical evidence for enhanced jury understanding. This knowledge will be underpinned through a summary of the overall usage of micro-CT imaging for suspicious child deaths within the United Kingdom, samples submitted, and specific case examples.

Abstract Text: Criminal investigations of suspicious child deaths are particularly complex to conduct, with additional requirements of multiple medical experts ranging from pediatricians, pathologists, radiologists, histopathologists and neuropathologists.[1-3] Particularly fracture dating from histopathology is an important part of the investigation for understanding the timeline and circumstances leading up to the death of the child and for correlating witness statements and identifying the person(s) responsible.[4] Currently, histopathology is the Gold Standard for fracture identification and more importantly fracture aging.[5] However, communicating histopathology evidence to the wider professionals involved in the investigation and for jury members, can be challenging, both technically and ethically, especially when complex pathological evidence requires a clear presentation that is easily understood.[4]

Within the UK there is a unique visualization center providing forensic micro-CT imaging as a service to the UK and International police forces. This service is a research collaboration between West Midlands Police, and the University of Warwick. Over the last decade, the center has been involved in nearly 90 pediatric cases, spanning 19 UK police forces.

Micro-CT imaging for suspicious child death is conducted after the autopsy and prior to bone histopathology for confirming trauma as identified from autopsy and ante-mortem and/or post-mortem imaging with a much higher imaging resolution, and for targeting areas of interest for the subsequent histopathology examination. After the histopathology examination, the 3D volume rendered micro-CT images can be merged with the histopathology data for visualizing fracture location and their ages, providing enhanced clarity of the evidence presented to the investigative team and for jury presentation. Using micro-CT images and 3D volume rendered videos is an effective way of contextualizing complex histopathological microscopic evidence.

The growing understanding within police investigations in the UK of how micro-CT can add value to complex suspicious child deaths has resulted in an increasing uptake of micro-CT imaging for such investigations. The most frequently submitted sample for micro-CT is the rib cage or ribs with 85% of cases, and the majority of cases, with 71%, are children under the age of 1 year.

I145 Postmortem Evaluation of Anomalous Aortic Origin of the Right Coronary Artery Using CT and MRI: A Retrospective Case Study

Yukiko Uemura, MD, The University of Tokyo, Bunkyo-Ku, Tokyo, Japan; Shigeki Tsuneya, MD, PhD, The University of Tokyo, Bunkyo-ku, Tokyo, Japan; Yohsuke Makino, MD, PhD, The University of Tokyo, Bunkyo-ku, Tokyo, Japan; Hirotaro Iwase, MD, PhD, Chiba University, Chiba, Chiba, Japan; Masatoshi Kojima, MA, Chiba University, Chu-o-Ku, Chiba, Japan; Go Inokuchi, MD, PhD, Chiba University, Chu-o-Ku, Chiba, Japan*

Learning Objectives: After attending this presentation, attendees will learn how Postmortem Computed Tomography (PMCT) and Postmortem Magnetic Resonance (PMMR) imaging can be used to detect Anomalous Aortic Origin of the Right Coronary Artery (AAORCA; Right Coronary Artery [RCA]). They will gain an understanding of the strengths and limitations of each modality, as well as key imaging features for evaluating coronary anomalies in forensic practice.

Impact Statement: This presentation will impact the forensic science community by highlighting the diagnostic potential of PMCT and PMMR in detecting anomalous origin of the RCA—a potentially fatal coronary anomaly. Incorporating these techniques may improve diagnostic accuracy in sudden cardiac death investigations and reduce the likelihood of missed structural heart abnormalities.

Purpose: AAORCA is a known contributor to sudden cardiac death, yet its detectability on postmortem imaging remains under-investigated.[1-8] This study evaluated the capability of PMCT and PMMR to identify AAORCA.

Methods: We reviewed the consecutive 8643 autopsy cases from autopsy database at the University of Tokyo and Chiba University and International University of Health and Welfare during 2016 to 2025 and extracted all the cases with AAORCA from left sinus or anomalous RCA origin from left coronary artery confirmed by autopsy. A total of 11 PMCT cases and 1 PMMR case were included in this study. Two independent reviewers assessed detectability of the anomaly on each imaging modality, defined by two criteria: the image clearly shows (1) left-sided origin of the RCA, and (2) RCA course between the aorta and pulmonary artery. Both features were required for positive detection. To complement this analysis and establish baseline coronary visualization capabilities, we evaluated RCA origin visibility on T1-weighted 3D sequences in an additional consecutive 48 PMMR cases without coronary anomalies, acquired at Chiba University between 2016 to 2025.

Results: Among the 11 CT cases, the anomaly was identified in 2 cases (18.1%). In both cases, intravascular gas facilitated visualization of the coronary artery course. Notably, in one of these positive cases, follow-up CT performed five days after the initial scan showed increased intravascular gas, which enhanced vessel contrast and enabled detection of the anomaly. One of these two CT-positive cases also underwent MRI, in which the anomalous RCA origin and its course were clearly depicted on T1-weighted 3D sequences. Among the 48 MRI cases without coronary anomalies, the RCA origin was identifiable on T1-weighted 3D sequences in 47 cases (97.9%).

Discussion and Conclusion: PMCT benefits from the absence of cardiac motion and provides high spatial resolution. However, poor contrast between the coronary artery lumen and wall and limited perivascular fat are making detection of coronary anomalies challenging. Taken together, these findings suggests that decomposition-related changes, such as gas accumulation, may enhance coronary artery visualization. T1-weighted 3D MRI sequences provided clear depiction of the RCA origin and course in non-decomposed cases. The superior soft tissue contrast of MRI enables consistent coronary artery evaluation, supporting the reliability of this modality for postmortem coronary assessment, particularly when CT findings are inconclusive.

Limitations: This study was limited to cases of AAORCA. Further evaluation of other coronary anomalies on postmortem imaging is warranted.

I146 Beyond the Scalpel: Integrating Virtopsy and Traditional Autopsy in Mass Disaster Victim Identification

Enrica Macorano, MD, University of Bari, Bari, Puglia, Italy; Francesco Introna, MD, University of Bari, Bari, Puglia, Italy*

Learning Objectives: Participants will explore the comparative value of conventional autopsy and virtopsy techniques in the forensic management of mass disasters. They will learn methodological strategies for integrating postmortem imaging (Postmortem Computed Tomography [PMCT], Magnetic Resonance Imaging [MRI]) with traditional autopsy to enhance victim identification and documentation. The session emphasizes practical workflow design and multidisciplinary coordination in disaster victim identification.

Impact Statement: This study underscores the growing role of virtopsy as a complementary tool to conventional autopsy in mass casualty scenarios. By combining historical experience with cutting-edge imaging technologies, the research promotes an integrated model that strengthens forensic preparedness and preserves critical evidentiary value.

Abstract Text: **Background:** Mass disasters challenge forensic science with the urgent need for accurate victim identification while ensuring comprehensive documentation. Traditional autopsy has long been the cornerstone of disaster victim identification (DVI); however, the emergence of post-mortem imaging technologies has introduced virtopsy as a non-invasive alternative or complement. This study reviews the application of both methods in Southern Italy's mass disasters and proposes an integrated approach for future protocols.

Methods: A comparative analysis was conducted on historical mass disaster cases in Apulia (1943-2016), focusing on the role of conventional autopsy and the potential implementation of virtopsy (PMCT, MRI). The review included autopsy reports, anthropological and odontological findings, and pilot virtopsy applications in simulated DVI scenarios. Operational workflows were evaluated against INTERPOL DVI guidelines and current literature to assess diagnostic yield, logistical feasibility, and evidentiary preservation.[1-3]

Results: Conventional autopsy provided irreplaceable anatomical, histological, and toxicological data, while virtopsy demonstrated significant advantages in rapid whole-body documentation, preservation of evidence integrity, and visualization of trauma patterns in situ. Limitations of virtopsy included reduced sensitivity for soft tissue pathology and the need for specialized infrastructure. The comparative analysis highlighted the complementarity of both approaches and informed the design of a hybrid workflow: initial virtopsy screening to document all remains and guide invasive procedures, followed by targeted autopsy for confirmatory findings and sampling.[4-6]

Conclusion: Returning to the fundamentals of forensic science in mass disasters requires both honoring the gold standard of autopsy and embracing technological innovations. Integrating virtopsy with traditional methods enhances accuracy, preserves evidence, and optimizes resource allocation. The proposed combined model offers a replicable framework for DVI protocols, balancing scientific rigor with operational efficiency.

I147 A Case-Based Analysis to Assess the Validity of the Hat Brim Line Rule in Cranial Trauma

Kiti Doci, MD, University of Parma, Parma, Emilia-Romagna, Italy; Alberto Amadasi, MD, PhD, Charitè Universitatsmedizin Berlin, Berlin, Berlin, Germany; Marcello Seligardi, MD*, University of Parma, Parma, Emilia-Romagna, Italy; Valentina Bugelli, MD, PhD, University of Parma, Parma, Emilia-Romagna, Italy; Federica Poli, MD, University of Parma, Parma, Emilia-Romagna, Italy; Sara Dagoli, PhD, University of Parma, Parma, Emilia-Romagna, Italy*

Learning Objectives: After attending this presentation, attendees will gain insight into the applicability of the "Hat Brim Line Rule" (HBL Rule) in differentiating accidental head trauma from intentionally inflicted injuries.

Impact Statement: This presentation will impact the forensic community by reviewing the validity of the HBL Rule and its applicability in a forensic setting.

Abstract Text: This study aims to evaluate the forensic reliability of the Hat Brim Line Rule (HBL Rule) in differentiating between accidental falls and intentionally inflicted blunt head trauma.[1-3] Given the frequent diagnostic ambiguity in cranial injuries, particularly in forensic autopsies, the HBL Rule offers a potentially useful anatomical reference point for assessing the origin of skull fractures.

A retrospective analysis was conducted on 305 anonymized autopsy reports from the digital archive of the Institute of Legal Medicine in Berlin, spanning from 2008 to 2024. Each case was classified based on the declared traumatic dynamics (fall from < 2 meters, fall from stairs, fall from >2 meters, or inflicted trauma) and analyzed for fracture location relative to three anatomical landmarks: Above G Line, Hat Brim Line (HBL), and Below External Auditory Meatus (EAM). Statistical associations were calculated using descriptive analysis and chi-square tests to compute the p-value.

The results revealed distinct trauma distribution patterns across the different injury mechanisms. In falls from < 2 m (n=27), fractures were most frequently localized to the hat brim line (10 cases), to both the hat brim line and below the EAM (9 cases), and solely below the EAM (8 cases). In falls >2 m (n=10), trauma patterns were more dispersed, with two cases involving all cranial regions. Staircase falls (n=7) showed a high incidence of multiple-region injuries, with four cases affecting the entire skull. Inflicted injuries (n=7) exhibited no dominant pattern, reflecting case heterogeneity. These findings contribute to a more nuanced understanding of trauma mechanisms in forensic settings.

Moreover, fractures located below the EAM were significantly more frequent in inflicted trauma cases—paradoxically contradicting the expectations of the HBL Rule. Falls from greater heights tended to involve fractures above the G Line, while staircase falls often produced complex, multi-region patterns. Although the HBL area was commonly involved across all trauma types, it was not uniquely associated with any specific etiology.

In conclusion, the Hat Brim Line Rule may serve as a useful auxiliary tool in the forensic differential diagnosis of cranial trauma, but it cannot independently distinguish between accidental and inflicted injuries. Its application should be integrated within a multidisciplinary framework that combines anatomical findings, contextual data, and advanced statistical or computational methods to improve diagnostic accuracy.

I148 A Unique Case and 25-Year Retrospective of Trash Chute and/or Compactor Death in Miami-Dade County

Mariana Voudouri, MD, District Nine Medical Examiner's Office, Orlando, FL; Alexander Blank, MD, AFB Forensic Solutions pLLC, Hillsboro, OR; Alexander Giachetti, PSM, Miami Dade Medical Examiner, Miami, FL; Nicholas J. Barna, II, MD, Miami Dade Medical Examiner, Miami, FL*

Learning Objectives: This presentation will provide attendees with a comprehensive understanding of the unique forensic and investigative challenges associated with fatalities involving garbage chutes and compactors. Participants will learn how to interpret complex autopsy findings within the context of scene dynamics, including crush injuries, mechanical asphyxia, and contributory factors such as psychiatric illness and substance use. Emphasis will be placed on the integration of investigative tools, particularly video surveillance and historical case data, to support accurate determination of cause and manner of death. Attendees will also gain insight into the behavioral and environmental circumstances that elevate risk in these rare but increasingly relevant fatal events.

Impact Statement: This presentation will provide attendees with a focused understanding of the forensic and investigative considerations involved in fatalities related to garbage chutes and compactors. Participants will learn to evaluate autopsy findings such as crush injuries and mechanical asphyxia in conjunction with scene dynamics and investigative context. By highlighting the importance of interdisciplinary collaboration, surveillance review, and contextual analysis, this work supports the advancement of best practices in forensic pathology and medicolegal death investigation.

Abstract Text: **Introduction:** Miami-Dade County has experienced a general trend of population growth and residential development over the past decades. Modern apartment buildings typically include garbage chutes and possibly attached compactor systems prior to truck loading. The waste management system of the county is a complex operation, which may involve related though distant investigative sites. We herein report a unique case involving a garbage chute and compactor related fatality. A review of historical data on such fatalities in the county was subsequently conducted.

Methods: A query of the Miami-Dade County Medical Examiner Department electronic database was performed. Search keywords included: "garbage, trash, rubbish, chute, dump, and mechanical / traumatic asphyxia. Identified cases were reviewed within their electronic files. Autopsies with routine toxicology and histology were performed on each case. Comparison of data primarily included: investigation (e.g. circumstances, location), autopsy findings (e.g. blunt force trauma, petechiae), toxicology, and death certification (e.g. cause, manner, how injury occurred). Data was compiled and analyzed using Microsoft Excel.

Results: The search yielded 5 total applicable cases of garbage chute and/or compactor fatalities over a 25 year period in Miami-Dade starting in the year 2000. The cases occurred in 2006 (x1), 2014 (x1), and 2024 (x3). Four of the decedents were phenotypic males between 30 and 50 years of age, while one was an elderly phenotypic female. One while-at-work fatality involved a decedent who fell into a recycling truck compactor and died several hours later at the hospital. Three decedents climbed into trash chutes, descended from height, and were subsequently compacted; neuropsychiatric conditions and/or substance abuse were important factors in these cases. One decedent volitionally entered the terminal reservoir of a large building chute system and was compacted at the time of collection by a garbage truck. Causes of death included variations of Crush/Blunt Force Injuries/Trauma, sometimes combined with Mechanical Asphyxia in part 1 of the death certificate. The manner of death for each case was certified as Accident.

Discussion: Systematic correlation of thorough investigation with postmortem findings is paramount in trash chute and compactor related fatalities. Video surveillance footage of the terminal events may prove crucial. Though certification styles may vary amongst examiners, asphyxiation should also be considered for inclusion based on the case findings. Factors such as underlying psychiatric disease or acute drug intoxication may be considered for inclusion on the death certificate in the "How Injury Occurred" section.

I149 Understanding Blunt Force Injuries: A Biomechanical and Forensic Comparison of Vertical and Horizontal Forces

Alejandro Partida, MD, Texas Tech University Health Science Center, El Paso, TX; Mario A. Rascon, MD, El Paso County Office of the Medical Examiner, El Paso, TX*

Learning Objectives: Attendees will learn to differentiate biomechanical mechanisms and skeletal injury patterns in vertical (falls from height) versus horizontal (motor vehicle collisions) blunt trauma. The presentation will outline how force vectors interact with age, sex, and Body Mass Index (BMI) to influence injury burden and will explore forensic implications for trauma interpretation.

Impact Statement: This presentation enhances forensic competence in identifying trauma mechanisms through skeletal injury patterns and demographic modifiers. By applying biomechanical concepts, it supports improved death scene reconstruction, autopsy interpretation, and informs trauma prevention efforts targeting high-risk populations.

Abstract Text: Blunt force trauma remains one of the most common mechanisms of accidental death encountered in medicolegal investigations. Among these, falls from height (vertical trauma) and motor vehicle collisions (horizontal trauma) are prominent causes. Although both result in blunt injuries, the biomechanical forces involved differ significantly in direction and magnitude, leading to distinct injury patterns. Despite the frequency of these trauma types, few comparative forensic studies have analyzed injury distribution using standardized autopsy datasets. This study aims to evaluate skeletal injury patterns and demographic modifiers associated with vertical versus horizontal blunt trauma in a medicolegal context.

A retrospective analysis was conducted on 50 adult accidental deaths evaluated by the El Paso County Office of the Medical Examiner. The cohort included 25 fatalities from falls from height and 25 from motor vehicle collisions involving seatbelt-restrained occupants. Exclusion criteria included pedestrian trauma, ejections, penetrating injuries, and advanced decomposition. For each case, demographic data (age, sex, BMI) and skeletal fractures across six anatomical regions (cranium, spine, ribs/sternum, pelvis, long bones, and upper extremities) were recorded. Fracture burden was defined as the number of distinct anatomical regions with fractures. Linear regression was used to analyze the relationship between BMI and injury burden for each trauma mechanism.

Vertical trauma cases demonstrated a higher frequency of cranial (56%), pelvic (48%), and rib/sternal (64%) fractures, consistent with axial compressive forces resulting from gravitational deceleration.[1,2] In contrast, horizontal trauma cases exhibited fewer cranial and pelvic injuries but showed an increased frequency of rib and extremity fractures, consistent with shear and lateral forces sustained during vehicular collisions.[3,4] A positive correlation between BMI and fracture burden was identified in vertical trauma cases, likely due to increased kinetic energy in heavier individuals. Conversely, an inverse correlation was noted in horizontal trauma, supporting the theory that soft tissue mass may have a protective, energy-distributing effect during collisions.[5,6]

Further stratification revealed that females and individuals aged 50 years or older experienced a higher fracture burden regardless of trauma type. These findings align with existing literature on age- and sex-related declines in bone density and increased skeletal fragility, particularly postmenopausal bone demineralization.[5,6]

Ultimately, this study highlights how biomechanical forces interact with individual characteristics to shape injury outcomes. Recognizing these distinct trauma signatures can improve postmortem interpretation and may also guide prevention strategies, from safer vehicle designs to targeted public health interventions for at-risk populations.

I150 Unusual/Atypical Deaths With Sharp Force Injuries

Priyanka Kaushal, BS, Saint Louis University School of Medicine, St. Louis, MO; Joseph A. Prahlow, MD, Medical Examiners Office, City of St. Louis, St. Louis, MO; Kanayo Tatsumi, MD, St Louis City Medical Examiners Office; Saint Louis University School of Medicine, St. Louis, MO; Tatiana Bihun, MD, Saint Louis City Medical Examiner's Office, St. Louis, MO; Katie Hanson, MD, St Louis City Medical Examiner's Office, St Louis, MO*

Learning Objectives: The goal of this presentation is to emphasize the importance of performing a complete forensic evaluation when faced with the investigation of sharp force injury deaths.

Impact Statement: This presentation will have a significant impact on the forensic community by shedding light on a range of unusual and complex cases involving homicides and suicides caused by sharp force injuries. By examining the forensic evidence, wound patterns, and investigative challenges associated with these cases, the presentation aims to enhance understanding, promote discussion, and improve the accuracy of future case assessments within the field.

Abstract Text: Homicides and suicides are common within the United States, with most resulting from gunshot wounds.[1,2] A much smaller number are related to sharp force injuries.[2] Deaths with inflicted sharp force injuries can present a challenge for death investigators. We present seven deaths with sharp force injuries, each with unusual circumstances or investigative findings.

An elderly man stabbed himself multiple times in the chest while providing a detailed written documentation from initial injury until death, which lasted many hours to possibly days. At autopsy, none of the stab wounds penetrated any body cavity or internal organ. Self-inflicted sharp force injury was a contributing factor in death. The manner of death (MOD) was suicide.

An elderly woman was found with over 100 sharp force injuries of the torso, resulting in a suspicion of homicide. Subsequent investigation revealed that she had a significant psychiatric history and the wounds were deemed to be self-inflicted.

A young man's body was discovered by police with multiple suspicious injuries. Investigation revealed that his wounds were self-inflicted sharp force injuries in the setting of chronic alcoholic ketosis. His MOD was suicide.

A middle-aged female resident of a psychiatric rehabilitation facility began screaming and subsequently died. Autopsy disclosed a superficial sharp force injury of the left wrist. Lividity was obvious and plentiful. Death was a result of an acute multi-drug intoxication. The self-inflicted wrist injury was instrumental in ruling the MOD as suicide.

Police responded to an "Emotionally Disturbed Person" call of an older man who then collapsed. During resuscitation attempts, a stab wound of the chest was discovered. A postmortem radiograph disclosed a massive tension pneumothorax. At autopsy, a large emphysematous bleb had been perforated and was the only internal injury identified. The MOD was homicide.

An adult male was exhibiting psychotic behavior. Police were called and confronted him, but he started to stab himself with scissors. The man became more agitated, at which time police shot him multiple times. Toxicology was positive for cocaine and cocaethylene. The cause of death was gunshot wounds of the torso, with a contributing cause of self-inflicted stab wounds of the neck. The MOD was homicide.

The nude body of a young man with a history of schizoaffective disorder was discovered submerged in his bathtub in his secured residence. There was evidence of significant bleeding, with blood smears throughout the bathroom. Autopsy disclosed multiple sharp force injuries of the upper extremities, as well as gastric Wishnewsky spots. He had no medical history other than his mental health issues. The COD was multiple sharp force injuries, with contributing factors of drowning and hypothermia. The MOD was suicide.

These atypical cases of sharp force injuries highlight the importance of integrating investigative and scene findings with autopsy and ancillary studies for accurate interpretation of forensic cases. A comprehensive evaluation of the police investigation, scene findings, medical record and social history review, toxicology results, and autopsy findings is essential for certifying the correct COD and MOD in deaths related to sharp force injury.

I151 Electrocutions Right or Wrong

Helmut G. Brosz, BASc, Forensic Science International Group, Markham, Ontario, Canada; Renee Knight, BASc, Toronto Police, Toronto, Ontario, Canada*

Learning Objectives: Pathologists will learn to distinguish between apparent electrocutions and other causes of death that mimic electrocutions based on actual cases and the documentation necessary to achieve a correct opinion.

Impact Statement: Pathologists will be impacted by an understanding of current, voltages, frequencies, duration, and confusing evidence that sometimes masks the correct conclusions as they may relate to other causes of death.

Abstract Text: This paper covers unusual apparent electrocutions and unusual non electrocution deaths and injuries that nay be accidental, personal misadventure, torture related, prankster and homicidal.[1] The voltages range from 120 to 345,000 volts AC in residential, public, indoor ,outdoor, utility and sexual settings. The cases and pictograms presented range from criminal torture to auto-erotic, to criminal modification to electrical devices and appliances with an intent to injure or kill. The willful bringing down of high voltage powerlines in order to start a wildfire can result in the perpetrators electrocution due to step potential with minimal physical evidence. Failed electrical sabotage has led to deaths due to misadventure. The injuries can range from catastrophic to none apparent. Electrical injuries can be complex and a devastating form of trauma. The survival rates depend on current magnitude ,timing, and duration as well as frequency. Body ohmic resistance varies from one person to another and varies for the same person depending on the amount of exertion that produces sweat. Clothing, shoes, tools and artifacts that are found at a scene can be important for the pathologist and engineers for the purpose of reconstruction. The deceased's medical records have also played an important role in the construction of an opinion of electrocution or other. Some deaths have been attributed to electrical failures when lightning was the cause of death. There exist museum-quality artifacts related to electrocutions. The paper will show some of the unusual artifacts that have played a role in the presenters 50 years of working, teaching, studying, and testifying in the electrocution and electrical field.

I152 SHOCK AND AWE! A Review of Electrocution Deaths at the Denver Office of the Medical Examiner/Coroner (2010–2023)

Logan Ritter, MD, DPHE Office of the Medical Examiner, Denver, CO; Meredith A. Frank, MD, DPHE Office of the Medical Examiner, Denver, CO; James L. Caruso, MD, DPHE Office of the Medical Examiner, Denver, CO; Ian J. Puffenberger, MD, DPHE Office of the Medical Examiner, Denver, CO; Sterling J. McLaren, MD, DPHE Office of the Medical Examiner, Denver, CO*

Learning Objectives: Attendees will learn about electrocution deaths through case reports of deaths certified in Denver, CO, during 2010–2023. Afterward, attendees should be able to identify the mechanisms of death in electrical injuries, the differences between low voltage, high voltage, and lightning injuries, typical autopsy findings, and the associated epidemiologic patterns of electrical deaths.

Impact Statement: Medical examiner and coroner offices infrequently see cases of electrocution deaths. This presentation aims to impact the forensic science community by providing case examples of deaths that occurred in the Denver jurisdiction due to different types of electrical injury. The aim of revisiting these cases is to further the audience's understanding of how death occurs with these injuries and which populations and geography are more likely to be involved.

Abstract Text: The Denver Office of the Medical Examiner/Coroner has received 10 cases of electricity related deaths (electrocutions) during the past 13 years. Electrocution deaths are relatively uncommon in the U.S. despite the high usage and availability of electric power. Death can result from the effects of current, thermal injuries, blast effects, or secondary injuries such as falls.[1]

Electrocutions rank as the second leading cause of death among U.S. construction workers, accounting for an average of 15% of traumatic deaths in the industry from 1980 to 1991.[2] Rates vary across the country, as higher rates are seen in regions with greater occupational exposure and less stringent safety practices.

Shocks with a low voltage (defined as less than 1000 volts) have been reported to carry about half of the mortality risk than those with high voltage (defined as greater than 1000 volts), at 2.6% compared to 5.2%, respectively.[3] The standard household in the United States has low voltage electrical wall outlets that carry 110-120 volts. Deaths caused by exposure to low voltage electricity is usually due to current involved and can cause cardiac, brainstem, or respiratory arrest. High voltage electrocutions are due to either contact with or arcing of electricity from overhead power lines and electrical equipment and are more commonly occupational exposures.[4] Electricians, linemen, and structural metal workers are at a particularly high risk, with the highest rates among 20-to-34-year-old males in the southern U.S. during summer months. Cases of high voltage electrical deaths usually include injuries due to thermal and blast effects. Lightning is the discharge of electrical energy from the atmosphere to Earth and can have very high current (up to 30 kilo amps) and temperatures (20,000˚C) but have an extremely short duration. Approximately 1/3 of strikes are fatal and death is usually instantaneous. The scenes of such cases can demonstrate scorched clothing or nearby objects, fusion of metal objects or secondary burns, and compass deviations.

In this presentation, multiple cases will be reviewed demonstrating the scene and autopsy findings through photographs that show the differences between low voltage, high voltage, and lightning strike deaths certified at the Denver Office of the Medical Examiner/Coroner during 2010-2023.

I153 When Science Isn't Independent: Fire Investigators, Medical Examiners, and Circular Logic

John J. Lentini, BA, Scientific Fire Analysis, LLC, Islamorada, FL*

Learning Objectives: After attending this presentation, the audience will be able to appreciate and hopefully avoid the potential for error when relying on a scientist in a different discipline. While deference to colleagues is essential, it can also be dangerous and lead to logical fallacies and false opinions.

Impact Statement: This presentation will affect the forensic science community by introducing additional skepticism when one is required to reach outside one's own discipline and rely on input from another scientist or investigator.

Abstract Text: In the realm of fire death investigations, the intersection of medical examiners and fire investigators is a critical point that is exquisitely susceptible to errors. Objective forensic investigation is essential but the risk of circular logic and feedback loops between different specialists can lead to wrongful conclusions about the cause and manner of death or the cause of the fire. As independent scientists, medical examiners are not expected to be part of the "team." It is, however, often necessary to interface with other disciplines in order to understand the evidence.

This interface is more critical in fire investigations than in many cases. When the *cause* of death is smoke inhalation the *manner* of death is often left up to the fire investigator to determine. If the fire investigator determines that a fire was intentionally set, the cause of death is smoke inhalation in the manner of death is homicide. But how reliable are fire investigators and how can fire investigators and medical examiners avoid falling into circular logic traps?

This presentation will cover three cases they have all been fully adjudicated, where the Medical Examiner was misled by the fire investigator or vice versa.

The first case, *Arizona v. Ray Girdler*, involves a medical examiner who became too much of a team player, resulting in the jury hearing some truly misleading testimony.[1]

The second case, *Texas v. Sonia Cacy*, involves a mistaken identification of gasoline on the victim's clothing which led the medical examiner to declare the manner of death to be homicide, and the fire investigator relying on the "homicide" determination as part of his conclusion that the fire was intentionally set.2

The third case, *Maryland v. Eshyna Young*, involves an outright error on the part of the medical examiner which should have been caught by the fire investigator, but was not. As a result, an innocent woman was charged with killing her mother when, in fact, the fire investigators' original conclusion at the fire was caused by careless smoking was correct but was tossed aside. The fire was called "incendiary" because according to the medical examiner, the victim was dead before the fire started and therefore, the defendant had to be lying.[3]

A better understanding of fire behavior on the part of the medical examiners and better communication on the part of the fire investigators could have prevented all three of these miscarriages from occurring.

I154 The Undying Dilemma of Time Since Death in Court: A Critical Analysis of Traditional and Innovative Methods for PMI Estimation

Simone Grassi, MD, PhD, University of Florence, Florence, Toscana, Italy; Hannah C. Jarvis, MRCS, Harris County Institute of Forensic Sciences, Rosharon, TX; Noemi Procopio, PhD, University of Lancashire, Preston, England, United Kingdom; Andrea Costantino, MD, Careggi University Hospital, Florence, Toscana, Italy*

Learning Objectives: The presentation will systematically discuss both the traditional and the more innovative molecular methods for Postmortem Interval (PMI) estimation, trying to assess which of them actually meet *Daubert* criteria. The potential role of artificial intelligence will also be briefly discussed.

Impact Statement: Participants will learn about state-of-the-art research toward improved methodologies for PMI estimation as well as current methods used in court. The core aim of the presentation is to stimulate a debate about whether current methods for PMI estimation are actually suitable for court evidence.

Abstract Text: In some countries, like Italy, the forensic pathologist is always questioned about the cause and manner of death and the post-mortem interval (PMI) in criminal proceedings, as this can assist in the inclusion or exclusion of a suspect. There is currently no such thing as a validated marker for PMI estimation, and of the many methods that have been proposed for this task, very few showed good levels of accuracy. Of the traditional PMI estimation methods, only post-mortem cooling and forensic entomology have been assessed suitable for Court evidence, and in Italy Henssge's nomogram is, in fact, the only method used in current practice. In the United States, opinions on the PMI may also be offered in criminal proceedings. In both countries, autopsy reports also routinely contain details on the presence of livor mortis, rigor mortis, and decompositional changes. In the US, the large error rates in the PMI estimation using these observations alone are accepted amongst Forensic Pathologists, and opinions tend to be limited to very broad time frames. In both countries, Forensic Entomologists and Anthropologists are highly underutilized.

Many of these challenges are not fully understood by law enforcement agencies investigating deaths, and judges and attorneys involved in the prosecution and defense of such cases. That being said, despite it is the main item in both countries, rectal temperature is less accurate than brain temperature in the early PMI (that is the most critical one) and the method itself is highly limited by many factors (e.g., it is validated only for adults; it assumes an ideal starting body temperature and limited changes in the environmental temperature; it is substantially used only when a homicide is suspected but it gives false responses if the body was moved). Forensic entomology can instead only provide a minimum PMI and not complete PMI estimations, as it has to account for the delay that may elapse between the death and the cadaveric colonization by insects. Finally, currently many -omics methods (such as microbiomics, proteomics and metabolomics) have been proposed for improving PMI estimations however, despite the relatively good accuracy reported for many of these studies, results are often limited to animal models (with few interspecies comparisons), or to small numbers of human individuals, and frequently obtained under controlled experimental conditions that fail to represent the actual ensemble of interfering variables that are normally present in forensic cases.

In the proposed oral presentation, from a double Italian-American perspective, we will try to systematically analyze whether the most popular traditional and innovative methods for PMI estimation actually meet the *Daubert* criteria to be used in criminal proceedings. We will also briefly discuss the potential role that Artificial Intelligence could play in trying to consider as many variables as possible in these complex problems.[1-7]

I155 A Deep Learning-Based Evaluation of Coronary Artery Stenosis in Forensic Autopsies Using Whole Slide Imaging

Nicola Pigaiani, MD, PhD, Section of Forensic Medicine, Department of Diagnostics and Public Health, University of Verona, Italy, Verona, Veneto, Italy; Shakiba Sharifi, MEng, Section of Engineering and Physics, Department of Engineering for Innovation Medicine, University of Verona, Italy, Verona, Veneto, Italy; Matteo Brunelli, MD, PhD, Section of Pathology, Department of Diagnostics and Public Health, University of Verona, Italy., Verona, Veneto, Italy; Marianna Garavello, MD, Section of Forensic Medicine, Department of Diagnostics and Public Health, University of Verona, Italy., Verona, Veneto, Italy; Alberto Chighine, MD, PhD, Section of Legal Medicine, Department of Medical Science and Public Health, University of Cagliari, Italy., Cagliari, Sardegna, Italy; Stefano Gobbo, MD, PhD, Section of Pathology, Department of Diagnostics and Public Health, University of Verona, Italy, Verona, Veneto, Italy*

Learning Objectives: Attendees of this presentation will gain insights into: (1) the limitations of traditional methods for coronary stenosis assessment in forensic practice; (2) the application of digital pathology and deep learning for anatomically informed, objective quantification of coronary lesions; and (3) how AI-based analysis of histological slides can be integrated into standardized workflows to improve diagnostic accuracy and forensic histopathology practice.

Impact Statement: This presentation will impact the forensic science community by demonstrating the potential of AI and digital pathology to transform coronary artery evaluation in autopsy practice. By enabling objective, reproducible quantification of stenosis, even in anatomically distorted or plaque-rich vessels, it strengthens the diagnostic foundation of sudden cardiac death investigations and promotes broader adoption of automated tools in forensic histopathology.

Abstract Text: Sudden cardiac death (SCD) remains a major issue in forensic pathology. Macroscopic and microscopic signs vary depending on the survival time following the precipitating event. The earliest histological changes, such as wavy fibers, early coagulative necrosis, edema, hemorrhage, and cytoplasmic hypereosinophilia, typically appear only after 4–12 hours. Macroscopically, acute coronary obstruction or critical stenosis due to stable (non-thrombosed) plaques supports a diagnosis of SCD.[1] While acute occlusion is often evident, identifying critical stenosis (≥75%) in stable plaques is more challenging, especially without thrombosis. Visual assessment is prone to error and subjectivity, particularly compared to digital pathology techniques, as shown by the only available study.[2]

Building on this, we developed an artificial intelligence (AI)-based tool using whole slide imaging (WSI) and QuPath software to improve accuracy and consistency in coronary stenosis quantification, potentially establishing a new diagnostic standard.

Ninety-seven histological slides, each containing one or more cross-sections of human coronary arteries, were scanned using the Aperio GT 450 DX scanner (Leica Biosystems, Nussloch, Germany). The digitalization process followed previously validated protocols.[3] A total of 238 regions of interest (ROIs) were extracted and split into training (70%), validation (20%), and test (10%) datasets. The system leverages deep learning (DL) models for semantic segmentation of coronary artery sections. Initial steps involved the detection and extraction of arterial regions from high-resolution slides, excluding irrelevant tissue. Neural networks trained on annotated data segmented the arterial wall, lumen, and plaque to calculate stenosis percentage and plaque area.

A key feature of the model is its ability to identify and approximate the course of the internal elastic lamina (IEL). Although the IEL does not directly represent the original lumen, it serves as a standardized anatomical reference for estimating the vessel's inner contour before plaque formation. In line with forensic and cardiovascular pathology protocols, the area enclosed by the IEL approximates the native luminal area and was used to calculate the degree of stenosis.[4] By reconstructing the IEL, even when partially disrupted, the model allows consistent estimation of plaque burden relative to the expected pre-disease profile. This reconstruction supports objective and reproducible stenosis quantification, reducing interpretative variability and enabling automated workflows in SCD investigations.

Preliminary implementation showed that the model accurately segments coronary structures and reconstructs the IEL. This improves the objective assessment of whether stenosis meets the ≥75% threshold, particularly in stable plaques where interpretation is uncertain. The DL-based approach also enabled visualization of lesion morphology and estimated original lumen contours, enhancing diagnostic clarity. The system is expected to significantly reduce analysis time, improve reproducibility, and support more reliable forensic conclusions in suspected SCD cases. To our knowledge, this is the first study to apply digital pathology combined with AI-based segmentation to the forensic evaluation of human coronary stenosis. By replacing subjective visual estimates with anatomically informed digital reconstructions, our method introduces a more objective and standardized framework. This work opens the door to broader applications of AI in forensic histopathology, with significant implications for research, diagnostics, and education.

I156 An Interpretation of Myocardial Injuries in Natural and Unnatural Deaths

Katarzyna Michaud, MD, University Center of Legal Medicine, University of Lausanne, Lausanne, Vaud, Switzerland*

Learning Objectives: After attending this presentation, attendees will understand the pathophysiology and postmortem diagnosis of myocardial injuries most relevant to routine forensic autopsy practice. They will understand the difference between myocardial infarction and other forms of myocardial injuries. They will be able to explain the possibilities and limitations of different postmortem diagnostic modalities.

Impact Statement: This presentation will impact the forensic community by providing a practical guide to the interpretation of myocardial findings at autopsy, taking into account possible natural and non-natural causes and postmortem artifacts.

Abstract Text: Myocardial injury is a common finding at forensic autopsy, given the wide variety of diseases and pathophysiological processes that can affect the myocardium. The most common cause of cardiomyocyte injury is ischemia (myocardial infarction) but can also be due to drugs, trauma, radiation, immunological effects and infectious diseases.[1] In the past updated 4th definition of myocardial infarction established by the Joint Task Force of three societies (the European Society of Cardiology, the American College of Cardiology Foundation, the American Heart Association and the World Heart Federation), an important distinction is made between myocardial injury which includes any form of acute myocardial damage or destruction and myocardial infarction resulting from myocardial ischemia only.[2] This knowledge is also important for pathologists and medical examiners performing autopsies. In fact, distinguishing between different ischemic and non-ischemic causes is of vital importance in determining the cause and mechanism of death, but it also enables the investigation of often difficult forensic scenarios, sometimes associated with post-mortem artifacts, as for example after resuscitation.[1,3-5]

During the presentation, the various causes of myocardial injuries will be illustrated (ischemia, ischemia and reperfusion, non-ischemic causes) with a brief presentation of their pathophysiology. The diagnostic modalities at autopsy including classical autopsy, post-mortem imaging (by post-mortem CT, CT- angiography, MRI), immunohistochemistry and postmortem chemistry (cardiac troponins) will be discussed and the practical approach to assessing these lesions at autopsy will be summarized using a diagnostic flowchart.

I157 Postmortem Diagnosis of Dilated Cardiomyopathy: Revisiting Fundamentals Through a Systematic Review

Simona Calabrese, MD, Unime, Messina, Sicilia, Italy; Vincenzo Cianci, MD*, UNIME, Messina, Sicilia, Italy; Alessio Asmundo, PhD, Unime, Messina, Sicilia, Italy; Cristina Mondello, PhD, University of Messina, Messina, Sicilia, Italy; Alessandro N. Nicolosi, MD, Unime, Messina, Sicilia, Italy; Anna Messina, MD, Messina University, Messina, Sicilia, Italy*

Learning Objectives: This review aims at highlighting the importance of combining classical autopsy techniques with targeted genetic testing to improve diagnostic confidence in suspected Dilated Cardiomyopathy (DCM) -related deaths. Establishing clearer postmortem criteria may reduce the risk of missed or misclassified cases, which is especially critical when the findings concern civil or criminal proceedings.

Impact Statement: The impact on our scientific community will consist in raising awareness on forensic investigations to establish an accurate postmortem diagnosis of DCM by reviewing key macroscopic and histological cardiac findings reported in the literature. The study underscores the importance of comprehensive and recommended/shared autopsy procedures, while also integrating the growing relevance of genetic analysis. Recognizing the inherited nature of many DCM cases is not only essential for postmortem diagnostics but also carries significant implications for family screening and preventive measures.

Abstract Text: Dilated cardiomyopathy (DCM) is a myocardial disorder characterized by structural and functional abnormalities, in particular left or biventricular chamber dilatation and systolic dysfunction, occurring without evidence of coronary artery disease, hypertension, valvular disease, or congenital heart defects.[1] It is a significant cause of sudden cardiac death, particularly in young individuals, often remaining undiagnosed until autopsy. Despite advances in genetic and imaging diagnostics, postmortem identification of DCM still relies heavily on histopathological and gross anatomical assessment, which can vary significantly across forensic institutions.[2] This study revisits foundational autopsy practices while integrating modern genetic insights, with the goal of enhancing diagnostic clarity and fulfilling our duty to accurately determine cause and mechanisms of death.

A systematic review of the literature was conducted following PRISMA guidelines.[3] Scientific databases (PubMed and Scopus) were searched for peer-reviewed articles published up to February 2025 describing postmortem findings in individuals diagnosed with DCM. Inclusion criteria were focused on studies reporting macroscopic cardiac findings (e.g., heart weight, chamber dilation), microscopic features (e.g., myocyte hypertrophy, interstitial fibrosis), and genetic variants identified postmortem or in related familial studies. Data were extracted and categorized to identify consistent diagnostic markers and to assess the frequency and relevance of genetic findings in autopsy-confirmed DCM cases.

From 2081 initial records, 31 studies met inclusion criteria. Common macroscopic features included increased heart weight (often > 350 g), dilated left or biventricular chambers, and thinning of the ventricular walls. Histologically, the most consistent findings were diffuse interstitial fibrosis, myocyte hypertrophy, and nuclear atypia. Particular attention was given to morphological features essential for distinguishing idiopathic DCM from post-ischemic forms and from end-stage hypertrophic cardiomyopathy (HCM). Notably, truncating variants in genes such as TTN, FLNC, DSP, PKP2 and MYH7 were frequently reported, particularly in young decedents with no significant history of cardiac disease. However, only about half of reviewed studies included any form of genetic analysis, reflecting a significant gap in current practice for the forensic pathologist.

In conclusion, by reviewing autopsy and genetic findings, our study aimed to define more consistent postmortem features of DCM in order to provide practical indications for a more accurate diagnosis, allow for an effective family screening/prevention and to eventually cope with professional liability cases.

I158 From Arteriosclerotic Cardiovascular Disease to Aortic Dissection: The Impact of Postmortem Imaging in Cause-of-Death Determinations

Carissa Longo, MD, University of California, San Francisco, San Francisco, CA; J. Jun Guan, MD, San Francisco Office of the Chief Medical Examiner, San Francisco, CA*

Learning Objectives: The goals of this presentation are to: (1) rvaluate the diagnostic value of Postmortem Computed Tomography (PMCT) in identifying acute aortic dissection as a specific cause of death in cases that might otherwise be broadly, but appropriately, attributed to Arteriosclerotic Cardiovascular Disease (ASCVD); (2) identify key postmortem imaging findings of acute aortic dissection using PMCT in cases limited to external examination; and (3) discuss how accurate identification of acute aortic dissections can improve public health data.

Impact Statement: This study highlights the role of PMCT in improving the identification of acute aortic dissection in external examination-only cases. By revealing specific findings that may otherwise go undetected, PMCT provides more accurate cause-of-death determinations. At the same time, these findings reinforce the continued relevance of ASCVD as a broad diagnostic category for sudden natural deaths in individuals over 50, as acute aortic dissections fall within this scope. This dual insight may enhance both forensic practice and the accuracy of public health data.

Abstract Text: Acute aortic dissection (AoD) is a life-threatening vascular condition characterized by a tear in the intimal layer of the aorta, resulting in separation of the aortic wall layers with potential for complete rupture.[1] The incidence of AoD is approximately 5 to 30 cases per 1 million people per year and primarily affects individuals between 50 and 65 years of age.[1] It is estimated that 3.9–5.4% of sudden deaths are attributable to acute aortic dissection rupture; however, the true incidence is likely underestimated in the forensics community given the common practices of attributing natural, non-suspicious deaths of decedents over the age of 50 or 60 to arteriosclerotic cardiovascular disease (ASCVD) or a similar diagnosis, such as hypertensive and/or atherosclerotic cardiovascular disease, with only administrative record review or external examination without further toxicology testing.[2]

The purpose of this study is to highlight the utility of postmortem computed tomography (PMCT) in diagnosing ruptured aortic dissection in external examination only cases performed at the San Francisco Office of the Chief Medical Examiner, paired with our Office's standard toxicologic testing. We conducted a retrospective case review of six external examination-only cases with PMCT findings of ruptured aortic dissection and hemopericardium since 2023. Of the six decedents identified, five were male and one female, with ages ranging from 53 to 68 years. The manner of death was classified as "Natural" in half of the cases and "Accident" in the remaining half. All three cases classified as "Accident" had scene findings or medical histories of substance use, with postmortem peripheral blood toxicology testing detecting cocaine. A history of uncontrolled hypertension was noted in two cases. PMCT findings demonstrated aortic dissection evidenced by false lumens of the thoracic ascending aorta and hemopericardium in all cases. Additionally, calcific atherosclerotic changes in the aorta and/or coronary arteries were observed in five cases.

This study suggests that PMCT is a valuable tool for visualizing and diagnosing aortic dissections, contributing to more accurate determination of cause of death and improved classification in public health data, although these deaths may still fit under the ASCVD umbrella. Limitations include the inability to evaluate for bicuspid aortic valve, connective tissue disease, or other aortopathies as etiologies of aortic dissection other than hypertensive disease; a partial internal examination may be considered in such cases.

I159 A 17-Year Review of Myocarditis Cases From the West Tennessee Regional Forensic Center

Alexandria Anderson, BA, West Tennessee Regional Forensic Center, University of Tennessee Health Science Center, Memphis, TN; Ibrahim Ortanca, MD, West Tennessee Regional Forensic Center, Memphis, TN*

Learning Objectives: Attendees will evaluate the demographic and circumstantial factors associated with myocarditis-related deaths in West Tennessee over a 17-year period, including age and sex distribution, cause and manner of death, drug involvement, autopsy findings, and incarceration status. Attendees will explore the wide range of clinical presentations of myocarditis, often non-specific or mild, that may precede death. This study highlights the significance of histopathological examination in diagnosing myocarditis, particularly when gross cardiac abnormalities are absent, providing forensic pathologists with essential context for accurate case interpretation.

Impact Statement: This study will impact the forensic science community by illustrating the wide variability in clinical presentation, demographic patterns, and investigative circumstances that can complicate the diagnosis of myocarditis-related deaths. This study emphasizes the significance of histopathological examination in diagnosing myocarditis, especially in the absence of gross pathological findings. These findings enhance the ability of medical examiners to accurately determine cause of death and improve recognition of myocarditis in forensic practice.

Abstract Text: The classical histopathological definition of myocarditis is described as cardiomyocyte damage with associated inflammatory infiltrates.[1] Clinically, it presents with a wide range of symptoms, including chest pain, arrhythmias, fever, and abdominal discomfort. In rare cases, myocarditis may lead to sudden cardiac death, which typically falls under the jurisdiction of a medical examiner.[2] This 17-year retrospective study evaluates myocarditis-related deaths at the West Tennessee Regional Forensic Center (WTRFC), focusing on demographic distribution, circumstances of death, prior clinical presentations, and autopsy findings.

A total of 20,650 people, who died between 2007 and 2024, were autopsied at WTRFC. Myocarditis was diagnosed in 57 of these cases, where it was determined to be either the primary cause of death or a contributing factor.

In 29 cases (51%), "myocarditis" or "arrhythmia due to myocarditis" was listed as the sole immediate cause of death. In the remaining cases, myocarditis was either the primary cause of death with contributing conditions or a contributing factor to another primary cause of death. In 13 cases (23%), drug toxicity was listed among the additional diagnoses. Correspondingly, 12 cases were classified as accidental deaths and two as undetermined; all involved drug use. The remaining cases were classified as natural deaths.

Of the 57 cases, 32 (56%) were male and 25 (44%) were female. Five decedents (9%) were infants younger than 12 months old, nine (16%) were between the ages of 1 and 18 years, and the remaining 43 (75%) adults over 18 years old. A specific subgroup included nine male inmates (16%), with manners of death classified as accidental (drug-related) in seven cases, natural in one, and undetermined in one.

Nineteen decedents (33%) were pronounced at the scene, 24 (42%) were found unresponsive and later pronounced at the hospital, and 14 (25%) were transported to the hospital by EMS or self-presented prior to death. Based on investigative findings and medical records, 12 decedents (21%) had recently visited a medical facility with documented symptoms. Reported presenting and/or recent visit symptoms included upper respiratory complaints (e.g., cold-like symptoms, cough, wheezing, runny nose, or congestion; n=8); non-specific pain (arms, legs, back, or generalized pain; n=7); vomiting (n=6); altered mental status, including erratic behavior or combativeness (n=5); chest or abdominal pain (n=5); fever (n=2); and lightheadedness (n=2).

At autopsy, gross examination of the heart was unremarkable in 22 cases (39%). The remaining cases demonstrated at least one gross pathological finding, including cardiomegaly (n=25; 44%), dilatation (n=14; 25%), myocardial discoloration (n=9; 16%), pericardial fluid discoloration (4; 7%), valvular vegetations (4; 7%) and pericardial adhesions (2; 4%).

Causative agents were identified in 12 cases through antemortem or postmortem testing, with six attributed to viral infections (including two COVID-19 cases), and six to bacterial infections.

Myocarditis can result in sudden cardiac death, with or without preceding symptoms, and affects individuals across all age groups and circumstances. Because gross cardiac abnormalities may be absent, histopathological examination of the heart is essential to ensure accurate diagnosis.

I160 Pediatric Drug-Related Deaths and Toxicological Findings From the Cook County Medical Examiner's Office: A Five-Year Retrospective Study

Santina Alessandra Severino, PharmD, Vanvitelli University, Naples, Campania, Italy; Anna Carfora, PhD, Vanvitelli University, Naples, Campania, Italy; Lorenzo Gitto, Cook County Medical Examiner's Office, Chicago, IL; Carlo Pietro Campobasso, MD, PhD, University of Campania "Luigi Vanvitelli", Naples, Naples, Campania, Italy; Federica Migliaccio, MD, Vanvitelli University, Naples, Campania, Italy*

Learning Objectives: After attending this presentation, attendees will better understand the autopsy and toxicological findings related to drug-related deaths in minors reported in a large metropolitan area.

Impact Statement: This presentation will impact the forensic science community by addressing the pediatric drug-related deaths highlighting the distribution among age, sex, and race, the most common causes and manners of death, the autopsy and toxicological results, and the circumstances of the fatal events.

Abstract Text: The drug epidemic in the United States, compounded by the ongoing fentanyl crisis, has led to a significant rise in cases of acute toxicity, including pediatric deaths.[1,2] According to the Centers for Disease Control and Prevention (CDC), an average of 22 adolescents died of drug overdoses each week in 2022. Opioids remain the leading agents involved in pediatric poisonings, followed by other illicit substances and even over-the-counter medications.[3] Acute drug toxicity in the pediatric population can result from various circumstances, including suicide, accidental ingestion, and, in some cases, homicide.[4]

A retrospective review of cases from the digital database LabLynx of the Cook County Medical Examiner's Office in Chicago, IL, was conducted for the period from June 2020 to June 2025. Subjects were categorized according to age classifications proposed by the CDC. The following data were reviewed: autopsy and toxicological findings, cause and manner of death, distribution by sex, age, and ethnicity, and the circumstances surrounding drug-related fatalities.

Seventy cases (43 males and 27 females) met the inclusion criteria, with a mean age of 10.8 ± 6.85 years. The subjects included 14 infants (0–1 year), 6 toddlers (1–3 years), 2 preschoolers (3–5 years), 5 middle childhood subjects (6–11 years), 4 young adolescents (12–14 years), and 39 adolescents (15–17 years). In terms of ethnicity, African American individuals comprised the largest group (35 cases), followed by White individuals (32 cases), Asian individuals (2 cases) and Other (1 case). Regarding the manner of death, 37 out of 70 cases were classified as accidental, 10 as homicides, 6 as suicides, and 17 as undetermined.

All victims tested positive for toxicological substances. Combined drug toxicity was identified in 45 cases, including 31 accidents, 10 undetermined deaths, 3 homicides, and 1 suicide. Opioids were the most commonly detected illicit substances. Fentanyl was present in 41 cases (28 accidental, 2 homicides, 11 undetermined), followed by fentanyl analogs such like acetyl fentanyl and methadone, which were detected in 6 cases, along with tramadol. Amphetamines—including 3,4-methylenedioxymethamphetamine (MDMA) and methamphetamine—were found in 10 accidental deaths. Prescription benzodiazepines such as clonazepam and alprazolam were identified in 7 cases, all classified as accidental deaths except for one homicide. Cocaine was detected in 5 accidental deaths and 1 suicide. Other opioids included heroin and oxycodone. Ethanol was present in 4 accidental cases only. Novel psychoactive substances (NPS) were also detected: fluorinated fentanyl analogs (e.g., para-fluoro-fentanyl) were found in 1 undetermined case, and designer benzodiazepines such as bromazolam were present in 5 accidental deaths. Other substances included carbon monoxide (CO), sodium nitrite (in one suicide), and acetaldehyde (in one accidental case). CO poisoning was involved in 5 accidental deaths, as well as 3 homicides and 3 undetermined cases. Prescription medications were primarily identified in suicidal and accidental deaths, including promethazine, diphenhydramine, bupropion, and others.

This study highlights distinct characteristics of drug-related deaths in the pediatric population, underscoring significant public health concerns and emphasizing the need for improved data interpretation and preventive strategies.

I161 Delayed Death Resulting From Child Abuse: An Analysis of an Uncommon Phenomenon in a Large Metropolitan Area

Ilaria Fracassi, MD, Department of Mental and Physical Health and Preventive Medicine, University of Campania "Luigi Vanvitelli", Napoli, Campania, Italy; Valentina Mormile, MD, Department of Mental and Physical Health and Preventive Medicine, University of Campania "Luigi Vanvitelli", Napoli, Campania, Italy; Lorenzo Gitto, Cook County Medical Examiner's Office, Chicago, Illinois; Carlo Pietro Campobasso, MD, PhD, University of Campania "Luigi Vanvitelli", Naples, Naples, Campania, Italy*

Learning Objectives: At the end of this presentation, attendees will better understand the clinical, pathological, and forensic characteristics of delayed deaths resulting from child abuse.

Impact Statement: This presentation will impact the forensic community by providing insights into delayed pediatric deaths due to child abuse, focusing on leading causes of death, characteristic autopsy findings, patterns of injury and long-term disability, and the circumstances surrounding each case of maltreatment.

Abstract Text: According to the Child Maltreatment Report, 546,159 children were victims of abuse and neglect in the United States in 2023, reflecting a 19.3% decrease compared to the 2019 national data.[1] However, the number of child deaths due to maltreatment increased by 9.6% over the same period. In 2023, the mortality rate for child abuse was 2.73 per 100,000 children, underscoring the severity and fatal outcomes of these cases. On average, approximately 5.39 children died each day from abuse and neglect in the U.S. According to UNICEF data, the risk of dying from violence increases sharply in late adolescence. While most child fatalities occur shortly after the abuse or neglect, some cases demonstrate a significant delay between the inflicted injuries and death. This scenario is often associated with Abusive Head Trauma (AHT) or thoracic and abdominal injuries.[2] These cases can be particularly challenging due to the variability in the manifestation and progression of the long-term sequelae of child abuse.

A 9-year retrospective analysis of cases from the digital database LabLynx of the Cook County Medical Examiner's Office in Chicago, IL, was performed from 2015 to 2024, to search for delayed child abuse-related deaths. Subjects between 0 and 18 years were included in the study, and they were subdivided according to age classifications proposed by the Centers for Disease Control and Prevention (CDC). Cases were reviewed for age, sex, race, cause of death, circumstances of death, time interval between injuries and death, role of the perpetrator, findings from autopsy, as well as toxicological and/or histological results.

Seven cases (five males and two females) met the inclusion criteria, all demonstrating long-term sequelae of Abusive Head Trauma (AHT). According to CDC age classifications, all victims were categorized as infants (under 1 year of age) at the time the AHT occurred, with ages ranging from 2 weeks to 7 months. The interval between the initial injury and death ranged from 1 to 15.5 years, with the majority of cases (5 out of 7) resulting in death at least 8 years after the original traumatic event. The age at the time of death ranged from 16 months to 16 years. Most victims exhibited intracranial and retinal hemorrhages, as well as diffuse brain injuries shortly after the AHT. The chronic consequences were predominantly neurological, including seizures, spastic quadriplegia, cerebral palsy, and hydrocephalus. Delayed developmental milestones were noted in three cases. At autopsy, no significant macroscopic abnormalities of the brain were observed in most cases, except for two showing brain swelling and widespread encephalomalacia. Microscopic examination revealed findings consistent with chronic ischemic brain injury in all cases, including focal sclerosis, Wallerian degeneration, and subdural hyalinized neomembranes. The cause of death was attributed to complications of brain injuries sustained from remote episodes of child abuse. In all cases, the manner of death was certified as homicide.

Fatal outcomes resulting from the long-term effects of prior abuse are rarely addressed in current forensic literature. The results of this study will be further discussed with attendees.

I162 Reading Between the Scars: Recognizing Intent in Pediatric Burn Injuries

Alice Buzzelli, MD, Parma University, Reggio Emilia, Emilia-Romagna, Italy; Valentina Bugelli, MD, PhD, University of Parma, Parma, Emilia-Romagna, Italy; Alberto Amadasi, PhD, Charité Universitätsmedizin Berlin, Berlin, Berlin, Germany; Lorenzo Franceschetti, MD, PhD, Milan University, Milan, Lombardia, Italy*

Learning Objectives: Burn injuries are common in both abused and non-abused children and represent a significant diagnostic challenge in forensic science. In fact, an accurate diagnosis of this type of injury is important to distinguish between accidental occurrences, intentional abuse, and self-inflicted harm in order to ensure adequate protection for the victim.

Impact Statement: A multidisciplinary approach is essential to accurately assess and correlate injury and object characteristics, and social and family context in order to discriminate accidentality from abuse. The integration of these diverse forensic disciplines strengthens the capacity of health care and protective services to implement targeted, effective interventions, thereby enhancing outcomes and ensuring the holistic well-being of affected pediatric patients.

Abstract Text: This case series describes three cases of childhood burns in which a comprehensive and accurate analysis of the injuries, correlated with parental statements and circumstantial data, was critical to determine the distinct origins of burns between accidentality, self-harm and abusiveness.

In the first case, an 8-year-old girl was brought to the hospital by her mother with multiple second-degree burns on her buttocks, right thigh, and right foot. The mother reported that these injuries had been caused accidentally by the explosion of a water bag filled with water that was hotter beyond its capacity. Forensic experts meticulously analyzed the burns, considering their location, morphology, depth, and extent. The consistency of these characteristics with the described causative scenario ultimately supported an accidental etiology.

In the second case, a 3-year-old girl was brought to the hospital by her mother who claimed that she had accidentally burned her face and neck while she was playing in the same room in which her mother was ironing. However, careful forensic analysis revealed that the precise shape, depth, and anatomical distribution of the burns closely matched the flat surface of an iron, significantly undermining the mother's account. Given these clear inconsistencies, the injuries were classified as intentionally inflicted, and protective measures were promptly initiated to ensure the child's safety.

In the last case, a 13-year-old girl with a history of multiple hospitalizations since the last two years was brought to the hospital by her mother with numerous skin lesions on her trunk and upper and lower limbs. Initially, these lesions suggested a rare dermatological disorder (e.g., pemphigus vulgaris or bullous pemphigoid), leading to multiple normal laboratory investigations. The forensic team pursued an integrated approach involving forensic toxicological analysis, which detected abnormal traces of aluminum on skin swabs. The only consistent aluminum-containing item in the child's environment was her deodorant. To further investigate the possibility of self-inflicted harm, covert surveillance was employed within the hospital setting, conclusively demonstrating the child deliberately inflicting the lesions upon herself. The final diagnosis was intentional self-harm associated with Munchausen syndrome, highlighting also the necessity of psychiatric evaluation.

In the first two cases, the accurate assessment of the location, morphology, extension, and depth of the burns in relation to the alleged causative tools (an exploded hot water bag and an iron) were crucial to differentiate accidentality from abuse. The third case presented a particular diagnostic challenge because of the initial suspicion of a natural disorder. Then the case was ultimately classified as intentional self-harm within the framework of a psychiatric illness.

Collectively, these cases underscore the critical importance of employing an integrative forensic approach that combines the expertise of forensic medicine together with other disciplines, and a thorough contextual analysis of familiar, social, and circumstantial evidence. Each case exemplifies how a meticulous multidisciplinary strategy can overcome initial diagnostic ambiguity and conclusively establish the etiology of burn injuries. Such an integrated methodology not only ensures accurate forensic conclusions but also plays a pivotal role in safeguarding vulnerable children from further harm.[1-3]

I163 Investigating the Phenomenon of Lesion Vitality on Human Ribs: From Untargeted Proteomics to the Application of Immunostainings for Specific Proteins

Nicola Galante, MD, University of Milan, Milan, Lombardia, Italy; Daniele Capitanio, PhD, University of Milan, Milan, Lombardia, Italy; Riccardo Zoia, MD, PhD, University of Milan, Milan, Lombardia, Italy; Alessandro Del Gobbo, MD, Ospedale Policlinico di Milano, Milan, Lombardia, Italy; Alessio Battistini, MD, PhD, University of Milan, Milan, Lombardia, Italy*

Learning Objectives: Attendees will learn how untargeted proteomics applied to bone marrow from fractured ribs can identify specific protein biomarkers—such as complement C9, fibrinogen, and Carbonic Anhydrase 2 (CAII)—that provide measurable indicators of lesion vitality in the forensic field. They will gain insights into the methodology, statistical validation, and diagnostic accuracy of these biomarkers and understand how this approach can enhance the timing and interpretation of rib trauma in medicolegal investigations.

Impact Statement: This presentation will enhance the competence of forensic pathologists by introducing a novel and evidence-based approach to assess lesion vitality on bone through untargeted proteomics. It will improve performance by providing validated biomarkers (e.g., fibrinogen, C9, CAII) with measurable diagnostic accuracy that can be integrated into routine forensic workflows. Ultimately, this method strengthens medicolegal conclusions regarding the evaluation of traumatic events and improves outcomes for stakeholders such as judicial authorities, insurance systems, and families.

Abstract Text: The research upon vital reactions is a hot topic in forensic pathology.[1] However, there are very few studies which focus on the bone tissue and scientific data are currently limited to conventional histopathology.[2,3] Therefore, the possibility to establish the timing of skeletal traumatic injury is difficult especially for short survival times. For these reasons, bone marrow may represent a potentially useful substrate for the identification of bone lesion vitality. Furthermore, novel omics techniques can improve the investigation of reliable forensic biomarkers.[4] This study provides the application of proteomics on human bone marrow of traumatized ribs with the purpose to: (1) define a significant pattern of vital reaction on broken ribs *versus* undamaged ones; (2) evaluate the proteomic changes over different known survival times; and (3) assess proteomic differences among resuscitation fractures *versus* other types of rib traumas (e.g., vehicle and train crashes, falling from heights). Furthermore, the most statistically significant proteins undergo an immunofluorescence or immunohistochemistry antibody-immunostaining to test their sensitivity, specificity and accuracy, respectively.

This study enrolls prospectively 25 cases with rib fractures and different survival times, and 15 controls with different causes of deaths but no traumatic injuries. Specifically, the survival times of cases include (7) < 1 hour, (4) = 1 hour, (4) = 2 hours, (5) = 5-10 hours, (2) 12 < t < 24 h, (3) t > 24 h up to 96 h; ratio men-to-women is 1,5:1 and the mean age 55,04. The selection of the case samples is based on the highest hemorrhagic infiltration which can be detected macroscopically; for controls, sampling is always conventionally taken on the 4th right rib. Then, soft tissues around each sample are mechanically removed and frozen at -80°C. Proteomic analyses are performed on the extracted bone marrows and results are expressed over log fold changes. Statistical tests include ANOVA applying the false discovery rate (q< 0,05). Then, immunohistochemical analysis is performed on 4 µm-thick paraffin-embedded tissue sections for carbonic anhydrase 2 (CAII) and complement C9. For immunofluorescence, sections are incubated with an anti-fibrinogen antibody which is visualized using a fluorescently labeled secondary antibody.

The trauma group significantly (q< 0,001) overexpresses 555 acute-phase inflammatory proteins, different extracellular matrix proteins, and bone-related specific proteins. Noteworthy, some of these proteins show very interesting patterns such as C9 which provides the best significant results over time, fibrinogen which statistically increases starting from 4 h after trauma, and carbonic anhydrase 2 which is linearly overexpressed in the first 12 h. There are no statistical differences between resuscitation fractures *versus* other types of rib blunt injuries. Immunohistochemical staining for C9 reveals sensitivity and specificity of 64% and 46%, respectively, and for CAII both sensitivity and specificity of 60%. Immunofluorescent staining for fibrinogen yields sensitivity, specificity and overall accuracy of 72%, 80%, and 75%, respectively, with a positive predictive value of 85%.

Untargeted proteomics applied to bone marrow of injured ribs gives the opportunity to identify proteins, which can be used in forensic field for the research upon lesion vitality.

I164 Systemic Calcium Dysregulation and Neuropathological Aging: A Retrospective Hospital Autopsy Study

Stacy K. Thomas, MD, PhD, Yale New Haven Hospital, Wallingford, CT; Hannah Sage, MD, Yale New Haven Hospital, New Haven, CT; Declan McGuone, MBBch, Yale New Haven Hospital, New Haven, CT; Cameron Stockford, BS, Yale School of Medicine, New Haven, CT; Barbara Ehrlich, PhD, Yale School of Medicine, New Haven, CT*

Learning Objectives: Attendees will review demographic characteristics of decedents undergoing unrestricted hospital autopsy in a tertiary health care setting, anatomic findings related to systemic calcium regulation at autopsy, and procedural inconsistencies in current hospital autopsy protocols.

Impact Statement: This presentation will inform forensic and hospital-based autopsy practitioners of systemic calcium-related findings encountered at autopsy and their association with age-related neuropathology as well as the need for greater standardization in autopsy documentation of systemic disease.

Abstract Text: Calcium homeostasis is essential for skeletal integrity and neuronal function, but its contribution to age-related brain pathology is uncharacterized in autopsy settings.[1] We hypothesized that systemic disruption of calcium homeostasis, as reflected in premortem clinical data and anatomic pathology findings at autopsy, is associated with an increased burden of neurodegenerative and cerebrovascular disease.

We performed a retrospective review of 213 unrestricted hospital autopsies performed at Yale New Haven Hospital (2023-24), on decedents older than 1 year of age who underwent formal neuropathological examination. Expanded data collection, (2014–2023) is ongoing.

Of the reviewed cases, 56% were male (n=112), with 65% aged 60–79 years (mean 66.8, range 1-94). The mean postmortem interval was 44.1 hours (range 2–204), with 15% (n=31) exceeding 72 hours. Clinically significant coronary artery atherosclerosis (≥50% stenosis) was present in 54% (n=115), but did not correlate with cerebrovascular atherosclerosis, (89.2%, n=190). Likewise, cerebrovascular atherosclerosis did not correlate with recent (8.5%, n=18) or remote (21.1%, n=45) infarcts.

Neuropathologic findings of Alzheimer's Disease Neuropathologic Change (ADNC) or Lewy body disease (LBD) were present in 6.6% (n=14) of cases, all of which had co-existent cerebrovascular atherosclerosis. Of these, 62.3% (n=9) had ADNC, 14.3% (n=2) had LBD, and 21.4% (n=3) had mixed pathology. Compared to the full cohort, cases with neurodegenerative pathology had a higher frequency of coronary artery atherosclerosis (57.1% vs. 54% overall), calcified aortic valves, (35.7% vs. 21.6% overall), and aortic calcification (71.4% vs. 66.2% overall). Rates of chronic cholelithiasis (50% vs. 23.9%), glomerulosclerosis (64.3% vs. 54.5%), and renovascular atherosclerosis (50% vs. 40.1%) were also increased in this group.

Notably, our review of autopsy records also revealed documentation gaps. For instance, although bone marrow sampling was routinely performed, cellularity was reported in only 55% (n=117) of cases, and assessments of osteoporosis were omitted in 26% (n=56) of cases.

This study suggests a possible association between systemic calcium homeostasis and chronic neurodegenerative disease and underscores a need for standardized autopsy protocols for better evaluation of calcific disease to inform aging-related research.

I165 The Applications of Humanitarian Principles in Forensic Death Investigations for Indigenous Communities

Steff King, MA, Simon Fraser University, Vancouver, British Columbia, Canada; Gail S. Anderson, PhD, Simon Fraser University, Burnaby, British Columbia, Canada*

Learning Objectives: After attending this presentation, attendees will understand how they can apply humanitarian forensic principles within their own investigative standard operating procedures to better support the needs of varying cultural, religious, and traditional communities.

Impact Statement: This presentation will impact the forensic science community by providing a critical framework that practitioners can apply to their own standard practices. The research will encourage forensic professionals to evaluate their current and future practices through a humanitarian lens, ultimately identifying the role and needs of the communities in which they serve.

Abstract Text: Despite growing public awareness and political attention, the crisis of Missing and Murdered Indigenous Peoples (MMIP) in Canada and the United States remains largely unresolved.[1-3] Indigenous families continue to report that the deaths and disappearances of their loved ones are investigated inadequately and without cultural sensitivity.[4,5] While national inquiries and government initiatives have acknowledged systemic failures, current medicolegal death investigation practices continue to reflect colonial frameworks that often exclude Indigenous participation, values, and needs.[6,7]

This project responds to these ongoing failures by returning to the fundamental principles of forensic science—truth-seeking, impartiality, respect for the dead, and service to the living. It examines how humanitarian forensic professionals—those who work in post-conflict, disaster, and culturally diverse environments—apply these foundational values to adapt forensic investigative strategies that support communities in crisis. The humanitarian-forensic literature emphasizes early engagement with affected communities to ensure that death investigations promote healing, justice, and dignity.[8,9] Although well-established internationally, these basic principles have yet to be fully implemented in the investigation of Indigenous deaths in North America.

The research centers on in-depth interviews and surveys with forensic professionals who have experience in both Canadian and U.S. medicolegal systems as well as global humanitarian settings. Participants included practitioners in forensic pathology, anthropology, odontology, archaeology, biology, criminalistics, and jurisprudence. Representing a range of international organizations, these experts brought an average of 20 years' experience across five continents. Their contributions focused on how standard investigative practices are adjusted in humanitarian contexts to align with local cultural and religious needs—often by re-centering the basic goal of forensic science: serving the communities it is meant to protect. The results present five core themes from expert experiences and insights: (1) Standardized procedures often fail to equitably serve culturally diverse communities; (2) It is possible to integrate some cultural traditions into forensic practice without compromising scientific or judicial integrity; (3) Building trust with communities enhances investigative outcomes and access to critical information; (4) Existing international frameworks and humanitarian protocols provide a solid foundation for rights-based forensic investigation; and (5) The forensic community must explore how the structural demands of the criminal justice system can conflict with alternative practices that better meet community needs.

This research proposes that humanitarian forensic approaches offer a model for reforming North American medicolegal death investigation systems, particularly in Indigenous cases. By centering the experiences of international humanitarian experts, and emphasizing core forensic values such as justice, dignity, and public service, this study provides a practical and ethical framework for adapting forensic practices to better serve culturally diverse populations. The ultimate goal is to support the creation of a community- and expert-informed resource for investigators, institutions, and policymakers seeking to implement culturally responsive strategies. In doing so, the project underscores the vital role humanitarian forensic professionals play in advancing equitable, community-centered approaches to death investigation that uphold both scientific standards and human rights.

I166 UMID: A National Initiative for DNA-Based Identification of Unidentified Dead Bodies in India

Chittaranjan Behera, MD, AIIMS New Delhi, Delhi, India*

Learning Objectives: This presentation will provide attendees with a comprehensive understanding of the Unidentified bodies and Missing person Identification portal and DNA database (UMID), India's first DNA database for identifying unidentified dead bodies. Participants will learn how the integration of phenotypic and genotypic data, supported by specialized bioinformatics software, enhances the accuracy and efficiency of forensic identification. The session will also outline the development of a centralized DNA database and its role in facilitating familial matching and regional ancestry prediction.

Impact Statement: This presentation will contribute to the forensic science community by advancing knowledge and application of integrated DNA technologies along with traditional methods in the identification of unidentified dead bodies. It will enhance the understanding of how genetic databases and automated matching systems can be effectively utilized to improve investigative processes. The UMID project also helps bring closure to families and supports legal investigations, showing its importance in strengthening forensic work in India.

Abstract Text: The identification of unidentified deceased is a pressing public health and forensic challenge in India, where many cases of missing individuals remain unresolved. Traditional identification methods largely depend on phenotypic data provided by law officials, which often falls short in accurately establishing identities. In response to this gap, the UMID project was launched as a first initiative in 2019 to create a comprehensive DNA Database and Identification Portal dedicated to unidentified bodies in India. Since its inception, UMID has expanded to six additional centers nationwide, collecting thousands of biological samples and establishing a database for DNA profiles. This genetic database has emerged as a fundamental tool, offering a more reliable approach to identification than traditional methods.

The primary aim of this study is to enhance the identification process for unidentified deceased individuals in India by broadening the scope of identification techniques to include both phenotypic and genotypic data. This approach provides an accessible and reliable resource for families of missing persons while advancing forensic practices within India. The project also aims to create a reference DNA database of relatives and claimants of missing persons, facilitating accurate matches with unidentified individuals within the UMID database. Additional objectives include examining genetic variation (allele distribution) across Indian regions through STR profiles and developing a machine learning model to predict regional ancestry, enhancing the potential for accurate identification. A long-term vision of the project includes the establishment of a National DNA Database and Identification Portal to address missing individual cases on a national scale.

The study involves the systematic collection of biological samples from unidentified bodies across multiple centers. The collected DNA is stored as STR profiles in the UMID database. A specialized bioinformatics software was also developed to automatically match STR profiles by comparing DNA profiles from unidentified bodies with reference profiles, identifying potential familial connections. The UMID database integrates phenotypic information from post-mortem reports with genotypic data to improve the accuracy of identification and enable geographic predictions based on genetic profiles.

Since expanding to multiple centers, the UMID project has successfully built a substantial DNA database for unidentified bodies, significantly streamlining the identification process. Families seeking missing persons can now access a centralized UMID identification portal, which incorporates both phenotype and genotype data, greatly improving the likelihood of successful identifications.

The UMID DNA database and identification portal represent a transformative advancement in identification of unidentified dead bodies in India. By enabling accurate identification of unidentified deceased, UMID not only brings closure to families but also supports legal investigations and addresses public concerns surrounding missing persons. The future expansion of this initiative into a National DNA Database holds promise for enhancing identification capabilities and strengthening India's approach to handling unidentified deceased cases.[1-4]

J1 The Evaluation of Malpractice in Psychiatry That Was Discussed in High Health Council During 2000–2008

Safa Celik, MD, PhD, Private Office, Kadıköy, Istanbul, Turkey; Nermin Celik, MD, PhD, Muayenehane, Kadıköy, Istanbul, Turkey; Ahmet Hakan Celik, MBBS, Medical School, Bologna, Italy, Kadıköy, Istanbul, Turkey*

Learning Objectives: Considering the importance of psychiatric malpractices in professional lives of psychiatrists, it will be beneficial to add medical malpractice training as a short course or study in training program of psychiatry students.

Impact Statement: This training will eliminate confusion in risky situations as well as raise awareness and decrease the anxiety of physicians about legal processes.

Aim: Malpractice is defined as a violation of standard care, an injury caused by negligence, an injury resulting in significant damage. There is a significant increase in the numbers of criminal and compensational suits in last years in all over the world. Some reasons for the increase in the number of trials are increasing awareness of the society with the influence of media and increased special interest of the attorneys in the society. Psychiatrists are facing relatively low number of claims of malpractice, compared to other medical specialties. There are not many studies examining malpractice cases in the field of psychiatry in Turkey. This study was conducted to contribute to the research need in the field of malpractice.

Materials and Methods: In the 2001-2007 period, 13 of the 2026 files (0.6%) in which the Supreme Health Council's opinion was requested by the courts were related to the field of psychiatry. In the study, the files were examined in terms of examination date, age, gender of the patients, the case and the negligent or non-negligent behavior of the doctors.

Findings: A total of 13 patients were analyzed in the study. The psychiatrist was found negligent in seven cases and non-negligent in four cases. Alleged mistakes in these cases were reported to be causing death or injury due to neglect of duty and negligence with imprudence and carelessness, malpractice and issuing false reports. Of 13 patients who underwent psychiatric examination, 10 were male, 3 were female. Two psychiatric examinations were made in private hospitals, two were made in military hospital, nine were made in a state hospital.

Conclusion: Considering the importance of psychiatric malpractices in professional lives of psychiatrists, it will be beneficial to add medical malpractice training as a short course or study in training program of psychiatry students. This raining will eliminate confusion in risky situations, will raise awareness and decrease the anxiety of physicians about legal processes.

J4 Zoanthropic Delusions Resulting From Acute Fentanyl and Methamphetamine Intoxication

Nidhi Checka, BS, Saint Louis University School of Medicine, Eden Prarie, MO; Tatiana Bihun, MD, Saint Louis City Medical Examiner's Office, St. Louis, MO*

Learning Objectives: Recognize the potential for unusual behavioral manifestations, such as zoanthropic hallucinations, in cases of acute drug intoxication, particularly involving fentanyl and methamphetamine. Integrate scene investigation findings (e.g., drug paraphernalia, witness statements, video footage) with autopsy findings and toxicology results to establish a comprehensive understanding of the circumstances surrounding a death.

Impact Statement: Investigators must know that drug intoxication, especially with potent combinations like fentanyl and methamphetamine, can lead to highly unusual behavioral manifestations, such as zoanthropic delusions. This is crucial because such bizarre behavior might initially mislead investigators towards other causes of death, like homicide. This case also demonstrates that no single piece of evidence (scene, autopsy, toxicology) is sufficient on its own; the combination of all three was critical to accurately determine the cause and manner of death.

Introduction: Zoanthropy is a rare psychiatric phenomenon in which individuals believe they have transformed into an animal. While its exact etiology remains unclear, there is literature suggesting a potential link between drug intoxication and zoanthropic delusions. Substances such as fentanyl and methamphetamine have been anecdotally implicated in such presentations, resulting in clinical cases where patients believe they have transformed into different species under administration of these drugs. We report a unique case involving concurrent fentanyl and methamphetamine intoxication resulting in dolphin-like zoanthropic delusions. A combination of scene investigation, autopsy findings, and postmortem toxicology was essential in determining the cause and manner of death.

Case Report: A 32-year-old male was found deceased near the St. Louis River with severe blunt force trauma. Several items of drug paraphernalia surrounded the area. The body was brought to the St. Louis Medical Examiner's office where a full autopsy and toxicology report was performed. The injuries discovered on autopsy were consistent with blunt force trauma, initially suggesting the cause of death was homicide. However, the toxicology report showed high levels of methamphetamine, xylazine, and fentanyl. Video footage from the scene showed the decedent crawling through a water stream from a fire hydrant and flopping toward the riverbank, behavior consistent with aquatic animal mimicry. Witnesses also reported the man producing dolphin-like vocalizations. The final cause of death was determined to be acute drug toxicity.

Discussion: Fentanyl is a potent synthetic opioid used in clinical settings for pain management. Some effects of fentanyl are euphoria, drowsiness, and even hallucinations. Due to its extreme potency, even amounts as small as 2 milligrams can be fatal for the average adult. Methamphetamines are a powerful stimulant used illicitly and clinically for treatment of Attention-Deficit Hyperactivity Disorder (ADHD). When abused illicitly, effects can include increased alertness, euphoria, and psychosis. Both fentanyl and methamphetamines pose a high risk of addiction and potential overdose. In rare cases, intoxication may provoke zoanthropic delusions, as observed in this situation. Awareness of such unusual presentations is important to consider in forensic and clinical settings.

Conclusion: Fentanyl and methamphetamine are clinically valuable but potentially lethal when misused. Comprehensive scene evaluation, autopsy, and toxicological analysis are essential for accurately determining the cause of death in cases involving suspected drug toxicity and unusual behavioral manifestations.

J5 Measuring Factors Associated With Identification Thresholds in Fingerprint Analysts

Nada Aggadi, BA, Indiana University, Bloomington, IN; Thomas Busey, PhD, Indiana University Bloomington, Bloomington, IN; Meredith Coon, MFS, Aver, LLC, Columbia, MD*

Learning Objectives: In this presentation, attendees will learn how individual and contextual factors influence identification thresholds in fingerprint analysts. Specifically, we will explore how need for closure, general self efficacy, and stress influence the frequency of identification decisions during latent print comparisons. Attendees will gain a deeper understanding of how forensic judgments are affected not only by evidence quality but also by the examiner's own traits and work environment. This research will help participants evaluate the implications of examiner variability.

Impact Statement: This presentation will impact the forensic science community by highlighting how psychological and environmental factors can contribute to variability in fingerprint identification decisions. By demonstrating that traits such as need for closure and workplace stress levels significantly influence identification thresholds, this research challenges the assumption that examiner decisions are purely evidence-driven. These findings highlight the importance of considering human factors in forensics and challenges the way results are currently communicated in the field.

Abstract Text: The goal of this research is to measure and identify factors associated with identification thresholds in fingerprint analysts. Conclusions reached in friction ridge comparisons require the application of individual thresholds, which reflect both the evidence and the decision-maker's internal criteria for rendering an identification. While previous studies have investigated the mechanisms behind value determinations or explored the perceived stress reported by forensic examiners, only a few have focused on how personality traits and environmental factors influence identification thresholds.[1] This study addresses that gap by examining how individual differences and workplace conditions may shape forensic judgments.

Participants were presented with a series of latent prints and tasked with making value determinations before proceeding to a full latent print comparison. After the comparison phase, participants completed a detailed survey assessing psychological traits such as Need for Closure and General-Self-Efficacy, as well as perceptions of their work environment such as stress. Our results demonstrate a significant positive correlation between Need for Closure scores and the number of Identification decisions made, as well as a significant positive correlation between reported Stress levels and Identification decisions. These findings suggest that forensic decision-making is not solely determined by the physical characteristics of the evidence, but is also shaped by psychological and contextual factors.

J6 Electronic Health Records, Artificial Intelligence, and the Forensic Psychiatric Examiner: Pitfalls and Implications

Vivian T. Chern Shnaidman, MD, Jersey Forensic Consulting LLC, Princeton, NJ*

Learning Objectives: Participants will be able to critically evaluate the limitations and risks associated with Electronic Health Records (EHRs) and emerging Artificial Intelligence (AI) tools utilized in and relied upon for forensic psychiatric evaluations. By analyzing real-world cases and reviewing current technological practices, attendees will develop the ability to distinguish between reliable documentation and flawed data, understand the potential misuse of AI-generated outputs, and formulate balanced, defensible forensic opinions that integrate clinical judgment with modern technological tools.

Impact Statement: This presentation addresses a critical and timely issue at the intersection of psychiatry, law, and technology. As AI becomes more prevalent in clinical settings, forensic psychiatrists must navigate both its promise and its perils. This talk equips professionals with tools to assess the reliability of EHRs and AI-assisted outputs in legal evaluations. By fostering awareness of technological limitations and ethical implications, the session promotes more accurate, consistent, and defensible forensic assessments in an increasingly digitized and data-driven legal landscape.

Abstract Text: The convergence of Electronic Health Records (EHRs) and Artificial Intelligence (AI) is rapidly transforming forensic psychiatric practice. Originally developed to improve continuity of care and streamline clinical documentation, EHRs are now central to forensic evaluations. However, their utility in legal contexts is far from straightforward. The lack of standardization across platforms, inconsistencies in documentation, and the sheer volume of often irrelevant or contradictory data introduce substantial obstacles for forensic examiners.

This presentation reviews the evolution of EHRs in the United States, from early institutional systems in the 1960s to federal mandates under HIPAA (1996), the establishment of the Office of the National Coordinator for Health IT (2004), and the CMS Meaningful Use Program (2011). Despite national efforts to build a unified and accessible record system, the modern EHR landscape remains fragmented and prone to error—especially within psychiatry.

To illustrate these pitfalls in a context relevant to forensic evaluations, a detailed case analysis is presented involving competing claims of testamentary capacity based on incomplete and conflicting EHR documentation. This case underscores the forensic risks of relying on disorganized records and undocumented clinical impressions.

Overlaying this already complex terrain is the emergence of AI tools—including large language models, natural language processing (NLP), and predictive algorithms—which promise to automate and enhance medical documentation. While these technologies offer speed and pattern recognition, they also raise serious concerns: algorithmic bias, lack of transparency, legal admissibility under *Daubert* or *Frye* standards, and ethical ambiguity regarding authorship and clinical interpretation.

This presentation examines the growing role of AI in generating, interpreting, and supplementing the medical record, and then evaluates its potential use in forensic psychiatric evaluations themselves. If the source documents are flawed, how does reliance on AI affect the integrity of the expert opinion? Could forensic psychiatric evaluations someday be conducted entirely by artificial intelligence?

We will explore these questions and propose a comprehensive framework for evaluating the strengths and limitations of both EHRs and AI-assisted tools. Practical strategies will be offered for integrating new technologies while preserving the ethical, clinical, and legal standards essential to forensic psychiatry

Artificial Intelligence; Forensic Psychiatry; Electronic Health Record

J7 Out With the Old, in With the New: An Alternative Approach to Evaluating Personality Disorder in Competency to Stand Trial

William Provosty, MD, USC Institute of Psychiatry, Law, and Behavioral Science, Los Angeles, CA*

Learning Objectives: After attending this presentation, attendees will understand: (1) the history of Competency to Stand Trial (CST) evaluations; (2) the limitations of the *Diagnostic and Statistical Manual of Mental Disorders, V, Text Revision's (DSM V-TR)* categorical classification system for Personality Disorder (PD) in CST evaluations; and (3) the benefits the Alternative Model for Personality Disorder (AMPD) offers in CST evaluations.

Impact Statement: This presentation will impact the forensic mental health community by: (1) raising awareness to the difficulties examiners encounter when assessing defendants with PD in CST evaluations; and (2) educating examiners on how to implement the AMPD's dimensional framework for competency evaluations, thus fostering descriptive, articulate, and persuasive reports.

Abstract Text: *Dusky v. U.S.*, 362 U.S. 402 (1960) established the standard for assessing a defendant's CST, defining it as "whether he has sufficient present ability to consult with his lawyer with a reasonable degree of rational understanding –and whether he has rational as well as factual understanding of the proceedings against him." The federal court defines the presence of a "mental disease" and its symptoms as sufficient grounds for incompetency, and while the term used to describe mental disease differs among states, the language is broad and encompasses PD.[1-3] Furthermore, the court ruling in *State v. Halder* 2008 Ohio-3345 implied the court's acceptance of PD as a requisite mental condition for incompetence, cementing that these conditions are to be considered in CST evaluations.[4] Given their prevalence, it is imperative that evaluators remain cognizant of the distinct challenges associated with personality disorders, such as their potential to mimic psychotic symptoms, e.g., paranoia and impulsivity. State v. Stock, 463 S.W.2d 889 (Mo. 1971), underscores the complexities evaluators encounter when assessing PD, and how divergent expert opinions can complicate proceedings, potentially leading to court error.[5]

The ability to explain a defendant's behaviors is vital to CST evaluations where evaluators must opine whether symptoms stem from mental illness and impact the defendant's ability to understand the court proceedings and/or consult with their attorney. The DSM V-TR's current categorical classification of PD poses multiple limitations in describing the intricacies of personality pathology.[6] This categorical framework encourages a dichotomic conceptualization, which oversimplifies the nuanced reality of human behavior. Additionally, the categorical model fails to consider the degree to which an individual possesses the diagnostic traits; without an insight into the severity of these traits, evaluators are limited in their ability to comprehensively interpret and rationalize behavior.[7] As evaluations focus on the individual, the use of categorical classifications, created using group data, lacks specificity. It also creates ambiguity in cases where defendants exhibit traits from various PDs but do not meet diagnostic criteria for a specific PD.

With the advent of the AMPD, personality pathology is conceptualized in terms of personality functioning and maladaptive trait domains, described on a continuum. Compared to the categorical model, this dimensional model has been described as more intuitive and translatable across clinicians from varying theoretical orientations.[8] The AMPD has also been empirically validated and used in various treatment modalities across psychiatry.[9] Moreover, it has demonstrated utility in violence risk assessment in PD.[10,11] Given the utility in forensic psychiatry, broader consideration is warranted, particularly in CST evaluations where a comprehensive understanding of the defendant's behavior is critical. The model's focus on domain presence and severity provides examiners with a way of clearly describing behaviors that interfere with evaluations. This presentation will focus on trait domains specific to CST evaluations, such as hostility, detachment, and suspiciousness, and how to implement this model in the evaluation and report writing.

J8 Misdemeanor Incompetent to Stand Trial (MIST) Reform: Lessons From Los Angeles County and Future Directions

Michael Dodge, MD, USC Institute of Psychiatry, Law, and Behavioral Science, Los Angeles, CA*

Learning Objectives: After attending this presentation, attendees will be able to: (1) understand challenges facing MIST defendants across the nation; (2) analyze the impact of recent MIST legislative reforms in Los Angeles County; and (3) describe the Sequential Intercept Model (SIM) to identify earlier points of intervention for this population.

Impact Statement: This presentation will impact the forensic sciences community by critically analyzing a recent legislation aimed at addressing the "competency services crisis." It will evaluate the impact of this recent policy aimed at diverting individuals with Severe Mental Illness (SMI) from the criminal justice system.

Abstract Text: The United States is in the midst of a "competency services crisis," a systemic failure to provide timely competency restoration that has been largely driven by defendants accused of low-level crimes.[1] This crisis reflects a decades-long transfer of individuals with SMI from psychiatric treatment facilities to carceral settings. From 1999 to 2014, the number of Incompetent to Stand Trial (IST) defendants increased by 72% in California, mirroring a national trend.[2] States, following due process lawsuits, have developed innovative solutions, increasingly turning to community and jail-based restoration services to reduce the strain on state hospital systems. For defendants facing misdemeanor charges, the competency restoration process often results in prolonged incarceration as competency restoration is prioritized over the usual psychiatric treatment goals.

In California, Senate Bill 317 (2022) largely eliminated competency restoration for the MIST population, instead mandating that courts refer individuals to community-based treatment or simply dismiss the charges.[3] This resulted in a sudden and significant increase in the number of individuals being diverted to the community without a corresponding increase in community programs needed to support them. In response to increased rates of recidivism amongst MIST defendants, SB 1400 (2024) was passed, requiring the court to determine a viable community treatment plan before charges could be dismissed.[4]

This presentation will discuss the Sequential Intercept Model (SIM), which describes how individuals with mental illness move through the criminal justice system.[5-7] Using this model, we will explore key points of interception to identify opportunities for the early diversion of MIST defendants.

J9 Considerations for Conducting Competency to Self-Represent Evaluations in Immigration Court

Kieu-Yen Luu, MD, USC Institute of Psychiatry, Law, and Behavioral Science, Los Angeles, CA*

Learning Objectives: After attending this presentation, attendees will understand: (1) the differences between Competency to Stand Trial (CST) evaluations in criminal vs. immigration proceedings, (2) the limitations of current practices for the identification and assessment for mentally incompetent respondents in removal proceedings, and (3) the framework used to assess for CST in immigration removal proceedings.

Impact Statement: This presentation will impact the forensic science community by: (1) providing an overview of the emergence of CST evaluations in immigration court, and (2) enhancing an evaluator's ability to conduct objective and comprehensive evaluations for CST in immigration removal proceedings.

Abstract Text: Competency to Stand Trial (CST) is a constitutional safeguard for due process that prevents the prosecution of individuals who are mentally incompetent. In *Dusky v. United States,* a landmark U.S. Supreme Court case, the legal criteria for CST are defined as, "sufficient present ability to consult with his lawyer with a reasonable degree of rational understanding and whether he has a rational as well as a factual understanding of the proceedings against him." In immigration court however, it was not until 2011, when the *Board of Immigration Appeals (BIA)* extended the due process right of CST to immigration respondents facing U.S. removal proceedings.[1,2]

The BIA established a standard for determining CST in removal hearings in the *Matter of M-A-M*. Similar to the *Dusky* standard, the respondent must have "a factual and rational understanding of the nature and object of the proceedings (and) can consult with the attorney or representative." The BIA also stated that the respondent must have "a reasonable opportunity to examine and present evidence and cross-examine witnesses."[3] However, re*: M-A-M* does not specify whether a respondent must have the capacity to do so. The Executive Office for Immigration Review (EOIR) clarified this in August 2013, by issuing guidelines that specify that respondents qualify as incompetent if they have a mental condition that impairs the ability to rationally and factually understand that they have "the right to present, examine, and object to evidence; ... (and) the right to cross-examine witnesses ..."[3] As such, it is presumed that a respondent found CST in removal proceedings is also competent to represent themselves (*pro se*). Competency to represent oneself is pertinent because respondents are not guaranteed legal representation in immigration court as they are for criminal court. Only when a respondent is deemed incompetent to stand trial (IST) are they provided with legal representation.

The majority of respondents awaiting removal proceedings represent themselves and the courts generally rule to uphold their removal. Research also shows that respondents with legal representation were three to ten times more likely to have their removal proceedings terminated or granted relief.[4] Additionally, researchers have raised concerns about the increased responsibility of immigration judges to determine competency without the consultation of a mental health professional, which may compromise the rights and protections afforded to mentally ill and incompetent respondents in removal proceedings.[5,6] Given the stakes for the respondent, concerns may be raised that a respondent would want to be found IST so that they obtain free legal representation. Therefore, evaluators need to consider the ethical implications of such evaluations and strive to maintain objectivity and follow the ethical guidelines set forth by the American Academy of Psychiatry and the Law.

The goal of this presentation is to inform evaluators about the legal proceedings in immigration court and offer guidance on assessing CST in removal proceedings. Ethical and political aspects of immigration will not be addressed. Attendees of this presentation will learn how to evaluate respondents for *pro se* following the guidelines stated in *re M-A-M* and other government entities.[3,6]

J10 Cursed or Ill? The Witches of the Past Re-Examined Today Through the Diagnostic Tools of Modern Forensic Psychology

Vincenzo Lusa, PhD, La Sapienza University, Roma, Lazio, Italy; Gianmarco Muraro, MSc, Accademia di Criminologia e Scienze Forensi, Cerea, Veneto, Italy; Anna Maria Casale, PsyD, Accademia di Criminologia e Scienze Forensi, Roma, Lazio, Italy*

Learning Objectives: After attending this presentation, participants will have a clearer understanding of how modern psychological and psychiatric sciences can rehabilitate those who were once wrongfully convicted.

Impact Statement: This presentation will have an impact on the forensic science community who will be able to understand how forensic psychology and psychiatry is able to reevaluate old forensic case reports that were once misjudged.

Abstract Text: Throughout history, countless women have been persecuted, silenced, or executed under the accusation of witchcraft. The term "witchcraft" has always functioned as a catch-all term for behaviors, beliefs, and identities that challenged the limits of what patriarchal and religious institutions considered acceptable. This work aims to reconsider, through the tools offered by forensic psychological and psychiatric sciences, several women once labeled as healers, mystics, outsiders, as well as spiritual guides, who in the past were condemned by both religious and secular authorities. It is indeed important to recall that many alleged witches were sentenced, starting from the Middle Ages, because they were subjected to inquisitorial procedures that gave judges the power to secretly investigate crimes and gather evidence of the accused's responsibility, without ever truly examining their actual psychological and mental condition.

The aim of this presentation is therefore to understand how the behaviors and acts of these women — once considered supernatural or threatening — can now be reframed through modern diagnostic categories in forensic psychiatry and psychology, by applying clinical models that could show they were instead affected by personality disorders or complex psychopathological profiles. Modern clinical psychology and psychiatry will thus revisit certain historical female figures associated with witchcraft, referring to case reports, some of which occurred specifically in New Orleans. To illustrate the goals of this work, among the various case reports examined (such as Mary Oneida Toups and Julie White), the case of Marie Laveau will also be analyzed — a voodoo priestess and community leader in nineteenth-century New Orleans. Marie Laveau exhibited a charismatic and theatrical style, strong community leadership, and spiritual involvement. In modern clinical terms, her behavior can partly be traced to Histrionic Personality Disorder — due to her attention-seeking and ritualistic role — and to schizotypal traits, related to magical thinking and ceremonial practices. The clinical reading adopted in this work will consider how behaviors that were once socially considered deviant — and therefore criminal and legally persecuted — may today overlap with recognized diagnostic criteria.[1]

Finally, this is not only a clinical reinterpretation, but a cultural act of reappropriation: transforming the image of the witch from deviant figure to symbol of resistance, identity, and complexity.

J11 A Forensic-Psychiatric Reconstruction of the Historical Case of Peter Kürten: "The Vampire of Düsseldorf"

Lucia Tarda, MD, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Matteo Antonio Sacco, MD, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Valerio Riccardo Aquila, PsyD, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Maria Cristina Verrina, MD*, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Maria Eugenia Caligiuri, MEng, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Alessandro Pasquale Tarallo, MD, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Francesca Lobello, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Isabella Aquila, MD, PhD*, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy*

Learning Objectives: After attending this presentation, attendees will gain an in-depth understanding of the forensic-psychiatric profile of Peter Kürten, considered one of the earliest documented cases of sexually motivated serial homicide.

Impact Statement: This presentation will impact the forensic science community by demonstrating how a detailed analysis of injury patterns on the victims' bodies, integrated with forensic psychiatric assessment, allowed for the reconstruction of Peter Kürten's complex psychopathological profile. Known as "The Vampire of Düsseldorf," his case contributed to redefining traditional interpretative models of sadistic sexual serial killers.

Introduction: Kürten is considered one of the first documented sadistic serial killers exhibiting clinical vampirism. The analysis of his crimes allowed for delineating a complex psychiatric profile, in which sadistic paraphilia intertwined with antisocial and narcissistic personality disorders, resulting in highly polymorphic homicidal behavior. The study of the injuries inflicted on the victims, integrated with the clinical assessment conducted in detention by Prof. Karl Berg, provided a foundational understanding of Kürten's psychopathology and the dynamics of his crimes, contributing significantly to the contemporary definition of sexual sadism within paraphilic disorders.

Materials and Methods: A historical-forensic reconstruction was conducted using an integrated approach, including direct consultation of judicial, autopsy, and psychiatric sources. The analysis focused on official documentation related to the investigation and trial. Special attention was given to *The Sadist*, written by Prof. Karl Berg, the forensic psychiatrist appointed to evaluate Kürten. This work served as the primary source for characterizing the offender's psychopathological profile. The book was critically examined to identify personality traits, behavioral dynamics, paraphilic structure, and psychiatric criteria for criminal responsibility. A bibliographic search was also carried out using keywords such as "Peter Kurten," "death," "Dusseldorf," and "vampire."

Historical Case: Peter Kürten, affected by Renfield's syndrome, was a German serial killer active mainly between February and November 1929 in Düsseldorf. He is attributed with at least 30 murders (9 confirmed), using scissors, knives, and other sharp instruments, in addition to 63 assaults and 7 attempted murders. Arrested on May 24, 1930, after being reported by his wife, he was tried and found guilty of all charges and sentenced to death. He was executed by guillotine on July 2, 1931. During incarceration, he was analyzed by Prof. Karl Berg, to whom he described his life and crimes, enabling Berg to publish *The Sadist*, a text that established the primary characteristics of the clinical profile of a sexual sadist.

Results and Discussion: The injuries on the corpses were heterogeneous and included stab wounds from scissors, knives, and axes, along with signs of strangulation. Most injuries affected the head, neck, and chest. From forensic-criminological analysis, Kürten displayed distinctive traits, including criminal polymorphism, complicating his identification. He varied victims (men, women, children), weapons (scissors, knives, hammers, strangulation), and wound patterns. His attacks were both premeditated and impulsive, with varying intervals. Stab wounds were inflicted to generate sadistic pleasure from blood. According to Berg, strangulation coerced sexual acts (cases of Dorrier, Reuter, Albermann) or allowed peri-mortem sexual violence (cases of Klein and Ohlinger). Berg concluded Kürten had engaged in nearly all forms of sadistic perversion.

From a forensic psychiatric perspective, Berg diagnosed Kürten with extreme sexual sadism, multiple paraphilic disorders, psychopathic personality with narcissistic traits, and Renfield's syndrome. Nonetheless, Berg concluded that Kürten was fully competent and legally responsible, with no evidence of insanity. This conclusion was confirmed by a panel of five psychiatric experts, establishing a historical precedent for evaluating criminal responsibility in serial killers.

J12 Enhanced Trauma-Informed Policing: Neurocognitive Impacts of Trauma and the Role of Leadership, Emotional Intelligence, and Organizational Justice

Gregory I. Mack, PhD, New York Police Department, Flushing,, NY; Monica Brooker, PhD*, New York Police Department, Valley Cottage, NY*

Learning Objectives: The goals of this presentation are to: (1) examine the neurocognitive impacts of trauma on officer decision-making and emotional regulation, (2) introduce the Enhanced Trauma-Informed Policing (ETIP) model and its foundational components, (3) explore the role of emotional intelligence and trauma-informed leadership in building resilience and organizational justice, and (4) provide actionable strategies to reduce cognitive overload, improve officer wellness, and strengthen public trust.

Impact Statement: This presentation advances practitioners' understanding of trauma-informed practice by exploring how neurocognitive disruptions are caused by trauma, particularly adverse childhood experiences, and their impact on decision-making among law enforcement officers. Through the ETIP model, practitioners will gain understanding of a systems-level approach that links individual wellness, emotional intelligence, and organizational justice. Attendees will gain actionable strategies to improve officer decision-making under stress, reduce punitive responses to trauma-driven behaviors, and enhance trust and legitimacy within both the department and the community.

Abstract Text: This session introduces Enhanced Trauma-Informed Policing (ETIP) as a novel, research-informed conceptual framework designed to support officer wellness, improve decision-making, and foster greater trust between law enforcement and the communities they serve. ETIP recognizes the unique and compounding traumas faced by police officers—including disproportionate exposure to adverse childhood experiences (ACEs), secondary or vicarious trauma, and occupational stressors—and examines how these experiences alter neurocognitive functioning in ways that affect decision-making, emotional regulation, and social interactions.

The authors pay special attention to psychoneurocognitive processes that drive meaning-making and decision-making among law enforcement officers. Given the high prevalence of adverse childhood experiences, first responders' decision-making may be shaped by unresolved trauma and detrimental meaning-making frameworks.

Trauma exposure can impair critical areas of the brain, such as the prefrontal cortex, amygdala, and hippocampus, leading to reduced impulse control, heightened threat perception, difficulty with collaboration, and challenges with nuanced judgment. For officers making high-stakes decisions under stress, these neurobiological impacts can result in emotion-driven, avoidant, or risk-altered decision patterns.

ETIP addresses these challenges through a scaffolded trauma-informed leadership model that integrates meaning-making processes, emotional intelligence (EI) skill-building, organizational justice principles, and a deep understanding of trauma's neurocognitive impacts. In sum, ETIP highlights how trauma-informed environments—when supported at all ranks—can improve decision-making, public interactions, community trust, and perceptions of procedural justice.[1-12]

J13 Understanding the Role of Moral Injury in Police Officer Suicide and Trauma Reactions

Stephanie Tacopina, PhD, New York City Police Department, Corona, NY; Marisol Habrahamshon, PsyD*, NYPD, Warwick, NY; Gregory I. Mack, PhD*, New York Police Department, Flushing, NY; Christina Gille, PsyD*, New York Police Department, Seaford, NY*

Learning Objectives: After attending this presentation, participants will be able to define moral injury and its effects on mental health in first responder populations, summarize the possible role of moral injury within law enforcement suicide, and describe various traumas experienced by law enforcement including moral injury, moral distress, vicarious trauma, and Post-Traumatic Stress Disorder (PTSD).

Impact Statement: Police officer suicide is a widespread concern and highly examined topic within law enforcement mental health. Moral injury is a relatively novel field of inquiry with numerous potential implications for law enforcement mental health. The effects of moral injury within law enforcement populations, and specifically on suicidal behavior in police officers, has received limited attention thus far. This presentation will notably impact the forensic community by describing moral injury, elucidating its importance and contribution to suicide in law enforcement, and describing its relationship to various types of traumas commonly experienced by police officers.

Abstract Text: Police officer suicide remains a widespread concern as it is a significant cause of death among police officers; they are routinely exposed to a wide variety of operational stressors (i.e., vicarious trauma) as well as organizational stressors that place them at an increased risk of completed suicide, suicide attempts, and other adverse consequences including poor physical, mental, and spiritual health.[1,2] Moral Injury (MI), a relatively novel concept within the field of psychological trauma, is present when there exists a betrayal of what one considers "right," either by oneself or others in high stress contexts.[3] Morally injurious events may cause a specific type of psychological trauma characterized by guilt, existential crisis, and loss of trust.[4] They can have vast mental health consequences including anxiety, depression, PTSD, and substance use.[5] Notably, MI has been linked to increased suicidal behavior including both ideation and attempts; it has thus been proposed as a contributing factor and alternative explanation for increasing rates of suicide and suicidal behavior in military populations.[6-8] Despite the vast amount of research investigating the causes of the disproportionate suicide rate among police officers, there has been little research examining the contribution of moral injury to police officer suicide and mental health concerns more generally.

This presentation will propose that moral injury and moral distress are highly relevant in police work, as officers are routinely exposed to events that are stressful, traumatic, and transgress moral beliefs; they may lead to adverse mental health consequences among law enforcement.[9] We will describe the concept of moral injury, review the current research examining its role in police officer trauma response and mental health functioning, and will propose a contribution of moral injury to police officer suicide and suicidal ideation. The importance of highlighting the potential involvement of moral injury in police officer psychological evaluations, intervention, and wellness programs will also be discussed.

J14 Wars and Natural Disasters: Vicarious Trauma Through Media Manipulation and Promotion or Suppression of Current Events

Jessica L. Morel, DO, Integrity Psychiatric Services PLLC, Fayetteville, NC; Vivian T. Chern Shnaidman, MD, Jersey Forensic Consulting LLC, Princeton, NJ*

Learning Objectives: Attendees will improve their ability to recognize media bias or inaccuracies. The attendee will learn when to collect data from multiple sources and how to minimize vicarious trauma from war and natural disaster media coverage. The attendee will be better able to recognize vicarious trauma resulting from media coverage of events.

Impact Statement: This presentation will impact the scientific community by highlighting the media's role in our understanding of current events and the development of vicarious trauma. Attendee's will be better able to assess and understand the varied trauma responses to the same event seen through different lenses.

Abstract Text: There is no doubt the media today influences our decisions from the brand of toothpaste we use to our view of world events. There has been recent criticism surrounding political events and media manipulation of the information the public receives. While political topics may cause an immediate visceral response, media coverage can affect trauma as well. The constant replay of images from 911 is a classic example of vicarious trauma transmitted through media. Here we will explore some more recent events and how media portrayal can affect vicarious trauma for different individuals. Among topics covered we will compare and contrast media coverage for the Israel/Hamas war from both inside and outside the United States and across media sources. We will also analyze the different media coverage and resultant public response to both the North Carolina and Texas catastrophic floods. Crimes in the news specifically those that involve disproportionate media response or inaccurate information will also be covered. Ultimately our goal is to open discussion about how media influences opinions and our emotions in response to traumatic events and how an individual might mitigate this external influence to minimize trauma. In a world of vast amounts of information available with a click, how does one ensure that the information is reliable, how does confirmation bias affect the sources we choose, and how does the overwhelming influx of constant media barrage affect emotion and trauma? We will welcome ample discussion with attendees at the end as one way to minimize trauma responses are to talk about them.

News media, in particular that with visual media, will be sought out for each event from all available sources within the US and outside the US should the event occur outside the US. We will analyze the overall tone of the articles, look for misinformation included, and look for manipulated media. Where possible if there are media articles about the same event with the same visuals we will compare and contrast their content. All attempts will be made to compare and contrast media sources that may have differing motivations for information sharing. For example, for overseas wars/conflicts every attempt will be made to obtain news sources from all countries involved.

J15 A Forensic Psychiatric Analysis of Paternal Filicide: A Narrative Literature Review

Andrea Cioffi, MD, University of Foggia, Foggia, Puglia, Italy; Camilla Cecannecchia, MD*, University of Foggia, Foggia, Puglia, Italy; Luigi Cipolloni, MD, PhD, University of Foggia, Foggia, Puglia, Italy; Stefania De Simone, PhD, University of Foggia, Foggia, Puglia, Italy; Francesco Orsini, MD, University of Foggia, Foggia, Puglia, Italy*

Learning Objectives: Attendees will receive an updated overview of the psychiatric, socio-demographic, and forensic characteristics of paternal filicide, examining underlying psychopathological dynamics, common methods, and precipitating factors. The presentation will outline key risk profiles and their implications for forensic practice, thereby enhancing the ability to identify and comprehensively assess these complex cases.

Impact Statement: This presentation aims to strengthen the expertise of forensic specialists in the evaluation of paternal filicide by promoting an integrated approach between forensic psychiatry and pathology. An in-depth analysis of motives, post-offense suicide and attempted suicide rates, prior violent behaviors, and psychiatric disorders among perpetrators will provide essential tools to refine forensic psychiatric assessment, with significant repercussions in judicial evaluations, particularly concerning criminal responsibility, assessment of dangerousness, and legal classification of the offense, and will guide the development of more effective preventive strategies.

Abstract Text: Paternal filicide constitutes an extreme and complex manifestation of intrafamilial violence, characterized by marked heterogeneity in psychopathological profiles, motivational dynamics, and methods employed. Although maternal filicide has historically been the primary focus of research, recent evidence indicates that fathers represent a substantial proportion of perpetrators, frequently linked to particularly violent acts and a high incidence of suicide or attempted suicide immediately following the homicide [1]

Since the 1990s, forensic psychiatric literature has increasingly recognized paternal filicide as a distinct category, underscoring the importance of differentiating between maternal and paternal perpetrators[2]. International studies have highlighted substantial differences in etiological factors, predominant psychiatric disorders, violence patterns, and the objectives of the homicidal act. This gender-differentiated approach is now well established as a critical dimension in understanding the phenomenon.[3,4]

A narrative review of international literature published between January 2000 and June 2025 was conducted through major scientific databases (PubMed, Google Scholar, Web of Science). Included were case reports and case series concerning paternal filicide. Cases were analyzed based on standardized variables including presence and characteristics of suicide or attempted suicide, perpetrator demographics and psychiatric history, victim demographics (age, sex), victim physical or psychiatric pathologies, motive and method of homicide, cause of death, and toxicological findings for both perpetrator and victim.

The review identified salient patterns useful for forensic assessment. Victims were predominantly male children older than one year. Highly lethal methods—firearms, sharp weapons, and asphyxiating means—were prevalently used. A notable finding was the elevated rate of suicide or attempted suicide by perpetrators immediately post-offense.

Regarding psychiatric profiles, major depressive disorder and bipolar disorder were the most frequently reported diagnoses among perpetrators. A considerable number had previous contact with mental health services before the offense, indicating potential gaps in prevention and management of pre-existing psychiatric conditions.

Additionally, histories of domestic violence and child abuse were common, pointing to a broader context of aggression and familial dysfunction. Frequent triggering factors included spousal revenge, “altruistic” motives (where the killing is perceived as benevolent to spare the child suffering), and intense custody-related conflicts. Chronic substance abuse, particularly alcohol, was a recurrent disinhibiting factor contributing to psychopathological deterioration.

These findings highlight the necessity of thorough investigation into the psychopathological dynamics often underlying paternal filicide, with direct implications for forensic evaluations concerning criminal responsibility, dangerousness, and attribution of aggravating or exculpatory circumstances, such as acute or chronic alcohol intoxication. Furthermore, identifying recurrent risk factors may guide more targeted preventive interventions, grounded in early detection of high-risk individuals through clinical, behavioral, and historical indicators—such as prior psychiatric contact, domestic violence, chronic substance abuse, and marked familial conflict. Timely recognition of these signs in clinical, judicial, or social contexts could activate multidisciplinary care pathways and contribute to preventing escalation toward lethal outcomes.[5]

J16 Capable or Circumvented? Challenges in the Forensic Assessment of Mental Infirmity and Psychic Deficiency in a Case of Circumvention of a Vulnerable Person

Rebecca Maggi, MD, University of Pisa, Pisa, Toscana, Italy; Carla Occhipinti, MD, University of Pisa, Pisa, Toscana, Italy; Marco Di Paolo, MD, PhD, University of Pisa, Pisa, Toscana, Italy; Ilaria Zampieri, PhD, IMT School for Advanced Studies, Lucca, Lucca, Toscana, Italy; Pietro Pietrini, MD, PhD, IMT School for Advanced Studies, Lucca, Lucca, Toscana, Italy; Pietro Ciulli, MD, University of Pisa, Pisa, Toscana, Italy*

Learning Objectives: This presentation aims to provide attendees with a comprehensive understanding of the medicolegal interpretation of mental infirmity and psychic deficiency within the framework of Article 643 of the Italian Penal Code, concerning circumvention of a vulnerable person. Particular emphasis will be placed on the methodological and epistemological complexities of retrospective capacity assessment, especially in those cases where the expert must rely exclusively on prior clinical documentation and third-party reports, which may not accurately reflect the subject's cognitive and volitional status at the time of the contested acts.

Impact Statement: By critically examining the conceptual and diagnostic boundaries of mental infirmity and psychic deficiency, this presentation will contribute to refining the competence of forensic practitioners involved in capacity assessments within legal proceedings concerning circumvention of a vulnerable person. The discussion will underscore the challenges of reconstructing the mental state of a deceased subject based on limited or potentially biased retrospective data, thus promoting a more rigorous and nuanced expert methodology with direct implications for the consistency and reliability of medicolegal conclusions.

Abstract Text: According to Article 643 of the Italian Penal Code, the offense of circumvention of a vulnerable person applies to anyone who, by exploiting another's condition of mental infirmity or psychic deficiency, induces them to perform a legal act that results in harm to themselves or others. The forensic assessment of such conditions plays a critical role in legal proceedings involving the alleged exploitation of vulnerable individuals, requiring careful consideration of both clinical and functional elements.[1]

The term *mental infirmity* (*infermità psichica*), as defined in Articles 88 and 89 of the Italian Penal Code, refers to "a mental disorder that excludes or substantially diminishes the individual's capacity to comprehend and to exercise free will." In contrast, *psychic deficiency* (*deficienza psichica*), particularly within the context of Article 643, does not necessarily imply the presence of a formally diagnosed psychiatric disorder. Rather, it encompasses a broader range of cognitive and volitional impairments—including reductions in critical faculties, judgment, or the ability to resist undue influence—that may arise from age, relational dynamics, or situational vulnerability, even in the absence of a pathological condition.[2]

This presentation examines the case of an elderly man who, in early April 2024, unexpectedly married his long-term caregiver and transferred to her a substantial portion of his financial and real estate assets. The caregiver, employed since 2020, had progressively assumed a central role in the man's life—escorting him to medical appointments and assisting with many daily functions. At the time of the marriage, witnesses and the civil registrar attested to his apparent lucidity and orientation. However, just days later, he was hospitalized for the conversion of a preexisting hematological condition into a more serious illness. While initially reported as mentally competent upon admission, his cognitive state deteriorated markedly in the final days preceding his death. Shortly before his passing, the man's daughter filed a criminal complaint, alleging that the caregiver had exploited his vulnerability for personal gain.

This case highlights the considerable challenges involved in retrospectively assessing not only the presence of a mental infirmity, but—perhaps even more critically—the existence of a state of psychic deficiency, as currently defined by prevailing Italian legal doctrine. Unlike mental infirmity, which generally requires a diagnosable psychiatric disorder, psychic deficiency often reflects a more subtle and context-dependent erosion of cognitive and volitional safeguards. Its identification rests on the ability to detect how such impairments may have rendered the individual particularly susceptible to external influence, especially in asymmetrical relational dynamics.

Yet, the retrospective nature of these assessments—often based on medical records, third-party reports, and partial documentation—limits the forensic expert's capacity to reconstruct with certainty the psychological condition of the individual at the time of the disputed acts. This underscores the importance of a multidimensional and jurisprudentially informed approach in evaluating cases of alleged circumvention, where the boundary between personal autonomy and suggestibility is often blurred and deeply contextual.

J17 Detecting Malingered mTBI Using the Neurobehavioral Symptom Inventory

Joseph H. Preckajlo, MA, Florida Institute of Technology, Union, NJ; Erica Baer, PhD, Kean University, Union, NJ; Richard Paul Conti, PhD, Kean University, Union, NJ*

Learning Objectives: This poster presentation describes how standard symptom checklists, such as the Neurobehavioral Symptom Inventory (NSI), may be susceptible to malingering in forensic evaluations. The session will examine the utility of embedding bogus items to enhance the detection of symptom exaggeration in individuals feigning mild traumatic brain injury (mTBI). Attendees will be able to critically evaluate methodological approaches for identifying response bias in neuropsychological assessment.

Impact Statement: This research contributes to the growing body of literature on malingering detection by demonstrating that naïve individuals can successfully feign mTBI on standard symptom inventories. The findings underscore the limitations of relying solely on self-report measures such as the NSI in forensic contexts and highlight the potential value of incorporating bogus items to improve detection accuracy. These results have direct implications for forensic neuropsychological practice, particularly in civil litigation involving alleged brain injuries.

Abstract Text: Malingering remains a substantial challenge in forensic neuropsychological assessment, particularly in cases involving alleged mild traumatic brain injury (mTBI). The intentional exaggeration or fabrication of symptoms for external gain, such as financial compensation or legal advantage, can complicate diagnostic accuracy and expert testimony. Although malingering is not classified as a mental disorder in the DSM-5-TR, the manual provides clinical heuristics for suspecting malingering, including involvement in medicolegal contexts, a marked discrepancy between reported and observed symptoms, and poor cooperation with evaluative procedures.[1] Among self-report measures commonly employed in neuropsychological screening, the Neurobehavioral Symptom Inventory (NSI) is widely used to assess post-concussive symptoms, despite concerns about its vulnerability to response bias.[2]

Previous research has demonstrated that untrained individuals can feign mTBI symptoms on standardized checklists, raising serious questions about the NSI's utility in forensic settings.[3] The present study evaluated the ability of naïve participants to malinger mTBI symptoms convincingly and assessed whether embedding bogus items could reduce the rate of successful symptom exaggeration. It was hypothesized that participants would be able to exceed the NSI's clinical cutoff score for probable symptom exaggeration and that the inclusion of implausible symptom items would lower this rate.

Ninety-six undergraduate participants (71 women, 25 men; M age = 21.7, SD = 1.3) were randomly assigned to one of two groups. Participants read a vignette describing a fictional case involving an individual who sustained a mTBI in a motor vehicle accident. They were instructed to complete the NSI as if they were the injured party and to convincingly simulate symptoms associated with post-concussive syndrome. Group 1 (n = 47) completed the standard NSI, while Group 2 (n = 49) completed a version with five bogus symptoms (e.g., implausible cognitive or sensory complaints).

Results showed 55.32% of participants in Group 1 exceeded the clinical cutoff score of 67 for symptom exaggeration, suggesting that more than half were able to successfully feign mTBI symptoms.[4] In Group 2, which included the bogus items, 51.02% exceeded the cutoff, reflecting a modest reduction in successful malingering. Further analysis revealed that participants in Group 2 endorsed an average of 3.42 bogus symptoms (SD = 1.2). This pattern suggests that a considerable portion of participants were willing to endorse symptoms with low face validity, supporting the utility of bogus items as a validity check.

These findings are consistent with prior literature demonstrating the susceptibility of post-concussive symptom measures to simulation and reinforce concerns regarding the empirical limitations of malingering criteria in forensic evaluations.[5,6] The study underscores the importance of incorporating symptom validity measures and embedded response bias indicators into forensic protocols. Although the addition of bogus items alone does not eliminate malingering, it represents a practical enhancement to the NSI and similar instruments in legal contexts.

In sum, this study contributes to a more nuanced understanding of malingering detection in mTBI assessment. It supports the use of multi-method strategies, including the integration of structured interviews, performance validity tests, and embedded symptom validity indicators, to improve the accuracy and integrity of forensic neuropsychological evaluations.

J20 Suicide Methods by Sex in a State With Limited Firearm Regulations

Brandi C. McCleskey, MD, UAB Heersink School of Medicine, Birmingham, AL Erin Tarnoff, BA, UAB Heersink School of Medicine, Birmingham, AL; Taylor M. Bain, BS, UAB Heersink School of Medicine, Birmingham, AL;*

Learning Objectives: after attending this presentation, attendees will: (1) understand the prevalence and most common methods of suicide completion in the United States; (2) identify the trends in suicidal methods between men and women; and (3) assess the relationship between suicide completion by firearm and limited firearm purchasing regulation.

Impact Statement: The results of our study show that Jefferson County, AL, has a firearm suicide rate higher than the national average. By this metric, males are more significantly affected than females. These findings highlight the connection between limited firearm regulation and suicide completion by firearm. Our study further supports the need for targeted prevention and policy to reduce suicide completion in those with greater access to firearms, such as residents of Jefferson County, AL.

Abstract Text: Suicide is a leading manner of death in the United States. More than half (53%) of all suicide deaths involve firearms. Men account for the majority of firearm-related suicide deaths (approximately 85–90%) while women make up 10–15%.[1-4] Literature suggests this disparity is due to men utilizing lethal means such as firearms at higher rates. Women are more likely to use less lethal methods such as drug overdose.[2,5,6] States with stricter firearm regulations (i.e., comprehensive background checks and waiting periods) are linked to lower rates of suicide by firearm.[7] Our study examines how the method of suicide completion differs between men and women in Jefferson County, Alabama, a county within a state with minimal firearm restrictions, and how these results compare to national trends.

We evaluated death certificates and other primary data sources for individuals whose death was ruled a manner of "suicide" between 2013 and 2024 in Jefferson County, AL. These deaths were categorized by method (i.e., means of death) and by the decedent's sex (male or female). Of all suicides during this period, 70% were completed with a firearm—substantially higher than the national average of 53%. Among decedents with firearm-related suicides, 85% were men and 15% were women. Men were more likely than women to die by nearly all documented means, including asphyxiation (drowning, chemical, and/or mechanical), falls, sharp force injuries, pedestrians struck by motor vehicles, and fire. In contrast, women were more likely to die by drug overdose, accounting for 65% of all drug overdose suicides. Overall, males comprised 81% of all suicide deaths, while females accounted for 19%.

Our results in Jefferson County, AL, mirror national trends in suicide methods. This study highlights the significantly lower rate of female suicide by firearm compared to male counterparts. Although the sex differential in firearm-related suicides remains consistent with national patterns, our findings show an overall increase in the use of firearms as a method of suicide completion. While this rate is higher than the national average, it is consistent with rates observed in other states with fewer firearm restrictions, supporting research that increased ease of firearm ownership and purchase may contribute to higher suicide completion rates among high-risk individuals.

J21 Likes, Dopamine, and Crime: The Challenge of Psychiatric Forensics in the Face of a Stimulus-Addicted Brain

Anna Beatriz-Rodrigues Geranio, University Estacio de Sá, Petrópolis, Rio de Janeiro, Brazil; Cristiane Viana Barbosa, MA*, UFF University Federal Fluminense, Petropolis, Rio de Janeiro, Brazil; Dineusa Maria Do Amaral, MBA*, Judicial Expert for the Court of the State of Paraná, Foz do Iguaçu, Parana, Brazil; Bruno Da Silveira Pataro Moreira, APM, Catholic University of Petrópolis, Petropolis, Rio de Janeiro, Brazil*

Learning Objectives: This presentation will hep attendees to understand the neuropsychiatric implications of dopamine in obsessive behavior within digital environments and reflect on the challenges this poses to forensic psychiatry, particularly in criminal cases involving stalkers and technological dependence.

Impact Statement: This study aims to shed light on a blind spot in forensic psychiatry: the role of social media in shaping addictive and dysfunctional behavioral patterns. In a world where dopamine has become the emotional currency of digital interactions, it is urgent to revisit classical parameters of criminal responsibility and dangerousness, considering the influence of a virtual environment designed to keep individuals in a state of constant stimulation.

Introduction: The digital era has profoundly transformed how individuals interact, perceive the world, and form emotional bonds. Likes, notifications, and virtual engagement are no longer simple forms of interaction; they have become dopamine reinforcers. When excessive, these stimuli may contribute to obsessive and pathological behaviors, such as stalking and digital dependence. Cases involving individuals with psychiatric disorders and obsessive online behavior, such as the one involving Brazilian TV host Ana Hickmann, challenge traditional forensic psychiatric models. This context demands new approaches to assess criminal responsibility in individuals influenced by compulsive digital behavior.

Objectives and Methods: This study aims to analyze how constant digital stimulation affects the brain's reward system and its implications for forensic psychiatric assessment. A literature review was conducted on the dopaminergic system, focusing on the role of the nucleus accumbens in motivation and pleasure-seeking behavior. The analysis also considered the diagnostic criteria of the *DSM-5* and Article 26 of the Brazilian Penal Code, which addresses criminal non-responsibility due to mental illness. The study proposes the use of technologies such as functional neuroimaging and neuropsychological assessments to support forensic evaluations in criminal cases involving digital compulsion.

Results and Discussion: Continuous exposure to digital stimuli can reinforce maladaptive behaviors, particularly in individuals with biological predispositions, leading to the development of disorders such as persistent delusional disorder. This clinical condition challenges psychiatric assessments, as the individual may understand the illegality of their actions but experience significant difficulty resisting the impulse, responding compulsively to digital rewards. Therefore, forensic analysis must go beyond the traditional binary classification of sanity versus insanity. An interdisciplinary approach involving neuropsychiatry, behavioral psychology, and studies on technological dependence is essential to assess the level of criminal responsibility accurately.

Conclusion: Forensic psychiatry must evolve to address the complexities of the digital age. It is not enough to evaluate whether the individual understood the illegality of their actions; it is necessary to assess whether they had the psychological capacity to resist digital compulsion. While this does not automatically imply non-imputability, it demands a more refined and contextual analysis capable of providing the courts with fair and up-to-date insights. Forensic practice must be scientific, sensitive, and aligned with the new dynamics of digital human behavior.[1-8]

J22 Intimate Partner Violence Against Women Murders: Forensic Features and Differences With Domestic Violence

Miguel Lorente, PhD, University of Granada, Granada, Andalucia, Spain; María Cuadros, MCrim, University of Granada, Granada, Andalucia, Spain*

Learning Objectives: Attendees will learn about the preliminary structure, influential variables, and initial findings from the analysis of homicides due to intimate partner violence against women in Spain, based on a database that includes all adjudicated homicide cases since 1997. This is the first database built from the judicial rulings of all tried homicides in Spain, offering information of high scientific and social value.

Impact Statement: The study presented offers the forensic scientific community an unprecedented, methodologically rigorous resource for the analysis of gender-based violence in Spain. By enabling a neutral and high-quality data analysis, it will enhance research accuracy, inform legal and policy strategies, and promote standardized data practices across institutions.

Abstract Text: The outcomes of a killing—and the methods by which murders are committed—are the result of the perpetrator's motivations and intended objectives. However, most crime classifications focus primarily on circumstances related to the victim, setting, instrumental factors, or perpetrator characteristics.[1] While necessary, such factors can obscure the deeper meaning behind certain forms of violence, particularly those related to structural violence.

Violence Against Women (VAW), especially in the context of intimate partner relationships, exhibits features distinct from other forms of interpersonal violence. It is a form of "moral violence"—not merely instrumental—used by men against women, driven by cultural and social norms with the primary aim of exerting control over women.[2,3] The motives and objectives of perpetrators in VAW-related homicides differ from those in other types of killings. These distinctions should be reflected in the methods and procedures used to commit the crimes and may provide key insights into the cognitive and emotional components involved.

This study analyzed all judicial sentences involving intimate partner femicides in Spain from 1997 to 2021 (the most recent year with available data), focusing on the modus operandi applied. The indicators assessed included:

- Mechanism and instrument used
- Use of a single or multiple mechanisms/instruments (simple or mixed)
- Use of bare hands as the killing method
- Degree of violence employed to carry out the homicide

Based on these indicators, the study presents several significant findings relevant to Forensic Science and fields related to support, prevention, assessment, protection, and investigation of VAW:

- There is no single or consistent pattern in the killing mechanisms used by men to murder their (former) partners. A total of nine distinct mechanisms were identified over the study period.
- The most frequent method of killing was stabbing (41.1%), followed by beating (14.1%). Mechanical asphyxiation, in its various forms, accounted for 8.7%, and firearms for 5.6%.
- The degree of violence employed has increased over time, with higher levels observed in recent years.

J23 Behind the Emergency Room Doors: Revealing Hidden Gender-Based Violence Through Clinical Forensic Medicine

Annachiara Vinci, MD, University of Bari "Aldo Moro", Medical-Legal Section of Policlinico di Bari, Bari, Puglia, Italy; Paolo Visci, University of Bari "Aldo Moro", Medical-Legal Section of Policlinico di Bari, Bari, Puglia, Italy; Alessandro Dell'Erba, MD, PhD, Policlinico di Bari, Bari, Puglia, Italy; Davide Ferorelli, MD, University of Bari "Aldo Moro", Medical-Legal Section of Policlinico di Bari, Bari, Puglia, Italy; Susanna Sabato, MD, University of Bari "Aldo Moro", Medical-Legal Section of Policlinico di Bari, Bari, Puglia, Italy; Gianmarco Sirago, MD, Università degli Studi di Bari "A.Moro", Bari, Puglia, Italy*

Learning Objectives: This research highlights the essential function of clinical forensic medicine in emergency contexts, revealing how its practices significantly improve victim identification and judicial processes related to gender-based violence.

Impact Statement: Strengthening clinical forensic practices within emergency departments decisively improves victim protection, judicial outcomes, enhances clinical care quality, and significantly contributes to comprehensive public health strategies against gender-based violence.

Abstract Text: Gender-based violence (GBV) continues to present a major challenge to public health and human rights worldwide. Despite significant legislative and policy efforts, GBV often remains unreported or inadequately managed in healthcare settings. This study retrospectively evaluates how clinical forensic medicine contributes to the effective recognition, documentation, and management of GBV.

This retrospective study reviewed 240 cases of suspected GBV presented to the emergency department of the Policlinico Hospital of Bari, Italy, from August 2019 to December 2023. Data sources included the EMUR-ISTAT database and hospital records, documenting demographics, violence type, injury specifics, and clinical forensic interventions. Statistical methods were applied to detect epidemiological patterns and identify management shortcomings.

A clear upward trend was observed in GBV-related emergency admissions, peaking notably in 2023 (n=68). Victims were mostly female (57.1%, n=137), predominantly within the 20-40 year age group. The majority of incidents involved physical assault and sexual violence. Clinical forensic evaluations revealed frequent inconsistencies and delays in documentation, negatively impacting judicial outcomes and the quality of victim care. Enhanced interdisciplinary cooperation was correlated with improved diagnostic accuracy and patient management.

Embedding clinical forensic expertise within emergency healthcare systems considerably enhances early GBV detection, evidence preservation, and holistic victim management. To further strengthen these outcomes, ongoing interdisciplinary training and improved coordination between healthcare professionals are essential. Ultimately, this integrative approach significantly enhances victim support and judicial efficacy.[1-5]

J24 The True Crime Effect: Examining True Crime Consumers' Beliefs About Forensic Science, Evidentiary Expectations, and Attitudes Toward the Criminal Justice System

Brianne M. Suldovsky, PhD, Portland State University, Portland, OR*

Learning Objectives: Presentation attendees will learn about current evidence regarding the impact of consuming true-crime media in the United States. They will also learn about the current state of public perception of forensic science, trial expectations, and criminal justice attitudes among true crime consumers.

Impact Statement: This presentation will impact the forensic science community by fostering a better understanding of public perception regarding forensic science. In turn, it will improve scientists' communication competency with public audiences.

Abstract Text: Media consumption has been shown to influence public perception on a wide variety of issues relevant to the criminal justice system, including crime incident rates and law enforcement officers.[1-3] The influence of media on public perception of forensic evidence and evidentiary expectations dubbed the *CSI Effect* has been explored for decades.[4,5] Mirroring its fictional namesake, much of the research to-date on the *CSI Effect* focuses on how the consumption of fictional media (e.g., television shows like "Crime Scene Investigation") relates to beliefs about forensic evidence and the criminal justice system. At the same time, much of the research on true-crime consumption focuses on motivations for consuming that type of content, the mental health effects of true crime consumption, and the nature of true-crime fandoms.[7-13]

What is less understood is the relationship between the amount of true crime media consumed and public perception of forensic evidence and the criminal justice system. Some experts have argued that true crime media in particular could be instrumental in challenging criminal justice systems and encouraging reform, while others suggest such media may reinforce traditional perspectives on crime and punishment.[6,13] Empirical evidence in this arena is lacking. This study helps address this scholarship gap in three ways. First, rather than comparing media consumers to non-consumers like many studies to-date, this study differentiates the proportion of media consumed that is non-fiction (true crime). Specifically, it identifies and compares three groups: those who do not consume media with crime and justice themes, those who consume mostly fictional media, and those who consume mostly non-fiction (true crime) media. This approach allows us to better understand the differential influence of different *types* of crime and justice media consumption on public perception. Second, it examines the beliefs of each consumer group in terms of their beliefs about forensic science (accuracy, salience, and bias), evidentiary expectations at trial (presence and inference of guilt), and attitudes toward the criminal justice system. Third and finally, this it uses a large, nationally representative sample of adults living in the United States, allowing for more robust and reliable statistical analyses.

Results show significant differences between each media group in terms of their beliefs about forensic evidence, trial expectations, and attitudes toward the criminal justice system. In terms of beliefs about forensic evidence, results demonstrate that true-crime consumers are more likely to find forensic science familiar and salient, more likely to harbor forensic evidence bias, and more likely to believe that forensic evidence is accurate. Regarding trial expectations, true-crime consumers are more likely to expect forensic evidence in criminal cases and more likely to infer guilt from forensic evidence within the context of a criminal trial. Finally, results show that true-crime consumers have significantly less favorable attitudes toward the criminal justice system. Recommendations and strategies for forensic scientists' communication with public audiences based on study results will be provided.

J25 Disparities in Disappearances: Public Perception of Missing Persons Cases and the Influence of Missing White Woman Syndrome

Erica Baer, PhD, Kean University, Union, NJ; Jaedan Carnahan, BS, Kean University, Rock Springs, WY; Richard Paul Conti, PhD, Kean University, Union, NJ; Dante McKinnell, MA, Kean University, Lawrenceville, NJ*

Learning Objectives: This presentation will provide an overview of the public perception of missing persons in the United States. By comparing public perceptions on missing persons cases and cases reported to the National Crime Information Center, attendees will be able to understand the gaps that exist and how the concept of Missing White Woman Syndrome may play a role.

Impact Statement: Previous research suggests there is a disparity in the cases of missing minority groups reported in print media, televised news programs, and true crime podcasts. Despite increasing knowledge of the concept of Missing White Woman Syndrome, public perceptions continue to be affected.

Abstract Text: In the United States, the media's portrayal of missing persons cases has long been influenced by racial and gender biases, a phenomenon widely recognized as Missing White Woman Syndrome (MWWS).[1-3] This term refers to the disproportionate media attention given to missing White women and girls, often at the expense of cases involving people of color, Indigenous individuals, and men. Such skewed coverage not only distorts public understanding of who goes missing but also has tangible consequences for how cases are investigated and prioritized. The aim of this study was to quantify the differences between the numbers of reported missing person and the public's perception of who, and how many, go missing in the United States.

The sample in this study included 80 responses from individuals living in the US over the age of 18. The sample consisted of 21 men, 57 women, one nonbinary individual, and 1 additional participant who chose not to disclose their gender. The mean age of the sample was 39.87 (SD = 15.70). Participants completed a survey of their perceptions of who goes missing in the United States. These results were compared to the 2024 National Crime Information Center (NCIC) Missing Person and Unidentified Person Statistics.[4]

An analysis of the data found most participants underestimated the number of missing persons reported each year, with 72.5% estimating the number of missing persons to be between 250,001 and 500,000 or below. Nearly half of the sample (43.75%) had previously heard of MWWS, with the same proportion also reporting they had not heard of the phenomenon. One-sample *t*-tests were conducted to determine whether the participants' estimates for gender and race categories differed significantly from the percentage reported missing in 2024. In this study, participants significantly underestimated the number of missing juveniles (difference of 10.80%), individuals under the age of 21 (17.21%), males (19.57%) and White individuals (18.20%). They overestimated the number of missing females (17.80%) and Asian individuals (16.14%) reported missing. There was no significant difference for the percentage of Black individuals reported missing (2.86%). Additionally, knowledge of the idea of MWWS did not significantly impact the estimates for any group.

The influence of MWWS on public perception of missing persons in the United States presents significant challenges for researchers and practitioners in the forensic sciences. This media-driven bias not only distorts societal understanding of who is most at risk of disappearance but also has the potential to shape investigative priorities, resource distribution, and policy development in ways that perpetuate systemic inequities. Forensic professionals must therefore engage critically with the sociocultural dynamics that inform case visibility and recognition. This includes advocating for inclusive data practices, equitable investigative protocols, and interdisciplinary collaboration that centers marginalized communities. By confronting the implications of MWWS, the forensic sciences can move toward a more just and representative framework that ensures all missing persons are afforded equal attention, dignity, and access to justice.

J26 A Fatal Case of Munchausen Syndrome by Proxy in the Father–Daughter Dyad

Federica Amirante, MD, Università degli Studi di Bari Aldo Moro, Bari, Lombardia, Italy; Anna Margari, MD, Università degli Studi di Bari Aldo Moro, Bari, Puglia, Italy; Roberto Catanesi, MD, PhD, Università degli Studi di Bari Aldo Moro, Bari, Puglia, Italy; Biagio Solarino, MD, PhD, Università degli Studi di Bari Aldo Moro, Bari, Puglia, Italy*

Learning Objectives: Attendees will learn how to recognize key clinical, forensic, and psychopathological patterns in rare cases of Munchausen Syndrome by Proxy (MSBP), emphasizing a case involving a paternal perpetrator and his daughter with a fatal outcome. This presentation will provide competencies for synthesizing multidisciplinary forensic evidence to distinguish between natural and non-natural causes of infant death and will offer critical insights into the role of forensic psychiatry in evaluating perpetrator profiles and their interpretation in legal contexts.

Impact Statement: This presentation will enhance the forensic science community's ability to manage complex child abuse cases involving MSBP. It will improve both diagnostic performance in medicolegal settings and the accuracy of cause-of-death determinations, especially in cases mimicking Sudden Infant Death Syndrome (SIDS). The approach fosters stronger interdisciplinary collaboration and critical evaluation of psychiatric evidence within legal contexts.

Abstract Text: Munchausen Syndrome by Proxy (MSBP), currently termed Factitious Disorder Imposed on Another (FDIA) according to DSM-V-TR, is a severe form of child abuse in which a caregiver induces or fabricates illness in a dependent.[1] This case study presents a rare and fatal instance involving a male perpetrator, an underrepresented demographic in FDIA literature, ultimately convicted of intentionally suffocating his three-month-old daughter.[2]

The case unfolded through multiple hospitalizations of the infant, with episodes of unexplained apnea and cyanosis, all reported by the father and never explained by clinical findings. An extensive workup, including cardiac, neurological and metabolic investigations, yielded no evidence of organic disease. A forensic report raised by physicians during hospitalization did not prevent the fatal event, which occurred shortly after during a subsequent admission.

Postmortem assessment followed standardized SUID/SIDS protocols and revealed non-specific but suggestive findings: hypoaerated lungs with hemosiderin-laden macrophages, minute suppleural petechiae and diffuse vascular congestion.[3-6] CT scans and toxicology were negative. Histopathology excluded active inflammation or infections. The integrated data supported the hypothesis of acute asphyxia without a natural cause.

Psychiatric evaluation of the father revealed a complex personality profile, including excessive conformity, interpersonal immaturity, and Cluster B personality traits (narcissistic-histrionic). He exhibited a marked tendency toward manipulative and deceptive behaviors, with a clinical picture consistent with longstanding somatic symptom disorder. In public, the father appeared caring and deeply involved with his daughter. Although the diagnosis of FDIA cannot be based solely on psychopathological features and requires the verification of deceptive behavior (7), his clinical profile was consistent with perpetrator traits described in the literature and later confirmed by judicial findings.[7-8]

The final legal ruling dismissed the defense's argument of diminished responsibility due to FDIA and confirmed full criminal liability for intentional homicide. This case underscores both the forensic challenge of diagnosing FDIA in real time and the importance of retrospective integration of medical, autopsy, and behavioral data. It also illustrates the diagnostic ambiguity of syndromic constructs like FDIA in courtrooms, where psychiatric labels may be misinterpreted or overemphasized.[9] This is a fatal case of FDIA occurring within a hospital setting, where healthcare providers encounter numerous ethical and legal challenges in managing the condition.[10] Balancing the duty to protect the victim with respecting the caregiver's autonomy demands careful and nuanced judgment. Ultimately, this case contributes to a better understanding of paternal MSBP and emphasizes the need for robust forensic methodology and cautious psychiatric interpretation.

J27 Reining in Juvenile Impulsive Aggression: A Novel Pharmacologic Treatment Algorithm in Forensic Psychiatric Settings

Maureen R. Cranley, BS, Saint Louis University School of Medicine, St. Louis, MO; Alan R. Felthous, MD, Saint Louis University School of Medicine, St. Louis, MO; Felicia Johnson, PhD, 22nd Judicial Circuit, St. Louis, MO*

Learning Objectives: Attendees will learn a structured, tiered algorithm for pharmacological treatment of impulsive aggression in juvenile forensic populations, informed by empirical evidence, neurobiological theory, and real-world data. They will gain tools to classify impulsive aggression behavioral phenotypes, integrate comorbidity-informed decision points, and apply a stepwise treatment model grounded in forensic and developmental psychiatry. The speaker will present the framework in sequenced tiers based on empirical strength and clinical applicability.

Impact Statement: This presentation will enhance the forensic clinician's ability to make defensible, evidence-based treatment decisions for high-risk youth presenting with impulsive aggression. By introducing the first structured pharmacologic algorithm tailored specifically for juvenile forensic settings, it enhances the clarity and credibility of expert testimony, informs risk management strategies, and promotes consistency and transparency in psychiatric recommendations within legal contexts.

Abstract Text: Juvenile impulsive aggression (IA), characterized by rapid, reactive, and dysregulated outbursts, remains a critical but under-addressed symptom in clinical psychiatry and forensic settings. While present across a range of childhood disorders, IA is not adequately captured by existing diagnostic categories, contributing to fragmented care and non-standardized treatment approaches.[1,2] IA contributes to a trajectory of poor academic performance, disrupted social functioning, and increased risk of adjudication and confinement in juvenile justice settings.[3] Pharmacological agents, including SSRIs, atypical antipsychotics, and mood stabilizers, have demonstrated efficacy in managing impulsive aggression.[4] However, clinicians face a substantial void: the absence of a standardized, evidence-based treatment algorithm for youth IA results in fragmented and inconsistent prescribing practices, driven more by diagnostic category than by behavioral pathology.[2,4]

Despite advancements in adult pharmacologic algorithms, no structured model tailored to the unique demands of juvenile forensic contexts currently exists.[5] Treatment pathways remain unclear and insufficient due to a lack of targeted evaluation of pharmacologic agents in populations with impulsive aggression and the absence of any FDA-approved medication indicated for IA.[4] Additionally, psychopharmacological research specifically focused on IA remains scarce, limiting clinicians' ability to tailor treatment to distinct behavioral profiles.[6] This presentation introduces a tiered, evidence-informed algorithm for treating IA in juveniles, the first structured pharmacological algorithm tailored to manage IA in juvenile forensic populations. Modeled after the tiered decision-making framework developed by Felthous and Stanford for adults and informed by the Treatment of Maladaptive Aggression in Youth (TMAY-II) consensus guidelines, the framework reflects the neurodevelopmental, diagnostic, and legal complexities specific to juvenile populations.[5,7]

The algorithm synthesizes behavioral phenotype classification, comorbidity-informed decision points, and neurobiological correlates such as fronto-limbic dysregulation and amygdala hyperreactivity.[2,3] To enhance clinical realism and forensic utility, data extracted from a retrospective chart review of juveniles treated at the Saint Louis City Juvenile Detention Center directly informs the algorithm. Integrating empirical evidence, neurophysiological theory, and real-world prescribing patterns led to the development of a sequenced, tiered algorithm designed to guide rational, individualized pharmacological interventions in high-risk youth. To our knowledge, this model represents the first structured pharmacologic algorithm specifically developed for addressing IA in juvenile forensic settings. By bridging a long-standing gap in forensic child psychiatry, the model offers clinicians an empirically supported and ethically defensible framework for managing high-risk youth. Its tiered structure enhances clinical decision making while bolstering expert testimony, guiding risk reduction strategies, and ensuring greater consistency in forensic psychiatry practice.

J29 The Development of the Willingness to Malinger Scale

Richard Paul Conti, PhD, Kean University, Union, NJ; Erica Baer, PhD, Kean University, Union, NJ; Joseph H. Preckajlo, MA, Florida Institute of Technology, Union, NJ*

Learning Objectives: This presentation will provide background and statistical support for the development of a scale evaluating a person's willingness to malinger. After viewing this presentation, attendees will better understand the different types of malingering and the situations where a person may be more prone to malinger.

Impact Statement: This presentation introduces a newly developed scale measuring willingness to malinger, addressing the persistent challenge of detecting malingering, particularly in high-stakes forensic contexts where motivation to deceive is strong. By equipping forensic psychologists and psychiatrists with a tool to assess an individual's predisposition to feign symptoms, the scale can assist researchers who study malingering and practitioners who encounter it.

Abstract Text: The *DSM-5-TR* defines malingering as "the intentional production of false or grossly exaggerated physical or psychological symptoms, motivated by external incentives such as avoiding military duty, avoiding work, obtaining financial compensation, evading criminal prosecution, or obtaining drugs."[1] The definition and criteria of malingering in the *DSM* have been criticized as being too narrow and lacking empirical support.[2-4] However, malingering is not a binary distinction. Rather, it is viewed along a continuum that can range from mild forms of exaggeration to the deliberate outright faking of symptoms.[2,5,6]

For this study, the sample included responses from 891 undergraduate students from a university in the Northeastern US. Participants completed the Willingness to Malinger Questionnaire-Revised (WMQ-R). Thirty respondents provided no answers for the scale items and were removed from further analysis. Overall missingness was minimal (M = 0.42%, range: 0.12% to 1.28% across scale items). Multiple imputation was conducted using the MICE package in R to impute missing scale items.

An exploratory factor analysis (EFA) was conducted using the psych package in R. Bartlett's test of sphericity was significant, $\chi^2(136) = 8090.907$, $p < .001$, and the overall Kaiser–Meyer–Olkin (KMO) measure was .9, indicating that the data were suitable for factor analysis. Using maximum likelihood extraction with oblimin rotation, a five-factor solution was supported based on the scree plot and parallel analysis. Factor 1 explained 25% of the total variance and included items related to risk-contingent malingering. Factor 2 explained 23% of the total variance, with items focusing on malingering to avoid legal consequences. Factor 3 explained 21% of the total variance and included items about external gain. Factor 4 explained 16% of the total variance and included items related to malingering for institutional accommodations. Factor 5 explained 15% of the total variance and included items related to faking good. Internal consistency for the scale was strong, with Cronbach's alpha between .93 and .95 across all five factors. The average inter-item correlation ranged from .85 to .97.

A confirmatory factor analysis (CFA) was conducted using the lavaan package in R. The initial model demonstrated good fit, $\chi^2(109) = 187.942$, $p < .001$, with the following fit indices: CFI = .998, TLI = .997, RMSEA = .041 (90% CI = [.031, .051]), SRMR = .042. Values of CFI and TLI above .95, RMSEA below .06, and SRMR below .08 are indicative of good model fit. Factor loadings for all items were statistically significant ($p < .001$) and ranged from .62 to .93, supporting the construct validity of the measure. Standardized residuals and modification indices were also examined, and no further modifications were considered.

The majority of participants were unwilling to malinger for any reason. The factor analysis conducted in this study suggests that a person's willingness to malinger is likely context-specific. In other words, the situation will dictate whether an individual will malinger, rather than the type of malingering. Further research is warranted to measure the willingness to malinger in clinical, forensic, and other non-academic populations.

J31 "Our Hands Were Tied": Fatal Interactions Between Law Enforcement and Individuals With Behavioral Health Histories

Michael J. Staley, PhD, DHHS Utah Office of the Medical Examiner, Taylorsville, UT; Deirdre Amaro, MD*, DHHS Utah Office of the Medical Examiner, Taylorsville, UT; Barrett Humble, BS, DHHS Utah Office of the Medical Examiner, Taylorsville, UT*

Learning Objectives: Participants will learn characteristics of individuals with behavioral health histories who were fatally injured by law enforcement during a crisis. Further, participants will be able to articulate the current systemic problems that exist between behavioral health providers and law enforcement.

Impact Statement: Law enforcement officers seek to ensure public safety and behavioral health providers seek to ensure the well-being of those who utilize its services. This presentation highlights opportunities to avoid fatal interactions between law enforcement and individuals with a behavioral health history, identify gaps in systems, and better understand who may be at a higher risk of dying as a result of a crisis-conflict with law enforcement.

Abstract Text: Law enforcement officers' use of deadly force has become a public concern over the past several years. Researchers have documented that individuals living with mental illness are more likely than those who do not have mental illness to die as a result of an officer-involved shooting.[1,2] These deaths represent public health, mental health, and public safety challenges with ramifications that extend far beyond the individuals involved. Since these deaths fall under medical examiner jurisdiction, a statewide office may allow for a broader and more in depth examination of the systemic failures that contribute to these deaths.

Researchers at the Utah Office of the Medical Examiner identified 41 deaths between 2020 and 2024 in which law enforcement officers ultimately used lethal force, resulting in the death of the suspect. We question, did officers attempt a non-lethal or less lethal intervention prior to switching to a lethal or likely lethal method of intervention? For example, did officers first attempt to negotiate with the subject? Did they attempt to use an electroconductive device or other less lethal means? And, in all cases, we examine whether there was an opportunity for a less lethal method to be used prior to officers switching to a more lethal method (i.e. firearms). Furthermore, deceased persons' psychiatric, behavioral, social, and medical histories were abstracted from medical charts, as well as histories with law enforcement and corrections to better understand system-level interactions that preceded the fatal encounter with law enforcement.

The authors will present thematic characteristics of individuals who had behavioral health histories, assess differences in deployment of less lethal means by law enforcement, describe who may be vulnerable to a fatal encounter with law enforcement in the future, and present recommendations for future areas of study with a focus on prevention.

K1 A Forensic Analysis of 2-Phenoxyethanol in Ballpoint Pen Strokes on Paper Under Natural Aging Conditions

Veronika Marinović, PhD, Forensic Science Centre "Ivan Vučetić", Zagreb, Grad Zagreb, Croatia; Ivana Bolanča Mirković, PhD, Faculty of Graphic Arts University of Zagreb, Zagreb, Grad Zagreb, Croatia; Andrea Ledić, MSc, Forensic Science Centre "Ivan Vucetic" MoI Croatia, Zagreb, Grad Zagreb, Croatia; Stjepan Brzica, MSc, Forensic Science Centre "Ivan Vučetić", Zagreb, Grad Zagreb, Croatia*

Learning Objectives: The participants will learn how 2-Phenoxyethanol (2-PE), as a key and frequently used solvent in ballpoint pen ink, behaves during the aging process. They will learn methods for monitoring its concentration change after applying paint to paper and the importance of this analysis in forensic dating documents.

Impact Statement: Aging analysis of ink helps to determine the authenticity and time of creation of disputed documents, which is often crucial in criminal and civil cases. Accurate dating of documents increases the reliability of forensic evidence and thus contributes to a fairer judicial process.

Abstract Text: Forensic analysis of ballpoint pen ink is crucial for the identification and dating of documents. Monitoring chemical changes in the composition of ink over time, particularly the concentration change of 2-phenoxyethanol (2-PE), provides valuable insight into ink durability and the authenticity of written documents. Ink aging involves both physical and chemical transformations, with changes in ink and solvents, such as 2-phenoxyethanol, one of the most monitored.1,2

The solvent 2-phenoxyethanol is commonly found in ballpoint pen inks. Therefore, analyzing its concentration change is key to understanding the long-term stability of ink and preserving document integrity.3-6 In this study, the focus was placed on monitoring the concentration changes of 2-phenoxyethanol in blue ballpoint pen ink applied to paper, subjected to varied ambient aging conditions (in the presence and absence of light). Exposure to light was intended to simulate typical indoor sunlight exposure through window glass, while the other samples were stored in a closed cabinet to replicate standard archival storage conditions.

Quantitative analysis was performed using high-performance liquid chromatography (HPLC) over 10 days, focusing on measuring the concentration change of 2-phenoxyethanol in blue ballpoint pen inks. The results showed that natural aging, whether in the presence or absence of light, led to a decrease in 2-phenoxyethanol concentration. A comparison of the two exposure conditions over the 10 days revealed notable differences in concentration on the first and second day, while measurements in the subsequent days began to converge, showing minimal or negligible variation.

It is important to note that the samples were not exposed to artificial light sources, such as fluorescent lamps or LED lighting, which could potentially influence the results and represent a possible direction for future research.

This study provides important insights into the chemical mechanisms underlying ink degradation under different environmental conditions. Understanding these chemical changes will enable forensic scientists and investigators to interpret analytical results with greater precision, thereby enhancing the reliability and accuracy of document identification and dating.[7-10]

Additionally, this research contributes to developing guidelines for evaluating document integrity over time, thereby improving methods for preserving forensic evidence in real-world contexts. Such approaches help ensure that evidence remains intact and that analytical results stay relevant and admissible even after extended periods, ultimately enhancing the effectiveness of forensic examinations within judicial proceedings, which is essential for upholding justice and security.[7-10]

K2 Network Graphs for Visualizing Handwriting Individuality

Clarissa Giefer, MS, South Dakota State University, Brookings, SD; Cami Fuglsby, PhD, Augustana University, Sioux Falls, SD; JoAnn Buscaglia, PhD, FBI Laboratory, Quantico, VA; Christopher P. Saunders, PhD, South Dakota State University, Brookings, SD; Jack Hietpas, PhD, John Jay College, New York, NY; Janean Hanka, MS, South Dakota State University, Brookings, SD*

Learning Objectives: The presented research will demonstrate how a complex dataset consisting of handwriting comparison scores can be represented to provide a rapid means to visually assess the biometric individuality of populations of handwriting profiles.

Impact Statement: This research will provide a tool that enables document examiners to detect potential exclusionary differences in writer profiles. The statistical methods developed for this research may help identify populations of writer profiles that are easily differentiated and those that consist of common features with low discrimination potential or unusually high within-writer variability.

Abstract Text: A common question when deciding whether or not to analyze a type of physical evidence is the degree to which the features of the traces derived from different sources can be distinguished. Colloquially, this "degree" is referred to as the "individuality" or "uniqueness" of the measured feature. For a statistically rigorous definition, we define individuality as the chance of observing two sources that are indistinguishable, with respect to a specified metric, when comparing large samples from the two sources. For comparisons in which two sources have indistinguishable profiles with respect to the metric, regardless of the sample size, it is concluded that they will not give rise to exclusionary differences. Following, we define biometric individuality as the random chance of observing two indistinguishable profiles, based on a specified metric threshold, within the population of relevant sources.[1] This concept is closely related to the idea of the biometric capacity of an automated identification system. In this work, we present strategies for visualizing the biometric individuality of populations of handwriting profiles using customized network graphs.[2]

Our focus is to study the score-based method developed by Davis et al. for sparse categorical data arising from level one features in the language-dependent predecessor of the FLASH ID© system.[3] Due to the complexity of the feature space inherent to handwriting comparisons, the chi-squared statistic for comparing two handwriting samples is not reliable when two samples share the same writing profile. This implies that defining exclusionary differences for handwriting comparisons is statistically and computationally difficult. To overcome this issue, we define a new test based on all pairwise comparisons, with respect to the chi-squared test statistic, between documents from two different writers. We then propose a level alpha test based on the expected values of scores, comparing within-writer scores between the two writers and the average within-writer scores with the between-writer scores. If we observe a significant difference among the three different expected values of scores, we conclude that we have observed a significant (exclusionary) difference between the writing profiles of the two writers.

Using the developed level-alpha significance test, we use the corresponding p-values between two writers to assess the occurrence of finding two writers with indistinguishable profiles. To achieve this goal, we model the distribution of p-values with a mixture model that allows us to make assessments about the confidence that a given p-value came from a comparison of writers with indistinguishable writing profiles. We summarized the results visually using network graphs to help identify groups of writers that have a high degree of confidence that they have indistinguishable writing profiles.

In this presentation, we illustrate the approach with a dataset of 100 writers, each writing 5 script copies of the modified "London Letter" described in "Construction and evaluation of classifiers for forensic document analysis."[1]

K3 A Support System for Document Analysis Through Detection and Recognition of Handwritten Documents

Enrique Bermejo, PhD, Panacea Cooperative Research, Granada, Andalucia, Spain; Alejandro Manzanares, MSc, Panacea Cooperative Research, Granada, Andalucia, Spain; Oscar Ibáñez, PhD, Universidade da Coruña, A Coruña, Galicia, Spain*

Learning Objectives: Attendees will learn how Artificial Intelligence (AI) and image processing techniques can be applied to forensic handwriting analysis to assist in locating patterns across documents. They will gain an understanding of how automated segmentation and text recognition enable rapid and objective comparisons between handwritten documents. Additionally, participants will see how these tools can integrate with existing forensic workflows, enhancing both the efficiency and reliability of handwriting examinations in real-world casework.

Impact Statement: This presentation will demonstrate how emerging technologies, particularly AI and image processing, can significantly enhance the capabilities of forensic handwriting analysis. By introducing a tool that automates key aspects of document comparison, it provides forensic experts with a more detailed and efficient approach to casework. The integration of these technologies into practical workflows bridges the gap between traditional forensic methods and modern computational advancements, promoting innovation and increased reliability within the forensic science community.

Abstract Text: Forensic handwriting analysis relies on identifying structural variations in letter formation and connecting strokes to distinguish between writers. These characteristics, including variations in slant, fluency, pressure or size, are shaped by individual motor habits and represent distinctive styles unique to each writer. Advances in technology, particularly in the fields of image processing and artificial intelligence, have opened new avenues for automating and enhancing the process of handwriting analysis, offering powerful tools to complement traditional forensic practices.

This work presents an analytical tool to assist examiners in the task of evaluating letter formation and structural differences in handwritten text by facilitating pattern detection. The methodology focuses on segmenting letters, identifying connecting strokes and measuring slant angles using advanced automatic techniques applied to scanned text. Additionally, the proposed system integrates text recognition capabilities, allowing for rapid comparison between two documents by correlating the isolated elements with their textual content.

Our contribution will be supported by a practical demonstration, tested on the IAM and CVL datasets for handwritten text identification, involving study cases requiring the analysis of mixed writing styles involving lower/upper-cases, disconnected, and cursive styles.

The proposed methodology not only enhances the efficiency of handwriting analysis but also serves as a bridge between traditional forensic expertise and emerging technologies. To this end, the tool is designed to be intuitive and seamlessly integrate with existing workflows, facilitating the query of words and letters while easing the process of identifying similarities across corresponding documents.[1,2]

K4 A Case Study on the Reliability of Electronic Signatures Across Varying Security Levels

Cristiane Viana Barbosa, MA, UFF, Universidade Federal Fluminense, Rio, Rio de Janeiro, Brazil; Dineusa Maria Do Amaral, MBA*, Judicial Expert for the Court of the State of Paraná, Foz do Iguaçu, Parana, Brazil; Anna Beatriz Rodrigues Geranio, University Estacio de Sá, Petropolis, Rio de Janeiro, Brazil*

Learning Objectives: By the conclusion of this presentation, participants will have a clear understanding of the varying security levels associated with digital signatures—classified as simple, advanced, and qualified—backed by a compelling case study. Attendees will learn to identify common vulnerabilities inherent in digital signing platforms, even those validated through official systems. They will gain the ability to apply traditional principles of graphoscopy and documentoscopy when analyzing digital documents. This knowledge will connect the foundational aspects of forensic analysis with contemporary authentication technologies.

Impact Statement: This case study reveals that although technological advancements have greatly enhanced digital authentication, traditional forensic techniques rooted in graphoscopy continue to be crucial in confirming the legal validity and authenticity of electronic documents. By highlighting vulnerabilities in both simple and advanced electronic signature methods, our research underscores the value that forensic experts bring in applying detailed analyses of modern technologies. These insights bear significant relevance for forensic practitioners in an increasingly digitized landscape, encouraging greater awareness of the limitations of automated validation systems and promoting best practices that are both secure and evidence-based.

Introduction: The global adoption of electronic signatures has increased significantly, especially in legal and commercial transactions. In Brazil, Provisional Measure No. 2.200-2/2001 and Law No. 14.063/2020 regulate their use. In the United States, the ESIGN Act and the UETA provide legal support for electronic documents. However, legal validity does not always guarantee technical security or forensic authenticity. This study presents an empirical analysis of the security of electronic signatures, viewed from the perspective of traditional document forensics.

Objectives and Methods: The research team created eight fictitious contracts, each signed with three types of digital signatures: simple (using tokens via email or WhatsApp), advanced (with selfies, Pix, or gov.br), and qualified (via ICP-Brasil digital certificates). Platforms such as Clicksign, gov.br, and the validator from Brazil's National Institute of Information Technology (ITI) were used for testing. Fraud scenarios included forged selfies, document editing, and misuse of third-party credentials.

Results and Discussion: Simple signatures proved to be the most vulnerable. In one test, a WhatsApp token enabled contract signing without identity verification, yet the system still validated it. In another case, a contract was signed using someone else's email and personal information, passing validation by both Clicksign and ITI. Advanced signatures showed mixed results. A selfie with a credit card instead of a valid ID was accepted. In another case, a 13-year-old's selfie with a functional badge passed without biometric verification. Pix payments authorized signing based solely on the transaction, without confirming the payer's identity. The gov.br advanced signature presented better security but relied solely on password confidentiality. When the researcher scanned the same signed document, it failed validation demonstrating the importance of using original files. Qualified digital signatures with ICP-Brasil certificates were the most secure. The ITI validator correctly flagged any post-signature alterations. In one case, converting a digitally signed PDF to Word and back resulted in the system identifying the document as invalid.

Conclusion: This study highlights significant vulnerabilities in electronic signatures, especially simple ones, emphasizing the need for measures beyond automated validation. It is crucial to explore forensic methods to verify authenticity more reliably. Comparing these findings to international standards reveals Brazil's need for stricter and more uniform validation criteria. These gaps raise technical, legal, and business concerns, as they affect trust in electronic signature technologies. To address this, experts suggest enhancing integration between forensic analysis and available digital solutions to ensure greater legal security, reliability, and traceability of signed electronic documents.[1-9]

K6 Forensic Document Examination and AI: A Brave New World

Stephanie A. Kingsbury, MSFS, Homeland Security Investigations, Forensic Laboratory, McLean, VA*

Learning Objectives: During this presentation, attendees will learn about forensic document examination and Artificial Intelligence (AI). Experiments utilizing AI programs such as ChatGPT and Google Gemini with uploaded samples of handwriting, both signatures and extended writing as well as travel and identity documents will be discussed. This presentation will discuss an initial assessment of AI to determine whether samples of images of original signatures and other writings will allow AI to generate another unrelated signature or writing that will fall within the writer's natural range of variation. Similarly, identification documents such as a driver's license will be uploaded and attempted to be altered without detection.

Impact Statement: The forensic science community will be impacted by this presentation by examining the capabilities and limits of AI with regard to common analysis techniques in questioned documents. The field of forensic document examination will be directly influenced in understanding what AI programs can accomplish when given specific prompts related to handwriting analysis and identity document examination.

Abstract Text: With the increasing accessibility and sophistication of artificial intelligence (AI) tools such as ChatGPT and Google Gemini, traditional pillars of forensic document examination (FDE) are facing new and complex challenges. This two-pronged experimental study explores the capabilities and limitations of AI in two key areas: handwriting analysis and identity document examination.

In handwriting examination, a foundational principle is that no individual writes exactly the same way twice, a concept known as *natural variation*. Forensic examiners use this inherent variability to assess whether a questioned writing sample could have been produced by a known individual. However, with publicly available handwriting samples—such as signatures or extended texts—can AI models be trained or prompted to generate new handwriting that falls convincingly within a writer's natural range of variation? This study investigates whether AI-generated handwriting can mimic individual variation convincingly enough to evade detection.

The second prong addresses the forensic analysis of identity documents, including the evaluation of printing methods and embedded security features. This research examines whether AI, when supplied with images of genuine documents, can alter or regenerate these materials in ways that challenge detection by trained forensic examiners.

As AI tools become more deeply embedded in society, understanding their potential for misuse—and the implications for forensic science—is essential. This study aims to assess current threats and establish a baseline for further research and policy discussion.

K7 DIY AI for Forensic Document Examiners

Mark T. Goff, BA, Michigan State Police, Lansing, MI*

Learning Objectives: This presentation will examine Google's NotebookLM and compare it to current and previous aggregate methods of Forensic Document Examination information repositories. This AI-powered research tool provides a new method of cataloging and searching for references, with the added ability to conduct plain text searches and receive compiled responses grounded in these defined sources.

Impact Statement: This presentation will impact the forensic science community by increasing awareness of advances in Artificial Intelligence (AI) Large Language Models (LLM). Using NotebookLM, Forensic Document Examiners (FDEs) will have a powerful resource for tackling difficult examinations, conducting research, training new examiners, preparing for testimony, or any task that requires the application of knowledge from a broad selection of sources.

Abstract Text: Google NotebookLM enables Forensic Document Examiners (FDEs) to populate a database with extensive information. This can include journal articles, PDFs, PowerPoint presentations related to FDE, digital versions of important books, and relevant websites. The tool also allows the addition of personal notes from lectures, trainings, and seminars, as well as videos from sources like YouTube and audio files. Content can further include published standards, local Standard Operating Procedures, and court transcripts. With authorization from the FDE's administration, even case files and laboratory notes can be added to provide context for the AI model.

Due to the niche nature of Forensic Document Examination, there is limited public information available for generic AI models to train on, which increases the risk of AI hallucinations. By using a directed AI model, FDEs can enhance response accuracy and reduce the risk of hallucinations common in AI chatbots. This risk is further mitigated when responses are directly cited from the FDEs' uploaded sources. When responses include cited information, FDEs can follow up by directly accessing the cited material for additional information and context.

This presentation will showcase various features of NotebookLM and include a live demonstration of its capabilities. Time permitting the presentation will allow questions from attendees for the various FDE Notebooks.

K8 I Had a Case. Hiding in Plain Sight

Kate Butler, BS, Florida Department of Law Enforcement, Pensacola, FL*

Learning Objectives: Attendees attending this presentation will learn and remember key details of a case where, without the submission of certain items of evidence that were hiding in plain sight, information on how a murder was committed may have gone unrecovered forever.

Impact Statement: The forensic science community may consider its scientists some of the best observers of the natural world. Forensic scientists examine and process millions of items of evidence every year. But, without submission of ALL of the evidence, forensic scientists may not get the whole story behind a criminal act or event. The case I am presenting today is a cautionary tale of not submitting all of the evidence to the crime lab. And, even once the evidence was submitted and analyzed, the conclusions were still hidden in plain sight for years.

Abstract Text: Forensic Document Examiners (FDEs) are often aware that many seemingly insignificant documents involved in criminal or civil litigation may contain conclusive proof of certain facts. Meaning, many of those trained to investigate crimes may overlook evidence that trained Forensic Document Examiners may find valuable or may find evidence of value after examination. This is the tale of such a case. From beginning to end, forensic document evidence, including handwriting and indented impressions, lay hidden in plain sight, overlooked in more ways and more times than once. Forensic Document Examination is frequently becoming one of the smallest and often under-utilized forensic disciplines in the general forensic science community. The evidence, which was discovered by the Forensic Document Examiner, consisted of handwriting entries and indented impressions in a notebook that was collected from the crime scene. This notebook, which would not have been examined if not for a request by the Forensic Document Examiner, offered attorneys and investigators a simple resolution to many burning questions of this homicide. A resolution, that without the contribution of the forensic document examiner, may never have seen light of day. Attendees at this presentation, which will hopefully include attorneys, practitioners, and students, may all learn a vital lesson about the importance of recognizing forensic document evidence, how often it is overlooked or undervalued, and how the resulting impact of not correctly assessing the conclusions reached in the examination of the forensic evidence can affect the outcome or verdict in a criminal or civil case.

K9 The Utility of Familial Linking of Counterfeit Identity Documents by Questioned Document Examination and Materials Analysis

Luther S. Schaeffer, MS, DHS/HSI/Homeland Security Investigations Forensic Laboratory, McLean, VA; Savanah Allinson, BSc*, DHS/HSI/Homeland Security Investigations Forensic Laboratory, Richmond, VA*

Learning Objectives: The presenters will demonstrate the synergy of questioned document examination and chemistry. Attendees will learn about the complementary analyses of counterfeit identity documents and how the information gathered can be used for databasing. The incorporation of chemical profiles with questioned document examination results are shown using the Imaged Documents and Exemplars Library (IDEAL) system, a cloud-based digital reference library created and maintained by the Department of Homeland Security (DHS) Investigations Forensic Laboratory.

Impact Statement: This presentation will impact the forensic science community by examining the current state of counterfeit identity documents and what information can be extracted from the deluge of seized counterfeit identity documents. The combination of questioned document examination with complementary analytical schemes will be demonstrated as well as discussion of how the data can be incorporated in a searchable digital reference library.

Abstract Text: The Homeland Security Investigations Forensic Laboratory's (HSI-FL) mission is to protect U.S. national security by providing expert quality forensic, scientific, intelligence, and investigative support services to DHS, ICE, HSI and other foreign and domestic agencies. HSI-FL is in the process of developing and deploying IDEAL, a digital database of high-resolution forensic images of travel and identity documents, digitized from the HSI Forensic Laboratory's vast collection of over 350,000 records collected from around the world over the past 40 years. It currently includes passports, ID cards, visas, immigration documents, civil and health records, and more. Accessible only to vetted government partners, IDEAL allows users to research genuine documents, their security features, associated reference material, and counterfeit versions to help authenticate suspect documents in the field. Reference material such as fraud alerts and government bulletins can accessed through desktop computers or a smartphone. Inclusion of counterfeit materials provides users with a detailed portrait of the quality and types of documents encountered by HSI and agency partners. The IDEAL system will also allow for chemical data to be uploaded and linked to documents providing yet another means for characterizing documents.

The activities highlighted in this session will include the collection, examination, and characterization of seized counterfeit state-issued credentials (i.e., driver's licenses) conducted at the forensic laboratory. Currently, the laboratory holds greater than 50,000 counterfeit driver's licenses and that number continues to climb. Staff at the HSI Forensic Laboratory located in operations, questioned documents, and counterfeit deterrence-adversarial analysis sections coordinate activities related to the evaluation of the online marketplaces as well as the physical items received in order to better understand and ultimately, disrupt the flow of the counterfeit items into consumer's hands. The US counterfeit driver's license market is massive, with societal costs estimated to be approximately 250 billion dollars annually. The marketplaces for counterfeit driver's licenses are estimated to bring in more than 500 million dollars annually, which can then be used to improve their products, start new marketplaces, or engage in other illicit activities.[1]

The effort of the HSI Forensic Lab is to develop a thorough understanding of the materials used in the production and construction of the cards, as well as fully document the methods of print production used. By amassing this information, the lab can then link "families" of the IDs and track where they are coming from and what tools the counterfeiters may have so that issuing authorities can respond and prevent future vulnerabilities by avoiding easily counterfeited security features, making changes to their existing design, and/or adding new features to their IDs. This presentation will provide an overview of improvements in the methods of printing seen in the illicit market and their products, the card assembly, and range of production quality observed at the HSI-FL, as well as chemical characterization of the materials used to construct these documents which will ultimately be incorporated into the IDEAL database.

K10 I Had a Case—Document Obliterations in a Homicide Investigation and a Return to Classic Forensic Techniques

Sarah Pryor, BS, TXDPS Crime Laboratory, Austin, TX; Angela Roe, MSc*, TXDPS Crime Laboratory, Austin, TX*

Learning Objectives: The goal of this presentation is to provide insight on a case where modern technology was not capable of yielding results and the examiner had to return to basic methodologies to transcribe the obliterated material. Attendees will learn: (1) how obliterations can obscure evidentiary material critical to investigations; (2) the limitations of modern forensic imaging technologies; (3) the effective application of classic forensic techniques such as oblique lighting and macroscopic/microscopic examination for deciphering overwritten and obscured text; and (4) how to approach similar cases with methodologies balancing emerging technology with foundational practices.

Impact Statement: This presentation will reinforce the importance of foundational forensic skills in an era increasingly reliant on advanced technology. It will demonstrate how the flexibility and adaptability of a forensic document examiner can influence the outcome of investigations. Attendees will be encouraged to re-evaluate the role of classical methods in contemporary casework, particularly when advanced instrumentation fails to yield definitive results.

Abstract Text: In the investigation of a homicide case, a questioned document (paperback novel) containing apparent obliterations emerged as a critical piece of evidence. This novel was obtained from the jail cell of one of the juvenile suspects in the case and was thought to contain the events of the murder including names and locations. The obliterations and overwritten portions were done by using a repetitive circular motion with the same ink/pen used to create the original handwriting. Initial attempts to recover the obscured writing using modern technologies including the Video Spectral Comparator (VSC) and imaging software (Adobe Photoshop) were unsuccessful due to the nature of the materials and the extent of the alterations.

This presentation details the step-by-step examination process employed by the examiner, highlighting the decision to re-engage traditional forensic document examination methodologies. These classical techniques ultimately enabled the transcription of the obliterated content and thereby assisted the agency in garnering plea deals.

The case underscores a recurring challenge in forensic document examination: when technology reaches its limit, the examiner's foundational skills and judgment remain indispensable. This presentation will also explore the procedural aspects of case triage, examiner persistence, and the integration of forensic findings into broader evidentiary context.

K11 Automating Toner-Based Sequence Determination in Forensic Document Examination: New Tools and Next Steps

Zain Bhaloo, MSc, Canada Border Services Agency, Ottawa, Ontario, Canada; Mathieu Arès, BS, Canada Border Services Agency, Ottawa, Ontario, Canada; Brent Ostrum, BS, Canada Border Services Agency, Ottawa, Ontario, Canada*

Learning Objectives: By attending this presentation, participants will be introduced to a new software application developed to automate the analysis of toner particle distribution for determining the sequence of printing and handwriting. Attendees will understand how the app incorporates statistical models, such as likelihood ratios, and will gain insight into future research aimed at validating the method with color toner documents and other potential variables.

Impact Statement: This presentation introduces a practical, scientifically grounded tool that improves objectivity and efficiency in the forensic analysis of printing and writing sequencing. By combining validated methods with automation and future research directions, the project strengthens the reliability of forensic conclusions and expands capabilities in non-intersecting stroke analysis, especially in complex or disputed legal scenarios.

Abstract Text: In forensic document examination, determining the sequence of non-intersecting handwriting and printed text can be vital in cases involving contracts, signatures, or disputed entries. A recently completed study introduced a method using background toner particle distribution and statistical modeling, including likelihood ratios, to determine whether writing or printing came first on a document. This method demonstrated reproducibility, accessibility, and applicability using infrared imaging and low-cost tools.

Building on that work, a software application has now been developed to streamline this analysis. This newly created app automates the imaging, counting, and statistical evaluation of toner particle distributions, offering forensic examiners a user-friendly interface to conduct toner-based sequence determinations with minimal manual intervention. It integrates background normalization, kernel density estimation, and visual LR interpretation tools, enabling fast, transparent, and reproducible assessments of questioned documents.

This presentation will provide a live demonstration of the application, including its capabilities, intended use cases, and integration with common imaging equipment and low computational requirement. The tool is designed to support both examiners working with access to original materials (printer, pen, and paper) and those working solely with a questioned document.

Looking ahead, the presentation will introduce the next phase of this research: a planned validation and methodological extension to documents produced with color toner. While the original study focused on black toner laser printers, color toner presents new challenges in particle detection, imaging under NIR/visible light, and ink-toner contrast. This upcoming research aims to evaluate whether similar statistical methods can be adapted to color toner systems and to identify any limitations or required adjustments

Document Sequencing; Toner Particle Distribution; Likelihood Ratios

K12 An Update on Standards Development Activities Related to Forensic Document Examination

Kevin P. Kulbacki, MSFS, KDX Forensics, Chicago, IL*

Learning Objectives: After attending this presentation, attendees will better understand the status of the current and upcoming Forensic Document Examination (FDE) standards being developed by the Organization of Scientific Area Committees (OSAC) FDE Subcommittee and the Academy Standards Board (ASB) FDE Consensus Body.

Impact Statement: This presentation will impact the forensic science community by creating greater awareness of the current standards development activities related to FDE. It will also increase awareness regarding training, tools, and resources that support implementation, compliance monitoring, and broader understanding.

Abstract Text: During this presentation, an update will be provided on the standards development activities related to Forensic Document Examination. This will begin with an introduction to OSAC and ASB, and an overview of the standard development process as it relates to both organizations.

Second, this presentation will discuss OSAC Proposed Standards at various stages of development. The OSAC FDE Subcommittee is currently working on new Draft Proposed Standards as well as on submitting current ASB standards to the OSAC Registry.

Third, this presentation will discuss Draft ASB Documents (including Best Practices, Standards, and Technical Reports) at various stages of development at ASB. The ASB FDE Consensus Body is currently working on multiple new documents.

Fourth, this presentation will discuss completed ASB Standards. As of the writing of this abstract, the ASB has published eight Forensic Document Examination Standards, including the Standard for Examination of Documents for Indentations, the Standard for the Examination of Documents for Alterations, the Standard for Examination Stamping Devices and Stamp Impressions, the Standard Scope of Expertise in Forensic Document Examination, the Standard for Examination of Handwritten Items, the Standard for the Preservation and Examination of Charred Documents, and the Standard for the Preservation and Examination of Liquid-Soaked Documents, and the Standard for Examination of Mechanical Checkwriters and Their Impressions. The ASB Forensic Document Examination Consensus Body is also currently working on multiple additional documents.

Finally, this presentation will highlight efforts by OSAC and ASB for supplemental training related to all standards that go through this process, as well as additional resources and tools designed to facilitate gap analysis, compliance monitoring, and outreach efforts. The categorization of the in-progress documents listed herein is accurate as of the writing of this abstract and may be subject to change prior to the presentation, which will reflect the most accurate information at that time.

Standards; ASB; OSAC

K13 Training for Success in Questioned Documents

Meredith Miller, MFS, Meredith DeKalb Miller, Evanston, IL*

Learning Objectives: Attendees will learn about the new Organization of Scientific Area Committees (OSAC) standard for Minimum Training Requirements for Forensic Document Examiners. Requirements for the Trainees, Trainer(s), Modules, and Methods of Assessment will be reviewed. This presentation will highlight changes from the previous Standard.

Impact Statement: Prospective trainees, trainers and the Forensic Document Examiner (FDE) community will understand the minimum requirements needed for a successful training program. These include pre-training program requirements, duration of training, methods of assessment, methodology, and the theories and principles governing forensic document examination.

Abstract Text: Past training requirements in the field of Forensic Document Examination have relied on individual agencies or mentors to provide appropriate training to prospective trainee's in various topics of instruction, including individual requirements, methods of assessment, and competency testing. That continued before the ASTM E2388 Standard Guide for Minimum Training Requirements for Forensic Document Examiners was introduced in 2005. At this point, FDEs had a collective framework of what minimum training standards should look like. Moving forward, the field of forensic document examination has expanded beyond basic training in handwriting, typewriting, and printing processes to include advancements in technology, quantitative theories, probabilities, statistics, and human factors. The new OSAC Minimum Training Standard encompasses these advancements and provides a template to agencies, trainers, and prospective trainees of the minimum standards required to train and enter the field of forensic document examination.

Fourteen modules introduce topics of instruction, prerequisites, estimated time of completion, section contents, objectives of learning, principles and theories, and a method of assessment including assignments, written exercises, oral tests, and practical exercises. Benchmark tools are available to the trainer(s) to evaluate a trainee's knowledge, skills and abilities for each training module.

The training standard provides guidance in overall topics but also detailed objectives for each module taking the guesswork out of whether provided training meets minimum requirements. While the scope of training is intended for new trainees, it will also benefit trained examiners in topics where additional training and continuing education is needed.[1-3]

K14 A Proposal for a Forensic Signature Examination Standard

Linton Aphzal Mohammed, PhD, Forensic Science Consultants, Inc., Poway, CA*

Learning Objectives: This presentation will provide attendees about the need and requirements for a Forensic Signature Examination Standard. The reasoning for the new standard will be presented. The reasons why a signature standard separate from the current handwriting examination standard is needed will be discussed. The kinematics and neuroscience of signatures will be discussed as scientific foundations for the signature standard.

Impact Statement: The aim of this presentation is to introduce Forensic handwriting and Document Examiners (FDEs) to a standardized method for signature examination. A standardized method may decrease differences in opinions between examiners. It should also make peer review more efficient.

Abstract Text: The ANSI/ASB Standard 070, First Edition 2022 Standard for the Examination of Handwritten Items often followed and referenced by many Forensic Document Examiners (FDEs).[1] This Standard gives a clear account of the limitations, interferences, equipment required, and handwriting examination methods and techniques. ANSI/ASB 070 clearly covers handwriting and hand printing. However, it has some limitations when signature examinations are involved.

Handwriting is designed for communication, whereas signatures are designed for identification. Handwriting must be similar sufficiently to allow all readers to comprehend what is written. Signatures on the other hand may be written in a text-based (legible), mixed style (semi-legible), or stylized (illegible) formats. Signatures are also comprised of a limited amount of handwriting. The motor programs for handwriting and signatures are different. Therefore, the examination of signatures and handwriting should be treated differently.[2] Factors such as aging can influence signatures in dissimilar ways that they can with handwriting. This can be important in the examination of documents such as holographic wills or signed suicide notes.

The kinematics of signatures are different from that of handwriting. FDEs must be cognizant of the underlying kinematic differences. While there will be significant overlap between the handwriting standard and the proposed signature standard, there are some specialized techniques for signature examination that are not covered in the ANSI/ASB 070. For example, observational drawings of questioned and known signatures are vital in signature examination. Knowing how to determine the ductus of strokes in a signature is different that with handwriting, particularly for mixed and stylized signatures. The complexity of signatures may have a different impact on an examination that it would for extended handwriting

Conclusion scales for signature examinations will be discussed briefly.

K15 Note Taking Requirements for New FDE Standards . That Seems Like a Lot

Mark T. Goff, BA, Michigan State Police, Lansing, MI*

Learning Objectives: Attendees of this workshop will learn: the fundamental definitions and note taking distinctions between legacy and current standards; the specific note-taking requirements outlined by new standards in forensic document examination; and practical methods for documenting examinations, observations, and results in a manner that meets examination standards.

Impact Statement: This presentation will significantly impact the Forensic Document Examiner (FDE) community by enhancing the understanding of standardized note-taking practices, which are crucial for maintaining the integrity and transparency of forensic examinations.

Abstract Text: This presentation is designed to provide forensic document examiners with the essential knowledge and practical skills required to meet the newer more stringent documentation standards. This comprehensive presentation will delve into the critical aspects of note-taking, emphasizing the importance of accurate and detailed documentation in forensic examinations with a focus on ANSI/ASB 070 Standard of the Examination of Handwritten Items and ANSI/ASB Standard 044 Standard for the Examination of Indentations.[1,2] Participants will explore the specific requirements outlined by the Academy Standards Board (ASB) standards and legacy standards of the Scientific Working Group for Forensic Document Examination (SWGDOC), gaining a thorough understanding of how to document examinations, observations, and results effectively. Through a combination of lecture and demonstrations, attendees will learn to maintain meticulous records that support the forensic examination process and facilitate both internal and external reviews. The presentation aims to enhance the consistency and reliability of forensic documentation, thereby strengthening the overall quality of forensic evidence examined by FDE's. By promoting best practices, this presentation will contribute to the continuous improvement of forensic document examination standards, ultimately benefiting the entire forensic community. This presentation will shine a light on the vast increase in specific note taking requirements, but participants will leave with practical techniques that can be immediately implemented to improve their documentation processes and ensure compliance with these more complex standards.

K16 Graphoscopy in the Digital Age: Revisiting Classical Principles in Light of Emerging Signature Technologies

Dineusa Maria Do Amaral, MBA, Judicial Expert for the Court of the State of Paraná, Foz do Iguaçu, Parana, Brazil; Cristiane Viana Barbosa, MA*, UFF, Universidade Federal Fluminense, Rio de Janeiro, Brazil; Anna Beatriz Rodrigues Geranio, University Estacio de Sá, Petrópolis, Rio de Janeiro, Brazil*

Learning Objectives: This work enhances the debate on modernizing graphoscopy by presenting a conceptual analysis that reaffirms the enduring importance of classical handwriting examination principles in digital scenarios. It aims to support the advancement of forensic training and the development of updated criteria for evaluating digital handwriting evidence, fostering collaboration between traditional forensic practices and emerging technological tools.

Impact Statement: This article addresses the challenges posed by digital signatures in the field of forensic handwriting examination, reinforcing the ongoing relevance of classical graphoscopic concepts. It aims to strengthen professional training and contribute to the refinement of technical guidelines used in analyzing digital writing evidence. By encouraging dialog between traditional forensic methods and emerging digital tools, this work supports a broader and more integrated approach to modern forensic practice.

Introduction: The digitization of documents and the growing adoption of technologies for electronic signatures have profoundly transformed the practice of forensic handwriting analysis. For many years, forensic handwriting analysis focused exclusively on handwritten text on paper. However, forensic handwriting analysts now face challenges posed by scanned images, mobile device inputs, biometric signatures, and even purely digital records based on cryptographic systems. Given this new reality, important questions arise: Do classical graphoscopic principles still apply in this context? How can spontaneity, rhythm, and graphic morphology be evaluated in records that no longer involve ink and paper? This paper aims to reflect on these questions, arguing that while the means of recording have changed, the basic principles that guide authorship identification remain valid. Furthermore, this paper argues that forensic document examiners should broaden and update their role by integrating knowledge of technology, biometrics, and digital analysis to meet emerging challenges.

Objectives and Methods: This study explores how classical graphoscopic principles can remain relevant in the context of digital and biometric signatures. Drawing on a theoretical and reflective approach, it examines how foundational elements of handwriting analysis adapt to modern technologies. This discussion builds on a literature review that includes both classical sources and recent research on behavioral biometrics, electronic authentication, and the challenges of analyzing scanned handwriting. The methodology is qualitative and exploratory, aiming to identify conceptual challenges and opportunities within current forensic practice.

Results and Discussion: The literature review revealed that although digitization and biometrics bring new ways of capturing handwriting, classical graphoscopic elements remain relevant. Features such as spontaneity, rhythm, and writing habits are still essential for authorship identification, though they now require new strategies for observation and interpretation. In the case of digitized signatures, technical limitations such as image resolution and lack of pressure or speed data hinder the complete application of traditional criteria. Nevertheless, examiners can still assess certain morphological and spatial features, provided they apply proper methodological caution. Biometric signatures captured via electronic devices offer greater forensic potential by preserving dynamic data. However, their reliability depends on standardization, file integrity, and the examiner's technical proficiency. For certified digital signatures under the ICP-Brasil system, there is no handwriting trace to be analyzed. In these cases, the expert's role shifts toward verifying document integrity, certificate authenticity, and temporal coherence. These observations highlight the need for forensic handwriting experts to broaden their skill set beyond pen and paper, incorporating metadata analysis, digital tools, and interdisciplinary collaboration.

Conclusion: Even amid technological changes that redefine how documents are signed and validated, the foundations of graphoscopy remain essential. While the methods of capturing handwriting evolve, the neuromotor and behavioral principles that shape writing continue to be critical for authorship assessment. Rather than being replaced, classical graphoscopy must evolve, expanding its scope and embracing innovation without abandoning its core principles. These findings raise further questions for the forensic community: What specific strategies can help align classical graphoscopic methods with digital signature technologies? How can experts ensure the reliability of biometric signatures while addressing their limitations? Moreover, what role will emerging tools play in the future of handwriting analysis and examiner training?[1-5]

K17 A Study of Baseline Alignment and Slant Within Various Handwriting Elements

Carl R. McClary, MS, Retired, Charleston, SC; Linton Aphzal Mohammed, PhD, Forensic Science Consultants, Inc., Poway, CA*

Learning Objectives: After attending this presentation, attendees will have a greater understanding of the level of consistency in how writers place characters in relation to a printed baseline. The study also shows the level of consistency in the slant of participants' writing. For both elements, signatures, sentences, phrases, and single words were analyzed. Additionally, other elements such as the effect of spatial constriction on slant and baseline alignment in signatures will be provided. The study is the second on this topic by the primary author, with the current one focusing on more experienced writers.

Impact Statement: The impact to the forensic science community will be the benefit of learning to what extent the characteristics of baseline alignment and slant are consistent. These characteristics are significant with respect to forensic document examination and are among those that examiners consider when forming an opinion on authorship. Those in training will find value in data that supports the tenets of consistency of baseline alignment and slant.

Abstract Text: The forensic document examination community has long utilized consistency of baseline alignment and slant as individualizing characteristics that provide strength to the resultant opinions in their work. For slant (slope), Kelly and Lindblom provide that it is the "most obvious features in an individual's handwriting."[1] Regarding disguise, they continue that "While gross changes in writing slant are relatively easy to achieve, slight changes in the slope are exceedingly difficult to maintain...". For baseline alignment, they define it as "the ruled or imaginary line on which the writing rests." In this study, a ruled line was utilized for subjects to replicate sentences, phrases, single words, and signatures. The form created for this study included instructions that either cursive or hand printing was allowed. For the seven requested signatures, a ruled line was provided for three of them and boxes, two smaller than the others, were provided for the remaining four. The spatial constrictions provided for in the boxes reflect real world circumstances, especially with business forms and digital signature tablets.

The results track those found in the 1997 published study by the primary author (1997 International Journal of Forensic Document Examination).[2] The earlier one, however, studied primarily college students, whereas the subjects in this study ranged from ages 18 to 91, with an average of 59. Males totaled 29 (36%), females 51 (64)%.

Those participants who received a "mixed" score for slant had variations generally greater than 20 degrees throughout the element being analyzed (e.g. sentences or phrases) and were considered not consistent. For those sentences considered to have been written with consistent baseline alignment there were some slight exceptions to that alignment, often occurring within the first word or words written.

Some participants exhibiting a greater than 20 degree variation for signatures were considered consistent if there was consistency of slant of similar characters within those signatures, representing a habit, nonetheless.

For the baseline alignment of signatures appearing on a written baseline, there was a score of 5.1% mixed, or 94.9% consistent. For the baseline alignment of signatures appearing within boxes, there was a score of 7.5% mixed, or 92.5% consistent. For all other elements (sentences, phrases, and single words) combined there was a score of 21.2% mixed, or 78.8% consistent. This score was not unexpected due to the highly variable conditions under which the writer was asked to perform, notably, lengthy writing and smaller words/phrases in which the writing instrument needed to be lifted and replaced from line to line.

Regarding analysis of slant, for signatures there were 5% mixed, or 95% consistent. For all other elements combined, there were 8.7% mixed, or 91.3% consistent. For both baseline alignment and slant elements, notations on the results of spatial constrictions will be provided.

K18 The Forensic Document Examiner Forum

Carl R. McClary, MS, Charleston, SC; Samiah Ibrahim, BSc, ForensInk, Ottawa, Ontario, Canada*

Learning Objectives: After attending this presentation, attendees will have access to new and different ideas, opinions, and methods to consider when approaching questioned document problems in the laboratory. These ideas and methods will represent experiences from different countries and cultures.

Impact Statement: The impact to the forensic science community would be the benefit to the attendees of an open exchange of ideas and viewpoints. As scientists, we often learn as much from another's thought processes and experiences as we do from books. The younger examiners can benefit from the experiences of the more-experienced examiners and those experienced examiners can benefit from seeing new and novel viewpoints.

Abstract Text: The concept of the Forensic Document Examiner Forum is not new to the Questioned Document community. In the authors experience, this format was first utilized at the Southeastern Association of Forensic Document Examiners (SAFDE) meetings in the early 1990s as a method of opening discussion on certain topics of interest to the members. At these meetings, there was a discussion starter on subjects upon which there may have been disparate opinions. Through forums of this type there have been many lively discussions on controversial topics. Not all discussions must necessarily be centered on difficult issues facing forensic document examiners. Discussions may also focus on the attendee's thoughts and interpretations of quotes from recognized texts in the field. Other discussions could begin with the conclusions and opinions of some of these famous authors in criminal and civil cases of notoriety, both past and present. This type of forum, one which is presented with international viewpoints, is an excellent way to poll attendees about their preferences on examination methods, conclusions, court testimony, or the current standards in the field. The Forum is particularly impactful for those examiners in training.

K19 Forensic Intelligence "Profiling" of Counterfeit Pharmaceutical Packaging Components

Vincent E. Salvatore, BS, MBA Candidate, CFE, GOSI Certified, Merck & Co., West Point, PA; Geoffrey D. Albert-Bolinski, BA, Merck & Co., West Point, PA; Christopher J. Hopkins, MS, Merck & Co., West Point, PA; Roy D. Ford, MBA, Merck & Co., West Point, PA; Anthony L. Zook, PhD, Merck & Co., West Point, PA*

Learning Objectives: After attending this presentation, attendees will: (1) understand the global rise in counterfeit pharmaceutical incidents and its impact on public health and safety, (2) recognize the limitations of targeting individual threats and the need for a strategic shift toward dismantling networks instead, (3) learn how questioned document techniques and forensic intelligence are used to profile threats and conduct link analysis, and (4) explore the role of artificial intelligence in automating manual workflows.

Impact Statement: This work advances forensic science by shifting focus from isolated criminals to dismantling entire threat networks. Through questioned document analysis and AI-driven image comparison, forensic experts can more effectively trace and disrupt large-scale fraudsters—enhancing global public health and safety efforts.

Abstract Text: The proliferation of counterfeit pharmaceutical medicines is trending upwards globally, increasing their already-significant impact on health care providers, law enforcement officials, government agencies, and most importantly: public health and safety. Within just 4 years from 2020 to 2024 from data provided by participating companies, the Pharmaceutical Security Institute reported a near 50% increase in unique counterfeiting, diversion, and theft events (4,369 à 6,430); spanning at least 17 drug therapeutic areas in close to 150 countries.[1]

The efforts addressing this escalating threat through targeting individual sellers have proven less effective, as these bad actors frequently resurface in new forms or locations. Instead, the focus is gradually shifting to the identification, comprehension, and dismantling of threat networks, as well as the illicit manufacturers of which they are comprised. These threats are dynamic, complex, and frequently evolving making it considerably difficult to trace samples back to their origin(s).

This presentation will touch on how this complexity is tackled, with a focus on how questioned document techniques partnered with forensic intelligence is utilized to characterize threat profiles through the analysis of both subtle and overt defects. It will additionally speak to how artificial intelligence, by way of automated image comparison, is finding expanded applications in a traditionally manually operated space. Finally, the presentation will culminate with a case study in which the methods presented were able to assist investigative and law enforcement partners discern multiple criminal networks involved with the same illegitimate product resulting in prioritized enforcement of those organizations. At its core, it highlights how fundamental forensic principles enhanced by modern tools remain vital in the fight against pharmaceutical fraud.

K20 Document Date Evidence From the Aptos Font, and Kerning in Microsoft Word

Thomas Phinney, MSc, Font Detective LLC, Portland, OR*

Learning Objectives: After attending this presentation, attendees will be aware of the date implications of the use of several specific fonts, including Aptos (and its early version, Bierstadt), as well as other new "default font candidates." They will also learn how Word's recent changes to default document format settings affect typical documents, and which changed setting is least likely to be adjusted by users.

Impact Statement: Applying the information from this presentation to questioned documents will, for documents using the fonts/features in question, allow document examiners to determine that some documents either could not have been created on their purported dates, or in other cases were unlikely to have been created on their purported dates.

Abstract Text: As most are already aware, Microsoft's default font change from Calibri to Aptos is of great interest, because (like Calibri) Aptos could not have been used before it was designed, and was much more likely to be used once it became Microsoft's default font in 2024. But Aptos was already available as early as 2021 under an earlier name: Bierstadt. Phinney discusses and shows subtle spacing differences between Aptos and Bierstadt, and discusses the timeline of availability.

Less well-known than the Calibri > Aptos change were all the *other* default document changes Microsoft Word made at the end of 2024: changes to default margins, point size and kerning. Margins and point size are commonly adjusted by users, but turning on kerning was quite uncommon—potentially providing supporting evidence regarding document creation dates.

In the overwhelming majority of cases, examining a document can determine the fonts used in a document and determine some, and possibly all, important formatting applied to the text, from document margins to whether built-in font kerning was active. This presentation will point out key identifying features of Aptos and Bierstadt that collectively differentiate them from other fonts, as well as how one can—sometimes—differentiate the two.

Document Analysis; Typeface Identification; Kerning

K21 The Use of Civil Service Handwriting in Foreign Identity Documents

Carolyn Bayer-Broring, MFS, Homeland Security Investigations Forensic Laboratory, McLean, VA*

Learning Objectives: While handwriting is become less visible in the United States in the issuance of identification documents such as certificates of birth, marriage, death, etc., there are still countries in the world where handwritten documents are more widely used. Documents from countries such as Haiti and Liberia can be observed with handwritten entries that look very similar from one issuing authority to the next, and yet the handwriting that is used differs from the "traditional" handwriting systems that many are familiar with having been taught in elementary school. This system of writing, where multiple issuing authorities utilize a similar handwriting style, is often referred to as "Civil Service Hand." This talk will delve into the history and use of Civil Service Hand in the issuance of identification documents.

Impact Statement: This talk will introduce viewers to the concept, style, and usage of the Civil Service Hand in the production and preparation of international identification documents. For viewers who don't see foreign-issued documents regularly, this may be of particular interest.

Abstract Text: The Homeland Security Investigations Forensic Laboratory is the only federal laboratory in the United States tasked with the examination of international travel and identification documents. While the phrase "travel and identification document" might traditionally make one think of passports, visas, identification cards, and drivers licenses, the scope of our examinations goes much further, to encompass a wide variety of documents used to establish nationality or citizenship, or to aid in the conversion of one's status within the US. This wider variety of documents may include things such as certificates of birth or death, marriage or divorce.

While handwriting is becoming less visible in the US in the issuance of these sorts of identification documents, in light of the efforts to make documents electronically accessible and fraud-proof, there are still countries in the world where handwritten documents are still widely used and accepted. Documents from countries such as Haiti and Liberia can be observed with handwritten entries that often bear handwriting that looks very similar from one issuing authority to the next, and yet the handwriting that is used differs from the "traditional" handwriting systems that many are familiar with having been taught in elementary school. This system of writing, where multiple issuing authorities utilize a similar handwriting style, is often referred to as "Civil Service Hand." This talk will delve into the history and use of Civil Service Hand in the issuance of identification documents.

K22 An Overview of the Voluntary Licensure Program for Forensic Document Examiners in the State of Texas: Updates and Eligibility Requirements

Keelie Johnson, BASc, Texas Department of Public Safety- Crime Laboratory Division, Austin, TX*

Learning Objectives: The objectives of this presentation are to: (1) summarize the current structure and purpose of the Texas voluntary licensure program specifically designed for Forensic Document Examiners (FDEs); (2) detail the updated eligibility requirements for voluntary licensure, including education, training, and casework experience relevant to FDE practice: (3) assess how recent updates align with national standards (e.g., Scientific Working Group for Forensic Document Examination [SWGDOC], American National Standards Institute/Academy Standards Board [ANSI/ASB], and Organization of Scientific Area Committees [OSAC]) and professional expectations within the FDE community; (4) identify the role of the Texas Department of Public Safety Crime Laboratory Division in shaping licensure criteria and promoting discipline-specific rigor; and (5) evaluate the benefits of voluntary licensure for FDEs, including professional recognition, standardization of practice, and enhanced credibility in the forensic and legal communities.

Impact Statement: This presentation serves as a vital resource for the forensic science community by delivering a comprehensive overview of the voluntary licensure program for FDEs administered by the Texas Forensic Science Commission (TFSC). The dissemination of this information supports ongoing efforts to professionalize forensic document examination, encourages continued professional development, and fosters greater confidence among legal stakeholders and the public in the reliability of forensic testimony.

Abstract Text: This presentation revisits and expands upon the voluntary licensure program for Forensic Document Examiners in Texas, building upon the foundational updates shared in the 2021 presentation. In response to ongoing discussions surrounding forensic science standardization and practitioner accountability, the Texas Forensic Science Commission (TFSC) has continued to evolve its licensure program's framework, including provisions for voluntary licensure of forensic document examiners (FDEs).

A key feature of the updated program is the alignment of licensure eligibility requirements with established national standards and best practices for the profession. The Texas Department of Public Safety Crime Laboratory Division's Forensic Document Examination discipline played an instrumental role in refining these eligibility criteria, offering critical recommendations to ensure that individuals seeking licensure possess the requisite knowledge, training, and practical experience. These recommendations emphasize the importance of formal education, documented casework proficiency, and ongoing professional development. By harmonizing the state's licensure requirements with the recognized standards of the professional community, this initiative serves to elevate the quality of Forensic Document Examination, safeguard the integrity of criminal investigations, and foster public confidence in the accuracy of forensic findings.

The presentation will explore the structure of the voluntary licensure pathway, including examination protocols, continuing education mandates, and adherence to ethical guidelines. Attendees will gain a clear understanding of the licensure process, benefits of participation, and the TFSC's strategic direction for quality assurance in forensic document examination.

K24 An Analysis of Stroke Order in Digitized Handwritten Intersections

Cristiane Viana Barbosa, MA, Universidade Federal Fluminense, Rio de Janeiro, Brazil; Dineusa Maria Do Amaral, MBA*, Judicial Expert for the Court of the State of Paraná, Foz do Iguaçu, Parana, Brazil; Anna Beatriz Rodrigues Geranio, University Estacio de Sá, Petrópolis, Rio de Janeiro, Brazil*

Learning Objectives: By the end of this presentation, participants will understand whether applying and comparing different digital filters can help determine the priority of handwritten strokes in intersections. They will also recognize the relevance of this type of analysis in broader forensic handwriting examinations.

Impact Statement: This study introduces a structured and comparative approach to using digital filters in the forensic analysis of handwriting intersections. It reinforces the relevance of these tools as support for broader document analysis and highlights the need for more advanced techniques, such as AI-based models.

Introduction: Analyzing stroke sequence in handwriting intersections is a recurring challenge in forensic handwriting examination. Determining which stroke came first can offer important clues about authorship, tampering, or forgery. With advances in digital tools and filters, there is a growing interest in improving the examination of digitized documents, where physical traces are no longer available..

Objectives and Methods: This study evaluated the effectiveness of digital filters in identifying stroke sequences in handwritten intersections. The team created eight controlled models using blue ballpoint pens of equal thickness, designing each intersection in horizontal or vertical directions. Samples were scanned at 300 and 600 dpi and saved in JPEG and PDF formats. We applied a sequence of filters using Fiji/ImageJ to enhance stroke features::

- Find Edges
- Difference of Gaussian
- Enhance Local Contrast (CLAHE)
- Tubeness
- Sharpen
- Bandpass
- Skeletonize
- Analyze Skeleton
- Manual contrast adjustments
- Morphological operations (e.g., erosion and dilation)

In PhotoScape, we applied Negative and Emboss filters, along with brightness, contrast, and hue adjustments to highlight overlaps and texture. In Peritus, we used brightness, contrast, and CLAHE filters, plus zoom and annotation tools. We also tested the Luminance Gradient filter from Photo Forensics to detect light intensity variations, suggesting stroke overlap. The team qualitatively analyzed each image to assess whether filters helped determine stroke order.

Results and Discussion: The digital filters revealed edge, brightness, and contrast patterns. However, none consistently determined stroke order. CLAHE improved the definition in some overlapping regions but gave no conclusive results. The Luminance Gradient filter highlighted intensity differences but was also insufficient as a standalone forensic tool.

These findings show that while digital tools enhance the visualization of subtle features in scanned documents, they do not offer reliable accuracy when used alone to determine stroke precedence. The limitations underscore the need for more advanced methods to address this persistent challenge in handwriting intersection analysis.

Conclusion: The filters tested on eight controlled samples of horizontal and vertical intersections did not reliably determine which stroke came first. Although all filters helped enhance visual elements, none provided conclusive forensic results. These findings confirm the limitations of basic visual and computational tools in analyzing stroke order in digitized handwriting. Still, this analysis is essential in forensic handwriting examination, especially in evaluating allograph construction. It also reinforces the expert's role in conducting a comprehensive analysis of the questioned document, not just the crossing point.

For future research, we suggest continuing to apply and compare other filters and image processing techniques to explore alternatives with better outcomes. In a later phase, we recommend developing more robust methods based on artificial intelligence and supervised learning. We propose building a database of handwriting intersections with known stroke order to support testing, algorithm training, and model development, enhancing the accuracy and efficiency of forensic analyses, especially when the original handwritten document is unavailable..[1-5]

L1 A Complete and Optimized Toxicological Database Solution for Investigative and Routine Testing on GC/MS

Jeremy P. Smith, MSc, Shimadzu Scientific Instruments, Columbia, MD*

Learning Objectives: Attendees/viewers will receive a thorough overview of a simple yet robust database solution for both routine and investigative toxicology work. Key objectives will include a detailed explanation of the database, which includes chromatography and detection parameters for more than 2,000 compounds relevant to the forensic toxicologist. Additionally, a workflow demonstration will be shown detailing how Tandem Mass Spectrometry (MS/MS) mode can be used to help discern specific chemical structures of a compound, which can help identify seized or unknown drug samples.

Impact Statement: This workflow introduces a reliable, user-friendly workflow on one of the communities most trusted analytical devices, Gas Chromatograph/Mass Spectrometry (GC/MS). This streamlined database solution simplifies method development for the forensic toxicologist, with the added confidence of compound comparison from a known library for confirmation. Furthermore, this database workflow is suitable for the seized drug chemist by providing scan data to discern chemical fingerprints that can be used to help identify unknown substances.

Abstract Text: Gas chromatography (GC) and gas chromatography-mass spectrometry (GC/MS) technology has long been a reliable and ubiquitous tool in analytical forensic work. This project discusses a simple yet highly robust workflow which was used for the detection and structural elucidation of synthetic cathinones.[1] The GCMS Forensic Toxicological Database version 2 is a powerful software add-on for the LabSolutions software suite from Shimadzu. Complete with all analytical parameters, the forensic toxicology database presented here alleviates the guesswork of method development. Including more than 2,000 relevant toxic substances, this robust solution is designed to streamline analysis by offering simultaneous screening and confirmation determinations. This database provides an impactful solution for forensic toxicologists using a well-established instrument in the forensic laboratory.

Method development can be time-consuming and challenging. Optimizing the analytical conditions for toxicological compounds is the first of several hurdles for a complete workflow. The GCMS Forensic Toxicological Database offers multiple pre-established methods for the purpose of routine testing for drug chemists and postmortem toxicologists. Like method development, data review takes time and skill to ensure the process is thorough and accurate. The GCMS Forensic Toxicology Database assists in this review by comparing data to a library of known compounds. Additionally, users have access to supplemental compound libraries, such as those from Wiley KnowItAll and the National Institute of Science and Technology (NIST). This database also allows the user to create smaller, focused sub-lists of compounds to provide a more concentrated workflow experience. Users may also manually update the database to ensure their analytical workflows stay current with the drug landscape. This database is designed to simplify method development and data review.[2]

The GCMS Forensic Toxicological Database contains unique identifying information for more than 2,000 compounds. These indicators include compound name, mass spectrum, retention time, ion ratios, and mass chromatograms. Once a sample is properly prepared, it may be analyzed by GCMS and the data compared to these known libraries for easy identification (1). The GCMS Forensic Toxicological Database streamlines the analysis and data review components of this workflow. Chromatograms are compared to libraries based on ion ratios, mass spectrum, and established retention times. Data review does not require manually searching through the total ion chromatogram (TIC), thus expediting the review process. Confirmation and quantitative results may be obtained by the addition of internal standards and known reference standard analysis.[1]

The GCMS Forensic Toxicological Database also includes a key feature for seized drug analysis. Upon initial inspection, these samples are considered unknown compounds and require sufficient investigation to discern proper identification. This GCMS database tool offers MS/MS mode analysis to help elucidate possible key chemical structures for unknown compound identification.[1] This added functionality makes the GCMS forensic toxicological database both an attractive and practical solution for routine and investigative analysis. No other database solutions contain complete analytical parameters, access to standard, third-party, and manually created compound libraries, and the tools necessary to conduct robust structural analysis in one dynamic software tool.[2]

L3 A Toxic Relationship: Advanced Analytical Screening Techniques for Decomposed Specimens

Rachel Lindenberger, PhD, North Carolina Office of the Chief Medical Examiner, Raleigh, NC; Paul Crowley, BS, North Carolina Office of the Chief Medical Examiner, Raleigh, NC; Sandra Bishop-Freeman, PhD, NC Office of the Chief Medical Examiner, Raleigh, NC*

Learning Objectives: After attending this presentation, attendees will be able to recognize the advantages of utilizing High-Resolution Mass Spectrometry (HRMS) screening techniques for decomposed postmortem specimens, with a focus on an Orbitrap system in full scan mode compared to targeted Parallel Reaction Monitoring (PRM).

Impact Statement: This presentation will impact the forensic science community by helping practitioners recognize and explore solutions to the analytical challenges associated with decomposed toxicological specimens and strategies to address them.

Abstract Text: The aim of this study is to explore how reducing the sample volume during extraction and using different Orbitrap acquisition modes can reduce the effects of decomposition products on analysis.[1] From 2018 to the summer of 2024, the North Carolina Office of the Chief Medical Examiner Toxicology Laboratory relied upon a targeted PRM methodology as one of its primary screening techniques. A 0.5mL aliquot of sample was subjected to a protein precipitation extraction using 3mL of acetone and reconstituted with 0.3mL phosphate buffer (pH 6.5). Instrumental analysis was performed using a ThermoScientific© Ultimate 3000 LC coupled to a ThermoScientific© Q Exactive Focus Orbitrap using a PRM method that utilized a targeted inclusion list. A full scan HRMS screening method was validated in accordance with ANSI/ASB 036 and implemented in summer 2024. In this methodology, a 0.25mL aliquot of sample was subjected to a salt-assisted protein precipitation extraction using 0.25mL of 3M ammonium acetate and 2.5mL of acetonitrile and reconstituted with 0.1mL of 90:10 (v:v) water:methanol. Instrumental analysis was performed using a ThermoScientific© Vanquish LC coupled to a ThermoScientific© Q Exactive Focus Orbitrap using full scan acquisition at a resolution of 70,000 with data independent fragmentation along with an exclusion list. Additional instrument parameters are summarized below.

A case example comparing the two methodologies demonstrates the advantages of the new full scan HRMS drug screen. Two decedents were found decomposing in a house with powder and drug paraphernalia between them. Screening was initially performed for both decedents using the targeted PRM methodology. Decedent 1 presumptively screened positive for fentanyl, and it confirmed in the liver at 330 ng/g. Decedent 2 did not screen positive for any of the target analytes. As the decedents were found together, there was a concern that decomposition was possibly suppressing and/or interfering with fentanyl in the screen, resulting in a false negative for decedent 2. The HRMS Orbitrap full scan screen was validated during the timeframe of these deaths, and it was applied to decedent 2. The full scan screen for decedent 2 was subsequently found to be presumptively positive for fentanyl, and it confirmed in the liver at 58 ng/g. This amount is above the LOD for both screening methods. Therefore, it appears that the lower sample volume resulted in a cleaner extract that was less prone to ion suppression caused by decomposition. Likewise, the HRMS full scan method was better able to leverage the high-resolution capabilities of the instrument compared to the PRM method to detect fentanyl.

	Targeted PRM	Full Scan
Column	ThermoScientific Hypersil Gold PFP (100x2.1 mm, 3 µm)	ThermoScientific Hypersil Gold C18 (100x2.1 mm, 3 µm)
Mobile Phase A	Water+0.1%FA	10 mM Ammonium Formate in water with 0.1% FA
Mobile Phase B	Methanol+0.1% FA	Methanol+0.1% FA
Column Temp	40 ºC	
Flow Rate	0.5 mL/min	
Gradient	2% B for 0.5min 2-95% B in 7min	1% B for 0.8min 1-2% B in 0.2min 2-98% B in 9.5min
MS/MS Resolution	17,500	
Isolation Window	2.0 *m/z*	0.8 *m/z*
Fentanyl LOD	1 ng/mL	0.5 ng/mL

L4 Advancing Forensic Sample Preparation: Capsule Phase Microextraction (CPME) as an Efficient Tool for Trace Evidence Analysis

Abuzar Kabir, PhD, Global Forensic and Justice Center and Department of Chemistry and Biochemistry, Florida International University, Miami, FL; Kenneth G. Furton, PhD, Florida International University, Miami, FL*

Learning Objectives: This presentation will describe the principles, fabrication, and practical application of CPME for trace-level detection of illicit drugs in complex forensic matrices, compare its analytical performance to conventional extraction methods, and evaluate its advantages for improving sustainability, chain-of-custody integrity, and efficiency in forensic toxicology workflows.

Impact Statement: This presentation demonstrates how CPME can significantly advance forensic toxicology by providing a greener, more efficient, and field-deployable alternative to conventional sample preparation methods. By enabling ultra-trace detection of illicit drugs in challenging postmortem matrices with enhanced sensitivity, reproducibility, and minimal solvent use, CPME supports more reliable evidence generation, strengthens chain-of-custody integrity, and aligns with modern sustainability goals. Adoption of CPME has the potential to improve case resolution timelines, reduce laboratory costs, and promote innovation in routine forensic workflows.

Abstract Text: In forensic science, the ability to isolate and concentrate trace-level analytes from complex matrices is paramount for reliable qualitative and quantitative determinations. Capsule Phase Microextraction (CPME) is an emerging microextraction technique that integrates the advantages of conventional solid phase microextraction (SPME) and fabric phase sorptive extraction (FPSE) while addressing their limitations in terms of sorbent stability, reusability, and extraction efficiency.[1-4]

CPME employs a robust, sol–gel derived sorbent encapsulated within a porous, inert membrane, forming a self-contained extraction device that can be directly immersed or used in headspace configurations. This unique design enhances analyte enrichment, minimizes matrix interferences, and enables straightforward handling, transportation, and storage of forensic samples post-extraction— critical factors for maintaining chain of custody and ensuring sample integrity.

This presentation highlights the fundamental principles of CPME, its fabrication process, and its recent applications in forensic toxicology and trace evidence analysis, including the detection of illicit drugs, explosives residues, and environmental contaminants in biological fluids and postmortem samples. Method validation studies demonstrate CPME's high extraction recoveries, excellent reproducibility (RSD < 5%), and remarkable limits of detection in the sub-ng/mL range, making it a viable alternative to conventional extraction methods.

The integration of CPME with advanced instrumental techniques such as GC–MS/MS and LC–MS/MS further enhances its potential for high-throughput, sensitive, and cost-effective forensic analyses. The presentation will also discuss practical considerations for field deployment, method development, and potential future directions for automating CPME in routine forensic workflows.

By offering a green, user-friendly, and highly effective sample preparation platform, CPME represents a significant advancement toward more sustainable and reliable forensic analytical practices.

L5 Analytical Challenges in the Detection of Δ8-Tetrahydrocannabinol and Its Metabolites in Dried Urine Spots

R. Deanna Brambila, MSFS, Sam Houston State University, Houston, TX; Eduardo Geraldo de Campos, PhD, Sam Houston State University, Huntsville, TX*

Learning Objectives: After attending this presentation, attendees will gain knowledge on an analytical workflow and its constraints for the detection of cannabinoids in Dried Urine Spots (DUS). More specifically, attendees will learn the limitations related to the recovery of the target cannabinoids and matrix effects in DUS.

Impact Statement: This presentation will impact the forensic community by providing preliminary data on the extraction efficiency and matrix effects observed in the analysis of Δ8-Tetrahydrocannabinol (Δ8-THC)and its metabolites in DUS using Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS). This study also serves as a basis for future work in implementing DUS for the detection of cannabinoids and other potential analytes.

Abstract Text: An alternative sampling technique gaining attention in forensic toxicology is DUS, which requires reduced volume of urine collected on paper. DUS also provides the ability for easy storage and transportation. Currently, no methods have targeted Δ^8-tetrahydrocannabinol (Δ^8-THC) and its metabolites in DUS.

DUS were prepared by spiking 25 µL of pooled human urine specimens to a previously punched spot from Whatman™ 903 cards and dried at room temperature, protected from light. A two-step extraction combining methanol extraction followed by an acidic liquid-liquid extraction with acetate buffer (pH 4 4.5) and hexane/ethyl acetate was developed based on previous literature.[1] Chromatographic separation was performed using an Agilent Poroshell 120 EC-C18 column (100 x 2.1 mm, 2.7 µm) and a flow rate of 0.5 mL/min in an Agilent 1290 Infinity II liquid chromatograph. Mobile phases were 0.1% formic acid in water and 0.1% formic acid in acetonitrile. The gradient was adapted from a method previously reported in the literature.[2] Mass spectrometric analyses were performed using an Agilent 6470 mass spectrometer operated in positive electrospray ionization (ESI) mode.

Although this study mainly focused on Δ^8-THC and its metabolites, a chromatographic method for the separation of Δ^9-THC and COOH-Δ^9-THC was developed to achieve an acceptable separation between the isomers. For Δ^9-THC and Δ^8-THC, the retention times were 9.626 and 9.853 min, respectively. The retention times for COOH-Δ^8-THC and COOH-Δ^9-THC were 5.034 and 5.224 min, respectively.

The recovery of cannabinoids from DUS ranged from 31.9-65.2% (at 50 ng/mL) and from 27.4-49.3% (at 200 ng/mL). Matrix effects were acceptable (below 25%) only for Δ^8-THC and 11-OH-Δ^8-THC. A time-dependent decrease in response for all analytes was observed after 24h and 48h at room temperature, attributed to instability associated with decreased extraction efficiency. A tentative limit of detection of 50 ng/mL met the positive identification criteria of retention time (± 0.2 min), ion ratios (within 20% of the target), signal-to-noise ratio (S/N) (at least 3:1), and Gaussian peak shape.

Currently, the implementation of DUS for the analysis of Δ^8-THC and its metabolites still presents some limitations, mostly due to low recovery of these substances in DUS. Analysis of the stability of cannabinoids in DUS demonstrated a time-dependent decrease in peak areas after 24h and 48h at room temperature, which suggests that the extraction efficiency is diminished over time. Although challenges existed, this study demonstrated that the method was, in fact, able to detect Δ^8-THC and its metabolites in DUS, using a two-step extraction, which had not been demonstrated before. A tentative cutoff of 50 ng/mL is in line with reported screening methods applicable to the analysis of routine specimens, especially in clinical cases.[3] Nevertheless, future investigations into the matrix effects using more sources, long-term stability and recovery beyond 48h, and the possibility to incorporate conjugate metabolites hydrolysis are recommended.

L6 Benzodope and Beyond: The Detection of Benzodiazepine and Opioid Mixtures in Blood and Alternative Matrices Using LC/MS/MS

Elizabeth Greco, BS, Sam Houston State University, Fate, TX; Meredith Robbins, MS, Travis County Medical Examiner, Austin, TX; Britni Skillman, PhD, Sam Houston State University, Huntsville, TX*

Learning Objectives: From this presentation, attendees will understand analytical performance differences between traditional and alternative toxicological matrices in the detection of Novel Psychoactive Substances (NPS), with a focus on NPS benzodiazepine and opioid drug classes. Attendees will learn about the validation of a method for detecting novel psychoactive benzodiazepines and opioids in forensic toxicology samples covering multiple matrices.

Impact Statement: This presentation will impact the forensic science community by offering a method by which NPS benzodiazepines and opioids can be determined in alternative forensic matrices in addition to traditional matrices such as blood. This will allow for a broader application within case scenarios where traditional matrices may not be available or in which additional matrix information may supplement results interpretation.

Abstract Text: Benzodiazepines and opioids are both CNS depressants that can produce effects such as decreased alertness, memory loss, relaxation, and fatigue.[1] Benzodiazepines are typically prescribed to treat anxiety, insomnia, and seizures, whereas opioids are usually prescribed for chronic pain.[2,3] Used in combination, they can produce synergistic effects, increasing the likelihood of adverse events with potentially fatal consequences. These risks may be increased in the illicit drug market where users may unknowingly consume this combination.[4] Additionally, novel psychoactive substances (NPS) from these classes have been identified in forensic casework.[5] Not only does this pose a threat to public health, but it also increases the need for detection of these compounds within forensic matrices. Traditionally, postmortem matrices include blood, urine, and vitreous humor. However, these may not always be available, such as in cases of decomposition, or results may be complicated by redistribution. In those scenarios, other matrices must be considered such as liver, spleen, or other soft tissues such as muscle or adipose tissue to support the interpretation of analytical results.[6]

In this study, a solid-phase extraction (SPE) method was developed and validated (per ANSI/ASB 036) for the detection of 10 analytes in whole, preserved bovine blood (250 µL) using liquid chromatography-tandem mass spectrometry (LC-MS/MS). Samples were buffered (100 mM phosphate buffer, pH 6.0), extracted on Cerex® Clin II SPE columns with a series of washes, and eluted with 5% ammonium hydroxide in ethyl acetate. This method was applied to tissue homogenates (poultry and bovine liver, heart, and fatty tissues). Analytes included bromazolam, clonazolam, desalkylgidazepam, etizolam, fentanyl, flualprazolam, flubromazepam, flubromazolam, *ortho*-methylfentanyl, and *para*-fluorofentanyl. Analysis was performed on an Agilent 1290 Infinity II LC coupled to an Agilent 6470 LC-MS/MS using gradient elution on a Poroshell 120 Phenyl Hexyl column (2.1 x 100 mm, 2.1 µm). Mobile phases consisted of 0.1% formic acid in water and in acetonitrile, respectively.

Quantitative performance was met with a blood calibration range of 0.1–100 ng/mL for opioids and 0.5–500 ng/mL for benzodiazepines. Bias and precision were assessed using controls in blood and matrix-matched controls for alternative matrices. Limits of detection (LOD) were administratively set at the limits of quantitation (LOQ) (0.1 or 0.5 ng/mL in blood) to ensure no quantifiable carryover. Tissue LOQs varied from 0.5–10 ng/mL dependent on analyte. Matrix effects in blood did not exceed ±25%, though some analytes showed variability between tissue sources (>20% CV). Additional blood and tissue matrices were assessed to determine there was no impact to LOD. The method was free from interferences from internal standards, matrices, or commonly encountered drugs of abuse. However, sample homogenization, extraction performance, and detection in tissues were inherently more variable, so the validation of the alternative matrices and tips for overcoming these challenges will be briefly discussed. Despite these challenges, detecting analytes in tissue samples provides critical value in postmortem toxicology when blood is unavailable or compromised. This method enhances the scope and flexibility of toxicological analysis in complex forensic cases, contributing to more accurate determinations of NPS in intoxications and deaths.

L7 Can *Lucilia Sericata* Larvae Produce Ethyl Glucuronide? An Experimental Study for Forensic Implications

Erika Buratti, PhD, University of Macerata, Macerata, Marche, Italy; Giulia Ricchezze, University of Macerata, Macerata, Marche, Italy; Alice Cerioni, PhD, University of Macerata, Macerata, Marche, Italy; Marta Cippitelli, PhD, University of Macerata, Macerata, Marche, Italy; Roberto Scendoni, MD, PhD, University of Macerata, Macerata, Marche, Italy; Gianmario Mietti, PhD, University of Macerata, Macerata, Marche, Italy*

Learning Objectives: This study investigates the ability of *Lucilia sericata* larvae to absorb ethanol and produce Ethyl Glucuronide (EtG) after feeding on ethanol-containing substrates. The results indicate that the metabolic and excretory systems of *Lucilia sericata* (Meigen, 1826) (Diptera, Calliphoridae) larvae are not responsible for EtG production. These findings emphasize critical interpretive considerations for toxicological analysis and underscore the need to better understand the metabolic capacities of necrophagous insects in forensic investigations.

Impact Statement: This discovery is essential for understanding the biochemical interactions between larvae and their environment. Moreover, the absence of EtG synthesis in larvae despite ethanol exposure reaffirms the value of EtG as a reliable external biomarker of antemortem alcohol consumption as it is not subject to insect-driven metabolic interference. This approach has the potential to enhance the accuracy of postmortem investigations by offering deeper insights into the biological and environmental conditions preceding death. By incorporating larval analysis into forensic protocols, practitioners may improve their ability to reconstruct the circumstances surrounding death.

Abstract Text: This study examines whether *Lucilia sericata* larvae are capable of producing ethyl glucuronide (EtG) after feeding on ethanol-containing substrates. The goal is to determine whether EtG detected in larvae collected from a corpse may be attributed to postmortem formation or reflects actual antemortem ethanol exposure. The findings aim to improve the accuracy of postmortem toxicology by clarifying biological and environmental contexts before death.

Forensic entomotoxicology explores the role of necrophagous insects in toxicological analysis, particularly in cases where conventional biological samples are unavailable or compromised.[1] Ethyl glucuronide (EtG) is a direct biomarker of alcohol consumption, formed as a result of repeated alcohol intake.[2] *Lucilia sericata* (Meigen, 1826) (Diptera, Calliphoridae) is a widely distributed necrophagous species in Italy, often among the first to colonize remains, and is extensively studied in forensic entomotoxicology.[3,4]

Understanding whether these insects can absorb ethanol from their feeding substrate and metabolize it into EtG has important implications in forensic toxicology and pathology. To date, no studies have definitively addressed this question.

To test this hypothesis, *Lucilia sericata* larvae were reared in a laboratory setting and divided into three groups. G_EtOH: meat spiked with ethanol; G_EtG: meat spiked with EtG; G_Neg: control group with unaltered meat. 40g of substrate were used for each group. For G_EtOH group, 12.5ml of ethanol were added to the meat; for G_Etg group, 200µg of EtG in aqueous solution were added. G_EtOH, G_EtG and G_Neg larvae were transferred to their specific substrate immediately after hatching. Each tested group consisted of between 20 and 25 larvae. EtG analysis was performed using Ultra-High-Performance Liquid Chromatography analysis (UHPLC), while ethanol detection was carried out using headspace Gas Chromatography-Flame Ionization Detector (GC-FID), employing both validated and adapted methods for larval matrices.[5,6] The larvae were left free to feed on their substrate and were subsequently sample at 24h and 72h. The pupae, formed at the end of the larval cycle, were sampled at 120h. This enabled assessment of whether time influenced EtG formation. The analyses for EtG by UHPLC and ethanol by GC-FID were conducted on groups of three larvae or pupae each (300 mg total sample), to allow a better resolution of the analysis results.

At the conclusion of the study, EtG was not detected in either the larvae or pupae from the G_EtOH group, although ethanol was present, confirming its absorption. The G_EtG and G_Neg groups yielded expected results, testing positive and negative for EtG, respectively. This is the result of an initial exploratory study with possible applications in the forensic field. These results reinforce the interpretation of EtG as an indicator of antemortem alcohol use when found in larvae, as its presence reflects preexisting levels in the corpse rather than de novo synthesis by the insect. This study highlights critical interpretative issues in toxicological analysis and supports the growing importance of understanding insect metabolism in forensic science. With ongoing advances in analytical techniques and experimental practice, the use of carrion-feeding larvae as forensic tools may increasingly become standard practice.

L8 The Classification of Mitragynine and 7-Hydroxymitragynine of Commercial Online Kratom Products, Local Kratom Bars, and Smoke Shops Via LC/MS/MS

Michaela Clarke, MS, Global Forensic and Justice Center and Department of Chemistry and Biochemistry, Florida International University, Miami, FL; Anthony P. DeCaprio, PhD, Florida International University, Miami, FL; Leonardo Maya, PhD, Florida International University, Miami, FL; Kenneth G. Furton, PhD, Florida International University, Miami, FL*

Learning Objectives: This presentation will provide attendees with insights into the variability of mitragynine and 7-hydroxymitragynine concentrations across various points of purchase, including online, bars, and smoke shops.

Impact Statement: Since 2013, the state of Florida has reported 587 overdose deaths involving kratom, including 46 cases attributed solely to kratom. Florida also represents the leading state in terms of kratom consumption and the prevalence of kratom bars.[1] This presentation aims to evaluate the concentrations of major kratom alkaloids in commercial products, thereby contributing to a better understanding of the unregulated kratom market.

Abstract Text: Kratom (*Mitragyna speciosa*), a plant indigenous to Southeast Asia, has gained increasing popularity in the United States as an alternative to addictive substances. The plant contains more than 25 alkaloids, with mitragynine representing approximately 66% of the total alkaloid content and 7-hydroxymitragynine about 2%.[2] Ingesting doses below 5 g generally produces stimulant-like effects, while consumption of doses greater than 15 g has been associated with psychosis, seizures, and nausea.[3]

This study aims to quantify concentrations of mitragynine and 7-hydroxymitragynine across kratom products sold online, bars, and smoke shops. Samples included powders, teas, shots, gummies, and tinctures.

A method was developed using an Agilent 1290 UHPLC system coupled to a 6460 LC/QqQ/MS-MS with a Zorbax Eclipse Plus C18 column (3.0 x 50 mm, 1.8 mm) and a guard column, operated in positive electrospray ionization mode. The aqueous mobile phase consisted of 5 mM ammonium formate in 0.1% formic acid (A) and 0.1% formic acid in acetonitrile. The gradient was performed at 95% A for one minute and 5% B for six minutes. Mitragynine, 7-hydroxymitragynine, and corresponding deuterated samples of mitragynine and 7-hydroxymitragynine were purchased from Cayman Chemical. Ten milligrams of kratom powder were dissolved in acidified acetonitrile, inverted 10 times, and allowed to settle for 2 hours. The top liquid was collected, and a 1ppm sample was prepared for analysis.

A calibration curve was created with concentrations ranging from 0.5 ppb to 100 ppb, spiked with 10 ppb of internal standard. LoDs were 0.23 ng/mL (mitragynine) and 0.09 ng/mL (7-hydroxymitragynine). LoQs were 0.70 ng/mL (mitragynine) and 0.28 ng/mL (7-hydroxymitragynine). Quantitative analysis of the three powder samples revealed mitragynine concentrations of 0.116 mg, 0.0902 mg, and 0.0625 mg, each of which was below the labeled amount indicated on the corresponding packaging. The measured concentrations of 7-hydroxymitragynine were 5.65×10^{-3} mg, 5.73×10^{-3} mg, and 5.45×10^{-3} mg, also markedly lower than the declared values. This method was able to detect very low concentrations of mitragynine and 7-hydroxymitragynine across different forms of kratom.

Future work will include quantifying other alkaloids in kratom that exhibit similar psychoactive effects to 7-hydroxymitragynine and mitragynine from the samples used within this project.

L9 Designing an Analytical Method to Screen for Contaminants in *Amanita Muscaria* Gummies Using Triple Quadrupole LC/MS/MS

Abigail Van de Water, BS, University of New Haven, West Haven, CT; Marisia A. Fikiet, PhD, University of New Haven, New Haven, CT; Robert H. Powers, PhD, University of New Haven, East Hampton, CT*

Learning Objectives: Attendees will be introduced to a repeatable method comprised of two main parts. First is the extraction method for gummy products, including alcohol precipitation and Solid-Phase Extraction (SPE) extraction. The second part is the development of a calibrated method for the detection of alpha-amanitin using a triple quadrupole Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) system. Attendees will also leave with a better understanding of the prevalence of *A. muscaria* in the recreational drug market and its risks.

Impact Statement: It is the author's goal that this study starts to fill the niche that exists within the forensic community as it pertains to these products given the low level of research present until now. This study will also help develop a method that can be easily used by various forensics labs.

Abstract Text: *Amanita muscaria* has recently emerged within the recreational drug market as a replacement for psilocybin, which has been designated a Schedule I substance since 1971.[1] Muscimol and ibotenic acid, two chemicals found in *A. muscaria*, boast similar effects to psilocybin such as "a feeling of weightlessness, visual and auditory hypersensitivity, space distortion, unawareness of time, and colored hallucinations."[2] What makes these products dangerous is not necessarily the mushroom itself, but rather the manufacturing process. A lack of regulation from any governing body invites easy contamination and a lack of transparency between manufactures and consumers which has already caused harmful poisoning events.[3] The deadliest of these contaminants is alpha-amanitin, a common substance found within the Amanita family. Due to the way in which *A. muscaria* is collected, amanitin-containing mushrooms that look like *A. muscaria* can make their way into the manufacturing process. A method is needed to screen popular *A. muscaria* products for contaminants and quantification. The method developed in this study has two parts: an extraction procedure and a triple quadrupole LC/MS/MS procedure. In the first part, gummies are melted in water and, using alcohol precipitation with ethanol, prepared for solid phase extraction (SPE). The SPE method uses methanol, chloroform, and water as its solvents. Once filtered, the samples are run on a triple-quadrupole LC/MS/MS, a common instrument in most forensics labs, and screened for contaminants. The instrument used is a Shimadzu LCMS-8060 system in MRM mode with positive ESI. The MRM mode monitors three product ions of alpha-amanitin. Before the application of the method to consumer products, its development included the creation of a calibration curve of alpha-amanitin which can be used for the eventual quantitation of the toxin in market products. Positive control gummies were made in-lab using a pectin base, then spiked with alpha-amanitin and the internal standard, phallacidin. The amount of alpha-amanitin is varied in the positive controls in triplicate to determine the limit of detection within a gummy matrix and provide method validation. While only one contaminant is being focused on in this study, the method can be adapted for other substances of interest.

L10 The Development and Validation of a Method for the Quantitative and Qualitative Analysis of Psychedelic Compounds in Antemortem and Postmortem Blood Using Liquid Chromatography/Tandem Mass Spectrometry

Paige Riley-Carrier, MS, Virginia Department of Forensic Science, Richmond, VA; Rebecca Wagner, PhD, Virginia Department of Forensic Science, Richmond, VA*

Learning Objectives: After attending this poster presentation, attendees will better understand how a liquid chromatography/tandem mass spectrometry method was developed for the detection of psychedelic compounds in antemortem and postmortem blood. Attendees will also gain knowledge on the application of the American National Standards Institute/Academy Standards Board (ANSI/ASB) Standard 036, Standard Practices for Method Validation in Forensic Toxicology, to develop and validate methods.

Impact Statement: Recently, medicinal applications of psychedelic compounds toward the treatment of post-traumatic stress disorder and other major depressive disorders have been suggested and been increasing in popularity. Subsequently, rates of decriminalization and legalization of these compounds continue to trend upward, directly impacting forensic toxicology testing. The expected increase in prevalence solidifies the need for a reliable and robust workflow for the identification and quantitation of such compounds within both the Toxicology Section of the Virginia Department of Forensic Science and the greater forensic toxicology community.

Abstract Text: Psychedelic compounds are being explored as treatment options for major depressive disorders.[1] Several psychedelic compounds, though, are categorized as Schedule I by the Controlled Substances Act, indicating a high potential for abuse and no accepted medical use.[2] Regardless, clinical research into the application of these substances display promise. These successes have led to an increased push for legislation regarding decriminalization and/or legalization across the United States.[3] As legislation changes, forensic toxicology laboratories must adapt their scope for driving under the influence of drugs and death investigation casework.

The study discussed herein had two objectives. First, method development was conducted to obtain optimal sample preparation and instrumental analysis conditions for 5-hydroxy-N,N-dimethyltryptamine, psilocin, N,N-dimethyltryptamine, 4-hydroxy-diethyltryptamine, 5-methoxy-N,N-dimethyltryptamine, 4-acetoxy-N,N-dimethyltryptamine, 2-oxo-3-hydroxy-lysergic acid diethylamide, 4-hydroxy-N,N-diisopropyltryptamine, 5-methoxy-N-iso-propyltryptamine, 4-acetoxy-diethyltryptamine, 5-methoxy-N,N-diisopropyltryptamine, and lysergic acid diethylamide. The second objective is to validate the optimized method in accordance with ANSI/ASB Standard 036, Standard Practices for Method Validation in Forensic Toxicology.[4]

A liquid chromatography-tandem mass spectrometry method was developed using an Agilent Technologies Zorbax Eclipse Plus C18 RR column (2.1 x 100 mm, 3.5-micron). Mobile Phase A consisted of 0.01% formic acid in water while Mobile Phase B consisted of 0.01% formic acid in methanol. Target compounds were separated under gradient conditions at 50°C, with a total run time of 8.5 minutes. Mass spectral data was acquired in positive mode using dynamic multiple reaction monitoring. The sample preparation procedure was a protein precipitation using 1 mL of biological specimen and 2 mL of acetonitrile. Samples were vortexed prior to centrifugation at approximately 2800 rpm for 15 minutes. After centrifugation, samples were frozen for 30 minutes at approximately -20°C before transferring the topmost layer for evaporation and subsequent concentration in Mobile Phase A. A final centrifugation step was performed followed by a transfer into autosampler vials for instrumental analysis. Due to the lack of certified reference materials for all compounds, and crosstalk caused by reference material decomposition, the compounds were separated into qualitative and quantitative methods.

Method validation is currently on-going, with a focus on employing the established optimal sample preparation procedure and instrumental analysis method to meet standard practice criteria including bias and precision, calibration model, carryover, interferences, ionization suppression/enhancement, limit of detection (LOD), lower limit of quantitation (LLOQ), dilution integrity, and stability.

Preliminary bias and precision experiments demonstrated structural instability of the target compounds producing a bias greater than ±20% for antemortem and postmortem blood. Therefore, pooled fortified samples will not be employed during the validation, rather, the samples will be fortified prior to each analysis. An administratively defined threshold concentration was established for the LOD for each compound within the method. For the quantitative compounds, the LOD was equal the LLOQ (2.0 ng/mL for psilocin, 1.0 ng/mL for all other quantitative compounds). For the qualitative compounds, the threshold concentration was 5.0 ng/mL for 5-hydroxy-N,N-dimethyltryptamine and 1.0 ng/mL for all other qualitative compounds. This method shows promise for forensic toxicology laboratories that need to adapt to the changing climate of psychedelic compound identification and quantitation in biological specimens

L11 Dissociation by Design: LC/MS/MS Detection and Validation of Phencyclidine, Ketamine, Metabolites, and Novel Structural Analogs in Blood and Urine

Andrea Bernal, BS, Sam Houston State University, Huntsville, TX; Britni Skillman, PhD, Sam Houston State University, Huntsville, TX*

Learning Objectives: In this presentation, attendees will learn about the quantitation of Phencyclidine (PCP), ketamine, metabolites, and selected emerging analogs in blood and the identification of these analytes in urine. The audience will understand the validation process for a liquid-liquid extraction paired with Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) for the detection of tenanalytes: PCP, ketamine, deschloroketamine, norketamine, deschloro-N-ethyl ketamine, 2-fluoro-2-oxo PCE, fluorexetamine, methoxetamine, 3-methoxy PCP, and 3-methyl PCP.

Impact Statement: This presentation will impact the forensic science community by introducing a validated method for extracting and detecting Novel Psychoactive Substance (NPS) dissociative anesthetics structurally similar to PCP and ketamine in blood and urine matrices. The method was developed with the intention of integration into crime laboratory toxicology procedures by using routine solvents and instrumentation (LC/MS/MS).

Introduction: In recent years, novel psychoactive substances (NPS) have continued to be produced and sold throughout the world. With constantly evolving drug trends, detection and identification of NPS in forensic casework can be difficult. From 2024-2025, the Center for Forensic Science Research and Education (CFSRE) reported that NPS stimulants and hallucinogens accounted for an average of 8-17% of NPS drug identifications in the United States.[1,2] Specifically, several analogs of phencyclidine (PCP) and ketamine have been increasing in prevalence to include analytes such as 3-methyl PCP, 3-methoxy PCP, and 2-fluoro-2-oxo PCE. As a result, new toxicological methodologies need to be developed and validated for the identification of these substances in casework.

Objectives: The purpose of this study was to develop and validate an extraction and detection method for PCP, ketamine, selected analogs and metabolites in blood and urine using LC-MS/MS.

Methods: For the isolation of the previously listed analytes, a liquid-liquid extraction protocol using 10 mM borate buffer and *N*-butyl chloride extraction solvent was optimized for sample preparation in blood or urine (0.5 mL). For chromatographic separation and detection, an LC-MS/MS method was optimized on an Agilent 1290 Infinity II LC coupled with an Agilent 6475 LC/TQ. Mobile phase A consisted of 0.1% formic acid in deionized water and mobile phase B consisted of 0.1% formic acid in acetonitrile. An Agilent Poroshell 120 EC-C18 (2.1 x 100 mm, 2.7 µm) column with a matching guard was utilized for chromatographic separation over 8.50 minutes. The method was validated according to ANSI/ASB Standard 036 for both matrices. For quantitation in blood, the following parameters were assessed: calibration model, limit of detection (LOD), limit of quantitation (LOQ), bias, precision, carryover, ionization suppression/enhancement and interferences. For qualitative identification in urine, ionization suppression/enhancement, limit of detection, carryover and interferences were assessed.

Results: All analytes were quantitatively validated in blood using a calibration range of 0.5 500 ng/mL with quadratic 1/x weighting. Bias and precision were evaluated at three concentrations (1.5, 125, and 400 ng/mL) and controls met all appropriate acceptance criteria. Matrix effects were acceptable and did not exceed ±20% in either matrix. The LOD and LOQ were 0.1 ng/mL and 0.5 ng/mL, respectively, for all analytes in blood, and the LOD in urine was 0.5 ng/mL. No carryover was observed following injection of a 500 ng/mL calibrator prepared in blood, nor following a 1000 ng/mL urine control. No interferences from the matrix, internal standard, or commonly encountered drugs of abuse and prescription drugs were detected. Notably, isomers fluorexetamine and 2-fluoro-2-oxo PCE were chromatographically separated.

Discussion: This study presents a validated LC-MS/MS method for the detection of PCP, ketamine, deschloroketamine, norketamine, deschloro-*N*-ethyl ketamine, 2-fluoro-2-oxo PCE, fluorexetamine, methoxetamine, 3-methoxy PCP, and 3-methyl PCP, offering a practical tool for forensic toxicology laboratories. This method demonstrated acceptable quantitative performance using a simple liquid-liquid extraction and can support the identification of emerging NPS substances related to PCP and ketamine in forensic toxicology casework.

L12 Ethanol Inhibition of Morphine Glucuronidation

Supraja Regunathan, BS, University of New Haven, West Haven, CT; Na Liu, PhD F-ABFT, Western New England University, Springfield, MA; Robert H. Powers, PhD, University of New Haven, East Hampton, CT*

Learning Objectives: This research explores how ethanol inhibits morphine metabolism by targeting the glucuronidation pathway catalyzed by UDP-glucuronosyltransferase enzymes. Attendees will learn enzyme kinetic approaches to evaluate competitive vs. non-competitive inhibition and understand the implications of ethanol–opioid co-consumption on morphine clearance.

Impact Statement: This study aims to improve forensic toxicologists' ability to interpret cases involving concurrent morphine and ethanol use by clarifying how ethanol alters morphine metabolism at the enzymatic level. These insights may help contextualize toxicological results in impaired driving, overdose, and postmortem investigations, ultimately strengthening case assessments and public health interventions.

Abstract Text: Morphine is the archetypal opioid analgesic, first isolated in the early 19th century. Despite the emergence of multiple potent functional analogues, morphine remains central to modern pain management.[1] Even with its therapeutic benefits, morphine's high potential for dependence and misuse has contributed to an ongoing opioid epidemic, with a rising trend of polysubstance abuse including alcohol.[2] Co-ingestion of ethanol with opioids enhances central nervous system (CNS) depression and increases the risk of fatal respiratory depression, even at therapeutic opioid doses.[3] While these additive pharmacodynamic effects are well established, less is known about the pharmacokinetic interactions that occur when ethanol alters morphine metabolism.

Morphine undergoes hepatic metabolism primarily via phase II glucuronidation, forming morphine-3- (M3G) and morphine-6-glucuronide (M6G) through UDP glucuronosyltransferase (UGT) enzymes.[4] M6G retains analgesic potency, whereas M3G is non-analgesic but may contribute to neuroexcitatory effects.[5] Inhibition of glucuronidation may prolong morphine's half-life and increase systemic exposure, potentially exacerbating depressant effects.[6]

Previous studies suggest ethanol can inhibit morphine glucuronidation, possibly by reducing the availability of the cofactor, UDP-glucuronic acid (UDPGA), or directly affecting UGT enzyme activity.[7-12] However, few studies have characterized the specific kinetic mechanism of this inhibition (competitive vs. non-competitive) or quantified its effect under physiologically relevant ethanol concentrations. We hypothesize that the co-ingestion of ethanol with morphine exacerbates its toxicity by inhibiting the UGTs that catalyze morphine metabolism, leading to an increased area under the curve (AUC) and prolonged half-life.

In this study, morphine glucuronidation was investigated in vitro using mouse liver microsomes.[13] Reaction mixtures included morphine at 2 mM and UDPGA (4 mM), incubated with or without ethanol at 0.2 g/dL, representing high blood ethanol concentrations associated with significant impairment and commonly encountered in impaired driving or fatal overdose cases. Samples were incubated for 30 minutes at 37°C, and each condition was tested in triplicate to ensure reproducibility. Finally, solid phase extraction was performed, and the glucuronides were quantified via HPLC-MS/MS.[14,15]

Results showed an approximately 20% reduction in peak areas of morphine glucuronides in ethanol-exposed samples compared to controls. Due to the limited substrate concentration range, reliable kinetic parameters (KM and Vmax) were not yet determined, but will be the focus of further experiments.

These preliminary findings suggest ethanol can reduce the rate of morphine glucuronidation leading to a prolonged half-life and increased AUC. This pharmacokinetic interaction may contribute to the exacerbation of morphine toxicity by ethanol co-ingestion. By clarifying the enzymatic basis of ethanol–opioid interactions, this study supports more informed toxicological interpretation of morphine cases in which ethanol is also present.

L13 The Extraction of Novel and Traditional Stimulants From Blood Using Protein Precipitation and Dispersive Pipette XTRaction for Liquid Chromatography/Triple Quadrupole Mass Spectrometry Analysis

Alexus M. Ceasar-Walker, BS, Sam Houston State University, Huntsville, TX; Eduardo Geraldo de Campos, PhD, Sam Houston State University, Huntsville, TX*

Learning Objectives: After attending this presentation, attendees will learn about a method combining dispersive pipette XTRaction and protein precipitation for the analysis of traditional and novel stimulants from blood using Liquid Chromatography/triple quadrupole Mass Spectrometry (LC/MS/MS). Attendees will gain knowledge on preliminary recovery, matrix effects, calibration model, and sensitivity data obtained with this method.

Impact Statement: This presentation will impact the forensic community by presenting the application potential of a sample preparation workflow based on dispersive pipette XTRaction and protein precipitation for the LC/MS/MS detection and quantification of amphetamine, cocaine, eutylone, MDA, MDMA, methamphetamine, N,N-dimethylpentylone, N-propyl butylone, and pentylone in blood. This study will pave the way for future method validation and applications to authentic specimens.

Abstract Text: This study describes the application of the dispersive pipette XTRaction (DPX Technologies) using weak anion exchange (WAX) tips combined with protein precipitation for the extraction of amphetamine, cocaine, eutylone, MDA, MDMA, methamphetamine, *N,N*-dimethylpentylone, *N*-propyl butylone and pentylone from blood, for liquid chromatography-triple quadrupole mass spectrometry (LC-MS/MS) analysis.

The sample preparation workflow was developed based on previously published literature.[1] Whole bovine blood (blank or fortified with the analytes of interest) was submitted to protein precipitation with cold acetonitrile. Samples were centrifuged for 10 min (10,000 rpm, at 4°C), and the supernatant was transferred using the XTR WAX tips. The supernatant was submitted to two additional aspiration/dispensing cycles using the XTR WAX tips. An aliquot of 10% HCl in methanol was added and the solvent was evaporated under nitrogen flow at 33°C to 35°C. The dry extracts were reconstituted in 100 µL of mobile phase at initial conditions and analyzed via LC-MS/MS. Chromatographic separation was performed using an Agilent Poroshell 120 EC-C18 column (2.1 x 100 mm, 2.7 µm) in an Agilent 1290 Infinity instrument. The detection was performed using an Agilent 6470 triple quadrupole mass spectrometer operating in positive ESI and multiple reaction monitoring mode.

Preliminary studies assessed recovery, matrix effects, and calibration models. Recovery and matrix effects were assessed at a concentration of 80 ng/mL using three sets of samples. Set 1 consisted of two blood samples spiked before extraction with all analytes and internal standards. Set 2 consisted of extracted blank blood samples (n = 2) spiked with all analytes and internal standards before evaporation. Set 3 consisted of neat quality control (in acetonitrile) spiked with all analytes and ISTD and injected in triplicate. Recovery was calculated as the ratio between the average peak areas for sets 1 and 2, for each analyte. Matrix effects were calculated as the ratio between average peak areas for sets 2 and 3, for each analyte.

Recovery ranged from 68.7% to 78.8%, and matrix effects ranged from 90.9% to 106.3%, which were considered acceptable. Average peak areas imprecision for all samples in sets 1, 2, and 3 was lower than 3%. The extraction of a single blank blood specimen exhibited no significant interferences to any analytes or ISTD. A calibration model in the range of 1 100 ng/mL using a six-point calibration curve was assessed. A quadratic model with 1/x weight resulted in R2 greater than 0.99 and acceptable calibrator accuracy for all analytes, except for cocaine. No carryover was observed after injecting a blank mobile phase three times after the 100 ng/mL calibrator.

The combination of protein precipitation and dispersive pipette XTRaction technique demonstrated acceptable efficiency and clean-up of blood specimens, successfully isolating the target analytes from a complex biofluid. The method needs to be further validated, but the preliminary results suggest that this approach has the potential to offer forensic laboratories a faster and more environmentally friendly alternative to solid phase extraction

L14 Fluorescent Detection of Heroin Using a Molecularly Imprinted Chitosan–UiO66 Metal Organic Framework (MOF)–Carbon Dot Hybrid Sensor

Somayeh Mohammadi, PhD, University of Texas at El Paso, El Paso, GA; Hamidreza Sharifan, PhD, University of Texas at El Paso, El Paso, TX*

Learning Objectives: Attendees will learn about the design and development of a novel molecularly imprinted chitosan–MOF–carbon dot hybrid sensor for selective heroin detection. The presentation will cover the synthesis process, fluorescence sensing mechanism, analytical performance, and forensic relevance. Participants will gain insights into how nanomaterial-based sensors can enhance drug detection sensitivity, specificity, and applicability in real-world forensic analysis.

Impact Statement: This presentation introduces an innovative fluorescence-based sensor for heroin detection that enhances analytical sensitivity, selectivity, and field applicability. It offers a rapid, low-cost, and environmentally friendly alternative to conventional forensic drug analysis methods, potentially improving drug screening in forensic laboratories and supporting law enforcement in combating opioid-related crimes.

Abstract Text: Due to the increasing trend of overdose reports of narcotic analgesics, we developed a fluorescent sensor using UiO66 metal-organic frameworks (MOFs) integrated with nitrogen and fluorine co-doped carbon dots (N,F-CDs). The designed selective molecularly imprinted polymer (MIP) was tested for detection of trace concentration of heroin (100 ng/mL) in water. The MIP matrix was engineered from a reflecting ratio of chitosan and doped with fluorescent UiO66 MOF–N,F-CDs to enhance sensor sensitivity and selectivity. The MIP composite was extensively characterized using fluorescence spectrophotometry, Ultraviolet-Visible spectroscopy (UV-Vis), scanning electron microscopy (SEM), zeta potential analysis, powder X-ray diffraction (PXRD), and Fourier-transform infrared (FTIR) spectroscopy. Fluorescence measurements revealed a significant enhancement ($p < 0.05$) in signal upon heroin binding to the MIP compared to the non-imprinted polymer (NIP). The optimal fluorescence response was observed at an excitation/emission wavelength of 370/470 nm. The sensor exhibited high specificity for heroin compared to other narcotics, showing negligible interference from structurally related compounds such as amphetamine, methamphetamine, codeine, methadone, cocaethylene, 3,4-Methylenedioxymethamphetamine (MDMA), benzoylecgonine, and tetracycline. A positive fluorescence response was observed in the 1–500 ng L^{-1} range of heroin. This sensor establishes a baseline for extending the detection method to complex biological matrices such as blood serum, saliva, and urine.[1,2]

L15 Forensic Toxicology on a Pre-Skeletonized Body: A Case Report on the Use of Multiple Biological Matrices

Anna Antonia Capurso, MD, University of Bari, Bari, Puglia, Italy; Domenico Urso, MD, Direzione Medica Ospedale Francavilla Fontana, Francavilla Fontana, Puglia, Italy; Valeria Santoro, MD, PhD, University of Bari, Bari, Puglia, Italy; Francesco Introna, MD, PhD, University of Bari, Bari, Puglia, Italy; Francesco Paolo Busardò, MD, PhD, Univpm, Ancona, Marche, Italy*

Learning Objectives: This case report will help the attendees assess issues related to decomposed bodies such as identification and toxicological investigations and implement the use of multiple/alternative biological matrices to perform toxicological investigations in decomposed bodies.

Impact Statement: When examining corpses in an advanced state of decomposition, obtaining routine and standardized samples for toxicological investigation may be difficult and the results may not be reliable. The use of alternative biological matrices can be useful to address such cases. The aim of the present study is to evaluate the applicability of alternative biological matrices and to test their reliability for toxicological investigation in a pre-skeletonized body.

Abstract Text: Toxicological analyses represent a crucial aspect of forensic investigations, especially when xenobiotics may have contributed to the cause of death. Blood and urine, as conventional biological matrices, are generally considered the gold-standard samples for toxicological analysis, but the situation becomes more complicated when examining partially/completely skeletonized bodies, in which such matrices are no longer available. In decomposed cadavers, it is sometimes necessary to use alternative matrices, depending on the peculiarities of the case, such as bones or larvae.[1-4] It is, however, necessary to consider the limitations of analyzing these matrices.[5]

This case concerns an unidentified pre-skeletonized cadaver discovered in a wooded area of the Puglia region (Italy) during spring. For personal identification, anthropologic and forensic odontology investigations were performed, comparing ante- and post-mortem x-ray orthopantomograms and dental formulas. The body was identified as belonging to a woman who had disappeared a month earlier in the same area. Police investigations revealed that she suffered from depression, for which she was undergoing pharmacological treatment. Given the suspicion that the cause of death was drug-related, since the autopsy revealed the absence of traumatic injuries, a toxicological investigation was conducted to search drugs the woman was known to be taking (sertraline, triazolam, flurazepam and quetiapine). Taking into account that the body was pre-skeletonized, with internal organs almost decomposed except for the kidneys, the presence of a renal cyst on the right kidney containing a considerable volume of urine represented an exceptional finding. A broad toxicological investigation was therefore conducted on the urine collected from the cyst, as well as on other matrices such as the ileo-psoas muscle, liver, hair, and larvae collected from the body. Bones were not analyzed due to the matrix's complexity.

The analyses were performed by liquid chromatography-high-resolution tandem mass spectrometry (LC-HRMS/MS). Briefly, the urine sample underwent β-glucuronidase hydrolysis and protein precipitation prior to injection; solid samples were crushed and sonicated in a 50:50 water:acetonitrile solution at 1 mg/ml and then processed following the same protocol as urine. LC separation was performed using a phenyl-hexyl-bonded column (100×2.1 mm, 2.6 µm; Phenomenex) with a 15.5-min mobile phase gradient composed of 2 mM ammonium formate in water with 0,1% formic acid (A) and 2 mM ammonium formate in acetonitrile:methanol:water 49.5:49.5:1 with 0.1% formic acid (B). MS detection was performed in full-scan/data-dependent MS/MS mode following electrospray ionization in positive mode.

Qualitative: results:

	Cyst content	Larvae	Liver	Ileo-psoas muscle	Hair
Flurazepam	X		X	X	X
N-desalkylflurazepam	X				
Sertraline	X	X	X	X	X
Quetiapine	X	X	X	X	X
Triazolam					
Mirtazapine					X
Trazodone					X

(X= presence)

Quantitative results:

	Cyst content	Hair
Flurazepam	41.4 µg/mL	2,340 pg/mg
Sertraline	2.0 µg/mL	6,910 pg/mg
Mirtazapine		299 pg/mg
Trazodone		15,2 pg/mg

Copyright 2026 by the AAFS. Permission to reprint, publish, or otherwise reproduce such material in any form other than photocopying must be obtained by the AAFS.

Despite the limitations posed by the peculiarity of the samples and the potential effects of postmortem redistribution, the toxicological findings are consistent with a fatal acute poly-drug intoxication (in a background of chronic use confirmed by hair findings) and, taken together with the scene evidence, supported the classification of the death as suicide.

L16 The Identification of the Novel Non-Opioid Analgesic Suzetrigine in Whole Blood and Urine using Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS)

Isabelle Parry, BS, Sam Houston State University, Huntsville, TX; Britni Skillman, PhD, Sam Houston State University, Huntsville, TX*

Learning Objectives: After attending this presentation, attendees will gain insight into a new non-opioid pain medication (suzetrigine) and a quantitative method for its detection in routine toxicology samples. Attendees will learn about the successful integration of suzetrigine into a panel that was previously validated for the detection of novel insomnia medications daridorexant, lemborexant, and suvorexant.

Impact Statement: Suzetrigine, an alternative to opioids for pain management, has promise in the medical community and could be greatly beneficial to public health. As suzetrigine becomes more widely used, it is important for the forensic science community to be aware of its presence and be equipped with a validated method to detect it in casework samples, especially as little is known about its abuse potential, comorbidity with pre-existing health conditions, and contraindications with other CYP3A-metabolized drugs.

Background: Approved in January 2025, suzetrigine is a novel non-opioid pain medication that targets the pain-signaling pathways' sodium channels in the peripheral nervous system with no activity on the brain's opioid receptors. Its full abuse potential is still unknown, but because opioids have a high, well-documented abuse potential, it will likely become more widely used as an alternative for acute pain management.[1] However, suzetrigine could still appear in casework as little is understood about its role in polydrug toxicity and comorbidity with pre-existing health conditions, such as liver disease. As such, this research aimed to develop a method to detect suzetrigine in blood and urine by adapting a previously validated method for three novel insomnia medications (daridorexant, lemborexant, and suvorexant).[2] The physicochemical properties of suzetrigine allowed for seamless integration to this pre-existing panel for extraction and quantification.

Objective: The goals were to modify an existing liquid-liquid extraction[2] to optimize suzetrigine recovery and to validate a modified LC/MS/MS method for the quantification suzetrigine in blood and for qualitative identification in urine.

Methods: A liquid-liquid extraction using sodium acetate buffer (pH 3.6, 0.4M) and *N*-butyl chloride was utilized to extract daridorexant, lemborexant, suvorexant, suzetrigine, and internal standard (suvorexant-D_6) from whole bovine blood and human urine. An Agilent 6475A Triple Quadrupole Liquid Chromatograph-Mass Spectrometer was used for quantitative analysis. Chromatographic separation was achieved using an Agilent Infinity Lab Poroshell 120 EC-C18 column (100 x 2.1 mm, 2.7 µm) with a 0.4 mL/min flow rate. The gradient elution had a total run time of 5.50 minutes and was achieved with mobile phases A and B, composed of 0.1% formic acid in deionized water and in acetonitrile, respectively. Electrospray ionization was utilized in positive ionization mode, and the mass analyzer was operated in multiple-reaction monitoring mode with one quantifier ion and one qualifier ion for each analyte and ITSD identification. The method was validated according to ANSI/ASB 036 guidelines.

Results: All validation parameters met acceptability requirements in ANSI/ASB 036. A quadratic calibration model with a 1/x weighing was utilized for suzetrigine. The calibration range was between 0.5- 1000 ng/mL with quality controls (QCs) at 1.5, 80, 400, and 800 ng/mL. The limit of detection in blood and urine was 0.25 ng/mL, while the limit of quantitation in blood was 0.5 ng/mL. Post-extraction addition at 5 ng/mL and 500 ng/mL yielded matrix effects less than ± 25%, but increased variability at the low concentration in blood was deemed to have no impact on LOD. No carryover was observed after the 1000 ng/mL calibrator in blood or after the 8000 ng/mL QC in urine. No interferences were observed from the internal standard, matrices or common drugs of abuse and prescription drugs.

Conclusion: An analytical workflow was adapted and validated for the quantification in blood and the qualitative identification in urine of suzetrigine, a novel non-opioid pain medication. Considering the addiction potential of opioid pain medications, this method will be valuable as the use of suzetrigine as an alternative becomes more prevalent in casework samples.

L17 An LC/MS/MS Analysis of Nitazenes

Hannah Kruse, MPS, Pennsylvania State University, State College, PA; William H. Campbell, PhD, Pennsylvania State University, State College, PA; Lucas Madak, BS, Pennsylvania State University, State College, PA*

Learning Objectives: After attending this presentation, attendees will understand High-Performance Liquid Chromatography (HPLC) optimization through column chemistry, column geometry, and mobile phase conditions. This will be illustrated by a method for nitazene separation and detection by Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS), specifically a Thermo Scientific Dionex UltiMate 3000 with a TSQ Vantage mass spectrometer.

Impact Statement: Nitazenes, or 2-benzylbenzimidazoles, are a new class of opioids that have arrived on the illegal market as a result of bans on fentanyl and its precursors. This impacts the forensic science community heavily as nitazenes pose issues with limited scheduling history and lack of validated analytical methods.[1]

Abstract Text: The specific compounds selected for this study were gathered from the 2024 DEA scheduling 21 U.S.C. § 802(32) including metodesnitazene, metonitazene, flunitazene, N-pyrrolidino etonitazene, clonitazene, isotonitazene, protonitazene, and butonitazene.[2] Sample preparation was completed first in an aqueous solution then in urine, where it was diluted tenfold.

Initial method development used a superficially porous 2.7 µm, C18 100 X 2.1mm column at 25°C. A flow rate of 0.4 mL/min was utilized at a gradient of 15%B to 75%B. Other column chemistries were looked at including biphenyl, phenyl-hexyl, and amide columns with 100 X 2.1 mm geometries from the same manufacturer. The biphenyl column was chosen for quantitation as it displayed the best selectivity of compounds, based on resolution defined by the European Pharmacopeia (EP) equation. A LOD range of 4 to 15 ng/mL and a LOQ range of 14 to 47 ng/mL was determined for aqueous calibration preparations with R^2 values between 0.94 to 0.99 for the various analytes. In urine, these values were 5 to 18 ng/mL for LOD, 17 to 51 ng/mL for LOQ, and 0.91 to 0.97 for R^2. The method was then transferred to 100 X 1.5 mm column. The smaller column internal diameter accentuated detection sensitivity and provided greater sensitivity decreasing the LOD ranges from 2 to 9 ng/mL for the aqueous calibration preparations. Mobile phase conditions were also investigated. Organic modifiers were acetonitrile or methanol (B); modifiers for pH control included 2.5 mM ammonium acetate acetic acid or simply 0.1% v/v formic acid. Formic acid was favored because it provided better ionization in the mass spectrometer and hence better signal intensities. This resulted in an order of magnitude greater sensitivity (NL:106 with formic acid compared to NL:105 for acetic acid modified mobile phases). Additionally, formic acid exhibited improved peak shape as determined by the EP method for asymmetry. The mass spectrometer was run in multiple reaction monitoring (MRM) mode as well as parent ion mode. Six of the eight analytes had a transition ion of m/z = 100. Parent ion scans provided potential methodology for identification of unknown nitazenes in drug samples. Next steps in the research will be to integrate these analytes into a broader forensic drug panel including common stimulants, depressants, and hallucinogens.

L18 A Lethal Intake of Cocaine: Accidental or Suicide? The Presentation of a Case After a Review of the Literature

Giulia Ricchezze, University of Macerata, Macerata, Marche, Italy; Alice Cerioni, PhD, University of Macerata, Macerata, Marche, Italy; Erika Buratti, PhD, University of Macerata, Macerata, Marche, Italy; Rino Froldi, MS, University of Macerata, Macerata, Marche, Italy; Roberto Scendoni, MD, PhD, University of Macerata, Macerata, Marche, Italy; Gianmario Mietti, PhD, University of Macerata, Macerata, Marche, Italy*

Learning Objectives: After attending this presentation, attendees will gain insight into a rare case of fatal cocaine intoxication with suspected suicidal intent, supported by detailed toxicological and pathological findings. The case underscores the importance of integrating scene investigation, personal history, and advanced toxicology to accurately determine the manner of death.

Impact Statement: This work contributes to the forensic science community by enhancing the understanding of non-recreational drug use patterns and improving the interpretation of complex drug-related fatalities.

Abstract Text: Cocaine is a powerful stimulant with a significant potential for fatal intoxication. This report presents the case of a 29-year-old male with a known history of substance abuse, who was found dead in a hotel room near his residence. There was no evidence of the presence of others in the room, and his phone was turned off. A small quantity of cocaine was found at the scene. External examination revealed no signs of violence. Nasal swabs tested positive for cocaine, supporting the hypothesis that death occurred after recent cocaine use and providing valuable information about the route of administration. Cocaine was likely insufflated, as further suggested by the presence of a rolled-up one-dollar bill found at the scene. Toxicological screening using gas chromatography-mass spectrometry (GC/MS) and headspace gas chromatography with flame ionization detection (HS-GC-FID) revealed markedly elevated concentrations of cocaine (1,602 ng/mL), its primary metabolite benzoylecgonine (89,173 ng/mL), cocaethylene (12,417 ng/mL), and ethanol (0.61 g/L) in peripheral blood. The presence of cocaine and its metabolites in bile and urine further supported recent and significant intake. Pathological examination, combined with toxicological findings, determined the cause of death to be acute cocaine intoxication, leading to cardiogenic shock. Before ruling the death a suicide, the deceased's personal history was considered. In the period leading up to his death, he had expressed profound distress to his family, largely due to his inability to find satisfying employment. He was also recently affected by sudden-onset total alopecia, which he struggled to cope with. His decision to book a hotel room alone and turn off his phone suggests a desire for isolation. The elevated levels of cocaine metabolites in peripheral blood suggest that the deceased survived for some time after the initial dose and continued using the drug well beyond the peak intoxication phase. The relatively low ethanol concentration, along with the absence of empty or partially empty bottles in the room, supports the hypothesis that he was in the descending phase of Widmark's curve at the time of death.

Although determining suicidal intent is challenging in the absence of a note, the deceased's personal history, the circumstances of the scene, autopsy findings, and toxicological results strongly suggest a non-recreational pattern of use, raising the possibility of an intentional overdose. As such, this case represents one of the rare instances in the literature where death resulted from a cocaine overdose potentially taken with suicidal intent.

This report will present a case that underscores the necessity, when it comes to an intoxication, to make a diagnosis based on the unequivocal convergence of a series of factors arising from the application of multiple criteria: anamnestic, circumstantial, anatomical-pathological, and chemical-toxicological. Furthermore, the presentation will demonstrate how combining analytical data with scene and behavioral context can inform distinctions between accidental, recreational, and intentional drug-related deaths. The insights gained are intended to support more nuanced, evidence-based conclusions in forensic investigations involving stimulant fatalities.

L19 Lethal Sodium Nitrite Intoxication: The Contribution of Immunoistochemical Markers

Roberta Bibbò, MD, Università degli Studi di Foggia, Foggia, Puglia, Italy; Stefania De Simone, PhD, University of Foggia, Foggia, Puglia, Italy; Alessandro Santurro, MD, PhD, University of Salerno, Salerno, Campania, Italy; Giovanni Pollice, MD, Università di Foggia, Foggia, Puglia, Italy; Maria Antonella Bosco, MD, Università degli studi di Foggia, Foggia, Puglia, Italy; Francesco Orsini, MD, University of Foggia, Foggia, Puglia, Italy*

Learning Objectives: Sodium Nitrite (NaNO2) intoxication is an increasingly common method of suicide. However, there are no specific signs and routine tests and toxicological tests do not always give reliable results. This study aims to validate scientifically useful methods for the diagnosis of NaNO2 intoxication, testing immunohistochemical techniques of three specific markers of hypoxia: HIF-1α, iNOS2, and VEGF.

Impact Statement: Deaths from suicidal NaNO2 intoxication are a challenge for forensic pathologists. This work highlighted how immunohistochemical techniques play a crucial role in clarifying death mechanisms in NaNO2 poisoning, showing an increase in oxidative stress affecting the INOS2, VEGF, and HIF1α lines.

Abstract Text: Sodium nitrite has many applications as a food preservative, antimicrobial, coloring agent, and antidote for cyanide poisoning, also proving lethal if ingested in excessive amounts. It is a method of suicide rarely described in the literature, but its rate is growing. On the web-market, sodium nitrite, widely available and inexpensive, facilitates its use as a method of suicide, especially among adolescents. In standard conditions, it appears as a water-soluble white-yellow colored crystalline powder with massive oxidizing power, causing hypotension and limiting oxygen transportation and delivery through methemoglobin formation. Although the mechanism of death is clearly consistent with asphyxia, the pathognomonic external signs typically associated with asphyxial death (like blue-grey hypostasis and subconjunctival petechiae) may be absent or inconspicuous during external examination. Regarding toxicology, the half-life of nitrite and its metabolites (methemoglobin and nitrate) in the blood is notably short, which poses a significant challenge in diagnosing nitrite intoxication, as it requires a high concentration of methemoglobin.

Seven cases of death caused by NaNO2 intoxication were examined; as a control case, a person who died from a stab wound was selected. Immunohistochemical analyses were carried out with specific antibodies to iNOS, HIF-1α and VEGF antigens on autopsy samples of heart, brain and lungs. On all samples collected during autopsy, 4 µm-thick paraffin-embedded sections were cut; they were pretreated by incubation for 120 minutes at 20°C using different substances; then they were incubated with the primary antigen. The sections were colored in contrast to H&E and observed under an optical microscope. VEGF and iNOS2 were found to be significantly expressed in samples of cardiac, pulmonary and encephalic tissue in cases of death from nitrate intoxication, while HIF1α showed good expressiveness in lung and brain samples but poor in heart samples. The expression of VEGF, HIF1α and INOS2 was very poor or absent in the control.[1-5]

L20 Liquid Chromatography-Tandem Mass Spectrometry Analysis of Natural and Semi-Synthetic Cannabinoids in Authentic Postmortem Blood Samples

Marco Ballotari, PhD, University of Florida, Gainesville, FL; Michael T. T. Truver, PhD, University of Florida, Gainesville, FL; Jennifer L. Hoyer, MS, University of Florida Forensic Toxicology, Gainesville, FL; Chris W. Chronister, PhD, University of Florida, Gainesville, FL; Bruce A. Goldberger, PhD, University of Florida College of Medicine, Gainesville, FL*

Learning Objectives: Attendees will learn about the quantitative analysis of natural and semi-synthetic cannabinoids in authentic postmortem blood samples, and the prevalence of natural and semi-synthetic cannabinoids in decedents.

Impact Statement: The presentation will highlight the application and common analytical challenges in regards to the analysis of natural and semi-synthetic cannabinoids in postmortem blood samples by liquid chromatography-tandem mass spectrometry (LC/MS/MS), and the prevalence of natural and semi-synthetic cannabinoids in decedents.

Abstract Text: Forensic toxicology laboratories have reported analytical challenges in regards to the identification and accurate quantification of semi-synthetic cannabinoids, such as Δ^8-tetrahydrocannabinol (Δ^8-THC), in biological specimens. These challenges are often associated with the difficulty in the chromatographic separation of the parent Δ^8- and Δ^9- isomers, metabolites, and other related compounds. Moreover, the interpretation of semi-synthetic cannabinoid data is limited by the lack of literature related to the typical concentrations of Δ^8-THC in postmortem casework.

In this study, 107 postmortem blood samples were selected based upon the prior identification of Δ^8-THC-COOH (N=105) and/or Δ^9-THC-COOH (N=84) in urine by immunoassay and gas chromatography-mass spectrometry. Natural and semi-synthetic cannabinoids were isolated from blood utilizing liquid-liquid extraction. The extracts were subjected to LC-MS/MS analysis. A Waters Acquity UPLC® BEH Shield RP18 (2.1 × 100 mm, 1.7 µm) (Milford, MA, USA) column at 20°C with the matching guard column was used. The mobile phases consisted of 0.1% formic acid in water and 0.1% formic acid in acetonitrile, with the flow rate set at 0.5 mL/min. The method was validated with guidance provided by the American Academy of Forensic Sciences Standards Board (ASB) Standard 036.

The Δ^8- and Δ^9- isomers of the parent THC, and the isomers of the hydroxy and carboxy metabolites were chromatographically resolved and passed validation criteria for the ASB parameters assessed. The assay was linear from 1 to 50 ng/mL for Δ^8-THC, Δ^9-THC, 11-OH-Δ^8-THC, and 11-OH-Δ^9-THC; and 5 to 250 ng/mL for Δ^8-THC-COOH and Δ^9-THC-COOH. The lower limit of quantitation was the concentration of the lowest non-zero calibrator. Results from the precision, and accuracy studies were within the acceptable ± 20% range for all the analytes. The stability of the extracts stored at 10°C for 72 h were within ± 20% of the tested t_0 concentration.

The quantitative results in postmortem blood are summarized in Table 1. Δ^8-THC and its metabolites were confirmed in blood in 59.8% of the cases previously identified by a positive urine drug test result for Δ^8-THC-COOH. Further, Δ^9-THC and its metabolites were confirmed in blood in 43.9% of the cases with positive urine drug test for Δ^9-THC-COOH. Both Δ^8- and Δ^9- analytes were confirmed in the blood samples of 29 (27.1%) cases.

The results of the study demonstrate the accurate identification and quantification of natural cannabinoids and semi-synthetic cannabinoids in postmortem blood. The typical blood concentrations of the parent Δ^8- and Δ^9- isomers and metabolites were presented.

Table 1. Quantitative results of cannabinoids in the authentic postmortem blood samples (N=107).

Analyte		Mean concentration ± S.D. (ng/mL)	Median concentration (ng/mL)	Range (ng/mL)
Δ^8-THC	(n=37)	10.2 ± 15.5	5.7	1.0 90.0
11-OH-Δ^8-THC	(n=11)	1.7 ± 0.6	1.6	1.1 2.8
Δ^8-THC-COOH	(n=66)	94.6 ± 190	48.0	5.1 1484
Δ^9-THC	(n=35)	5.0 ± 7.0	2.5	1.0 41.0
11-OH-Δ^9-THC	(n=14)	4.5 ± 5.5	2.7	1.1 21.0
Δ^9-THC-COOH	(n=50)	32.4 ± 38.0	14.0	5.5 166

L21 Methods of Separating Isomers of Fentanyl Analogs Via High-Performance Liquid Chromatography

David J. Cirota, MPS, The Pennsylvania State University, Lewistown, PA; William H. Campbell, PhD, Penn State University, University Park, PA; Margaret Frohnhoefer, BSc, Pennsylvania State University, Middle Village, NY*

Learning Objectives: Following this presentation, attendees will gain exposure to novel High-Performance Liquid Chromatography (HPLC) methods for separating isomers of fentanyl analogs. Various column geometries, mobile phase modifiers, and pH conditions will be investigated throughout the presentation of optimized methods.

Impact Statement: Fentanyl and its ever-increasing slate of potent analogs present consistent problems for the forensic science community. Analogs can take several isomeric forms such as positional and geometric isomers. Isomers share masses and frequently have identical mass spectrometric fragmentation, which makes them difficult to distinguish. Therefore, HPLC separation is critical for unique identification. This research will provide tools necessary to separate the isomers for the purpose of profiling complex drug samples containing fentanyl analogs through simple chromatographic methods using tandem mass spectrometry for detection.

Abstract Text: This research aimed to develop an HPLC method to separate a broad panel of fentanyl analog isomers with high pH mobile phases. Method development focused on optimizing chromatographic conditions for isomer separation, including column geometry, mobile phase modifiers, pH conditions, and gradients. The base panel included three sets of geometric isomers (Fluorofentanyls, Despropionyl Fluorofentanyls, Fluoroisobutyryl Fentanyls), alongside one set of positional isomers (Methylfentanyls). The final panel was supplemented with other common fentanyl analogs (e.g. Acetylfentanyl, Phenylfentanyl), as well as an array of other forensically relevant opioids, stimulants, and cutting agents.

Chromatography utilized superficially porous, high pH stable C18 phases on 2.7µm, 90Å, 100 x 2.1mm columns initially, but the final method was transferred to a 150 x 2.1mm column for enhanced resolution. High pH stable phases are sterically hindered to prevent silica degradation by basic mobile phases. High surface area C18 columns and Pentafluorophenyl columns were attempted as well, but failed to resolve the isomers.

Method development began with the aqueous mobile phase modified with 20mM ammonium acetate, which provided partial separation for most isomer sets. However, this strong ion concentration presented ion capture problems on the mass spectrometer. The final method employed an aqueous mobile phase with 5mM ammonium acetate and 0.1% ammonium hydroxide at a pH of 10. At this high pH, fentanyl and its analogs are in their neutral forms rather than ionic, which was paramount to this method's success. Acetonitrile (ACN) provided superior separation compared to methanol as the organic mobile phase. The final method had a 35-70% ACN gradient with a 15 minute run time and 0.4mL/minute flow rate.

Compounds were detected using LC/MS/MS in multiple reaction monitoring (MRM) mode for quantitation. For each compound, standard curves were generated with R^2 values of at least 0.96. Future research will seek to expand this panel to address newly emerging compounds in illicit drug markets.

L23 Postmortem Electrolyte Profiling as a Forensic Biomarker: Differentiating Causes of Death

Ji Eun Jung, PhD, Forensic Chemistry Division, National Forensic Service Seoul Institute, Republic of Korea, Seoul, Yangcheon-gu, Seoul-t'ukpyolsi, Republic of Korea; Songhie An, PhD, Forensic Chemistry Division, National Forensic Service Seoul Institute, Republic of Korea, Seoul, Seoul-t'ukpyolsi, Republic of Korea; Wooyong Park, MSc, Department of Chemistry, National Forensic Service, Republic of Korea, Wonju-si, Kangwon-do, Republic of Korea; Geum Mun Nam, PhD, Gwangju Institute, National Forensic Service (NFS), Republic of Korea, Nam-myeon, Jangseong-gun, Cholla-namdo, Republic of Korea; Eunhui Park, MSc, Department of Chemistry, National Forensic Service, Republic of Korea, Wonju-si, Kangwon-do, Republic of Korea*

Learning Objectives: The goals of this presentation are: (1) to explain the role of postmortem electrolyte profiling as an objective forensic biomarker for differentiating causes of death, particularly in intoxication, external causes, and natural deaths; (2) to interpret statistical differences in electrolyte concentrations (sodium, potassium, chloride, ionized calcium, and magnesium) across groups and recognize their forensic significance; and (3) to evaluate the diagnostic utility of decreased sodium and ionized calcium in suspected antidepressant intoxication cases and assess their value in supporting cause-of-death determination.

Impact Statement: This presentation underscores the valuable role of postmortem blood electrolyte analysis as a robust biochemical tool that supports forensic pathologists, forensic chemists, and toxicologists in accurately determining causes of death. By systematically analyzing electrolyte concentration differences across diverse categories of death—including drug intoxication, trauma, and natural causes—this study provides novel insights into biochemical markers that can enhance diagnostic precision. The findings advocate for broader integration of electrolyte profiling into routine forensic workflows, offering a scientifically sound and accessible approach that complements existing methods such as vitreous humor analysis. Ultimately, this work has the potential to improve forensic investigations, aid case resolution, and contribute to advancing standards in forensic science.

Abstract Text: Electrolytes play a critical role in homeostasis by regulating fluid balance, neuromuscular excitability, and cellular signaling. Severe disturbances such as hyponatremia, hypernatremia, or hyperkalemia can result in seizures, coma, or cardiac arrest. Although routinely measured in clinical practice, their forensic application remains limited.

We analyzed 236 postmortem blood samples using the NOVA Biomedical Stat Profile Prime® analyzer. Cases were categorized into intoxication (n=120), external causes (n=38), and natural deaths (n=76). The intoxication group comprised a broad spectrum of agents: antidepressants (TCAs, SSRIs, SNRIs, trazodone, tianeptine); cyanide; therapeutic drugs including metformin, tramadol, and fentanyl; pesticides and agrochemicals such as phosphamidon, hexaconazole, colchicine, lambda-cyhalothrin, amlodipine, and valsartan; nitrites including sodium nitrite ingestion with methemoglobinemia (metHb 38%); insecticides and hypnotics; and miscellaneous substances such as detergents and soy sauce ingestion.

Mean concentrations (mmol/L, ±SD):
- Na: external 108.1 ± 17.8; natural 102.4 ± 21.3; intoxication 86.7 ± 18.4
- K: 46.9 ± 13.8; 53.2 ± 19.2; 67.4 ± 18.3
- Cl: 92.2 ± 8.3; 92.5 ± 10.6; 96.1 ± 9.2
- iCa: 0.92 ± 0.28; 0.88 ± 0.29; 0.66 ± 0.26
- iMg: 1.21 ± 0.26; 1.20 ± 0.23; 1.13 ± 0.25

The specificity of blood electrolyte concentrations was observed in intoxication deaths, and notably, in suspected antidepressant intoxication cases, decreased sodium and ionized calcium were identified. All blood samples were analyzed immediately after autopsy, minimizing the confounding effects of postmortem interval (PMI). The observed electrolyte variations therefore reflect the cause of death rather than decomposition, with the exception of potassium, which is substantially influenced by postmortem changes.

Postmortem blood electrolyte profiling provides objective biochemical markers in forensic practice. In suspected antidepressant intoxications, decreased sodium and ionized calcium may serve as key evidence for cause-of-death determination. This study shows that electrolyte analysis complements autopsy and toxicology, enhancing diagnostic accuracy in complex intoxication cases. Future research should expand datasets, refine statistical modeling, and establish postmortem reference ranges.

L24 Potency Testing for 24 Cannabinoids in Hemp and Cannabis-Infused Products

Mingjing Sun, PhD, Kean University, Union, NJ*

Learning Objectives: By the end of this presentation, attendees will be able to: (1) understand the challenges associated with labeling accuracy and cannabinoid standardization in edible cannabis products; (2) understand the development and validation of a fast and sensitive Multiple Reaction Monitoring (MRM) method using triple quadrupole mass spectrometry for the quantification of 24 phytocannabinoids; (3) interpret analytical results from commercial cannabis-infused gummies and assess how product content compares to labeled claims; (4) recognize the implications of cannabinoid mislabeling for public health and the importance of implementing standardized testing protocols in the cannabis industry.

Impact Statement: This presentation will inform the forensic science community about the growing analytical challenges posed by the cannabis market, particularly in the context of inconsistent labeling and public safety risks. By showcasing a validated method for comprehensive cannabinoid quantification, this work emphasizes the critical need for accurate testing and regulatory enforcement. The findings support the development of standardized protocols that can improve product integrity, enhance consumer safety, and ensure forensic laboratories are equipped to handle evolving demands in cannabis product analysis.

Abstract Text: Cannabis remains the most widely used federally illegal drug in the United States. As legalization expands, 47 states permit medical use, while 24 states and Washington, D.C., allow both medical and recreational use. Among cannabis products, edibles—such as gummies, chocolates, baked goods, and beverages infused with cannabinoids—have rapidly gained popularity and represent a growing segment of the industry. However, these products pose significant regulatory and public health challenges due to inconsistent labeling and lack of standardization.

Accurate measurement of cannabinoids in infused products is therefore essential to ensure consumer safety and product integrity. In this study, our aim was to develop a fast and sensitive method to detect the most common phytocannabinoids and apply it to cannabis-infused products to assess potency and verify product quality and safety.

We established a multiple reaction monitoring (MRM) method using a Waters TQ Absolute Triple Quadrupole Mass Spectrometer for the quantitative analysis of 24 major phytocannabinoids. These included CBN, CBD, Δ9-THC, Δ8-THC, CBC, CBG, CBDV, CBDA, CBGA, Δ9-THCAA, Δ9-THCVA-A, CBGV, CBL, CBGVA, Δ9-THCV, CBLA, CBNA, CBDVA, CBCVA, CBCV, CBCA, Δ8-THCV, Δ8-THCVA-A, and Δ8-THCAA. Using a Cortecs C18 column, all cannabinoids were successfully separated within 12 minutes, including four key sets of isomers: Δ9-THC/Δ8-THC, Δ9-THCAA/Δ8-THCAA, Δ9-THCV/Δ8-THCV, and Δ9-THCVA/Δ8-THCVA. The gradient conditions were as follows: (A: 0.1% formic acid in water; B: 0.1% formic acid in acetonitrile): A 50% → 1% (0–8 min); 1% (8–10 min); 50% (10.1–18 min). The method demonstrated excellent sensitivity, with limits of detection (LOD) for most cannabinoids reaching 0.05 ng/mL.

The method was applied to six commercial cannabis-infused gummies. Samples were extracted using the QuEChERS method. Briefly, 1 g of homogenized gummy was dissolved in 10 mL deionized water, followed by the addition of 10 mL acetonitrile. The mixture was vortexed for 1 minute, after which a pouch of QuEChERS extraction salts was added. The solution was vortexed again for 1 minute, then centrifuged at 4000 rpm for 5 minutes. The upper acetonitrile layer was collected and analyzed by LC-MS/MS.

Across these samples, 16 cannabinoids were detected. Of these, 15 (93.8%) were outside the ±10% range of their labeled concentrations. Notably, two samples contained THC concentrations more than twice the amounts stated on their labels. All six products had at least one cannabinoid that deviated significantly from the labeled content.

These findings highlight substantial inconsistencies in cannabinoid labeling and raise serious concerns about product accuracy and consumer safety. They underscore the urgent need for stricter regulatory oversight and standardized testing protocols in the cannabis industry.

L25 Quadrupole Time-Of-Flight vs. Orbitrap: Scoring High Resolution Mass Spectrometry Performance for New Psychoactive Substance Screening in Human Matrices

Akshita Verma, MS, Florida International University, Miami, FL; Anthony P. DeCaprio, PhD, Florida International University, Miami, FL; Natalia Soares Quinete, PhD, Florida International University, Miami, FL*

Learning Objectives: Attendees will learn the importance of non-targeted screening of New Psychoactive Substances (NPS) and how to systematically compare the analytical performance of two High Resolution Mass Spectrometry (HRMS) platforms, Liquid Chromatography/Quadrupole Time-Of-Flight/Mass Spectrometry (LC/QTOF/MS) and LC/Q-Orbitrap/MS. They will understand key analytical parameters such as sensitivity, selectivity, precision, and matrix effects across urine, blood, and oral fluid. The session will also introduce a novel, easy-to-apply scoring system to simplify platform comparison, guiding optimal instrument selection for forensic toxicology applications.

Impact Statement: This presentation will provide forensic toxicologists with practical guidance on selecting the most suitable HRMS platform for NPS screening by comparing performance in complex biological matrices. By introducing a standardized scoring system, the study promotes more informed, data-driven decisions for toxicology labs, improving efficiency, accuracy, and adaptability in identifying emerging drugs in forensic casework and research.

Background: The continuous emergence of new psychoactive substances (NPS) poses significant analytical challenges in forensic and clinical toxicology. Non-targeted high-resolution mass spectrometry (HRMS) techniques are essential for broad-spectrum screening of such compounds. Among HRMS platforms, quadrupole time-of-flight (QTOF) and Orbitrap mass spectrometers are widely used. Though both offer high resolution and accurate mass capabilities, they differ in acquisition speed, sensitivity, and operational characteristics. This study compares these two techniques for *non targeted analysis* of NPS, aiming to establish a framework to select the optimal platform using a unified scoring system.

Objectives: The primary goal was to systematically compare the analytical performance of QTOF and Orbitrap platforms using a 40-compound NPS test mixture. Key parameters included sensitivity (LOD), selectivity, linearity, precision (% coefficient of variance), and matrix effects across urine, whole blood, and oral fluid samples. A secondary aim was developing a scoring system to translate complex data into comparative scores, facilitating platform selection for routine or research screening.

Methods: A 40-compound NPS mix was spiked into commercially sourced drug-free pooled urine, whole blood, and oral fluid samples. Urine underwent a dilute-and-shoot method, while whole blood and oral fluid samples were processed by protein precipitation. Samples were analyzed on Agilent's LC-QTOF 6546-MS and Thermo's LC-Q-Exactive Orbitrap-MS using positive ESI mode. QTOF utilized Auto MS/MS and All-Ions MS/MS acquisition strategies at collision energies of 10, 20, and 40 eV. Orbitrap data acquisition was via data-dependent MS/MS (ddMS2) with stepped collision energies. Data were processed using vendor software and compound identification used accurate mass-based library matching (in-house PCDL). A scoring system normalized performance across matrices and instruments. Each metric was scored 0-2 (or 0-1 for selectivity/true identity). Aggregated scores compared relative performance of these acquisition strategies in each matrix.

Results: Both platforms detected most NPS compounds across matrices. Orbitrap-MS showed superior mass accuracy, sensitivity, and precision, especially in whole blood and oral fluid. QTOF/MS performed similarly in urine and demonstrated better tolerance to ion suppression in some cases. Linearity was acceptable on both, with Orbitrap providing more consistent calibration. Matrix effects were most pronounced in whole blood but did not alter overall trends. The scoring system highlighted Orbitrap's strengths in accuracy, sensitivity, and precision, while QTOF excelled in selectivity and robustness in simpler matrices. QTOF's All-Ions MS/MS acquisition allowed more uniform fragmentation data across compounds. The Auto MS/MS method outperformed AIF overall, securing a total score of 1266, compared to AIF's 1246/1680 possible.

Conclusion/Discussion: Nontargeted HRMS is critical for monitoring the evolving NPS landscape, enabling detection of unknowns without prior targeting. Selecting the appropriate platform is challenging due to complex performance metrics and matrix-dependent effects. This study offers a simplified scoring system to distill key analytical parameters into an intuitive comparison framework, facilitating informed instrument choice beyond raw data. Both QTOF and Orbitrap platforms are suitable for NPS detection, but their performance must be considered relative to specific laboratory needs, matrix types, and operational priorities. The scoring system helps toxicology labs make faster, evidence-based decisions for adapting HRMS strategies to comprehensive NPS screening.

L26 A Rapid LC/MS/MS Analysis of EtG and EtS in Urine

Samantha Herbick, MFS, Restek Corporation, Belefonte, PA; Jamie York, PhD, Restek Corporation, Bellefonte, PA; Jared Burkhart, BSc, Restek Corporation, Bellefonte, PA*

Learning Objectives: After attending this presentation, attendees will understand the analytical challenges posed for analyzing alcohol metabolites, ethyl glucuronide and ethyl sulfate. They will be introduced to a robust and reliable Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) method capable of retaining both Ethyl Glucuronide (EtG) and Ethyl Sulfate (EtS) while effectively resolving urinary matrix interferences—without requiring column pre-conditioning.

Impact Statement: This presentation will impact the forensic science community by introducing a robust method for EtG and EtS analysis. The method's utility is demonstrated through calibration in synthetic urine and quality control testing across six different lots of urine, including samples from individuals with kidney and liver disease.

Abstract Text: Ethyl Glucuronide (EtG) and Ethyl Sulfate (EtS) are widely recognized biomarkers for alcohol consumption. The analysis of these compounds poses challenges due to their polar nature, making them challenging to retain by reversed phase chromatography. Additionally, isobaric matrix interferences in urine must be fully resolved from the analytes to obtain accurate data.

In this work, a rapid LC/MS/MS method was developed that provides excellent resolution between the matrix interferences and the analytes of interest. The goal of this study was to establish a robust method capable of retaining both EtG and EtS while resolving urinary matrix interferences without the need for time consuming column pre-conditioning.

Synthetic urine was fortified with EtG and EtS from 15-1,000 ng/mL to prepare nine calibration standards using a 1/x weighted quadratic regression. Quality control (QC) samples were prepared at 50, 80, 200, and 800 ng/mL using six lots of human urine, including samples from kidney disease patients. Urine (50 uL) was aliquoted to a 2 mL centrifuge tube and was mixed with isotopically labeled internal standards. Cold acetonitrile (150 uL) was added to the tube, vortexed for ~30 seconds, and centrifuged for 10 minutes at 4,200 rpm. The supernatant (100 uL) was aliquoted to an autosampler vial and water (900 uL) was added before the sample was capped, vortexed for ~30 seconds, and 10 uL injected onto the LC/MS/MS for analysis. A Force Biphenyl column (100 x 3 mm, 3 µm) was used for analysis with mobile phases containing 0.1% formic acid in both water and methanol. The chromatographic separation was achieved under gradient conditions with an overall cycle time of 5 minutes.

The developed method successfully resolved matrix interferences from the analytes of interest and no significant matrix interferences were observed across all QC urine lots. Validation exercises were performed by ANSI/ASB standard 036 guidelines. Linearity was demonstrated for both analytes with $r^2 \geq 0.995$, and the method exhibited acceptable (+/- 15%) intra- and inter-day precision and accuracy.

The Force Biphenyl column offered improved robustness over multi-mode columns, which often require extensive pre-conditioning. In contrast, the Force Biphenyl allowed immediate use without compromising performance. It also provides flexibility for analyzing a broad range of compounds, including drugs of abuse and novel psychoactive substances, reducing the need for column changes.

L28 A Review of Xylazine-Related Deaths Over a Two-Year Period at the West Tennessee Regional Forensic Center

Anfisa Baiandurova, MD, University of Tennessee Health Science Center- West Tennessee Regional Forensic Center, Memphis, TN; Danielle K. Harrell, DO, University of Tennessee Health Science Center- West Tennessee Regional Forensic Center, Memphis, TN*

Learning Objectives: Attendees will learn about the association of xylazine in illicit fentanyl-related overdoses. This presentation will also address case circumstances, demographic information, and other drugs detected on postmortem toxicology in deaths associated with xylazine.

Impact Statement: This presentation will have a meaningful impact on the forensic community by bringing increased awareness to xylazine-related deaths and emphasizing the complexity of additional significant toxicologic findings.

Abstract Text: Xylazine is a non-opiate veterinary sedative which has been detected as an adulterant in the illicit drug supply in the United States and has been implicated in many drug-related deaths.[1] Most xylazine-related deaths also involved the presence of fentanyl on postmortem toxicology.[1-3] This study aimed to evaluate all deaths the West Tennessee Regional Forensic Center over a two-year period for additional positive toxicological findings, case presentation, demographics, and manner of death.

Methods: The Medicolegal Death Investigation program (MDILog) was used to review deaths which xylazine was detected on toxicology analysis and was ultimately attributed to death examined at the West Tennessee Regional Forensic Center between March 2023 and April 2025. We examined circumstances surrounding death, age, sex, race, autopsy findings, cause of death and manner of death.

Results: A total of 57 cases fit the study criteria, and a detailed review was performed of each cases. Eighty-eight percent of cases received an autopsy examination (50/57). The average age was 38 years, with a range of 1 to 66 years. Fifty-eight percent were male (33/57) and forty-two percent female (24/57). Fentanyl was detected in 100% of cases with median 24.0 ng/mL (range 1.7–411 ng/mL). Acetyl fentanyl was detected in 18% (10/57) and para-fluorofentanyl was detected in 10.5% of cases (6/57). Cocaine was detected in 40.4% of cases (23/57) and methamphetamine was detected in 26.3% of cases (15/57). The manner of death was classified as accident in fifty-five cases (96.5%). Two cases the manner of death was undetermined, both were one year of age at the time of death. Thirty-three (19/57) cases had circumstances of drug paraphernalia reported on scene.

Conclusions: The findings of fentanyl in all reviewed cases are consistent with previously reported data.[1-3] The majority of xylazine related deaths were due to accidental overdoses, with an important finding of two pediatric deaths, both one year of age, had fentanyl with xylazine on postmortem toxicology, and were the only two cases with an undetermined manner of death. Two future goals are to evaluate deaths where toxicology was positive for xylazine and not attributed to the cause of death, and also to explore working with forensic crime scene investigations to determine if paraphernalia on deaths scene attributed to xylazine overdose tests positive for xylazine.

L29 Screening for Nitazene Analogs Using Neutral Losses and Common Fragments by Liquid Chromatography/Quadrupole Time-of-Flight/Mass Spectrometry

Angelique B. McDowell, BS, NPS Discovery, Center for Forensic Science Research & Education, Horsham, PA; Barry K. Logan, PhD, Center for Forensic Science Research & Education, Horsham, PA; Alex J. Krotulski, PhD, Center for Forensic Science Research & Education, Horsham, PA; Joshua S. DeBord, PhD, Center for Forensic Science Research & Education, Horsham, PA*

Learning Objectives: Attendees of this presentation will gain understanding of the fundamentals of Neutral Loss (NL) and Common Fragment (CF) screening as a strategy for detecting unknown Novel Psychoactive Substances (NPS), focusing on the detection of nitazene analogs. The presentation will outline the steps taken to utilize high-resolution, Quadrupole Time-Of-Flight/Mass Spectrometry (QTOF/MS) for screening known and unknown nitazene analogs, the ongoing efforts to build a continually updated complementary data processing workflow, and the practical challenges encountered throughout the method development process.

Impact Statement: This presentation will benefit the forensic science community by outlining the selection and structures of relevant CFs and NLs that can improve the detection of nitazene analogs in forensic casework. Unlike tandem mass spectral techniques that rely upon molecular ion targets, the targets for NL/CF screening are class-based, non-specific, and characteristic of their fragmentation mechanisms, thus proposing a practical solution to the challenge of detecting both theoretical and truly unknown nitazene analogs.

Abstract Text: Screening for novel psychoactive substances (NPS) in forensic chemistry and toxicology has become increasingly challenging due to the shifting dynamics of the recreational drug market. The rapid emergence and disappearance of these substances and the lack of available reference standards complicate traditional screening approaches based on spectral comparisons. This presentation details the ongoing development of a screening method designed to overcome these limitations by utilizing characteristic neutral losses (NL) and common fragments (CF) associated with known nitazene analogs.

Under collision-induced dissociation, analytes break into fragment ions often shared among structural analogs and can be used to infer the presence of specific substances, drug classes, or structural moieties. Nitazene analogs produce characteristic NL during fragmentation, measurable with precursor/product-ion-transition-associated MS/MS acquisition modes. A coupled screening method for both CF and NL can detect suspect nitazene analogs and enable preliminary identification without relying on potentially unavailable library spectra/standards.

This presentation outlines the development of a liquid chromatography quadrupole time-of-flight mass spectrometry (LC-QTOF-MS) screening method aimed at identifying nitazene analogs in drug material samples. The method currently targets eighteen NL and nineteen CF shared among forty nitazene analogs chosen from a 2022 data set—a master list of characteristic NL and CF across a variety of drug classes. These data were obtained by analyzing Cayman Chemical reference standards using a coupled TOF-MS (+)/Product Ion (+) IDA method on a TripleTOF 5600+ LC-QTOF-MS (SCIEX, [Framingham, MA]). Chromatographic separation was achieved by a standard reverse phase gradient using ammonium formate (10mM, pH 3), methanol/acetonitrile (50:50), and a Phenomenex® Kinetex C18 analytical column (50mm x 3.0mm, 2.6µm). The total runtime was 15.5 minutes. The ten most abundant fragments observed per analyte were logged, with recurring fragment ions categorized as CF and analyte-specific mass differences categorized as NL.

To be included in this screening's preliminary list, each NL/CF had to be observed in at least three known analogs across the 2022 data set. This list informed the creation of an IDA method using a SCIEX X500R LC/QTOF/MS. Method parameters were selected to align with those of the routine qualitative method used in the drug analysis workflow, and parameters used for chromatographic separation matched those applied in the 2022 analysis.

One round of sample acquisition has been completed with this preliminary method. The barrier to routine implementation/validation is the lack of commercially available software to support a processing method to review the identified targets. Proposed positive screening criteria require unknown components having one diagnostic NL and one CF. This approach facilitates screening both known nitazene analogs and unknown compounds as suspect nitazenes when observing characteristic NL and/or CF, enabling early-stage detection and classification of related compounds in complex matrices. Development of a data processing method remains ongoing. This preliminary work demonstrates a promising approach for detecting unknown nitazene analogs, offering greater flexibility in responding to rapidly evolving drug trends by relying on structural features. Future work will focus on developing a data processing method, method validation, and method comparison.

L30 Semi-Synthetic Cannabinoids: The Newest Challenge in Analyzing THC Isomers

Jared Burkhart, BSc, Restek Corporation, Bellefonte, PA; Haley P. Berkland, MSFS, Restek Corporation, Bellefonte, PA*

Learning Objectives: After attending this presentation, attendees will understand the necessity of expanding cannabinoid toxicology testing to include emerging semi-synthetic cannabinoid compounds. Attendees will also learn about the practical considerations of incorporating these compounds into an existing Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) method for the analysis of cannabinoids.

Impact Statement: This presentation will impact the forensic science community by demonstrating the importance of expanding toxicology testing scopes to include semi-synthetic cannabinoids and provide direction on how to effectively analyze for them by LC/MS/MS.

Abstract Text: Over the past several years, Δ8-THC has made headlines as a popular "legal" alternative to Δ9-THC. The rise in popularity of Δ8-THC led to a new analytical challenge for toxicology laboratories—differentiating between the Δ8 and Δ9 isomer forms. For labs performing this testing by LC/MS/MS, complete separation of these isomers and their metabolites is necessary for accurate quantitation.

Recently, a new group of compounds referred to as semi-synthetic cannabinoids have emerged on the market. Drug monitoring groups in the U.S. have suggested that these compounds be added to toxicology testing scopes due to increased use and detection.[1]

Many toxicology laboratories have already implemented LC-MS/MS methods to simultaneously analyze for Δ8-THC and Δ9-THC in casework. In this work, six emerging semi-synthetic cannabinoids were added to an existing LC-MS/MS used for the analysis of Δ8-THC, Δ9-THC, and their hydroxy and carboxy metabolites in whole blood. The six cannabinoids (9(R)-HHC, 9(S)-HHC, Δ10-THC, THC-O-Acetate, THCP, and CBDP) were all identified as scope recommendations in early 2025.[1]

The six semi-synthetic cannabinoids were run on the original method conditions. The method used a Raptor FluoroPhenyl 100 x 3 mm, 2.7 µm column and mobile phases of water and methanol, both acidified with 0.1% formic acid. The column temperature was 40°C, the flow rate was 0.8 mL/min, and gradient elution was used. While resolution was achieved for all compounds, including isomers, using the original method conditions, THCP and THC-O-Acetate eluted at 100% B, where matrix interferences are known to wash off the column. To prevent interference, the method conditions were altered to allow these compounds more time on the column. Additional resolution for the isomers was also achieved by dropping the column temperature from 40°C to 30°C. All six semi-synthetic cannabinoids were successfully integrated into a pre-existing LC-MS/MS method for the analysis of THC isomers in whole blood.

L31 A Stability Assessment of Nitazenes in Aqueous Solutions for the Development of Sample Preparation Procedures

Sara L. Kuberski, BS, Sam Houston State University, Huntsville, TX; Britni Skillman, PhD, Sam Houston State University, Huntsville, TX*

Learning Objectives: Analysts will learn about the pH-dependent stability of nitazenes in different aqueous environments. This includes evaluating degradation patterns in common extraction buffers and under extreme pH conditions relevant to toxicological sample preparation.

Impact Statement: These results may improve sample preparation and extraction development protocols by providing insight into conditions that result in nitazene instability. Protocols with conditions that may lead to instability can be adjusted, compensated for analytically, or exposure time to destabilizing environments can be minimized. Addressing stability concerns ensures accurate quantitation and reliable toxicological interpretation.

Abstract Text: Nitazene opioids have become more prevalent in seized drug and toxicological samples over the last several years.[1,2] In response, more laboratories have developed analytical methods to detect these compounds. Sample preparation is a crucial step and frequently involves adjusting pH with various reagents and buffers to isolate analytes from matrix components. Therefore, it is important to consider how pH adjustments could affect analyte stability. To address this need, this study evaluated the stability of seven nitazenes in common extraction buffers (0.1 M sodium acetate buffer, pH 3.5; 0.1 M sodium phosphate buffer, pH 6.0; 0.05 M sodium borate buffer, pH 9.0) and extreme pH solutions (0.01 M hydrochloric acid (HCl), pH 2; 0.1 M ammonium hydroxide (NH_4OH), pH 11). The analytes were 4'-OH nitazene, 5-methyl etodesnitazene, isotonitazene, metodesnitazene, *N*-piperidinyl etonitazene, *N*-pyrrolidino etonitazene, and protonitazene.

At ambient temperature, aqueous solutions were prepared at 20 ng/mL of target drug in appropriate solvent in glass conical vials. Solutions were sampled (50 µL) in triplicate at timepoints of 0, 0.5, 1, 2, 3, and 4 hours for all conditions, and at 6 and 8 hours for common extraction buffers. Internal standard was added (5 µL of 500 ng/mL isotonitazene-$^{13}C_6$ and metodesnitazene-D_4 in methanol) after sampling. Samples were vortexed and diluted 1:10 with mobile phase (90:10 0.1% formic acid and 5 mM ammonium formate in water (A): 0.1% formic acid in acetonitrile (B)) resulting in a final concentration of ~2 ng/mL (5 ng/mL for internal standards).

An Agilent 1290 Infinity II Liquid Chromatograph and an Agilent 6470 Triple Quadrupole Mass Spectrometer were used for analysis. Gradient elution was performed using an Agilent Poroshell 120 EC-C18 column (2.1 x 100 mm, 2.7 µm) and guard column over 9 minutes, starting at 90:10 A:B mobile phase. Data acquisition was performed in multiple-reaction monitoring mode with positive electrospray ionization. Stability was evaluated by comparing mean peak area ratios at each timepoint to the mean at t_0 for each pH condition. Analytes were deemed unstable if the change in peak area ratio exceeded ±20%.

All seven nitazenes were stable for ≥4 hours in 0.01 M HCl and 8 hours in pH 3.5 acetate buffer. All analytes were stable for ≥4 hours in deionized water except for protonitazene, which was stable for up to 3 hours. However, some nitazenes showed inconsistent responses in pH 6.0 phosphate buffer and most demonstrated variability exceeding ±20% in 0.1 M NH_4OH and pH 9.0 borate buffer, with a variety of analytes showing greater instability at different timepoints (some ranging from -24% to +82% in 0.1 M NH_4OH and -40% to +118% in borate buffer). Notably, this variability frequently presented as unacceptable increases in signal rather than degradation-related decreases, requiring more investigation of mechanism. Special consideration should be given to extraction protocols involving alkaline conditions, including evaluation of internal standard performance and limiting exposure to high pH environments. Conversely, acidic conditions may offer a stabilizing effect for these compounds. Incorporating these findings into method development can improve quantitation accuracy and overall reliability in toxicological analysis.

L32 Substance Consumption Informative Research (SCIRe): Testing Hair From Electronic Music Festivals

Ana Pego, PhD, John Jay College of Criminal Justice, New York, NY; Bruno Pereira dos Santos, MSc, Universidade Federal de Ciências da Saúde de Porto Alegre, Porto Alegre, Rio Grande do Sul, Brazil; Marta Concheiro-Guisan, PhD, John Jay College, New York, NY; Joao Pedro Matias, MS, European Union Drugs Agency (EUDA), Lisbon, Lisboa, Portugal; Sarah Eller, PhD, Universidade Federal de Ciências da Saúde de Porto Alegre (UFCSPA), Porti Alegre, Rio Grande do Sul, Brazil; Tiago Franco de Oliveira, PhD, Universidade Federal de Ciências da Saúde de Porto Alegre (UFCSPA), Porto Alegre, Rio Grande do Sul, Brazil*

Learning Objectives: After attending this presentation, participants will be able to: (1) describe the advantages of using hair as a biological matrix for detecting drug use patterns in forensic and public health contexts; (2) summarize the methodology used in field-based toxicological analysis, including hair sample collection at music festivals and Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) analysis; (3) interpret preliminary findings on drug prevalence among festival attendees, with emphasis on the most commonly detected substances (e.g., nicotine, cocaine, MDMA); and (4) evaluate how toxicological data can inform harm reduction strategies for psychoactive substance use in recreational settings

Impact Statement: This presentation contributes to the forensic science community by demonstrating the feasibility and value of combining field-based toxicological sampling with hair analysis to uncover drug consumption patterns in high-risk settings. The findings offer actionable insights for forensic professionals, public health authorities, and policy makers to develop targeted harm reduction strategies, ultimately supporting safer environments at music festivals and similar events.

Background: In recent years, we have witnessed an alarming increase in the consumption of psychoactive substances, especially at electronic music parties, representing a significant challenge to public health.[1] Thus, the SCIRe project appears as a beacon in this scenario, seeking to identify patterns and trends in drug consumption through advanced toxicological analysis techniques. For this purpose, hair matrix was chosen given its incredible ability to provide a timeline of drug use. Our mission is to dispel the obscurantism surrounding this consumption and promote the implementation of harm reduction policies, making society itself safer and more aware.

Methods: Volunteers were recruited at the Origens Electronic Music Festival in the city of São Francisco de Paula in the state of Rio Grande do Sul, Brazil. Hair samples were collected by cutting a pencil-thickness amount of hair from the vertex posterior region (crown of the head) and storing it into individually labeled foil wraps followed by a paper envelope.[2] To each subject, a questionnaire was also applied including 22 questions from demographics to drug usage habits, together with the relevant consent forms. Hair samples were extracted via general methanolic incubation for 16 h, followed by a clean-up step and identification via liquid-chromatography tandem mass-spectrometry (LC/MS/MS).

Results: From all collected samples (n=30), 26 have tested positive for at least one of the 14 substances tested. The top three substances detected were nicotine (n=22), cocaine (n=19) and MDMA (n=10). The sociodemographic results of the pilot study point to an equal gender distribution (50% female, 43.3% male and 6.3% not informed) and volunteers with an average age of 30.5 ± 4.8 years, of whom, 70% complete higher education. Furthermore, 86.7% reported recreational use of a psychoactive substance in the last 24 hours prior to collection.

Conclusions: It was possible to observe a significantly high positivity rate for one or multiple psychoactive substances (26 out of 30). The substances that showed the greatest positivity were nicotine, cocaine and MDMA, which are compounds known to stimulate the central nervous system. This highlights the elevated incidence of drugs of abuse in the context of electronic music festivals and their detection could aid the formulation of appropriate and helpful harm reduction measures to benefit the user and provide safe-using guidelines.

L33 Teaching Undergraduates Toxicology Skills Via a Mock Urinalysis LC/MS/MS Protocol

George T. Cattan, Loyola University New Orleans, New Orleans, LA; Nina Ratusznik, BS, Loyola University New Orleans, New Orleans, LA; Anna S. Duggar, PhD, Loyola University New Orleans, New Orleans, LA; CJ Stephenson, PhD, Loyola University New Orleans, New Orlean, LA; Michael H. Sosin, MSc, Alliance Laboratories, New York, NY*

Learning Objectives: Attendees will learn about the design of a forensic toxicology undergraduate laboratory experiment using Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) for the detection of drugs of abuse in urine samples. The presentation will include the process of method development for undergraduate teaching experiments, simulated sample preparation techniques, and operation of a triple quadrupole mass spectrometer.

Impact Statement: This presentation equips forensic science educators with a structured approach to introducing LC/MS/MS techniques and toxicological analysis in undergraduate education. The approach aligns laboratory instruction with industry practices, boosting the competence and preparedness of future forensic scientists while providing undergraduate students with a hands-on introduction to aspects of the forensic science field.

Abstract Text: Undergraduate forensic science faculty are faced with the challenge of providing relevant practical exercises to accompany theoretical instruction. Instructional laboratory experiments are crucial in forensic chemistry education, as they provide practical experience with experimental techniques and instrumentation, promote a deeper understanding of theoretical concepts, and enhance problem-solving and critical-thinking skills. Efforts to create undergraduate forensic laboratory exercises confront particular challenges, such as safe ways for students to get practical experiences with drugs of abuse (DOA) and biological fluids like blood or urine.

This study develops an undergraduate laboratory experiment based on industry-standard toxicological practices, particularly the application of liquid chromatography-tandem mass spectroscopy (LC-MS/MS). Previous studies introducing undergraduate chemistry students to LC/MS analysis of drugs have focused on the extraction of analytes from non-biological sample matrices.[1-3] Only a single publication considers the analysis of DOA in synthetic serum, but emphasizes protein precipitation and MRM optimization.[4] The use of realistic laboratory exercises can additionally provide students with valuable experience with workflows, quantitation, and proper interpretation and reporting of results.

This experiment expands on prior teaching applications to include additional aspects of forensic toxicology, including the safe handling of biological samples, chain of custody, and the use of internal and external standards. The discussion will also center on the operation of a triple quadrupole mass spectrometer with a multi-reaction monitoring scan (MRM), in the context of student learning outcomes related to determining transitions and collision energies. Students also gain exposure to the concept of cut-off levels and SAMHSA and ASB reporting norms.

L34 The Chiral Separation of Hexahydrocannabinol (HHC) Metabolites Reveals 9S-4'OH-HHC as Major Urinary Side-Chain Hydroxylation

Markus Roman, BSc, National Board of Forensic Medicine, Linkoping, Ostergotlands Lan, Sweden; Wu Xiongyu, PhD, Linkoping University, Linkoping, Ostergotlands Lan, Sweden; Henrik Gréen, PhD, National Board of Forensic Medicine, Linkoping, Ostergotlands Lan, Sweden; Robert Kronstrand, PhD, National Board of Forensic Medicine, Linkoping, Ostergotlands Lan, Sweden*

Learning Objectives: Upon attending this lecture, the attendees will learn about the complex metabolism of HHC and how supercritical fluid chromatography can be used to separate enantiomers and epimers in a compound with multiple stereogenic centers.

Impact Statement: This lecture will impact the scientific community by providing new information of the major metabolites of HHC useful for the practicing toxicologist as well as providers of reference materials for forensic toxicology.

Abstract Text: Hexahydrocannabinol (HHC), prevalent in both USA and Europe, is a semi-synthetic cannabinoid with three stereogenic centers, however HHC has only been reported with the 6a and 10a carbons in the R-form whereas C9 have had both R- and S-configuration in products. HHC metabolism differs from that of tetrahydrocannabinol with monohydroxylations more abundant than carboxylation.[1,2] In a paper by Schirmer et al. a side-chain hydroxylation was proposed as one major metabolite tentatively identified at C4' (4'OH-HHC).[1] However, neither the 9R/9S configuration nor that at the C4' was discerned. In a paper by Lindbom et al., 5'OH-HHC was suggested as the most abundant side-chain hydroxylation.[2] Identity was strengthened by comparison with an in-house synthesized standard for 5'-OH-HHC. Unfortunately, standards for other side-chain hydroxyls were not available and neither could the 9S/9R configuration be confirmed.

To confirm either of 4'OH-HHC or 5'OH-HHC as primary metabolite and to elucidate the C9 and C4' epimer composition we synthesized and purified reference material for 9R-4'S-OH-HHC, 9R-4'R-OH-HHC as well as their 9S isomers and developed a chiral method to investigate their abundance in urine samples previously confirmed to contain HHC metabolites.[2]

Synthesis was performed using phloroglucinol, verbenol, racemic 4-pentyn-2-ol as building blocks and yielded 4'OH-HHC racemic at C9 and C4'. Further purification using preparative HPLC and characterization with NMR confirmed the 9S and 9R configuration. Analysis was performed on an Agilent 1260 Infinity II SFC with a chiral Trefoil AMY1 2.5µm column (2.1mm*150mm). Mobile phase A was supercritical CO2, phase B was 2-propanol. Data acquisition was performed with multiple reaction monitoring on an Agilent Ultivo triple quadrupole mass spectrometer with electrospray ionization in positive mode. Urine samples were prepared using salting out liquid liquid extraction. Urine (100µL) was hydrolyzed at room temperature for 2 hours using 100µL of Kura B-One beta-glucuronidase. Then 400µL cold acetonitrile was added and subsequently 200µL of 10M ammoniumacetate. Samples were shaken and centrifuged for 10 minutes at 4000g. The supernatant was evaporated and reconstituted in 75µL methanol.

It was not possible to separate 9S-4'S-OH-HHC and 9S-4'R-OH-HHC so these are reported as an areasum. Parent HHC was present in 8 (9R) and 7 samples (9S). Three samples had a 9R/9S ratio of 1 but the metabolic profile suggested a stereoselective metabolism with the 9S configuration predominant for both the 4'-OH-HHC as well as 5'-OH-HHC. As can be seen in Table 1, 9S-4'-OH-HHC had the highest peak area in most samples. 9S-5'-OH-HHC was present in all but 1 sample but with low peak areas.

In conclusion, the two epimers of 9S-4'-OH-HHC dominated followed by 9R-4'S-OH-HHC and we propose that certified reference material should be provided for the 9R/9S-4'-OH-HHC epimers so they can be target analytes together with 5'-OH-HHC and reported separately.

Table 1.

	9S-4'S/R-OH-HHC	9R-4'S-OH-HHC	9R-4'R-OH-HHC	9S-5'OH-HHC	9R-5'OH-HHC

L35 Tracking Toxicity: A Preliminary Forensic-Epidemiological Overview of Drug-Related Deaths in Northwestern Italy (2012–2024)

Federica Trevissoi, MD, Department of Cardiac, Thoracic, Vascular Sciences and Public Health, Unit of Legal Medicine and Toxicology, University of Padova, Padua, Veneto, Italy; Valentina Martini, MSc, Department of Public Health, Experimental and Forensic Medicine, Unit of Legal Medicine, University of Pavia, Pavia, Lombardia, Italy; Guido Viel, MD, PhD, University of Padova, Department of Cardiac, Thoracic, Vascular Sciences and Public Health, Padova, Veneto, Italy; Luca Morini, PhD, University of Pavia, Pavia, Lombardia, Italy; Camilla Torriani, MSc, Department of Public Health, Experimental and Forensic Medicine, Unit of Biostatistics and Clinical Epidemiology, University of Pavia, Pavia, Lombardia, Italy; Maria Cristina Monti, PhD, Department of Public Health, Experimental and Forensic Medicine, Unit of Biostatistics and Clinical Epidemiology, University of Pavia, Pavia, Lombardia, Italy*

Learning Objectives: After attending this presentation, participants will have an updated understanding of the epidemiological trends of drug-related deaths in Northwestern Italy. The presentation will focus on the latest changes in trends compared to previous decades, highlighting the increase in cocaine and poly-drug use. The presentation will also address how forensic data analysis can support public health and prevention strategies for the general population as well as possible interventions for high-risk groups.

Impact Statement: The data presented in this study are relevant not only to the field of forensic toxicology but also in terms of public health. If a rigorous description of deaths related to acute intoxication is provided, health institutions can obtain valuable information for epidemiological surveillance on drug-related deaths and for the design and implementation of preventive strategies and campaigns to promote healthy lifestyles and inform the general population about drugs and associated risks, in accordance with temporal shifts in usage patterns.

Abstract Text: This study reports preliminary results regarding deaths requiring toxicological analysis that were referred to the Forensic Toxicology Laboratory at the University of Pavia from the surrounding jurisdiction. The main objective was to identify epidemiological trends, as well as the demographic and toxicological characteristics of the cases, in order to better understand the circumstances of deaths involving the simultaneous use of psychoactive substances. The examined sample includes approximately 1,500 cases (from 2012 to 2024), in which forensic autopsies were performed, followed by toxicological analyses. Collected data included variables such as age, sex, date and cause of death, toxicological results (e.g., identified substances and their concentrations), and pre-existing pathological conditions. Additional sociodemographic information, such as occupation and marital status, was also available. The substances detected were classified into main categories, such as alcohol, opioids, stimulants, and prescription drugs. The results were analyzed over time to identify changes in abuse and intoxication patterns. The most recent data were compared with those from previous decades, as the Pavia Forensic Toxicology Laboratory has been monitoring these trends and providing ten-year updates since 1966.[1-4] This comparison showed variations in the use of certain substances. In particular, there was a marked increase in cocaine-related deaths, while morphine-related deaths presented a more irregular trend, peaking in 2019 but following an overall downward trend compared to the previous decade. Conversely, a sharp increase was observed in deaths involving multiple psychoactive substances. NPS were also investigated, including cathinones, synthetic opioids, synthetic and semisynthetic cannabinoids, piperazine and phenethylamine derivatives, dimethyltryptamine, and designer benzodiazepines. Within these groups, cases of prior intake of cathinones, furanylfentanyl, and two compounds belonging to the phenethylamine class were identified. Although limited to a few isolated cases, this phenomenon represents a novel observation compared with previous decades and indicates the emerging use of specific NPS within the surrounding jurisdiction. The study underscores the importance of continuous monitoring of toxicological trends to inform public health policies and strengthen risk management strategies related to substance use.

L36 Urine Drug Testing in a Few Drops: Assessing Dried Urine Spots for the Detection of Synthetic Cathinones Using Liquid Chromatography/Triple Quadrupole/Mass Spectrometry

Julia Hintermeister, BA, Sam Houston State University, Huntsville, TX; Eduardo Geraldo de Campos, PhD, Sam Houston State University, Huntsville, TX*

Learning Objectives: After attending this presentation, attendees will learn about a method for the detection of N,N-Dimethylpentylone (DMP), eutylone and pentylone in Dried Urine Spots (DUS) using Liquid Chromatography/Triple Quadrupole/Mass Spectrometry (LC/QqQ/MS). Attendees will also identify the advantages, limitations and future research needs regarding the application of DUS in the analysis of the target synthetic cathinones.

Impact Statement: This presentation will impact the forensic community by the description of an analytical workflow for the detection of three synthetic cathinones in DUS. This presentation will disseminate the potential strengths and limitations of DUS in terms of sensitivity, matrix effects, recovery, and selectivity and open the way for future applications and research.

Abstract Text: Dried urine spots (DUS) are a novel microsampling approach that provides an overall less complex matrix for the detection of analytes and their metabolites. The implementation of DUS may also facilitate sample storage and transportation. DUS can be beneficial to the toxicological analysis of synthetic cathinones, eutylone, DMP, and pentylone, analytes that are frequently reported in forensic casework.

DUS were prepared by spotting 25 µL of urine to pre-cut spots from a Whatman™ 903 card and dried for 2h, at room temperature while protected from ambient light. Samples were extracted using 1 mL of methanol for 20 minutes in an ultrasound bath. The supernatant was collected and mixed with 50 µL of 10% HCl in methanol, evaporated under nitrogen flow, and reconstituted using mobile phase at the initial conditions. Analyses were performed using an Agilent 1290 Infinity II liquid chromatograph coupled to an Agilent 6470 triple quadrupole mass spectrometer. An Agilent Poroshell 120 EC-C18 column (2.1 x 100 mm, 2.7 µm) was used for separation. Mobile phases consisted of 0.1% formic acid in water and 0.1% formic acid in acetonitrile. The mass spectrometer was operated using positive ESI and multiple reaction monitoring mode.

A cut-off of 10 ng/mL met all the positive identification criteria over two different days, with the coefficient of variation for peak areas ranging from 11% to 15% across three different matrix sources. No interferences from common drugs (MDA, MDMA, methamphetamine, PCP, phenylpropanolamine, benzoylecgonine, cocaethylene, cocaine, diazepam, nordiazepam, oxazepam and temazepam) nor from three different sources of commercially available, pooled urine specimens were observed. An interferent peak from the internal standard, pentylone-d_3, was observed for DMP. Significant ion suppression was observed for all synthetic cathinones, ranging from 42.2% to 63.4%. Variations in matrix effects were also observed, with coefficients of variation below 20% observed for eutylone (low quality control (LQC) and high quality control (HQC)) and pentylone (HQC only). For DMP, the coefficients of variation were 32.3% and 21.6% for the LQC and HQC, respectively. The extraction efficiency was considered acceptable, with recoveries ranging from 65.0% to 89.5%. No carryover was observed subsequently to the analysis of a DUS sample fortified with all analytes at 1000 ng/mL.

DUS is a promising alternative microsampling approach for screening DMP, eutylone and pentylone. Currently, to the best of the author's knowledge, this is the first report on the analysis of the target synthetic cathinones in DUS. The analytes were detected at a low concentration (10 ng/mL) suggesting acceptable sensitivity. Nevertheless, it is important to consider that ion suppression was observed for all compounds, which could affect the sensitivity at concentrations below 10 ng/mL. Acceptable extraction efficiencies were observed using a fast ultrasound-assisted extraction with methanol. Matrix effects and recoveries may be explained based on the high content of water/water-soluble substances in urine and the polarity of methanol. Additional studies are needed to further fully validate this method and investigate the stability of these substances in DUS.

L37 Using the New Stellar Mass Spectrometer and Automated Extraction for Drugs of Abuse Testing in Whole Blood

Courtney Patterson, MS, Thermo Fisher Scientific, San Jose, CA; Jingshu Guo, PhD, Thermo Fisher Scientific, Roseville, MN; Kerry H. Hassell, PhD, Thermo Fisher Scientific, San Jose, CA*

Learning Objectives: After attending this presentation, attendees will understand: 1. How a complete and quantitative workflow for 85 drugs of abuse in whole blood using the Stellar Mass Spectrometer (MS) can increase productivity in the lab with a fast extraction and short Liquid Chromatography (LC) gradient. 2. The ability to use Collision-Induced Dissociation (CID) and Higher-energy Collisional Dissociation (HCD) fragmentation on the Stellar MS allows the user to obtain optimized fragmentation. 3. Highly reproducible data and lower limit cutoffs can be achieved by automated extraction using DPX ToT tips and a Hamilton STAR liquid handler.

Impact Statement: This work will impact theforesnic community by showing how a automated extraction and method on the Stellar MS can increase productivity with faster run times, lower the achievable cutoff levels to detect less than 0.5 ng/mL, and provide confidence in results with consistent ion ratios.

Introduction: As workloads increase in forensic laboratories, efficiency and robustness is of paramount importance. Creating faster methods for targeted panels can help improve productivity as well as implementing automation in the extraction process. Meeting the LOQ targets outlined by ANSI/ASB requires both robust extraction methods and high-performance analytical instrumentation with the sensitivity, selectivity, and accuracy for detecting and quantifying drugs of abuse in whole blood. This workflow on the Stellar mass spectrometer combines increased efficiency in the sample preparation with robustness in full scan MS^n data.

Objectives: To develop a whole blood LC-MS assay with automation for quantitation of 85 drugs of abuse that satisfy levels specified in ANSI/ASB Standards 119 and 120.

Methods: Calibration levels (ranging from 0.05 to 500 ng/mL) were made by spiking a stock solution of 87 target analytes (including opioids, stimulants, cocaine, and THC) into human whole blood. 10 real samples were provided by a customer's toxicology lab for a case study. 100 µL of each sample were then extracted by a protein precipitation using DPX Low Porosity ToT technology on the Hamilton Star. Drug analytes were separated on a Thermo Scientific™ Accucore™ Biphenyl column using a 5-minute method connected to a Thermo Scientific™ Vanquish™ Horizon UHPLC system. Data was acquired on the Thermo Scientific™ Stellar™ mass spectrometer using targeted-MS2 (tMS2) mode. Optimized HCD or CID fragmentation was used to provide unique and high-intensity fragments. Thermo Scientific™ TraceFinder™ 5.2 software was used for data acquisition and processing.

Results: Chromatography exhibited ample separation for isomers including codeine hydrocodone and morphine hydromorphone. Limits of quantitation (LOQ) were determined for the 87 drugs as low as 0.05 ng/mL. LOQ was defined as the back-calculated concentration where % difference and % RSD were less than 20%. All 85 drugs were confirmed with retention times, MS2, or MS3 ion ratios.

Discussion: This fast, quantitative Stellar mass spectrometry method with automation was used to detect and confirm drugs of abuse in whole blood. LOQ's for each drug satisfied the cutoffs specified in ANSI/ASB Standards 119 and 120. The ability to use HCD or CID fragmentation allowed for optimizing each compound based on most favorable energies and fragments. Case study samples were analyzed, and statistical analysis was performed.

L38 Δ9-THCP and Δ9-THCH Biomarkers Formed by Human Liver Microsomes

Kathryn James, BS, Virginia Commonwealth University, Richmond, VA; Alaina K. Holt, PhD, Virginia Commonwealth University, Richmond, VA; Michelle R. Peace, PhD, Virginia Commonwealth University, Richmond, VA; Justin Poklis, BS, Virginia Commonwealth University, Richmond, VA*

Learning Objectives: Attendees will learn about the in vitro metabolism of two Δ9-tetrahydrocannabinol (Δ9-THC) analogs, Δ9-tetrahydrocannabiphorol (Δ9-THCP) and Δ9-tetrahydrocannabihexol (Δ9-THCH), metabolized using human liver microsomes. Through this presentation, attendees will understand how liquid chromatography-tandem mass spectrometry (LC-MS/MS) techniques were used to identify potential metabolites.

Impact Statement: Following the 2018 Agricultural Improvement Act, the rise in the distribution of THC analogs has led to public health and public safety concerns. The metabolites of these compounds have not been confirmed. It is important to determine the predominant biomarkers of THC/Cannabidiol (CBD) analogs. The presumptive identification of Δ9-THCP and Δ9-THCH metabolites using human liver microsomes can help update clinical and forensic testing practices.

Abstract Text: Following the 2018 Agricultural Improvement Act, the rise in tetrahydrocannabinol (THC) analog distribution has led to public safety concerns. It is important to determine the predominant biomarkers of THC analogs to help clinical and forensic laboratories identify past consumption, yet the metabolism of most THC analogs remain unstudied. Δ9-tetrahydrocannabiphorol (THCP) and Δ9-tetrahydrocannabihexol (THCH) have structures similar to Δ9-THC, varying only in the length of the aliphatic chain (THC=5; THCH=6; THCP=7). The objective of this study was to identify the major biomarkers of Δ9-THCP and Δ9-THCH following in-vivo metabolism.

Δ9-THCP, Δ9-THCH, and Δ9-THC (control) were metabolized using human liver microsomes. In brief, blanks (0 ng/mL) and samples (800 ng/mL) were incubated with human liver microsomes, phosphate buffer (pH 7.4), nicotinamide adenine dinucleotide phosphate, and magnesium chloride at 37 °C. The reaction was quenched use ice-cold acetonitrile with internal standard (Δ9-THC-d3) at 0, 5, 30, 45, 60, 90,120, and 240 minutes to elucidate the metabolic profile. The acetonitrile extract was dried down under nitrogen and reconstituted in starting mobile phase conditions for liquid chromatography-tandem mass spectrometry (LC-MS/MS) analysis. With each analytical run, a seven-point calibration curve (10-1000 ng/mL) was prepared with the three parent compounds. Quality controls (QCs) were prepared at low (30 ng/mL), mid (300 ng/mL) and high (750 ng/mL) concentration along with blanks with and without internal standard.

Analysis was performed on a SCIEX Triple Quad 6500+. Chromatographic separation used a Zorbaz Eclipse XDBC18 column and an isocratic gradient of water:methanol (10:90, v/v) with 0.1 mM ammonium formate and a flow rate of 0.5 mL/min. Data was collected in positive scan mode (100-500 m/z) and multiple reaction monitoring (MRM) mode. Theoretical transitions for Δ9-THCP and Δ9-THCH metabolites were hypothesized based on the structural similarity to Δ9-THC and its primary metabolites, 11-hydroxy-Δ9-THC and 11-nor-Δ9-carboxy-THC. The metabolization of the parent compounds, Δ9-THCP and Δ9-THCH, into their biomarkers 11-hydroxy-Δ9-THCP (11-OH-Δ9-THCP), 11-nor-Δ9-carboxy-THCP (Δ9-THCP-COOH), 11-hydroxy-Δ9-THCH (11-OH-Δ9-THCH), and 11-nor-Δ9-xarboxy-THCH (Δ9-THCH-COOH) was monitored through the collected time points.

Incubation blanks did not contain any parent or metabolites at any timepoint. Both the scanning and MRM methods identified the predicted metabolites for all analytes (THC, THCH, THCP). As the metabolites formed, parent compounds decreased through the 240-minute incubation period. Both THCH and THCP followed similar metabolism patterns as THC. The formation of the metabolites, 11-OH-Δ9-THCP and 11-OH-Δ9-THCH, from the parent compounds occurred within 5 minutes of microsomal addition. Metabolization of the hydroxylated compounds into Δ9-THCP-COOH and Δ9-THCH-COOH occurred by the 45-minute time point. All parent compounds were fully metabolized by 30 minutes. The presented study demonstrates THCP and THCH follow similar metabolism pathways as THC. The method can be adopted to assess the metabolism of other THC analogs of interest which are flooding the commercial market. The identification of biomarkers can help contribute to prioritizing reference material(s).

L39 An Update on Standards Development Activities in Forensic Toxicology

Marc A. LeBeau, PhD, LeBeau Forensic Toxicology Consulting, O'Fallon, MO*

Learning Objectives: After this presentation, attendees will have gained a comprehensive understanding of the latest discipline-specific standards in forensic toxicology, including their current stage in development, publication process, and anticipated impact on professional practices in the field.

Impact Statement: The presentation will raise awareness of standards development activities related to forensic toxicology. It will also enhance understanding of training, tools, and resources that support implementation, compliance, and broader knowledge.

Abstract Text: Standards continue to influence daily practices in forensic toxicology. Over the past decade, the Organization of Scientific Area Committees (OSAC) for Forensic Science, in conjunction with the Academy Standards Board (ASB), has issued a total of 18 standards pertaining to forensic toxicology. This presentation aims to provide an update on the standards currently published, those approaching finalization, and upcoming standards anticipated in the near future.

The Organization of Scientific Area Committees (OSAC) for Forensic Science was established to enhance the nation's use of forensic science by encouraging discipline-specific standards. To achieve this, OSAC drafts standards that are sent to standards-developing organizations (SDOs), which further refine and publish them. OSAC also reviews published standards and includes them in the OSAC Registry, a central repository of high-quality, consensus-based, and technically sound standards.

This presentation will present updates related to standards development in forensic toxicology, with a focus on those documents published within the last year, as well as those that are in development and open for public comment. Specifically, the talk will focus on the following documents:

Newly Published Documents:

- ANSI/ASB Standard 017: *Standard Practices for Metrological Traceability in Forensic Toxicology*; 2nd Edition, 2025
- ANSI/ASB Standard 056: Standard for Evaluation of Measurement Uncertainty in Forensic Toxicology; 1st Edition, 2025
- ANSI/ASB Technical Report 208: Forensic Toxicology: Terms and Definitions; 1st Edition, 2025

Documents Under Development:

- ASB Standard 058: Standard for the Identification and Quantitation of Volatile Compounds in Biological Fluids 1st Edition, TBD
- ASB Standard 036: Standard for Test Method Selection, Development, Validation, and Verification in Forensic Toxicology; 2nd Edition, TBD
- ASB Guideline 236: Guideline for Conducting Test Method Development, Validation, and Verification in Forensic Toxicology, 1st Edition, TBD
- ASB Standard 037: Standard for Reports and Testimony in Forensic Toxicology; 2nd Edition, TBD
- ASB Standard 054: Standard for Quality Control Programs in Forensic Toxicology Laboratories; 2nd Edition, TBD
- ASB Standard 173; Standard for Education, Training, Continuing Education, and Certification of Forensic Toxicology Laboratory Personnel, 1st Edition, TBD

Opportunities for supplemental training related to discipline-specific standards will be offered, along with additional resources and tools aimed at supporting gap analysis, compliance monitoring, and outreach activities.

L40 From Bench to Court: Enhancing Analytical Validation With the Methods Validation App

Giovanni Solarino, MSc, Department of Chemistry, University of Turin, Turin, Piemonte, Italy; Alberto Mazzoleni, MSc, DataBloom Srl, Department of Chemistry, University of Turin, Turin, Piemonte, Italy; Eugenio Alladio, PhD, Department of Chemistry, University of Turin, Torino, Piemonte, Italy*

Learning Objectives: By the end of this presentation, attendees will understand the common challenges forensic laboratories face when dealing with analytical method validation and how a tool like Methods Validation App (MVA) can help to overcome them. The session will show how MVA can reduce errors, save time, and make validation easier even for non-expert analysts. Attendees will also learn what MVA does and how it works.

Impact Statement: This presentation will provide a practical solution to improve the efficiency and reliability of analytical method validation. The adoption of MVA by forensic laboratories leads to more consistent and defensible analytical results. Ultimately, MVA can help forensic professionals save time and increase productivity.

Methods: Validation App (MVA) is a new digital tool addressing the growing demand for efficient, standardized, and reliable methods validation workflow in regulated laboratories. Leveraging Python's flexibility, MVA offers a clean, and user-friendly interface that simplifies complex statistical processes for analysts. Unlike other traditional tools, MVA intuitive layout allows users to perform essential validation tasks without requiring technical expertise, being thus helpful even for non-specialists in this field.

In the forensic science, where analytical methods must be scientifically valid and legally defensible, MVA supports the reliability demanded by courts and accrediting systems. The software implements a protocol that maximizes the number of validation parameters obtained from a minimal set of experiments.[1,2] Key tasks such as calibration study, limit of detection, precision, and accuracy are automatically performed. MVA thus supports laboratories in meeting major regulatory requirements by reducing human error, ensuring results consistency, and accelerating evaluations.[3] It also offers benefits in other fields (e.g., pharmaceuticals, environmental testing, food safety) where method validation is a regulatory requirement.

In summary, MVA combines robust statistical tools with an easy-to-use interface, enhancing productivity and making method validation more accessible to a broader range of analysts. It's definitely a robust, modern solution for laboratories aiming to efficiently validate analytical methods.

L41 Expiration, Collection, and Storage: A Multi-Factor Investigation of Blood Alcohol Testing

Sarah B. Douglas, MS, Tennessee Bureau of Investigation, Nashville, TN; Roth C.S Woolley, BS, Boston University School of Medicine, Boston, MA*

Learning Objectives: The purpose of this study is to address the stability of ethanol concentrations within blood samples collected and stored in a variety of environments. This was done via a comparison of expired and unexpired blood collection tubes, multiple collection environments, including recommended collection protocol, uncapped outdoor, uncapped in bathroom, and uncapped in laboratory, as well as storage conditions. There were multiple storage conditions, including refrigerator, room temperature, and inside a vehicle trunk. Donor blood samples were used in this study and were artificially spiked with ethanol. Initial Blood Alcohol Concentration (BAC) levels were tested prior to exposure in various storage conditions. A final BAC level was determined after the two-week storage period. This study assesses important factors related to blood alcohol testing and presents the potential for ethanol degradation under non-ideal storage conditions.

Impact Statement: The results of this study impact the forensic community by calling attention to how improper storage, collection, and expiration status can alter the results of BAC testing.

Abstract Text: A frequent argument in impaired driving cases involving blood alcohol concentration (BAC) is that ethanol may have been produced post collection via microbial fermentation. Prior studies have addressed individual factors such as tube expiration status, collection method, storage environment, and blood glucose level. This study, however, aims to assess the validity of these concerns by combining the previously mentioned factors into a single study, specifically within 10 mL BD Vacutainer® Grey Top Tubes containing sodium fluoride (100 mg) and potassium oxalate (20 mg). Expired and unexpired blood collection tubes were compared, exposing them to a variety of environmental conditions intended to simulate various collection scenarios. These scenarios consisted of following the recommended collection technique, as well as allowing the tubes to sit uncapped for one hour on a laboratory bench, a restroom, or outdoors. Following exposure, the tubes were loaded with 5 mL of hyperglycemic donor blood (>300mg/dL glucose), artificially spiked with ethanol (0.5 mL) and placed into one of the three storage conditions for two weeks: refrigerated (2-8°C), room temperature (20-25°C), and in a vehicle trunk (outside temperature 23-33.8°C). Upon completion of the two-week storage period, all samples were stored in a refrigerated storage vault.

All samples underwent three BAC measurements: an initial baseline measurement prior to storage, a second analysis following the two-week storage period, and a final analysis after six months of refrigerated storage. The results of this study illustrate that there is no significant effect on BAC levels when using a 10 mL BD Vacutainer® tube past its expiration. No de novo ethanol synthesis was detected; all ethanol-negative samples yielded non-detectable BAC measurements throughout the study. No significant differences in BAC levels were observed among the various simulated collection environments. The greatest decrease in ethanol concentration occurred in samples stored in the vehicle trunk, followed by those stored at room temperature, with refrigerated samples showing the smallest decrease.[1-5]

L42 Behind the Calm: Benzodiazepines in Blood and Oral Fluid Samples in Alabama

Kristin S. Umstead, BS, Alabama Department of Forensic Sciences, Hoover, AL; Curt S. Harper, PhD, Alabama Department of Forensic Sciences, Hoover, AL*

Learning Objectives: After attending this presentation, attendees will understand trends related to the detection of benzodiazepines and zolpidem in driving-under-the-influence cases in Alabama. Attendees will understand the laboratory testing process for both blood and oral fluid and the screening of oral fluid using roadside devices.

Impact Statement: This presentation will impact the forensic sciences community by providing knowledge of benzodiazepine detection trends in blood and oral fluid and the relationship between the two matrices.

Abstract Text: Benzodiazepines (BZDs) are widely prescribed in the United States to treat anxiety, insomnia, and seizures. They act as a central nervous system depressant and can cause dizziness, drowsiness, delayed reaction time, and confusion. Due to their impairing effects, they are routinely detected in driving under the influence of drugs (DUI/D) cases. The Alabama Department of Forensic Sciences (ADFS) has implemented a comprehensive oral fluid testing program that includes both roadside screening and laboratory confirmation testing. The analysis of both blood and oral fluid (OF) samples provides more data regarding recency of use and helps to identify any substance that could potentially contribute to impairment.

Driving under the influence and traffic accident cases were evaluated over a seven-year period (2018-2025). All cases were screened by enzyme-linked immunoassay using either a Tecan Freedom Evo75 with Immunalysis reagents or a Randox Evidence Plus Analyzer. Confirmation testing of benzodiazepines and zolpidem in blood was performed by liquid-liquid extraction and in OF using dispersive pipette extraction (DPX) tips purchased from DPX Technologies, LLC (Columbia, SC). Both blood and OF samples were analyzed using an Agilent 6460/6470/Ultivo Triple Quadrupole LC/MS/MS. Roadside OF screening devices approved for use in Alabama include the Abbott SoToxa, Drager DrugTest 5000, Randox MultiSTAT, and Securetec Drugwipe. Cases with both blood and OF samples were compared and interesting case studies were identified and highlighted.

The prevalence and concentrations of five benzodiazepines (alprazolam, clonazepam, diazepam, nordiazepam, lorazepam) and zolpidem in blood and OF were compared. Median concentrations in blood were higher than OF for all targets except lorazepam where the median concentrations were similar. Median OF to blood ratios ranged from 0.05 to 0.3 highlighting a major difference when compared to other drug classes where the ratio is greater than unity.[1,2] All benzodiazepines analyzed had a lower positivity rate in OF compared to blood. Clonazepam exhibited the lowest OF positivity rate (22%) while alprazolam (86%) and zolpidem (100%) exhibited the highest.

A majority of the cases that were positive for benzodiazepines or zolpidem had higher concentrations detected in blood versus OF. Benzodiazepines have been shown to have low partioning between blood and oral fluid as they are highly protein bound and weakly acidic[1]. Cases with high OF concentrations may indicate alternate administration routes (i.e., snorting, crushing, etc.). The lower concentrations and positivity rate highlight a challenge for roadside OF device screening. While they can aid law enforcement officers by indicating potential drug usage, confirmation samples of both blood and OF should be collected and sent for laboratory testing to give the most comprehensive data regarding drug use. Benzodiazepines require sensitive LC/MS confirmation methods in order to meet the OF confirmation cutoffs (i.e.1 ng/mL) recommended by the National Safety Council's Alcohol, Drugs, and Impairment Division.[3]

L43 Bromazolam in Driving Investigations: An Update

Jolene J. Bierly, MSFS, NMS Labs, Horsham, PA; Donna M. Papsun, MS, NMS Labs, Horsham, PA; Barry Logan, PhD, NMS Labs, Horsham, PA*

Learning Objectives: After attending this presentation, attendees will better understand the current prevalence and impact of bromazolam, a benzodiazepine not approved by the Food and Drug Administration (FDA), in driving investigations.

Impact Statement: This presentation will impact the forensic science community by demonstrating the need for comprehensive toxicology testing in driving investigations and the inclusion of prevalent designer drugs in testing scopes.

Abstract Text: The National Safety Council has recommended including designer benzodiazepines in driving under the influence of drugs (DUID) test scopes, due to their potential to impair driving and continued prevalence.[1] Bromazolam is a designer benzodiazepine used recreationally with no recognized medical use. Central nervous system depression and driving impairment have been documented following its use. This group previously reported on the prevalence of bromazolam in DUID casework submitted to NMS Labs from 2021-2023.[2] Since that time, bromazolam identifications in DUID cases have increased significantly. This work documents the changes in bromazolam prevalence since 2023 to better ascertain its impact on traffic safety.

Antemortem blood specimens submitted for routine DUID testing between June 1, 2023, when bromazolam directed testing became available, and June 30, 2025, were reviewed. Bromazolam-positive DUID cases were isolated and evaluated for concentration ranges, concomitant findings, and case histories. Confirmation and quantification were performed by liquid chromatography/mass spectrometry (LC-MS/MS) following liquid-liquid extraction with a reporting limit of 2.0 ng/mL. The method was validated to the ANAB/ASB Standard 036. Testing was ordered as a directed test based on case history or from a liquid chromatography/time-of-flight mass spectrometry (LC/TOF/MS) screen result with a reporting limit of 2.0 ng/mL.

Between June 2023 and June 2025, 672 DUID specimens were submitted for bromazolam testing. Collection dates ranged from February 2023 to May 2025 and submissions were received from 11 different states. Bromazolam was confirmed in 503 DUID cases with a mean ± SD, median, and range of 104 ± 119 ng/mL, 72 ng/mL, and 2.3 to 1300 ng/mL. This represents a 400% increase in identifications compared to 2021-2023 (n=98). Annual positive identifications tripled between 2023 (n = 83) and 2024 (n=249) with 173 identifications reported through June 2025. The overall positivity rate was 75%. When additional testing was performed, bromazolam was most frequently combined with cannabinoids (58%), stimulants (52%), and opioids (51%). Observations in bromazolam positive driving cases included drowsiness, slurred speech, poor balance and coordination, inability to follow instructions, erratic driving, and motor vehicle crashes.

Bromazolam continues to pose a significant threat to public health and safety due to its CNS depressant effects and increasing prevalence in DUID casework. This review found an approximate 400% increase in bromazolam identifications since 2023 with identifications occurring across all geographical areas of the United States. Collection dates indicate bromazolam was consistently identified throughout the evaluation period. Prevalent designer drugs should be included in toxicological testing in driving investigations to improve traffic safety.

L44 The Detection of Fluorofentanyl in Urine Driving Under the Influence (DUI) Cases

Kenson Jean, BS, University of Miami, Miami, FL; Kristin W. Kahl, MS, University of Miami, Miami, FL; Lisa Reidy, PhD, University of Miami, Miami, FL*

Learning Objectives: From this presentation, the attendees will learn about the analytical methods used for detecting fluorofentanyl. This presentation will also illustrate the occurrence of fluorofentanyl and its occurrence with fentanyl and other drugs in DUI cases in South Florida.

Impact Statement: This presentation will impact the forensic science community by providing data from Miami-Dade County and Broward County in Southeast Florida on the prevalence of fluorofentanyl and fentanyl and how often they are detected together in urine DUI cases. This presentation will also discuss the increase in fluorofentanyl detection in fentanyl-positive cases in recent years.

Abstract Text: With the ongoing opioid epidemic, the rapid change in fentanyl analogs and other synthetic opioids are proving to be challenging in forensic toxicology. Most of these drugs have high potency and require sensitive confirmatory methodologies to identify them. Fentanyl and its analogs have similar effects to other opioids, including analgesia, sedation, drowsiness, dizziness, and respiratory depression, all can impair the ability to operate a motor vehicle.[1] Fluorofentanyl is a potent fentanyl analog that has a similar molecular structure as fentanyl except for the addition of fluorine substitution on the aniline ring.[2] Fluorofentanyl has become increasingly reported in recent years, typically alongside fentanyl. Fluorofentanyl may be an unintentional byproduct of using fluoroanliline as the precursor instead of aniline or an intentional adulterant to enhance fentanyl's effects.[3] Studies have shown that fluorofentanyl potency compared to fentanyl is dependent on the isomer of fluorofentanyl.[4,5]

At the University of Miami Toxicology Laboratory (UMTL), urine DUI cases are screened using targeted liquid chromatography/tandem mass spectrometry (LC/MSMS) methodology and broad screening for basic drugs by gas chromatography/mass spectrometry (GC/MS) and LC/Time-of-Flight (TOF). Additional confirmatory tests are utilized for drugs that are not detected by at least two of the aforementioned analytical tests. A confirmatory methodology for designer opioids that includes fentanyl and fluorofentanyl has been validated according to ANSI/ASB Standard 036 requirements. This method utilizes targeted LC/MS/MS, however, a limitation of this methodology is the inability to distinguish between the *meta-, ortho-,* and *para-* isomers of fluorofentanyl. This method has a limit of detection of 0.1 ng/mL for fluorofentanyl and 0.5 ng/mL for fentanyl.

Urine samples from suspected DUI cases in Miami-Dade and Broward Counties submitted to UMTL from 2022 to June 2025 were reviewed. Between 2022 to 2024, fluorofentanyl was reported in 20 cases and fentanyl in 57 cases, with all fluorofentanyl positive cases also positive for fentanyl except for one. All fluorofentanyl positive cases also confirmed other drugs or metabolites, signifying polydrug use. Other opioids, cocaine, and their respective metabolites were the most commonly reported drugs alongside fluorofentanyl. In the first six months of 2025, fluorofentanyl was confirmed in 1 urine DUI while fentanyl was confirmed in 6 urine.

In totality, approximately one-third of fentanyl-positive urine DUI cases also confirmed fluorofentanyl, the most frequently reported fentanyl analog during this period. After years of dominance, fluorofentanyl now appears to be declining in Miami-Dade and Broward DUI cases. Its prevalence will continue to be monitored in 2025.

L45 Postmortem Hair Testing for Fentanyl and Analogs: Experimental, Forensic, and Interpretative Aspects

Nicola Pigaiani, MD, PhD, Section of Forensic Medicine, Department of Diagnostics and Public Health, University of Verona, Italy, Verona, Veneto, Italy; Marco Ballotari, PhD, University of Florida, Gainesville, FL; Federica Bortolotti, MD, PhD, Unit of Forensic Medicine, Department of Diagnostics and Public Health, University of Verona, Veneto, Italy; Gregory G. Davis, MD, Department of Pathology, University of Alabama at Birmingham, Birmingham, AL; Rossella Gottardo, PhD, Unit of Forensic Medicine, Department of Diagnostics and Public Health, University of Verona, Veneto, Italy; Karen S. Scott, PhD, Department of Pathology, University of Alabama at Birmingham, Birmingham, AL*

Learning Objectives: Attendees of this presentation will gain information on: (1) the analytical and interpretative potential of postmortem hair analysis as a complementary matrix in forensic toxicology; (2) how hair testing enables geographic and demographic surveillance of synthetic opioid exposure, facilitating the identification of overdose hot spots and vulnerable populations; and (3) how to integrate hair toxicology results into the broader framework of postmortem investigations.

Impact Statement: This presentation will impact the forensic science community by highlighting the value of postmortem hair testing in enhancing the scope and depth of forensic toxicological investigations. By bridging individual casework with population-level drug surveillance, it reinforces the role of forensic science in addressing the synthetic opioid crisis through both diagnostic precision and public health insight.

Background: Fentanyl and its analogues constitute the largest and most lethal category among synthetic opioids.[1] In 2023, synthetic opioids excluding methadone, mainly illicit fentanyl, were responsible for approximately 73,000 overdose deaths in the United States, highlighting the urgent need for enhanced forensic and public health surveillance.[2]

In this context, hair testing emerges as a valuable toxicological matrix offering extended detection windows. In addition, hair testing provides information on chronic or repeated drug intake and could give indications on the victim's drug tolerance, aiding the medical examiner in toxicology data interpretation.[3]

This study aimed to assess the feasibility, reliability, and interpretative value of hair analysis for detecting fentanyl and its analogs in postmortem forensic casework. The broader goal was to evaluate the method's potential to support epidemiological mapping of opioid exposure and inform preventive strategies.

Materials and Methods: Hair samples (n = 250) were collected from all postmortem cases examined by the Jefferson County Coroner/Medical Examiner's Office between January and March 2023. Standard toxicological analysis was performed on available biological matrices (blood, urine, vitreous humor, bile, or tissues), incorporating immunoassay screening and confirmatory GC/MS.

Six cm proximal hair specimens, after being washed with aqueous 3% Tween solution, were analyzed using a newly validated ultra-high-performance liquid chromatography-tandem mass spectrometry (UHPLC-MS/MS) method. The method targeted and quantified fentanyl, other analogs, and adulterants. Linearity was verified in the range of 3-10,000 pg/mg for fentanyl, norfentanyl, β-hydroxyfentanyl; 9-10,000 pg/mg for 4-ANPP; 3-1,200 pg/mg for acetylfentanyl, acetyl norfentanyl, carfentanil, norcarfentanil, ocfentanil, furanylfentanyl, and U-47700; 18.8-1,200 pg/mg for despropionyl para-fluorofentanyl; 62.5–10,000 pg/mg for xylazine.[4]

Results: Hair samples tested positive for fentanyl or its analogues in 129 out of 250 cases (51.6%), including 92 males (71.31%) and 37 females (28.69%), with a mean age of 41.72 years. Manner of death among positive cases was classified as accident (n = 92), homicide (n = 14), natural (n = 10), suicide (n = 7), and undetermined (n = 6). Drug-related deaths (opioids, n = 76; other drugs, n = 13) and firearm-related deaths (n = 19) were most prevalent. Fentanyl was identified in 125 of 129 positive hair samples, and 101 of those also contained analogues. Frequently detected compounds included norfentanyl (n = 83, 66.4%), β-hydroxyfentanyl (n = 42, 33.6%), acetylfentanyl (n = 16, 12.8%), 4-ANPP (n = 83, 66.4%), and despropionyl para-fluorofentanyl (n = 26, 20.8%). Xylazine, a common adulterant, was present in 51 cases (40.8%). Geospatial mapping identified specific neighborhoods in Jefferson County with high concentrations of hair-positive and xylazine-positive subjects. Age and cause of death were significant risk factors for hair positivity.

Conclusions: This study confirms that hair is a robust and informative matrix for detecting fentanyl and analogues in postmortem cases. It offers critical advantages in decomposed bodies or cases lacking viable blood or urine. Furthermore, hair testing enables localized surveillance of opioid spread, aiding forensic investigations and public health responses. Routine implementation of hair analysis could substantially enhance understanding and management of the synthetic opioid crisis.

L46 MDMA Toxicity: A Fatal Case of Ayus-Arieff Syndrome

Chiara Carsana, MD, University of Milan, Milan, Lombardia, Italy; Bianca Beltrame, MD*, University of Brescia, Venice, Veneto, Italy; Andrea Verzeletti, MD, PhD, University of Brescia, Brescia, Lombardia, Italy; Mauro Minoli, BPharm, University of Milan, Milan, Lombardia, Italy; Lorenzo Franceschetti, MD, PhD, University of Milan, Milan, Lombardia, Italy*

Learning Objectives: The primary aims of this presentation are two-fold: to inform forensic pathologists of this specific cause of death, aiding accurate postmortem diagnosis, and to alert clinicians about the early recognition and urgent treatment required for electrolyte disturbances in patients presenting with MDMA intoxication.

Impact Statement: This presentation addresses a rare and severe consequence of MDMA intoxication: acute hyponatremia progressing to cerebral edema, Ayus-Arieff Syndrome, and ultimately death. The forensic scientific community will gain critical insights into this lethal pathophysiological mechanism never described in a man.

Abstract Text: MDMA (3,4-Methylenedioxymethamphetamine), a recreational drug often perceived as relatively safe, is associated with acute and chronic toxicities.[1] Multiple theories explain MDMA-induced hyponatremia, including inappropriate ADH secretion (SIADH), excessive water intake triggered by drug-induced hyperthermia, direct stimulation of aquaporin-2 channels increasing renal water reabsorption, and loss of hypotonic fluids via excessive sweating from vigorous physical activity.[2,3]

Severe hyponatremia manifests with neurological symptoms such as headache, lethargy, confusion, seizures, coma, and cerebral oedema. Ayus-Arieff Syndrome describes a severe, self-reinforcing condition where cytotoxic cerebral edema triggers neurogenic pulmonary edema, causing hypoxia, further impairing brain cell volume regulation and exacerbating cerebral edema, thus establishing a fatal cycle.[4]

We present the case of a young male who died due to acute hyponatremia and cerebral edema following MDMA intoxication. After consuming MDMA dissolved in an alcoholic beverage at a nightclub, he rapidly deteriorated from initial euphoria to loss of consciousness, becoming unresponsive with a Glasgow Coma Scale score of 3, fixed mydriatic pupils, generalized hypertonia with tremors, severe hyperthermia (41.5°C), tachypnea, and desaturation upon emergency department admission. Toxicological analysis revealed the presence of amphetamines and opioids.

Despite intensive care management and toxicological guidance, the patient succumbed to progressive cerebral and pulmonary edema. Autopsy findings were unremarkable macroscopically; however, toxicological analysis confirmed high MDMA levels in cardiac (1.93 µg/mL) and femoral blood (1.90 µg/mL), near known lethal concentrations. Hair analysis suggested habitual MDMA use (9.71 ng/mg proximal segment). Opioids were instead administrated during the emergency care setting, in accordance with medical records. Circumstantial evidence indicated ingestion of high-purity MDMA crystals dissolved in water, significantly increasing overdose risk.

This case report uniquely highlights forensic investigation from death to pathogenesis rather than the common clinical-to-pathological sequence. It also documents a fatality in a young male, differing from typical epidemiological data in the current scientific literature, only reporting few cases of MDMA-related hyponatremia deaths, all in females.[3-5]

In conclusion, awareness of Ayus-Arieff Syndrome is essential in forensic investigations of drug-related fatalities and critical in clinical settings for prompt recognition and management of severe electrolyte imbalances to prevent fatal outcomes.

L47 The Positivity of Clonazepam and 7-Aminoclonazepam in DUID Versus Postmortem Casework: Microbial Biotransformation as a Pre-Analytical Factor

Haley L. Bibey, MSFS, NMS Labs, Rising Sun, MD; Donna M. Papsun, MS, NMS Labs, Horsham, PA; Brittany K. Casey, PhD, NMS Labs, Horsham, PA; Shayna Kasher, MSFS, NMS Labs, Horsham, PA*

Learning Objectives: After attending this presentation, attendees will: (1) learn about the utility of evaluating parent nitro-benzodiazepine to metabolite positivity rates to investigate possible microbial biotransformation in postmortem blood; (2) review the comparison of 2022-2024 Driving Under the Influence of Drugs (DUID) and Postmortem (PM) data reported from National Medical Services (NMS) labs for clonazepam and 7-aminoclonazepam; and (3) understand the need to consider potential microbial biotransformation when evaluating or interpreting results in postmortem casework.

Impact Statement: It is well understood in the forensic toxicology field that interpretation of PM casework is complex. Microbial biotransformation in PM toxicology is a lesser-known factor to consider for interpretation of toxicology results. This presentation will impact the forensic science community by providing a data-driven forensic casework study that illustrates that PM microbial biotransformation should be considered during toxicological interpretation of clonazepam and 7-aminoclonazepam.

Abstract Text: Clonazepam is a prescription nitro-benzodiazepine used to treat and manage seizure and panic disorders.It is also a popular drug of misuse due to its central nervous system depressant effects, which can include sedation, muscle relaxation, anxiolysis, and cognitive deficits.[1,2]

Clonazepam is metabolized via nitro-reduction to its primary inactive metabolite, 7-aminoclonazepam (7-AMC)[1]. Nitro-benzodiazepines are known to be particularly unstable in postmortem (PM) blood, especially in samples contaminated with bacteria. Previous studies have shown that bacteria active during decomposition are capable of metabolizing clonazepam, affecting both the positivity and parent-to-metabolite ratio of clonazepam and 7-AMC.[2,3] Proper sample preservation is important in attempts to control PM microbial biotransformation. Research has demonstrated that temperature control and addition of preservatives, such as sodium fluoride, can significantly slow, or potentially eliminate, the process.[2,3] However, PM blood is typically not collected in ideal, controlled conditions, and therefore, microbial activity is possible despite appropriate sample collection. Comparatively, blood collected from living individuals remains largely unaffected by this, as bacteria is uncommonly found in antemortem blood due to the sterile nature of sample collection and the absence of postmortem bacterial growth and translocation.[2,3]

To investigate the role of bacterial transformation in forensic casework in a complementary data-driven approach to *in vitro* studies, a review of clonazepam and 7-AMC positivity in PM and driving under the influence of drugs (DUID) casework reported from our laboratory between 2022-2024 was performed. Benzodiazepines are included within all routine PM and DUID panels requested in medicolegal investigations. Panels that utilize immunoassay screening have a benzodiazepine reporting limit (RL) of 100 ng/mL. Panels that utilize liquid chromatography-time of flight/mass spectrometry (LC-TOF/MS) for screening have a RL of 10 ng/mL for both clonazepam and 7-AMC. Quantitative confirmation is achieved by liquid chromatography-tandem mass spectrometry (LC-MS/MS); the RLs for clonazepam and 7-AMC are 2 and 5 ng/mL, respectively.

In 2022-2024 DUID casework, (N= 7,918), clonazepam and 7-AMC were found together in approximately 22% of cases (n= 1,776). 7-AMC was reported in the absence of clonazepam in approximately 0.4% (n= 38) of cases. In 2022-2024 PM casework (N= 53,843), clonazepam and 7-AMC were found together in approximately 9% of cases (n= 4,805); comparatively, 7-AMC was solely reported in approximately 15% of cases (n= 8,229).

This study illustrates a decreased co-reporting of clonazepam and 7-AMC in PM cases compared to DUID cases. The difference between the two populations is likely multifactorial, with PM microbial biotransformation playing a role, and not likely related to differences in population positivity. It is important to acknowledge that there are other pre-analytical factors that could impact this decrease in clonazepam positivity between DUID and PM populations. Postmortem sample collection and testing intervals, sample preservation, postmortem redistribution, blood pH, and the metabolism of clonazepam into 7-AMC prior to death should all be acknowledged as additional variables. While the analysis of PM casework is multi-faceted, the understanding of microbial conversion of nitro-benzodiazepines into their metabolite(s) should be one factor, of many, considered during case interpretation.

L48 "The Matrix": Is the Brain Suitable to Overcome PM Redistribution in Cocaine Overdoses?

Pascale Basilicata, PhD, University of Naples Federico II, Napoli, Campania, Italy; Mariagrazia Marisei, MD, University of Naples Federico II, Naples, Campania, Italy; Maria Pieri, PhD*, University of Naples Federico II, Napoli, Campania, Italy; Angela Silvestre, PhD, University of Naples Federico II, Napoli, Campania, Italy; Angela Simonelli, PhD, University of Naples Federico II, Napoli, Campania, Italy; Rossella Guadagni, PhD, University of Naples Federico II, Napoli, Campania, Italy*

Learning Objectives: By attending this presentation, participants will understand the importance of extending toxicological analyses to non-conventional matrices to ascertain the cause of death in suspect cases of cocaine overdose.

Impact Statement: This presentation will impact the forensic community by highlighting the suitability of brain matrix as a valid and complementary one to integrate data derived from postmortem blood analysis.

Abstract Text: Cocaine postmortem redistribution hinders the interpretation of blood levels, thus making it necessary to extend toxicological analyses to other biological matrices to establish causality in case of acute intoxication. In countries such as Italy, where there is no Coroner's Office, the choice of matrix to be sampled is the prerogative of the forensic toxicologist, who is responsible for all the choices and evaluations that underlie all phases of the analysis, up to the interpretation of the results. The study focused on comparing results obtained in post-mortem blood and brain samples from judicial cases resulted positive to cocaine, in order to strengthen the diagnosis of "deaths after acute intoxication." Unlike other matrices, postmortem drug concentrations in brain are close to or equal to those found immediately before death. Brain is characterized by poor presence of highly polar molecules (as benzoylecgonine, the main cocaine metabolite), and therefore, the presence of such polar analyte in the brain would result from *in situ* formation over time after the last intake. In such hypothesis, in presence of brain cocaine concentration at levels much higher than those of its metabolite, it would be highly likely to assume that death occurred due to acute intoxication.

As previously reported, the ratio cocaine/benzoylecgonine (COC/BE) can be useful to discriminate acute intoxication as cause-of-death.[1]

Eight cases of judicial autopsies, performed between June and October 2024, were selected for which a positivity to cocaine resulted in both peripheral post-mortem blood and brain. The selected cases were predominantly male (7 out of 8) aged between 32 and 50 years old. The fatalities occurred under a variety of conditions, including car accidents, suicide, cardiac arrest, and body found at home and in prison. Toxicological analyses involved an initial immunochemical screening test on peripheral post-mortem blood samples and subsequent confirmation analyses performed in GC/MS and GC/MS/MS in both blood and brain homogenate samples. In cases of acute intoxication (as established by other circumstances) the ratio cocaine/benzoylecgonine determined in the brain matrix was approximately ten times higher than blood one. COC/BE brain ratio was only 2-3 times higher than blood one in cases for which death could not be attributed to acute cocaine intoxication. Results thus confirm the suitability of such an approach for an effective acute cocaine intoxication diagnosis and may represent the starting point for future developments and applications.

L49 Unintentional Fentanyl Overdoses Among Cocaine Users: Investigating "Powder and Rock Confusion" Through a Scene-Integrated Toxicological Model

Emily Dalgo, MA, King County Medical Examiner's Office, Seattle, WA; Alana Golding, BS*, King County Medical Examiner's Office, Seattle, WA; Maria E. Esquivel, BA*, King County Medical Examiner's Office, Seattle, WA; Rhonda Mittenzwei, MD*, King County Medical Examiner's Office, Seattle, WA*

Learning Objectives: Attendees will learn how to apply a novel, scene-integrated toxicological framework to identify likely cases of unintentional fentanyl use among individuals who appear to have intended to use cocaine. Learners will be able to recognize key toxicological indicators and scene patterns and utilize histories that distinguish "powder and rock confusion" deaths, thus improving their ability to detect emerging trends in fentanyl-involved mortality.

Impact Statement: This presentation will strengthen forensic practitioners' abilities to synthesize point-of-care screening tests, toxicology results, scene evidence, and clinical history to recognize unintentional fentanyl use in stimulant-use contexts. By enhancing awareness of this under-recognized pattern, the framework strengthens investigative performance and supports more precise surveillance of fentanyl-related fatalities, enabling forensic professionals to contribute actionable insights to public health stakeholders and inform targeted harm reduction strategies for stimulant-using populations.

Abstract Text: Fentanyl continues to drive overdose fatalities across the United States, a trend reflected in King County, WA's, "real-time" overdose surveillance program.[1-4] However, recent deaths encountered by the Medical Examiner's Office suggest that not all fentanyl-involved deaths reflect intentional opioid use. We have identified a subset of cocaine users who have died from acute fentanyl intoxication without evidence of opioid use history or apparent intent to use opioids, raising critical questions about cocaine misidentification at the point of sale or time of use.

This study introduces a novel, multimodal forensic framework to identify "powder confusion" and "rock confusion" deaths: cases in which individuals intending to use cocaine either in powder or base form unknowingly use fentanyl and succumb to its toxic effects. These are not cases of fentanyl-laced cocaine, but of visual misidentification, where the substance used was fentanyl presented as, or mistaken for, cocaine; paraphernalia identified at scenes and analyzed in-house and routes of administration confirmed by point-of-care screening testing are of particular use in identifying such scenarios.[3] These cases expand understanding of fentanyl-involved fatalities by highlighting a distinct and under-recognized pathway to mortality that becomes visible only through careful integration of postmortem toxicological analysis, scene evidence, and substance use history. Forensic toxicology serves as the critical link revealing these hidden trends, enabling a clearer picture of how stimulant-using populations are impacted by fentanyl and informing more effective public health responses.

Using a retrospective review of fatal overdoses in King County, Washington from January 2022 to June 2025, we synthesized information from five integrated data domains:[4]

- Cause and manner of death
- Postmortem toxicology, including fentanyl/norfentanyl ratios to assess usage habits and temporal relationship between usage and death[5,6]
- Scene investigation, focusing on cocaine-specific paraphernalia, absence of opioid-related items, contexts linked with stimulant use, and route of administration
- Drug evidence analysis, including Raman spectroscopy (TruNarc, Rigaku), mass spectrometry (MX908), and gas chromatography/mass spectrometry (GC/MS) via The Street Drug Analysis Lab at The University of North Carolina, Chapel Hill and The Washington State Patrol Toxicology Laboratory Division
- Electronic health records and known substance use history, emphasizing known stimulant use without documented opioid use

Preliminary findings indicate that up to 14% of monthly fentanyl-involved deaths may reflect powder or rock confusion. Toxicology findings varied, with some decedents testing positive for opioids alone and others a combination of opioids, cocaine, and/or additional stimulants. These cases often include stimulant-linked scene contexts (e.g., party environments), postmortem toxicology patterns suggestive of opioid naïveté, and lethality despite relatively low fentanyl concentrations. These findings suggest that habitual stimulant users, particularly those using cocaine, remain at significant, and often unrecognized, opioid-related mortality risk. By returning to investigative fundamentals, integrating multiple forensic domains, and utilizing point-of-care testing, our framework demonstrates how a multidisciplinary approach can reveal hidden drivers of fentanyl mortality with substantial implications for public health, harm reduction, and community outreach. This reinforces the relevance of forensic science in the public health domain where insights from death investigations can inform harm reduction efforts and better characterize at-risk populations.

L50 Ketamine-Induced Nephritis and Cystitis: A Forensic Autopsy Case Report

Kanokphun Chaisaksiri, MD, Faculty of Medicine, Siriraj Hospital, Bangkok Noi, Krung Thep, Thailand; Peerayuht Phuangphung, MD, PhD, Faculty of Medicine, Siriraj Hospital, Bangkok Noi, Krung Thep, Thailand; Ngoentra Tantranont, MD, Faculty of Medicine, Siriraj Hospital, Bangkok Noi, Krung Thep, Thailand; Sakda Sathirareuangchai, MD, Faculty of Medicine Siriraj Hospital, Bangkok Noi, Krung Thep, Thailand*

Learning Objectives: Ketamine has emerged as a commonly misused dissociative hallucinogen. The attendees should be able to recognize and identify urinary bladder and kidney pathology in a ketamine abuser during forensic autopsy.

Impact Statement: This case report demonstrates pathologic findings in a ketamine abuser with urinary tract complications. Identification of these findings during autopsy should prompt forensic pathologists to perform toxicological analysis for ketamine.

Abstract Text: Ketamine was initially developed as an anesthetic agent, primarily for the induction and maintenance of anesthesia during surgical procedures. Its mechanism of action involves acting as an antagonist of N-methyl-D-aspartate (NMDA) receptors in the central nervous system. However, in recent years, ketamine has emerged as a commonly misused dissociative hallucinogen, largely due to its capacity to induce visual hallucinations and dissociative, out-of-body experiences.[1]

A 32-year-old male with a long history of ketamine abuse and chronic kidney disease was found unconscious by a family member. He was transferred to the emergency department at a nearby hospital. Upon arrival, he was unresponsive and had no palpable pulse. Cardiopulmonary resuscitation was performed for 30 minutes, and he was pronounced dead. A postmortem inquest was conducted due to the undetermined cause of death. The body was transferred to the Department of Forensic Medicine, Faculty of Medicine Siriraj Hospital, for a comprehensive autopsy and further investigation.

The autopsy revealed unremarkable findings in the central nervous system and cardiopulmonary examinations. Both kidneys exhibited numerous foci of yellow discoloration, and weighed 160 grams (right) and 140 grams (left). The renal pelves were dilated and filled with pus. Cut surfaces also demonstrated yellow areas in the renal cortices. Microscopic examination of the kidney showed mixed acute and chronic inflammatory infiltrates, primarily in the interstitium. Many tubules contain neutrophil accumulation and Tamm-Horsfall protein (uromodulin). The urinary bladder mucosa appeared hemorrhagic. Microscopic examination revealed markedly denuded urothelial liningand mixed inflammatory infiltrates throughout the bladder wall.

Ketamine and norketamine were both detected by Liquid Chromatography/Quadrupole Time-of-Flight/Mass Spectrometry (LC/QTOF/MS) in the blood and urine. Blood ketamine and norketamine concentrations were 828.39 ng/mL and 427.64 ng/mL, respectively. Urinary ketamine and norketamine concentrations were 1282.76 ng/mL and 537.47 ng/mL, respectively. These results are consistent with recent ketamine use. Based on the autopsy findings and the toxicologic test results, the cause of death was determined to be acute ketamine intoxication in a chronic ketamine abuser.

Cystitis is a well-known complication of ketamine use, as ketamine and its metabolite norketamine are primarily excreted in the urine and can induce an inflammatory reaction on the bladder mucosa. Patients usually presented with dysuria and hematuria, which, if left untreated, may result in hydronephrosis and subsequent decline in renal function. (1) Kidney injury in most cases is believed to result from obstructive uropathy. Since renal biopsy is rarely performed, the prevalence of ketamine-induced nephritis is undetermined. A case of ketamine-induced interstitial nephritis has been reported in a patient who was prescribed ketamine as an analgesic agent.[2] In this case, although an infectious etiology cannot be entirely excluded, the progression of cystitis into bilateral pyelonephritis in a patient without congenital anomaly of the urinary tract is clinically uncommon.

This autopsy demonstrates the pathology of ketamine abuse in the bladder and kidneys. The presence of purulent inflammation in both kidneys should prompt the forensic pathologist to consider toxicological analysis of blood and urine for ketamine. Ketamine-induced nephritis should be distinguished from acute pyelonephritis through clinical history and microscopic examination.

L51 The Fog of Regulation: Adverse Events and Cannabinoid Products

Kelsey S. Moss, BS, Virginia Commonwealth University, Richmond, VA; Alaina K. Holt, PhD, Virginia Commonwealth University, Richmond, VA; Michelle R. Peace, PhD, Virginia Commonwealth University, Richmond, VA; Justin Poklis, BS, Virginia Commonwealth University, Richmond, VA*

Learning Objectives: Attendees will learn about three cases of adverse events, potentially linked to unregulated cannabinoid products, and the chemical composition of these products. They will gain insight to the potential dangers of mislabeling and lack of quality assurance in the unregulated cannabinoid market.

Impact Statement: This presentation will expand the forensic science community's knowledge of the unregulated cannabinoid market by providing analytical data on the chemical composition of products potentially associated with adverse events. It highlights the utility of a Gas Chromatograph/Mass Spectrometry (GC/MS) screening technique and an updated Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) quantitation method.

Introduction: The unregulated cannabis industry has significantly expanded in recent years, from availability to chemical composition, driven by regulatory gaps in the 2018 Agricultural Improvement Act. A multitude of products are incorrectly labelled in terms of concentrations and/or ingredient lists. Many of these products contain synthetic cannabinoids with limited pharmacological data, yet commonly include suggested dosing. The lack of clear, consistent oversight in the quality assurance of these products poses a risk to consumers for adverse effects.

Commercially available products (vapes, tinctures, gummies) containing various phyto- and synthetic cannabinoids were submitted to the Laboratory for Forensic Toxicology Research at Virginia Commonwealth University from three cases involving adverse events following product use.

Case One: Young adult, male, hospitalized after use of vape products resulting in reported changes in behavior ("in and out of reality," and nearly "catatonic"). Two cannabinoid vaping products were analyzed: a "Modus Breezy Blend" vape, labeled "CB9-A, Pegasus Delta 8, and THC-P," and a Magnolia Hemp vape labeled "THC + CBD."

Case Two: Adult, male, reported missing by his wife who stated her husband had a history of opioid use, was acting erratic and speaking of "the flood". Three vapes, two tinctures, and one jar of gummies were analyzed: three "Geek THCX" vapes of unique flavors, labeled "D9 + THC-P + HTE" or "THC-A melted diamonds"; a "Mend balance 1:1" tincture labeled "1:1 ratio of CBD:THC"; a "Jar Co. Hash Rosin" tincture labeled "THC"; and "Cake" gummies labeled "Delta 9 + THC-A."

Case Three: Adult, male, reported experiencing hallucinations and "didn't feel quite the same" following use of a vape product to help with back pain. A Super Chill vape cartridge was analyzed which had no other identifying information.

Methods: Product constituents were identified using a Shimadzu QP-2020 gas chromatograph mass spectrometer (GC/MS). Cannabinoid concentrations were determined using a Shimadzu LCMS-8050 liquid chromatograph tandem mass spectrometer (LC/MS/MS).

Case One Results: vapes contained cannabinoids and terpenes.
Modus Breezy Blend contained D8-THC (34%), D9-THC (3.1%), D9-THC-P (1.2%), and tentatively identified D-4(8)-iso-THC. Magnolia Hemp contained CBD (14.9%) and D8-THC (13.3%), not consistent with the 1:25 THC:CBD label.

Case Two Results: vapes and tinctures contained cannabinoids and terpenes. Tinctures also contained medium chain triglycerides. Geek Blackberry Kush contained D8-THC (28.8%), D9-THC (5.0%), D9-THC-P (4.9%), D-4(8)-iso-THC (TBD). Geek Wedding Cake contained D8-THC (26.0%), D9-THC (3.9%), D9-THC-P (3.9%), D-4(8)-iso-THC (TBD). Geek Granddaddy Purple (qualitative due to limited sample), D8-THC, D9-THC, D9-THC-P. Mend contained CBD (0.4%) and D9-THC (0.4%). Jar Co. contained D9-THC (0.8%).

Case Three Results: vape contained cannabinoids, terpenes, glycerin, and a synthetic cannabinoid. CBD (25.3%) and MDMB-4en-PINACA (TBD).

Discussion: Case histories and analysis demonstrate ongoing potential safety concerns regarding the cannabis products. Submitted products varied in label accuracy, including concentrations and ingredients. Continued chemical surveillance of products and consumer education is necessary to help prevent future public health incidents.

L52 Exploring the Prevalence of Delta-8 THC in the United States: A Comprehensive Review Across Multiple Matrices and Casework Populations

Jennifer L. Swatek, MS, NMS Labs, Horsham, PA; Samantha H. Curran, BS, NMS Labs, Horsham, PA; Ayako Chan-Hosokawa, MS, NMS Labs, Horsham, PA*

Learning Objectives: After attending this presentation, attendees will understand how federal and state-level legislation has contributed to the emergence of Delta-8 Tetrahydrocannabinol (D8-THC) in the current drug landscape.

Impact Statement: This presentation will impact the forensic science community by providing insight into the analytical and interpretation challenges associated with D8-THC. It underscores the influence of legislation on drug trends throughout the United States and highlights the need for continued surveillance of semi-synthetic cannabinoid isomers. These findings are particularly relevant as cannabis laws continue to evolve at the state level.

Abstract Text: Delta-9 tetrahydrocannabinol (D9-THC), the primary psychoactive compound in cannabis, remains a Schedule I substance under U.S. federal law, though many states have legalized cannabis for medical and/or recreational use. The 2018 Hemp Farm Bill further complicated regulations by allowing hemp-derived cannabinoids like Delta-8 THC (D8-THC) to be sold with minimal oversight. Though less potent than D9-THC, D8-THC's growing prevalence presents new challenges in forensic toxicology.

This study evaluated the prevalence of D9-THC and D8-THC in DUID blood specimens from 2022 to 2024, and in urine casework analyzed in 2024 across postmortem (PM), DUID, drug-facilitated crimes (DFC), and clinical casework. Data were also examined by state cannabis legalization status to assess potential influence of legal access.

A retrospective data review was conducted on routine cannabinoid confirmation testing via LC/MS/MS. Blood samples from DUID cases were tested for D9-THC (LOQ = 0.50 ng/mL) and the two primary metabolites: 11-hydroxy D9-THC and D9-carboxy THC (D9-THCC; LOQ = 1.0 ng/mL and 5.0 ng/mL, respectively). Urine specimens, spanning various case types, were hydrolyzed and analyzed for D9-THCC (LOQ = 5.0 ng/mL). Detection of D8-THC (LOQ = 0.50 ng/mL in blood) and its metabolite (D8-THCC; LOQ = 5.0 ng/mL in both matrices) was carried out retrospectively by integrating chromatographic peaks from routine D9-cannabinoid tests that were validated to separate the isomers. Positive results were categorized as D9-THC only, D8-THC only, or co-positivity. State legalization status was based on laws one year prior to data collection.

Of the 43,970 DUID blood cases, 40,016 (91%) were positive for D9-THC, D8-THC, and/or their metabolites. Among these, 38,388 (95%) were positive for D9-cannabinoid(s), and 6,025 (15%) for D8-cannabinoid(s). Estimated mean D8-THC concentrations were higher when detected alone (8.8±14 ng/mL) versus when found in combination with D9-THC (3.4±7.9 ng/mL); median = 3.5 ng/mL and 1.5 ng/mL, respectively. In contrast, D9-THC mean concentrations remained relatively consistent whether detected alone (8.0±14 ng/mL) or with D8-THC (9.7±12 ng/mL); median = 4.7 ng/mL and 6.2 ng/mL, respectively. D8-cannabinoid detection increased from 10% to 18% over the study period.

In 2024, 3,851 urine cases were analyzed, with 3,667 (95%) testing positive for D9- and/or D8-THCC. D9-THCC was identified in 3,284 (85%) cases and D8-THCC in 1,757 (45%). Co-positivity was highest in the DUID cases (49%), while D9-THCC alone was most common in clinical (67%), PM (57%), and DFC (53%) cases. Of note, urine is not routinely quantified, particularly in forensic casework, potentially explaining the difference in D8-cannabinoid trends compared to blood.

Geographic trends revealed that D9-THC detected alone was most prevalent in states where cannabis is recreationally legal: 91% in blood and 64% in urine. D8-THC use was more common in states with medical-only cannabis laws (14% in blood, 37% in urine) or where cannabis remains illegal (18% in blood, 66% in urine).

These findings underscore the evolving cannabinoid landscape in forensic toxicology and the impact of legislation on drug use patterns. While D9-THC remains dominant, rising D8-THC detection—especially in states with restrictive cannabis laws—highlights the need for ongoing surveillance and analytical preparedness.

L53 High Hopes: Assessing Label Accuracy and Microbiological Contamination of Cannabis Vapes

Logan Peters, BS, Virginia Commonwealth University, Richmond, VA; Ankita Gola, BS, Department of Forensic Science, Virginia Commonwealth University, Bowie, MD; Michelle R. Peace, PhD, Virginia Commonwealth University, Richmond, VA; Alaina K. Holt, PhD, Virginia Commonwealth University, Richmond, VA; Justin Poklis, BS, Virginia Commonwealth University, Richmond, VA*

Learning Objectives: Attendees will be able to describe the methods used to analyze cannabis products for quality control and quality assurance. Further, attendees will better understand issues with labeling practices in the cannabis market and the potential threat these issues pose to consumer health and safety.

Impact Statement: This presentation will inform the forensic science community of quality assurance and quality control concerns in the cannabis marketplace and highlight the need for increased regulations.

Introduction: The rapid expansion of the cannabis market has outpaced regulatory oversight, raising concerns about product safety and labeling accuracy. Semi-synthetic cannabinoids, such as Δ8-tetrahydrocannabinol (Δ8 -THC) and hexahydrocannabinol (HHC), often appear in unregulated products and pose unknown health risks. Other contaminants such as solvents, pesticides, and vitamin E acetate have been linked to adverse effects. Previous studies have also demonstrated the presence of microbiologicals in cannabis products. As consumer access to cannabis products increases, robust product surveillance is essential to protect public health and inform evidence-based regulation.

Objectives: This study investigated discrepancies between labeled cannabinoid content and actual cannabinoid content as well as assessed potential contamination in commercial cannabis products.

Methods: Sixteen commercially available cannabis vaping products were purchased from several brick and mortar outlets in Washington, D.C. On opening, products were prepared for volatiles and microbiological analysis. For volatiles analysis, mixed ethanol, methanol, acetone, and isopropanol calibrators (1-50%) and controls (2, 6, 40%) were prepared in water with each analytical run. 100 uL of controls, calibrators, and samples were prepared and analyzed by adding 1 mL of internal standard (t-butanol) and using a Shimadzu HS-20 headspace gas chromatograph (GC-2030AF) with dual flame ionization detector. Chromatographic separation was achieved using BAC 1 and BAC 2 Restek columns. Microbiological samples were prepared as a 1:10 dilution using ultrapure water. 1 mL of the dilution was was plated on Thermo Fisher Petrifilm microbiological plates (yeast and mold, aerobic count, E. coli). Positive controls were prepared using Thermo Fisher Culti-Loops. Controls and samples were incubated and interpreted according to manufacturer instructions. Products were screened using a Shimadzu QP-2020 gas chromatograph mass spectrometer to identify chemical constituents. In brief, a 40 µg/mL methanolic dilution of each sample, along with double blanks and a quality control test mix containing various drugs of interest were analyzed. Reference materials and spectral libraries were used for identification.

Results: Ethanol was identified in five products. Microbiologicals (yeast, mold, e-coli, coliform, aerobic bacteria) were not identified in any product. All products with labeled cannabinoids were found to contain unlabeled compounds. Labeled cannabinoids were not detected in ten of the products.

Discussion/Conclusion: Unlabeled volatile compounds, such as ethanol, continue to be in commercially available vaping products. In this limited sample set, no microbiologicals were detected. Similar to previous studies, labeling inconsistencies of psychoactive components remains problematic. These findings underscore the risks associated with unregulated cannabis products and the potential for adverse health effects due to mislabeling and chemical contamination. Continued surveillance and regulatory enforcement are essential to ensure consumer safety and product integrity in the expanding cannabis market.

L54 Chemical Roulette: The Safety Gamble of Over-the-Counter Nutraceuticals

Lillie Thomas, MS, Virginia Commonwealth University, Richmond, VA; Justin Poklis, BS, Virginia Commonwealth University, Richmond, VA; Michelle R. Peace, PhD, Virginia Commonwealth University, Richmond, VA*

Learning Objectives: Attendants will learn about nutraceuticals and residual solvents that may be present in samples. The audience will also be exposed to products available on the market that can be considered nutraceuticals.

Impact Statement: This presentation shares with the community commercially available products that their patients/stakeholders have access to. These products may contain residual solvents and other chemical components not listed in the products' ingredient list.

Abstract Text: Nutraceutical products are derived from plant and/or food sources and claim a wide range of therapeutic benefits. Nootropic and cannabidiol (CBD) products are widely promoted for their therapeutic benefits across a broad range of health conditions. Nutraceuticals marketed as dietary supplements are regulated by the U.S. Food and Drug Administration (FDA) as a subset of food, not as drugs. Unlike pharmaceuticals, dietary supplements do not require pre-market approval from the FDA. Consequently, nutraceutical products are not required to meet the safety, efficacy, and quality standards established by the International Council for Harmonisation of Technical Requirements for Pharmaceuticals for Human Uses (ICH).[1] These products are frequently promoted as cure-all remedies and alternatives to prescription medications. One popular class of nutraceuticals is nootropics or 'smart drugs'/ 'cognitive enhancers'. This diverse group of substances is believed to enhance brain function. CBD, a nonpsychoactive cannabinoid derived from the *Cannabis sativa* plant, is widely available in products across all markets. The FDA maintains that CBD cannot be added to food products or marketed as a dietary supplement, as it is the active ingredient in the FDA-approved drug Epidiolex. Presented is an evaluation of label accuracy and an analysis of seven nootropic products and thirteen CBD products, formulated as capsules, gels, gummies, oils, pills, and tinctures.

For the analysis of psychoactive compounds, each nootropic and CBD product was weighed, aliquoted, and extracted using methanol. Reference standards, along with controls, blanks, and sample extracts were analyzed using a Shimadzu QP-2020 gas chromatograph–mass spectrometer (GC/MS) equipped with an Agilent HP-5MS analytical column (30 m × 0.25 mm × 0.25 µm). For the analysis of residual solvents, aliquots of each gel, gummy, oil, and tincture product, along with two Restek residual solvent reference standards (Residual Solvents #1 and Class 3–Mix A) and blank samples, were analyzed using headspace gas chromatography coupled with a flame ionization detector (FID) and a mass spectrometer detector. Separation was achieved using a Thermo Scientific TG-ALC Plus II analytical column (30 m × 0.32 mm × 0.60 µm).

The ingredient lists on product packaging did not always reflect the actual contents of the products. Notably, truBrain's 'Non-caff', advertised as an energy booster, was found to contain phenmetrazine, a controlled substance and appetite suppressant. Several products listed CBD as an ingredient, but no CBD was detected in the analytical results. Conversely, some CBD products contained unlisted cannabinoids, such as cannabigerol (CBG) and delta 9-tetrahydrocannabinol (D9-THC). All products tested contained at least one residual solvent, including methanol, ethanol, n-pentane, and ethyl acetate. The presence of undisclosed compounds, cannabinoids, and/or residual solvents raises significant concerns regarding potential adverse effects and represents a public health and safety issue.

L55 Analysis of Δ8-Tetrahydrocannabinol, Δ9-Tetrahydrocannabinol, and Cannabidiol Metabolites in Authentic Meconium Samples

Marco Ballotari, PhD, University of Florida, Gainesville, FL; Michael T. T. Truver, PhD, University of Florida, Gainesville, FL; Bruce A. Goldberger, PhD, University of Florida College of Medicine, Gainesville, FL; Sarah H. Bartock, PhD, Quest Diagnostics, Chantilly, VA; Wen Dui, PhD, Quest Diagnostics, Chantilly, VA; Kay Roussos-Ross, MD, University of Florida, Gainesville, FA*

Learning Objectives: Attendees will learn about the quantitative analysis of natural and semi-synthetic cannabinoids in meconium samples and how these data assist in the identification of maternal use of cannabinoids.

Impact Statement: This presentation will highlight the quantification of Δ8-tetrahydrocannabinol, Δ9-tetrahydrocannabinol, and cannabidiol metabolites in meconium samples as a tool to assess the prevalence of drug use during pregnancy.

Abstract Text: Cannabis use, either medical or non-medical, during pregnancy for relief of pregnancy-related symptoms such as nausea, anxiety, and sleep disturbance can lead to potential adverse clinical and neurodevelopmental outcomes. The consumption of cannabis-related products during pregnancy is increasing. Testing of conventional matrices, such as blood and urine, provides information regarding the recent intake of drugs, whereas the analysis of alternative specimens, such as meconium, provides information regarding maternal use and potential in utero exposure during the third trimester of pregnancy. In this study, meconium samples (n=19) were obtained from neonates at birth delivered at University of Florida (UF), Health in Gainesville, Florida from November 2022 to May 2025. The study was approved by the University of Florida Institutional Review Board. All participants of the study completed a questionnaire regarding cannabis and cannabidiol use during pregnancy. The meconium samples were stored at -20°C, and the storage time from collection to analysis ranged between 1 and 20 months. The analysis of the carboxy metabolites of Δ^8- and Δ^9-tetrahydrocannabinol (Δ^8-THC and Δ^9-THC) and cannabidiol (CBD) in the meconium samples was performed at Quest Diagnostics in Chantilly, Virginia. The method was fully validated in accordance with the Clinical Laboratory Improvement Amendments (CLIA) regulations for laboratory-developed tests. Meconium samples were subjected to base hydrolysis and dilution with neutralization prior to liquid chromatography-tandem mass spectrometry analysis. The analytical measurement range for 11-nor-Δ^8-carboxy-THC (Δ^8-THC-COOH), 11-nor-Δ^9-carboxy-THC (Δ^9-THC-COOH), and 7-carboxy-cannabidiol (7-COOH-CBD) was 2.5-5000 ng/mL utilizing urine-based calibrators and quality controls with demonstrated matrix equivalency. Quantitative results were reported in ng/g, adjusted for the sample weight used. The limit of quantitation was 5 ng/g for analytes.

The most frequently identified analyte was Δ^9-THC-COOH, quantified in 12 samples, and Δ^8-THC-COOH was quantified in 5 of the Δ^9-THC-COOH positive samples (Table 1). None of the meconium samples tested positive for Δ^8-THC-COOH only or 7-COOH-CBD.

According to participant self-report, Δ^9-THC-COOH was identified in all neonates born to mothers who ingested cannabis during the third trimester; and Δ^8-THC-COOH and Δ^9-THC-COOH were not present in the meconium of the neonates born to mothers (control subjects) who did not ingest cannabis during the third trimester. Further, 7-COOH-CBD was not identified in the meconium of two participants whose mothers reported the ingestion of cannabidiol during the third trimester.

In conclusion, Δ^8-THC-COOH and Δ^9-THC-COOH were identified in the meconium of neonates of pregnant women who reported the use of cannabis during their third trimester. A quantitative analysis of natural and semi-synthetic cannabinoids in meconium samples was presented as a tool to assess drug use patterns during pregnancy. These data will support our study of the potential benefits or harm of cannabis use during the perinatal period.

Table 1. Quantitative results of cannabinoids in the meconium samples (N=19)

Compound Name	Mean Concentration ± S.D. (ng/g)	Median Concentration (ng/g)	Range (ng/g)
Δ^9-THC-COOH (n=12)	405 ± 782	113	5.9 2755
Δ^8-THC-COOH (n=5)	13.6 ± 6.9	15.7	6.1 19.8

L56 The Laboratory Impact of a Paradigm Shift in Reporting Postmortem Cannabinoids

Shayna Kasher, MSFS, NMS Labs, Horsham, PA; Daniel Isenschmid, PhD, NMS Labs, Horsham, PA; Donna M. Papsun, MS, NMS Labs, Horsham, PA; Sherri L. Kacinko, PhD, NMS Labs, Horsham, PA; Haley L. Bibey, MSFS, NMS Labs, Rising Sun, MD*

Learning Objectives: The goal of this presentation is to highlight the limited interpretive value of postmortem cannabinoid concentrations and to present the operational impact of changing analytical testing and reporting for postmortem cannabinoids to align with their toxicological utility.

Impact Statement: This presentation will impact the forensic science community by discussing how our laboratory adjusted testing and reporting protocols for postmortem cannabinoids and the effects of this change on sample consumption, instrument capacity, cancellations, and turnaround time. This change reduced the significant strain placed on laboratory resources, including analyst workload and the consumption of resources as well as lowering the risk for over-interpreting postmortem cannabinoid concentrations.

Abstract Text: Postmortem (PM) concentrations of Delta-9 THC and its metabolites are affected by multiple factors that can make interpretation forensically unreliable. Dramatic differences in concentrations between collection sites have occurred in cases due to postmortem redistribution (PMR) and other factors. Higher THC concentrations were reported in peripheral blood compared to central blood in postmortem cases.[1,2] Additionally, THC concentrations exceeding Delta-9 Carboxy THC concentrations were observed significantly more frequently in PM cases than driving under the influence (DUI) cases.[3] This suggests considerable changes in blood THC concentrations after death, supporting previous research that THC undergoes greater PMR with increased PM intervals.[4] Since THC has no established lethal concentration, postmortem concentrations have minimal impact on the determination of cause/manner of death in most cases.[5]

Forensic laboratories are experiencing significant postmortem cannabinoid positivity. At our laboratory, an average of 58,376 samples per year were sent to cannabinoid confirmation testing between 2020-2024, consisting of 70-85% postmortem blood samples with an overall positive confirmation rate of 76%. The prevalence of semi-synthetic cannabinoids created additional reporting challenges, with cancellations of postmortem samples increasing from 10.1% in 2021 to 17.2% in 2024 due to Delta-8 isomers interfering with analytical results.

Recommended forensic toxicology practices traditionally include immunoassay screening and quantitative confirmation by a separate technique. However, due to the limited interpretive value of postmortem cannabinoid concentrations, case interpretation is rarely impacted by not obtaining quantitative results. Confirming PM cannabinoids is a significant drain of resources with the large volume of testing. Therefore, our laboratory shifted reporting of PM cannabinoids to a presumptive positive result based on positive immunoassay screening, with a notation acknowledging the limitation of results without mass spectrometry confirmation. Quantitative confirmatory testing is still performed for DUI, drug facilitated crime (DFC), and other antemortem casework.

Implementing this change at our laboratory significantly reduced cannabinoid confirmation testing by liquid chromatography/ tandem mass spectrometry. After an initial change to qualitative postmortem cannabinoid reporting in March 2025, testing decreased from a quarterly average of 14,092 samples in 2023-2024 to only 8,274 samples in quarter two of 2025. This preliminary data demonstrated a 33% decrease in cannabinoid confirmation testing with a corresponding 28% reduction in cancellations. We anticipate that by the end of 2025, approximately 3,000 samples will be analyzed quarterly for non-DUI cannabinoid testing. This projected 75-80% total decrease in confirmatory testing is expected to lessen analyst workload by 60 total hours per week, increase instrument capacity by 45%, and reduce turnaround time.

An increasing consensus among the death investigation and forensic toxicology communities is that despite their high rate of positivity, postmortem cannabinoids hold little interpretive value. Implementing a screening-only approach fulfills cannabinoid reporting/tracking needs while improving laboratory efficiency/turnaround time, avoiding unnecessary consumption of resources, and simplifying reporting and interpretation. It avoids reporting cancellations in confirmation testing due to interferences by cannabinoid isomers, making reports less confusing, and forensic professionals would not be faced with interpreting unreliable concentrations. Laboratory scopes and testing protocols should be routinely assessed to continue providing necessary, interpretable results for death investigation cases.

L57 A Comparison of Selectivity and Peak Shape of Forensically Relevant Compounds Between Four Column Types

Margaret Frohnhoefer, BSc, Pennsylvania State University, Middle Village, NY; William H. Campbell, PhD, Penn State University, University Park, PA*

Learning Objectives: This presentation aims at providing further education on Tandem Liquid Chromatography Triple Quadrupole Mass Spectrometry (LC/MS/MS) and the effect that varying column phases have on the selectivity and peak shape of forensically significant analytes. The research explores the differences observed between a C18, a permanently charged C18, a biphenyl, and high pH stable C18 column and allows attendees to better grasp the benefits of employing various column chemistries.

Impact Statement: This research project has significant impacts on the forensic science community by evaluating varying column chemistries that can be utilized in LC/MS/MS instrumentation that have affected specificity and peak shape. The results obtained from the project note substantial differences in both peak shape and specificity when comparing different stationary phases.

Abstract Text: As the usage of Tandem Liquid Chromatography Triple Quadrupole Mass Spectrometry (LC/MS/MS) gains traction, it has become useful to evaluate different column stationary phases chemistries. Column chemistry can and does impact analyte selectivity and potentially peak shape. Improving peak shape and selectivity can improve the accuracy and reliability of the data obtained through LC/MS/MS instrumentation. The goal of this research project was to evaluate column performance on a panel of 28 drugs of significance in forensics. Column chemistries that were evaluated included a C18, a permanently charged C18, a biphenyl, and high pH stable C18 column. All columns were manufactured using 2.7micron solid core media.

A panel of 28 drugs, including important metabolites, of varying classifications were used. The first step of this project was to determine optimized instrument parameters. The method used a gradient of 5% to 80% acetonitrile (mobile phase B). Mobile phase A was water. Both A and B were modified with 0.1% formic acid. Gradient time was 9.5 minutes. A 7-minute equilibration time was used prior to each injection and the flow rate was 0.40mL/min. Mass spectral transitions were determined and used to build the final method in which time segments were used to optimize signal intensity. Standard curves were produced for each phase type for performance comparison.

Upon completion of this research, substantial differences in peak shape and selectivity between the column types were observed. The biphenyl and positively charged column provided the best overall peak shape. Additionally, we noted substantial differences in selectivity depending on the phase type. These results have significant implications when issues with coelution and sensitivity arise, as evaluating the interactions with different phases may improve the overall data obtained. Future work will aim to expand this panel with an additional 32 analytes.

L58 Tiny Samples, Big Impact: Detecting Prenatal Alcohol Exposure Using PEth in Dried Blood Spots and LC/MSMS

Stephanie Rodriguez, BS, John Jay College, New York, NY; Baylee Clore, BS, John Jay College, New York, NY; Marta Concheiro-Guisan, PhD, John Jay College, New York, NY*

Learning Objectives: Attendees will learn how Phosphatidylethanol 16:0/18:1 (POPEth) and 16:0/18:2 (PLPEth) can serve as sensitive biomarkers to detect and monitor alcohol consumption using Dried Blood Spots (DBS). This presentation will present the validation of a highly sensitive Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) method for measuring POPEth and PLPEth in DBS and its application in monitoring prenatal alcohol exposure.

Impact Statement: This presentation will improve the forensic science community's ability to detect alcohol exposure, especially in pregnant individuals. By enhancing detection levels, a more accurate exposure assessment can improve outcomes for maternal and fetal health by facilitating early intervention.

Abstract Text: While the window of detection for direct ethanol measurement in the blood can be up to eight hours, the alcohol metabolite, phosphatidylethanol (PEth), can be measured anywhere from 7 days to 1 month later, depending on the level of consumption. PEth is a unique phospholipid formed from phosphatidylcholine present in the membranes of red blood cells. For accurate and reliable measurement of PEth, the analysis of the most abundant analogs, phosphatidylethanol 16:0/18:1 (POPEth) and 16:0/18:2 (PLPEth), is recommended. Assessment of drinking history is useful in multiple forensic and clinical settings, such as determining prenatal alcohol exposure.

This study aimed to improve on current methods for the analysis and detection of POEth and PLEth using dried blood spots (DBS) and liquid chromatography-tandem mass spectrometry (LC-MS/MS). This method was applied to high-risk pregnant women across three visits to investigate alcohol use during pregnancy (n=344). The samples were collected at UTHealth, Houston, TX. DBS samples were collected on Whatman 903 protein saver cards. One 12.7mm whole punch from DBS was extracted in one mL of methanol for 90 minutes in the presence of the internal standards (POEth-d5 and PLEth-d5, 20 µL at 0.1 µg/mL), followed by centrifugation, evaporation, and reconstitution with 200 µL acetonitrile: methanol, 90:10 v/v. The chromatography separation was conducted in gradient mode with a C18 column. Mobile phase A was composed of acetonitrile and 10mM ammonium acetate (70:30 v/v), and mobile phase B was composed of 2-propanol. The analysis was achieved by LC-MSMS in negative ESI mode. Two multiple reaction monitoring transitions were monitored per compound. The method was linear from 5 to 800 ng/mL (not forced, $1/x^2$ weighting, n=5), and the limit of detection (LOD) and quantification (LOQ) was 5 ng/mL. Precision and bias were evaluated at 10, 40, and 400 ng/mL (n=15). Intra- and inter-day precision (CV) for both analytes were below 19.1%, with bias ranging from -3.4 to 11.0%. Matrix effect and extraction efficiency were evaluated at 10 and 400 ng/mL (n=10). No matrix effect was detected, and the extraction efficiency ranged from 45% to 70%. POPEth and PLPEth extracts were stable in the autosampler for 48h. No endogenous nor exogenous interferences were detected (n=10). No issues were encountered regarding the volume effect (20-60 µL blood spots) or the volcano effect (n=3) at 10 and 400 ng/mL. Among the 344 DBS samples, 311 were positive for POPEth, and 320 for PLPEth. Mean±SD concentrations were 32.3±87.9 ng/mL for POPEth, 35.2±94.1 ng/mL for PLPEth, and the ratio POPEth/PLPEth was 0.8±0.5. (POPEth >200 ng/mL). These primary findings demonstrate that DBS-PEth analysis can improve the detection of prenatal alcohol exposure.

L59 Sealed Syringe Rotation Saturation Improves Safety and Efficiency in Postmortem CO-Hb Measurement

Songhie An, PhD, National Forensic Service, Seoul Institute, Department of Forensic Chemistry, Seoul, Seoul-t'ukpyolsi, Republic of Korea; Yujeong Kim, PhD, Department of Chemistry, National Forensic Service-Seoul Institute, Seoul, Seoul-t'ukpyolsi, Republic of Korea; Wooyong Park, MSc, Department of Chemistry, National Forensic Service, Republic of Korea, Wonju-si, Kangwon-do, Republic of Korea*

Learning Objectives: After reviewing this poster, participants will be able to describe the Sealed-Syringe Rotation Saturation (SSRS) workflow for carboxy-haemoglobin (CO-Hb) analysis, explain how it minimizes carbon-monoxide exposure compared with bubbling, and outline the key validation metrics—linearity, precision, and limit of quantification—that demonstrate the method's forensic reliability and operational efficiency.

Impact Statement: This method significantly improves routine CO-Hb analysis by integrating gas-tight syringe saturation with rotor mixing, drastically cutting analyst CO exposure, streamlining parallel sample handling, and offering validated accuracy, thereby advancing both occupational safety and procedural efficiency in forensic toxicology laboratories worldwide.

Abstract Text: Colorless and odorless gases such as carbon monoxide (CO) present unique forensic challenges because they remain undetected until serious injury or death occurs. CO—long dubbed the "silent killer"—is still a leading cause of accidental and intentional poisoning in Korea, making postmortem carboxy-haemoglobin (CO-Hb) quantification a routine requirement in forensic laboratories. The most widely used saturation method introduces CO into blood by sequentially bubbling the gas through open vials inside a fume hood. Although analytically reliable, this workflow is slow and, more critically, can leak CO from the hood into the analyst's breathing zone at concentrations exceeding recommended occupational limits.[1]

To eliminate this hidden hazard we developed a sealed-syringe rotation saturation (SSRS) technique. Approximately 5 mL of postmortem blood is drawn into a 10 mL gas-tight syringe; the remaining head-space is filled with CO from a Tedlar® bag. The syringe is mounted on a rotor and turned at 40 rpm for 15 min, allowing complete saturation of hemoglobin. Residual free CO is then expelled, the head-space replaced with nitrogen, and the syringe rotated for a further 15 min to strip excess gas.[2] Gas chromatography with thermal-conductivity detection (GC-TCD) confirmed that SSRS yields CO-Hb values statistically indistinguishable from to the bubbling method. Oximetry showed full saturation within the first 15 min, matching—and often exceeding—the efficiency of bubbling while avoiding sample foaming or hemolysis. Because the rotor accepts two 12-slot syringe plates, batches of up to 24 samples can be processed in parallel, making SSRS faster than sequential bubbling when sample numbers are high. Method validation produced a linear response ($R^2 > 0.99$), intra-day precision of 9 % CV, and a limit of quantification of 10 % CO-Hb, equivalent to existing protocols.

These results demonstrate that SSRS maintains analytical accuracy, substantially reduces operator exposure to CO, and significantly increases throughput—thereby turning a routine toxicological assay into a safer, more efficient procedure.

L60 Strategies for Mitigating the Effects of High Gabapentin Concentrations in Urine Specimens

Haley P. Berkland, MSFS, Restek Corporation, Bellefonte, PA*

Learning Objectives: By attending this presentation, attendees will gain knowledge of how high concentrations of gabapentin in urine can create analytical challenges when analyzed by Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) and learn different strategies to mitigate these challenges.

Impact Statement: This presentation will impact the forensic science community by examining a common interference between gabapentin and amphetamine and providing various analytical strategies to resolve it.

Abstract Text: Gabapentin is an anti-convulsant drug that is prescribed for the treatment of neuropathic pain and seizures, as well as for many off label uses. Due to the pharmacokinetics of gabapentin, urine specimens often contain extremely high concentrations of the compound.[1] When analyzed by LC-MS/MS, high concentrations of gabapentin can have significant analytical implications, particularly for the compound amphetamine. Interference between gabapentin and amphetamine has been well documented, and can result in signal suppression, poor peak shape, and shifting retention times.[2] Other analytical challenges include saturation of the mass spectrometry detector and column overload.

In this work, we explored several strategies to mitigate the effects of high gabapentin concentrations in urine samples. A method used in the analysis of 60 drugs of abuse in urine was used to test samples containing varying concentrations of gabapentin and amphetamine. After data was collected, the signal of amphetamine was compared in each sample to determine if interference from gabapentin was occurring. The method utilized a Raptor Biphenyl 50 x 2.1 mm, 2.7 µm column and a mobile phase of water and methanol, both acidified with 0.1% formic acid. The flow rate was 0.6 mL/min, the column temperature was 45°C, and the injection volume was 5 µL. Gradient elution was employed. In samples containing high amounts of gabapentin, amphetamine showed decreased sensitivity due to signal suppression and shifted retention time. Different strategies were investigated to see if the interference between gabapentin and amphetamine could be resolved. These strategies included using alternate column lengths and diameters, decreasing injection volume, and testing different mobile phase additives.

It was determined that the best approach for reducing interference was to fully chromatographically resolve gabapentin and amphetamine and ensuring that gabapentin was the first compound to elute. This was accomplished by switching the additive in mobile phase A from formic acid to ammonium formate, which impacted the elution order of early eluting compounds. Resolution was further improved by switching a 100 x 2.1 mm column. Detector saturation and column overload were mitigated by reducing the injection volume from 5 µL to 2 µL. Significant carryover was observed due to the high analyte concentrations and was eliminated by adding a small amount of 2-propanol to mobile phase B. Performance of the other analytes in the method was not negatively affected by the change in method parameters. The redeveloped method can be used to effectively analyze 60 drugs of abuse in urine without interference between gabapentin and amphetamine.

L61 The Optimization and Validation of a Method for Detecting Single Doses of Diphenhydramine in Hair From a Controlled Dosing Study

Kaylyn A. Keith, MS, Florida International University, Miami, FL; Anthony P. DeCaprio, PhD, Florida International University, Miami, FL*

Learning Objectives: This research provides an optimized and validated method for the detection of single doses of drugs in hair in cases of drug facilitated crime. The validated method was also applied to authentic single dose samples with the goal of detection.

Impact Statement: Hair is an important matrix in forensic toxicology. Currently there are no standardized methods for drug detection in hair, creating the need for validated methods. There is also limited research in detecting single doses, which is a primary goal of this research.

Abstract Text: Hair is an important matrix in forensic toxicology as it provides an extended detection window for drugs. On average, it takes approximately 10 days after ingestion for a drug to become incorporated into the hair and emerge from the scalp. Once incorporated, drugs may be detectable for weeks to months following exposure. This long detection period is particularly useful in investigations of drug facilitated crime (DFC), where only a single dose may be involved.

Hair analysis is inherently complex, involving numerous preparatory steps and variable experimental conditions. The primary objective of this study was to optimize the extraction procedure and develop a quantitative LC-QqQ-MS method suitable for the detection of single-dose exposures. A statistical Design of Experiments (DoE) framework was employed to systematically evaluate hair extraction parameters for target drugs and metabolites using authentic Hair Reference Materials (HRMs). The optimized procedure was then validated in accordance with ANSI/ASB Standard 036, with particular emphasis on achieving limits of detection (LOD) and quantitation (LOQ) appropriate for DFC investigations. Following validation, the method was applied to authentic hair specimens collected from a single-dose diphenhydramine (DPH) study to assess its capability to detect single-dose incorporation.

Hair samples were decontaminated using water/DCM washes and homogenized into a fine powder using a mini-bead ball mill. Extraction was performed via a solvent-swelling technique in which hair was incubated at 37 ºC in a mixture of methanol, acetonitrile, and 2mM ammonium formate (25:25:50, v/v/v). A 2^3 factorial DoE assessed the effects of sample mass (5 vs. 20mg), extraction duration (2 vs. 6h), and the application of ultrasonic treatment (present vs. absent). Extraction efficiency was compared using HRM with known concentrations of drugs and metabolites.

The DoE method optimization was completed using authentic HRM pooled from 11 drug-positive donors containing 16 different drugs and metabolites. Results indicated that the 5 mg hair mass with a 6 h extraction and ultrasonic treatment produced the highest overall recoveries. Statistical analysis of the DoE matrix demonstrated that sample mass (5mg) was a significant factor ($p < 0.05$) across all analytes and HRM samples, whereas extraction time and ultrasonication exhibited compound-specific trends but did not reach statistical significance. This final optimized method was fully validated before analyzing authentic single dose samples.

A controlled single-dose study was conducted in 30 participants with diverse hair types and colors. Each subject received a single dose of DPH, and hair specimens were collected 30 and 60 days post-dosing. Samples underwent segmental analysis, in which hair was cut into 5 mm segments from root to tip. Segments were analyzed individually using the optimized method with the objective being detection of the DHD single-dose.

The Quantitative analysis was performed on an Agilent 1290 UHPLC coupled to a 6470 triple quadrupole mass spectrometer (LC-QqQ-MS/MS), enabling screening and quantification of 45 drugs and metabolites relevant to DFC. The optimized method provides a reliable workflow for quantitative drug analysis in hair. The LC-QqQ-MS/MS procedure demonstrated high selectivity and sensitivity across 45 analytes, with performance suitable for detecting low concentrations consistent with single-doses.[1-3]

L62 Analyzing the Impact of Centrifugation and Sample Preparation on Drugs of Abuse in Oral Fluids

Samantha Herbick, MFS, Restek Corporation, Belefonte, PA; Jared Burkhart, BSc, Restek Corporation, Bellefonte, PA*

Learning Objectives: By attending this presentation, attendees will understand the impact that centrifugation has on volume and analyte recovery. They will also understand the necessity of performing a sample clean up to oral fluid samples when analyzing drugs of abuse by Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS).

Impact Statement: This work benefits the forensic science community by discussing the impact of centrifugation on volume recovery and analyte recovery in oral fluid samples as well as the effect that an efficient sample preparation can have when analyzing drugs of abuse in oral fluids.

Abstract Text: Oral fluid is becoming an increasingly popular matrix due to its ease of collection. While oral fluid is a relatively simple matrix to collect, the collection kits can cause issues downstream. Kits often consist of an applicator with a sponge attached, a tube filled with 3 mL of buffer solution, and a cap. The sponge is used to collect oral fluid which is then placed in the buffer solution to ensure analyte stability and inhibit bacterial growth. The total volume of solution for testing should be 4 mL (1 mL of oral fluid and 3 mL of buffer), however, it is often very difficult to recover the full volume of solution, which can affect volume and analyte recovery. There are different techniques to manipulate the sponge and improve sample recovery, such as manual compression and centrifugation. Additionally, the buffers used with the kits contain surfactants that can lead to issues downstream such as matrix interferences and shortened column lifetimes, so it is important to remove these buffers during sample preparation. In this work, two sample removal techniques will be compared by examining volume and analyte recovery, as well as highlighting the benefits of sample preparation when analyzing oral fluid samples.

An LC-MS/MS method was developed using a biphenyl analytical column and mobile phases consisting of water, and methanol both containing 0.1% formic acid. A total of 31 common drugs of abuse were separated under gradient conditions, with a cycle time of 7 minutes. The samples were prepared in synthetic oral fluid and combined with Quantisal™ buffer and kits. Two recovery techniques were compared and tested in triplicate: manual compression and centrifugation. Samples were prepared using a salt-assisted liquid-liquid extraction (SALLE).

The two techniques were compared by examining volume and analyte recovery. Volume recovery was tested by pouring the solution into a graduated cylinder and recording the total volume recovered using each technique. When using centrifugation, on average, an additional 200 µL were collected compared to the manual compression. Analyte recovery was compared by spiking a known concentration, 50 ng/mL, into each of the samples. These samples were evaluated using a calibration curve prepared only using 1 mL of fortified synthetic oral fluid and 3 mL of buffer. The recovery and peak area of all analytes improved when using the centrifuge. Accuracy and precision were also compared by analyzing if the results fell within +/- 15% of the target value as well as comparing %RSD values. The use of extraction aids was also investigated and compared to these benchmarks.

Through examining volume recovery and analyte recovery when using the two techniques, it was clear that the centrifugation technique showed the best results for total volume recovered as well as increased analyte recovery when analyzed quantitatively. This work clearly demonstrates that centrifugation paired with efficient sample clean up not only improves analyte sensitivity but also lengthens the lifetime of the column when analyzing drugs of abuse in oral fluid.

L63 The Critical Role of Ascorbic Acid and Sodium Fluoride Preservative in the Stability of 4-PrO-DMT in Blood

Christopher McGrowder, BS, John Jay College, New York, NY; Marta Concheiro-Guisan, PhD, John Jay College, New York, NY*

Learning Objectives: Attendees will learn how the stability of the novel tryptamine, 4-Propionoxy-N,N-Dimethyltryptamine (4-PrO-DMT), varies in blood depending on the concentration of the antioxidant ascorbic acid, the type of anticoagulant/preservative, and the biological species.

Impact Statement: This presentation will enhance the forensic community's ability to preserve 4-PrO-DMT in blood. This will allow differentiation of 4-PrO-DMT exposure from psilocybin and other novel tryptamines, such as psilacetin, which are also psilocin prodrugs. These findings support a more reliable toxicological interpretation involving psychedelic tryptamines.

Abstract Text: 4-propionoxy-N,N-dimethyltryptamine (4-PrO-DMT) is a synthetic prodrug of psilocin, increasingly encountered as a novel psychedelic recreational drug. However, its instability in biological matrices, due to rapid hydrolysis to psilocin, presents a challenge in forensic toxicology. Accurate identification and interpretation require validated preservation strategies. The goal of this project was to determine the optimal concentration of ascorbic acid (AA), an antioxidant, needed to stabilize 4-PrO-DMT in blood, as well as to evaluate several anticoagulants and preservatives.

Different AA concentrations (50-250 mM) were tested in sheep plasma (with an equal volume of plasma and AA) to determine the optimal stabilization conditions of 4-PrO-DMT at 100 ng/mL. No significant degradation was observed at 250 mM, which was selected for all subsequent experiments in human, bovine, and sheep blood. The blood preservatives and anticoagulants investigated in human blood were sodium heparin, sodium citrate, dipotassium ethylenediaminetetraacetate (K_2EDTA), and sodium fluoride/potassium oxalate (NaFl/KOx), as well as bovine and sheep blood with potassium citrate or Alsever's solution. Blood samples with AA (0.5 mL blood + 0.5 mL AA) were fortified with 4-PrO-DMT at 100 ng/mL and left for 15, 30, and 60 min at room temperature. Three 100 µL aliquots (50 µL plasma/blood + 50 µL AA solution) were fortified with internal standards (psilocin-d10 and psilocybin-d4) at 25 ng/mL. The samples underwent protein precipitation (250 µL of cold acetonitrile), followed by centrifugation, evaporation, and reconstitution in 100 µL of mobile phase A (0.1% formic acid in water with 10 mM ammonium formate) and mobile phase B (0.1% formic acid in acetonitrile), in a 95:5 v/v ratio.

The analysis was achieved by liquid chromatography-tandem mass spectrometry in positive ESI mode. Two multiple reaction monitoring transitions per compound were monitored. Chromatographic separation was performed using a reversed-phase column in gradient mode. The total run time was 10 minutes, with a flow rate of 0.3 mL/min and a column oven temperature of 40°C.

The most effective stabilization was with 250 mM AA and sheep and bovine blood with potassium citrate or Alsever's solution, as well as NaFl/KOx-preserved human blood. These conditions exhibited a minimal loss of 4-PrO-DMT (< 20%) and psilocin formation of ≤10 ng/mL over 60 min at room temperature. In contrast, citrate, heparin, and K_2EDTA human blood samples exhibited rapid degradation. 4-PrO-DMT showed a loss of ≥ 80-100% in 15 and 60 min. Psilocin rose to ≥43–55 ng/mL for these preservatives in human blood, indicating substantial hydrolysis.

These findings demonstrate that antioxidant concentration, preservative selection, and biological species critically influence the stability of this psilocin prodrug in blood. The recommended conditions involved equal volumes of 250 mM AA and NaF/KOx-preserved human blood. 4-PrO-DMT showed more stability issues in human blood compared to bovine/sheep blood. This study provides essential guidance for forensic laboratories in selecting appropriate storage conditions for the reliable detection and quantification of 4-PrO-DMT, ultimately improving interpretive toxicology in cases involving psychedelic compounds.

L64 Nitazene Analogs Placed Under Generic Control in China: Understanding the Framework and Preparing for the Next Novel Synthetic Opioid Wave

Alex J. Krotulski, PhD, Center for Forensic Science Research & Education, Horsham, PA; Sara E. Walton, MS, Center for Forensic Science Research and Education, Horsham, PA; Donna M. Papsun, MS, NMS Labs, Horsham, PA; Joshua S. DeBord, PhD, Center for Forensic Science Research & Education, Horsham, PA; Barry K. Logan, PhD, NMS Labs, Horsham, PA*

Learning Objectives: After attending this presentation, attendees will be able to assess the impacts of Chinese generic controls placed on nitazene analogs and how this could affect forensic casework and drug testing. This presentation will review the life cycle of nitazene analogs since their emergence in 2019 and forecast novel synthetic opioid alternatives for the next wave.

Impact Statement: This presentation will impact the forensic science community by expanding knowledge of nitazene analogs as it relates to legislation, nomenclature, and emerging drug trends. Attendees will understand generic control efforts and be able to put into action a plan for detecting and identifying new opioids that are anticipated to emerge in the recreational drug supply.

Abstract Text: The landscape of novel synthetic opioids (NSO) in the United States has continually changed over the last decade, largely influenced by national and international legislative control efforts. After class-wide scheduling of fentanyl analogs in the U.S. and China in 2018, the then-novel subclass of nitazene analogs (or 2-benzyl benzimidazoles) emerged in 2019, beginning with isotonitazene and continuing through various structural modifications. The U.S. Drug Enforcement Administration and the World Health Organization have placed individual nitazene analogs under control over the last five years; however, the impacts of these efforts have been mixed and limited at times (i.e., there remains continued proliferation of metonitazene). Legislative actions in source or producer countries in recent years have been most effective in eliminating novel substances from drug markets worldwide. Specific examples include China's control of fentanyl analogs in 2018 and more recently synthetic cannabinoids in 2021.

In June 2025, China's Ministry of Public Security announced the placement of nitazene analogs under generic national control, effective July 1. Similar to the way fentanyl analogs were controlled, nitazene analogs were defined by primary structural components and their potential modifications. The language of the legislative action defines the prototype etonitazene and modifications to: (1) the 5-nitro-1H-benzimidazole core, (2) the methylene linker, (3) the 4-ethoxyphenyl moiety, and (4) the N,N-diethylamino head group. This generic definition currently includes all known nitazene analogs observed in illicit drug samples and toxicology specimens.

A key aspect to monitoring drug markets, especially changes in the wake of drug scheduling, is the implementation of a drug early warning system (EWS). In 2018, the Center for Forensic Science Research and Education (CFSRE) launched NPS Discovery, its drug EWS dedicated to the analysis of toxicology specimens from fatal and non-fatal overdoses and drug materials from recreational drug supplies. Samples are analyzed in comprehensive, non-targeted workflows by mass spectrometry to allow for detection of previously known drugs and the characterization of newly emergent substances. Since 2018, the CFSRE has detected nearly 300 novel psychoactive substances totaling more than 20,000 identifications across various sample types. To date in 2025, 3 new nitazene analogs have been identified, a portion of 12 total nitazene analogs and 20 total NSOs. Nitazene analogs comprised approximately 30% of more than 600 total NSO identifications, while fentanyl analogs compared nearly all of the remaining 70%.

It is too early to verify the impacts of China's generic controls on nitazene analogs; however, historical context suggests a significant market shift is likely. If the nitazene analogs are eradicated like the fentanyl analogs were, other NSO subclasses may increase in prevalence, e.g., the orphine analogs (or piperidine benzimidazolones), or new opioid agonists may emerge setting into motion a string of new derivatives. If the trajectory follows similar to the synthetic cannabinoids, chemical precursors for the nitazene analogs may become common, which could result in the persistence of a previously well-characterized analog (e.g., protonitazene). Maintaining real-time, routine drug testing strategies as part of an established, sophisticated drug EWS will be paramount to tracking the next wave of NSOs.

L65 Pharmacodynamic Effects and Plasma Pharmacokinetics of N,N-Dimethyltryptamine (DMT) After Intranasal Versus Subcutaneous Administration in Male Rats

Sara E. Walton, MS, Center for Forensic Science Research and Education, Horsham, PA; Michael Baumann, PhD, NIDA, Baltimore, MD; Alex J. Krotulski, PhD, Center for Forensic Science Research & Education, Horsham, PA; Grant Glatfelter, PhD, NIDA, Baltimore, MD; Christopher Witowski, PhD, Psilera, Tampa, FL; Jacqueline von Salm, PhD, Psilera, Tampa, FL*

Learning Objectives: After attending this presentation, attendees will be able to assess the pharmacokinetics and pharmacodynamics of DMT after administration on rodent models and apply analytical knowledge to human specimens.

Impact Statement: This presentation will impact the forensic science community by providing pharmacokinetic and pharmacodynamic information for novel psychoactive substances (specifically DMT) to apply to authentic human data.

Abstract Text: Over the past decade, there has been renewed interest in the therapeutic utility of psychedelic substances that act as serotonin-2A receptor (5-HT_{2A}) agonists in the central nervous system (CNS). *N*,*N*-Dimethyltryptamine (DMT) is a structural analog of psilocybin that produces rapid, intense, and short-lived psychedelic effects, suggesting DMT might be a useful alternative in some clinical contexts. Because DMT is rapidly degraded by monoamine oxidase enzymes in the gastrointestinal tract, orally ingested DMT requires co-administration of MAOIs to achieve pharmacological activity. DMT, as a standalone drug, is not pharmacologically active after oral ingestion, and as such, other routes of administration, such as intravenous (IV), intramuscular, inhalation, insufflation, or transdermal, are required to reduce gastrointestinal first-pass effects.

To examine the pharmacodynamic effects and plasma pharmacokinetics of DMT, male Sprague-Dawley rats fitted with IV catheters and temperature transponders received DMT (1, 3, 10 mg/kg) or saline vehicle by intranasal (IN) or subcutaneous (SC) routes. For the IN DMT experiments, blood samples (300 µL) were withdrawn via IV catheters immediately before and at 5, 10, 20, 40, and 80 min after injection. For the SC DMT experiments, blood samples were withdrawn immediately before and at 10, 20, 40, 80, and 160 min after injection. Motor activity, flat body posture and wet dog shakes were observed, and body temperature was measured. A laboratory method was developed and validated to quantitate DMT and metabolites in rat plasma via liquid chromatography tandem quadrupole mass spectrometry (LC-QQQ-MS) using a Waters Xevo TQ-S Micro coupled with a Waters Acuity UPLC®. Samples were prepared using solid phase extraction. The method was successfully validated following the standards issued by the AAFS Standards Board 036.

DMT produced a similar spectrum of pharmacodynamic effects after SC and IN administration. Both routes produced dose-related increases in flat body posture, whereas effects on wet dog shakes were more variable with dose-related effects only after SC dosing. DMT administration by either route caused decreases in body temperature, but hypothermic effects were dose-related only after SC administration. DMT displayed more rapid pharmacokinetics after the IN route ($t_{1/2}$ range = 11.9-14.3 min) when compared to the SC route ($t_{1/2}$ range = 45.5-122.7 min), and peak concentrations were greater with IN. DMT and DMT *N*-oxide concentrations after IN were generally dose-proportional, though analyte concentrations appeared higher than predicted after the 10 mg/kg IN dose. DMT concentrations after SC were dose-proportional, and concentrations after 3 mg/kg SC DMT were significantly greater than those after 1 mg/kg at 20- and 40-min post-treatment. DMT displayed a much faster clearance after IN versus SC administration and C_{max} values were generally higher with the IN route. DMT *N*-oxide concentrations tracked with the parent drug and reached similar absolute concentrations in plasma.

Our findings show the feasibility of using IN administration to deliver DMT in a reproducible and non-invasive manner for examining the acute and sustained effects of DMT in clinical settings. Importantly, the maximal DMT concentrations in rats given low IN doses overlap with those reported in humans receiving psychoactive doses.

L66 The Prevalence of Other Additive Novel Psychoactive Substances and Polydrug Positivity in Clinical Urine Specimens

Jillian Neifeld, MS, Quest Diagnostics, Chantilly, VA; Theresa M. Meli, MS, Quest Diagnostics, Chantilly, VA; Sarah H. Bartock, PhD, Quest Diagnostics, Chantilly, VA; Alicia Bland, MS, Quest Diagnostics, Chantilly, VA; Michael Smith, PhD, Quest Diagnostics, Chantilly, VA*

Learning Objectives: Attendees will learn about the Novel Psychoactive Substances (NPS) class of other additives, which includes compounds like xylazine and medetomidine. They will also learn about polydrug positivity of these analytes with other NPS.

Impact Statement: This presentation will impact the forensic science community by showing the presence of NPS in clinical urine specimens, with a focus on commonly seen NPS additives. These substances are frequently seen in combination with other NPS and can enhance drug effects.

Abstract Text: Novel psychoactive substances (NPS) are compounds designed to mimic popular drugs of abuse like cocaine and marijuana. These compounds were designed as alternative, "legal" ways to take drugs. These compounds are frequently changing, which makes developing analytical NPS methods even more challenging. This also poses challenges for regulatory agencies that are trying to schedule these compounds and makes finding appropriate treatment options more difficult.[1-4]

Compounds that do not fit into class-specific NPS categories are called other additive NPS or oddball NPS. For example, xylazine and medetomidine are veterinary tranquilizers that are now being found in patient specimens. They are frequently mixed with fentanyl, as well as other NPS, to enhance the effects a user may feel.[5,6] Tianeptine, which has opioid-like effects, is commonly referred to as "gas station heroin" and has not been made illegal in all states.[7] Phenibut can induce euphoria, calmness, and reduce anxiety.[8]

To determine positivity of these other additive NPS, a retrospective analysis of urine specimens analyzed with the NPS method at Quest Diagnostics from January to June 2025 was performed. These specimens are antemortem clinical specimens from doctor's offices, pain clinics, rehabilitation centers, and hospitals. This validated NPS method tests for 88 NPS in 6 categories (other additives, designer fentanyl analogs, designer benzodiazepines, designer opioids, designer stimulants, and synthetic cannabinoids). Metabolites were detected whenever possible. Cutoff concentrations for NPS ranged from 1.0 ng/mL to 20 ng/mL.

During the study period, 6,024 specimens were positive for at least 1 NPS. In total, 2,709 (45.0% of positive specimens) were positive for an analyte in the other additives class: 2,479 (41.1% of positive specimens) were positive for xylazine, 309 (5.1%) were positive for medetomidine, 120 (2.0%) were positive for phenibut, and 100 (1.7%) were positive for tianeptine and/or its metabolite. Other additives were seen without other NPS in 1,204 specimens (19.9% of positive specimens) and were mixed with other NPS in 1,514 specimens (25.1% of positive specimens). Of the specimens in which other NPS classes were also positive, the designer fentanyl analogs class were positive in 1,092 (18.1% of total positive) specimens, designer benzodiazepines were positive in 334 (5.5%) specimens, designer opioids were positive in 126 (2.1%) specimens, designer stimulants were positive in 45 (0.7%) specimens, and synthetic cannabinoids were positive in 33 (0.5%) specimens.

This retrospective analysis of urine specimens analyzed for NPS shows that almost half of all positive specimens contained an analyte from the other additive class, indicating that analyzing for this class is important when determining which drugs an individual may have taken. However, in a majority of specimens positive for other additives, an additional NPS class was also positive, showing the importance of testing for as many NPS as possible.

L67 The Emergence of Synthetic Cannabinoids in Maryland Correctional Facilities: 2023–2025

Stephanie A. Dean, MD, Maryland Office of the Chief Medical Examiner, Baltimore, MD; Jack M. Titus, MD, Maryland Office of the Chief Medical Examiner, Baltimore, MD; Rebecca Phipps, PhD, Maryland Office of the Chief Medical Examiner, Baltimore, MD*

Learning Objectives: After attending this presentation, attendees will learn about the scene and investigative findings, autopsy findings, and toxicology findings pertaining to synthetic cannabinoids in Maryland correctional facilities.

Impact Statement: This presentation will impact the forensic science community by increasing awareness of these drugs and the methods by which they are used and detected, which is quickly becoming a public health issue in the incarcerated population. The use of these substances in correctional facilities strain already limited resources and contribute to a volatile environment of a vulnerable population.

Abstract Text: Synthetic cannabinoids, which first emerged as a drug of abuse in the general population in the early 2000s, have recently been seen with increased frequency in the incarcerated population. A wide structural diversity coupled with high potency and ease of distribution, have made this class of drugs a convenient substance of use in correctional facilities across the United States. These substances are typically prepared as a powder that is then subsequently dissolved in a solvent and sprayed or soaked onto plant material or paper, often falling within traditional surveillance gaps. Physiologic effects are unpredictable, variable, and range from behavioral changes to cardiac arrhythmias, seizure, and death.

The Maryland Office of the Chief Medical Examiner (OCME) is a statewide agency responsible for investigating deaths that occur in Maryland's 24 state and additional local (county) correctional facilities. Beginning in 2024, a sharp re-emergence of synthetic cannabinoid deaths were observed in our population, almost exclusively occurring in inmates. Additionally, three inmate-inmate homicides were observed over the same period of time in which the decedent was reported to be exhibiting features consistent with synthetic cannabinoid intoxication, precipitating an altercation, and tested positive for synthetic cannabinoids. In all of the reported cases, in-house routine toxicology testing was performed for a wide range of therapeutic and abused drugs. No significant findings were detected from in-house toxicology testing. Due to investigative findings strongly suggesting an overdose death or drug use, expanded toxicology was requested via the Drug Enforcement Administration (DEA) toxicology testing program through the University of California San Francisco (UCSF) Clinical Toxicology and Environmental Biomonitoring Lab. Between 2023-2025 (to date; data will be extended to end of year), there were 57 total inmates, with 9 testing positive for synthetic cannabinoids. There was one additional potential case that could not be confirmed due to an extended hospital stay which precluded relevant postmortem toxicology testing. MDMB-4en-PINACA was the dominant compound in 2024, while 5F-MDMB-PINACA emerged as the dominant compound in 2025. During this period of time, there were only two cases of inmates in which the drug(s) of abuse contributing to death was not synthetic cannabinoids.

Synthetic cannabinoids in correctional facilities poses a distinct and escalating challenge. Addressing this issue and defining future directions will require a coordinated, nationwide response, utilizing cross-agency collaboration with sharing of data and case comparisons.[1,2]

L68 Pediatric Postmortem Forensic Toxicology: Children Are Not Small Adults

Nikolas P. Lemos, PhD, Lemos Toxicology Services LLC, San Francisco, CA; Timothy P. Rohrig, PhD, Pharmacology Toxicology Consultants, Fernandina Beach, FL; Kari M. Midthun, PhD, NMS Labs, Horsham, PA; Carl Schmidt, MD, University of Michigan, Lambertville, MI; D. Kimberley Molina, MD, Bexar County Medical Examiner's Office, San Antonio, TX; Sarah B. Riley, PhD, St. Louis University School of Medicine, Berkeley, MO*

Learning Objectives: After attending this presentation, attendees will gain an appreciation of the specific requirements and challenges facing forensic medicolegal scientists who investigate toxicology-related aspects of postmortem pediatric cases. The session's speakers will share their own approach style and roadmaps for pediatric cases involving forensic toxicology in both a general and case-specific sense.

Impact Statement: This presentation will impact the forensic science community by offering guidelines and tools to medicolegal death investigators who are investigating toxicology-related deaths in the pediatric population.

Abstract Text: In this 26th annual joint session of the Toxicology and Pathology/Biology sections, a group of postmortem pediatric cases involving toxicological findings are presented. The moderators will facilitate the presentations by inviting pathologists and/or toxicologists to describe each case's history, scene findings, anatomic and toxicological findings. Audience members will then have the opportunity to interact with the presenters and other audience members to help bring each presentation to a conclusion utilizing expertise and commentary from both the presenter(s) and the audience.

This joint session serves as an open forum to help illuminate and clarify how pediatric postmortem forensic toxicology cases are handled in various jurisdictions and by various professionals working on each case. The joint session's format typically consists of a set of short case presentations or issue-specific concerns, including pharmaco/toxicokinetic data and other relevant ancillary information, followed by audience participation to provide interpretive clarity around case-specific impacts of the toxicological findings.

This session, attended by members from various sections of the Academy, allows the opportunity for different perspectives and points of view regarding case issues to be heard, discussed, debated and challenges which often leads to integrative consensus, or differing opinions, as to the cause and manner of each child's death presented in the session.

LW1 Olof: Ancestors Heir or Disney Snowman? Solving Something Cold

Cathryn Fahey, BS, Idaho State Police Forensic Services, Meridian, ID; Daren Boyd, BS, Idaho State Police Forensic Services, Meridian, ID; Tamara Mick, BS, Idaho State Police Forensic Services, Meridian, ID; Katherine White, BSc, Idaho State Police Forensic Services, Meridian, ID; Janey Dunn, MScFS, Idaho State Police Forensic Services, Meridian, ID; Jerrie Northrup, BS, Idaho State Police Forensic Services, Meridian, ID*

Learning Objectives: Attendees will learn how multidisciplinary approaches—including Forensic Investigative Genetic Genealogy (FIGG) and forensic document analysis —can be integrated to resolve an unidentified human remains cold case. This case study will demonstrate how these methods provide critical investigative leads and reduce speculation in the development of identity hypotheses.

Impact Statement: This presentation will enhance the forensic science community by demonstrating the value of a multidisciplinary approach that integrates FIGG, document analysis, and historical research. It underscores how collaboration across specialties—and the inclusion of an in-house genealogist—can improve case resolution efficiency, reduce reliance on speculative leads, and deliver meaningful outcomes for stakeholders, including law enforcement, families, and the broader community.

Abstract Text: In 2014, the cranial cap of an unidentified individual was discovered in a remote location of Hoo Doo Mountain in Bonner County, Idaho. Despite additional search efforts, only a few scattered personal items were recovered nearby, none of which yielded cluse to the decedent's identity or the circumstances surrounding his death. With limited physical evidence and no missing persons match, the case quickly grew cold

A multidiscipline collaboration was initiated to advance the investigation. The University of North Texas Center for Human Identification developed a CODIS-eligible DNA profile but yielded no hits. Othram Inc. subsequently extracted and sequenced DNA from the cranial cap to build a SNP profile suitable for forensic investigative genetic genealogy (FIGG). Othram's genealogical research allowed researchers to identify distant familial matches. Reference samples were collected from potential relatives for kinship comparison using autosomal SNP testing

With support from a SAKI (Sexual Assault Kit Initiative) grant, the Idaho State Police continued the genealogical investigation in-house. Forensic document examination utilizing a Video Spectral Comparator 900 also revealed obscured identifying information on personal effects found near the remains, corroborating the FIGG findings.

This case study highlights how interagency cooperation, advanced DNA technologies, and FIGG can overcome challenges posed by limited physical evidence remains, degraded documentation, and incomplete historical records. When combined with interviews of distant relatives and an unexpected collaboration with a professional genealogist in Sweden, these efforts ultimately led to the identification of the decedent. This integrated approach between forensic analyses, FIGG, and law enforcement investigation provided insight into the individual's identity and life history and brought a long-awaited resolution to the case.

LW2 America 250: Forensic Science and the Hessian Soldiers' Remains "Intrenched" in a Mass Grave at Red Bank Battlefield, Gloucester County, New Jersey

Thomas A. Crist, PhD, Utica University, Utica, NY; Anna W. Delaney, DCrim, New Jersey State Police, Hamilton, NJ; Stuart Alexander, DMD, NJ State Police, Cranbury, NJ*

Learning Objectives: By attending this presentation, attendees will learn about the Battle of Red Bank (New Jersey) where in 1777 an outnumbered American Patriot force defeated a contingent of about 1,200 Hessian infantry and grenadiers fighting for the British. The forensic analysis of the mass grave where the Hessian soldiers' dismembered remains were buried will also be discussed, together with a remarkable artifact that depicts the battle-related trauma and "intrenchment" of the Hessians at Red Bank.

Impact Statement: This presentation will impact the forensic science community by demonstrating the effective use of forensic anthropology, odontology, geochemistry, and facial approximation to respectfully excavate and analyze commingled skeletal remains from the Revolutionary War.

Abstract Text: As part of America's 250th anniversary, the unexpected discovery of skeletal remains at what is now Red Bank Battlefield Park in Gloucester County, NJ, provides a unique opportunity to describe how forensic science has revealed the hidden story of a lesser-known but significant battle during the American Revolution.[1] Further, the irregular burial of the remains underscores the necessary task of collecting and disposing dismembered body parts from all fields of battle, a practice that was both common but little discussed during the Revolutionary War.

"We buried 75 hesians in one Grave in the intrenchment." Sergeant John Smith of the 1st Rhode Island Regiment made this diary entry after the Battle of Red Bank on October 22, 1777. His detail was tasked with collecting the remains of Hessian soldiers who had died during the battle and burying them in the trench that surrounded Fort Mercer, a large earthen structure built earlier that year along the Delaware River to defend the city of Philadelphia located six miles upstream.

During the summer of 2022, archaeologists searching for the remains of the fort unearthed a mass grave of dismembered and commingled skeletal remains[3], the only site of its kind from the American Revolution. Mixed among the body parts were uniform buttons and buckles, musket balls, and a rare King George III gold guinea minted in 1766. A multidisciplinary team of forensic anthropologists, a forensic odontologist, and geochemists later confirmed that the remains represent at least 15 of the Hessian soldiers that Sergeant Smith had described burying some 245 years earlier.

As part of the ongoing project, facial approximations have now strikingly brought two of the Hessian soldiers back to life.[4] And in an amazing coincidence, a powder horn carved by another soldier from the Rhode Island Regiment who had also fought in the Battle of Red Bank depicts not only the injuries that soldiers of both sides suffered, but also the "intrenchment" of the Hessians' body parts next to Fort Mercer. This paper presents the results of the forensic team's work and the artifacts that unveil one of the most compelling hidden stories of the American Revolution.

LW3 Many Minds or Many Frauds? The Insane Case of Billy Milligan

George D. Annas, MD, Forensic Psychiatry Consulting, LLC, Alexandria, VA*

Learning Objectives: After attending this presentation, attendees will: (1) gain knowledge of the use and misuse of the insanity defense in the United States via a historical criminal case; and (2) understand the facts vs. the fiction of "Multiple Personality Disorder"/Dissociative Identity Disorder.

Impact Statement: This presentation is intended to impact the forensic science community in the following ways: (1) improve skill in analyzing and approaching the insanity defense for defense attorneys and prosecutors; (2) provide clarity and understanding in how an expert witnesses can often blatantly miss the "big picture" via a historical case, and (3) improve expertise in vetting and working with expert witnesses in mental health and the complexity that can arise when trying to choose an expert.

Abstract Text: To this day there are some who wonder if William S. Milligan was a "victim" of serious mental illness and truly not responsible for the crimes he committed. Arrested in October of 1977 and charged with raping three female University of Ohio students at gunpoint, Milligan was already no stranger to the wrong side of the law. A registered sex offender with a long rap sheet, his case initially looked like straightforward prosecution. But soon after his arrest this case would become nothing short of a fiasco, culminating with the first ever insanity acquittal in the United States for a defendant claiming "Multiple Personality Disorder." Milligan's story found its way into multiple media venues, including a non-fiction bestseller by famous novelist Andrew Keyes, titled "*The Minds of Billy Milligan*," as well as a 2021 *Netflix* documentary series.[1,2]

What can we learn today about a historical case from so long ago and a defendant who is long deceased? Perhaps with 20/20 hindsight one would opine that the man who would later break out of a mental institution and be the prime suspect in 2 murders, had simply conned everyone. But, if so what else could have been done to more critically to determine this at the time of his prosecution?

In this presentation, I will analyze Milligan's case from the perspective of how a forensic psychiatrist should approach a claim of insanity and demonstrate the fundamental errors that occurred in both the side of the mental health experts and to a lesser extent the courts that relied on their opinions.[3] I will also discuss the ongoing debate over the existence of "Multiple Personality Disorder," currently known as Dissociative Identity Disorder (DID), as well as the validity of using this in an insanity defense.[4] In the end, I intend to demonstrate how the courts can reliably navigate even a complex case involving multiple experts, when one expert answers the right question.

LW4 `The Loaded Case of the Banned Bullet

Maria Nektaria Antoniou, LLM, MSt, University of Oxford, Oxford, England, United Kingdom; Nicholas Marquez-Grant, PhD, Cranfield University, Oxford, England, United Kingdom; Rick Schulting, PhD, University of Oxford, Oxford, England, United Kingdom*

Learning Objectives: This presentation reviews late 19th- and early 20th-century reports and scientific publications on the dumdum, then a new and highly controversial type of expanding bullet. The real-life risks inherent in a lack of scientific method and rigor are highlighted. Attendees will thereby learn how a more limited understanding of the principles that underpin valid scientific inquiry led to outrageous arguments and passionate accusations in diplomatically precarious situations.

Impact Statement: Examining historical arguments for the introduction of the dumdum bullet in warfare demonstrates the danger of using the forensic sciences to coat prejudice in scientific legitimacy. Additionally, dissecting the controversy on whether dumdums were used in World War I, which was exacerbated by available forensic evidence, indicates the risks of reaching conclusions from evidence that appears deceptively straightforward to interpret. This presentation highlights the importance of critical thinking, data-driven rigor, independence, and peer review.

Abstract Text: Military and medical commentators of the late 19th century were less than impressed with the introduction of the full metal jacket bullet (FMJ) in warfare, finding that it had more limited wounding potential than earlier types.[1] British publications, in particular, also wondered whether the more humane FMJ might not be sufficient in non-European wars to "stop a rush, a charge of savages or of fanatical dervishes."[2] Dumdum bullets (non-fully jacketed ones that expanded inside human tissue) were invented as a more powerful alternative to the FMJ.[1,3-5]

Much controversy followed this invention, with surgeons performing experiments or observing its effects in real time.[6] The overwhelming sentiment that dumdums would cause unnecessary suffering led to a ban on expanding bullets in war among several nations.[7] Britain, however, supported the use of dumdums in "savage" warfare, arguing that colonized peoples were not so severely affected by FMJ bullets and would continue fighting when struck by them.[8-11] These arguments, objectionable even at the time,[9] were based on anecdotal "evidence" from battlefields outside Europe.[12,13] This discourse highlights the racial prejudice behind purported scientific rationales that have historically been used to legitimize actions well understood to be inhumane.[14,15] The flaws in the ways these conclusions were drawn are discussed.

Meanwhile, the existing ban on expanding bullets was put to the test in World War I (WWI), with both the Allies and Central Powers accusing each other of violating the prohibition.[16-18] Surgeons treating soldiers would often report what they interpreted as wounds caused by illegal bullets.[19,20] However, these surgeons would have mostly been familiar with wounding patterns caused by the round-nosed bullets used in earlier conflicts, which produced entry and exit wounds of approximately equal size.[21,22] Conversely, WWI saw use of the pointed bullet. From the descriptions of the disputed gunshot wounds, it appears that the wounds that caused so many impassioned accusations were likely to be normal exit wounds caused by the new pointed bullet, which tumbled in the body leading to large exit wounds.[23-25] Interestingly, certain (more experienced) surgeons of the time also voiced the opinion that the described wounds were not made by dumdums, albeit with varying justifications.[26-30] Whether or not such prohibited ammunition was used in WWI (a question still debated among historians), reviewing this topic demonstrates that the ability to clarify violations of the law was inhibited by a lack of insight into what constituted persuasive evidence in an era of extremely rapid technological advancement.

The case of the expanding bullet highlights the need for scientists to be conscious of the danger of imbuing their methods with prejudices and preconceptions, whether social or scientific. It also indicates the need for continuity in training and support of new forensic scientists, especially in the context of mass-fatality incidents where less experienced personnel will often be called to contribute. Although erroneous conclusions are bound to be drawn occasionally where new technologies are concerned, the scientific community today should be sufficiently equipped to avoid at least those based on prejudice or lack of method.

LW5 The (Not Always) Good Old Times: The Inquisition as the Basis of Modern Forensic Investigation

Matteo Borrini, PhD, Liverpool John Moores University, Liverpool, England, United Kingdom; Vincenzo Lusa, JD, Università Sapienza Rome, Roma, Lazio, Italy*

Learning Objectives: After attending this presentation, attendees will have gained a deeper understanding of the impact of the Inquisition trial on the development of the modern juridical system and forensic investigations. They will also observe how the legal legacy of the past is reflected in the present, reinforcing the principles and objectives of today's fair trial.

Impact Statement: This presentation will impact the forensic science community by offering a historically re-evaluation of the medieval inquisitorial process, which highlights its crucial role in the evolution of forensic investigation and modern criminal procedure.

Abstract Text: Contrary to the dominant narrative, the Inquisition introduced fundamental procedural innovations that helped transform legal systems across Europe and laid the groundwork for the development of structured, evidence-based investigations

Before the rise of the inquisitorial method, medieval justice mainly relied on supernatural mechanisms, such as ordeals by fire or water, combat, and divine judgment. The inquisitorial process replaced this system with one in which public authority took on an active role in investigating facts, collecting testimony, and establishing the truth. The Fourth Lateran Council in 1215, along with earlier canonical reforms (e.g., the bull *Ad abolendam* issued by Pope Lucius III in 1184), formally recognizing the legitimacy of judicial inquiry initiated without a private accuser. These measures allowed investigations based on suspicion, following structured procedures that emphasized record-keeping, interrogation under oath, and systematic documentation

The process was developed primarily within ecclesiastical courts and became a prototype for secular courts in continental Europe. Judges acting *ex officio* could summon witnesses, collect depositions, and evaluate evidence in secret proceedings. This emphasis on documentary evidence and the written dossier (still fundamental today) represented a radical improvement from the oral, influencing the development of modern institutions (e.g. *juge d'instruction* in France). The inquisitorial model, while lacking many of the protections and adversarial safeguards of modern justice systems, introduced key procedural tools that are now essential in forensic practice, including the preservation of evidence, the use of expert testimony, and a structured approach to fact-finding

Critics of the inquisitorial system rightly point to its coercive approach, particularly in its use of torture and the presumption of guilt. However, Canon law increasingly required that confessions be voluntary, and procedural manuals from the period (e.g., Bernard Gui's Practica inquisitionis) demonstrate an early concern for consistency, evidentiary value, and procedural formality. These elements reflect the emergence of a modern sense of legal rationality in contrast to the previous accusatory system dependent on private retaliation or divine intervention

The Inquisition legacy can be detected today in civil law jurisdictions where pre-trial investigations are still conducted under the authority of judges who supervise the gathering of evidence and oversee procedural fairness. Even in systems that formally adopt an adversarial structure, elements of inquisitorial logic remain, particularly in the role of prosecutors and investigative magistrates who bear the responsibility of collecting and presenting factual information

The authors argue that, although marked by significant flaws, the inquisitorial process was a critical stage in the development of modern procedural justice. It represented the first consistent attempt by European legal institutions to establish truth through structured, rational inquiry rather than through ordeal, reputation, or combat. Far from being an anachronism to be discarded, the inquisitorial tradition provided many of the conceptual and institutional tools that continue to underpin the modern pursuit of justice. By recognizing this legacy, the presentation not only corrects a common historical misunderstanding but also better evaluates the complex roots of contemporary forensic investigation.

LW6 Where in the World Are All These Skeletons From? Anthropology, Odontology, Stable Isotopes, and Ethics

Wolf D. Bueschgen, DMD, Charleston County Coroner, Charleston, SC; Suzanne Abel, PhD, Charleston County Coroner's Office, North Charleston, SC*

Learning Objectives: The objectives of this presentation are to: (1)understand and appreciate the value of a multidisciplinary approach in case analysis; (2) to recognize how emerging forensic techniques can complement and reinforce traditional methods, and (3) appreciate the ethical concerns that may limit analysis and how community engagement can help address these challenges.

Impact Statement: This presentation highlights the power of multidisciplinary analysis and the role of advanced forensic techniques in answering historical questions.

Abstract Text: In 2013, during renovations of the Gaillard Center in Charleston, South Carolina, the burials of 36 individuals were uncovered. Local laws required construction to halt until the Coroner determined the final disposition of the remains. Due to the urgency to resume construction, archaeologists rapidly excavated the site over several days, and the remains were subsequently studied off-site.

Initial analysis used the *Standards for Data Collection from Human Skeletal Remains* and combined anthropological methods with historical research. Early findings suggested the site was likely an 18th-century plantation cemetery for enslaved individuals—a historically significant and rare sample.

Community interest grew rapidly, prompting the City of Charleston to formally document the remains. This interest catalyzed partnerships with local and national academic institutions, enabling a comprehensive suite of analyses, including stable isotope testing, mitogenomics, and traditional anthropological and odontological methods.

The community played a vital role in facilitating this research, leading to the identification of ancestry, health, and aspects of life history of these unknown individuals—now respectfully referred to as the Anson Street Ancestors. This project stands as a rare and powerful example of how ethical considerations, community collaboration, and multidisciplinary science can come together to tell meaningful stories from the past.

Although the remains are from the 18th century, the techniques used are directly applicable to modern forensic and anthropological investigations.[1-4]

Y1 The Feasibility of Using ATR/FTIR for the Differentiation of Different Brands of Brown Eyeliners

Urja Desai, MS, Towson University, Owings Mills, MD*

Learning Objectives: Attendees will learn: (1) the experimental parameters needed to produce Attenuated Total Reflectance/Fourier Transform Infrared (ATR/FTIR) spectra of brown eyeliners, including relative standard deviations for differentiating peaks; (2) how the Infrared (IR) spectra of six different brands of brown eyeliner differ from one another; (3) how the IR spectra of brown eyeliners differ from those of black eyeliners; (4) the wavenumbers that are relevant for these previously mentioned differences; and (5) How the IR spectra of brown and black eyeliners change with time.

Impact Statement: Research has been carried out on the analysis of cosmetic evidence like lipsticks and black eyeliners, but very little research involving brown eyeliners has been carried out thus far. As the makeup industry continues to grow, the use of colored makeup products has increased. Understanding the chemical composition of brown eyeliners and the capabilities of using ATR/FTIR to differentiate one brand from another as well as differentiating between brown and black eyeliners is a significant step forward in the analysis of trace evidence analysis with cosmetics with the goal of incorporating into forensic workflow.

Abstract Text: The purpose of this work was to attempt to discriminate between different brands of brown colored eyeliners. Research involving cosmetic products like lipsticks have been carried out in the past, however little research has involved eyeliners.[1] Eye makeup products, including eyeliners, are a commonly used cosmetic product that could be used as trace evidence in certain situations. Traces of eyeliner could be transferred onto clothing or found at the scene of a crime, giving it evidentiary value in a criminal investigation. While there has been some research carried out analyzing the accuracy of discrimination of black eyeliners, this technique had not been applied to colored eyeliners[2]. Our work involved ATR-FTIR analysis of 6 brown eyeliners from different brands applied to a tissue. Differences were observed in the spectra at 500 cm^{-1} 1000 cm^{-1} 1600 cm^{-1}, and 3300 cm^{-1} eluding to a difference in functional groups due to the use of different ingredients in eyeliners made by different brands. These differences were further analyzed using discriminate function analysis. We further report on the ability to differentiate brown eyeliners from black eyeliners using the obtained IR spectra. Finally, we report on the effect that time has on the IR spectra obtained from the eyeliners, thus informing the analyst of the forensic usefulness of collecting the eyeliner evidence.

Y2 Intimate Partner Violence Against Women Murders: Forensic Features and Differences With Domestic Violence

Miguel Lorente, PhD, University of Granada, Granada, Andalucia, Spain; María Cuadros, MCrim, University of Granada, Granada, Andalucia, Spain*

Learning Objectives: Attendees will be the first to learn about the preliminary structure, influential variables, and initial findings from the analysis of homicides due to intimate partner violence against women in Spain, based on a database that includes all adjudicated homicide cases since 1997 (847 sentences).[1] This is the first database built from the judicial rulings of all tried homicides in Spain, offering information of high scientific and social value.

Impact Statement: The study presented offers the forensic scientific community an unprecedented, methodologically rigorous resource for the analysis of gender-based violence in Spain. By enabling a neutral and high-quality data analysis, it will enhance research accuracy, inform legal and policy strategies, and promote standardized data practices across institutions.

Abstract Text: The outcomes of a killing—and the methods by which murders are committed—are the result of the perpetrator's motivations and intended objectives. However, most crime classifications focus primarily on circumstances related to the victim, setting, instrumental factors, or perpetrator characteristics. While necessary, such factors can obscure the deeper meaning behind certain forms of violence, particularly those related to structural violence.

Violence Against Women (VAW), especially in the context of intimate partner relationships, exhibits features distinct from other forms of interpersonal violence. It is a form of "moral violence"—not merely instrumental—used by men against women, driven by cultural and social norms with the primary aim of exerting control over women.

The motives and objectives of perpetrators in VAW-related homicides differ from those in other types of killings. These distinctions should be reflected in the methods and procedures used to commit the crimes and may provide key insights into the cognitive and emotional components involved.

This study analyzed all judicial sentences involving intimate partner femicides in Spain from 1997 to 2021 (the most recent year with available data), focusing on the modus operandi applied. A total of 847 sentences were analyzed. The data derive from a newly created, unpublished database compiled by the research team, based on judicial rulings provided by the Spanish General Council of the Judiciary (Consejo General del Poder Judicial, CGPJ). This is the first database to systematize all adjudicated homicide cases in Spain, offering unprecedented scientific and social value. The indicators assessed included:

- Mechanism and instrument used
- Use of a single or multiple mechanisms/instruments (simple or mixed)
- Use of bare hands as the killing method
- Degree of violence employed to carry out the homicide

Based on these indicators, the study presents several significant findings relevant to Forensic Science and fields related to support, prevention, assessment, protection, and investigation of VAW:

- There is no single or consistent pattern in the killing mechanisms used by men to murder their (former) partners. A total of nine distinct mechanisms were identified over the study period.
- The most frequent method of killing was stabbing (41.1%), followed by beating (14.1%). Mechanical asphyxiation, in its various forms, accounted for 8.7%, and firearms for 5.6%.
- The degree of violence employed has increased over time, with higher levels observed in recent years.

Y3 A Comparative Analysis of Textile Damage Caused by Canines vs. Firearms and Knives

Tabitha L. Hammond, BS, Cedar Crest College, Woodhull, NY; Sandra Koch, PhD, National Institute of Standards and Technology, Gaithersburg, MD; Lawrence Quarino, PhD, Cedar Crest College, Allentown, PA; Andra Lewis, PhD, Cedar Crest College, Allentown, PA*

Learning Objectives: After attending this presentation, attendees will gain a better understanding of the distinct characteristics of textile damage caused by canines compared to that inflicted by firearms and sharp-edged weapons. Key factors contributing to these differences will be examined.

Impact Statement: This research will help advance forensic science by systematically investigating canine-induced textile damage, a frequently underexplored area with significant implications for case interpretation involving both identified and unidentified sources. By addressing this knowledge gap, the study seeks to contribute to the establishment of standardized analytical protocols, thereby enhancing the accuracy of forensic assessments.

Abstract Text: Textile damage plays a crucial role in forensic investigations by helping examiners reconstruct events, identify the type of force used, determine whether damage occurred before or after death, and evaluate consistency with witness statements. This analysis involves detailed examination of damage features including cuts, tears, and punctures utilizing both stereomicroscopes and compound microscopes.[1] While most research focuses on knife and firearm-related damage, animal-inflicted injuries, particularly from dogs, have received less attention, despite their potential to mimic other trauma types and complicate crime scenes.[2-4] The 1980 Azaria Chamberlain case highlighted the importance of this work, as textile analysis helped prove a dingo attack caused the child's death, overturning her mother's wrongful conviction.[5]

Textile damage incurred during controlled attacks by four trained apprehension canines were compared to damage from a plain-edged knife and 9mm firearm projectiles. Control bite samples were collected over three canine training sessions using a "feed bite" technique to minimize claw interference and ensure consistent placement of the samples. Denim swatches along with cotton and polyester long-sleeve shirts were placed over the right arm of a tactile bite suit and presented to the dogs. Resulting damage was analyzed using photography, stereomicroscopy, and compound microscopy.

Macroscopic analysis revealed punctures in only 14% of denim samples while 86% of the samples exhibited tooth impressions. In contrast, cotton and polyester samples showed punctured damage 100% of the time with additional tooth impressions. These findings highlight material-dependent variation in canine-inflicted damage between woven (denim) and knitted (cotton, polyester) fabrics.

Compound microscopy revealed that firearm damage produced rounded, split, flattened, or melted fibers, especially in polyester and at close range, while knife damage resulted in clean, angled cuts. Canine damage was characterized by chewed or irregularly flattened fibers, distinct from both firearm and knife effects. These findings highlight the value of microscopic fiber analysis in distinguishing human from animal-inflicted textile damage, improving forensic accuracy when fabric evidence is critical.

Furthermore, statistical analysis showed no significant effect of fabric type or color on damage appearance. The Friedman test found that fabric had no effect with p-values of 0.22, 0.37, and 1, all exceeding $\alpha = 0.05$. Similarly, the Wilcoxon Signed-Rank test found no color effect, with W-values for cotton ($W = 86 > 83$) and polyester ($W = 43 > 40$) above critical thresholds. However, a Kruskal-Wallis test with Dunn's post hoc analysis (critical $Z = \pm 2.94$) revealed a significant difference between canine and shooting damage ($Z = 4.74$), but not between canine and stabbing ($Z = 1.55$). A Mann-Whitney U test also identified a significant difference between shooting and stabbing ($U = 0$, $Z = -3.78$, $p = 0.00016$, $n_1 = 10$, $n_2 = 10$). These findings indicate that while fabric characteristics did not significantly influence damage appearance, certain damage types, especially between firearms and knives, can be statistically distinguished.

Y4 Investigating the Patterning of Postmortem Fractures in Human Dentition

Bec M. Krolczyk, BS, Texas State University, Sachse, TX; Danny J. Wescott, PhD, Texas State University, San Marcos, TX*

Learning Objectives: After attending this presentation, attendees will learn how to recognize common postmortem fracture patterns in human dentition. Attendees will also understand how these fractures begin to propagate throughout the internal dental tissues through 3D modeling from micro-Computed Tomography (micro-CT) analysis. Overall, this presentation will illustrate how to apply both macroscopic and microscopic approaches to evaluating postmortem crack propagation in human dentition.

Impact Statement: This presentation will improve forensic anthropology's understanding of taphonomic damage to human dentition. Understanding the common patterning of postmortem fractures in human dentition will provide a foundation for future research understanding the relationship between antemortem dental trauma and postmortem dental damage, along with differentiating between perimortem and postmortem fractures in human dental tissues.

Abstract Text: The goal of this project was to investigate common patterns of postmortem dental fractures in human dentition during decomposition to help differentiate antemortem and postmortem breakage. Human dentition can significantly aid forensic anthropologists when generating a biological profile in instances of poor skeletal preservation. While the highly mineralized dental tissues allow teeth to preserve well in strenuous taphonomic conditions, human dentition can still fracture due to dehydration from heat.[1] The patterning and mechanics of postmortem dental fractures have been extensively reviewed concerning extreme thermal alteration events, such as fire damage, but fractures caused by gradual dehydration from outdoor surface decomposition have been relatively unexplored.[2] To address this gap of dental taphonomic research, this study reviews fractures induced by outdoor surface decomposition in the Forensic Anthropology Research Facility at the Forensic Anthropology Center at Texas State.

For this project, a fracture is defined as a path of complete separation in the external and internal dental tissues, while a crack is defined as an incomplete separation of these tissues.[3] To evaluate the common patterns of postmortem fractures caused by gradual dehydration in human dentition, this study reviewed the maxillary dentition of 140 donors from the Texas State Donated Skeletal Collection (TSXTDSC)[4]. Following the universal numbering system, teeth #6 through #11 for each of these individuals were analyzed for specific patterns of postmortem fractures. In addition, ten recently extracted central incisors were imaged with an NSI X5000 micro-CT system to map the antemortem crack propagation network with Dragonfly's deep learning segmentation tool.[5] From both data sets, a total of 787 teeth were included within this project's sample to calculate the frequencies of the resulting fracture patterns from 362 of these teeth.

The results of both the macroscopic and microscopic approaches revealed postmortem fracture patterns similar to antemortem craze lines, which are commonly caused by mastication, parafunction, and thermocycling.[1] The most common fracture pattern found throughout these teeth consists of a single longitudinal fracture that extends from the incisal aspect of the crown to the CEJ. This specific pattern can be found in the observed teeth with a frequency of 59.3% for tooth #6 (n = 54), 48.0% for tooth #7 (n = 50), 43.4% for tooth #8 (n = 76), 44.0% for tooth #9 (n = 75), 48.4% for tooth #10 (n = 62), and 62.2% for tooth #11 (n = 45). As the frequencies for this prominent pattern decreased for the incisors, the frequencies of two additional patterns were also noted and calculated while recording the data. The organization of the postmortem fractures in the central incisors within the TXSTDSC revealed a connection to the antemortem crack propagation in the segmented models of the extracted central incisors. From this connection and the calculated frequencies, this study illustrates three specific patterns of postmortem fracturing in maxillary dentition to both highlight the relationship between antemortem use and postmortem fracturing in human dentition and serve as a foundation for differentiating between perimortem and postmortem dental fractures in future research.

Y5 The Differentiation and Identification of Fentanyl Analogs Using Portable Ion Trap Mass Spectrometry

Mei Yuan, BS, University of New Haven, West Haven, CT; Ella M. Galvan, BS, University of New Haven, Albany, OR; Jeffery D. Johnson, Jr., PhD, 1st Detective, Austin, TX; Seth Fisher, BS, AstroTech Corp, Austin, TX; Pauline E. Leary, PhD, Noble, Stanfordville, NY; Brooke W. Kammrath, PhD, University of New Haven, West Haven, CT*

Learning Objectives: Attendees will learn how portable ion trap mass spectrometers are being optimized to address the evolving illicit drug landscape, specifically to improve their detection accuracy and response in high-security environments for fentanyl and its analogs. The presentation will explain the process of building a comprehensive fentanyl detection library using 250 synthetic opioids, including 210 fentanyl analogs, and how this enhances real-time identification.

Impact Statement: This presentation will impact the forensic science community by detailing how portable mass spectrometry can be used to address the complex and dynamic illicit drug landscape through the rapid, reliable, and real-time detection and identification of suspected samples. Ultimately, this work contributes to more effective interception of illicit synthetic opioids and fentanyl at borders and in high-security environments.

Abstract Text: The continually evolving and complex drug landscape presents a formidable challenge for first responders who need reliable tools for their detection and identification. Fentanyl is a potent synthetic opioid analgesic used to manage pain which recently became a significant public health threat due to the illicit drug market. In 2023, overdose deaths exceeded 100,000 in the United States, with over 70% of those involving a synthetic opioid such as fentanyl or tramadol.[1] These drugs are being transported to the United States across borders, and thus it has become a national priority to develop tools to help stop their proliferation.[2] Portable technologies provide the best potential for addressing this problem, with a specific emphasis on identification of fentanyl and its analogs in the field. This research involves analyzing 250 synthetic opioids and related substances, including 210 fentanyl analogs, to build a comprehensive fentanyl detection library for a portable ion trap mass spectrometer (1st Detect Tracer 1000) designed for rapid identification of drugs and explosives. Ion trap mass spectrometers operate by using electrostatic and radio frequency fields to confine charged particles. This offers high sensitivity, resolution, and the ability to study ion-molecule reactions. It was hypothesized that expanding the instrument's library with a wide range of fentanyl analogs would improve classification and detection performance in real-world scenarios. Results support this hypothesis, showing improved detection and accuracy with the updated spectral library. To further validate the enhanced library, its detection and identification accuracy were evaluated using mixed samples and adjudicated case samples. This project aims to evaluate and ultimately improve the detection and identification capabilities of portable ion trap mass spectrometry for fentanyl, fentanyl analogs, and other synthetic opioids, thus supporting its use in high-security environments like airports and other border crossings.

Y6 Comparative Evaluation of Machine Learning Models for Criminal Attribute Estimation: Explainable AI Perspectives

Daisuke Imoto, PhD, National Research Institute of Police Science, Kashiwa-shi, Chiba, Japan; Kazuki Hirama, PhD, National Research Institute of Police Science, Kashiwa-shi, Chiba, Japan; Kengo Furuhashi, PhD, National Research Institute of Police Science, Kashiwa-shi, Chiba, Japan; Yusuke Otsuka, MPhil, National Research Institute of Police Science, Kashiwa-shi, Chiba, Japan; Kaeko Yokota, PhD, National Research Institute of Police Science, Kashiwa-shi, Chiba, Japan; Masakatsu Honma, PhD, National Research Institute of Police Science, Kashiwa-shi, Chiba, Japan*

Learning Objectives: After attending this presentation, attendees will understand how to fairly evaluate Machine Learning (ML) models for criminal attribute estimation under both frequentist and Bayesian scenarios. The contribution of explanatory variables to predictive variables in each ML model can be interpretably visualized by applying Shapley Additive Explanations (SHAP) -based explainable AI (XAI) analysis.

Impact Statement: This presentation will impact the forensic science community by providing a fair evaluation protocol on ML-based criminal attribute estimation analysis. Concretely, this study also provides results on which ML model has higher accuracy for which target variable, and which ML model performs better on average. Furthermore, the study also discusses the possible effectiveness of a SHAP-based XAI analysis.

Abstract Text: Criminal attribute estimation seeks to infer offender attributes—such as age group, occupation, or prior convictions—from case-related evidence, including crime type, time, and modus operandi. This study systematically evaluates fifteen machine learning (ML) models, including an ensemble model, spanning both classical methods (e.g., logistic regression, support vector regression, RandomForest) and advanced approaches (gradient-boosting models such as XGBoost, LightGBM, and CatBoost, and deep neural network), under both frequentist and Bayesian evaluation frameworks.[1-5] To enhance interpretability, we apply SHAP, a representative XAI method, to facilitate visualizing the contribution of explanatory variables as well as probability calculation based on predictive value distributions, providing insights for forensic practitioners.[6] Using nationwide statistical data on 10 predictive variables in sexual crimes and 11 predictive variables in murders in Japan, with training and evaluation data split at a 7:3 ratio, we evaluated ML model performance under both frequentist and Bayesian scenarios by optimizing the hyperparameters of each ML model by cross-validation using the training dataset. Results indicate that advanced methods, particularly three gradient-boosting models, tend to perform well on average under both frequentist and Bayesian evaluations, although classical methods such as logistic regression, Lasso regression, and PLS regression have high accuracy in some cases. Furthermore, we explore the relationship between the SHAP contributions to the predictive variable and the prediction characteristics of each model, and discuss its use for decision-making on the predictive variable. These findings suggest that combining ML models with XAI and properly selecting either a frequentist or Bayesian setting offers promising support for applying predictive models in forensic criminal profiling context.

Y7 A Bloody Window to the Past: STR Analysis of DNA From a Bloodstained Civil War Surgical Table

Nadia L. Walter, Liberty University, Landisville, PA; Alyssa M. Spillar, BS, Eurofins Biopharma Product Testing, Columbia, MO; Thomas McClintock, PhD, DNA Diagnostics, Inc., Lynchburg, VA; Kristin Mossé, MScFS, Liberty University, Lynchburg, VA*

Learning Objectives: Attendees will learn how basic Short Tandem Repeat (STR) analysis techniques are applied to presumably 150-year-old DNA extracted from bloodstains on a surgical table recovered from a Civil War field hospital. They will understand the collection, extraction, quantification, and analysis techniques of DNA retrieved from aged bloodstains on a wooden substrate. Attendees will grasp the historical context of the last battle of the American Civil War and the significance of obtaining full STR profiles from centuries-old DNA as it relates to confirming historical accounts or even applications in cold cases.

Impact Statement: The forensic science community will benefit from this presentation by understanding the extent of STR analysis and the longevity of DNA from aged bloodstains, as well as collection and extraction techniques. This information expands the bounds of current DNA analysis and signifies that even 150-year-old DNA has the potential to be accurately analyzed, impacting historical records and crime scenes alike.

Abstract Text: This study aimed to generate DNA profiles from the bloody Hillsman House surgical table via STR analysis while also determining the best method of sample collection and analysis from a wooden substrate.

During the Battle at Sailor's Creek in 1865, the historical Hillsman House served as a field hospital where hundreds of Civil War soldiers were treated.[1] In 2016, Jones and McClintock collected and analyzed samples from bloodstains on the floorboards of the house, showing that historical DNA is still viable for profiling.[1] During this process, marks on the floorboard were presumed to be from the surgical table, which was no longer there. The original wooden surgical table was since acquired, and the presumed bloodstains on it were observed. A wooden substrate is difficult to obtain DNA from, so a literature review was performed to optimize collection and extraction methodology.

First, stains on the table were visualized using an alternate light source (ALS). Both swabbings and scrapings of the table were collected and stored before presumptive testing with Phenolphthalein, Leucomalachite Green (LMG), and the RSID Blood Kit was performed to determine the presence of blood. The DNA was then extracted with two different extraction kits, the Qiagen Investigator® Lyse & Spin Basket Kit and the Qiagen DNeasy® Blood and Tissue Kit, which were later compared. Quantification of the DNA was done using the NanoDrop® 2000 spectrophotometer before the samples were amplified by PCR and subjected to capillary electrophoresis with the Applied Biosystems® Genetic Analyzer 3500, utilizing two different injection times that were later compared. Resulting electropherograms were analyzed with GeneMapper® ID-X software at 24 loci.

Full profiles were able to be developed from the 150-year-old DNA, demonstrating the longevity of viable DNA, which may be used to corroborate historical records. Bloodstains on a wooden substrate proved to be a feasible source for DNA. The comparison of collection and extraction methods has valuable applications in crime labs.

Y8 Direct Analysis of Ink on Documents and Other Substrates Using Attenuated Total Reflectance/Fourier Transform Infrared Microscopy

Sophie Krumhansl, APM, University of Mississippi, University, MS; Cadence Manning*, University of Mississippi, University, MS; Boluwatife Olubusoye, BS, University of Mississippi, University, MS; James Cizdziel, PhD, University of Mississippi, University, MS*

Learning Objectives: (1) to understand the role of ink analysis in forensic science: Explain the importance of identifying and differentiating inks for verifying the authenticity of questioned documents and supporting forensic investigations; (2) to describe the Application of micro-Attenuated Total Reflection/Fourier Transform Infrared (μ-ATR/FTIR) in ink analysis: Detail how the technique is used as a non-destructive technique to chemically characterize ink on various substrates; (3) to evaluate the effectiveness of μ-ATR/FTIR with chemometrics: Discuss how combining μ-ATR/FTIR with chemometric data processing enables ink identification and differentiation; (4) to assess the potential of μ-ATR-FTIR in forensic workflows: Highlight the advantages of μ-ATR/FTIR its potential integration into forensic science practices for analyzing ink samples; and (5) to explore the technical features of the analytical system: Outline the operational principles of the FTIR microscope for precise ink analysis.

Impact Statement: This poster will introduce μ-ATR/FTIR combined with chemometrics to analyze ink on documents and other substrates. The microspectroscopy technique is non-destructive, has minimal to no sample preparation, and the potential to be integrated into forensic workflows to advance forensic science for the pursuit of justice.

Abstract Text: The identification and differentiation of inks are critical for verifying the authenticity of questioned documents and in other forensic scenarios. In this work, we investigated μ-ATR/FTIR) combined with chemometrics to analyze ink on documents and other substrates. The microspectroscopy technique is non-destructive, has little to no sample preparation, and the potential to be integrated into forensic workflows to advance forensic science for the pursuit of justice. Samples were chemically characterized by μ-ATR/FTIR using a Bruker LUMOS II microscope with a liquid nitrogen cooled MCT detector using single spot analysis with a resolution of 4 cm^{-1} and 12 scans. The LUMOS system uses a retractable ATR crystal that is controlled by high-precision piezo-electrical motors integrated into the lens. This allows precise positioning of the germanium ATR crystal on traces of ink documents and other substrates to collect vibrational spectra on the ink residues. The data were processed using the instrument's OPUS v8.5 software. Herein we show preliminary data that demonstrate the method is capable of generating relatively high-quality FTIR spectra for ink on a variety of substrates with spectral characteristics that can aid in their identification and differentiation. Overall, this work suggests that μ-ATR/FTIR deserves further scrutiny as a rapid and non-destructive method of analysis of small traces of ink on forensically relevant samples.

Y9 Understanding Sleep-Related Infant Deaths: A Forensic Perspective on SIDS, SUID, and Safe Sleep Practices

Sandra D. Shapiro, DNP, University of North Florida, Jacksonville, FL; Rachel M. Thomas, PhD, University of North Florida, Jacksonville, FL; Orli Grinstein-Cohen, PhD, Ben-Gurion University of the Negev, Beer Sheva South District, HaDarom, Israel*

Learning Objectives: (1) to define SIDS, SUIDS, related terms and mechanisms of injury; (2) to describe Florida's burden of infant death due to sleep-related causes; (3) to review factors associated with mortality and barriers to safe sleep; (4) to describe ways to effectively communicate SIDS risk reduction messages to parents and caregivers; and (5) to list components of successful and evidence-based initiatives.

Impact Statement: This presentation equips forensic professionals with essential knowledge on Sudden Infant Death Syndrome (SIDS), Sudden Unexpected Infant Death (SUID), and unsafe sleep environments. By examining forensic indicators, public health data, and evidence-based prevention strategies, participants will better understand the burden of sleep-related infant deaths and their role in advancing safe sleep education and advocacy within multidisciplinary teams.

Abstract Text: Each year, roughly 3500 babies die in the US due to sleep-related deaths, making it a leading contributor to infant mortality. These deaths rank third after congenital anomalies and cardiac conditions, underscoring the urgent need for forensic and public health collaboration in prevention and education. This poster presents a forensic analysis of Sudden Infant Death Syndrome (SIDS), Sudden Unexpected/Unexplained Infant Death (SUID), and unsafe sleep environments contributing to infant mortality. Using current research and public health data, we will define key terms, examine the mechanisms behind sleep-related infant deaths, and review national guidelines and campaigns and how they have shaped our understanding and prevention efforts. We will take a closer look at the rates of infant death in the US due to unsafe sleep and place these within broader national and global trends demonstrating a large discrepancy between the US and other Western societies. Learners will learn about the common risk factors, such as infant age, sleep position, caregiver behaviors, and environmental hazards, and explore how the social and cultural barriers continue to challenge safe sleep education and practice. The poster also emphasizes the role of nurses and death investigators in identifying unsafe sleep conditions, communicating findings, and supporting prevention efforts. Evidence-based safe sleep initiatives and practical strategies for educating families and caregivers are summarized to support multidisciplinary collaboration in reducing infant mortality.[1-17]

Y10 Utilizing Fourier Transform Infrared Spectroscopy for Age-at-Death Estimations in Human Skeletal Remains: A Pilot Study

Anna K. Maier, MSc, Texas State University, San Marcos, TX*

Learning Objectives: After attending this presentation, attendees will gain a better understanding of the challenges associated with traditional age-at-death estimation methods of human skeletal remains. Moreover, this presentation shows how new analytical techniques, such as Fourier Transform Infrared Spectroscopy (FTIR), are being tested to provide a quantitative approach and refine traditional methodologies.

Impact Statement: This presentation will impact the community by introducing a new tool for estimating age-at-death, enhancing anthropologists' capabilities in identification. By applying this tool, the accuracy and efficiency of identifying unknown remains can be improved and a new area of research fostered in the ongoing global concern of identifying unidentified human remains.

Abstract Text: One of the most significant issues in identifying unknown individuals is the problem of age-at-death estimation. While a major component of the biological profile, age-at-death estimation remains a challenging task for forensic anthropologists. Currently, these age estimations rely on subjective morphological assessments, vary between observers, and often rest on weak statistical foundations.[1-6] The lack of replicability and reliability is especially problematic when aiming to meet the "*Daubert* Criteria" in court. In short, the lack of reliable, accurate, and narrow age range estimations represents a human rights problem and a salient issue for the U.S. criminal justice system.[7]

This presentation hypothesizes that FTIR offers a reliable and accurate quantitative method for age-at-death estimation, addressing current limitations in forensic anthropology. The research on FTIR use for age estimation is new and limited, yet preliminary results show potential for highly accurate age estimations in European samples.[3,8] To date, no research has been conducted on FTIR analysis in correlation with age on a U.S. sample with a more diverse population and a higher variability in age and population affinity.

For this study, 41 human femoral segments (20 males and 21 females) with a mean age of 51, as well as 41 human rib segments (21 males and 20 females) with a mean age of 62, were sampled from the Texas State Donated Skeletal Collection. A total of 3-5mg of bone sample was taken from each individual and scanned in triplicate using an FTIR Bruker Alpha II. Six FTIR indices were analyzed: Carbonate-to-phosphate ratio, crystallinity index, mineral-to-matrix ratio, collagen content, API, and BPI.

Overall, the results confirm the data provided in previous publications by Pedrosa et al. from 2020, who showed that femoral type B carbonate content, femoral carbonate to phosphate ratio, and total carbonate to type B carbonate index are related to age at death and observable through FTIR analysis.[8] The results of this present study show correlations between age and BPI and API, and further significant relationships were confirmed through the Kruskal-Wallis test between the age groups and the FTIR indices

Although the results are promising, further research is needed to validate these findings using a larger and more demographically diverse sample set. Additionally, future studies should incorporate a wider range of skeletal elements and assess intra-bone variability by analyzing samples from different regions of the bone.

Y11 A Field-Ready Method for Wildlife Identification Using Non-Invasive Genetic Sampling

Rosemary C. van der Net, BS, Duquesne University, Pittsburgh, NJ; Pamela Marshall, PhD, Duquesne University, Pittsburgh, PA; Jan Janecka, PhD, Duquesne University, Pittsburgh, PA; Joshua Robinson, MS, Duquesne University, Pittsburgh, PA; Andrea Kautz, MS, Powdermill Nature Preserve, Rector, PA; Joseph Saxfield, BS, Powdermill Nature Preserve, Rector, PA*

Learning Objectives: This presentation describes a new method of DNA analysis for wildlife identification. It can be deployed in the field and used for conservation studies as well as wildlife forensic casework. The audience will learn how it works and the benefits compared to current, traditional methodology.

Impact Statement: This presentation will inform the forensic community of a new method that can be performed in the field and has many advantages over traditional wildlife DNA analysis methods.

Abstract Text: Non-invasive genetic sampling enables the collection of DNA from wildlife without capturing, handling, or physically restraining animals, thereby minimizing disturbance to the animals and their environment. While traditional DNA extraction kits, such as those used for scat, are effective, they often require extensive equipment and time, and are limited in throughput, making them impractical for field deployment. This study explores the use of Nanopore MinION technology, a portable real-time DNA sequencer, in combination with a novel field-friendly DNA extraction protocol to streamline wildlife genetic analysis. The objective of this study was to develop a rapid, cost- and time-efficient, and scalable DNA extraction method suitable for field conditions, capable of processing multiple scat samples simultaneously, and compatible with MinION sequencing.

The protocol utilizes Axygen paramagnetic beads to bind DNA directly from scat samples, eliminating the need for centrifugation and requiring only Tris-HCl and Proteinase K as reagents. Samples collected between 2018 and 2024 from the Snow Leopard Conservancy in Bhutan and Powdermill Nature Reserve in Pennsylvania were dissolved in either Tris-HCl or water, both yielding comparable results. The resulting method proved highly effective for field use and suitable for preparing amplicons for MinION sequencing. Comparative analysis using next-generation sequencing demonstrated successful identification of both target species and their prey. However, some discrepancies in prey identification were observed between this method and the traditional Qiagen extraction kit.

Overall, the new protocol offers significant advantages in terms of time efficiency and practicality, allowing for the extraction of up to 16 samples in approximately 90 minutes. This approach is particularly well-suited for conservation genetics and large-scale non-invasive sampling efforts. Additionally, it holds promise for forensic applications, including the identification of species involved in wildlife crimes.

Y12 A New Spin on DNA Extraction: Validating SpermX GenSpin Differential Extraction for Sexual Assault Evidence Processing

Tori E. Tyree, BS, Marshall University, Ona, WV; Amy McGuckian, MFS, Palm Beach County Sheriff's Office, West, FL; Julie Sikorsky, MSc, Palm Beach County Sheriff's Office, West Palm Beach, FL; Kelly J. Beatty, MSFS, Marshall University, Huntington, WV*

Learning Objectives: Attendees will learn how the SpermX GenSpin Differential Extraction protocol utilizes nanofiber membrane technology to enhance sperm cell isolation and improve male DNA recovery from mixed biological samples. This presentation will explain how the GenSpin method differs from traditional differential extraction techniques and highlight its performance across validation studies, including sensitivity, precision and accuracy, mixture analysis, and mock casework. Attendees will also gain insight into how this streamlined, high-yield protocol reduces epithelial DNA carry-over and increases Short Tandem Repeat (STR) profile completeness, offering a more efficient and consistent approach for processing sexual assault evidence in forensic laboratories.

Impact Statement: This poster will provide forensic practitioners with evidence-based insight into an innovative manual differential extraction method that enhances male DNA recovery and profile completeness from sexual assault evidence. By presenting the effectiveness and operational advantages of the SpermX GenSpin protocol, this work supports laboratories in adopting more efficient and reproducible workflows. The findings have the potential to improve the quality, consistency, and reliability of DNA results, contributing to advancements in sexual assault kit processing and forensic laboratory practices.

Abstract Text: The purpose of this study was to evaluate male DNA recovery from sexual assault evidence samples utilizing the SpermX GenSpin Differential Extraction protocol in comparison to traditional manual differential extraction methods. This study presents an internal validation of the SpermX GenSpin protocol, which uses a nanofiber membrane to selectively capture sperm cells while allowing epithelial cell DNA to pass through. This selective trapping mechanism enhances sperm cell isolation, improves male DNA recovery, and results in cleaner separation of male and female DNA fractions.

Sexual assault evidence frequently contains mixed biological material, requiring differential extraction to separate sperm cells from epithelial cells.[1] Traditional differential extraction methods are often labor-intensive, time-consuming, and susceptible to variability in male DNA yield.[1] The SpermX GenSpin Differential Extraction protocol offers a novel, manual differential extraction method that streamlines processing while enhancing sperm cell isolation and male DNA recovery.

This validation study assessed the protocol's performance across a range of studies, including sensitivity, precision and accuracy, mixtures, and mock casework. The SpermX GenSpin Differential Extraction method consistently produced higher male DNA yields and more complete short tandem repeat (STR) profiles, with reduced carry-over from epithelial DNA. Its simplified workflow offers a high-yield alternative to traditional labor-intensive differential extraction methods.

These findings support the SpermX GenSpin protocol as an effective and high-performing manual differential extraction method for processing mixed biological evidence containing seminal fluid. Its robust performance and operational efficiency make it a potential tool for improving the quality and consistency of forensic DNA results in sexual assault cases.

Y14 Revisiting the Resolution and Accuracy of Year-of-Birth Estimations Based on Bomb Pulse Radiocarbon (14C) Dating of Human Enamel

Camille Martin, BA, Department of Anthropology, New York University, Teaneck, NJ; Rhonda Quinn, PhD, Department of Natural and Social Sciences, Bowling Green State University-Firelands, Huron, OH*

Learning Objectives: After attending this presentation, attendees will understand the variables that impact method accuracy and resolution of bomb curve 14C dating of enamel for estimating Year-Of-Birth (YOB) of unidentified deceased persons. Attendees will be presented with a review of method development and how variation in crown formation ages specific to tooth type and number influence resulting YOB estimations. Emphasis will be given to best practices for method application to forensic casework.

Impact Statement: This presentation will impact the forensic science community by: (1) understanding how tooth formation standards of crown initiation to crown completion are crucial to determining year-of-birth from bomb pulse 14C-derived chronological ages; (2) examining sources of variation and effects on estimation error; (3) highlighting bomb pulse 14C tooth enamel analysis as a tool for forensic casework involving unidentified deceased persons.

Abstract Text: Bomb pulse radiocarbon (^{14}C) dating of enamel is used by forensic anthropologists to estimate the year-of-birth (YOB) of unidentified deceased persons. The method was developed by comparing actual YOBs with bomb pulse ^{14}C-derived calendar years from enamel samples of known decedents.[1-4] Previous work using regression analysis yielded strong linear relationships (R^2>0.9) and narrow error margins (±1.3 years) for YOB estimations.[1-3] Furthermore, method resolution was determined by combining all measured teeth into one regression analysis and did not consider variation in crown formation ages by tooth type and number.[1-4] Most importantly, method development relied on chronological ages of crown completion derived from a single published European dataset; however, the actual ages of crown formation for the known decedents were not available.[5]

In this study, a compilation of all reported enamel ^{14}C measurements from known decedents (n = 166) was used to estimate the chronological age ranges of each tooth by type and number. Using standard atlases of tooth formation stages, typical chronological age ranges from crown initiation to crown completion were compared to bomb pulse ^{14}C-derived chronological ages.[6] Regression models were applied to compare actual YOB to ^{14}C-estimated YOB for each individual, and the resulting confidence intervals were evaluated in relation to typical chronological age ranges of crown formation.

Analysis of ^{14}C-estimated chronological ages of crown formation generated in this study compared to average crown growth ages used to estimate YOB revealed between three and nine statistical outliers per tooth type and number in the compiled dataset.[1-3] Potential sources of variation and error in method development are discussed, including decedents with atypical enamel formation ages, time lags in ^{14}C uptake, and misidentification of tooth type or number within the dataset. Depending on tooth type and number, variation in crown formation ages spans three to ten years, which exceeds confidence intervals derived from regression models when all teeth are combined.[1-3] Integrating crown formation age ranges is advised when applying bomb pulse ^{14}C dating of tooth enamel to forensic casework in order to capture probable YOB ranges.

Y15 Fungal Succession During Decomposition: A DNA-Based Analysis of Forensic Significance

Lewis Burnett, Southern University at New Orleans, New Orleans, LA; Brittney Sylvester, Southern University at New Orleans, New Orleans, LA; Latavia Williams, Southern University at New Orleans, New Orleans, LA; Alyssa Lavasseur, Southern University at New Orleans, New Orleans, LA; Georgia A. Williams, MS, George Mason University, Manassas, VA; Meiko Thompson, PhD, Southern University at New Orleans, New Orleans, LA*

Learning Objectives: This presentation will enable attendees to explain the forensic relevance of fungi in decomposition, particularly their role in breaking down complex tissues during advanced stages. They will learn the DNA-based methodology for characterizing fungal succession from key anatomical sites. Attendees will be able to predict how fungal community dynamics differ from bacterial patterns over time and assess the value of integrating both data types to create more robust and comprehensive tools for Postmortem Interval (PMI) estimation.

Impact Statement: By focusing on fungi, this study expands the scope of forensic microbiology beyond bacteria and addresses a critical gap in decomposition research. Findings may lead to the incorporation of fungal markers into microbial-based PMI estimation models, improving their accuracy and applicability in forensic casework.

Abstract Text: While bacterial succession has been extensively studied for PMI estimation, the forensic relevance of fungal communities remains comparatively unexplored.[1] Fungi are crucial decomposers in ecosystems, specialized in breaking down complex organic compounds like keratin and cellulose, and may provide critical indicators during advanced decay stages when bacterial communities often stabilize.[2] This gap limits the comprehensiveness of microbial-based forensic models. The objective of this study was to characterize the dynamics of fungal community succession on decomposing remains using DNA-based methods and to evaluate their potential to serve as a complementary tool for PMI estimation.

This research was conducted at the George Mason University Body Farm during the summer of 2024. A domestic pig (*Sus scrofa domestica*) carcass was placed on the soil surface under natural environmental conditions. To comprehensively profile mycobiome succession, swab samples were collected daily from multiple anatomical sites—including the oral, abdominal, and rectal cavities—for the first 21 days of decomposition, transitioning to a weekly schedule until July 24, 2024. All samples were preserved at -80°C for subsequent DNA extraction. Fungal communities were targeted for polymerase chain reaction (PCR) amplification of the internal transcribed spacer (ITS) region, with sequencing data to be analyzed for taxonomic identification and temporal tracking of fungal taxa.

Data analysis is currently ongoing; however, based on ecological principles and prior literature, it is anticipated that fungal succession will follow a distinct timeline from bacteria. We hypothesize that fungal diversity and abundance will peak during the advanced stages of decomposition, with a notable succession of saprotrophic taxa. Furthermore, we expect to observe site-specific colonization patterns influenced by both endogenous sources and the influx of environmental fungi from the surrounding soil and vegetation.

This study is expected to demonstrate that fungi contribute predictable and forensically informative succession patterns throughout decomposition. The findings will expand the scope of forensic microbiology beyond prokaryotes and address a significant research gap. Ultimately, integrating fungal succession data with established bacterial models promises to enhance the accuracy and reliability of PMI estimation, particularly for remains in later stages of decay, thereby providing a more powerful, multi-kingdom analytical tool for forensic investigations.

Y16 Exposing Forgery: Ink Analysis via Raman Spectroscopy

Alex J. Potter, MSFS, Towson University, York, PA; Ellen H. Hondrogiannis, PhD, Towson University, Towson, MD; Mary Devadas, PhD, Towson University, Towson, MD*

Learning Objectives: Attendees of the presentation will have the opportunity to learn the following: (1) the importance of ink analysis to forensic science; (2) the limitations of current techniques Raman Spectroscopy and the data processing required; (3) capabilities of portable Raman Spectroscopy and SERS; and (4) will recognize the difficulties in black ink differentiation

Impact Statement: The research being proposed will impact the forensic science community as it will bring more attention to the capabilities of Raman Spectroscopy and SERS when differentiating pen ink. Analysts will be better informed about the suitability of this instrumentation for their laboratories. Ink analysis is an important aspect of forensics, and this research aims to continue to update current techniques being used.

Abstract Text: Ink analysis has been an important category of forensic trace analysis for nearly a century.[1] This field of forensic analysis encompasses casework dealing with forgery and fraud, which is just as relevant today as it was 100 years ago and making it appealing for questioned document analysts. The United States Secret Service investigates over 500 new ink cases each year. Their current standard method for ink analysis uses Thin Layer Chromatography (TLC), a destructive and time-consuming technique.[2] Portable Raman spectroscopy is a non-destructive technique that has been used for analysis of various trace evidence including pen inks.

The aim of this study is to bridge the gaps between differentiating black colored inks with Raman spectroscopy. This is relevant as there has been prior research on ink analysis, however, the majority features blue ink as black is more difficult to differentiate.[3] Raman offers a non-destructive way to analyze ink samples, benefiting those who utilize this instrument to investigate important matrices.[4] We report on the usefulness of the portable Raman spectrometer to differentiate black colored inks, as well as investigating the ability of differentiating aged ink samples with the addition of SERS.

After attending this presentation, attendees will understand the use of portable Raman spectroscopy to determine whether evidence writing could have originated from the source ink. Attendees will further understand how the presence of gold nanoparticles affect the Raman signal to produce the surface enhanced Raman (SERS) effect. The application of SERS is particularly significant in the case of older and faded documents where one must transform the weak analyte signal to a stronger signal that is more easily interpreted by the forensic analyst. Our previous work with gunshot residue and SERS further illustrated the usefulness of transforming the data to allow a better view of the analyte signal.[5] Both the application of SERS and data processing will expand our current understanding of forensic ink analysis.

This report will present a case study in Raman used for pen ink analysis. It is recommended that investigators working with inks familiarize themselves with the abilities of Raman spectroscopy in analyzing ink samples in a nondestructive way. Application of this nondestructive method allows the original ink sample to be retained allowing for better traceability back to the evidence as well as results that are more defendable in court since there is less manipulation of the sample such as that which occurs when the evidence is subjected to the current technique of thin layer chromatography.

Y17 Enhancing Nuclear DNA Recovery From Soil: A Comparative Analysis of Resin, Silica Membrane, and Silica Bead Extraction Methods

Ashley Espinoza, MS, University of Massachusetts, Amherst, Amherst, CA; Todd Disotell, PhD, UMass Amherst, Amherst, MA*

Learning Objectives: By the end of this session, participants will be able to compare different DNA extraction methods and evaluate their effectiveness in recovering biological media from soil. Participants will also be able to identify key environmental factors that contribute to DNA degradation in soil samples.

Impact Statement: The impact of this primary research is to contribute more data on the effects soil composition and environmental factors have on nuclear DNA degradation and the success of recovery. Ultimately, the goal is to aid in establishing a protocol and standardize the extraction of biological media from soil samples.

Abstract Text: Soil is often underutilized in medicolegal investigations as it acts as a repository for all biological material, including molecular evidence. The aim is to conduct a preliminary study that compares different DNA extraction methods to determine which yields the highest DNA from soil samples of degraded biological media (blood). Three nuclear DNA (nDNA) extraction kits/protocols (Kasu and Shives (2015) and Rohland et al. (2018) a and b) are applied to collected soil samples containing biological media.[1,2] The soil samples containing biological media were exposed to the local environmental conditions in Amherst, MA, to assess the influence of environmental factors on degradation. Each nDNA extraction method is evaluated by overall efficiency of extraction (i.e., allelic dropout and peak height) and the ability to generate the full 27 loci STR DNA profiles. Previous studies have reported contradictory results regarding the most effective kits or protocols in extracting nDNA from soil samples (resin, silica membrane, or silica beads). There is a lack of standardization and replicable data sets in soil extraction methods due to varying soil composition, climate, and environmental conditions. Ultimately, the goal of this study is to contribute data and aid in the standardization and implementation of soil extraction methods within the field of forensic science. The results will be available and included into the poster.[3-7]

Y18 Accuracy of the Transition Analysis 3 (TA3) Method for Age Estimation in the John A. Williams Human Skeletal Collection

Blue Wonhof, MS, Western Oregon University, Albany, OR*

Learning Objectives: Attendees will learn how TA3 estimates age-at-death using a large suite of skeletal traits and advanced statistical modeling. By the end of the presentation, they will be able to evaluate TA3's accuracy, reliability, and limitations compared to other studies on the method.

Impact Statement: This research strengthens the forensic science community's ability to critically assess the reliability of age-at-death estimation methods, particularly TA3. By identifying strengths, limitations, and areas for refinement, the study contributes to improving methodological accuracy and ultimately supports more reliable identifications in forensic casework.

Abstract Text: This study evaluates the accuracy and reliability of TA3, a multifactorial forensic age estimation method, using 71 individuals from the John A. Williams Human Skeletal Collection at Western Carolina University. Individuals were selected based on known age-at-death and sufficient skeletal preservation to be scored for over 75% of the 121 morphological traits specified by TA3. Age estimations were generated using standardized procedures and analyzed in IBM SPSS to assess absolute error, intra-observer reliability, and the role of demographic and skeletal variables in estimation accuracy. Results revealed a mean absolute error (MAE) of 8.14 years, with 92.96% of individuals falling within the TA3-predicted age intervals. While intra-observer agreement was low overall (Cohen's Kappa = 0.079), perfect agreement (Kappa = 1.0) was achieved when individuals were grouped by age category (young, middle, and old adult). No significant differences in error were observed by sex; however, younger individuals exhibited higher error rates ($p = .002$). Skeletal element-specific analyses revealed variation in reliability, with the trapezium yielding the lowest average error (5.93) and the scapula the highest (9.74). By region, the tibia, fibula, and calcaneus yielded the lowest MAE (7.34) and the humerus the highest (9.2). These findings bring to light both the limitations of TA3 in forensic age estimation, particularly in younger age groups, and the potential of certain skeletal regions.

Y19 Visual Examination of Physical Properties of Blood as a Result of Ignitable Liquid and High Heat Affect From an Arson Scene

Victoria Bascou, BS, Texas Tech University, Lewisburg, TN*

Learning Objectives: The goal of this presentation is for attendees to learn about how extreme temperatures (temperatures greater than 200°C) affect both the physical properties (color, viscosity, shape of stain) of blood and how the presence of ignitable liquids may affect the visual examination of blood when detected at a fire scene. An evaluation of the effects on blood seen from extreme heat and the presence of ignitable liquids was studied to better understand how blood can commonly be affected by events at an arson scene. Learning objectives include identifying the presence of ignitable liquids in combination with blood, evaluating how the blood's shape, color, and/or viscosity may change because of heat and ignitable liquid presence, and examining the relevance of these effects on blood's physical properties. This research provides results that can aid in the visual examination of blood at an arson scene.

Impact Statement: This experiment was conducted to identify the effects on blood seen at an arson scene. The effects on the blood were analyzed after the introduction of high heat and ignitable liquids, simulating the events of an arson scene. Results from this research will identify how blood is commonly affected by the events and factors related to an arson scene, which will provide a basis for future researchers to utilize when visually examining their own arson scenes. These results will have an impact on the forensic science community as they will help individuals to understand the ways in which blood can be affected by different variables from an arson scene. By understanding what can affect the presence of blood found at crime scenes, such as high heat and ignitable liquids, investigators can adapt their methods for the optimized examination of blood at arson scenes.

Abstract Text: Ignitable Liquid Residue (ILR) analysis is a subdiscipline of forensic science that focuses on investigating burned debris, substrates, and ignitable liquids from a crime scene. A fire investigation will often occur at a crime scene where a fire occurred to correctly identify the origin of the fire and whether the fire was set intentionally or not. A fire set intentionally can lead to criminal charges ILR analysis can occur from the debris and substrates recovered from a scene to help in this determination. Much research regarding ILR analysis investigates the interactions between different substrates (wood, cotton, latex) and various ignitable liquids, such as gasoline and lighter fluid. Analysis of substrates or ignitable liquid samples obtained from a scene are often analyzed via Gas Chromatography/Mass Spectrometry (GC/MS). However, many labs do not have access to a GC/MS or other instrument for chemical analysis of ignitable liquids oftentimes investigators must rely on visual examination of these substances at the scene. Research on ILR analysis has focused on the investigation of IL effects on substrates as well as the classification of ILs. Despite extensive research into the classification of ILRs, limited research has been conducted to examine the physical properties of ignitable liquids after being exposed to heat from a fire. This research proposes the visual examination of blood, which is commonly found as an interfering substance at a crime scene, to identify how the physical properties (color, viscosity, shape of stain) of blood is affected by the presence of ignitable liquids as a scene coupled with the extreme heat from a fire.

Y20 The Quantitation of Organic Compounds in Smokeless Powder Using High-Performance Liquid Chromatography

Kayla M. South, BS, Towson University, Stevens, PA; Ellen H. Hondrogiannis, PhD, Towson University, Towson, MD*

Learning Objectives: Attendees of the presentation will have the opportunity to learn the following: (1) the need for smokeless powder research in the field of forensic trace analysis; (2) the need for organic compounds capable of definitively identifying GSR; (3) the limitations of Gas Chromatography/Mass Spectrometry (GC/MS) for Gunshot Residue (GSR) analysis; (4) the capabilities of High-Performance Liquid Chromatography (HPLC) and Surface-Enhanced Raman Spectroscopy (SERS); and (5) how smokeless powders can be differentiated.

Impact Statement: The proposed research will impact the forensic science community by bringing attention to HPLC and SERS in the characterization of GSR. Information regarding alternative instrumentation for GSR analysis and organic compound detection will aid analysts in determining instrument and method suitability for their laboratories. GSR analysis is an important aspect of forensic trace investigations, and this research aims to improve upon the current techniques used.

Abstract Text: GSR is an integral part of forensic trace analysis in investigations where a firearm has been discharged. The current standard for GSR characterization utilizes Scanning Electron Microscopy/Energy Dispersive X-Ray Spectrometry (SEM/EDS) to identify the inorganic components lead, barium, and antimony.[1] Ammunition manufacturers introduced lead-free ammunition, which established a need for alternative methods of GSR characterization.[2] Analytical approaches shifted focus to the detection of the inorganic and/or organic compounds in GSR using a variety of instrumentation.[3] The overall goal in our laboratory is to use SERS to enhance the signal from the nitrated diphenylamine derivatives in the GSR. To support this effort, we must first quantify the amount of these derivatives in smokeless powder.

While manufacturers often list the amounts of organic compounds in the SPs, they are only relative amounts. In addition, these relative amounts change as a result of degradation of the energetics, followed by reactions with stabilizers. These reactions result in a decrease of the stabilizer content and increase in the resulting nitrated stabilizer products.

The purpose of this study is to quantify nitrated diphenylamine derivatives and other organic compounds in various smokeless powders using HPLC. This study is relevant since it will allow us to measure the amount of these compounds in SP as a starting point for the SERS analysis. Characterizing SPs with different organic compounds will further allow us to study the effect that these different analytes have on the SERS signal.

After attending this presentation, attendees will understand the optimal parameters for the separation of these compounds using HPLC in addition to the number and amount of nitrated derivatives in 5 smokeless powders. Based on our HPLC data we will rank the SPs based on the number and amount of nitrated derivatives present, which correlates with our ability to enhance their signal. This enhancement is needed due to the very low amounts of these analytes recovered in GSR. This helps to better inform the forensic community about the value of the SPs for evidence. Attendees will further understand the types of organic compounds needed for GSR characterization and why the previous methods of analysis needed to be adjusted for use in current forensic investigations. Based on our previous work of the Gas Chromatography/Mass Spectrometry (GC/MS) analysis of SP extracts we report on the advantages of using HPLC for the characterization and quantification of SP extracts. The use of GC/MS for the analysis of these compounds highlighted the need for alternative instrumentation due to the decomposition of a significant target analyte. Our previous work with gunshot residue and SERS further demonstrates the effectiveness of advanced instrumentation to enhance an analyte signal.[4]

It is recommended that analysts working with GSR familiarize themselves with organic compounds found in GSR in addition to the capabilities of HPLC in detecting them for GSR characterization. After this presentation, attendees will note the potential of HPLC as a useful tool for definitively identifying residue evidence as GSR in forensic trace analysis.

Y21 Network Graphs for Visualizing Handwriting Individuality

Clarissa Giefer, MS, South Dakota State University, Brookings, SD; Cami Fuglsby, PhD, Augustana University, Sioux Falls, SD; Janean Hanka, MS, South Dakota State University, Brookings, SD; Jack Hietpas, PhD, John Jay College, New York, NY; JoAnn Buscaglia, PhD, FBI Laboratory, Quantico, VA; Christopher P. Saunders, PhD, South Dakota State University, Brookings, SD*

Learning Objectives: The presented research will demonstrate how a complex dataset consisting of handwriting comparison scores can be represented to provide a rapid means to visually assess the biometric individuality of populations of handwriting profiles.

Impact Statement: This research will provide a tool that enables document examiners to detect potential exclusionary differences in writer profiles. The statistical methods developed for this research may help identify populations of writer profiles that are easily differentiated and those that consist of common features with low discrimination potential or unusually high within-writer variability.

Abstract Text: A common question when deciding whether or not to analyze a type of physical evidence is the degree to which the features of the traces derived from different sources can be distinguished. Colloquially, this "degree" is referred to as the "individuality" or "uniqueness" of the measured feature. For a statistically rigorous definition, we define individuality as the chance of observing two sources that are indistinguishable, with respect to a specified metric, when comparing large samples from the two sources. For comparisons in which two sources have indistinguishable profiles with respect to the metric, regardless of the sample size, it is concluded that they will not give rise to exclusionary differences. Following, we define biometric individuality as the random chance of observing two indistinguishable profiles, based on a specified metric threshold, within the population of relevant sources.[1] This concept is closely related to the idea of the biometric capacity of an automated identification system. In this work, we present strategies for visualizing the biometric individuality of populations of handwriting profiles using customized network graphs.[2]

Our focus is to study the score-based method developed by Davis et al. for sparse categorical data arising from level one features in the language-dependent predecessor of the FLASH ID© system.[3] Due to the complexity of the feature space inherent to handwriting comparisons, the chi-squared statistic for comparing two handwriting samples is not reliable when two samples share the same writing profile. This implies that defining exclusionary differences for handwriting comparisons is statistically and computationally difficult. To overcome this issue, we define a new test based on all pairwise comparisons, with respect to the chi-squared test statistic, between documents from two different writers. We then propose a level alpha test based on the expected values of scores, comparing within-writer scores between the two writers and the average within-writer scores with the between-writer scores. If we observe a significant difference among the three different expected values of scores, we conclude that we have observed a significant (exclusionary) difference between the writing profiles of the two writers.

Using the developed level-alpha significance test, we use the corresponding p-values between two writers to assess the occurrence of finding two writers with indistinguishable profiles. To achieve this goal, we model the distribution of p-values with a mixture model that allows us to make assessments about the confidence that a given p-value came from a comparison of writers with indistinguishable writing profiles. We summarized the results visually using network graphs to help identify groups of writers that have a high degree of confidence that they have indistinguishable writing profiles.

In this presentation, we illustrate the approach with a dataset of 100 writers, each writing five script copies of the modified "London Letter."[1]

Y22 Direct Analysis in Real Time Tandem Mass Spectrometry (DART-MS/MS) for the Characterization and Profiling of Street-Level Fentanyl Samples

Joel E.R Moss, Arcadia University, Glenside, PA; Alexis D. Quinter, MASc, CFSRE, Horsham, PA; Heather L. Harris, MFS, Arcadia University, Glenside, PA; Nicholas E. Khorozov, MS, Center for Forensic Science Research & Education, Hatboro, PA; Joshua S. DeBord, PhD, Center for Forensic Science Research & Education, Horsham, PA*

Learning Objectives: After attending this presentation, attendees will understand the application and limitations of DART-MS/MS for common source determinations of street-level fentanyl samples.

Impact Statement: This presentation will impact the forensic science community by demonstrating the ability of DART-MS/MS to quickly and effectively analyze seized fentanyl samples. Sample profiles, comprised of the relative signals of fentanyl, and common fentanyl-related substances, will be generated and compared to determine whether if common origin can be established.

Abstract Text: The illegal synthesis of fentanyl and fentanyl analogs continues to pose a great risk to public health and safety due to their high potency.[1] The detection and identification of fentanyl and fentanyl-related substances in seized drug evidence is crucial in forensic investigations. DART coupled with Mass Spectrometry (MS or MS/MS) has been demonstrated to be a rapid and sensitive technique capable of detecting various controlled substances including fentanyl and its analogs.[2] However, the configuration of a triple quadrupole tandem mass spectrometer coupled to a DART ion source to analyze seized fentanyl samples has not yet been reported.

This study evaluated the use of a EVOQ DART-TQ+ (Bruker) to reliably produce comparable profiles of seized fentanyl samples. The method's parameters were optimized including the scanning mode, the DART gas [He] temperature, cone temperature, grid/cone voltage, and cone gas pressure. Method validation studies include limit of detection (LOD), carryover, and common interferences.

Following the validation, several previously analyzed street-level fentanyl samples will be analyzed and profiled using DART-MS/MS. The samples have been previously demonstrated to have associated or discriminated based upon quantitative analysis[3]. The DART-MS/MS profiles will be statistically compared to one another to assess whether association/discrimination can be performed. The potential of DART-MS/MS to rapidly uncover linkages through fentanyl profiling could be extremely valuable for law enforcement investigations.

Y23 Investigating the Effects of Soil pH and Fluoride Content on Hydroxyapatite Degradation Using pXRF Technology

Madeline June Leeah, BA, Texas Tech University, Lubbock, TX*

Learning Objectives: The learning objectives for this presentation are: (1) a basic understanding of forensic taphonomy in outdoor burial contexts, specifically the influence of soil pH and fluoride content. Attendees should walk away from the presentation knowing that soil environments greatly affect the condition of skeletal human remains; (2) a basic understanding of the inorganic, mineral component of bone: Calcium Hydroxyapatite (CA). Attendees should be able to identify the elements of CaHA that are most likely to be affected by soil content; (3) an increased/new understanding of the usefulness of Portable X-Ray Fluorescence (pXRF) technology in forensic anthropology. Attendees should have reinforced knowledge of pXRF technology and/or new knowledge regarding its use in forensic anthropological research; (4) a new understanding of novel methods for measuring soil pH, utilizing pXRF technology, and monitoring changes over time; (5) the importance of "bridging the gap" between forensic science subdisciplines, specifically forensic chemistry and forensic anthropology; and (6) attendees should walk away with a renewed understanding of basic concepts within forensic anthropology, along with novel ways to apply these basics in more specific research contexts.

Impact Statement: While there is extensive research by anthropologists and biologists on the degradation of human remains in burial environments, there are few studies that seek to contextualize this degradation at its most basic, elemental level. A deeper understanding of how bone degradation takes place in different environments—and how those environments, in turn, affect the condition and chemical make-up of remains—can help forensic scientists, anthropologists, and archaeologists add to the existing knowledge of how the environment affects human remains (often referred to as taphonomy or diagenesis). In addition, pXRF is an important resource in the "toolbox" of a forensic scientist or anthropologist. It is a good idea to further understand how to apply this technology in building a taphonomic profile of human skeletal remains. This research bridges the scientific gaps between two major fields: chemistry and forensic anthropology. It provides a multidisciplinary approach to understanding bone degradation, taphonomic processes, and the postmortem and post-depositional intervals. Finally, in line with this year's theme, this research aims to open a dialog regarding the question: how can we utilize new technologies and methods to re-examine the foundational concepts of forensic science, specifically anthropology and chemistry?

Abstract Text: Forensic anthropologists often rely on the analysis of bone to determine what has happened to human skeletal remains during the postmortem interval (PMI). Understanding the PMI can aid in identification efforts of decedents, as well as provide context surrounding burial environments and decomposition processes such as skeletonization and the eventual breakdown of bone. Soil pH is an important factor that influences the decomposition of human remains, specifically the breakdown of calcium hydroxyapatite (CaHA), the main mineral component of bone. Soil fluoride content is another factor that can potentially affect the degradation of CaHA. While studies report the macroscopic "before" and "after" of the effect of soil pH on bone degradation, few publications report on the process buried bones undergo at the elemental level when subjected to different pH levels. At present, there are no published reports of how fluoride content affects CaHA degradation. To monitor, document, and understand the effect of soil pH and fluoride content on hydroxyapatite degradation, portable x-ray fluorescence (pXRF) technology was used to detect and analyze changes in twelve pig bone samples across a soil pH range from 4.0-8.5. Results indicate that an acidic soil environment causes a decrease in CaHA, likely due to hydrolysis. Specimens placed in basic soils showed less of a decrease over the same period. A sample placed in fluoride-rich soil showed a decrease similar to those samples placed in acidic soils, suggesting a loss of calcium and possible replacement with fluorapatite. The acidic and basic soil results reinforce existing literature, while the fluoride-rich soil results promote the possibility of better preservation in fluoride-rich soil. Overall, this research provides a novel, replicable method of testing how different soils affect the decomposition process. In addition, this research has confirmed the usefulness of pXRF for investigating taphonomic changes to skeletal remains. Future research aims include more experimental trials to understand the role of fluoride in CaHA decomposition, as well as efforts to further standardize and calibrate pXRF for bone analysis.

Y24 When Experts Lie: Fraudulent Forensics, Wrongful Convictions, and the Call for Basics and Reform

Megan R. Cramer, Embry-Riddle Aeronautical University, Prescott, AZ; Jordan M. Stephens*, Embry Riddle, Aeronautical University, Escondido, CA*

Learning Objectives: Participants will learn to identify key sources of error in forensic investigations that contribute to wrongful convictions. They should be able to examine cognitive biases in analysts, law enforcement, and even in their own thinking. Participants will also be able to compare the effectiveness and limitations of common forensic evidence analyses, explaining how overreliance on certain technologies and the lack of review can harm investigations. With this knowledge, they should be able to propose meaningful reforms aimed at improving standards and reducing wrongful convictions.

Impact Statement: This presentation will highlight the flaws in forensics that contribute to wrongful convictions. By addressing issues such as cognitive bias, lack of standardized procedures, fraudulent analysts, and overreliance on certain technologies, the presentation encourages the forensic science community to critically evaluate current practices. It will provide analysts, students, and researchers with information to recognize weaknesses in forensic investigations and to advocate for reforms in education, training, and administrative oversight. This work will reinforce the importance of ethics, objectivity, and basic investigative practices to strengthen the credibility of forensic science and restore public trust in the field.

Abstract Text: Since 1989, over 3,700 innocent people in the United States have been exonerated, yet this number represents only a fraction of those wrongfully convicted.[1] While advances such as DNA evidence have revolutionized forensic science, they have also created an overreliance on certain methods that are still mishandled, misinterpreted, and abused. Wrongful convictions highlight systemic failures in forensic science, law enforcement practices, and administrative oversight. A return to the basics of careful, ethical investigative work, national standards, and accountability may be the most effective way to restore integrity to the field.

This study reviewed literature on wrongful convictions across six key areas: law enforcement influence, administrative organization, trace evidence analysis, fingerprint analysis, DNA analysis, and drug or DUI cases. Across each category, recurring problems emerged. Issues like cognitive bias, lack of training, pressure to produce quick results, absence of universal guidelines, and monopolization of forensic services contributed to the disorganization.[2-4] Police-run labs face dual problems of bias and underfunding, where the drive to push cases forward often undermines scientific accuracy.[3] Reports of disappearing evidence, falsified results, and unstandardized procedures erode reliability.

Certain forms of evidence are especially prone to misuse. Bite marks and hair analysis have proven unreliable yet continue to influence convictions.[5] Fingerprint comparisons also remain vulnerable to examiner subjectivity and bias.[6] Drug and DUI testing is plagued by fraud, increasing caseloads, and a lack of clear investigative protocols.[7,8] Even DNA, often treated as the gold standard of forensic science, can be contaminated, degraded, or misinterpreted, leading to false certainty in court.[5]

Solutions must begin with education, instilling the principle that ethics and accuracy outweigh speed and conviction rates. Administrative reform is also needed, including independent oversight of forensic labs, standardized investigative guidelines, and safeguards against monopolies where one lab tests and reviews its own results. The Embry-Riddle Cold Case Task Force provides an example of how revisiting cases with fundamental investigative techniques can succeed where previous forensic biases failed and leads were ignored by poorly trained law enforcement officers and analysts.

Ultimately, forensic science must embrace humility. Technology cannot replace careful police work, patience in the lab, unbiased review, and a commitment to justice. Without reform, the cycle of wrongful convictions will persist, undermining both public trust and the very purpose of forensic science.

Y25 Analysis of Smokeless Powder Using Infrared and Uv-Visible Spectroscopy With a Focus on Nitrated Derivatives of Diphenylamine

Meredith G. Elko, Towson University, Egg Harbor Township, NJ; Ellen H. Hondrogiannis, PhD, Towson University, Towson, MD; Mary Devadas, PhD, Towson University, Towson, MD*

Learning Objectives: Attendees of this presentation will learn how UV-Visible (UV-Vis) and infrared (ATR/FTIR) spectroscopy can be used together to identify analytes present in smokeless powder. UV-Vis spectroscopy is useful for the initial screening of smokeless powders and identifying the presence of 2-nDPA and 4-nDPA as they each have distinct peaks outside an overlap range of other common analytes of smokeless powder: diphenylamine (DPA), 2,4-dinitrotoulune (2,4-DNT), ethyl centrlaite (EC), and N-nitrodiphenylamine (N-nDPA). ATR/FTIR is most useful for identifying the analytes that make up less than 15% of the smokeless powder as opposed to less than 1%. However, IR does not explicitly show analytes known to be present due to UV-Vis or HPLC results.

Impact Statement: My presentation will inform trace evidence analysts in the forensic science community of the combined capabilities of UV-Vis and ATR/FTIR spectroscopy in identifying the unique combination of analytes present in a given smokeless powder, which then has the possibility of aiding in the identification of a gunshot residue sample. ATR/FTIR can identify the major analyte(s) in the powder, and UV-Vis can identify the presence of 2-nDPA or 4-nDPA. Utilizing two techniques that are non-destructive and efficient allows them to be easily integrated into the daily workflow of forensic scientists.

Abstract Text: This presentation will inform trace evidence analysts in the forensic science community of the combined capabilities of UV-Vis and ATR/FTIR spectroscopy in identifying the unique combination of analytes present in a given smokeless powder, which then has the possibility of aiding in the identification of a gunshot residue sample. Since the removal of lead from smokeless powders, the focus has shifted to analysis of the organic compounds present.[1] Utilizing two techniques that are non-destructive and efficient allows them to be easily integrated into the daily workflow.

Attendees of this presentation will learn how UV-Visible (UV-Vis) and infrared (ATR/FTIR) spectroscopy can be used together to identify analytes present in smokeless powder. UV-Vis spectroscopy is useful for the initial screening of smokeless powders and identifying the presence of 2-nitrodiphenylamine (2-nDPA) and 4-nirtodiphenylamine (4-nDPA) as they each have distinct peaks outside an overlap range of other common analytes of smokeless powder: diphenylamine (DPA), 2,4-dinitrotoulune (2,4-DNT), ethyl centrlaite (EC), and N-nitrodiphenylamine (N-nDPA). ATR/FTIR is most useful for identifying the analytes that make up less than 15% of the smokeless powder in comparison to those that make up less than 1% of the powder. However, IR does not explicitly show analytes known to be present due to UV-Vis or HPLC results.

Two extraction procedures were carried out on the same smokeless powder to determine which method extracts more organic components. The procedure, which contained vortexing as the primary agitation instrument, extracted a higher concentration of organic components. This procedure was used for the rest of the study. UV-Vis and ATR/FTIR standard spectra were obtained for the common analytes present in smokeless powders. These standards allowed us to determine any unique peaks associated with a given analyte for comparison to a smokeless powder's spectrum. A UV-Visible spectra of highly concentrated Hodgdon 4895 (H4895) revealed the presence of nitrated derivatives of diphenylamine (DPA) not listed in the official powder make-up. The ATR/FTIR spectra of H4895 matched the spectrum of the more abundant analyte, but did not explicitly show unique peaks associated with the lower percentage analytes listed or the nitrated derivatives of DPA seen using UV-Vis.

Y26 Suicide by Sodium Nitrite/Nitrate: A 10-Year Retrospective Review

Rachel Guest, MD, Baylor College of Medicine, Houston, TX; John W. Powell III, MD, Harris County Institute of Forensic Sciences, Manvel, TX*

Learning Objectives: Attendees will learn about the emerging trend of sodium nitrite/nitrate ingestion as a method of suicide, with emphasis on demographic patterns, clinical and toxicological findings, and forensic implications. Twenty-two cases over a ten-year period will be presented, highlighting temporal trends, case characteristics, and challenges for medicolegal evaluation.

Impact Statement: Intentional ingestion of sodium nitrite/nitrate has become an increasingly recognized method of suicide worldwide. During the past six years of our 10-year study period, we identified 22 cases of intentional sodium nitrite/nitrate poisoning, confirmed through autopsy findings, toxicological analysis, and scene investigations. This study seeks to raise awareness of this growing trend among clinical, public health, and medicolegal professionals and to underscore the scene characteristics and autopsy findings that should prompt consideration of sodium nitrite/nitrate poisoning in suspected cases.

Abstract Text: Background: Sodium nitrite/nitrate is an inorganic, odorless, and water-soluble salt commonly used as a preservative with anticorrosive and antimicrobial properties.[1,2] Intentional ingestion has emerged as an increasingly common method of suicide worldwide, likely due to its ease of use and lack of federal purchasing regulations.[2-6] Ingesting sodium nitrite/nitrate can cause methemoglobinemia, a hematologic disorder in which oxidized hemoglobin cannot carry oxygen, which can be fatal if untreated.[7] A prior case series conducted at our institution underscored the variability of methemoglobin levels in fatal versus non-fatal cases and highlighted the importance of interpreting postmortem saturation values in suspected nitrite/nitrate poisonings.[8]

This case series builds on that work by enhancing the forensic science community's competence in identifying sodium nitrite/nitrate-related suicides and recognizing the unique investigative challenges they present. By highlighting demographic patterns, scene findings, and toxicological results, this study aims to improve investigative performance and preparedness for future occurrences. The findings are also intended to deepen understanding of this emerging method of suicide, support early recognition in both forensic and clinical settings, and guide public health interventions for at-risk populations.

Methods: A search of the Harris County Institute of Forensic Sciences (HCIFS) database was conducted to identify all cases in which the terms "nitrite" or "nitrate" were listed in the cause of death statement over a 10-year period, from January 2015 to December 2024. This search yielded 28 cases, which were then cross-referenced with their corresponding autopsy reports. Following review, 6 cases were excluded due to the cause of death being attributed to accidental overdoses of isobutyl nitrite, a psychoactive recreational inhalant. The remaining 22 cases were included for analysis. Case characteristics assessed included age, sex, race, cause of death, location of death, scene findings, manner of death, and autopsy and toxicology results. Routine toxicological analysis was conducted at HCIFS, and postmortem blood samples were submitted to an external laboratory for methemoglobin and/or nitrite/nitrate analysis.

Results: Between 2015 and 2024, 22 deaths were attributed to sodium nitrite/nitrate toxicity, all resulting from intentional ingestion and classified as suicides. Strikingly, all cases occurred within the last six years of the study period, with none identified prior to 2019, underscoring the recent and rapid emergence of this method of suicide. Decedents ranged in age from 17 to 65 years (mean 28.0 years, SD 13.4), with near equal sex distribution. Psychiatric history was present in the majority of cases, most commonly depression, and several individuals had prior suicidal ideation or attempts. Scene investigations revealed ingestion most often occurred in the decedent's residence, where associated items such as chemical containers, measuring tools, or residue were typically discovered. In a minority of cases, the compound was traceable to mail-order sources. Suicide notes or other clear evidence of intent were documented in approximately half of the cases.

Discussion/Conclusion: These findings establish sodium nitrite/nitrate ingestion as a distinct and emerging suicide method characterized by demographic diversity, frequent psychiatric comorbidity, and consistent scene indicators, highlighting the importance of early recognition in both forensic investigation and public health surveillance.

Y27 DNA Extraction From Bone: A Novel Workflow Using Theralin and Magnetic Beads

Marguerite E. Godwin, BS, George Mason University, McLean, VA; Mark R. Wilson, PhD, George Mason University, Fredericksburg, VA; Charla Marshall, PhD, DNAID Services, Lewes, DE; Joseph A. DiZinno, DDS, George Mason University, Alexandria, VA*

Learning Objectives: This presentation will introduce the use of a novel bone demineralization reagent, Theralin, that will be paired with Prepfiler magnetic beads to optimize a powder-free DNA extraction workflow for skeletal samples. Attendees will gain insight into the comparative performance of multiple experimental extraction methods, the outcomes of direct Polymerase Chain Reaction (PCR) testing with BSA to evaluate inhibition, and measurable data on DNA recovery efficiency from Theralin-treated bone.

Impact Statement: This presentation will positively impact the forensic science community by contributing to the development of a skeletal DNA recovery workflow that can be standardized, efficient, and less prone to contamination. By eliminating the need for destructive bone powdering, minimizing PCR inhibition, and streamlining extraction protocols, this presentation aims to improve laboratory performance and strengthen the reliability of skeletal remains in human identification efforts.

Abstract Text: The recovery of DNA from skeletal remains continues to challenge forensic scientists due to the mineralized matrix of bone and frequent co-extraction of inhibitors that interfere with downstream amplification. Traditional methods often require the destructive pulverization of bone followed by EDTA demineralization, a process that increases contamination risks and may contribute to DNA degradation.[1-4] Theralin, a novel precipitating fixative, offers an alternative by demineralizing intact bone into a soft, gum-like state. This allows for digestion and sectioning without the need for powderization.[5,6]

In this study, the efficiency of DNA extraction from Theralin-treated bone is evaluated using two different DNA extraction workflows. Method A utilizes the PrepFiler BTA kit lysis buffers, DTT, proteinase K, and magnetic bead binding.[6-8] Method B combines PrepFiler BTA kit-based lysis with a phenol-chloroform cleanup prior to bead binding.[9,10] Approximately 0.1g samples of human bone are treated with Theralin and replicates are prepared with either a spike-in of known DNA or un-spiked samples to test for endogenous DNA recovery. DNA yield, degradation, and internal positive control (IPC) performance is assessed using data from quantification before continuing on to assess the STR profile quality. In addition, direct PCR experiments are conducted with pre-extraction Theralin™-treated samples, with and without the addition of bovine serum albumin (BSA), to determine whether the fixative introduces inhibitory effects in downstream amplification.[11]

Prior research demonstrates that magnetic bead-based extractions paired with demineralization improve recovery success compared to methods lacking a demineralization step.[12] Studies also show that phenol-chloroform organic extraction improves purity and minimizes inhibitors carryover, even outperforming longer, multi-step protocols.[9,13] Building on these concepts, this study tests the compatibility and optimization of Theralin with PrepFiler magnetic bead extraction alongside a direct PCR workflow to determine if the Theralin treatment itself is inhibitory to DNA extraction. If validated, this study could introduce a workflow that reduces contamination risks, minimizes destructive processing of samples, and provides forensic laboratories with a reliable method for skeletal DNA recovery using Theralin.

Y28 The Application of ATR/FTIR Spectroscopy for the Identification of Cosmetic Foundations Versus Environmental Materials Such as Food or Soil on Cloth

Jaden Force, BS, Towson University, Baltimore, MD; Kelly M. Elkins, PhD, Towson University, Towson, MD*

Learning Objectives: This poster will provide attendees with a better understanding of the capabilities of Attenuated Total Reflectance (ATR) Fourier Transform Infrared (FTIR) spectroscopy when analyzing cosmetic foundations in a forensic context. Specifically, if ATR/FTIR is capable of discriminating between cosmetic foundations on cotton cloth and other potential sources of staining or discoloration such as food, beverages, dirt, and even other types of cosmetic products.

Impact Statement: Previous studies have found ATR/FTIR capable of discriminating different cosmetic foundations to a relatively high degree. However, if a piece of evidence such as article of clothing is recovered and has an area of discoloration on it, investigators likely will not be able to visually distinguish between discoloration due to transfer of a cosmetic foundation and other potential sources of discoloration. This project seeks to better define the capabilities and limitations of ATR/FTIR spectroscopy and statistical methods in differentiating cosmetic foundations as compared to other visually similar substances.

Abstract Text: Various cosmetics may be encountered as trace evidence in criminal investigations due to their ability to be transferred and the frequency with which they are worn. Previous studies on forensic cosmetic evidence have largely focused on cosmetics such as lipsticks and eyeliner, with a comparatively limited number of studies published on cosmetic foundations. Of the studies published on the analysis of cosmetic foundations using FTIR so far, it was found to be fairly successful when discriminating between different foundations. However, discoloration and stains can be caused by a variety of substances such as food, beverages, dirt, and other cosmetic products. This project seeks to evaluate if ATR/FTIR is first capable of discriminating between discoloration caused by a cosmetic foundation and discoloration caused by another visually similar substance. Thirty different foundations three shades within a single product line from ten different brands were evaluated along with a variety of "look-alikes" including other cosmetic products such as concealers, skin tints, and eyeshadows. Samples were applied to one half of a piece of white cotton cloth and the other, clean half was run as the background on the ATR/FTIR spectrometer in the mid-IR range. Collected spectral data were then be subjected to discriminant analysis of the stretches in order to evaluate if the foundation samples can be differentiated from the "look-alikes."

Y29 Optimizing DNA Extraction and Communicating PhenoTrivium Panel Results for Cold Case Skeletal Samples

Madison N. Townsend, BS, Western Carolina University, Cullowhee, NC; Brittania J. Bintz, MS, Western Carolina University, Cullowhee, NC; Maureen P. Hickman, MS, Western Carolina University, Cullowhee, NC; Tiffany B. Fracchia, PhD, Vanderbilt University, Nashville, TN; Alice Gooding, PhD, Kennesaw State University, Kennesaw, GA; Frankie West, PhD, Western Carolina University, Cullowhee, NC*

Learning Objectives: Attendees will learn how different DNA extraction methods impact the quality and yield of DNA from skeletal samples for Massively Parallel Sequencing (MPS), with a focus on forensic applications. They will gain insight into how different extraction techniques impact coverage, sensitivity, and read generation using the Ion AmpliSeq™ PhenoTrivium SNP Panel to generate phenotypic and biogeographic ancestry profiles from degraded skeletal samples.[6]

Impact Statement: This presentation will enhance the forensic science community's understanding of optimized bone extraction by providing evidence-based guidance on selecting DNA extraction methods for degraded skeletal samples that will undergo downstream analyses using MPS. By comparing data generated using the Ion GeneStudio™ S5 platform, we will demonstrate which extraction method is best for generating MPS data, specifically, phenotypic and ancestry profiles which may be used to communicate with law enforcement to translate into actionable investigative leads.

Abstract Text: The identification of skeletal remains from cold cases presents a persistent challenge in forensic science. Recent advancements in forensic genetics, particularly MPS, offer new opportunities for recovery of high-quality DNA data from degraded skeletal samples including detailed phenotypic and biogeographic ancestry profiles.[1,2] This research aims to evaluate the efficiency of four DNA extraction methods including the Promega Bone DNA Extraction Kit, a protocol developed by Rohland and colleagues specifically for ancient samples, the Applied Biosystems PrepFilerÔ BTA Forensic DNA Extraction Kit, and a modification of the PrepFiler® BTA kit to include an extended incubation. Eleven skeletal samples were evaluated via Quantitative PCR (qPCR) using the Quantifiler™ Trio kit, this assessed the DNA yield and quality. From this assessment the six highest-yielding samples from each extraction method were selected for downstream library preparation and MPS.[3]

Libraries were prepared using the Ion AmpliSeq™ PhenoTrivium Panel with the Ion Precision ID kit on the Ion Chef™ System to automate library construction and templating. Sequencing was performed on the Ion GeneStudio™ S5 platform using an Ion 530™ Chip, allowing medium-throughput, high-quality data generation.[4]. Sequencing data was analyzed using HIrisPlex-S and associated bioinformatics pipelines to generate phenotypic and ancestry predictions for each selected sample.[5] This approach enables simultaneous evaluation of externally visible characteristics, biogeographic ancestry, and Y-chromosomal lineage markers in degraded skeletal DNA.

This research provides several key contributions. First, it identifies the extraction method that maximizes DNA yield and sequencing quality for MPS on the Ion-based platform, informing best practices for skeletal DNA analysis in forensic casework. Second, it demonstrates the utility of the Ion AmpliSeq™ PhenoTrivium Panel for generating phenotypic and ancestry profiles even from highly degraded skeletal material. Collectively, these findings advance forensic methodologies for skeletal remains for MPS applications.

Y30 The Development of Recombinase Polymerase Amplification (RPA) to Augment mini STR Amplification of 'Touch' DNA Samples for Human Identification (HID) Workflows

Joseph M. Rahm, MSFS, Florida International University, East Longmeadow, MA; DeEtta Mills, PhD, Florida International University, Miami, FL*

Learning Objectives: This presentation will explainh ow isothermal amplification can be used to augment Polymerase Chain Reaction (PCR).

Impact Statement: This presentation provides a proof of concept for the use of isothermal amplification, RPA ,with forensic DNA samples, RPA-PCR assay

Abstract Text: The commonplace nature of touch DNA at crime scenes has allowed for successful DNA typing to identify crime victims and suspects. However, it has also highlighted limitations with the widely used PCR that is used to generate human identification profiles.[1,2] Stochastic effects associated with touch DNA—allelic drop out/stutter--make DNA profiles less discriminate and therefore less useful.[3] Researchers have shown that use of an isothermal method, Recombinase Polymerase Amplification (RPA), reduced the occurrence of stutter in the detection of cancer microsatellites or short tandem repeats (STR) by 70% in low level DNA samples compared to PCR using fluorescent primers and fragment size detection by capillary electrophoresis.[4] Furthermore, RPA has also been shown to be highly resistant to inhibition caused by samples in complex matrices, like touch DNA samples collected from steel and brick which contain amplification inhibiting ions and debris, respectively.[5]

The use of inhibition-resistant RPA combined with its low limit of detection, or ability to amplify DNA with high fidelity from as little as one cell means it could potentially be used as a vital tool to augment the targets used to create DNA profiles from the most challenging samples.[4,6] Testing the proposed RPA-PCR solution to improve the profile quality of touch DNA samples was initially done with an optimal amount of DNA, 3 ng, for processing with RPA. Primers for specific core STR targets, Amelogenin, D5, D16, and Penta D, were 25-30 base pairs in length to fit the requirements of the recombinase enzyme that forms a complex with each primer to drive the amplification reaction.[7] The occurrence of non-specific amplification plagues isothermal amplification methods was seen in core STR markers larger than 200 base pairs, D5, D16, and Penta D, although Amelogenin was successful.[7,8] Next, the amplification of STR mini loci, D7, D21, TH01, CSF1PO, Amelogenin, and FGA was done using RPA at 32 C using the magnesium concentrations specified in a recent study. Samples were analyzed using capillary electrophoresis, diluted and re-run on the genetic analyzer to check for migration effects. The only RPA products suitable augmentation with PCR were Amelogenin fragments due to the formation of RPA product concatemers for other markers. The core STR Amelogenin product was used as the template for PCR amplification for the STR mini Amelogenin marker. The quality of alleles produced from the RPA-PCR was compared to the same assay with the addition of a direct spike of 1 ng of DNA to provide insight into the viability of RPA mechanisms as a tool to eventually augment touch DNA samples using RPA templates as the input for PCR amplification of mini STRs in forensic DNA workflows for Human Identification. This preliminary study shows that it is possible to utilize RPA products to augment PCR reactions but not yet at the analytical thresholds of most touch DNA samples, further optimization must be done to develop the RPA-PCR assay for other mini STR makers.

Y31 Investigating the Correlation Between Body Mass and Hip Joint Measurements in a Taiwanese Non-Adult Sample

Rachel Riddell, BA, George Mason University, Vienna, VA; An-Di Yim, PhD, George Mason University, Manassas, VA*

Learning Objectives: After attending this presentation, attendees will learn how hip joint morphology can be used to estimate body mass in non-adult skeletal remains, specifically in the Taiwanese population. This presentation will provide an insight into the applicability and limitations of current methods of body mass estimations involving the hip joint, as well as emphasize the need for population- and age-specific standards for these measurements in the field of forensic anthropology. Additionally, this research will highlight the importance of diverse skeletal samples in methodological development to further inform and improve accuracy in forensic identification.

Impact Statement: This research will impact the forensic science community by providing a better understanding of the applicability and limitations of current methods of body mass estimations involving the hip joint and highlighting the importance of diverse skeletal samples in methodological development to further inform accuracy in forensic identification.

Abstract Text: Previous studies have examined the effect of mechanical stimuli on bone morphology with relation to weight-bearing structures of the hip. Notably, a recent study out of Texas State University has examined this relationship in adults, analyzing how variations in body mass index (BMI) correspond to macroscopic differences of the femur, with additional attention to patterns of sexual dimorphism. While these studies have made progress to incorporate measurements of the lower limbs to inform an adult body mass index (BMI) score, the application of this methodology to the non-adult skeleton remains has not been studied. This gap in the current literature is critical, as an accurate estimation of body mass in juvenile remains can be essential for forensic identification, especially in cases involving unidentified or fragmented nonadult remains. This study investigated the correlation between body mass and specific measurements of the hip joint in a Taiwanese non-adult sample, addressing a significant gap in forensic anthropology and forensic science.

This study used 85 computed tomography (CT) scans of individuals assigned males and females at birth between 1 and 15 years old from National Taiwan University Hospital. Three-dimensional (3D) models of proximal femurs were created and aligned using 3D Slicer. The sample was divided into separate weight categories based on the BMI: normal (< 95th percentile) and obese (≥ 95th percentile), and Multivariate Procrustes analysis was used to compare the shape of the proximal femur across body mass and age categories to explore a potential correlation. The findings indicated there is a slight difference between normal weight and obese non-adult individuals, starting around puberty (age 12 for males and age 11 for females) in the Taiwanese sample. These results correspond with previous studies on adult femoral shape change as it relates to obesity, providing valuable insight into the effects of childhood obesity on bone morphology—especially while the bone is still developing—as well as contribute towards a greater accuracy in forensic investigations involving juvenile skeletal remains.

Y32 Basic Tools, New Approaches: Using Mandibular Canine Index and 3D Imaging for Subadult Sex Determination

Jorja Hill, Liverpool John Moores University, Norton Canes, England, United Kingdom; Satu Valoriani, PhD, Liverpool John Moores University, Liverpool, England, United Kingdom*

Learning Objectives: After attending this presentation, attendees will gain an understanding of the current research gaps in the field of forensic human identification for subadults. The importance of testing existing methods aimed at adults, on subadult samples, to determine reliability and validity will be demonstrated. The need for integrating digital and traditional anthropometric methods will also be explored.

Impact Statement: This study evaluates the effectiveness of the Mandibular Canine Index (MCI) for sex estimation in subadults using 3D Computed Tomography (CT) scans. The findings highlight the potential of digital imaging to expand forensic identification methods to younger age groups and underscore the need for standardized approaches in subadult analysis.

Abstract Text: One of the first steps in the identification of commingled remains and/or from mass disasters is to separate the sexes, halving the possible matching identities. Standard sex determination methods, such as analysis of cranial and innominate morphology, cannot be used on subadults, as the sexually dimorphic traits that distinguish the sexes are not yet developed, making the identification of subadults a more difficult task.[1] Human teeth are highly preserved and able to withstand situations like mass disaster, making them useful when identifying fragmented remains. Tooth development is already a well-established age estimation method for subadults, so the question of whether metrics can be taken from these teeth to determine sex is posed.[2] This research aims to assess the accuracy of an existing dental-based sex determination method and to examine whether there are significant size differences between the sexes of subadult individuals.

Current literature identifies the mandibular canine as the most sexually dimorphic tooth in the human dentition.[3] Accordingly, this study measures the mesio-distal widths and inter-canine arch widths of the mandibular canines using the Mandibular Canine Index (MCI) method.[4] The youngest individual that the MCI method appears to have been tested on was 13 years old but was grouped within an adult sample[5]. For this study, a sample of only subadults was analyzed using 100 CT scans from the New Mexico Decedents Image Database (NMDID).[6] This included 50 males and 50 females between 6 and 15 years old. As CT scans were used, those with unerupted permanent canines were considered. Of the 50 males and 50 females, 20 of each had unerupted canines and 30 had erupted canines. Scans were visualized, segmented and measured using 3D Slicer 5.8.1.

Individual MCIs were calculated and then compared to a standard MCI created for the whole sample, resulting in sex classifications. Prediction accuracy was calculated, along with other descriptive statistics. Sexual dimorphism levels of 6.677% were calculated for the mesio-distal widths, and 10.526% for the MCI. However, a negative sexual dimorphism of -1.095% was observed in the inter-canine arch width measurements. Overall sex prediction accuracy was 61%. Females showed a more accurate prediction accuracy of 64% compared to 58% in males. Unerupted canines yielded a more accurate prediction at 65% compared to 58% for erupted canines.

This study underscores the value of integrating 3D imaging with traditional anthropometric methods, demonstrating the potential advantages of digital measurements in subadults, particularly the ability to include younger age groups in analyses. Additionally, the research highlights a gap in the existing literature regarding standardised methods for subadult forensic identification, emphasizing the need for further investigation and the continued development of age-related standards.

Y33 Differentiating Blunt Force Trauma Fractures From Thermal Fractures in Fleshed and Skeletal Deer Heads

Alyssa A. Ranney, MS, Minnesota State Mankato, New Auburn, WI*

Learning Objectives: After attending this presentation, attendees will better understand how thermal alteration affects blunt force trauma analysis and how it differs between fleshed and skeletal remains.

Impact Statement: This presentation will impact the forensic science community by supplementing current literature on identifying blunt force trauma fractures after thermal alteration on both fleshed and skeletal deer crania.

Abstract Text: Blunt-force trauma deaths are one of the most common cases encountered by forensic anthropologists because they involve accidental, suicidal, and homicidal deaths. In some forensic cases, blunt force trauma is sometimes concealed by thermal alteration to cover evidence.[1] Thermal alteration often makes identifying pre-existing blunt force trauma fractures in forensic cases more difficult. Anthropologists face numerous challenges trying to understand both the effects of the fire and the blunt force impact. Distinguishing thermal trauma from pre-burning trauma becomes difficult due to the complexity of the mechanical and chemical properties that affect blunt force and thermal trauma.[2]

There have been numerous studies testing the degree to which thermal alteration conceals blunt force trauma, but they have typically focused on either using fleshed or skeletal remains, not both. Additionally, these studies have had varying results depending on whether mechanical or manual trauma had been applied, and whether the missing soft tissue structures were accounted for during the trauma replication and burning process in the skeletal studies. The goal of this study was to determine how thermal trauma conceals or alters blunt force trauma fractures and how thermal concealment differs between skeletal and fleshed remains. This study aims to contribute and help clarify the contradictory results in previous literature by using specific characteristics that previous studies have attributed to either blunt force trauma or thermal trauma and comparing them in fleshed and skeletal remains under the same conditions.

For this study, a sample of fourteen deer heads was used. Two of the deer heads were used on the day to test the blunt force trauma machine, while the other twelve were divided into controls (6) and simulated trauma (6). Both categories contained three fleshed remains and three skeletal remains. Blunt force trauma was experimentally replicated using a homemade trauma machine that represents a hammer-swinging. The blunt force trauma machine ensured that all deer crania were hit in the frontal region with the same amount of applied force. All samples were then subjected to an open-air outdoor wood fire to replicate forensic cases. Samples were placed in the horizontal plane and burned for a total of 45 minutes before being allowed to cool down overnight.[3]

The crania were then analyzed, and fracture type, fracture margins, color changes, and soft tissue survival were recorded4. The results showed that blunt force trauma fractures were distinguishable from thermal trauma fractures in both the skeletal and fleshed remains. Additionally, fracture type, color changes, and soft tissue survival differed between the fleshed and skeletal remains, concluding that thermal concealment can be distinguished in different phases of decomposition.

Y34 Evaluating IR Spectra Variation of Pepper-Based Defense Products

Jocelyn P. Polanco, BS, Towson University, Spencerville, MD*

Learning Objectives: Attendees will learn: (1) the sample preparation used in the experiment; (2) what Fourier Transform Infrared (FTIR) experimental parameters were used to obtain the spectra; (3) how the spectra of pepper sprays and pepper gels differ from one another; and (4) the wavenumbers that are used for comparison of spectra.

Impact Statement: Currently, there is a shortage in the literature for studies that compare pepper sprays and pepper gels. The extraction of the pepper defense products remain unclear in the literature. The extraction method(s) utilized is solvent free, saving on time and money. FTIR analysis has a shorter analysis time compared to Gas Chromatograph/Mass Spectrometry (GC/MS). FTIR is also cheaper and the cost and time of training is not as much as GC/MS.

Abstract Text: After attending this presentation, attendees will become familiar with the sampling of nonlethal defense products, the FTIR experimental methods, the wavenumbers used to compare spectra, the spectrum of capsaicin, and the differences between the FTIR spectra of pepper gels and sprays.

Pepper based defense products are widely available in the United States of America.[1,2] They are commonly used by law enforcement agencies for being nonlethal and temporary.[2] Due to its availability, they can be used in a criminal context by a victim, perpetrator, or law enforcement.

Capsaicinoids in oleoresin capsicum are the active ingredients that gives pepper-based defense products their incapacitating effect.[1,2] Currently, forensic laboratories test for capsaicin, a capsaicinoid, but do not differentiate between pepper gels and pepper sprays. Since, both are pepper-based defense products they utilize similar ingredients, however pepper gels include a thickening agent.[3] Pepper spray and pepper gel from the brand Mace were dispensed onto a white cotton matrix that was placed into a centrifuge tube and capped. The sample was placed on the stage and FTIR spectra were then taken and compared. An FTIR spectrum of capsaicin was also taken for comparison. Specific capsaicin peaks were identified then found on the spectra of the pepper-based products for evaluation. The differences noted will be presented.

Y35 Enhancing Forensic Toxicology Through Postmortem Applications: Evaluating the Viability of Skin Swabbing as a Drug Testing Matrix

Hannah D. Schaeffer, BS, Duquesne University, Scottdale, PA; Abigail V. Burke, MS, Virginia Department of Forensic Science, Manassas, VA; Rebecca Wagner, PhD, Virginia Department of Forensic Science, Richmond, VA; Jennifer L. Hammers, DO, Jennifer Hammers Pathology LLC, Duquesne University, Pittsburgh, PA; Stephanie J. Wetzel, PhD, Duquesne University, Pittsburgh, PA*

Learning Objectives: This research aims to examine the viability of utilizing skin swabbing as a potential method for extracting, detecting, and quantifying illicit substances present within collected samples. Additionally, it tests the null hypothesis, skin swabbing is not a viable method for drug testing, by way of a p-value test and performs a six-way Analysis of Variance (ANOVA) test to compare each matrix, focusing on the factors of effectiveness, testing duration, and cost efficiency.

Impact Statement: Traditional drug testing matrices, such as blood and urine, present limitations in invasiveness, cost, and logistical requirements. These limitations prompt reconsideration of an optimal matrix and exploration of novel alternatives. This research permits the designation of the most adequate matrix while introducing the potential of skin swabbing as a noninvasive, cost-effective additive matrix that would augment existing drug testing options.

Abstract Text: The CDC reported 70.3 million individuals abused drugs, resulting in 89,740 overdose-related deaths in 2024.[1,2] Drug abuse has influenced drug testing practices, particularly in criminal investigations, as law enforcement uncovers patterns through trafficking routes, polydrug networks, adulterated substances, user demographics, cross-addiction, and distribution platforms.[3,4] Frequently abused drugs within this application include amphetamine, cocaine, cannabinoids, phencyclidine, morphine, buprenorphine, oxycodone, fentanyl, and methadone.[5]

This study examined the viability of utilizing skin swabbing as a potential method for the extraction, detection, and quantification of drugs present within collected samples. Furthermore, forward advancements in this novel technique were formulated through comprehensive statistical analysis and compared to established toxicological matrices by effectiveness, testing duration, and cost efficiency.

Ten samples were collected from each of the five overdose decedents (n=50) used for this study at the Westmoreland County Coroner's Office: four skin swabs, two oral fluid samples, one vitreous humor sample, one blood sample, one hair sample, and one urine sample. Before collection, target skin areas were cleaned with water. Skin samples were collected via abrasive swabs from the calves, neck, armpits, and behind the knees. Apart from the skin swabs, each matrix underwent different previously established solid-phase extraction methods. The skin swab extraction method combined DNA extraction methods for buccal samples from cotton swabs and toxicology methods for solid phase extraction from tissue samples. The skin samples were then compared against established toxicology matrices, which acted as controls for this study.

The Agilent 1200 Series LC Stack and 6460 Triple Quad Mass Spectrometer were used in conjunction with Dynamic Multiple Reaction Monitoring (MRMs) to identify the presence of seven target drugs: methamphetamine, benzoylecgonine, alprazolam, morphine, 6-MAM, oxycodone, and fentanyl. Quantification was completed using a calibration curve derived from peak height ratios of the nondeuterated and deuterated target drugs in nine standards, with concentrations ranging from 1500 ng/mL to 5.86 ng/mL. All chromatograms were analyzed using MassHunter Workstation Qualitative Analysis software.

Results were cross-referenced against autopsy toxicology reports. A six-way ANOVA assessed each matrix in comparison to one another, using a 95% confidence interval and p-value analysis to determine statistical significance and test the null hypothesis: skin swabbing is not a viable method for drug testing. Currently, preliminary testing revealed skin swabbing as a viable method for collection, as chromatograms yielded prominent peaks viable for identification and quantification of methamphetamine, benzoylecgonine, morphine, oxycodone, and alprazolam. The skin swabbing extraction method utilizes procedures congruent with DNA extraction by employing a homogenous mixture, proteinase K, a heating period, and lysis buffer to produce accurate concentrations and viable chromatograms for the target drugs.[6] Chromatograms produced from the established matrices prove their methods yield adequate results.

Preliminary results suggest skin swabbing is a viable matrix for a noninvasive and cost-effective method of drug testing. While this research only utilizes postmortem individuals as its subjects, introducing a potential gap in the field, it is hypothesized that findings will be reciprocal to living subjects. However, further research on living donors is required to verify this hypothesis due to variability in skin behavior.

Y36 Color Spectrophotometer as a Powerful Tool to Evaluate Human Fluid Stains on Denim Fabrics

Shelby Barrager, Pittsburg State Chemistry Department, Pittsburg, KS; Mazeyar Parvinzadeh Gashti, PhD, Pittsburg State University, Pittsburg, KS*

Learning Objectives: The main learning objectives of this research is as follows: (1) to understand the potential of color spectrophotometry as a non-destructive analytical tool for forensic evaluation of human body fluid stains on denim; (2) to examine how color coordinate properties (L*, a*, b*) of different fluids change over time and under varying environmental conditions (room temperature, dark storage, daylight exposure); and (3) to explore the forensic implications of stain aging patterns and their role in improving accuracy and reliability in body fluid identification.

Impact Statement: This research highlights the potential of color spectrophotometry as a rapid, objective, and non-destructive method for the forensic evaluation of body fluid stains on denim. By quantitatively analyzing colorimetric changes in different fluids under varying aging and environmental conditions, the study provides valuable insights into the temporal stability and distinguishing features of common forensic stains. The findings can support forensic practitioners in developing standardized protocols for preliminary stain identification, reducing reliance on destructive chemical tests, and preserving evidence for downstream molecular analyses. Ultimately, this work advances the use of optical technologies in forensic science and strengthens the reliability of evidence interpretation in criminal investigations.

Abstract Text: The forensic identification of body fluid stains plays a critical role in crime scene investigation, where accurate and non-destructive analytical tools are highly valuable. Traditional approaches often rely on chemical presumptive tests or molecular analyses, which may be destructive, time-consuming, or subject to false positives. Color spectrophotometry offers an alternative technique by enabling objective, quantitative evaluation of stains based on their optical and colorimetric properties.

The aim of this study is to investigate the application of color spectrophotometry as a non-destructive analytical method to characterize and differentiate various human body fluid stains on denim fabric. Standard denim samples were stained with seven different fluids—blood, semen, saliva, vaginal fluid, menstrual blood, urine, and sweat. Each stain was subjected to spectrophotometric analysis to record color coordinates (L*, a*, b* values), providing a precise numerical description of color variation. To assess the influence of environmental factors, the stains were aged under three storage conditions: room temperature, dark room, and exposure to daylight lamp, for durations of 7 days, 14 days, 1 month, and 2 months.

This study seeks to evaluate how the optical signatures of stains change over time and under different conditions, with the goal of identifying characteristic patterns that may aid in stain recognition and differentiation. The findings are expected to contribute to the development of a rapid, reproducible, and non-invasive tool for forensic analysis of body fluid evidence, particularly when applied to commonly encountered substrates such as denim.[1-6]

Y38 Toward Mass Spectrometry Imaging of Latent Prints Using Visible Matrix-Assisted Laser Desorption Electrospray Ionization

Julia X. Morelli, The University of Tampa, Tampa, FL; Kenyon Evans-Nguyen, PhD, The University of Tampa, Tampa, FL*

Learning Objectives: Attendees will gain a general understanding of how Matrix-Assisted Laser Desorption Electrospray Ionization (MALDESI) can be implemented in forensic latent print analysis. Additionally, attendees will learn how this technique can provide spatially-resolved chemical information for potential contaminants found on a fingerprint.

Impact Statement: Work in development of a prototype visible MALDESI instrument specifically designed for improved Mass Spectrometry Imaging (MSI) of latent prints will be presented. After implementation, this instrument could be smoothly incorporated into current workflows for latent print development that rely on rhodamine-based dyes such as RAM. Examiners would then obtain not only fingerprint images, but also chemical information detailing the spatial distribution of relevant exogenous compounds, such as drugs and explosives.

Abstract Text: Mass spectrometry imaging (MSI) produces chemical images of fingerprints, allowing for the determination of amino acids as well as potential contaminants (i.e., drugs and explosives). This technique can aid in identifying an individual as well as their activities. Previous MSI work in fingerprints relies on vacuum Matrix Assisted Laser Desorption Ionization (MALDI). However, the sample preparation process for MALDI does not integrate well within the traditional workflow of latent print examiners. Implementing a rhodamine-based dye, which examiners already use to develop latent prints on non-porous surfaces, as a matrix for visible Matrix-Assisted Laser Desorption Electrospray Ionization (MALDESI) would help address this gap in research.[1,2] Thus, this work aims to investigate pigments common to latent print dye stains as potential matrices for MALDESI-MSI to better integrate chemical imaging into the traditional workflow of a latent print examiner.

The MALDESI source, based on the design of Muddiman and co-workers, was constructed in-house and coupled with a Thermo LTQ XL Linear Ion Trap.[3] Samples were ablated on a glass slide using a focused beam from an Nd:YAG laser (Continuum Minilite) with an output of 532 nm through a 5x magnifying objective. Aerosols of the ablated sample were subsequently ionized by a nano-spray emitter with a flow of 1:1 acetonitrile: water + 0.1% formic acid and captured using an extended ion transfer inlet. An X-Y-Z motion stage controlled by an Arduino board enabled mass spectrometry imaging, with each scan at a given position being counted as a pixel within a chemical image.

Initial experiments involved investigating explosive standards, including potassium perchlorate (100 µg/mL), in a saturated Rhodamine-6G solution and deposited onto glass slides. Preliminary data with this model system indicate that visible MALDESI with a rhodamine matrix is feasible. Current work is focused on the full implementation of the constructed visible MALDESI source for MSI of latent prints developed with rhodamine/RAM dye, including the incorporation of recent software programming that coordinates the motion stage movement, laser firing, and data collection.

Y39 Assessing the Prevalence of p-Phenylenediamine in Henna Tattoo Inks Purchased in Northern Delaware

Laell Sands, Lincoln University of Pennsylvania, Lincoln University, PA; Muhammed T. Taimoor Chaundry, MPhil, Medical City for Military and Security Services, Ministry of Defence, Mucant, Sultanate of Oman, Muscat, Masqat, Oman; Tom Gluodenis, PhD, Lincoln University, HBCU Undergraduate Center for Forensic Science, Lincoln University, PA; John Stallworth, BS, Lincoln University, HBCU Undergraduate Center for Forensic Science, Lincoln University, PA*

Learning Objectives: The audience will gain knowledge of the potential dangers of henna tattoos and the toxicity of Para-Phenylenediamine (PPD). They will also become aware of the regulatory environment regarding PPD in consumer samples.

Impact Statement: This study will raise awareness to the toxic nature of PPD and its potential impact on public health and safety.

Abstract Text: Henna holds cultural significance as a temporary dye applied to the skin for celebrations, blessings, and beautification in South Asia. Henna tattoos have become increasingly popular in the United States as henna artists offer services to both children and adults. Para-phenylenediamine or PPD is a chemical additive incorporated into henna tattoo ink and hair dyes to enhance the black color and offer long-lasting appearance. PPD is a potent allergen and potential carcinogen which when in direct contact with skin can lead to scarring, severe swelling and blistering. Ingestion of PPD can cause swelling in the upper respiratory tract and in the larynx ultimately leading to organ failure. As the popularity of henna tattoos continues to increase, so does the rise of concern for the presence of PPD in these beauty products.[1] In 2001, the U.S Food and Drug Administration (FDA) banned PPD from being used in products that require direct application to the skin.[2] In the interest of public safety, the FDA requires ingredient declaration for cosmetic products under the Fair Packaging and Labeling Act (FPLA). Many imported products, however, do not have the ingredients printed in English nor does the FPLA apply to cosmetic samples and products used by professionals (i.e., application at a salon, booth at a fair, or boardwalk).

The objective of this study is to determine the prevalence of PPD in henna ink purchased from Asian grocery stores in Northern Delaware. A secondary objective is to assess any differences in PPD prevalence across the various types of henna ink: pink, green, black, blue, red, and natural brown.

The GC/MS methodology for this study was that published by Wang and Krynitsky but modified for a DB5-MS column and optimized to reduce the retention time to less than 4 minutes.[3] In total 14 samples were collected for this study from Asian grocery stores in Northern Delaware. Multiple varieties of henna ink were purchased across various manufacturers to assess potential variability. Two henna hair dyes were also purchased as positive controls as they were likely to contain PPD. Samples were stored in the dark and refrigerated in their original packaging until processed for analysis.

The results from the samples revealed the presence of PPD in the two hair dyes as expected and in one of the black henna tattoo inks at a concentration of 1ppm. The method detection limit was determined to be 8ppb and the limit of quantitation was determined to be 40 ppb. The spike recovery was 9.9 +/- 0.3 ppm (n=4) which equates to a 99% recovery.

In conclusion, the potential for PPD adulteration of henna tattoo inks does exist despite current legislation. The limited number of samples made it difficult to draw any conclusions regarding a correlation between PPD concentration and type of henna ink. Next steps are to expand the study to a larger number of samples and to develop a DART-MS method for the analysis with the goal of eliminating the need for lengthy sample preparation.

Y40 Petroleum-Utilizing and Hemolytic Soil Microbes: Environmental Impacts on Decomposition in Forensic Contexts

Tristen M. Howell, Southern University at New Orleans, New Orleans, LA; Lewis Burnett, Southern University at New Orleans, New Orleans, LA; Brittney Sylvester, Southern University at New Orleans, New Orleans, LA; Latavia Williams, Southern University at New Orleans, New Orleans, LA; Georgia A. Williams, MS, George Mason University, Manassas, VA; Meiko Thompson, PhD, Southern University at New Orleans, New Orleans, LA*

Learning Objectives: This presentation will enable attendees to identify key mechanisms, such as the presence of petroleum-degrading and hemolytic bacteria, through which contaminated environments modify decomposition ecology. They will learn to outline the selective culturing approach for isolating microorganisms with these specific metabolic functions and predict how their activity alters decomposition trajectories compared to pristine environments. Ultimately, attendees will be able to assess the critical importance of accounting for site-specific contamination when interpreting microbial and taphonomic evidence for estimating the Postmortem Interval (PMI).

Impact Statement: By integrating environmental microbiology with forensic decomposition research, this study highlights the need to consider soil contamination as a variable in forensic casework. Petroleum-utilizing and hemolytic microbes may represent novel indicators of decomposition in impacted environments, expanding the forensic toolkit for PMI estimation and environmental forensics.

Abstract Text: Environmental contamination, particularly from petroleum products, presents a unique variable that can alter local microbial ecology and potentially confound the decomposition processes used in forensic science.[1] The presence of petroleum-degrading and hemolytic microorganisms may accelerate or modify soft tissue breakdown in ways that complicate postmortem interval (PMI) estimation, yet these interactions remain poorly characterized in forensic contexts.[2] The objective of this study was to isolate and characterize soil microorganisms from a contaminated site that are capable of petroleum metabolism and hemolysis, thereby providing crucial insight into how polluted environments affect the microbial communities central to decomposition.

Soil samples were collected from petroleum-impacted areas in southern Louisiana. Microorganisms were extracted using a sterile water suspension and cultured on three distinct media types to select for specific metabolic functions: nutrient agar for general heterotrophic growth, Bushnell-Haas agar supplemented with diesel as the sole carbon source to select for petroleum-degrading organisms, and blood agar to identify microorganisms with hemolytic activity capable of breaking down blood cells. All plates were incubated aerobically and monitored for colony growth and hemolytic zones at 11 and 22 days. Colony morphology and activity were documented, and representative isolates from each functional group were preserved for future DNA extraction and molecular identification via 16S rRNA gene sequencing.

Data analysis is ongoing; however, preliminary findings based on colony morphology suggest successful isolation of distinct microbial communities on each selective medium. We anticipate the presence of known petroleum-degrading taxa and predict that a subset of isolates will demonstrate hemolytic capability. These differences in growth across the media types are expected to highlight specific functional groups whose combined metabolic activities could significantly accelerate decomposition dynamics in contaminated soils.

This study is expected to directly identify soil microbial taxa capable of both hemolysis and petroleum metabolism, supporting the hypothesis that contaminated environments host a unique microbiome that can alter standard decomposition processes. The findings will provide a critical foundation for future research into decomposition ecology in polluted settings and may ultimately help forensic scientists account for significant environmental variation when estimating PMI in industrial or accidentally contaminated areas.

Y41 The Evaluation and Comparison of Portable FTIR/Raman Instruments for Field Testing of Illicit Drugs

Sydney R. Ma, BS, The George Washington University, Falls Church, VA; Alexandra K. Evans, MFS, U.S. Postal Inspection Service, Dulles, VA; Ya-Chih (Jessica) Cheng, PhD, The George Washington University, Washington, DC; Ira S. Lurie, PhD, The George Washington University, Washington, DC*

Learning Objectives: This poster will cover a comprehensive evaluation and comparison of two portable spectroscopy instruments for in-field drug testing. The instruments (Raman 785nm and combination Fourier Transform Infrared (FTIR) /Raman 785nm) have been evaluated using reference standards and a wide variety of seized illicit drug samples obtained from casework.

Impact Statement: Chemical field-testing instruments are utilized by law enforcement officers, first responders, and forensic scientists to give a preliminary screening of what substance might be present in an unidentified sample. It is critical that we understand both the strengths and limitations of portable FTIR and Raman instruments for reliable assessments to be made. This review highlights the strengths and weaknesses of these instruments testing common illicit narcotics and their mixtures, such that operators can have a better understanding of whether these instruments can provide a reliable presumptive identification. Also, notes on each instrument's practicality and ease-of-use have been included for those considering these field-testing options.

Abstract Text: Field testing of suspected narcotics and other unknown materials plays a vital role in supporting law enforcement criminal investigations, first responder personnel, and harm reduction drug checking services. On-site evaluation provides a rapid assessment of unknowns, a critical advantage when handling potentially hazardous materials such as fentanyl. For criminal investigations, on-site testing capabilities can help triage evidence submissions to forensic laboratories, potentially alleviating casework backlogs. Portable instruments can range in size, cost, and selectivity of analysis/discriminating capabilities, but the main goal is the same: rapid, accurate identification.[1,2]

Common field-testing techniques include color tests and immunoassays, each with their own set of limitations. Both techniques require operator interaction with potentially hazardous samples, reagents, and subjectivity with interpreting results. In addition, both are only able to analyze at low molecular selectivity and lack capabilities to identify multiple substances during a single test.[3,4] With the illicit drug market growing each year, it has become more common to see mixtures and new compounds, both of which can be challenging with these current techniques.[5] Thus, there has been a recent push for more selective, portable analysis mirroring that of which is conducted in the forensic laboratories. Portable gas chromatography and liquid chromatography instruments have been possible solutions, but both require mobile phase supply and have longer analysis times and larger footprints. Fast forward to the mid-2010's, portable FTIR and Raman instruments were marketed as solutions to fill these gaps.

Raman spectroscopy offers the advantage of requiring no sample preparation, allowing unknown substances to be analyzed through transparent packaging-eliminating exposure risk for field personnel.[2] In contrast, Fourier Transform Infrared (FTIR) spectroscopy is also a valuable analytical tool, though it generally requires some sample handling/preparation. Both are highly selective techniques, offering broad identification of substances when equipped with comprehensive on-board libraries.[6] To the researcher's knowledge, there has been limited studies on the effectiveness of both portable analytical techniques using real seized drugs, alone and in mixtures. Based on the limited, prior research of similar portable instruments, it is anticipated that mixtures and low concentrations of the target analyte can be potential limitations, whereas casework samples should be easily identifiable.[7]

This report aims to summarize and compare the effectiveness of the two instruments- one utilizes Raman (785nm) and the other using a combination of both FTIR and Raman (785nm). Both instruments were first evaluated testing one-component mixtures using common adulterants spanning each of the following groups: cocaine, ketamine, phenethylamines, benzodiazepines, and opioids. Following the mixture studies, real casework samples were analyzed to compare identification capabilities. All testing was conducted in triplicate. Practical notes such as ease-of-use, perceived longevity, analysis time, and depth of on-board libraries were also recorded in this evaluation. Full statistical analysis will be provided once the project is finalized.

Y42 Microbial Succession in Uncovered Remains: Establishing a Baseline for Postmortem Interval Estimation

Diamon Raymond, Southern University at New Orleans, New Orleans, LA; Brittney Sylvester, Southern University at New Orleans, New Orleans, LA; Latavia Williams, Southern University at New Orleans, New Orleans, LA; Alyssa Lavasseur, Southern University at New Orleans, New Orleans, Louisiana; Georgia A. Williams, MS, George Mason University, Manassas, VA; Meiko Thompson, PhD, Southern University at New Orleans, New Orleans, LA*

Learning Objectives: This presentation will enable attendees to identify key microbial succession trends in surface-exposed, uncovered remains and differentiate the colonization patterns of key anatomical sites for Postmortem Interval (PMI) estimation. They will learn to articulate why this baseline model is fundamental to forensic taphonomy and apply this foundational knowledge to critically evaluate how variables, such as clothing or burial, alter standard decomposition processes.

Impact Statement: By documenting microbial succession in uncovered remains, this research strengthens the reliability of microbiome-based PMI models. The results will provide the forensic community with comparative data necessary to distinguish between natural decomposition patterns and those altered by environmental or human factors.

Abstract Text: Establishing a microbial baseline from uncovered remains is a critical first step in forensic taphonomy, providing a reference model against which the effects of other variables can be measured.[1] While microbial succession shows great promise for postmortem interval (PMI) estimation, standardized data from controlled, surface-exposed scenarios is essential for building reliable comparative frameworks. This study aimed to characterize the baseline microbial community dynamics across key anatomical sites of a naked porcine model to generate foundational data for future forensic PMI estimation models.

The research was conducted at the George Mason University Body Farm during the summer of 2024. A domestic pig (*Sus scrofa domestica*) carcass was placed on the soil surface, fully exposed to natural environmental conditions. To establish a high-resolution timeline of microbial succession, swab samples were collected daily from the oral cavity, abdominal cavity, and rectal cavity for the first 21 days of decomposition, followed by weekly sampling until July 24, 2024. All samples were preserved at -80°C for DNA extraction and subsequent 16S rRNA gene sequencing. Planned bioinformatic analyses include profiling microbial community composition, calculating alpha and beta diversity indices, and conducting a comparative assessment of succession patterns between anatomical sites.

While data analysis is ongoing, prior research suggests that uncovered remains will exhibit rapid and predictable microbial succession.[2] We hypothesize that aerobic bacterial taxa will dominate the early stages of decomposition, with a subsequent shift toward anaerobic taxa as oxygen becomes limited during advanced decay. Furthermore, we anticipate significant differences in microbial colonization patterns among anatomical sites, with the nutrient-rich and protected rectal cavity expected to provide the most stable and consistent succession pattern for PMI estimation.

This study will yield a critical dataset on baseline microbial succession in surface-exposed remains. The findings are expected to confirm distinct, site-specific successional trends and establish the rectal cavity as a highly useful site for PMI modeling. Ultimately, this work provides an essential reference point for future forensic research, enabling more accurate interpretation of decomposition in complex but common scenarios involving clothing, concealment, or burial.

Y43 The Determination of Neurotransmitter Levels in Rat Brain Following Opioid-Sedative Exposure Using Liquid-Chromatography Quadrupole-Time-of-Flight Mass Spectrometry

Laerissa Reveil, MS, Virginia Commonwealth University, Richmond, VA; Maria Lasaosa, PhD, Virginia Commonwealth University, Richmond, VA; Amanda Furman, MS, Virginia Commonwealth University, Richmond, VA; Alia Marie Iqbal O'Meara, MD, Virginia Commonwealth University, Richmond, VA; Matthew Halquist, PhD, Virginia Commonwealth University, Richmond, VA*

Learning Objectives: Attendees will be able to explain how sedation can impact neurotransmitter brain levels in a delirium model of study and differentiate the effects of neuroinflammation vs. drug exposure on neurotransmitters. Attendees will also be able to summarize criteria required for full method validation under Food and Drug Administration guidelines.

Impact Statement: With a high incidence of delirium from illicit and clinical use of drugs, understanding its pathogenesis is imperative. Quantitative analysis of neurotransmitter levels is necessary to measurably identify biomarkers of delirium as it could inform on effective treatment strategies.

Abstract Text: Clinical or illicit use of opioids and benzodiazepines can cause delirium, a condition from which cognitive dysfunction occurs.[1] This dysfunction is thought to result from the imbalance of neurotransmitters (NTs), essential players in memory, learning, and cognition.[2,3] Behaviorally, delirium is exhibited by observable changes in attention, thinking, memory, and psychomotor function.[1] Untreated delirium contributes to increased morbidity and mortality rates and can lead to reduced quality of life and long-term cognitive impairment.[2] Clinical diagnosis of delirium relies on behavioral assessments, which are subjective and have low success rates in detection.[4] Quantification of changes in NT levels would provide demonstrative evidence for the effect of sedation in the development of delirium.[2] This study aims to validate a bioanalytical method to measure dopamine (DOP), serotonin (SERT), glutamic acid (GLU), gamma-aminobutyric acid (GABA), gamma-hydroxybutyric acid (GHB), and acetylcholine (ACT) levels in rat plasma and brain.

Five NTs, in positive mode, and GHB, in negative mode, were chromatographically separated using liquid chromatography quadrupole-time-of-flight mass spectrometry. The standard curve of 10-5000 ng/mL in 90:10 ACN:H_2O and quality controls (QCs), in diluted, pooled rat plasma or brain, were extracted using a protein precipitation method with ice-cold 1:1 H_2O:MeOH + 0.5% formic acid. Following the Food and Drug Administration M10 Bioanalytical Method Validation and Study Sample Analysis Guidance for Industry, QCs in plasma were evaluated for accuracy, precision, carryover, and stability over four days, and QCs in brain were partially validated for accuracy and precision over three days.

The method was applied to measure NTs from rats in a delirium model. Male and female Sprague-Dawley rats were repeatedly treated over five days with saline (n=24), lipopolysaccharide-induced inflammation (LPS; n=20), morphine- (MOR; 2-4 mg/kg/dose) and midazolam- (MDZ; 5-9 mg/kg/dose) induced sedation (n=17), or LPS+MOR/MDZ (n=15). Rat brains were halved, homogenized in HALT protease inhibitor cocktail, and extracted for NTs.

Across all six analytes, the limit of detection ranged from 5-100 ng/mL and the lower limit of quantitation ranged from 10-250 ng/mL. The accuracy and precision of QCs in rat plasma and brain were acceptable under validation guidelines. Within-run accuracy and precision of QCs in plasma (n=6 per level) across all analytes were within ±14% and 13%, respectively. Between-run accuracy and precision were within ±6% and 9%, respectively. QCs in plasma were stable under short-term and freeze-thaw conditions. Carryover was not observed. No significant differences in ACT, SERT, DOP, and GABA brain levels were determined across the treatment groups compared to saline. Significant changes in GHB (p=0.0314) and GLU (p=0.0004) levels from MOR/MDZ and GLU (p=0.0349) from LPS+MOR/MDZ were observed.

We successfully validated two methods for the analysis of NTs in rat plasma and brain. These data suggest that neither inflammation nor sedation significantly affect ACT, SERT, DOP, and GABA brain levels. Sedation alone significantly increased GHB and GLU levels, and an additive effect of inflammation and sedation also increased GLU levels. However, inflammation alone did not impact GHB or GLU levels. NTs may be a promising biomarker for delirium caused by sedation.

Y44 Using Positive and Negative Image Overlap for Image Forensics: Examples From Taiwan

Teng-Kai Shih, BASc, Criminal Investigation Bureau, Taipei, Taipei, Taiwan; Min-Neng Hsu, PhD, Criminal Investigation Bureau, Taipei City, Taipei, Taiwan;Wen-Chao Yang, DSc, Central Police University, Taipei, Taipei, Taiwan; Wen Chung Chen, LLM, Criminal Investigation Bureau, Taipei City, Taipei, Taiwan; Jen-YI Fang, MSc, Criminal Investigation Bureau, Taipei, Taipei, Taiwan*

Learning Objectives: This presentation will apply the technique of overlaying positive and negative images with adjusted transparency to detect subtle alterations in images, thereby enhancing the efficiency of image forensic analysis.

Impact Statement: We show that the technique of overlaying positive and negative images offers a reliable and practical approach for verifying the authenticity of digital photos or videos, especially in forensic or legal investigations.

Abstract Text: In the digital age, surveillance footage and photographs are frequently subject to tampering. These modifications are often made by partially editing the original material, making the changes so subtle that they are difficult to detect with the naked eye.

To reveal these slight edits, forensic experts overlay the original image (positive) with the altered image (negative), setting the transparency of the negative image to 50%. If the two images are identical, the result appears as a uniform gray. Any differences, however, become clearly visible. This simple yet effective technique has been applied in real cases in Taiwan. Here are three examples:

Case 1: Stolen Photography with Partial Edits

A photographer's work was often stolen and slightly altered by others. Traditionally, forensic experts used feature-matching methods to compare images, but when the content was very similar, these methods were not effective. By overlaying the positive and negative versions of the image, even subtle changes could be detected quickly, significantly improving the efficiency of the verification process.

Case 2: Video Timestamp Tampering

A victim was repeatedly accused based on videos that had tampered timestamps. The victim was unable to prove that the content of the videos was the same. Forensic experts extracted specific frames from the videos and used the overlay technique to successfully demonstrate that the content was indeed identical. This case shows that the technique is useful not only for photo analysis but also for video verification.

Case 3: Identifying the Same Thief in Surveillance Footage

In a theft case, a shop owner wanted to prove that two incidents were committed by the same person. However, due to the wide-angle lens of the surveillance camera, clear personal features were not captured. Forensic experts used the positive-negative overlay technique to compare the suspect's height and match blurry patterns on their clothing, ultimately

Y45 Vitreous Fluid as a Stable Matrix for Postmortem Toxicology

Miriam Fisher, MD, University of Utah, Salt Lake City, UT; Ben Murie, MD, State of Utah, Salt Lake City, UT*

Learning Objectives: This presentation will: (1) describe the diagnostic limitations of blood samples in postmortem toxicology, particularly for volatile substances such as isopropanol and acetone; (2) explain the advantages of vitreous fluid analysis in forensic toxicology, including its resistance to contamination, postmortem redistribution, and microbial degradation; (3) evaluate the role of vitreous fluid as a complementary or primary matrix where blood samples may be compromised due to decomposition, contamination, or collection artifacts; and (4) apply knowledge from case studies to real-world investigations, increasing the accuracy of cause and manner of death determinations.

Impact Statement: This presentation will impact the forensic science community by emphasizing the diagnostic value of vitreous fluid in postmortem toxicology, specifically in cases of volatile substances such as isopropanol and acetone. Isopropanol intoxication presents unique challenges due to its rapid metabolism to acetone, potential for contamination from disinfectants, and overlapping presentations with other types of ketoacidosis.[1,2] Through case analysis and literature review, this study demonstrates that vitreous fluid, due to its chemical stability and reduced susceptibility to contamination and postmortem redistribution, is a critical and reliable matrix for accurate diagnosis in poisoning cases.[3,6] Routine use of vitreous fluid can significantly enhance diagnostic accuracy and support clearer determinations of cause and manner of death.

Abstract Text: Isopropanol intoxication presents a significant diagnostic challenge in forensic toxicology due to its rapid metabolism to acetone, potential for contamination during specimen collection, and its overlap with other forms of ketoacidosis.[1,4] This study explores the utility of vitreous fluid as a diagnostic medium in postmortem toxicology in cases of isopropanol poisoning. A case report is presented involving a 69-year-old woman found deceased in a bathtub with a history of manic and intoxicated behavior, suggesting possible surreptitious consumption of isopropanol. Initial toxicology results from blood samples showed an isopropanol concentration that raised concerns regarding potential contamination from venipuncture site disinfection. Vitreous fluid analysis was performed to exclude contamination, revealing a consistent isopropanol concentration, which confirmed the cause of death as acute isopropanol toxicity.[2]

Further literature review supports the use of vitreous fluid in postmortem toxicology for volatile compounds like isopropanol and acetone.[3] Vitreous humor is a more reliable matrix for the detection of volatile substances due to being less susceptible to postmortem redistribution, microbial degradation, and surface contamination compared to blood.[6] Markers such as β-hydroxybutyrate, which are crucial in distinguishing different types of ketoacidosis, remain stable in vitreous fluid, allowing for more accurate diagnosis.[4,5] This study highlights the importance of incorporating vitreous fluid testing in forensic investigations, particularly when blood specimens may be compromised. The findings suggest that vitreous fluid should be considered a primary or complementary sample in suspected poisoning deaths, improving diagnostic accuracy in complex toxicological cases.

Y46 The Effects of Latent Print Development Techniques on Over-the-Counter Drug Detection by Liquid Chromatography Triple Quadrupole Mass Spectrometry

Jessica Pichat, BS, Duquesne University, Succasunna, NJ; Ashley N. Ebert, PhD, Oakwood Laboratories, Oakwood Village, OH; Lyndsie N. Ferrara, PhD, Duquesne University, Pittsburgh, PA; Stephanie J. Wetzel, PhD, Duquesne University, Pittsburgh, PA*

Learning Objectives: Attendees will learn the effects that latent print development techniques will have on the detection of Over-The-Counter drugs (OTC). This information will allow attendees to better understand how to process evidence that can yield both latent prints and drug chemistry results.

Impact Statement: This presentation will impact the forensic science community by informing crime laboratories of different possibilities on how evidence can be processed by multiple units, particularly latent prints and drug chemistry. Ultimately, this research will serve as a basis to determine if evidence processed for fingerprints can still be viable for drug detection.

Abstract Text: Fingerprints can be left on any surface when handled with bare hands and can be key evidence to tie a suspect to the location of a crime or a piece of evidence. Latent prints are the most common type of fingerprints found at crime scenes.[1] They occur when fingerprints are not visible to the naked eye and are often the result of sweat and oils from the finger left on the surface.[2] Latent prints need to be developed to visualize the specific ridge patterns, which allow examiners to make identifications when comparing to reference fingerprints. These development techniques are effective in visualization but consequentially could destroy other types of evidence from being obtained such as chemical substances. While most crime laboratories have systems in place regarding evidence processing in different units, this research examined the effects of fingerprinting development techniques on the detection of over the counter (OTC) drugs by liquid chromatography triple-quadrupole mass spectrometry (LC-QQQ-MS). Prior research has confirmed the ability to detect drugs from undeveloped fingerprints using various instruments.[3,4] However, minimal research has been performed to analyze the effect of fingerprinting techniques on the detection of drugs from fingerprints and no prior studies utilized LC-QQQ-MS for analysis.[5] Common development techniques utilized by crime laboratories such as black fingerprinting powder, magnetic fingerprinting powder, ninhydrin, 1,8-Diazafluoren-9-one (DFO), and cyanoacrylate fuming were tested on OTC drug contaminated latent prints that were deposited on either glass or paper.[6] Samples were extracted and analyzed for the presence of the OTC drugs (caffeine, acetaminophen, and acetylsalicylic acid) by LC-QQQ-MS. Most development techniques had little to no effect in the detection of the drug present, however, it was noted that the porous samples developed by ninhydrin and DFO had less drug recovery than the non-porous samples. These results can inform laboratories of new possibilities of evidence processing orders when both drugs and possible latent prints are present. In conclusion, this research indicates that drug chemistry can be used to detect drugs from fingerprints that have undergone development techniques.

Y47 Lying Labels? An Analysis of Caffeine Content in Common United Kingdom Caffeinated Products

Noah Cannon, Texas A&M University, Austin, TX; John Paul Planchet*, Texas A&M University, San Antonio, TX; Carolina Sartori*, Texas A&M University Fort Worth, TX*

Learning Objectives: Attendees will learn how caffeine concentration in United Kingdom energy drinks and caffeine tablets can be experimentally determined, along with the process of designing and testing research methods. The presentation will highlight challenges faced and limitations with High-Performance Liquid Chromatography (HPLC) analysis of caffeine and solid phase extraction involving coffee. By the end, attendees will be able to recognize effective and ineffective approaches to caffeine analysis in forensic and research settings.

Impact Statement: This presentation is forensically relevant in relation to food fraud and analytical accuracy. It will enhance the forensic community's competence by demonstrating which methodologies are effective—and which are not—when analyzing caffeine pills and energy drinks from the United Kingdom. By identifying limitations and reliable approaches, the presentation supports stronger performance in applying chemical analysis to forensic investigations and further research.

Abstract Text: This study aimed to determine whether the caffeine content listed on five energy drinks (Red Bull, Sugar-Free Red Bull, C4, Monster, and Tenzing) and two caffeine tablets (Pro Plus and Sainsbury's Energy Lift) corresponded to the actual concentrations present. Food fraud is a nationwide concern, and chemical analysis provides a means of quality control and detection of potential fraud. High-Performance Liquid Chromatography (HPLC) was employed to separate and detect caffeine, while Solid Phase Extraction (SPE) was used for sample cleanup prior to analysis. Method optimization was necessary, including reducing injection volume (20 µL to 0.5 µL) to minimize saturation, shortening the run time (10 minutes to 6 minutes) for efficiency, and adjusting the mobile phase (20/80 to 40/60 methanol-to-water) to achieve optimal peaks. Dissolution of the caffeine pills was used to determine concentration. Coffee was initially included as a sample, but filtration alone was insufficient for SPE; centrifugation is proposed as a solution to separate solids prior to analysis. Initial results indicated that all caffeine concentrations were below the labeled amount, with the exception of the Sainsbury's tablet. Unfortunately, due to time constraints, full testing of the energy drinks was not completed. However, future work re-running the SPE with 1 mL rather than 100 mL may provide more accurate results and would be the next step in any future research.

Y48 An Assessment of the FARO Freestyle 2 Handheld Scanner on Skeletal Analyses in the Estimation of the Biological Profile

Chloe R. Cummings, BS, George Mason University, Fairfax, VA; An-Di Yim, PhD, George Mason University, Manassas, VA*

Learning Objectives: After attending this presentation, attendees will have a better understanding of how virtual models derived from the FARO Freestyle 2 Handheld Scanner can be used to estimate a biological profile and contribute to forensic anthropology casework and research.

Impact Statement: This presentation will impact the forensic science community by providing evidence as to the accuracy and reliability of FARO Freestyle 2 Handheld Scanner on biological profile estimation. As virtual methodology and virtual influences become more heavily used across the field, this presentation contributes to the discussion of their utility in forensic anthropology.

Abstract Text: In forensic anthropology, skeletal materials can be assessed via both morphological and metric data to estimate a biological profile. Traditionally, these analyses are performed by manually handling the remains. Digital methods, such as laser surface scanning, computed tomography (CT) scanning, and 3D photogrammetry, can potentially be used to supplement or replace direct observations, making forensic anthropology consultation more accessible. Results for the reliability of 3D scanning and photogrammetry techniques are mixed within the literature and warrant further investigation. This study evaluates whether virtual skeletal models generated by the FARO Freestyle 2 3D scanning method can be used to estimate biological profiles using established nonmetric standards and protocol. We further compare the results with previous studies to assess the reliability of 3D scanning and its use in forensic anthropology.

Two sets of skeletons from the George Mason University Forensic Science Program Teaching Collection were used for this study. A total of 10 participants with varying experience levels in assessing skeletal nonmetric traits were recruited from the Washington Metropolitan Area and surrounding regions. Around 30 to 50 participants will be recruited overall throughout the course of this study. Each participant was asked to assess the skulls and pelves in person using the Morpho PASSÉ user manual scoring guidelines for sex estimation, macromorphoscopic traits for population affinity estimation, and Suchey-Brooks and Hartnett pubic symphysis phase descriptions for age estimation. 6 8 weeks following this initial survey, the same participants were asked to evaluate the virtual models via a Qualtrics survey with access to an interactive online 3D-viewing platform (Sketchfab). JMP Pro, a statistical software, was used to assess the reliability of the scores and the accuracy of the resulting biological profile estimation results.

The results showed that while there is good inter-observer agreement (Cronbach's alpha = 0.875) for actual skeletal scoring, the inter-observer agreement for the virtual models are decreased. However, some elements of the biological profile can still be estimated accurately via the virtual methodology, such as nonmetric sex estimation, as the trait scores more strongly utilize size and shape of the skeletal features across a spectrum of scores. These traits are likely easier to capture and discern through 3D photogrammetry[A2] On the other hand, age-related changes or macromorphoscopic traits for population affinity estimation are more difficult to assess through the FARO Freestyle 2 scans, as the feature details can be lost within the point cloud generated through 3D photogrammetry and the subsequent rendering and modeling methods.

Y49 Vicarious Trauma and its Effects on Public Safety Professional's Ability to Complete Unbiased Investigations

Madison K. Turner, Embry-Riddle Aeronautical University, Prescott, AZ; Kelly Crockett, MSFS, Embry-Riddle Aeronautical University, Prescott, AZ*

Learning Objectives: After attending this poster session, participants will be able to describe how repeated exposure to traumatic events affects public safety personnel, identify the ways this exposure influences job performance and personal well-being, and recognize strategies to prevent or mitigate vicarious trauma. Attendees will gain an understanding of how stress-management frameworks such as the Job Demands–Resources (JD-R) model and Critical Incident Stress Debriefing (CISD) can be applied to support officers' mental health.

Impact Statement: This presentation will impact the forensic science community by raising awareness of the psychological risks faced by public safety professionals. It will highlight how unaddressed trauma can undermine investigations and damage community trust, while also offering evidence-based strategies to maintain professional competence and well-being.

Abstract Text: Public safety professionals routinely respond to incidents ranging from domestic disputes to violent crimes. This repeated exposure puts officers at risk for vicarious trauma (VT), a condition in which individuals develop stress symptoms from indirect exposure to others' trauma.[3,7] VT often overlaps with secondary traumatic stress, burnout (exhaustion from long-term overwork and emotional strain), and post-traumatic stress disorder (PTSD).[6] Together, these conditions can hinder an officer's capacity to remain objective, increasing the likelihood of biased investigations and adversarial attitudes toward the communities they serve. After attending this poster session, participants will be able to understand the emotional strain of working in forensic disciplines and the effects it has on job performance and personal relationships.

This poster synthesizes literature on the prevalence of vicarious trauma in public safety and reviews longitudinal research on effective coping mechanisms.[2,4] Specifically, it applies the Job Demands–Resources (JD-R) model, which explains how workplace stress arises when demands exceed available resources, and the Critical Incident Stress Debriefing (CISD) model, a structured group discussion process designed to mitigate stress after traumatic events.[1,5] Findings suggest that implementing structured debriefings, increasing organizational support, and normalizing access to mental health resources reduce fatigue and improve investigative accuracy. It will also address how the combination of VT, developmental experiences, and adversarial attitudes will negatively impact public safety professionals' ability to investigate without bias.

The presentation emphasizes the importance of institutional recognition of VT and proactive strategies for prevention. By framing public safety personnel's well-being as integral to justice outcomes, this work underscores the necessity of embedding resilience practices in forensic and investigative disciplines.

Y50 An Evaluation of Immunoassay Test Strips for Detection of Medetomidine in Urine and Drug Products

Liliane Audet, BS, Arcadia University, Glenside, PA; Alex J. Krotulski, PhD, Center for Forensic Science Research & Education, Horsham, PA; Heather L. Harris, MFS, Arcadia University, Glenside, PA; Alyssa G. Reyes, MS, Center for Forensic Science Research and Education (CFSRE), Horsham, PA*

Learning Objectives: The presentation will provide an overview of the effects of medetomidine, its enantiomers, and concerns about its proliferation in the United States drug supply. It will detail the validation of medetomidine lateral flow immunoassays (test strips) released by BTNX Inc. and WiseBatch Harm Reduction. Both brands of medetomidine test strips have been found to target the active enantiomer, dexmedetomidine. WiseBatch test strips show higher specificity, selectivity, and efficiency when identifying the presence of dexmedetomidine in laboratory settings and authentic samples.

Impact Statement: The medetomidine test strips made by BTNX Inc. and WiseBatch Harm Reduction have been found to be highly effective for identifying dexmedetomidine in laboratory drug samples. Their high efficiency makes them a viable option to increase harm reduction for drug users, potentially leading to greater awareness of the threats this drug can pose and fewer overdoses connected to its ingestion.

Abstract Text: Medetomidine (Domitor®), an α2-adrenoreceptor agonist used in veterinary medicine, has been found in the drug supplies of multiple states, beginning with Maryland in late 2022[1]. The proliferation of this drug and its connection to multiple overdoses has created a need for lateral flow immunoassays (LFI, also referred to as test strips) to increase harm reduction measures.[1,2] Medetomidine is a racemic mixture of the pharmacologically inactive L-enantiomer, levomedetomidine, and the pharmacologically active D-enantiomer, dexmedetomidine.[1,3,4] On its own, dexmedetomidine (Precedex®, Dextor®) has been approved for use in human clinical medicine[4,5]. Both medetomidine and dexmedetomidine have sedative, analgesic, anxiolysis, and muscle relaxation properties on mammalian subjects.[3,5-8] At toxic doses bradycardia, respiratory depression, hypothermia, and sudden hypertension followed by extended hypotension are common and can contribute to user death alone or in tandem with other drugs of abuse.[4,7,9] Dexmedetomidine has greater potency than medetomidine, making it equally effective at lower doses; high doses of levomedetomidine are needed to mimic a small fraction of the effects of medetomidine or dexmedetomidine.[3,10] In this research project medetomidine test strips from two different companies, BTNX Inc. and WiseBatch Harm Reduction, are being validated with 16 common drugs of abuse, 8 common cutting agents, 7 other α2-adrenoreceptor agonists and 3-hydroxy-medetomidine. All cross reactivity trials had negative results (denoted by a pink line in the Test (T) zone of the test strips), though those for detomidine and 3-hydroxy-medetomidine were very faint. The target molecule of both brands of test strips was found to be dexmedetomidine with a cut-off concentration of 1,000 ng/mL.[11] Current data suggests both brands of test strips are sensitive and specific to dexmedetomidine, though WiseBatch is the more sensitive of the two. Quantitative analysis has shown that BTNX Inc. test strips have the capacity to detect medetomidine at concentrations as low as 47.97ng/mL in authentic urine samples, whereas WiseBatch has been found to detect medetomidine concentrations as low as 9.43ng/mL in those same samples. This makes both brands efficient for medetomidine detection and harm reduction. Future directions include qualitative testing to assess the ratio of levomedetomidine versus dexmedetomidine present in each of the utilized authentic samples.

Y51 An Evaluation of Alternative Solvents for Forensic Fire Debris Analysis

Tessa Monroe, The University of Tampa, Tampa, FL; Jenna E. Leppek, BS, Michigan State University, Canton, MI; Hannah Jewell LaVoie, BS, Michigan State University, Okemos, MI; Ruth Waddell Smith, PhD, Michigan State University, East Lansing, MI; Kenyon Evans-Nguyen, PhD, The University of Tampa, Tampa, FL*

Learning Objectives: Attendees will learn about alternative solvents for fire debris analysis that mitigate health risks associated with traditionally recommended solvents while optimizing extraction.

Impact Statement: This work impacts the forensic science community by investigating alternative solvents for forensic fire debris analysis that mitigate health risks associated with traditionally recommended solvents while optimizing extraction.

Abstract Text: Ignitable liquids are commonly used as accelerants to set intentional fires and are extracted from the resulting debris to aid in forensic investigations. Forensic chemists follow a well-established set of protocols, cataloged in a series of ASTM standards including ASTM E1618, for the analysis of fire debris. These standards have proven effective.[1] However, many of the solvents used in these protocols have associated safety concerns. Thus, there is a need to identify alternative solvents for fire debris analysis. The ASTM E1386 standard lists three solvents recommended for the extraction of ignitable liquid residues: carbon disulfide, diethyl ether, and pentane.[2] Each solvent has disadvantages. Carbon disulfide poses recognized adverse health effects and diethyl ether can form explosive compounds, igniting unexpectedly. While relatively safe, pentane is less effective in extracting ignitable liquid residue in comparison to the other solvents. Dichloromethane and hexane, while not listed in the ASTM standards, have also been used for fire debris analysis and have similar drawbacks associated. Dichloromethane was recently placed under severe restrictions by the Environmental Protection Agency and hexane, like pentane, is less effective in its extraction.[3] This project aims to identify and experimentally evaluate additional solvents that mitigate the drawbacks associated with the recommended solvents.

A wide range of solvents were rapidly screened using theoretical calculations, particularly, the Hildebrand solubility parameter (δ). In general, the closer the δ value of a solvent is to that of a solute, the better the dissolution and the miscibility will be.[4] Therefore, a solvent used for analysis of ignitable liquids can be selected based on compounds present.

Liquids representing different ASTM classes (ex: gasoline, petroleum distillates, isoparaffinic products, aromatics, naphthenic-paraffinic products) were first analyzed by gas chromatography-mass spectrometry (GC-MS) to calculate δ values for compounds characteristic of the different classes, and suitable solvents with similar δ values were identified. This research tested undegraded samples of ignitable liquids in the following solvents: pentane, ethyl acetate, as well as various mixtures of pentane and ethyl acetate. Each liquid was then prepared in the selected solvents and re-analyzed by GC/MS.

The average normalized abundance of key compounds in each ignitable liquid when prepared in each solvent was compared. For example, for gasoline, the abundances of toluene, *p*-xylene, 1,3,5-trimethylbenzene, and 2-methylnapthalene in the different solvents were evaluated.[1] Using a two sample t-test, the abundance of these compounds was significantly higher when extracted with ethyl acetate compared to pentane: toluene: $p = 3.70 \times 10^{-6}$, *p*-xylene: $p=2.10 \times 10^{-8}$, 1,3,5-trimethylbenzene: $p=2.30 \times 10^{-6}$, 2-methylnapthalene: $p=9.80 \times 10^{-11}$. These preliminary data demonstrate that ethyl acetate extracts key compounds in gasoline at a higher normalized abundance than pentane.

Y52 An Evaluation of Vapor Pressures of Ignitable Liquids, Water and Fire Debris Analysis, and the Effects on Extraction

Carson Kleider, BS, ATF/Marshall University, Huntington, WV*

Learning Objectives: Attendees will learn the current methods and guidelines used for fire debris analysis and specific parameters in which the process may be affected (i.e., Activated Charcoal Strip [ACS] size, ACS adsorption, oven extraction time, solvent extraction volume). They will also learn how semi-quantitation of Ignitable Liquids (ILs) may be done to observe the behavior of ILs of different classes/ molecular weights. The saturation of the Gas Chromatograph/Mass Spectrometry (GC/MS) detector impacts the results of the chromatogram was a very important aspect of this project to distinguish between saturation occurring from the GC/MS detector or from the ACS.

Impact Statement: The American Society for Testing and Materials (ASTM) E1412 guidelines have been outstanding procedures used for many years for fire debris analysis. Fire debris should be treated in the same manner because the way materials burn has not changed. However, improvements have been made to the manufacturing of adsorbent materials used, as well as the sensitivity of instruments used. With the increase in instrument sensitivity and porosity of adsorbent medium, the extraction procedure may need adjustments, as well, to follow the apparatuses used in extraction. This project may also give a better understanding of what is occurring inside the paint can during extraction and the behavior of certain ignitable liquids.

Abstract Text: Fire debris analysts examine evidence from fire scenes for ignitable liquids to assist fire investigators in determining whether a fire was accidental or intentional. The primary goal of fire and emergency crews is to quickly extinguish the fire. Therefore, fire debris evidence often arrives in the laboratory wet, having been sealed in airtight metal cans. Analysts typically extract ignitable liquids from samples by suspending an ACS in the sealed container, and heating it. The compounds from the ignitable liquid are desorbed with a solvent for GC/MS analysis.

Previous studies investigated factors such as extraction time, ACS saturation, and adsorption efficiency. However, advances in ACS manufacturing and substantial improvements in GC-MS sensitivity present an opportunity to build upon these earlier findings. Furthermore, older studies often employed complex ignitable liquid mixtures like gasoline, which complicated interpretation and limited the ability to conduct semi-quantitative analyses.

This study investigated ACS extraction using current ASTM E1412 guidelines while simplifying the analysis by focusing on ten representative compounds: ethanol, isooctane, n-heptane, toluene, 1-octene, 1,2,4-trimethylbenzene, n-decane, indane, naphthalene, and n-heptadecane. Extractions used varied starting volumes and extraction times. The objective was to compare predicted headspace concentrations with GC/MS responses and also to evaluate the influence of water.

Contrary to predictions, higher vapor pressure compounds were not consistently observed in greater abundance during shorter extractions. Instead, ACS affinity appeared to govern adsorption. Other experimental parameters were found to be significant. Desorption solvent volume affected compound recovery and GC/MS detector saturation, while adsorption times showed little variation, suggesting that equilibrium is reached more quickly than previously reported. Water had a limited overall effect, but its presence did prevent the detection of ethanol in wet samples. This was likely due to ethanol's adsorption by the water.

Y53 A Quick Method of Measuring Bullet Angles on Auto Metal Surface at Crime Scenes: A Novel Method Using a Digital Angle Measurer

Heather Armistead, BS, California State University-Long Beach, Long Beach, CA; John Z. Wang, PhD, California State University-Long Beach, Artesia, CA*

Learning Objectives: After attending this presentation, attendees will learn a new method to quickly determine a bullet travel direction and measure its bullet impact angles in 20 seconds on auto metal surfaces using a digital angle measurer.

Impact Statement: During a crime scene investigation of a shooting-related incident on auto metal surfaces: Two technical challenges still require further exploration: (1) how to quickly determine the bullet travel direction; and (2) how to quickly measure the bullet impact angle? This presentation will impact the forensic community in general and the fields of crime scene investigations in particular by providing a quicker measurement with better accuracy and reliability, thus rendering a better theory of crime scene reconstruction at trial.

Abstract Text: When a bullet hits an auto metal surface, it usually penetrates the surface, which contains information on two import parameters: The bullet direction and the impact angle. The bullet direction can be determined by three phenomena: "boat-wave" and "pinch point" on the entrance and "obtruding teeth" on the exit. The bullet impact angle is relatively more difficult to determine. There is a correlation between the two: the smaller angle of the bullet trajectory, the more oblong the bullet shape tends to be. However, a specific bullet impact angle is much needed to estimate the shooter's position. While the trajectory rod method uses four tools: a rod, a digital level finder, a digital protractor and a plumb to obtain a bullet angle, the ellipse method takes a photo of the bullet defect, and uses a software to measure the major axis (length) and minor axis (width) of the elliptical hole using the sine function for the angle of impact. Both methods are complicated, time-consuming, and non-friendly usage and are less accurate and reliable, especially on curved entrance and exit shape from a low degree of shooting on auto metal surfaces. With a quasi-experimental design similar to a real shooting incident, the project took place in an outdoor shooting range where a piece of an auto metal (about 12" by 10") was used as the target and was shot from 10 feet away. Under a purposive sampling, three calibers of pistols were selected due to the frequent criminal encounters: a 9 mm pistol (the most common pistols in overall shooting incidents), a .380 (the most common pistols in drive-by-shootings), and a .40 (with more powder and heavier grains) at three angles: 30°, 60°, and 90°. After the shooting, one of the researchers recorded the calibers, the direction, and the angles, and the other researcher conducted the measurement without knowing the ground truth, similar to a Black Box Study. A digital angle measurer was utilized, which has three features: (1) It has two legs with each one end digitally connected; (2) One leg serves as a baseline and the other has a digital viewer; (3) When the baseline leg lies on a flat surface, the other leg moves to align with a target plane to display the angle. However, since a bullet hole on an auto metal surface can be horizontal or vertical, the digital angle measurer is not able to measure the shooting angle directly. This project employs a special tool and places it onto the base-line leg so that the device can touch the curved surface of the bullet hole. The other leg with the digital viewer can be stretched out to reach a horizontal plane for an angle. The preliminary result indicates both the bullet travel direction and the bullet impact angle can be determined and measured in about 20 seconds. The poster will illustrate the bullet holes on both sides to show the three phenomena, the digital angle measurer by photos, and the measuring steps with detail descriptions.

Y54 Developmental Changes in Frontal Sinus Morphology: Significance in a Forensic Context

Allison L. Deemter, MA, Western Michigan University Homer Stryker M.D. School of Medicine, Allegan, MI*

Learning Objectives: Upon completion of this presentation, those who attend will comprehend morphological changes that occur in the frontal sinus with age. Embryological origins of the frontal sinus as well as ontogenetic trends will be discussed. Attendees will understand the significance of these morphological changes through the comparison of antemortem and postmortem imaging in a forensic case.

Impact Statement: This presentation will enhance awareness within the forensic science community regarding age-related changes in frontal sinus morphology. Given that frontal sinus traits are commonly employed in scientific identification due to their individualistic nature, understanding their developmental variability is essential. A forensic case study from Western Michigan University Homer Stryker M.D. School of Medicine (WMed) will highlight the practical implications of these developmental changes in real-world forensic identification.

Abstract Text: Obtaining positive identification for individuals is a crucial function of medicolegal offices. Fingerprints, dentition, and deoxyribonucleic acid (DNA) are commonly analyzed in this process due to their individualistic nature. The frontal sinus is another feature frequently used in scientific identification, as it is a highly variable attribute.[1,2] The frontal sinus is located above the orbits within the frontal bone and typically contains two lobes that are divided by the inter-sinus septum. Distinctions of frontal sinus morphology that add variability include frontal sinus presence/absence, asymmetry of lobes, size, and location. The arcades and septa differ in size, shape, and number between individuals.[3]

Despite frontal sinus morphology being a reliable identifying feature when antemortem and postmortem radiographs are available, it is not without limitation. A crucial hindrance that professionals should be aware of is how the frontal sinus develops and changes over time. Embryological development of the frontal sinus occurs either by protrusion of the frontal recess, or through the emergence of ethmoidal air cells.[4] The frontal sinus can typically first be seen radiographically around 3 years of age with continued growth into early adulthood.[5]

Frontal sinus development is a critical consideration in cases, such as the following, where forensic identification is required. A 17-year-old male was the driver of a vehicle that was struck by a semi-truck. The decedent was pronounced on-scene and brought to WMed for postmortem examination. Antemortem radiographs of the 17-year-old decedent's head and neck were available, which were taken at 6-years-old. Lodox scans were taken at postmortem examination and compared to the antemortem radiographs. On antemortem imaging, ethmoid air cells are apparent, however the frontal sinus is not visually pneumatized, which is common for this age group.

Postmortem imaging, however, shows the presence of a frontal sinus that is well-pneumatized. The midline septum appears slightly deviated toward the left side and there is clear asymmetry between the right and left lobe. The right lobe is larger with more complex internal contouring, while the left lobe is smaller and narrower with simpler shape.

This disparity in sinus morphology illustrates an essential consideration: developmental changes can limit the reliability of frontal sinus comparisons in scientific identification, particularly when antemortem and postmortem images span different developmental stages. In this case, reliance solely on frontal sinus morphology could have led to misidentification. Therefore, frontal sinus morphology should not be used for identification when the decedent is younger than 20-years-old, or when antemortem imaging was taken prior to complete development of the frontal sinus.

Y55 Single Step Fingerprint Fumigation With Common Dyes

Abigail M. Proffitt, Liberty University Department of Biology & Chemistry, Evington, VA; Jared Filegar*, Liberty University Department of Biology & Chemistry, Mechanicsville, VA; Kristin Mossé, MSFS, Liberty University, Lynchburg, VA*

Learning Objectives: The concepts of cyanoacrylate fumigation of latent prints and the procedures of how to incorporate pigments into the latent prints to eliminate secondary staining processes will be explored and discussed.

Impact Statement: This experiment aims to simply the technique of visualizing latent fingerprints via cyanoacrylate fumigation by using common dyes from markers and other easily accessible pigment materials. This is done with the hope that the separate fumigation and staining procedures can be consolidated into a singular procedure that allows for visualization immediately without a secondary process.

Abstract Text: This research intends to investigate a new methodology for fingerprint fumigation by using various dyes from markers and highlighters to reduce time constraints and simplify the process of increasing the visibility of latent fingerprints. A current chemical procedure for fingerprinting is called cyanoacrylate fuming, a technique which uses super glue to develop latent fingerprints. Latent fingerprints are created by oils secreted from the pores of fingers that are left invisible to the naked eye. This process involves placing the material with the fingerprint in the fumigation chamber with a small drop of super glue and heating it past its boiling point. The super glue creates concentrated gaseous cyanoacrylate that reacts with solid components left behind by the finger oil, like amino acids and proteins. However, after the reaction is complete, a second staining process is needed to fully visualize the print, as the super glue dries down clearly. This research aims to consolidate this method into one step by adding dyes to the super glue. Our hypothesis postulates that adding various dyes into the fumigation chamber will allow the gaseous phase of cyanoacrylate to attach to the colored substrates and bind to the physical components of finger oils to visualize latent prints in a single procedure. This procedure will follow the standardized fumigation procedure; however, two different methods will be carried out. One method will consist of coloring a cotton ball with the dye and super glue then setting it up in the chamber to proceed with the normal fumigation mechanism. The other method involves using various solutions to concentrate the dye and incorporating that mixture into the super glue on a cotton ball. This new methodology will be carried out on multiple, forensically relevant surfaces. This research could limit the amount of time it takes to visualize latent prints as well as limit human error that can happen with the current secondary technique of dusting or staining since smearing is common.

Y56 When Cleanliness Obscures: How Can Common Disinfecting Cleaners Hinder Forensic Investigations?

Shaifer L. Goalen, BS, Texas A&M University, Galveston, TX; Kristin Ornelas, Galveston Police Department, Galveston, TX*

Learning Objectives: Upon completion of this presentation, attendees will be able to identify the specific chemical compounds in common household disinfectants that interfere with presumptive blood tests. They will understand the contrasting mechanisms by which these cleaners cause either false positive results with BlueStar® or false negative results with the Phenolphthalein (Kastle-Meyers) Test, thereby informing more reliable crime scene protocols.

Impact Statement: This research directly impacts the forensic science community by providing evidence-based data on the limitations of two primary presumptive blood tests when cleaning agents are present. The findings will enhance practitioner competence in interpreting test results and promote procedural changes that limit the liability associated with false indications of blood evidence.

Abstract Text: The successful detection and analysis of latent blood evidence are critical to the criminal justice process, yet crime scenes are frequently subjected to cleaning attempts using common household disinfectant agents. This study investigated the chemical interference of ten commercial disinfectant cleaners on the efficacy of two standard presumptive blood tests: the BlueStar® chemiluminescence reagent and the Phenolphthalein (Kastle-Meyers) Test.[1,3] Human bloodstains were passively applied to both gloss and matte ceramic tile substrates, allowed to dry for ten minutes, cleaned with the respective disinfectants, and subsequently tested using both presumptive methods. The hypothesis posited that highly oxidative compounds, particularly bleach, would have the greatest disruptive effect on detection. The results demonstrated that the active ingredients in the cleaner's function as active chemical disruptors, producing complex and ambiguous indications. Highly acidic compounds, notably those containing high percentages of ammonium chloride (e.g., Clorox® and Field & Future®), were the most effective inhibitors, resulting in negative Phenolphthalein tests in two out of five targeted trials (n=5) despite the known presence of blood. Conversely, these same cleaners showed limited to no BlueStar® fluorescence. In contrast, highly oxidative agents like Pure Bleach, along with high-concentration isopropyl alcohols, resulted in either visible BlueStar® fluorescence where blood was present, or demonstrated chemical false positives in control tests, rendering positive chemiluminescence unreliable.[2] In conclusion, the application of household disinfectants introduces two distinct and complicating sources of error: acidic compounds trigger false negatives during Phenolphthalein testing, while oxidative compounds and alcohol bases risk false positives with BlueStar®. Given the ambiguous potential for both false positives and negatives, it is recommended that forensic personnel utilize the Phenolphthalein Test primarily to confirm the presence of hemoglobin, followed by BlueStar® only secondarily, thus minimizing contamination and false indications.[3] Further research is necessary to incorporate these findings into standardized, evidence-based crime scene processing protocols.

Y57 A Comparison of Genetic Analysis Methodologies on Spermatozoa DNA Recovered From the Orifices of Burned Human Remains

Andrew J. Brown, Western Carolina University, Kernersville, NC; Brittania Bintz, MS, Western Carolina University, Cullowhee, NC; Darren A. Solomon, MS, Bureau of Alcohol, Tobacco, Firearms and Explosives, Charlotte, NC; David Schuable, BS, SAFE Laboratories and Engineering Corp., Sanford, NC; Charles Giblin, PE, Bureau of Alcohol Tobacco Firearms and Explosives, Washington, DC; Rebecca L. George, PhD, Western Carolina University, Cullowhee, NC*

Learning Objectives: After attending this presentation, attendees will understand the principles of DNA survivability in high-temperature environments, the optimal methodology used to assess spermatozoa DNA persistence in internal cavities, and the comparative results of genetic analyses, including traditional Short Tandem Repeat (STR) typing, STR typing using the Ion GeneStudioÔ S5 prime Massively Parallel Sequencing (MPS) platform, and single nucleotide Polymorphism (SNP) analysis.

Impact Statement: This presentation will impact the forensic science community by providing foundational data on the likelihood of recovering probative genetic evidence from fire-damaged remains, where evidence is often presumed to be destroyed. These findings will contribute to strengthening the investigative workflow and standards of procedure when approaching heavily altered fire damaged remains and evidence collection.

Abstract Text: In 2024, in collaboration with the Bureau of Alcohol, Tobacco, Firearms, and Explosives (ATF) and Western Carolina University's (WCU) Forensic Anthropology program, a study was conducted to assess the survivability of spermatozoa DNA in internal cavities of unembalmed human cadavers exposed to a high-intensity, low-duration fire. Cadavers were from the WCU willed body donation program and had previously consented to post-mortem DNA and destructive testing. In preparation for the fires, a full-scale wood-frame flashover cell was constructed to have a three-wall configuration with a ceiling. Prior to ignition, a pooled sample consisting of seminal fluid from at least two donors was pipetted into the oral, anal, and vaginal (when applicable) orifices of a male and a female cadaver to simulate sexual assault. A fire was ignited and allowed to intensify, transition through flashover then burn in post-flashover conditions for a total of 7 minutes. After the fire was extinguished, orifices were swabbed (x6) using Copan 4N6 FLOQswabs™, and swabs were numbered according to the order in which they were collected. DNA was extracted from swabs 3-6 using the Qiagen EZ1&2™ DNA Investigator™ kit and extracts were quantified using the Applied Biosystems™ Quantifiler™ Trio kit.[1,2] Initially, STR profiling of recovered DNA was accomplished using both traditional and massively parallel methods. STR targets were amplified from an aliquot of each extract using the Applied Biosystems™ GlobalFiler™ kit and fragment analysis was performed on the Applied Biosystems™ SeqStudio™ Genetic Analyzer.[3] Resulting data consisted of mixed profiles concordant with references from cadaver and seminal fluid donors and showed varying levels of success with the major contributor of the seminal fluid mixture yielding higher allele recovery than the minor contributor, as expected. Percent recovery for the major contributor was calculated to be 77.60% (Swab 3), 30.73% (Swab 4), 27.08% (Swab 5) and 20.83% (Swab 6) for samples obtained from the female cadaver and 29.86% (Swab 3), 19.44% (Swab 4), 16.67% (Swab 5), and 15.28% (Swab 6) for samples obtained from the male cadaver. In general, swabs collected early in succession were more likely to produce for the donor(s) of seminal fluid. Due to increased sensitivity and potential for mixture deconvolution, MPS STR profiling was also performed on the extracts using the Precision ID GlobalFiler™ panel.[4] Analysis of these results revealed allele recoveries for the major seminal fluid contributor of 77.28% (Swab 3), 29.35% (Swab 4), 20.65% (Swab 5), and 11.96% (Swab 6) for samples obtained from the female cadaver and 24.64% (Swab 3), 14.45% (Swab 4), 12.13% (Swab 5), and 10.15% (Swab 6) from the male cadaver. Additional SNP-based human identification MPS studies were conducted on the aforementioned extracts using the Applied Biosystems™ Precision ID Identity Panel and Ion GeneStudio™ S5 Prime to determine whether more discriminatory information could be obtained from these samples.[5] Overall, the results suggest that despite extreme thermal conditions, internal body cavities provide insulation that enables preservation of DNA evidence when a victim is exposed to high temperatures, ultimately highlighting the utility of DNA analysis in investigations involving thermally altered remains.

Y58 The Impact of Firearm Type and Orientation on Gunshot Residue Distribution Patterns on a Shooter

Emily J. Miller, BS, University of New Haven, New Haven, CT; Peter Valentin, PhD, University of New Haven, West Haven, CT; Virginia M. Maxwell, DPhil, University of New Haven, Hebron, CT*

Learning Objectives: After attending the poster session, attendees will better understand how certain external factors can affect the deposition and distribution of Gunshot Residue (GSR). They will also recognize the importance of accounting for these variables during evidence sampling and analysis.

Impact Statement: The information on this poster could influence the forensic science community by encouraging changes to existing GSR collection protocols used by forensic scientists and crime scene investigators. Additionally, it may encourage further research into other external factors to improve GSR collection techniques in real-world scenarios.

Abstract Text: When a firearm is discharged, both organic and inorganic GSR are expelled through the openings in the firearm and deposited on nearby surfaces.[1] Primer GSR (pGSR), which is part of the inorganic GSR, consists of lead, barium, and antimony, whereas organic residue is composed of nitrocellulose and/or nitroglycerin.[2] Nitrites are also classified as inorganic GSR. Although they originate from organic compounds, they are inorganic byproducts formed by the combustion of smokeless powder in a firearm. All these residues are commingled because they are produced as part of the same firing event.[2] Nitrite residues can be detected using various chemical testing methods, including the Modified Greiss Test, the Walker Test, and the Marshall Test.[3] Given the relative abundance of nitrite residue, developing a method for assessing pGSR distribution patterns based on the nitrite distribution would be beneficial. By accurately mapping nitrite distribution, we can identify the locations with the highest likelihood of having pGSR for sampling.

Previous researchers used a Video Spectral Comparator (VSC) because of its ability to select a specific wavelength and barrier filter combination, thereby taking advantage of the inherent fluorescence of the nitrite residue.[4] While multiple studies have confirmed the use of the VSC to analyze GSR on clothing, there appears to be a lack of research focusing on GSR fluorescence on the individual who discharged the firearm. This study addresses these gaps by investigating GSR distribution patterns on 100% cotton, long-sleeve black shirts, and examining how these patterns are affected by the firearm type and its orientation during discharge. After the firearm is discharged, the shirts are doffed and later photographed with the VSC to create a map of GSR distribution. The results will indicate the extent to which firearm type and orientation may contribute to any changes in GSR distribution on the shirt of the shooter. These findings could help develop updated GSR collection protocols, potentially reducing false negatives and enhancing the accuracy and reliability of firearm-related forensic examinations. The results are expected to demonstrate that the distribution patterns are significantly influenced by firearm type and orientation, highlighting the need to modify GSR collection protocols when the shooter's position can be determined from case information.

Y59 Effects on Skeletonization and Skeletal Weathering Across Contrasting Annual Seasonal Cycles

Maeghan Fisher, BS, Fairmont State University, New Cumberland, WV; Kristy D. Henson, PhD, Fairmont State University, Fairmont, WV*

Learning Objectives: This presentation discusses the potential of using seasonal environment changes to determine skeletal weathering patterns. After attending this presentation, attendees will recognize seasonal changes to skeletal weathering patterns and how long the skeletal material was exposed to environmental factors.

Impact Statement: This presentation can assist when one encounters unknown skeletal remains by helping determine how long the skeletal material has been exposed to the elements based on weathering patterns.

Abstract Text: Human decomposition is complex and heavily influenced by weather and carrion activity.[1-4] Seasons affect postmortem intervals differently and once skeletonized, weather not only continues to alter the skeleton, it then becomes challenging to determine the time of death. Skeletal weathering can increase postmortem fracture risk and alter ante and perimortem skeletal trauma.[1] The objective of this study was to twofold, first to examine skeletal weathering during the four seasons in West Virginia; second to replicate seasonal changes in a controlled environment. Deer long bones were placed outside for 30 days for Spring, Summer, Fall, and Winter, and long bones were placed in a controlled indoor location setup to mimic each season for 30 days, including UV, precipitation, and temperature. All bones were macroscopically analyzed, completely skeletonized with dermestid beetles, then macroscopically analyzed again with longitudinal weathering fractures length and width recorded with digital calipers.

Results showed weathering fractures on 25% of winter, summer, and fall simulated samples and 75% of spring simulated samples. Longitudinal fracture size between simulated samples was not significantly different ($p = 0.52$). Control and simulated longitudinal fractures were significantly different ($p = 0.00004$), with larger fractures appearing in the simulated sample. Macroscopically, bones exposed directly to UV experienced bleaching and mummification in both the control and simulated samples. Control bones were exposed to invertebrates and mold growth, which did not affect the simulated samples. Seasonal changes were different but not significant. Because the simulated and control samples were significantly different, more data is needed to determine if one can use simulated weather environments to assist with PMI determination.

Y60 Investigating the Postmortem Degradation of Identifiable Fingerprint Minutiae Over Time

Emma L. Scheidt, BA, George Mason University, Oakton, VA; Sahar Rahman, BA, George Mason University, Fairfax, VA*

Learning Objectives: By the end of this presentation, attendees will be able to describe the process of postmortem fingerprint degradation and its relationship to decomposition stages, identify how the number of identifiable minutiae changes over time in postmortem samples, understand the methods used to collect and analyze fingerprints from a human donor in a research setting, and recognize the implications of fingerprint degradation for forensic identification in real-world casework.

Impact Statement: This research enhances understanding of how fingerprint quality degrades postmortem, providing valuable data that can improve postmortem interval estimates and support identification efforts in forensic casework. By documenting the decline in identifiable minutiae over time, this study contributes to developing more reliable standards for fingerprint analysis in deceased individuals, ultimately strengthening the accuracy and credibility of forensic identifications.

Abstract Text: Fingerprint identification is one of the most reliable and widely used methods of personal identification in forensic science due to the uniqueness and permanence of ridge patterns. In particular, minutiae are crucial in matching prints and confirming identity. However, after death, the decomposition process such as skin slippage can quickly degrade the outer epidermal layer where fingerprints are found, making it increasingly difficult to obtain usable prints. This study tracks the degradation of fingerprint quality in a postmortem context. A donor from the George Mason University Forensic Science Research and Training Laboratory was used for this study. Following the donor's placement in May 2025, postmortem fingerprints were collected daily using traditional ink pads and fingerprint paper until no viable prints could be obtained. Each print was then scanned and analyzed using the FBI's NIST biometric comparison tool to quantify the number of identifiable minutiae. Our results showed that by Day 5, there was a 76% decline in identifiable minutiae compared to Day 0. Even though fingerprints could be collected from this donor until day 8, the minutiae points were not sufficient for identification after day 5. These findings suggest a rapid decline in fingerprint viability following initial decomposition stages. Future research will expand the sample size and examine seasonal variations to better understand decomposition timelines related to fingerprints and improve postmortem identification through fingerprint analysis.

Y61 An Evaluation of DNA Recovery From Fingernails Post-Hair Washing

Alexia A. Cassman, BS, Sam Houston State University, Huntsville, NV; Tyra Volney, MS, Houston Forensic Science Center, Huntsville, TX; Tim Kalafut, PhD, Sam Houston State University, Huntsville, TX*

Learning Objectives: Attendees will learn how showering events impact the persistence of self and foreign DNA found under fingernails. They will understand the implications of foreign DNA under fingernail swabs in day-to-day context, which can then be used in a comparison to case work samples.

Impact Statement: This research adds to the forensic science community by evaluating the quality of foreign DNA found under fingernails as it relates to specific showering activities. The results of this study can be used in activity-level analysis of case contexts where the victim allegedly showered prior to some violent crime taking place. The general implications of this study broaden the knowledge of practitioners and researchers alike in activity-level research and more specifically in persistence and background levels of self and foreign DNA under fingernails.

Abstract Text: Traditionally, criminal investigations have focused on who was the source of DNA found at a crime scene. However, advances in sensitivity of analysis have shifted lawyers focus in court to how the DNA got to the crime scene. Questions concerning activity level analysis have caused a need to focus on the quality of profiles under various conditions associated with an activity rather than the mere recovery of DNA.

This study evaluated the persistence of foreign DNA under fingernails following showering and hair washing activities. Three events were studied in this experiment, showering and hair washing, showering only, and hair washing only. Volunteers were asked to swab one hand prior to the showering/hair washing activity, and then swab the other hand after. They recorded whether the dominant/non-dominant had was swabbed as the before or after sample. The participants collected replicate swabs from multiple events, and alternated the before/after swab each time relative to hand dominance. Analysis focused on the quality of self and foreign DNA found on samples taken before and after events. Foreign DNA was detected in 42% of the "before" fingernail samples (collected prior to the washing activity), with the majority (21 of 25) comprising one to three foreign alleles. There were four samples with seven or more alleles, with a maximum of 16 foreign alleles. These results suggest that while foreign DNA could be present under fingernails in a practical context as background DNA, the expectation is for the foreign DNA to be a trace level donor, contributing just a few alleles. Only 19% of the "after" samples showed foreign alleles, with only a single sample having more than seven alleles (15)

These results compare favorably with previous work, even though the DNA profiling kit used here is considered more sensitive than those from fifteen years ago.[1-3] The higher incidence of foreign DNA here (42%), compared to the <20% by Matte et al. and Cook and Dixon, may reflect the increased sensitivity of the current typing chemistry.[1,2] Dowlman et al. showed a similar incidence of foreign DNA (41%), but they noted a relatively high volunteer population with partners or children compared to the current study.[3] Overall, the quality of profiles in terms of number of foreign alleles is very similar in the current study compared to the three prior studies.

Results from this study are valuable in cases where showering and hair washing events occurred prior to a violent event, especially when the accused person and victim have spent time together. Data from this study can inform probabilities of recovering foreign DNA when a time-line matters as part of the activity level evaluation of the DNA findings, as well as contributing to the body of work on the recovery of DNA from fingernails in general.

Y62 Evaluating the Efficiency of Laundry Sanitizers on the Removal and Transfer of DNA in a Washing Machine

Nicole Agre, BS, University of Central Oklahoma, Edmond, OK; Rhonda Williams, PhD, University of Central Oklahoma, Edmond, OK*

Learning Objectives: After reading this poster, the viewer will have a more thorough understanding of the importance of DNA evidence on clothing and the steps that can be taken to attempt to erase DNA evidence. Furthermore, the viewer will learn about a new laundry product on the market, laundry sanitizers, and how this product affects DNA persistence and transfer while in a washing machine.

Impact Statement: This poster presentation will affect the forensic science community by offering data to fill a hole in the current literature in regard to laundry sanitizers. These laundry products have become increasingly popular in the past several years but have not been studied in their effectiveness on DNA evidence. Furthermore, this provides more data on the comparison between the conventional collection technique of swabbing and a newer technique, wet vacuuming.

Abstract Text: Articles of clothing are very important pieces of evidence in an investigation due to their potential for DNA evidence. This evidence can be potentially removed through washing. Despite these efforts, DNA can still persist on clothing even through the washing process.[1,2] Sometimes, this even results in DNA transferring to clean clothing in a washing machine.[2,3] There is some research on which parts of the washing process actually remove the most DNA. Variables such as higher water temperature, machine vs handing washing, the type of fabric, and added laundry products can lead to more DNA being removed from the piece of clothing.[2,4-6] There is a laundry product, laundry sanitizers, that have gained more popularity in the last several years. Laundry sanitizers have had little research conducted on how they would affect DNA persistence on clothing. It is hypothesized that laundry sanitizers will reduce the amount of DNA collected from cloth, but that wet vacuuming vs conventional swabbing will yield more DNA in collection.

In this research project, several worn T-shirts were washed with a variety of laundry sanitizers and then collected with either swabs or M-Vac™ wet vacuuming. The samples were then cut into thirds for analytical replicates, extracted, and quantified to see how much DNA was present after washing. It was found that the laundry sanitizers generally did well at removing DNA with most samples having very little DNA present. Other variables studied, such as brand of laundry sanitizer and set of directions followed, did not seem to have an effect on DNA persistence from preliminary data. The collection method did seem to have some effect, with the swabs collecting more DNA from the T-shirts. Laundry sanitizers also did well at their purpose of killing bacteria. Swabs from the collars of the T-shirts were streaked on agar plates, and there was little to no growth on the plates after incubation. DNA transfer was also studied in this experiment. Whole blood was placed on a washcloth and then washed with a pristine washcloth in a washing machine. The pristine washcloth was then collected using either a swab or wet vacuuming, cut into thirds for analytical replicates, extracted, and quantified to see how much DNA persisted and also transferred through the washing process. In this case, there were also fairly low levels of DNA present after the washing process. From preliminary data, variables such as brand did not seem to have an effect. The amount of blood put on the washcloth and the method of collection did seem to have an effect. In this experiment, the wet vacuuming seemed to yield more DNA than the swabbing. This information and knowledge can be used to provide context to investigators about the probability of collecting usable evidence from clothing if there are laundry sanitizers used on the evidence. This data can also be used to help select the best collection method when it comes to clothing and other porous substrates.

Y63 An Expanded Evaluation of XRD and SEM-EDS for the Characterization of Inorganic Particles in Eyeshadows

Taylin Naquin, Loyola University New Orleans, Violet, LA; Anna S. Duggar, PhD, Loyola University New Orleans, New Orleans, LA*

Learning Objectives: By engaging with this poster, attendees will recognize the forensic potential of cosmetics, particularly the inorganic particles present in eyeshadows, as a possible trace. They will see how multivariate statistical methods, applied to data collected from these samples using X-Ray Diffraction (XRD) and Scanning Electron Microscopy With Energy-Dispersive X-Ray Spectroscopy (SEM-EDS), help forensic scientists understand the individual and combined contributions of these techniques. Broadly, the presentation will build awareness of the extent to which these techniques can distinguish between manufacturers and shades through bulk and particle-centered analysis.

Impact Statement: This research advances the forensic evaluation of cosmetic trace evidence by applying XRD, SEM-EDS, and chemometric analysis. The findings support microscopy as a valuable tool for evaluating cosmetic transfer evidence and establish practical methods that may serve to strengthen future applications in casework.

Abstract Text: Cosmetics, those products applied to the body to enhance appearance, represent a potential form of transfer evidence. Prior research investigated the potential of the inorganic fraction of eyeshadows, particularly the mineral components present as pigments, shine, and fillers, as providing class characteristics that might identify manufacturer, color, or lot.

In that earlier research, inorganic particles of eyeshadow were isolated using a density separation, and the purified material was then characterized via a combination of powder X-ray diffraction (XRD) and microscopical examination using scanning electron microscopy with energy dispersive x-ray spectroscopy for elemental analysis (SEM-EDS). Results of this prior research, performed on a limited, closed set, were promising: when comparing across a set of four colors and two manufacturers, diffractograms showed visual differences between the two manufacturers. Comparison across colors was less discriminating, particularly in white and mauve shades.

This work expands upon those earlier findings by opening the set of manufacturers to five different companies, with palettes selected for visual similarities in color and to cover a range of price points. In addition to the expanded manufacturers, this research grew to include up to six colors on each manufacturer's palette. Multivariate analysis was applied, using the R statistics package and the RStudio interface to perform PCA, LDA, LOO-CV, and HCA cluster analysis, in order to determine the extent of the classifiability of the samples.

Results yielded from this expanded set provide information as to the limits of these methods: although the diffractograms obtained from a few of the manufacturers continued to be distinguishable, other manufacturers seemed less classifiable by XRD. SEM-EDS continued to provide opportunities for differentiation, both in morphology and elemental particle composition. Microscopic particles were often visually recognizable as coming from two different shades or two different manufacturers, and individual particles, even in similar shades, often demonstrated noticeable differences in elemental composition.

The results of this study provide a cohesive argument for the value of microscopy and microscopical analysis in the evaluation of cosmetic transfer evidence. The potential—and constraints—of XRD analysis on this sample set are quantitatively investigated and demonstrated. Additionally, a feasible method for collection of transferred cosmetic material for combined XRD and SEM-EDS analysis is proposed. A small number of short-term worn samples and two different lot numbers across one manufacturer were also evaluated as the foundation for future research.

Y64 An Analysis of Changes in Fingerprints Before and After Recent Death on Paper Documents Using Statistical and Technical Methods

Khalid Aldaoud, BA, Ministry of Interior KSA, Ar Riyad, Ar Riyad, Saudi Arabia; Zainab Almansoor, MS, Ministry of Interior, Ar Riyad, Ar Riyad, Saudi Arabia; Sara Alsubaie, MA, Ministry of Interior, Ar Riyad, Ar Riyad, Saudi Arabia*

Learning Objectives: Attendees will understand the morphological and structural changes that occur in fingerprints before and after death, be able to apply statistical methods to evaluate the reliability of fingerprint evidence on paper documents, and recognize the technical approaches used to analyze postmortem fingerprint changes in forensic investigations.

Impact Statement: This study highlights how fingerprints change after death, offering forensic experts improved methods for analyzing fingerprints on paper documents and enhancing the reliability of postmortem identification.

Abstract Text: This study aims to analyze the changes in fingerprints printed on paper before and after recent death, in order to directly determine whether a document was signed prior to or following death, and thus avoid forgery. The research was conducted on four individuals whose fingerprints were collected both before and immediately after death using ink (Sirchie ink pad). The fingerprints were then measured and compared using a comparison microscope, focusing on ridge thickness, ridge-to-ridge distances, skin desquamation, and pore visibility. Statistical analysis was performed using the paired-sample t-test to compare pre- and postmortem measurements, and Cohen's *d* test was applied to assess the scientific effect size of these differences.

The results revealed noticeable differences in ridge thickness and ridge-to-ridge spacing, with an increase in the degree of skin desquamation and no significant changes in pore visibility. Statistical analysis confirmed that the observed differences between pre- and postmortem fingerprints were not due to chance ($t = 2.19$, $p < 0.05$; Cohen's $d = 0.28$), indicating a small to moderate scientific effect.

This study demonstrates the presence of measurable postmortem changes in fingerprints, which may be utilized to verify the authenticity of documents and to determine whether they were signed before or after death. The findings highlight the importance of analyzing fine fingerprint details and ridge characteristics as a reliable forensic tool to prevent forgery and confirm the validity of legal documents.

Y65 The Development and Validation of an Analytical Method for the Determination of Stress Biomarkers in Hair

Brooke Fontaine, BS, John Jay College, New York, NY; Alexis A. Palma*, John Jay College of Criminal Justice, Woodside, NY; Marta Concheiro-Guisan, PhD, John Jay College, New York, NY*

Learning Objectives: Attendees will learn how cortisol, cortisone, and endocannabinoids can serve as sensitive biomarkers for stress in hair samples. This presentation will demonstrate the development and validation of a highly sensitive Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) method for the detection of these biomarkers in hair.

Impact Statement: This presentation will improve the forensic science community's ability to detect stress biomarkers in hair. This will allow for a long-term detection window with implications in various forensic and clinical settings.

Abstract Text: Chronic stress can lead to long-lasting health problems, such as anxiety, depression, and heart disease, among others.[2] The hormone cortisol and the endocannabinoids (lipid-based neurotransmitters) regulate the human stress response.[1,3] Hair is an ideal matrix to monitor stress biomarkers because it allows their evaluation for an extended time period, and it is not affected by circadian variations.[1] This study aimed to develop and validate an analytical method for stress biomarkers in hair. Due to the endogenous nature of cortisol, cortisone, and endocannabinoids, anandamide (AEA), 2-arachidonoylglycerol (2-AG), oleoylethanolamide (OEA), and palmitoylethanolamide (PEA), the analytical method was performed using surrogate analytes (13C-labeled or deuterated analogs). Different parameters were critically evaluated: snippets/hair powder, extraction methods, incubation (solvents, time, temperature), hair amount, and reconstitution solvents. The best procedure employed 20 mg of pulverized hair, and an incubation in 1 mL of methanol:acetonitrile (75:25) in an ultrasound at 55°C for 2h. The extract was evaporated, reconstituted in 200 µL 0.1% formic acid water:acetonitrile (70:30), and analyzed by Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS). The chromatography separation used a reversed-phase column in gradient mode, and 0.1% formic acid in water and methanol as the mobile phases. ESI operated in positive and negative modes, and two MRM transitions were monitored per compound. The method showed good linearity, 1-500 for 13C3-cortisol and cortisone, 10-500 for AEA-d_4, 20-500 for 2-AG-d_5, and 100-20,000 pg/mg for OEA-d_4 and PEA-d_5. Imprecision and bias (n=15) were < 17.5% and from -16.2% to 5.2%, respectively. No matrix effect (n=10, CV< 20%) was detected for cortisol and cortisone (3-14%). However, all endocannabinoids showed ion suppression (-84 to -95%). Extraction efficiency ranged from 70 to 100%, and process efficiency from 5 to 80%. Extracts were stable in the autosampler (10°C, 24h), and no exogenous interferences or carryover were observed. A sensitive and specific method for determining cortisol, cortisone, and four endocannabinoids in hair was developed and validated. Using 20 mg, the method achieved a limit of quantification of 1 to 100pg/mg, depending on the compound. This method will be used to monitor stress biomarkers in high-risk and cannabis user pregnant women (n=137).

Y66 A Forensic Approach to the Identification and Interpretation of Intimate Partner Violence (IPV) in Human Skeletal Remains

Catarina A. Vazquez, Tulane University, San Marcos, TX*

Learning Objectives: Attendees will: (1) develop a general understanding of IPV-associated trauma patterns found in the clinical literature and specific skeletal injuries that are most common in IPV cases; (2) recognize the expansive potential of applying IPV clinical data to identify and interpret trauma in deceased individuals; (3) learn about a proposed method for identifying IPV in skeletal death investigations, including how the system was developed and evaluated; and (4) learn how to apply this method to forensic anthropology cases and other casework that relies on skeletal analysis

Impact Statement: While several existing studies have attempted to establish IPV fracture patterns in living individuals through radiological reports and differentiate between injuries caused by accidents or abuse, it is unknown if IPV injuries can be identified in human skeletal remains. This project uses an osteological approach to address this gap in the field by applying clinical IPV patterns to donated human remains and developing a system to assist with identification of IPV in this specific context. This research aims to enable medicolegal experts, including forensic anthropologists, to create a more complete picture of the life histories of unidentified individuals, which can be instrumental in determining whether abuse may have played a factor in forensic cases when experiences with gendered violence are unknown.

Abstract Text: Intimate partner violence (IPV), which encompasses physical violence, sexual violence, stalking, and psychological abuse that occurs in intimate and romantic relationships, is a global issue that disproportionately affects women and is the leading cause of femicide worldwide.[1,2] Clinical researchers have established and published IPV physical trauma patterns by documenting associated injuries including lacerations, contusions, and fractures to better aid in identification of IPV victims.[3] While IPV physical injury screening is now common-practice in many hospitals, less information is known about the possibility of expanding the application of these injury patterns to identify IPV victims postmortem, specifically in cases where individuals are skeletonized. This study investigates the translatability and potential value of applying IPV clinical data to human skeletal remains by developing a weighted scoring system based on IPV-associated fracture frequencies that are reported in the clinical literature. This system was used to score 43 female donor skeletons of reproductive age at the Texas State Donated Skeletal Collection in San Marcos, Texas in July 2025 for evidence of IPV-associated fractures. Additionally, the reliability of this system was evaluated through interobserver statistical analysis on a subset of the sample. By comparing the fracture and abuse prevalence rates in the sample with those presented in the clinical literature, this study will illustrate that clear IPV skeletal injury patterns exist, and will present a method with the potential to improve our ability to identify skeletonized IPV victims in forensic contexts.

Y67 Postmortem Predators: Identifying and Tracking Scavengers of Remains in a Northwest European Context

Sarina Riechmann, MSc, University of Central Lancashire, Preston, England, United Kingdom*

Learning Objectives: After attending this YSFS poster presentation, attendees will understand the impact of vertebrate scavengers on human remains in Northwestern Europe. Attendees will learn how scavengers in this region alter surface-deposited human analogs through tissue destruction, Bone Surface Modification (BSM), and spatial distribution within simulated but realistic forensic contexts. Furthermore, attendees will recognize the differences in scavenging behaviors among species from the Felidae, Canidae, and Accipitridae families, influenced by factors such as season, environmental region, and whether the populations are captive or wild.

Impact Statement: This YSFS poster presentation will impact the forensic science community by informing about: (1) the applicability of captive-based scavenging studies in wildlife enclosures to real-world forensic scenarios involving crime scenes; and (2) the potential to develop models that identify northwestern European scavengers, from family to species level, and associate their BSMs with spatial dispersal patterns in order to predict human remains' dispersal and location. These predictive, family-specific models aim to improve search strategies and recovery operations in cases of homicide, disaster, suicide, or missing persons. Ultimately, this work supports both forensic casework and broader humanitarian efforts

Abstract Text: Scavenger interactions with human remains complicate forensic investigations. Animals may unintentionally but actively destroy remains, disrupt decomposition, and alter post-mortem interval (PMI) estimates.[1-4] Some animals may even scatter, relocate, cache, or hoard remains, which can prolong search efforts, cause incomplete recoveries, and negatively affect investigation, victim identification, and family closure.[1-13] Despite this, current research in this field largely relies on non-European data and non-human cadavers, limiting its applicability to European forensic casework.[8] Focused research into scavenger interference with human remains, particularly patterns of bone surface modification (BSM) and spatial distribution, in a Northwestern European context is needed to address geographical gaps and support law enforcements. This YSFS poster presentation introduces an ongoing doctoral research project addressing this gap, outlining its aims, methodology, and preliminary results. The research proposes that scavenging by animals follows identifiable sequences, leaving distinct BSM and spatial distribution patterns that can be modeled to guide forensic operations. To test this, research was conducted at wildlife sanctuaries and the Taphonomic Research in Anthropology: Centre for Experimental Studies (TRACES), a 13-acre animal taphonomy facility at the University of Central Lancashire (UCLan), United Kingdom. Research used surface-deposited small animal and whole deer carcasses as human analogues, monitored scavenger activity with remote camera traps across seasons and habitats, incorporated Geographic Information System (GIS) analysis software to map spatial dispersals, and employed 3D Keyence microscopy in combination with GIS analysis software to characterize BSMs. Research compared scavenging behaviors between captive and wild felids, canids, and raptors to: (1) evaluate captive-to-wild applicability, and (2) develop models linking BSMs and dispersal patterns to scavenger families. At TRACES, scavenger activity was influenced by environmental factors like habitat. Open areas experienced increased carcass scattering and scavenger visits than forested areas. At wildlife sanctuaries, species-specific behaviors were evident: Scottish wildcats often relocated remains to elevated or hidden sites, suggesting caching; Arctic foxes occasionally scattered remains across multiple sites, demonstrating competitive scavenging and hoarding; Steppe eagles rarely scattered remains, exhibiting competitive scavenging and localized feeding. Scavenging behavior, particularly involving carcass scattering, appeared to be influenced by scavenger species, carcass mass, environment, feeding history, and social structure. Smaller carcasses were scattered over greater distances, likely due to their lighter weight, allowing broader territorial distribution, especially in species like wildcats and foxes. Larger carcasses were scattered less and remained more localized, likely due to their heavier weight and associated energetic transport cost, aligning with the optimal foraging theory that proposes that animals balance energy expenditure with energetic gain when making foraging decisions.[14-16] Despite species-specific differences, all fully consumed provided carcasses, left minimal remnants, and showed limited investigatory behavior, likely influenced by captivity. Overall, this research supports the hypothesis that scavenging patterns are identifiable and family-specific, linking scavenger identity to anatomical targeting, BSM types, and dispersal patterns. Insights explore scavenging dynamics, evaluate captive-to-wild applicability, and contribute to predictive models that link BSM and dispersal patterns to scavenger families, aiding contextualization and recovery of surface-exposed human remains in European forensic casework.

Y68 Attempting More Detailed Discrimination of Plants Using Next-Generation Sequencing

Ryuta Nakamura, MS, National Research Institute of Police Science, Kashiwa, Chiba, Japan; Hitomi S. Kikkawa, PhD, National Research Institute of Police Science, Kashiwa, Chiba, Japan; Koichiro Tsuge, PhD, National Research Institute of Police Science, Kashiwa, Chiba, Japan*

Learning Objectives: This presentation verifies the extent to which plant discrimination is possible using Next-Generation Sequencing (NGS). By conducting Sanger sequencing and NGS on plants of the genus *Eupatorium*, we demonstrated that NGS enables species identification within this genus, which is difficult with Sanger sequencing. Although individual discrimination proved difficult due to factors like clones, the potential for habitat discrimination was indicated. Therefore, NGS is expected to be effectively utilized for more detailed analysis of plants.

Impact Statement: This study demonstrates the potential for NGS to be effectively utilized for more detailed discrimination of plants. Even for plant groups that are difficult to discriminate at the species level using Sanger sequencing, NGS enabled species and habitat discrimination.

Abstract Text: Plant fragments, including leaves and seeds, may be left at crime scenes and serve as evidence. In Japan, current forensic analysis involves morphological observation and DNA analysis using Sanger sequencing to discriminate between individuals and identify at species level. Meanwhile, recent advances in plant taxonomy utilize NGS to perform analyses using extensive DNA information, revealing phylogenetic relationships beyond the species level.[1] This approach may enable the discrimination and identification of forensic samples that were previously difficult to discriminate. Furthermore, it may be possible to obtain information more detailed than species level, such as where the plant grew or which individual it originated from. Therefore, this study aimed to explore the extent to which plant identification—including species identification, habitat identification, and individual identification—is possible through NGS analysis. Therefore, this study aims to investigate how far down the levels—such as species, habitat, and individual—can be discriminated by NGS.

The sample species was *Eupatorium* (Asteraceae). This genus is a plant group that can serve as forensic evidence, growing throughout Japan in various environments from plains to mountainous regions. We collected samples from specimens growing in botanical gardens and wild individuals, and we performed species identification based on collection sites and morphology. We selected representative samples of each species and performed Sanger sequencing targeting *rbcL* region, *matK* region, *psbA-trnH* region on chloroplast DNA, and the ITS region on nuclear DNA.[2,3] Additionally, we selected representative samples for the purpose of distinguishing between species, habitats, and individuals, and conducted NGS. For NGS library preparation, we used MIG-seq method.[4] Based on the analysis results, we verified the extent to which species, habitat, and individual identification is possible.

As a result, Sanger sequencing of chloroplast DNA revealed few mutations in any region, making species identification difficult. Compared to chloroplast DNA, nuclear DNA showed higher mutation rates, enabling identification of some species. However, identification was not possible for varieties and some other species.

NGS using MIG-seq method enabled species identification in the majority of samples. Focusing on habitats, discrimination was possible between populations from regions that were sufficiently distant and clearly distinguishable. Regarding individual discrimination, highly similar results were obtained between samples from the same origin, such as leaves collected from the same individual or leaves collected from the same pot in different years. However, in some cases, samples from different origins sometimes yielded similarly very close analysis results. This is presumed to be due to the base sequences being so similar, possibly due to clones, that they could not be distinguished. Therefore, even for samples yielding very close results, it is considered difficult to conclude they originated from the same individual. Conversely, samples with clearly different analysis results can be considered to have originated from different individuals. From the above, NGS using MIG-seq method enabled species discrimination in plant groups that could not be discriminated by Sanger sequencing and demonstrated the potential for habitat discrimination. Therefore, this method is expected to be effectively utilized for plant analysis.

Y69 Unveiling the Interference of Alcohol Intoxication on Salivary Detection of Codeine: A UV/Vis Spectroscopic Insight

Danae Alvarez, University of Texas at El Paso, El Paso, TX; Madison A. Carrillo*, University of Texas at El Paso, El Paso, TX; Hamidreza Sharifan, PhD, University of Texas at El Paso, El Paso, TX*

Learning Objectives: (1) identify how methanol (as a model for alcohol intoxication) alters the spectroscopic detection of codeine in saliva samples; (2) explain the relationship between increasing methanol concentrations and the decrease in codeine recovery rates using Ultraviolet/Visible (UV/Vis) spectroscopy; (3) evaluate the potential matrix effects or chemical interactions between alcohol and codeine that contribute to signal suppression in spectrophotometric analysis; (4) improve the interpretation of saliva-based toxicology results in forensic and clinical cases involving alcohol consumption; and (5) recognize the importance of considering interfering substances (alcohol) in the reliability of drug testing and forensic toxicology protocols.

Impact Statement: This finding indicates that alcohol interferes with the spectroscopic detection of codeine, providing a clear indication that there should be a consideration of alcohol consumption when interpreting saliva-based drug tests. The outcome highlights the importance of accounting for intoxication levels to prevent false negatives and ensure accurate case evaluations.

Abstract Text: This study examines the impact of methanol on codeine detection using UV/Vis spectroscopy, arguing that methanol significantly alters absorbance readings and compromises the reliability of results in both routine drug screenings and postmortem toxicological analyses. The detection of codeine accurately in saliva is critical for forensic and clinical applications, yet the presence of alcohol at intoxication levels may impact the reliability of these tests increasing false negatives. The study focuses on the interaction between saliva and codeine in the presence of alcohol and the purpose is to determine how solvent type and concentration affect codeine's chemical stability. Ultraviolet/visible (UV/Vis) spectroscopy is used as a rapid detection method as the results provide a dose-response correlation, reporting an inversely proportional relationship between alcohol concentrations and the codeine recovery rate, which is being reduced. Specifically, codeine recovery dropped from approximately 35% to less than 10% as the alcohol dose increased from 5 ppm to 25 ppm. This finding indicates that alcohol interferes with the spectroscopic detection of codeine, providing a clear indication that there should be a consideration of alcohol consumption when interpreting saliva-based drug tests. The outcome highlights the importance of accounting for intoxication levels to ensure accurate forensic toxicology assessments and case evaluations.

Y71 Homicide by Hot Dog: Choking in the Setting of Blunt Force Trauma of the Jaw by Another

Reece Foehr, BS, Saint Louis University School of Medicine, St Louis, MO; Kayden Hadlock, BS, Saint Louis University School of Medicine, Saint Louis, MO; Katie Hanson, MD, St Louis City Medical Examiner's Office, St Louis, MO*

Learning Objectives: After attending this presentation, attendees will be able to: (1) differentiate between cause and manner of death by examining how forensic pathologists distinguish accidental from homicidal deaths, particularly in complex cases involving delayed complications; (2) understand the role of contributory injuries in certifying manner of death, with a focus on how non-lethal trauma can create conditions that lead to fatal outcomes; (3) analyze the impact of volitional acts of harm (regardless of intent to kill) on the determination of homicide in medicolegal death investigations; (4) apply forensic pathology principles to real-world cases by evaluating how pre-existing injuries, intoxication, and anatomical factors can interplay in fatal choking incidents; and (5) identify key autopsy findings and investigative elements that support certification of homicide in cases with delayed or indirect mechanisms of death.

Impact Statement: This presentation will enhance the forensic science community's understanding of how seemingly accidental deaths may, upon deeper investigation, meet the criteria for homicide. By examining a complex case in which a prior assault directly contributed to a fatal choking event, attendees will gain critical insight into the nuanced decision-making process involved in determining manner of death. The presentation reinforces the importance of thorough case histories, multidisciplinary collaboration, and contextual analysis in forensic pathology. It will ultimately support more accurate death certification, promote consistency in medicolegal investigations, and contribute to the pursuit of justice in cases where the causal chain of death is indirect but legally significant.

Abstract Text: Certifying a death as homicide as opposed to an accident carries significant weight, and many factors come into play for a forensic pathologist to be pushed one way or another. While often a major component, intent to cause death is notably not a requirement to certify a death as a homicide. Rather, there may solely exist a volitional act committed to cause harm or fear.

We present the unusual case of a 49-year-old found choking in the hallway of his apartment. Emergency medical personnel attempted to intubate and found nearly an entire hot dog in the airway. The hotdog was removed, but after failed resuscitation attempts, the decedent was pronounced dead at the hospital. What may have seemed like a straight forward case of choking on a food bolus took an interesting turn when it was discovered that the decedent had visited the emergency department the day prior for an apparent assault at a fast food restaurant. During the altercation, he sustained fractures to the orbital floor, nasal bone, and a displaced fracture of the mandibular ramus. The decedent was advised to adhere to a soft chew diet and no further medical treatment was required at the time.

A full autopsy was performed including external exam, internal exam and toxicology. On external exam, the decedent was found to be edentulous and review of records revealed he was not wearing dentures at the time of the choking incident. During the internal exam, a partial facial peel was performed to visualize the broken jaw. A complete fracture of the mandibular ramus was discovered. Additionally, toxicology revealed the decedent to have a blood ethanol level of 102 mg/dL.

The cause of death was determined to be asphyxiation due to mechanical obstruction of the airway. The manner of death was more difficult to determine. Asphyxiation is a common cause of accidental death associated with acute alcohol intoxication especially in the case of the decedent who did not have teeth. However, it was determined that the inability to tolerate solid food in this decedent who had been recently assaulted met the burden of proof for homicide given the clear volitional act of harm directly contributing to the decedent's death.

Homicide; Asphyxiation; Volition

Y72 Deadlining: Gentrification and the Spatial Forensics of Missing and Murdered Black Women in Washington, DC

Avery E. Bernard Johns, BA, Howard University: Humanities and Social Sciences Scholar, Washington, DC*

Learning Objectives: By attending this session, participants will learn how to use spatial forensic analysis with ArcGIS and heat-mapping codes to identify geographic crime patterns in unsolved cases. The session will demonstrate how spatial analysis can be employed to map gentrification as a significant investigative factor, highlighting how structural changes can distort case resolutions and contribute to a disproportionate number of missing and murdered individuals, particularly among different racial groups. Using Washington, DC, as a case study, attendees will examine how geography, race, and systemic neglect shape both patterns of victimization and the resolution of cases. Attendees will gain access to a publicly available database and interactive map created for this research, providing them with practical tools to explore unsolved case data and visualize the effects of displacement and social exclusion, to see if the data is representative in their areas.

Impact Statement: This presentation strengthens competence in the forensic sciences by addressing a critical research gap: the failure to account for gentrification as a primary spatial factor shaping disappearance and femicide. That competence is operationalized through a publicly accessible database and interactive mapping tool, representing one of the first systematic efforts to integrate spatial forensic methods with the study of gentrification, while also addressing underreported populations by providing a resource to help identify and locate individuals who might otherwise remain invisible in official records. The impact on the field is the provision of transferable methods and open-access resources that expand investigative capacity, enable comparative research across jurisdictions, and advance the evidentiary foundations needed for systemic reform.

Abstract Text: As gentrification restructures the demographics of urban spaces, geo-spatial forensic analysis indicates that the preexisting majority population, most critically Black female populations, exhibit disappearance and unresolved homicide rates several times higher than predicted by baseline demographic proportions. This overrepresentation constitutes a disparity beyond what population share alone can account for. Existing scholarship rarely employs geo-spatial forensics in studying violence against missing and murdered black women, who make up the second most murdered population in the country, instead linking risk to socioeconomic disenfranchisement or firearm access.[1-3] Such reliance on aggregate data equates violence with "Black spaces," obscuring the evidentiary fact that disproportionate victimization exists in gentrified, predominantly white geographies.

To address this gap, the objective of this study is to apply forensic geo-spatial analysis to test whether spatial restructuring through gentrification serves as a structural driver of disproportionate disappearance and homicide rates among Black women, beyond what demographic proportions predict.

This study applied a mixed-methods design integrating historical-structural analysis and geo-spatial forensics to examine how gentrification in Washington, DC, (1960s–2025) shaped disappearance and homicide outcomes for Black women. A literature review grounded in social exclusion theory framed risk as a structural product of displacement, fractured surveillance, and institutional neglect. ArcGIS layered Census demographics, NCRC displacement reports, and Urban Institute data to measure population change, displacement risk, and income shifts. A custom Google Maps heat map, coded in JavaScript, CSS, and HTML, visualized the disappearance and homicide cases with case-level details. The study observed outcomes with demographic baselines to identify disproportionality, baseline deviations, and clustering in high-displacement zones.

This study concludes that gentrification functions as a measurable determinant of violence against Black women in Washington, DC. Disproportionate risk emerges not in historically Black neighborhoods but in gentrified White spaces, where disappearance and homicide outcomes exceed demographic expectations. These findings reframe violence as a structural outcome of displacement and demographic restructuring, rather than a consequence of population density.

The results demonstrate that gentrification in Washington, DC, has fundamentally altered baseline expectations for disappearance and homicide outcomes among Black women. Between 2000 and 2013, the city experienced the most intense gentrification in the nation, displacing more than 20,000 Black residents.[4] In the Southeast, where Black women represent the most significant population share, absolute case counts remain the highest, but proportional disparities are relatively low. By contrast, in gentrified quadrants with smaller Black female populations: Northeast, Northwest, and Southwest, disappearance and homicide outcomes rise disproportionately above demographic baselines, with overrepresentation clustering in high-displacement zones.

The significance of this study lies in demonstrating that geo-spatial forensic analysis provides measurable evidence of how gentrification produces disproportionate risks of disappearance and homicide for Black women. By moving beyond theoretical frameworks that describe violence without evidencing its structural imprint, this work establishes geo-spatial forensics as a critical method for identifying and visualizing zones of elevated vulnerability, an approach with direct implications for improving case visibility, investigative prioritization, and ultimately case outcomes for missing and murdered women of color.

Y73 Identification of Ignitable Liquids in the Post-Fire Carpet Debris by Complementary GC/MS and DART-MS Methods

Mikayla Miles, BS, Middle Tennessee State University, Murfreesboro, TN; Shruthi Perna, PhD, Middle Tennessee State University, Murfreesboro, TN; Ngee Chong, PhD, Middle Tennessee State University, Murfreesboro, TN; Mengliang Zhang, PhD, Ohio University, Athens, OH*

Learning Objectives: Attendees will learn the practical use and complementary nature of DART-MS when paired with Gas Chromatograph/Mass Spectrometry (GC/MS). Furthermore, they will also learn about the utilization of headspace extraction for the cryogenic preconcentration of volatile constituents from residual carpet materials collected after fires. The headspace chemical profiles of carpet samples collected under normal combustion and oxygen-deficient thermal weathering conditions are compared.

Impact Statement: This presentation will demonstrate how DART-MS can be applied alongside longstanding methods such as GC/MS to enhance the analytical results of fire debris. By combining the GC/MS dataset of volatile constituents with m/z < 300 and the DART-MS data of minimally volatile compounds within the m/z range of 300-1000 amu, the more comprehensive chemical profiles of the Ignitable Liquids (ILs) can be generated for arson investigations. In addition, it will highlight the benefit of headspace extraction for circumventing the matrix interferences during the mass spectrometric analysis burned carpet materials.

Abstract Text: During an accelerant-induced fire, oxidative combustion of exposed combustible materials, such as wood, carpet, or paper, occurs and degrades the hydrocarbons essential for the identification of ignitable liquids (ILs). Once a fire occurs, a canine alert system is used to detect accelerants, with a positive alert warranting the use of GC/MS to analyze the arson debris and to identify specific classes of ILs typically used in arson cases, such as gasoline or paint thinner. Preliminary results have shown the degradation of the hydrocarbons during oxidative combustion of carpet material but have also indicated the preservation of hydrocarbons with different degrees of weathering in ignitable liquids in unexposed carpet material. It is suspected that ILs can seep under heavy objects or furniture, and due to oxygen deficiency, vaporization and pyrolysis processes can occur without combustion, preserving most of the hydrocarbons in ILs.

The goal of our research is to highlight the distinctions between exposed, burned carpet material and unexposed, thermally affected carpet material subjected to weights to simulate the heavy objects or furniture, such as bookshelves, filing cabinets, or bed posts. The weights used are a stack of paver stones that will be placed on the carpet, leaving half of the carpet piece exposed. The carpet samples will be sprayed with ILs, like gasoline, paint thinner, diesel, or lighter fluid, and a controlled burn will be conducted. After the burn, the exposed and unexposed portions of the carpet will be prepared using headspace and solvent extraction modes for complementary analysis with GC/MS and direct analysis in real time mass spectrometry (DART-MS).

In preliminary results[1], the analysis with DART-MS utilized Solid Phase Microextraction (SPME) techniques for the extraction of the ILs present in fire debris, but it was found that SPME introduced sources of variability into the experiment, including temperature and position of the SPME fiber in the DART-MS helium stream. The temperature range of 120-150°C was necessary for extracting less volatile compounds; however, this also degraded the SPME fiber at a faster rate. To ensure the position remained fixed, a custom SPME holder was required to maintain it at a specific depth in the helium gas stream. To reduce variability seen in SPME, we are evaluating alternative headspace sampling methods. The results have also shown that less volatile characteristic compounds from ILs were recovered and matched well with IL samples analyzed with DART-MS.[1] The SPME-DART-MS approach yields mass spectra that show the prominent soft ionization of high proton affinity compounds such as ethylene glycol ethers and polyisobutylene succinimides, which are minimally volatile compounds found in some ILs, in sharp contrast to the dominant volatile compounds observed only in GC/MS. The use of headspace sampling for GC/MS can highlight the more volatile and characteristic components of ILs and help in the identification of ILs. The objectives of our research are to explore the feasibility of headspace extraction for the identification of ILs and to evaluate the complementary nature of GC/MS and DART-MS for arson investigations.

Y74 A Preliminary Study on How Shooting Distance and Lens Focal Length at Crime Scenes Affect Footwear Impression Examination

Wen-Chung Chen, Criminal Investigation Bureau, Taipei City, Taipei, Taiwan; Kuo-Lan Liu, PhD, Police Department of Taichung City Government, Taichung City, Taichung, Taiwan; Min-Neng Hsu, PhD, Criminal Investigation Bureau, Taipei City, Taipei, Taiwan*

Learning Objectives: Using a zoom lens commonly carried by scene investigators and simulating practical shooting distances within typical scene environments, this study examines how shooting distance and focal length may affect the dimensional accuracy of footwear impression photographs. The aim is to raise awareness of these photographic parameters, ensure accurate image capture at crime scenes, and improve image quality to facilitate subsequent footwear comparison and examination.

Impact Statement: When sufficient space is available at the crime scene, footwear impressions should be photographed using a longer focal length (70 mm or above) and a greater shooting distance (80 cm or more). Under these conditions, the resulting images yield higher dimensional accuracy and better frame coverage of the impressions. During subsequent footwear examination, when the scene images are enlarged to their natural size, the dimensional discrepancy compared with the standard impressions generated from the suspect's shoe outsole is minimal, which is advantageous for comparison. Additionally, the scale embedded in the scene image can be evaluated against a standard reference scale. If the difference between the two is small (with a maximum deviation of less than 0.1 cm), it indicates that the scale in the scene image is accurate, further supporting reliable footwear analysis. However, in situations where space is restricted—such as when the shooting distance is less than 40 cm, for example, footwear impressions on car seat cushions—photography alone is insufficient. In such cases, the impressions should also be collected using adhesive lifting film or an electrostatic dust lifter to facilitate subsequent comparison. To ensure optimal image quality when photographing footwear impressions, investigators should use a tripod, position an L-shaped scale, and capture the image vertically. This approach produces higher-quality scene photographs. In this study, a zoom lens commonly carried by crime scene personnel was used to simulate practical shooting distances. The effects of shooting distance and focal length on the dimensional accuracy of footwear impression images were analyzed. The findings are intended to raise awareness of these photographic parameters, help investigators properly capture footwear impressions at crime scenes, and improve image quality to support accurate forensic comparison.

Abstract Text: In crime scene investigations, footwear impressions are among the primary types of evidence searched for and collected by forensic personnel. In recent years, investigators have employed linear light sources to detect latent footwear impressions and use these impressions to associate suspects with crime scenes or link serial cases. As a result, footwear evidence has played a significant role in judicial investigations and prosecutions. In addition to identifying potential suspects, the location, number, and orientation of footwear impressions at a scene can help infer the number of offenders and reconstruct their movement paths within the crime scene.

Methods for collecting footwear impressions at crime scenes include photography, electrostatic lifting, adhesive lifting, and casting with dental stone. Among these, photography is the most commonly used method by crime scene investigators in Taiwan. The photographed impressions are submitted to the agency for examination. The primary techniques for footwear impression comparison are side-by-side comparison and superimposition. Both require enlarging the crime scene footwear image to its natural size and using the scale included in the photograph as a reference, followed by comparison with the standard footwear impressions produced from a suspect's shoe outsole pattern. This underscores the critical importance of photographic quality in footwear impression comparisons.

However, the shooting distance and lens focal length used during photography may affect the accuracy of the scale, and insufficient scale precision can compromise the reliability of pattern comparison. This study analyzes the degree of dimensional variation in footwear impression images captured under different shooting distances and focal lengths. The findings indicate that when the shooting distance is 80 cm or greater and the focal length is 70 mm or above, the discrepancy between the photographed footwear impressions and the corresponding standard outsole patterns is less than 0.1 cm, demonstrating minimal dimensional error under these shooting conditions. Conversely, when the shooting distance is 40 cm or less and the focal length is 24 mm, the discrepancy is 0.3 cm or greater, exceeding the pattern differences typically observed between footwear half-sizes (0.3 cm). This suggests that such photographic conditions may produce dimensional inaccuracies sufficient to create ambiguity regarding footwear size.

Using a zoom lens commonly carried by scene investigators and simulating practical shooting distances within typical scene environments, this study examines how shooting distance and focal length may affect the dimensional accuracy of footwear impression photographs. The aim is to raise awareness of these photographic parameters, ensure accurate image capture at crime scenes, and improve image quality to facilitate subsequent footwear comparison and examination.

Y75 Would You Like Fries With That? A Case of Fatal Asphyxia Due to Food Bolus Airway Obstruction in the Setting of Xylazine and Fentanyl Intoxication

Kayden Hadlock, BS, Saint Louis University School of Medicine, Saint Louis, MO; Reece Foehr, BS, Saint Louis University School of Medicine, St Louis, MO; Katie Hanson, MD, St Louis City Medical Examiner's Office, St Louis, MO*

Learning Objectives: By the end of this presentation, attendees will be able to: (1) identify the mechanisms by which Central Nervous System (CNS) depressants such as fentanyl and xylazine suppress protective airway reflexes, predisposing individuals to fatal choking events; (2) describe the forensic approach to investigating suspected asphyxial deaths, including scene findings, autopsy features, and toxicology results; and (3) recognize the importance of considering polysubstance intoxication in the differential diagnosis of unexpected food-related airway obstruction deaths.

Impact Statement: This presentation highlights an unusual mechanism of drug-related death—fatal airway obstruction from food bolus aspiration in the context of fentanyl and xylazine intoxication. By emphasizing how CNS depressants can suppress protective airway reflexes, this case broadens awareness of atypical presentations of opioid-related fatalities. It underscores the need for careful scene investigation, thorough autopsy, and toxicologic correlation in determining cause and manner of death. For the forensic science community, these findings reinforce the importance of recognizing polysubstance effects beyond classic respiratory depression, ultimately improving death certification accuracy and public health surveillance.

Abstract Text: Asphyxial deaths can be challenging to investigate. Generally, sober and neurologically intact adults do not choke to death and therefore explanations for their deaths must be found. Some event must have overridden the normal swallow and gag reflexes that would have prevented a fatal asphyxiation.

We present the case of an asphyxial death due to choking on an impressively large food bolus in an initially unknown decedent. A 40-year-old male was found unresponsive at a park by lawncare workers. When emergency medical personnel arrived, no resuscitative efforts were performed due to the obvious signs of death which included the stiff cold nature of the decedent and lividity. No signs of traumatic injury were observed. On the scene an empty box of French fries and fast food bag were observed along with the individual's backpack and blankets. It was noted that several French fries were located in the decedent's mouth. No evidence of illicit drugs or paraphernalia were present at the scene.

A full autopsy was performed including external exam, internal exam and toxicology. During the internal exam a large food bolus of partially chewed food matter consistent with French fries was found extending from the upper airway including the mouth down to the right and left mainstem bronchi. The stomach contained about 1000 mL of partially digested food matter. When the toxicology results returned the blood was positive for xylazine (detected) and fentanyl (9.3 ng/ml.

Drug intoxication is the most significant contributor to deaths caused by unintentional injury and is the leading cause of preventable death for all age groups over the last 11 years. Opioid overdoses have rapidly increased over the past decade and contribute to these alarming statistics. Typically, a death from CNS depressants is due to respiratory depression and eventual apnea. However, these drugs can suppress protective reflexes such as the cough and gag reflex, increasing the risk of aspiration or airway obstruction. Acute ethanol is the most common intoxicant underlying choking deaths, however other depressant substances are occasionally responsible, as this case illustrates. The decedent maintained the ability to eat food while intoxicated with multiple CNS depressants most notably xylazine and fentanyl. His intoxication likely diminished his protective reflexes, leading to his airway being obstructed by French fries.

The cause of death was determined to be asphyxia due to upper airway obstruction due to food bolus. The manner of death was determined as accidental.

Y76 Microbial Succession in Clothed Remains: Forensic Insights into Postmortem Interval Estimation

Brittney Sylvester, Southern University at New Orleans, New Orleans, LA; Latavia Williams, Southern University at New Orleans, New Orleans, LA; Lewis Burnett, Southern University at New Orleans, New Orleans, LA; Alyssa Lavasseur, Southern University at New Orleans, New Orleans, LA; Georgia A. Williams, MS, George Mason University, Manassas, VA; Meiko Thompson, PhD, Southern University at New Orleans, New Orleans, LA*

Learning Objectives: Attendees will learn how clothing alters decomposition and microbial colonization, enabling them to compare microbial succession patterns across oral, abdominal, and rectal sites in a clothed model. Ultimately, they will be able to evaluate the potential of microbial community data to improve Postmortem Interval (PMI) estimation for clothed remains, a critical context in forensic investigations.

Impact Statement: This work will contribute to forensic science by expanding microbial succession studies to include clothed remains, which are frequently encountered in forensic casework. The results may strengthen the reliability of microbial community data as a tool for PMI estimation and help forensic practitioners interpret decomposition in real-world scenarios.

Abstract Text: Clothing is a frequently encountered variable in forensic recovery contexts that can alter the progression of decomposition by retaining moisture, modulating temperature, and acting as a barrier to insect access.[1] While microbial succession has emerged as a powerful and reliable tool for estimating the postmortem interval (PMI), the specific influence of textile coverings on this microbial colonization remains poorly characterized.[2] This gap in knowledge limits the application of microbiome-based models to clothed remains, which represent a significant portion of forensic casework. The objective of this study was to characterize and compare microbial succession patterns across key anatomical sites in a clothed decomposition model to assess its impact on PMI estimation.

This research was conducted at the George Mason University Body Farm during the summer of 2024. A domestic pig (*Sus scrofa domestica*) carcass, dressed in a standard clothing ensemble, was placed on the soil surface under natural environmental conditions. To capture a comprehensive view of the decomposition microbiome, swab samples were systematically collected from three anatomical cavities: the oral, abdominal, and rectal cavities. Sampling was performed daily for the first 21 days, transitioning to a weekly schedule until July 24, 2024. All collected samples were immediately preserved at -80°C to ensure the integrity of nucleic acids for subsequent DNA extraction and high-throughput 16S rRNA gene sequencing.

Data analysis is currently ongoing; however, comparative bioinformatic analyses will focus on quantifying changes in microbial community structure, calculating alpha and beta diversity indices, and tracking the succession of key bacterial and fungal taxa across the different anatomical sites and over time. Based on established ecological principles, we hypothesize that microbial succession will follow distinct, site-specific trajectories due to the varying initial microbial communities and environmental modifications induced by the clothing. Specifically, we anticipate that the rectal cavity, with its dense and specialized starting microbiome, may provide more consistent and resilient indicators of PMI compared to the more exposed oral and abdominal cavities.

This study aims to demonstrate that clothing significantly influences the successional trajectory of the postmortem microbiome. The findings will contribute critical data to forensic science by explicitly incorporating a common real-world variable—clothing—into microbial succession models. Ultimately, this work aims to strengthen the reliability of microbial community data as a tool for PMI estimation and provide forensic practitioners with a refined framework for interpreting decomposition in clothed human remains.

Y77 Computationally-Guided Design of a Molecularly Imprinted Polymer for the Detection of Psilocybin in Unregulated Drug Products

Hannah Peterson, BS, Virginia Commonwealth University, Richmond, VA; Balaji Nagarajan, APM, Balaji Nagarajan, Richmond, VA; Matthew Halquist, PhD, Virginia Commonwealth University, Richmond, VA*

Learning Objectives: The attendees of this presentation will learn about unregulated psilocybin drug products, what they are, and the potential risks attributed with consuming them. Additionally, thorough background information on Molecularly Imprinted Polymers (MIP) and their significance to the analysis of these products will be provided so that attendees understand the basics of MIP synthesis and their applications. The attendees will also become knowledgeable on why the use of quantum mechanics and molecular dynamics will assist in selecting the most appropriate components and solvents to be used in MIP synthesis.

Impact Statement: This presentation introduces the forensic science community to the development of a psilocybin-selective MIP and its potential as a reusable, selective tool for the analysis of various psilocybin products. In addition, discussions will inform the community about the lack of quality assurance and control surrounding unregulated psilocybin drug products, the potential risk they pose to public health, and the potential for a psilocybin-selective MIP to be implemented into forensic investigations.

Abstract Text: Psilocybin, a major compound found in various hallucinogenic mushrooms, has been utilized for centuries in religious and cultural practices for its mind-altering effects and ability to create audiovisual hallucinations and feelings of euphoria.[1] Psilocybin has been at the forefront of numerous studies that highlight the drug's ability to alleviate some of the physical or emotional pain associated with PTSD, terminal cancer diagnoses, treatment-resistant depression, and even substance use disorders.[2,3] This research, paired with the ongoing legalization of psilocybin across the country, has led to an uptick in the production of unregulated psilocybin drug products. Drug products such as gummies and chocolates that claim to ease anxiety and illicit hallucinations have been frequently sold in drug stores, vape shops, and even online. Unfortunately, the lack of regulations, quality assurance, or quality control during manufacturing has led to one product being associated with numerous hospitalizations and deaths.[4] This necessitates the development of an efficient method that allows for the determination of psilocybin concentrations as well as the presence of adulterants. While this analysis could be performed via solid phase extraction (SPE), this technique can result in non-specific interactions between the analyte and sorbent.[5] Instead, a psilocybin-selective molecularly imprinted polymer (MIP) can be developed that offers a high selectivity for psilocybin due to size-specific binding sites within the polymer. Additionally, MIPs are often classified as a green chemistry technique due to their stability and reusability which limits the solvent consumption and lab waste associated with other extraction techniques (6). The goal of this proposal is to develop a psilocybin-selective MIP to analyze unregulated psilocybin drug products and identify any adulterants within them. The main hypothesis is that the psilocybin-selective MIP will possess a higher selectivity and recovery for psilocybin compared to SPE. To test this hypothesis, the following three aims will be carefully performed. Aim 1 will implement quantum mechanics and molecular dynamics (QM/MD) to determine the most appropriate polymerization components and solvents to use in the MIP polymerization process. This will be done by computationally creating molecular complexes and identifying which conditions yield the lowest energy complex. Aim 2 will synthesize three of the most favorable complexes determined by QM/MD and characterize each using scanning electron microscopy, thermogravimetric analysis, imprinting factor, and binding capacity. Aim 3 will apply the characterized MIP for analysis of the psilocybin drug products to determine psilocybin concentrations as well as potential adulterants and compare the results to analysis performed with traditional SPE. This proposal sets out to investigate unregulated psilocybin drug products and accurately quantify the compounds present within them. In doing so, fundamental knowledge on the risks of consuming these products will be gained which is instrumental to the health and safety of the general public and the individuals that seek out these products to minimize their physical or mental pain.

Y78 Back to Basics: Approaching Cold Cases With Open-Source Intelligence An Undergraduate Perspective

Kelly Crockett, MSFS, Embry-Riddle Aeronautical University, Prescott, AZ; Maylynn Burns, Embry-Riddle Aeronautical University, Prescott, AZ*

Learning Objectives: Attendees will learn about the process that undergraduate students use when working on cold cases in the university setting. Attendees will also learn the benefits of using open-source intelligence when looking into cold cases.

Impact Statement: This presentation will impact the forensic science community by highlighting how emerging professionals bring fresh perspectives to the analysis of cold cases. This can help established members of the community broaden their own approaches, especially through the use of open-source intelligence.

Abstract Text: After attending this poster session, participants will gain insight into how undergraduate students investigate cold cases when information is limited. This session will contribute to the forensic science community by highlighting how emerging professionals, guided by faculty members, bring fresh perspectives to the analysis of cold cases. By considering these alternative viewpoints, established researchers can broaden their own approaches and expand their understanding of complex case evidence. Cold cases are investigations where evidence was limited at the time of occurrence, with leads often ending soon after the case began. They remain important to the forensic science community because new technologies and perspectives can bring fresh opportunities for analysis. At the undergraduate level, cold cases provide students with valuable experience in examining real cases. These cases are often older and require different approaches than those typically taught in classes.

Today, students have the advantage of instant access to information through AI tools, surveillance, and digitized records. However, older cases often lack reliable surveillance footage or accessible records. As a result, students must rely on open-source intelligence to identify patterns or uncover new information. This process encourages students to think creatively and take the mindset of an investigator. Open-source intelligence also allows students and early-career forensic scientists to better understand the historical context of a case to generate insights about what may have occurred.

This poster will showcase different types of open-source intelligence and demonstrate how they can be applied to cold cases from various time periods. It will highlight the importance of training students and emerging forensic scientists to explore all possible avenues when approaching a case, researching not only evidence directly linked to the case, but also the broader context of the time in which the case occurred.[1-9]

Y79 A Comparative Analysis of Volatile Memory Analysis Tools in Digital Forensics

Jaden McIntosh, BS, University of Central Oklahoma, Edmond, OK*

Learning Objectives: This presentation identifies the key differences in analytical output between the Volatility 3 Framework and Mandiant Redline when examining a Windows 10 memory image created by FTK Imager and helps with recognition of specific limitations of memory analysis tools in recovering certain digital artifacts like user logins or browser history. Finally, this presentation highlights the importance of tool validation and testing to ensure reliability and accuracy in digital forensic investigations.

Impact Statement: The impact of this presentation is primarily based on showcasing the necessity for rigorous and ongoing tool validation and testing, ensuring that practitioners adopt a critical approach to selecting software to rely on. Additionally, the lessons from this research can help forensic examiners make more informed decisions when selecting tools for an investigation.

Abstract Text: Volatile memory (RAM) forensics is a critical component of modern digital investigations, offering insights into transient system activities not available in nonvolatile storage. However, the accuracy and reliability of forensic analysis tools can vary significantly, creating a challenge for examiners who must select the appropriate tool for an investigation. This research provides a comparative performance analysis of two widely used, open-source memory analysis tools: the Volatility 3 Framework (v2.1.1.0) and Mandiant Redline (v1.23.1). A controlled experiment was conducted on a Windows 10 Enterprise system following the execution of scripted events (process creation/termination, user logins, file encryption, and web browsing). A complete RAM image was captured using Exterro FTK Imager (v4.3.0.1) and subsequently analyzed by both tools. The results revealed a significant disparity in efficacy. Redline consistently failed to parse the memory image, yielding no analyzable data. In contrast, the Volatility Framework successfully identified all 20 running processes and an average of 1-2 terminated processes. While Volatility detected indicators of encryption, it did not recover the specific encrypted files, nor did it extract artifacts related to user logins or browser history. These findings suggest that Volatility may be more reliable than Redline for this test configuration, but underscore the critical importance of rigorous tool validation, as even effective tools may have significant limitations in recovering certain evidentiary artifacts.

Y80 Bone and Tooth: Elemental Analysis of Cremated Remains

Ella G. Mitchell, Texas A&M University, Plano, TX; Dustin W. Holland*, Texas A&M University, College Station, TX*

Learning Objectives: How can cremation temperature be determined from the dentin and bone fragments left behind? How could elemental averages taken from the Scanning Electron Microscopy (SEM) and Energy-Dispersive X-Ray Spectroscopy (EDS) indicate sex?

Impact Statement: Much of remain identification is believed to be lost after cremation. The purpose of this presentation is to determine if cremation temperature and sex identification can be made from cremated fragments.

Abstract Text: The purpose of this research is to determine if elemental analysis of cremated remains can be used to determine biological factors and cremation temperature of the remains. It is often believed that identification information is lost after the process of cremation. Within the field of forensics identifying key information from cremated remains can be difficult. There has not been a significant amount of research done in the field to determine if sex is identifiable from cremated remains although new techniques to do this are beginning to be presented as potential ways to gain this information. Some of these techniques include the use of scanning electron microscopes, energy dispersive spectrometry, and hand held XRF analysis.[1,2] Identifying these traits in cremated remains could be vital in helping with the identification of missing persons. For this project a scanning electron microscope was used along with energy dispersive spectrometry, also known as SEM and EDS, were used to scan a sample of cremated dentin fragment and a sample of bone fragment. These scans were then analyzed to see if it is possible to determine biological indicators and for indicators of cremation temperature. Samples were scanned across multiple sites to determine differences in elemental composition across a single sample and averages of the sites were taken to compare to literature values on the biological indicators. These scans tested for phosphorous, oxygen, and calcium levels in cremated remains samples. To determine cremation temperature a color guide was used as research indicates that as dentin is exposed to different cremation temperatures demonstrates different colors within the burned bone as well as the presence of fractures within the bone fragments.[3] An analysis of the color of the dentin samples and color and fractures of the bone were conducted to determine the average cremation temperatures of the samples.

Y81 ATR/FTIR Characterization of Pressure Sensitive Adhesives: Before and After Chemical Fingerprint Processing

Meagan R. MiguelPablo, Towson University, Windsor Mill, MD; Khanh-Hoa Tran-Ba, PhD, Department of Chemistry & Forensic Science, Towson University, Towson, MD*

Learning Objectives: Attendees can expect to learn how the treatment of Pressure Sensitive Adhesives (PSAs) with chemical fingerprint processing techniques can affect the comparability of Attenuated Total Reflectance/Fourier Transform Infrared spectra (ATR/FTIR). Attendees will also learn how and why the recommended chemical fingerprint processing techniques used were chosen. We will also discuss the effects of the individual chemical treatments used as well as the methods used to compare and analyze the PSAs and their corresponding spectra using ATR/FTIR standard software.

Impact Statement: Acquisition of DNA and fingerprints routinely take priority over the collection of trace evidence data due to the level of discrimination between known and questioned sources. Validating the ability to utilize spectra collected from trace evidence such as chemically treated samples of PSAs would be beneficial to forensic chemical analysts. The ability to adequately compare a questioned (treated PSA) to a known source (untreated PSA) by analyzing the spectral evidence produced, including the chemical information provided by the specific polymers involved, before and after chemical treatment will add to the level of discrimination provided by the standard spectral comparison in addition to alleviating the potential dilemma of choosing which analysis should take priority (fingerprints or trace evidence data). Understanding whether chemical fingerprint processing techniques can render spectral data unusable can aid in the determination of what order evidence collection should take place.

Abstract Text: We are studying the effect of recommended chemical fingerprint processing techniques on the comparability of ATR/FTIR spectra of PSAs. PSAs are commonly known as tape. This study aims to identify whether the recommended chemical fingerprint processing techniques employed by forensic analysts negatively impact the ability to identify and compare ATR/FTIR spectra of treated PSAs against polymer standard spectra and untreated, control samples of the same PSAs. PSAs are commonly used in crimes because they are easily accessible, household items, that service criminals as tools in the crimes they commit. Forensic labs frequently process PSAs such as "duct tape, electrical tape, packaging tape, and strapping tape" collected from crimes that involve kidnapping, murder, and rape.[1,2] Common fingerprint processing techniques for PSA's involve chemical processing methods that are employed to enhance a fingerprint making it easier to visualize. A research team in Australia conducted a similar experiment exploring the effects of three fingerprint processing techniques on PSAs and the ATR/FTIR spectra they produce.[3] Our goal was to not only validate or corroborate the findings published by the Australian research team by introducing overlap in the methods and materials used, but to also expand on the research by introducing two aspects not explored by the research team. We introduced an additional chemical fingerprint processing technique (gentian violet in addition to Cyanoacrylate fuming, RAM dye, and Wet powder) as well as attempted to compare polymer standard spectra to the treated and untreated samples to identify if the effect in comparison is due to a change or manipulation of the polymer in the PSA adhesive or backing components. We also organized and standardized the samples analyzed by using a minimum of four different brands of each of the four different tape types (duct, electrical, masking, packaging) to better account for variability in spectral comparison between brands of the same type of tape. ATR/FTIR is a nondestructive method for collecting data from potentially limited sources making it ideal for processing and collecting data from this type of sample. We found that CA fuming does have a significant effect on the spectral comparison of treated and untreated samples resulting in less-than-ideal spectral matches. We are actively analyzing the effect of the treatments on polymer identification and the other processing methods as well. However, based on the data analysis we have been able to do so far, we believe a viable comparison may still be made with the other treatment chemicals used and the untreated PSAs apart from RAM dye as that is a follow up treatment to Cyanoacrylate fuming. The recommended chemical fingerprint processing techniques were identified by referencing FBI Guidelines.[4] Qualitative analysis of the spectra collected were performed visually, and quantitative analyses are being performed using the OMNIC software compatible with the ATR/FTIR instrument.

Y82 Investigation of Gas Chromatography (GC) Coupled With Mass Spectrometry (MS) and Vacuum Ultraviolet (VUV) Spectroscopy for Analysis of Ignitable Liquid Samples

Bryn Boznanski, BS, The George Washington University, Washington, DC; Ira S. Lurie, PhD, The George Washington University, Washington, DC; Walter Rowe, PhD, The George Washington University, Woodbridge, VA*

Learning Objectives: After attending this presentation, attendees will better understand the analysis of ignitable liquids using GC/MS/VUV to better distinguish ignitable liquid samples. In addition, attendees will be familiarized with the PIONA (paraffin, isoparaffin, olefin, naphthene, and aromatic) class system.

Impact Statement: This presentation will impact the forensic science community by providing a more accurate analytical technique for ignitable liquid analysis that forensic laboratories can implement without modifying the current industry standard method (ASTM E1618).

Abstract Text: While GC/MS is the industry standard for ignitable liquid analysis, the main challenge is the ability to distinguish between compounds with similar masses or structural isomers. In addition, ignitable liquids like gasoline may come in complex mixtures that cannot be properly identified by GC/MS alone. VUV spectroscopy offers greater specificity because it can detect the **π-π*** transitions that occur in aromatic and alkene compounds and **σ-σ*** that occur in all compounds, like many ignitable liquids. GC/VUV can also deconvolute co-eluting analytes. In this study, we evaluate GC/MS/VUV to determine the complementary nature of both detection techniques, and to determine if combining both techniques increases the overall specificity of analysis. In addition, VUV detection will provide valuable information on the distinct functional groups in various ignitable liquid classes to better distinguish different types of ignitable liquids.

The initial steps of the project involve establishing and adjusting the chromatographic conditions on the GC/MS/VUV based on guidelines from similar research projects and ASTM standards prior to running samples. The VUV Analyze software, based on the PIONA class system, involves calibration with three samples- a retention time standard (VUV/RT), a quantitative standard (VUV-1), and a gasoline standard (VUV-CS). For this project several samples of four ignitable liquid classes gasoline, diesel, lighter fluid, and kerosene were analyzed by GC/VUV. The VUV software produces the percentage of each PIONA class, highlights their location in the chromatogram, and provides other valuable data that can be used in tandem with the GC/MS data in identifying ignitable liquids. Based on the proposed methodology, the different classes of samples were easily distinguished aided by the complementary nature of both detection techniques.

Y83 Protective and Risk Factors in Sex Trafficking

Sophia Thompson, Embry-Riddle Aeronautical University, Scappoose, OR*

Learning Objectives: This presentation provides an overview of strategies and practical skills for combating human trafficking, emphasizing the role of forensic science in prevention and intervention. Participants will explore how victim backgrounds and experiences influence trafficking dynamics, enhancing their ability to apply a survivor-centered approach in investigations. The session emphasizes actionable methods for identifying risks and supporting rehabilitation efforts. Attendees will leave with a deeper understanding of how forensic competence in the area of human trafficking can directly inform effective prevention and protection measures.

Impact Statement: This presentation will impact the forensic science community by enhancing the ability to apply knowledge directly to combating human trafficking, with a strong focus on prevention efforts. Additionally, it emphasizes understanding victim backgrounds and experiences, fostering a survivor-centered approach that informs both investigative strategies and rehabilitation initiatives.

Abstract Text: This presentation examines protective factors in sex trafficking and their role in reducing vulnerability and guiding prevention efforts. Protective factors: elements that shield individuals from exploitation, are contrasted with risk factors, which increase susceptibility.[1] While existing literature has focused on identifying and weighting risk factors, recent research emphasize the potential of protective factors to prevent trafficking before it occurs.[2]

Bowman et al. identified protective factors within the disabled community with particular regard to sex trafficking.[3] Despite this focus, the adaptability of these findings translate well into other areas. However, the protective factors the did identify can translate well into other demographics as well. Despite what Lathen suggests, that there is no specific demographic that is at risk but rather than individual, it can be rebutted that specific communities can benefit from these prevention efforts by emphasizing an importance on protective factors.[4] In Knight et al., they discovered novel risk and protective factors, expanding the framework contributing other factors to the literature.[5] Case studies by Carstens show that factors can function as protective or risk-enhancing depending on context.[6] Each of these studies identified call "classic risk factors" and some identified both "classic" and "novel" protective risk factors. Carstens, however, was the only one to explore a relationship between risk and protective factors and trafficking.

By integrating protective factors into prevention programs, this work highlights proactive strategies for combating sex trafficking. Attendees will learn how strengthening protective influences can enhance resilience, inform prevention programs, and guide evidence-based interventions, demonstrating the direct impact of focused, informed approaches in reducing exploitation and supporting survivors.

Y84 Determining the Feasibility of UV/Vis and ATR/FTIR in Identifying Neat Analytes in Smokeless Powders

Rorie J. Anderson, BS, Towson University, Northampton, PA; Ellen H. Hondrogiannis, PhD, Towson University, Towson, MD; Mary Devadas, PhD, Towson University, Towson, MD*

Learning Objectives: After attending this presentation, attendees will learn that in the presence of other neat analytes, we are able to identify the presence of Dibutyl Phthalate (DBP) using Attenuated Total Reflectance/Fourier Transform Infrared (ATR/FTIR) when compared to a spectrum of the H335 Smokeless Powder (SP). Additionally, comparing the spectra acquired from ATR/FTIR of only the neat analytes reveals that there are unique, identifiable peaks for Ethyl Centralite (EC), Diphenylamine (dpa), 2-nitrodiphenylamine (2-ndpa), 4-nitrodiphenylamine (4-ndpa), and n-nitrosodiphenylamine (n-ndPA). Attendees will further learn that from comparing a Ultraviolet/Visible (UV/Vis) spectroscopy spectrum of H335 SP to literature spectra of the neat analytes, we can identify the presence of the nitrated derivatives 2-nDPA and 4-nDPA, as the absorbance of these individual analytes does not overlap with other neat analytes. Although not every neat analyte can be definitively identified, both ATR/FTIR and UV/vis have the potential to expand our knowledge on the identification of SPs.

Impact Statement: The information presented in this presentation will inform trace analysts in the forensic science community of the capabilities of ATR/FTIR in screening for the presence of DBP in smokeless powder. If DBP is identified, then the sample should be subjected to UV/Vis spectroscopy to search for the presence of the nitrated derivatives (2-nitrodiphenylamine and 4-nitrodiphenylamine), as these derivatives are a unique characteristic of SP decomposition that cannot be produced from the surrounding environment. After this presentation, attendees will see that ATR/FTIR and UV/Vis technology have the potential to be tools in the identification of SPs found at crime scenes.

Abstract Text: In 2019, firearms were related to approximately 250,000 deaths worldwide. An estimated 37,000 of those deaths occurred in the USA alone, emphasizing not only the evident power of firearms, but also the urgent need for reliable forensic analytical methods.[1] Following the removal of heavy metals like lead and barium from ammunition primer due to environmental concerns, the job of the forensic analyst has become increasingly complicated.[2] This change has forced a return back to the basic fundamentals of forensic science, as the previous identification methods now yield limited evidential value.

The aim of this study is to test the feasibility of ATRFTIR and UV/Vis spectroscopy technology in identifying the organic compounds extracted from smokeless powder (SP). This is relevant as gunshot residue identification can no longer rely on the presence of inorganic heavy metals. We evaluate the value of these nondestructive methods by comparing and analyzing experimentally obtained spectra of neat analytes to determine if the analytes could be identified in a spectrum of the SP.

The information presented in this presentation will inform trace analysts in the forensic science community of the capabilities of ATR/FTIR in screening for the presence of DBP in smokeless powder. If DBP is identified, then the sample should be subjected to UV/Vis to search for the presence of the nitrated derivatives (2-nitrodiphenylamine and 4-nitrodiphenylamine), as these derivatives are a unique characteristic of SP decomposition that cannot be produced from the surrounding environment. After this presentation, attendees will see that ATR/FTIR and UV/Vis technology have the potential to be tools in the identification of SPs found at crime scenes.

Y85 Transfer of Material Derived From Polymer-Jacketed Bullets During Cycling and Discharge

Ethan A. Frazer, MS, Perth, Ontario, Canada; Peter J. Diaczuk, PhD, John Jay College or Criminal Justice, New York, NY*

Learning Objectives: This research aims to highlight how the polymer coating of Syntech bullets may hinder traditional identification methods used by firearms examiners and provides a supplementary method that can be used in cases involving this ammunition. The audience will learn about limitations of existing examination methods on this brand of polymer-coated bullets and will understand how the methods used in this research have merit both as an alternative and supplemental examination technique. Additionally, the audience will be given the ability to explore the practical applications of this research to cases involving this, or similar, ammunition.

Impact Statement: The findings of this research are impactful as they highlight significant areas of growth in the examination of polymer-coated bullets, which otherwise hinder traditional forensic examination methods. This research demonstrates the first documentation, to the knowledge of the authors, of polymer residue on the feed ramp of the cycling/discharging firearm. Additionally, it is the first documented study that has found Syntech residue within the interior of the firearm. The techniques illustrated in the presentation are rapid, affordable, and have application to both crime scenes (collection and evidence preservation) and laboratories (evidence analysis).

Abstract Text: This study aims to find alternate ways to connect a polymer-coated bullet to the handgun from which it was fired. Federal Ammunition's Syntech Total Synthetic Jacket (TSJ) line is the focus of this study as the polymer coating presents unique challenges to firearms examiners by not retaining the individualizing striations found in traditional unjacketed or metal-jacketed bullets[1,2].

In this study, 9mm TSJ ammunition was fired through a number of traditionally rifled aftermarket Glock 19 and Glock 43 barrels. Cloth targets were set up at varying distances in an attempt to capture ejected residue and determine at what distances the residue can be observed on fabric targets. After shooting, the barrel was removed for examination.

The feed ramp and barrel bore were cleaned separately, with all removed contents examined with a stereomicroscope for the characteristic "lipstick" red polymer. Examination of the feed ramp found notable deposits of the red residue in over 75% of trials, with the remaining trials providing inconclusive results. Similar residue was found in the barrel bore in only 30% of trials. However, none of the bore recoveries showed more than two microscopic fragments.

The front and reverse side of cloth targets were also examined using a stereomicroscope. Ejected polymer fragments were found to be propelled up to 18 inches but showed significant variability in the consistency of their deposit. Fragments were also present on the reverse side of the targets in close range shots after being pushed through the cloth upon impact.

The findings suggest that Syntech TSJ bullets will deposit polymer jacketing residue on the feed ramp when chambering a round, creating a unique and colorful identifier. This is the first known observation of this phenomenon and would suggest a new method for firearms examiners when faced with this ammunition. Additionally, it gives firearms examiners new context when examining targets which may have polymer residue on the backside of targets or layered between fabric.

Y86 Microbes in the Mist: Microbiological Analysis of E-Liquids and Aerosols

Ankita Gola, BS, Department of Forensic Science, Virginia Commonwealth University, Bowie, MD; Jessemia Meekins, BS, Laboratory for Forensic Toxicology Research, Richmond, VA; Alaina K. Holt, PhD, Virginia Commonwealth University, Richmond, VA; Justin L. Poklis, BS, Virginia Commonwealth University, Richmond, VA; Christopher Ehrhardt, PhD, Virginia Commonwealth University, Richmond, VA; Michelle R. Peace, PhD, Virginia Commonwealth University, Richmond, VA*

Learning Objectives: Attendees will be able to discuss the potential impact and health implications of microbiologicals identified in nicotine and cannabinoid electronic cigarette formulations and aerosols from vaping products confiscated from underage users across Virginia health districts.

Impact Statement: This presentation will inform the forensic science community on microbial contamination found in electronic cigarette e-liquids and aerosols, as well as the potential risks associated with inhaling these microbes. Additionally, this presentation will highlight the types of electronic cigarettes commonly used by youth < 18 in Virginia schools and means of access, facilitating discreet substance use.

Introduction: Despite ongoing efforts by the Food and Drug Administration to regulate electronic cigarettes (e-cigs), thousands of unregulated products remain on the market. These unregulated e-cigs are associated with significant quality assurance concerns. Microbial toxins detected in e-liquids have been linked to contamination arising from unsanitary manufacturing practices, improper storage conditions, or from the raw starting materials themselves, such as tobacco and cannabis.

Objectives: To determine if e-liquids and aerosols from confiscated vaping products contained microbiologicals.

Methods: Vaping products confiscated from minors during the 2024–2025 school year were categorized by Virginia's five health districts, product composition (nicotine- or cannabinoid-based), and mouthpiece condition (clean or dirty). A total of 87 nicotine devices (43 clean, 44 dirty) and 22 cannabinoid devices (4 clean, 18 dirty) were randomly selected for analysis. E-liquids and/or aerosols were tested for yeast, mold, aerobic count (AC), *Escherichia coli* (*E. coli*), and coliform. From the selected products, 18 nicotine (9 clean, 9 dirty) and 6 cannabinoid (2 clean, 4 dirty) devices were used to generate aerosols (10 four-second puffs) that were captured using an in-house trapping system. All e-liquids and captured aerosols were diluted in type-1 water and plated on 3M® Petrifilm™ plates. Positive (cultiloops, Thermo Scientific™) and negative (water) controls for each microbe were analyzed and incubated with the samples according to manufacturer specifications. In accordance with Virginia regulatory thresholds, samples were positive if AC >100 colony forming units (CFU) per mL or g, yeast/mold >10 CFU/mL or g, or *E. coli*/coliform >0 CFU/mL or g.

Results: In nicotine e-liquids (n=43 clean, n=44 dirty), microbes exceeding thresholds included yeast (2 clean), mold (2 clean), AC (1 clean), and coliform (1 clean). In nicotine aerosols (n=9 clean, n=9 dirty), microbes exceeding thresholds included yeast (1 clean, 1 dirty), mold (1 dirty), and AC (2 clean, 1 dirty). For cannabinoid e-liquids (n=4 clean, n=18 dirty), microbes exceeding thresholds included yeast (4 dirty) and mold (2 clean, 1 dirty). In cannabinoid aerosols (n=2 clean, n=4 dirty), only AC exceeded thresholds (1 clean, 2 dirty).

Of the three products (1 nicotine, 2 cannabinoid) that showed microbial growth in both e-liquids and aerosols, one cannabinoid product was positive in both matrices: mold [13 CFU/mL] and AC [252 CFU/g]. In aerosol samples, total CFU/g of product aerosolized ranged: yeast [0–22], mold [0–19], and AC [0–2,288]. In e-liquids, CFU/mL values ranged: yeast [0–20], mold [0–50,000], AC [0–400,000], and coliform [0–1,100].

Discussion: Microbes were identified in both nicotine- and cannabinoid-containing e-liquids and were successfully aerosolized, demonstrating that these organisms can reach the aerosol phase and remain viable. Instances in which microbial growth was observed in aerosols but not in the corresponding e-liquids suggest possible mouthpiece contamination due to unsanitary storage conditions. Inhalation exposure to such microbes poses significant health risks, including fever, rash, gastrointestinal illness, respiratory disease, and in severe cases, death.

Y87 Microbial Succession in Buried Remains: A Controlled Pig Study at Three Feet Depth

Latavia Williams, Southern University at New Orleans, New Orleans, LA; Brittney Sylvester, Southern University at New Orleans, New Orleans, LA; Alyssa Lavasseur, Southern University at New Orleans, New Orleans, LA; Lewis Burnett, Southern University at New Orleans, New Orleans, LA; Georgia A. Williams, MS, George Mason University, Manassas, VA; Meiko Thompson, PhD, Southern University at New Orleans, New Orleans, LA*

Learning Objectives: This presentation will equip attendees to explain how burial conditions like oxygen limitation and temperature buffering alter decomposition and microbial communities. Attendees will be able to compare microbial succession in buried remains—such as a shift toward anaerobic taxa—to established patterns in surface remains. Finally, they will learn to evaluate the potential of site-specific microbial data from oral, abdominal, and rectal cavities to improve Postmortem Interval (PMI) estimation models for clandestine burials.

Impact Statement: By focusing on buried remains, this research addresses a critical gap in forensic microbiology. Results may strengthen the application of microbial community analysis in forensic casework, especially in homicide investigations where concealment is common.

Abstract Text: Clandestine burials present a complex challenge for forensic investigations, as decomposition dynamics in subterranean environments differ significantly from surface scenarios.[1] Burial conditions alter critical factors such as temperature, oxygen availability, and insect activity, which can delay and reshape the decomposition process. While microbial succession has emerged as a promising tool for PMI estimation, its patterns within buried remains are poorly understood.[2] This gap limits the application of microbiological methods to a critical set of forensic cases. The objective of this study was to characterize microbial succession in a buried porcine model to identify consistent, site-specific patterns that could aid in PMI estimation for interred remains.

This research was conducted at the George Mason University Body Farm during the summer of 2024. A domestic pig (*Sus scrofa domestica*) carcass was buried at a depth of three feet in a soil grave under natural environmental conditions. To comprehensively track microbial changes, swab samples were collected daily from three anatomical sites—the oral, abdominal, and rectal cavities—for the first 21 days of decomposition, followed by weekly sampling until July 24, 2024. All samples were preserved at -80°C to ensure nucleic acid integrity for subsequent DNA extraction and 16S rRNA gene sequencing.

Data analysis is currently ongoing; the planned bioinformatic and statistical analyses will focus on characterizing microbial community structure shifts over time, comparing the relative abundance of anaerobic versus aerobic taxa, and evaluating succession patterns specific to each anatomical cavity. Based on established ecological principles and prior research, it is anticipated that burial will slow the overall rate of decomposition compared to surface remains. We hypothesize that anaerobic microbial taxa will dominate the early successional stages due to oxygen-limited conditions and that reduced insect access will delay the microbial community transitions typically observed in surface decomposition models.

This study is expected to demonstrate that burial depth significantly modifies the trajectory of postmortem microbial succession. The findings will contribute crucial data to the emerging field of forensic microbiology by defining decomposition signatures specific to buried remains. Ultimately, recognizing these distinct patterns may enhance the accuracy of microbial-based PMI models for clandestine burials, providing investigators with a more reliable tool for estimating time since death in some of the most challenging forensic scenarios.

Y88 Various Animal Species' Microscopic Hair Analysis

Bryanna D. Smith, Liberty University, Ocoee, FL; Kristin Mossé, MSFS, Liberty University, Lynchburg, VA*

Learning Objectives: This presentation with show and explain the microscopic similarities and differences between hair and fur of non-domesticated animal species. Attendees will learn how the research was conducted, its impact on modern forensics and ideas for potential future research and application in the field.

Impact Statement: Human hair analysis is widely known and used in forensics, alongside animal hair analysis of domesticated animals such as cats and dogs. However, this research attempts to document non-domesticated animal hair data so that it could expand the reach of current forensic hair analysis and allow this type of animal hair to be used and examined as exclusive class evidence.

Abstract Text: This research aims to determine whether animal hair characteristics can reliably differentiate various animal species, a study with potential forensic applications. Both human hair and animal hair are comprised of three key components: the cuticle (the outer coating composed of overlapping scales), the cortex (protein-rich structure that surrounds the medulla and contains pigments) and the medulla (the central core, which may be absent). The goal of this research project is to document data collected from microscopic analysis of a variety of non-domesticated animal hair/fur samples, such as bear, skunk, or wolf, to determine detailed similar and different characteristics between them on the microscopic level. The research utilizes a compound microscope, polarizing microscope, and comparison microscope to make observations about the hair. The data collected includes hair type, color, and texture, as well as the presence of any ovoid bodies, medullary pattern, structure, and margin. Cuticle data is also collected such as the position of the cuticle in relation to longitudinal direction of the hair, cuticle pattern and margin, and the distance between cuticle margins. The primary hypothesis is that distinct medullary patterns, structures, margins, cuticle patterns, among other characteristics in fur and guard hairs can serve as species identifiers. Research conducted thus far, as it is an ongoing research project, has deemed that non-domestic animal hair is diverse enough when this data is studied to be considered class evidence that can be used in an exclusionary manner. This type of research has significance for wildlife forensics as well as the trace evidence discipline if/when such evidence is found at a crime scene, on a suspect, or on a victim that can link them together.

Y89 An Investigation of Water Effect on Ignitable Liquid Residue Analysis by Coupling Solid-Phase Microextraction With Direct Analysis in Real Time-Mass Spectrometry

Victoria Bascou, BS, Texas Tech University, Lewisburg, TN*

Learning Objectives: The goal of this presentation is for attendees to learn about the ignitable liquid residue analysis of gasoline. An evaluation of the water effect on the analysis of gasoline via Direct Analysis in Real-Time-Mass Spectrometry (DART-MS) was studied to better understand how ignitable liquids can be affected during detection. Learning objectives include identifying water-to-gasoline ratios and the effect of these ratios on the detection of gasoline signals; evaluating the intensity of the gasoline signals after the introduction of the water effect; and proving the relevance of water's presence when combined with gasoline. This research provides results that can aid in differentiating and identifying ignitable liquids depending on their exposed conditions to other interference liquids.

Impact Statement: This work was probative in nature, with an emphasis on establishing a qualitative method to determine whether water has an effect on gasoline signals using Solid-Phase Microextraction (SPME) for extraction and DART-MS for analysis. The method used was intended to show what effect was seen on the gasoline signal intensities. Results from this research showed that water does have a diminishing effect on the intensity of the gasoline signals detected via DART-MS analysis. Though preliminary in nature, these results provide a basis for future researchers analyzing water or other interfering substance's effect on ignitable liquids. These results will have an impact on the forensic science community as they will help individuals to understand the ways in which ignitable liquids can be affected by different variables from the crime scene. By understanding what can affect the detection of ignitable liquids found at crime scenes, such as water, investigators and chemists can adapt their methods for better collection and analysis of ignitable liquid residue samples.

Abstract Text: Arson investigation and explosive analysis is a subfield of forensic science that focuses on examining the physical evidence that is collected from a scene in which a fire occurred. Accelerants and Ignitable Liquids (ILs) are often used in arson fires to maximize the damage that the fire creates. The identification of the presence of the ILs used at an arson scene and their residues can aid in the criminal investigation related to the scene by determining if the fire was deliberate or not. DART-MS is known for its ability to analyze less volatile weather-exposed compounds, such as gasoline, and to demonstrate sensitive detection of explosives. In recent research, the DART-MS was coupled with SPME. SPME is a common technique used in sample preparation that utilizes a fiber coated with liquid polymer or solid sorbent that can extract analytes from various media, The coupling of SPME with DART-MS allows for the analysis of IL residue on substrates (i.e., wood floor, paper). The impact of water, one of the most common fire-extinguishing agents, on ILR detection is largely unknown. This study hypothesizes that water could interfere with gasoline residue analysis by DART-MS which is dependent on the gasoline to water ratios and the type of substrates. The objective is to conduct a comprehensive evaluation of the water effect in gasoline residue detection by DART-MS method to provide results that will aid in a better understanding of water and substrates factors in the IL detection method. Sample mixtures of gasoline with varying ratios of water were created and analyzed using these methods of analysis. Data produced from these methods of analysis included a Total Ion Chromatogram (TIC) and mass spectra for each sample analyzed. Results were expected to show some effect on the intensity of the ratios of the gasoline signals, and the results showed the expected effect; the water affected the gasoline signals by decreasing their overall intensity. Results from this research can be utilized in future experiments to further enhance and optimize the methodologies used when continuing the pattern of analysis with other ignitable liquids or substrates.

Y91 Time Since Intercourse and Serological Testing in Sexual Assault Homicides: A Case Report and Brief Review of the Literature

Peyton R. Byers, BS, Duquesne University, Pittsburgh, PA; Pamela Marshall, PhD, Duquesne University, Pittsburgh, PA*

Learning Objectives: This presentation explores a forensic case study focused on the spatial distribution of seminal fluid in underwear, aiming to refine investigative methodologies in sexual assault and sexual assault homicide cases. This study evaluates how the location of seminal fluid can influence case interpretation and contribute to more informed forensic analyses in future investigations.

Impact Statement: This presentation offers critical insights for forensic professionals by highlighting the evidentiary value of stain pattern analysis in sexual assault and homicide investigations.

Abstract Text: Underwear serves as a vital source of evidence in sexual assault cases, offering opportunities for serological testing, DNA profiling, and visual inspection that may support victim testimony or aid in reconstructing events. Prior studies have demonstrated that male DNA is frequently recovered from commonly handled areas such as bra straps and the sides of underwear.[1] However, there remains a significant gap in research regarding the precise locations of seminal fluid deposition following sexual assault. Existing literature confirms that seminal fluid can be detected in underwear, yet its forensic implications are underexplored.[2]

This study presents the case of a woman who was the victim of a sexual assault homicide, discovered lying on her left side with seminal fluid confined to the left portion of the inner gusset of her underwear. Due to the scarcity of targeted research on underwear stain patterns, the interpretation of this evidence was initially ambiguous. The investigation addresses the central question: How can postcoital seminal fluid stain patterns on underwear improve our understanding of sexual assault dynamics? To answer this, the case was analyzed in relation to the victim's body position, time since intercourse intervals, and the gravitational drainage of seminal fluid.

The findings offer critical insights for forensic professionals, highlighting the evidentiary value of stain pattern analysis in sexual assault and homicide investigations.

Y92 The Development of Preprocessing Workflow for Computed Tomography Images for Artificial Intelligence Applications in Forensic Anthropological Research

Gargi Jani, MSc, National Forensic Sciences University, Gandhinagar, Gujarat, India; Smit Patel, BEng, Pandit Deendayal Energy University, Gandhinagar, Gujarat, India; Mohendra Roy, PhD, Pandit Deendayal Energy University, Gandhinagar, Gujarat, India; Bhoomika Patel, PhD, National Forensic Sciences University, Gandhinagar, Gujarat, India*

Learning Objectives: Attendees will gain an understanding of the essential preprocessing steps required for preparing and creating a medical image database necessary for applying Machine Learning (ML) /Deep Learning (DL) algorithms for various forensic anthropological research applications.

Impact Statement: This presentation will contribute to the forensic science community by showcasing a data preprocessing workflow developed in alignment with established best practices. The workflow supports the implementation of artificial intelligence (ML/DL) algorithms on CT-scan images across various forensic anthropology applications. By standardizing and streamlining data preparation, it will not only contribute to database preparation and but also will subsequently enhance model performance while significantly reducing the effort required by researchers to develop effective AI-based solutions.

Abstract Text: Biological Profiling of the remains and studying the anatomy is fundamental of forensic anthropological practice.[1,2] Physical bone collections are required to develop techniques for biological profiling as well as for teaching purpose.[2] However, there are availability concerns as well as ethical considerations associated with it.[3] With digitization techniques being increasingly utilized, CT scans and MRI have been used to create virtual skeletal databases that can be utilized for 3D visualizations, research, and teaching.[4] To create these databases, data de-identification, removal of noise, data sorting and curation is required in addition to obtaining institutional ethical permissions.[5]

These steps can be achieved by medical imaging software, however with increasing interest in implementing ML/DL in the field of forensic anthropology large number of datasets needs to be processed to make it suitable for research, which might be time consuming.[2] To reduce the manual operations and automate the process, we propose a workflow for preparing the CT-scan images for researchers to perform analysis and implementing AI- models.

An automated workflow is developed with 200 thorax CT scans obtained from multiple centers. The process involves (1) anonymizing metadata, (2) removing irrelevant pixels (e.g., patient tables etc.), (3) denoising, and (4) Thresholding. To achieve this, we developed a script that eliminates fields containing personal information from the metadata. Following this, a deep learning algorithm is applied to detect unwanted outlier pixels and determine their locations within the 3D voxel space. These identified positions are then used as masks to remove the corresponding pixels from the DICOM image samples. Thresholding was implemented to segment the hard tissue from the CT scans.

The process of anonymization achieved 100% success rate whereas the removal of outlier pixels reaches approximately 99% accuracy. The results of the same shall be discussed in detail during the presentation.

This workflow can be integrated into a single platform that combines anonymization and image preprocessing. Such a platform provides a unified solution for both de-identifying samples and preparing images, enabling the creation of datasets for AI applications as well as preparation of database for research and teaching.

Y93 Recalibrating Forensic Science: DNA, Microbial Signatures, and Methodological Equity in Montana's Differential Burial Contexts

Kaylee M. Hinds, MA, University of Montana, Missoula, MT; Meradeth H. Snow, PhD, University of Montana, Missoula, MT*

Learning Objectives: Attendees will learn how microbial and DNA degradation patterns vary by burial depth and environment, how to apply both cost-effective and professional molecular techniques in forensic decomposition studies, and how to evaluate ethical and logistical barriers to implementing standardized protocols in under-resourced or untrained regions.

Impact Statement: This presentation will impact the forensic science community by providing a scalable, accessible framework for postmortem analysis that emphasizes scientific rigor, equitable resource use, and interdisciplinary collaboration in cold case and burial investigations.

Abstract Text: This presentation examines the role of microbial and genetic analyses in understanding differential burial conditions across rural Montana, with a focus on the ethical, standardized, and accessible implementation of forensic methods. In the context of increasing calls for forensic justice in cold case identification, mass burial investigations, and the recognition of Indigenous residential school victims, this work highlights how funding disparities and methodological complexity can hinder scientific rigor and equitable access to forensic tools in underserved regions.

By exploring bacterial community structures and DNA degradation patterns in controlled and natural burial sites, this research supports the development of adaptable protocols that respect local constraints while maintaining scientific integrity.

This work directly aligns with the 2026 AAFS theme by prioritizing practitioner-focused, ethically grounded science that reinforces the interconnected role of scene investigators, laboratory analysts, and policy-makers in the pursuit of justice. We argue for a return to fundamental forensic principles, standardization, neutrality, and transparency, while advancing inclusive practices through collaboration with nonprofit agencies and regional crime labs. We also urge the forensic community to critically assess not just what science is done, but who gets to do it, how it's funded, and who benefits from its outcomes.

This study employed an experimental field design in the Lubrecht Experimental Forest of western Montana, where three pig cadavers, serving as human proxies, were placed in surface, partial, and fully buried conditions and monitored over the course of one year. Supplementary samples were obtained from two additional pig remains discovered nearby, representing an earlier deposition timeline (approximately 15 years) and offering comparative long-term data. Sampling focused on soft tissues, skeletal elements, and surrounding topsoil to assess postmortem DNA preservation and microbial community shifts across burial contexts. The design integrates molecular, microbial, and environmental data collection to evaluate how oxygen exposure, burial depth, and regional climate influence decomposition processes and DNA degradation, using a combination of equipment types, from professional-grade genomics platforms to back-to-basics methods such as low-cost agar kits, manual spreading techniques, and anaerobic growth pouches that prioritize accessibility and field adaptability.

The findings reveal distinct molecular and microbial trajectories associated with burial depth, local microenvironment, and exposure duration. Shifts in colony morphology, CFU abundance, and pH correlate strongly with observable decomposition stages, reinforcing the utility of microbial profiling in postmortem interval estimation. Importantly, this work demonstrates that high-quality forensic data can be generated using a combination of cost-effective and advanced methodologies, offering a scalable model for under-resourced regions. By situating these biological patterns within a framework of ethical accessibility and scientific rigor, this study underscores the value of adaptable protocols that serve both forensic accuracy and broader social equity.

Y94 Microbial Succession in Carpet-Wrapped Remains: Implications for Postmortem Interval Estimation

Alyssa Lavasseur, Southern University at New Orleans, New Orleans, LA; Brittney Sylvester, Southern University at New Orleans, New Orleans, LA; Latavia Williams, Southern University at New Orleans, New Orleans, LA; Lewis Burnett, Southern University at New Orleans, New Orleans, LA; Georgia A. Williams, MS, George Mason University, Manassas, VA; Meiko Thompson, PhD, Southern University at New Orleans, New Orleans, LA*

Learning Objectives: This presentation will enable attendees to identify how carpet wrapping modifies decomposition by creating a unique microclimate and restricting insect access. They will learn the methodology for sampling and analyzing microbial succession from oral, abdominal, and rectal sites on wrapped remains. Attendees will be able to predict how microbial communities in this concealed context differ from standard surface scenarios and assess the potential of this site-specific data to improve Postmortem Interval (PMI) estimation models for concealed remains in forensic casework.

Impact Statement: By investigating a realistic concealment scenario, this research expands forensic microbiology to contexts frequently encountered in homicide and clandestine disposal cases. Results will enhance the forensic community's ability to interpret decomposition evidence when remains are intentionally hidden.

Abstract Text: The concealment of remains using common household materials like carpet is a frequent complication in forensic casework. This wrapping alters critical decomposition dynamics by limiting insect colonization, retaining moisture, and buffering temperature fluctuations.[1] While microbial succession has emerged as a powerful tool for PMI estimation, its progression in wrapped remains is still poorly characterized, creating a significant gap in applying this method to a common forensic scenario.[2] This study aims to characterize microbial community succession in a carpet-wrapped porcine model and evaluate the forensic utility of different anatomical sampling sites for PMI estimation.

The research was conducted at the George Mason University Body Farm during the summer of 2024. A domestic pig (*Sus scrofa domestica*) carcass was fully wrapped in a segment of residential carpet and placed on the soil surface under natural environmental conditions. To track microbial changes, swab samples were systematically collected daily from three anatomical cavities—oral, abdominal, and rectal—for the first 21 days of decomposition, followed by weekly sampling until July 24, 2024. All samples were preserved at -80°C for subsequent DNA extraction and 16S rRNA gene sequencing.

Data analysis is currently ongoing; planned bioinformatic analyses include microbial community profiling, comparisons of alpha and beta diversity across anatomical sites, and a direct evaluation of how concealment alters successional patterns relative to data from uncovered surface remains. Based on prior taphonomic research, it is hypothesized that the carpet will slow the external decomposition processes and delay the establishment of surface-dwelling microbial communities due to a reduction in insect activity. In contrast, internal sites, particularly the nutrient-rich and protected rectal cavity, are anticipated to display more consistent and measurable succession trends that may be more reliably correlated with PMI.

This study will provide essential baseline data on the influence of carpet concealment on the postmortem microbiome. The findings are expected to demonstrate that wrapping significantly modifies microbial succession trajectories. By identifying which anatomical sites provide the most robust data despite concealment, this research will contribute directly to the development of more accurate, microbial-based PMI estimation models tailored for concealed remains, thereby enhancing tools available for forensic investigations.

Y95 A Reevaluation of a Mandibular Tori Scoring Method: Limitations and Revisions

Amanda Jokela, BA, California State University, Los Angeles, Rancho Cucamonga, CA; Danny J. Wescott, PhD, Texas State University, San Marcos, TX; Michele M. Bleuze, PhD, California State University, Los Angeles, Los Angeles, CA*

Learning Objectives: After attending this presentation, attendees will be informed about a scoring method for mandibular tori developed by Hasset.[1] Attendees will gain valuable insights into its applications, limitations, suggestions for novel improvements, and future possibilities for personal identification of deceased individuals.

Impact Statement: This presentation will impact the forensic science community by demonstrating the value of a revised approach to an established scoring method in the analysis of mandibular tori, which will help in future analysis of the trait and its forensic applications.

Abstract Text: Mandibular tori are non-cancerous bony growths occurring on the lingual surface of the mandible. While the etiology of mandibular tori remains a topic of debate, prevailing consensus suggests that both genetic and environmental factors contribute to the development of the trait.[2,3]

This poster presents a case study ($n = 50$) of an existing method for scoring mandibular tori on a contemporary donation sample.[1] Mandibular tori trait expression has potential applications in personal identification, making scoring accuracy imperative.[4] The sample used for this analysis consists of mandibles from the Texas State University Donated Skeletal Collection.[5] The age at death of the individuals ranged from 31 to 95 years, of which 16 were females and 34 were males. Utilizing the established Hasset[1] scoring method for mandibular tori, the methodology was found to be insufficient to accurately characterize the range of expression in human mandibles within the sample.[3]

Due to the established method's broad numerical range for *pronounced* expression and intra-observer error as a result of the chosen instrumentation, a revision to the method is suggested. The revision refines the description of the metric scoring and introduces the use of an alternative measuring instrument. Specifically, the alternate measuring instrument, a modified stainless steel pocket ruler, is adapted to fit within the confines of a mandible. The updated method enables unobstructed measurements from the lingual surface of the tooth to the lingual surface of the tori, overall improving accuracy and ensuring a more reliable quantification of the trait's morphology by minimizing the obstruction of the caliper arms. Lastly, improving the current method can lead to a better understanding of the variation in mandibular tori concerning age, population affinity, sex, and environmental influences.[3-

Y96 Optimizing Trace DNA Recovery: A Comparative Evaluation of Swab Types on Various Substrates

Mara Dominguez, BA, Arcadia University, Reading, PA; Anna Franzoni, MSc, Copan Italia Spa, Brescia, Lombardia, Italy; Nicole Novroski, PhD, Center for Human Identification, College of Biomedical and Translational Sciences, UNTHSC, Fort Worth, TX; Fabio Oldoni, PhD, Arcadia University, Glenside, PA*

Learning Objectives: After attending this presentation, participants will understand the relative effectiveness of the single-swab method using 4N6FLOQSwabs compared to the traditional double-swab method with cotton swabs for recovering touch DNA from plastic, metal, wood, and poly-cotton fabric substrates.

Impact Statement: This study contributes to forensic science by examining whether a single moistened nylon swab can replace the standard double-swab cotton method, potentially simplifying and improving touch DNA collection protocols, increasing total DNA yield from crime scene evidence sample, and enhancing the likelihood of obtaining usable DNA profiles.

Abstract Text: Touch DNA, a subset of trace DNA, is frequently encountered in forensic investigations, yet recovering sufficient DNA from touched surfaces remains a challenge.[1] Traditionally, the double swab method—applying a moistened swab followed by a dry swab—is the standard for collecting touch DNA using cotton swabs. However, advancements in swab design, such as the flocked Copan 4N6FLOQSwabs, may offer higher DNA yields and eliminate the need for dual swabbing.[2]

This study compared the effectiveness of three swabbing methods across four substrates: metal, wood, plastic, and poly-cotton fabric. Ten participants were recruited, each placing their dominant hand on one of the substrates for five minutes. The substrate was then swabbed using one of the following collection methods: (1) double cotton swab (Puritan) (2) single dry 4504C 4N6FLOQSwab, or (3) single moistened 4504C 4N6FLOQSwab. A one-hour period was included between trials to allow DNA on the hand to replenish, after which participants repeated the procedure two more times with the remaining collection methods. DNA was extracted and eluted in 35ul, quantified using the GlobalFiler Trio Quantification Kit on a QuantStudio real-time PCR system. Following quantification, samples were amplified using the GlobalFiler Amplification Kit on a ProFlex PCR system. Finally, the amplicons underwent capillary electrophoresis for fragment separation using the SeqStudio Genetic Analyzer and results were analyzed using the GeneMapper ID-X software.

Preliminary data from five participants showed that the single dry 4504C 4N6FLOQSwab yielded the highest total DNA recovery, with an average of 4.50 ng. The moistened 4504C 4N6FLOQSwab produced the second-highest yield, averaging 2.06 ng. The double-swab method yielded the lowest average recovery at 0.78 ng. For quantifiable DNA, the same trend was observed: the dry 4504C swab produced the highest concentration (0.129 ng/uL), followed by the moistened 4504C swab (0.059 ng/uL), and the double cotton swab (0.022 ng/uL)

Additionally, all swab types across all surfaces produced either complete or partial single or mixed DNA profiles, demonstrating the feasibility of the collection methods. However, many samples—particularly those from fabric substrates collected with Copan swabs—resulted in mixed profiles, suggesting that porous surfaces retain higher amounts of DNA. Overall, the dry Copan 4N6FLOQSwab appears to be a promising alternative to the double-swab method for touch DNA collection, offering greater recovery rates and simplified procedures without the need for additional swabs or added moisture.

Y97 Characterization of Microsatellite Markers for Forensic Identification of *Gypsophila*

Laila M. Mansour, John Jay College of Criminal Justice, Brooklyn, NY; Nathan Lents, PhD, John Jay College of Criminal Justice, New York, NY*

Learning Objectives: After attending this presentation, attendees will have an improved understanding of the molecular applications for forensic botany and the discovery and characterization of microsatellites that can be used for discrimination of individuals within a species.

Impact Statement: Plant residue is widely found at crime scenes but is underutilized in forensic investigations. Current methods depend primarily on visual inspection, which is subjective and can therefore result in challenges in court, and current molecular applications are still in development. The development of Short Tandem Repeat (STR) profiling of plant tissue will provide a powerful new tool for forensic crime scene investigation that will allow for the discrimination of individual plants within a species.

Abstract Text: Forensic botany is currently underutilized in the field of forensic science despite the widespread finding of plant residue at crime scenes, as current techniques in the field depend primarily on visual inspection, which is subjective and can therefore result in challenges in court.[1,2] The use of molecular applications of forensic botany are promising but depend on DNA-based identification of plant species, which is complicated by the complex nature of the plant genome and widespread presence of Polymerase Chain Reaction (PCR) inhibitors in certain plant species that can limit downstream applications.[1,2] Due to these complications, researchers in the forensic botany field have been unable to reach a consensus on the best genomic reason to utilize for species identification in plants. Furthermore, while the genomes of a few commercially available species have been sequenced and annotated, there is still more progress to be made in order to discriminate individuals within a species. Utilizing species-specific primers developed to differentiate wild populations of *gypsophila* in North America, this research aims to characterize microsatellite markers to differentiate commercially available gypsophila plants in New York City.[3] The development of STR profiling of plant tissue will provide a powerful new tool for forensic crime scene investigation.

Y98 The Correlation of the Dimensions of Hands and Feet With Height in an Indigenous Population of the Tribal District of Himachal Pradesh, India

Yatiraj Meghraj Singi, MD, All India Institute of Medical Sciences, Bilaspur, Bilaspur, Himachal Pradesh, India; Dipen Dabhi, MD, All India Institute of Medical Sciences, Bilaspur, Bilaspur, Himachal Pradesh, India*

Learning Objectives: By the end of this presentation, attendees will be able to: (1) understand the correlation between hand and foot dimensions and stature within an indigenous tribal population from Himachal Pradesh, India; (2) identify the most reliable anthropometric parameters for accurate stature estimation in forensic contexts; (3) evaluate gender-based and regional variations affecting the predictive value of hand and foot measurements; and (4) apply the study's findings to forensic casework involving partial or dismembered remains, particularly in populations with limited anthropometric reference data.

Impact Statement: This study enhances the accuracy of stature estimation in forensic anthropology by establishing population-specific regression models based on hand and foot dimensions in an indigenous tribal population of Himachal Pradesh, India. Most existing models rely on generalized datasets, which often result in inaccuracies when applied to diverse populations. By addressing this gap, our findings provide forensic practitioners with more precise tools for identifying unknown or fragmented human remains, particularly in cases involving mass disasters, crime investigations, and cross-border identifications. Furthermore, the study highlights the influence of gender and regional variations on anthropometric relationships, offering insights that can refine forensic protocols globally. This research contributes to the development of region-specific reference standards, advancing the scientific rigor and reliability of forensic stature estimation methods and ultimately improving outcomes in human identification across diverse demographic contexts.

Introduction: Stature is considered as one of the parameters for personal identification and one of the 'big fours' of forensic anthropology. The stature of an individual is an inherent characteristic, assessment of which is considered pivotal in the identification of unknown human remains. The current study focuses on understanding the relationship between hand and foot measurements with height in the indigenous population of Kinnaur and Lahaul and Spiti districts of Himachal Pradesh, India. Stature estimation is a crucial aspect in forensic and anthropological fields, especially for identifying individuals from dismembered bodies. This study aims to fill the gap in the existing literature by focusing on a specific indigenous population, thereby enhancing the accuracy of stature estimation methods in forensic science and physical anthropology.

Primary objective of this research is to analyze the anthropometric relationships between the dimensions of feet and hands with the height of the individuals. The study also aims to estimate gender variations in these dimensions and analyze the correlation between hand and foot measurements. The study involved 383 individuals aged between 18 and 50 years from the tribal areas of Himachal Pradesh, ensuring that participants were residents for atleast three generations.

Methodology: The study was carried out after obtaining the Ethical Approval from Institute Ethics Committee. The participants were recruited through door-to-door surveys and random sampling methods. After obtaining their consent, the height was measured using a stadiometer (in cm), while hand and foot dimensions of both extremities were measured using a digital vernier caliper (in mm).

Results: The overall mean stature of the population was found to be 163.78 ± 9.68 cm, with a mean right foot length of 241.09 ± 15.68 mm and a mean left foot length of 241.66 ± 15.67 mm. For males, the mean stature was 168.43 ± 8.84 cm, with the mean right and left foot lengths being 248.93 ± 12.38 mm and 249.82 ± 12.51 mm, respectively. For females, the mean stature was 156.71 ± 5.91 cm, with mean right and left foot lengths of 229.17 ± 12.30 mm and 229.24 ± 11.22 mm, respectively. Foot length emerged as the most reliable metric for estimating stature across both genders. However, the study found regional variations, with right foot length being more accurate for predicting stature in Kinnaur and Lahaul districts, while left foot length was more reliable in the Spiti district. The mean right hand length was 183.15 ±12.17 mm and the left hand length was 183.11 ± 12.12 mm. Of both the hands, the right hand was more reliable predictor of the height of the individual.

Conclusions: This study offers significant insights into the estimation of an individual's stature using anthropometric measurements of the hand and foot. It demonstrates that foot length is the most reliable metric for stature prediction. The findings can be applied in forensic science and anthropological investigations, aiding in the accurate estimation of stature from hand and foot measurements, particularly in the unique indigenous population of Tribal populations living in the Kinnaur and Lahaul and Spiti districts of Himachal Pradesh, India.

Y99 Ear Lobe Crease as a Coronary Artery Disease Risk Stratification Tool in Autopsies of Asian Populations

Minjung Hong, MD, Seoul National University College of Medicine, Seoul, Seoul-t'ukpyolsi, Republic of Korea; Seong Ho Yoo, MD, PhD, Seoul National University College of Medicine, Seoul, Seoul-t'ukpyolsi, Republic of Korea*

Learning Objectives: After attending this presentation, Attendees will understand the validated association between Ear Lobe Crease (ELC) and Coronary Artery Disease (CAD) in Asian populations, characterized by a robust dose–response relationship (R^2=0.960). Attendees will apply age-stratified screening algorithms achieving perfect sensitivity and Negative Predictive Value (NPV) for individuals aged 50 years and younger. Additionally, attendees will recognize ELC as an indicator of systemic vascular pathology including myocardial fibrosis and basilar atherosclerosis, enabling evidence-based decisions for multi-organ vascular assessment during forensic examination.

Impact Statement: This presentation introduces validated, age-optimized screening criteria that substantially enhance forensic case triage. The demonstrated overall NPV of 95.0% and perfect NPV for individuals ≤50 years enable efficient exclusion of CAD-related mortality, optimizing resource allocation in forensic facilities. The 22-fold increased odds of myocardial fibrosis among ELC-positive cases supports new protocols for comprehensive vascular examination, thereby improving the accuracy of atherosclerosis-related mortality determination in Asian populations.

Abstract Text: The ELC has long been suggested as a clinical marker of CAD.[1] Forensic investigations have highlighted its diagnostic accuracy, particularly its high NPV for excluding CAD-related mortality.[2] While associations with systemic vascular disease, including cerebrovascular pathology, have been reported, validation in Asian populations remains limited.[3]

This study analyzed 599 consecutive forensic autopsies conducted at the Department of Forensic Medicine, Seoul National University College of Medicine. Objectives were: (1) to validate the ELC–CAD association in an Asian population, (2) to develop age-optimized screening models, and (3) to assess systemic vascular correlations. The study cohort (mean age 51.8±14.3 years; 77.8% male; mean BMI 23.0±4.0 kg/m²) was evaluated for ELC severity (grades 0–3). Vascular pathology included coronary stenosis (≥50% luminal narrowing), basilar artery atherosclerosis, myocardial fibrosis, and intracranial hemorrhage. Four prediction models (logistic regression, ridge regression, gradient boosting, random forest) were tested using ELC grade, sex, age, and BMI.

ELC exhibited a robust grade-dependent relationship with CAD, with prevalence increasing from 2.2% (grade 0) to 31.5% (grade 1), 49.8% (grade 2), and 100% (grade 3), demonstrating a near-perfect correlation (R^2=0.960, $p < 0.001$). Each one-step increase in ELC grade conferred a 4.88-fold higher risk of significant coronary stenosis ($p < 0.001$). Logistic regression yielded the best screening performance, achieving 93.5% sensitivity and 96.6% NPV overall. Age-stratified analysis showed perfect performance for individuals ≤50 years (n=327), with 100% sensitivity, 100% NPV, and an AUC of 0.916. Within this group, ELC remained a strong predictor (adjusted OR=5.71, $p < 0.001$), alongside BMI (OR=1.17, p=0.002).)

Systemic vascular analysis revealed significant associations between ELC and both basilar atherosclerosis (adjusted OR=2.28, p=0.035) and myocardial fibrosis (adjusted OR=22.74, $p < 0.001$). No significant association was observed with intracranial hemorrhage (p=0.365).

This large-scale Asian forensic autopsy series validates ELC as a powerful screening tool for CAD, particularly for individuals ≤50 years, where perfect sensitivity and NPV were achieved. The dose–response relationship strengthens the biological plausibility of the ELC–CAD link. Associations with myocardial fibrosis and basilar atherosclerosis further establish ELC as a systemic vascular biomarker. These findings position ELC as a validated and practical risk stratification tool in forensic pathology, guiding comprehensive multi-organ vascular assessment beyond the coronary system.

Y100 Dermestid (Flesh-Eating) Beetle Effect on Skeletal Remains Study

Gabriella DE Ramm, Fairmont State University, Fairview, PA; Kristy D. Henson, PhD, Fairmont State University, Fairmont, WV*

Learning Objectives: This presentation discusses how dermestid beetles alter cortical and trabecular bone during detritivore activity. Upon attend this presentation, attendees will understand ways in which dermestid beetles can alter the presence of ante- and postmortem skeletal modifications and how to identify beetle presence in skeletal remains.

Impact Statement: This research enhances understanding of decomposition by examining how dermestid beetles interact with bone during the skeletonization process adding new data on how carrion activity can alter skeletal remains.

Abstract Text: Scavenger activity is expected when one discovers human remains and markings vertebrate detritivores leave on skeletal material is regularly studied.[1] Scavengers create pseudo-lesions that that can limit forensic skeletal analysis, but invertebrate affects are recently being studied. Some labs use Dermestid beetles to remove soft tissue as they offer a non-invasive flensing option and are easy to maintain.[2,3] These beetles have been known to penetrate the bone and their effects on bone have not been studied.[4]

The objective of this study was to assess the extent beetles alter bone in a controlled environment. Deer long bones (n = 25) were skinned and placed in a dermestid beetle colony until all soft tissue were removed. Once the bones were completely cleaned, they were removed and decreased.[2,3] After degreasing, the bones were macroscopically analyzed for overall beetle presence and the presence of beetle feedings marks. Weathering fractures and epiphyses were analyzed for beetle feeding marks using a dissecting microscope. Finally, the epiphyses and mid diaphysis were cut to examine the trabecular bone and medullary cavity for evidence of beetle presence. Results showed 96% (n = 24; SD 0.2) of bones had evidence of beetles, larva, or pulpal chambers in the bone, 100% (n = 25; SD 0) showed evidence of beetle feeding on the epiphyses or diaphysis, and 1.78% (n = 4; SD 0.06) indicated evidence of beetle activity inside the trabecular bone or medullary cavity. Beetle feeding marks were present on longitudinal weathering fractures, changing the appearance of the cortical bone. This is important as beetle markings can alter ante, peri, or postmortem skeletal lesions.

Understanding how scavengers like dermestid beetles interact with skeletal remains can aid forensic scientists in estimating postmortem intervals.[1] It is important to consider invertebrates during the decomposition process as they can alter a forensic anthropologist's ability to accurately analyze ante, peri, or postmortem skeletal trauma. More research is needed regarding invertebrate affects to skeletal remains.

Y101 Sick as a Dog: A Case of a Missing Face

Maura Thurber, MHS, University of Iowa Health Care, Iowa City, IA; Alexis M. Kollasch-McGarvey, MD, University of Iowa Hospitals and Clinics, Iowa City, IA; Eric Bracken, MS, Carver College of Medicine, Iowa City, IA; Dennis Firchau, MD, University of Iowa Carver College of Medicine, Iowa City, IA; Robert Francis Weis, MD, Muscatine County Medical Examiner Office, Muscatine, IA; Melissa M. Blessing, DO, Johnson County Medical Examiner and University of Iowa Health Care, Iowa City, IA, Iowa City, IA*

Learning Objectives: In this presentation, attendees will be reminded of the classic gross and microscopic appearance of postmortem injuries, particularly those inflicted by scavenging carnivores, and recognize patterns of postmortem predatory disruption of corpses in indoor versus outdoor settings, with indoor scavenging by pets disproportionately involving the face. This case contributes to a growing body of evidence that domestic dogs may inflict a particular pattern of postmortem injury to their owners, potentially as part of an anxiety response to witnessing their sudden death.

Impact Statement: This presentation will solidify the forensic community's ability to determine cause and manner of death in cases involving postmortem disruption and recognize various patterns of animal scavenging based on environmental factors. Postmortem mutilation by animals can complicate interpretation of crime scenes and determination of the cause and manner of death, particularly in cases of pronounced animal scavenging or under-reported scenarios such as postmortem scavenging by domestic pets.

Abstract Text: Postmortem animal scavenging is commonly recognized among medicolegal death investigators and forensic pathologists as a cause of artefactual destruction of human remains and disorganization of crime scenes in outdoor and indoor deaths. Hunger is a commonly cited motivation in outdoor settings; in these cases, there is disproportionate involvement of the trunk and limbs and relative sparing of the head. Scavenging by indoor domestic dogs within a short postmortem interval is a rarely reported phenomenon with a pattern of findings that may represent an alternative motive besides hunger. Herein, we describe a dramatic case of indoor canine scavenging in a non-aggressive pet with readily available food.

The decedent was a 58-year-old male with history of alcohol dependence, hypertension, and gastrointestinal disease requiring ileostomy, who resided with his mother. He reportedly quit drinking "cold turkey" 3 days prior to death and complained of being sick and vomiting. His mother found him deceased in his bed approximately five hours after last being known alive, clothed and supine in a relaxed posture, with marked disruption of the face and neck after reportedly sleeping with the family's two German Shepherd dogs. Vomit was in a nearby wastebasket. Blood was beneath the decedent, but no blood spray/spatter was noted. Apparent blood was on the muzzle and front paw of the male dog, who had never displayed aggressive behavior toward his owners or others. The female dog showed no evidence of postmortem interaction with the decedent. Accessible dog food was in the kitchen.

Autopsy revealed an adult male with subtotal skeletonization of the face and neck, and no defensive-type wounds. The skin and soft tissues of the face were completely avulsed with dried, orange-tan, irregular borders. Puncture wounds in the inferolateral mandible were consistent with canine tooth marks and the mental protuberance was partially absent. The left common carotid artery was disrupted. Surrounding neck musculature was coated with dried, maroon blood and canine hair. Histology showed no evidence of vital tissue response.

Pets have been reported to bite and lick their obtunded owner's faces, suggested to represent a stress response or resuscitative effort. Unwitnessed alcohol withdrawal-related seizure activity and/or attraction to vomitus at the mouth are other possibilities in our case. Some authors suggest progression to bone destruction may represent transition to hunger-based motivation; However, the short postmortem interval and presence of accessible food in our case contradicts that suggestion. This case does contribute to a growing body of literature suggesting a distinct pattern of domestic canine preferences for the face, underscoring the suggestion that animal predation in an indoor context may in part be due to displacement behavior in addition to other motivators. The opposing actions of the two dogs in this case exemplifies the differences that can be seen in animal behavior and postmortem animal predation despite having similar circumstances.

While etiology of scavenging is unknown in our case, the limited body of literature describing domestic canine preferences for the face is concordant. While visually dramatic, these findings should not be misinterpreted as antemortem injuries.

Y102 Forensic Differentiation of Canine Hair

Allison Kelley, Liberty University, Lynchburg, VA; Kristin Mossé, MSFS, Liberty University, Lynchburg, VA*

Learning Objectives: This presentation demonstrates how microscopic analysis will be applied to identify and differentiate between breeds of canines, while considering gender, age, and diet. Attendees can learn how evaluating various characteristics of dog hair may have significance in the trace evidence discipline when these are found at a crime scene or on a victim or suspect.

Impact Statement: There is little to no research currently on the hair analysis differentiation between canine breeds, and this research can enhance proficiency in trace evidence by introducing areas for further examination. It can improve performance by providing a new utilization of microscopic analysis that experts can attempt to use when canine hair is relevant in a case.

Abstract Text: The goal of this research is to determine whether the characteristics of dog hair can effectively differentiate between canine breeds, which is important for forensic applications. While there is extensive literature on human hair analysis, there is not much to be found on canine hair, although dogs are present at many crime scenes. This research ultimately aims to gather sufficient data on a wide range of dog breeds to compile a comprehensive database to identify differences in dog hair, contributing to the discipline of trace evidence hair analysis within forensic science. The central hypothesis in this study is that specific medullary patterns, medullary structures, cuticle patterns, and other distinctive features in guard and fur hair can be used to identify canine breed from an unknown hair. Preliminary research has analyzed hair from breeds such as Black Mouth Cur, Blue Heeler/Border Collie mix, Dachshund, Pug, and miniature Schnauzer. Characteristics like color, texture, length, presence of ovoid bodies, medullary features, and appearance under a polarizing microscope are recorded and considered. The methods of analysis include using both a polarizing light microscope and a comparison microscope alongside a compound microscope to visualize and examine these traits of canine hair. From the canine hair obtained by donations, ten samples are taken and analyzed to earn a representative view of the dog breed's specific hair characteristics. Also, cuticle casts are prepared to evaluate the cuticle differences between breeds. Current findings show differences in medullary qualities even between guard and fur hair from the same animal. Future research hopes to study enough different breeds to see significant differences in hair features, and expand the growing database. Additionally, a quantitative approach will be explored by documenting hair shaft diameters, medulla diameters, and height of cuticles.

Y103 Taphonomic Processes Etch Bones: An Experimental Look at Plant Root Etching on Bovine Bones

Emily E. Caudill, BS, Middle Tennessee State University, McIntyre, GS; Shannon C. Hodge, PhD, Middle Tennessee State University, Murfreesboro, TN; Thomas Holland, PhD;*

Learning Objectives: Attendees will learn how plant roots can alter bone surfaces over a short period and recognize the characteristics and visual signs of root etching. Additionally, attendees will learn about the relevance of root etching in archaeological and forensic contexts. Lastly, attendees will be able to discuss potential projects to further research.

Impact Statement: I believe this presentation is a good step forward in developing methods and a database for analyzing remains with plant root etchings. More needs to be done to quantify and verify how different root types can leave different patterns, and if they are distinguishable by their patterns. While my project is just a small undergraduate study, I believe there could be much more research done in this area that could help both medicolegal investigations and archaeological work with Postmortem Interval (PMI) timelines or potentially with location, if different root types have different patterns.

Abstract Text: Taphonomy is the study that examines the changes that biological remains undergo after death. This project focuses on the aspect of taphonomy that investigates how plant roots interact with skeletal material and how it is applicable in forensic contexts. The experiment explores the effect of root etching on buried bovine rib bones over a nine-month duration within a controlled greenhouse environment. For the experimental setup, four plant species, including *Acer saccharinum L., Buddleia davidii L., Cynodon dactylon, Mentha spicata L.,* and two control samples were evaluated. Results show that root staining and mechanical root action can occur within this period; however, conclusive evidence of rootlet etching is inconclusive without the use of Scanning Electron Microscopy (SEM) analysis. Additionally, unexpected differential staining was noted on some of the bones, which was proposed to be due to components within the potting mix. Moreover, the presence of intrusive *Fatoua villosa* highlighted the difficulties posed by uncontrolled environmental factors in medico-legal scenes. The results found within this experiment can advance forensic anthropology by refining timelines for root interactions with remains, suggesting possible uses in medico-legal investigations. Furthermore, this study shows that future research in the area of plant root etching and mechanical root action should be highly considered.

Y104 Surveillance Shopping of Unregulated Dual Chamber E-Cigarette Devices Assessing Accessibility and Consumer Risk

Kevin Lester, Virginia Commonwealth University Department of Forensic Science, Richmond, VA; Michelle R. Peace, PhD, Virginia Commonwealth University, Richmond, VA; Alaina K. Holt, PhD, Virginia Commonwealth University, Richmond, VA; Justin Poklis, BAS, Medical College of Virginia, Richmond, VA*

Learning Objectives: Attendees will be able to describe the design features, chemical composition, and quality assurance concerns of unregulated dual-chamber nicotine and cannabis vaping devices.

Impact Statement: This presentation will highlight the emergence of unregulated dual-chamber nicotine and cannabis vaping devices and the potential impact on public health, discrete vaping, and the ability to change the e-liquid that is delivered to the user.

Background: Dual-chamber (D-C) electronic cigarettes (e-cigarettes) are an emerging generation of e-cigarettes. Their design allows users to select one chamber or a blend of the two. D-C products are advertised as dual-cannabinoids (various flavors and/or cannabinoid content), semi-synthetic cannabinoids, or a "spliff" (one side nicotine, one side cannabinoid), allowing for the switch between psychoactive components.

Objectives: To analyze commercially available dual-chamber devices containing synthetic cannabinoids alone or in combination with nicotine to determine functionality and chemical composition.

Methods: Five D-C brands (Cookies "all-in-one"; Space Gods "Super Baked"; Ghost "Slide"; ELFTHC "spliffboyz"; and fume RNBW "electric spliff") were purchased online. Devices were disassembled to determine their design, components, and functions. After disassembly, the liquid formulations were sampled for chemical characterization from each chamber. The composition of the liquid formulations was analyzed using a Gas Chromatography/Mass Spectrometry (GC/MS) method, and nicotine and cannabinoids were quantified using Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) methods.

Results: The Cookies "all-in-one" vape (dual cannabinoid) uses a button for selection. The Space Gods "Super Baked" and Ghost "Slide" (dual cannabinoid) feature a sliding mouthpiece for selection. The ELFTHC and fume vapes (spliffs) use a switch mechanism on the bottom of the product to select the chamber. All brands had a heating element in each chamber, which led to a single mouthpiece. All products claimed to have < 0.3% of Δ9-tetrahydrocannabinol (Δ9-THC). The Cookies vape advertised tanks with 1 g of tetrahydrocannabinolic acid (THCA). One tank contained 48 mg of Δ9-THC and 414 mg of Δ8-THC; the other contained 35 mg of Δ9-THC and 308 mg of Δ8-THC. The Space Gods' device advertised 4500 mg Δ10-THC, 500 mg Δ8-THC, 165 mg THCP, and 135 mg hexahydrocannabiphorol (HHCP). Both tanks contained 196 mg of Δ9-THC, 1,876 mg of Δ8-THC, 511 mg of (R)-HHC, and 91 mg of (S)-HHC. The Ghost device advertised a mixture of tetrahydrocannabihexol (THCH), Δ9-THCP, and Δ10-THC. Both tanks contained 375 mg of Δ9-THC, 2,079 mg of Δ8-THC, 434 mg of (R)-HHC, and 231 mg of (S)-HHC. The ELFTHC device advertised "3000 mg THC" (the back label listed Δ8-THC, THC, and Δ9-tetrahydrocannabiphorol (THCP)) and a 7 mL tank with 5% nicotine. One tank contained 135 mg Δ9-THC and 927 mg Δ8-THC; the other contained 2.2% nicotine. The RNBW device advertised "3000 mg THCA" (the back label listed Δ8-THC, THCA, and THCP) and a 7 mL tank with 5% nicotine. One tank contained 132 mg of Δ9-THC and 1,212 mg of Δ8-THC, while the other contained 99 mg of Δ9-THC, 198 mg of Δ8-THC, and 2% nicotine.

Conclusion: These novel devices allow for discrete switching between psychoactive components. Discrepancies between labeled and determined concentrations were demonstrated. All cannabinoid tanks contained >0.3% Δ9-THC and substantially more Δ8-THC. One product contained cannabinoids in the nicotine side of a "spliff" device, and all products contained unlisted cannabinoids. The dual-chambered cannabinoid e-cigarette findings highlight ongoing issues with the unregulated e-cigarette market. Clearer regulatory oversight and consumer awareness is needed to ensure accurate labeling, product transparency, and safe use.

Presenting Author Index—2026

The presenting author index can provide a quick reference to find when and in what section presenting authors are scheduled to present at the 2026 Annual Scientific Conference. The reference table below assists you in finding the section in which the presentation will be given. Letters correspond to the scientific discipline/section in which the presentation is being made while the number corresponds to the numerical sequence of the presentation within the section.

A	Anthropology
B	Criminalistics
C	Digital & Multimedia Sciences
D	Engineering & Applied Sciences
E	Forensic Nursing Science
F	General
G	Jurisprudence
H	Odontology
I	Pathology/Biology
J	Psychiatry & Behavioral Science
K	Questioned Documents
L	Toxicology
LW	Last Word Society
Y	YFSF Poster
CB	Case Break Session
DD	Deep Dive Session
LS	Luncheon Seminar
S	Special Session
W	Workshop
