Learning Objectives: After attending this presentation, attendees will understand: (1) how forensic drug chemists can support the development and implementation of fentanyl canine detection strategies using analytical and organic chemistry expertise; (2) how to collaborate with drug detection canine practitioners to maximize training goals; and (3) how to evaluate field operations for fentanyl interdiction strategies.

Impact Statement: This presentation will inform the forensic science community on strategies they can take to apply their expertise in seized drug chemistry to advance scientific approaches for canine fentanyl detection. The integration of analytical laboratory testing and canine trials demonstrates the development and application of fentanyl training aids that represent the most current drug landscape, serving as a model for training aid development to address other emerging synthetic drug threats.

Abstract Text: In 2017, United States Customs and Border Protection (CBP) became the first law enforcement agency in the world to train canines to detect fentanyl, in rapid response to this synthetic drug threat.1 CBP Laboratories and Scientific Services (LSS) Canine Training Aids Program quickly deployed fentanyl training aids to support this effort. However, since that time, fentanyl manufacturing and trafficking has shifted from production in China of extremely pure fentanyl and its analogs to more current haphazard "cooking operations" in clandestine labs in Mexico as well as "super labs" in Canada. To ensure that training aid materials match the current threat landscape, LSS has characterized 100+ recent border seizures to determine the most representative materials that should be considered for training aids and deployed new fentanyl training aids to CBP canine units in 2025.

CBP/LSS uses a variety of qualitative and quantitative analytical techniques to comprehensively characterize seizures of illicitly manufactured fentanyl for canine training aid purposes, including Gas Chromatography/Mass Spectrometry (GC/MS), Fourier Transform Infrared Spectroscopy (FTIR), Gas Chromatography/Flame Ionization Detection (GC/FID), and benchtop 1H Nuclear Magnetic Resonance. Forensic drug chemists at state and local labs are well-versed and well-positioned to use the same techniques to support their local canine units. Importantly, forensic drug chemists can also learn from LSS's experience in the application of Solid Phase Microextraction/Gas Chromatography/Mass Spectrometry (SPME/GC/MS) to characterize the volatile organic Compounds (VOCs) that comprise the chemical odor profiles to better understand the odors of drug materials encountered by CBP canines.

LSS analysis has found that the primary VOCs detected in illicitly manufactured fentanyl are related to the synthetic routes, precursor chemicals, solvents/reagents, adulterants, by-products, and degradation products, contributing to different types of odor profile "variants." In partnership with CBP's canine programs, LSS designed and conducted several canine trials to demonstrate and evaluate canine performance using these fentanyl aids consisting of these variants. These studies serve as a model that forensic drug chemists can use to collaborate with their local canine units to ensure the highest quality and most appropriate materials are used to meet training goals.

This presentation will discuss the analytical strategies that all forensic science practitioners can implement to assess and select the most appropriate seized fentanyl materials for use as training aids for law enforcement canine teams operating in their jurisdictions. As of 2020, approximately 16,000 canine teams are employed by state and local law enforcement agencies in the United States, which rivals the number of forensic scientists employed by all United States forensic laboratories at 15,600.2 Many of these canine units are considering adding fentanyl as a trained odor and will be relying on the experience and expertise offered by forensic drug chemists to guide them in identifying the most appropriate materials. LSS has been a leader in demonstrating how forensic scientists can collaborate with canine practitioners to integrate forensic chemistry expertise with detection dog training and operations. These same evidence-based practices can be translated and implemented by other forensic laboratories to advance canine fentanyl detection efforts across the United States.

B200 The Development and Evaluation of a Novel Alternative Canine Training Aid for Fentanyl

Jonathan McGrath, PhD, U.S. Customs and Border Protection, Laboratories and Scientific Services, Houston, TX; Kristine K. Tanabe, PhD, U.S. Customs and Border Protection, Long Beach, CA*

Learning Objectives: After attending this presentation, attendees will understand: (1) the role of alternative training aids in canine training, specifically for synthetic drug threats like fentanyl; (2) the developmental process to identify and select chemical compounds that mimic the odor of fentanyl; and (3) the design of robust canine trials to verify the effectiveness of an alternative fentanyl training aid and evaluate canine performance following implementation of the training aid in daily field operations.

Impact Statement: This presentation will inform the forensic science community on strategies to develop, assess, and implement novel alternative canine training aids for drugs, specifically for fentanyl. This information can be used by forensic scientists in collaborations with drug detection canine experts to advance evidence-based practices to support the implementation of alternative training aids, particularly for the safe and effective detection of fentanyl. This model can be applied to the development of novel alternative training aids for other emerging synthetic drug threats.

Abstract Text: In 2017, the United States Customs and Border Protection (CBP) became the first law enforcement agency in the world to train canines to detect fentanyl.[1] While the CBP Laboratories and Scientific Services (LSS) Canine Training Aids Program quickly deployed fentanyl training aids to support this effort, CBP's canine program requested that LSS develop a pseudo-narcotic training aid for fentanyl that can be used as a safe alternative to real fentanyl. LSS regularly produces pseudo-narcotic training aids, or "mimics," for cocaine, methamphetamine, heroin, and ecstasy, whereby the Volatile Organic Compounds (VOCs) selected for the training aid production imitates the real odor of a target material. While CBP canine teams use real drug training aids on a biweekly basis to maintain canine performance, this requires supervision by canine instructors. The role of pseudo-narcotic training aids supplements these training protocols by allowing individual canine handlers to conduct more frequent (daily) performance checks directly in the operational environment, using a non-controlled substance.

CBP/LSS identified a series of candidate chemicals for potential use as a pseudo-fentanyl training aid by characterizing the chemical odor profiles of several high-purity fentanyl border seizures using Solid Phase Microextraction/Gas Chromatography/ Mass Spectrometry (SPME/GC/MS). Once the most common chemical odorants were identified, LSS developed a series of promising training aid formulations using a highly absorbent base material that can be easily used by CBP canine handlers. LSS worked with the CBP canine academy to assess canine performance of these training aid formulations, first using drug detection canines that were certified to detect fentanyl, followed by using "green canines" trained only to the odor of the pseudo-fentanyl aids. LSS also assessed canine performance using CBP operational drug detection dogs at the Southwest border. Through these canine assessments, LSS identified an optimal training aid formulation to advance canine fentanyl detection strategies. The development of these canine trials aligned with the recent draft "Standard for the Systematic Verification of Alternative Training Aids for Detection Canine Disciplines" developed by the National Institute of Standards and Technology (NIST) Organization of Scientific Area Committees (OSAC) Dogs and Sensors Subcommittee and demonstrates the utility of this standard by the forensic science and detection canine communities.[2] Based on the successful results of these trials, CBP submitted a patent application for this pseudo-fentanyl training aid, which was accepted by the United States Patent and Trademark Office in 2025.[3]

This presentation will discuss the training aid formulation and production processes, as well as the design of the canine trials to demonstrate to the forensic science community the scientific approaches for assessing the effectiveness and utility of novel alternative canine training aids. LSS is working with CBP's canine programs to evaluate the implementation of this new training aid by canine handlers in the field, and LSS is available to collaborate with forensic science and canine drug detection communities to support technology transfer activities. This experience serves as a model that can be applied to the development of novel alternative training aids that advance canine detection strategies for other emerging synthetic drug threats as they arise in the future.

B201 Canine Training Aid Development of Novel Target Odors to Advance Strategies to Combat Fentanyl Precursors at the Border

Armando Avallone, MS, U.S. Customs and Border Protection, Houston, TX; Jonathan McGrath, PhD*, U.S. Customs and Border Protection, Laboratories and Scientific Services, Houston, TX*

Learning Objectives: After attending this presentation, attendees will understand: (1) how forensic drug chemists can support the development and implementation of novel canine detection strategies using analytical and organic chemistry expertise; (2) how to collaborate with drug detector dog practitioners to maximize the training experience; and (3) how to evaluate field operations to understand the benefits and challenges when implementing innovative and novel training aid materials.

Impact Statement: This presentation will inform the forensic science community on strategies they can take to apply their expertise in seized drug chemistry to advance scientific approaches in the field of canine detection. The integration of analytical laboratory testing and canine trials demonstrates the development and application of new training aids, particularly for fentanyl precursor chemicals.

Abstract Text: One of the objectives of the United States Customs and Border Protection (CBP) "Strategy to Combat Fentanyl and Other Synthetic Drugs" is to improve the detection of synthetic drug precursor chemicals.[1] CBP has a unique role as it has the opportunity to interdict shipments of these chemicals used in the illicit manufacture fentanyl and other synthetic drugs while they are moving through the global supply chain.[2] In 2023, the CBP Laboratories and Scientific Services (LSS) Canine Training Aids Program coordinated with the CBP Office of Field Operations National Canine Enforcement Program (OFO/NCEP) and the Office of Training and Development Field Operation Canine Academy (OTD/FOK9) to establish a ground-breaking pilot program of six dogs trained to detect fentanyl precursor chemicals and other emerging drug threats. This approach required the innovative development of brand-new types of training aids to support both canine training, deployment, and evaluation for this seven-month pilot project in 2024. Successful implementation warranted further expansion of this canine unit in 2025.

As there are several types of synthetic pathways to manufacture fentanyl, including the Jansen, Siegfried, Gupta, and modified-Gupta routes, LSS needed to consider several different precursor targets to initiate the pilot program by collecting information on the relevant Volatile Organic Compounds (VOCs) that the canines may encounter during search operations for these precursor materials.[3,4] In this first phase, LSS performed analysis using Solid Phase Microextraction/Gas Chromatography/Mass Spectrometry (SPME/GC/MS) to characterize the Chemical Odor Profiles (COPs) of both reference and seizure materials. The second phase included coordination with FOK9 to develop the most representative training aids to conduct the canine training of six dogs dedicated for this pilot program. Based on the COP analysis, LSS also provided materials of interest to assess canine response behavior of materials that exhibit similar VOCs, such as similar precursor chemicals and real fentanyl, which provided useful information prior to canine field deployment. The final phase of LSS support provided scientific advice to OFO NCEP during the implementation of these canine teams into the operational environment. LSS scientists located onsite at Forward Operating Laboratories (FOLs) are able to provide rapid presumptive results to inform OFO's enforcement actions. LSS also provided reach-back support to understand the chemical odor profiles of materials encountered in the field that have similar odor profiles to the trained target materials. This constant scientific feedback loop is yielding valuable information to advance CBP's understanding of the benefits and limitations of this pilot program and expand the program to include additional fentanyl precursor chemicals.

This collaborative pilot program demonstrates the role and value of integrating forensic chemistry expertise with detection dog training and operations. CBP has learned how to rapidly leverage scientific capabilities to address and evaluate operational needs and strategies that are developing evidence-based knowledge to inform agency decision-making. As the illicit drug markets shift to create an even greater assortment of synthetic drugs, these training aid development strategies can be flexed to target the highest mission priorities.

B202 Canine Training Aid Substrate Optimization: Non-Targeted Contamination, and VOC Adsorption and Desorption

Fernando Zaldivar, BS, Florida International University, Miami, FL; Natalia Gil Guitierrez, Florida International University, Miami, FL; Kenneth G. Furton, PhD, Florida International University, Miami, FL; Lauryn DeGreeff, PhD, Florida International University, Miami, FL; Eduardo Moreira, Florida International University, Miami, FL*

Learning Objectives: By the end of this presentation, attendees will be able to: (1) explain how substrate structure and composition influence the availability and fidelity of canine-training odor cues.; (2) compare adsorption and desorption performances of five candidate substrates (cotton gauze, Getxent tube, cellulose/SiO_2 composite, Fabric Phase Sorptive Extraction [FPSE] media, Polydimethylsiloxane [PDMS]) across four representative Volatile Organic Compounds (VOCs); (3) assess each substrate's susceptibility to non-target environmental contamination and the practical trade-offs this creates for field use; and (4) apply substrate-selection criteria—sorptive capacity, volatility retention, and selectivity—to design or choose training aids that improve detection-dog accuracy in specific scenarios.

Impact Statement: Engineering the substrate, not just choosing the right target odorant, proves pivotal for canine training aids, delivering more consistent, contamination-resistant odor cues that sharpen detection-dog accuracy.

Abstract Text: Detection dogs rely on training aids that reproducibly present target odors.[1] Regardless of the training aids, at their core, they are composed of a substrate matrix and a representative target odor. While dogs can be trained using various types of training aids, the learning process remains the same: positive reinforcement through repeated exposure to the aid. Consequently, the type and structure of the substrate carrying the odorant play a critical role in odor availability and fidelity, ultimately impacting the overall reliability of detection.[2] This study evaluated five substrates: cotton gauze, Getxent polymer tube, cellulose/silicon dioxide composite powder, FPSE media, and PDMS, each with four target odorants (decanal, 1-bromooctane, acetic acid, and 2,4-dinitrotoluene) to compare the substrates' adsorption/desorption efficiency and their susceptibility to contamination.

To study adsorption of target odorants onto each substrate, the substrates were sealed inside a container, and the headspace was then filled with the target analyte vapor by a dynamic gas system. The relative quantity of the target vapor was measured initially and again following an equilibration period by Solid Phase Microextraction (SPME) with characterization by Gas Chromatography/Mass Spectrometry (GC/MS). The subsequent decrease in headspace concentration was proportionally related to the VOC sorbed by the substrate. Desorption was additionally quantified by Thermogravimetric Analysis (TGA), tracking mass loss from fully saturated substrates under a programmed temperature ramp, providing a measure of the VOC released.

Additionally, the susceptibility of the substrates to non-targeted contamination was assessed. The substrates were exposed to training locations similar to those detection dogs would experience during active training and then analyzed for the presence of environmental VOCs in the substrate headspace. The contamination of VOCs onto the substrates was characterized by SPME-GC/MS.

The study revealed a range of performance rather than a single "best" material. Each substrate displayed a distinct adsorption-or-release profile; some followed Langmuir-type adsorption isotherms, whereas others exhibited an initial "burst release." Likewise, some substrates were more prone to pick up a wider variety of contaminants but perhaps in lower concentrations, while others would capture fewer contaminant types but in higher concentrations. All substrates showed a preference for specific compound types. No single substrate was universally superior—each presented trade-offs between odor stability and contamination susceptibility.

Substrate choice is a fundamental factor in canine training-aid efficacy. Simple, readily available materials can be convenient but may provide less stable VOC release and be prone to contaminant uptake. Engineered polymers can deliver prolonged odor profiles, especially for less-polar VOCs, thereby improving consistency in training. High-capacity sorbents effectively capture target odorants but may also sequester unwanted volatiles if not carefully managed. Optimizing parameters such as sorptive capacity, volatility retention, and inertness improves the selectivity and reliability of training aids, ultimately enhancing the fidelity of forensic canine detection. Moreover, choosing inert, non-hazardous materials and minimizing contamination safeguards canine welfare and upholds ethical training practices. These findings illustrate that strengthening fundamental material performance can directly enhance the effectiveness of detection-dog operations.

B203 Standards Development Activities Related to Ignitable Liquids, Explosives, and Gunshot Residue

Laura Hernandez, BS, Verity Labs, Inc., Las Cruces, NM*

Learning Objectives: After attending this presentation, attendees will have a better understanding of the status of discipline-specific consensus standards related to Ignitable Liquids (IL), Explosives (E), and Gunshot Residue (GSR).

Impact Statement: The presentation will impact the forensic science community by creating a greater awareness of the standards development activities related to IL, E, and GSR disciplines.

Abstract Text: The Organization of Scientific Area Committees (OSAC) for Forensic Science plays an important role in elevating the quality and reliability of forensic practices across the United States. Established with a clear mandate to strengthen forensic science, OSAC fosters the implementation of robust, discipline-specific standards. This critical mission is achieved through a rigorous two-pronged approach.

Firstly, OSAC undertakes a comprehensive review of existing consensus standards. Those that demonstrably meet the field's highest expectations for technical soundness and widespread acceptance are then formally recognized and placed on the OSAC Registry. This Registry acts as a centralized hub, ensuring that forensic practitioners and laboratories can identify high-quality, consensus-based, and technically sound guidelines. It serves as a benchmark for best practices, promoting consistency across various forensic disciplines.

Secondly, in instances where no suitable consensus standards currently exist, OSAC proactively drafts new standards. These meticulously developed drafts are then forwarded to accredited Standards Developing Organizations (SDOs) for further refinement, broader consensus building, and eventual publication. Following this publication, the newly approved standards undergo a re-evaluation by OSAC, assessing their efficacy and suitability for inclusion on the OSAC Registry. This cyclical process ensures a continuous evolution and improvement of forensic science standards.

This presentation will delve into the standard development activities specifically undertaken by OSAC pertaining to IL, E, and GSR analysis. We will explore the latest additions to the OSAC Registry. Furthermore, we will introduce newly proposed OSAC standards that are poised to shape future practices. The discussion will also encompass published standards that are currently awaiting the Registry approval process, standards actively under development at the SDO, and those still in their foundational stages within OSAC itself, providing a holistic overview of the ongoing efforts to enhance forensic science through standardization.

C2 CrimeEye: A Deep Learning Approach to Suspect Identification From Low-Resolution CCTV Footage

Abhishek Kumar Singh, BEng, Directorate of Revenue Intelligence, India, Pune, Maharashtra, India; Navdha Bhardwaj, MSc, Indian Institute of Technology, Mandi, Mandi, Himachal Pradesh, India*

Learning Objectives: Attendees will learn to implement automated face recognition in forensic Closed-Circuit Television (CCTV) analysis, enhancing suspect detection accuracy, reducing manual effort, and supporting fast, reliable legal investigations.

Impact Statement: This presentation introduces a transformative AI-driven solution that revolutionizes forensic investigations by automating suspect detection from CCTV footage, significantly enhancing speed, accuracy, and judicial reliability.

Abstract Text: In today's world of forensic science, the role of CCTV systems is very crucial and gives instant help in making strong decisions in assault, abduction, hit-and-run, and homicide cases. But the regular method of manually going through CCTV footage for a set time is not only very time consuming but also means something important can easily be missed by the human eye. This research paper aims at introducing a new, fully automated system for detecting suspects using face recognition, specially designed for forensic use, and focused on processing CCTV data from active crime scenes or other places under investigation.

The system uses Multi-task Cascaded Convolutional Networks, which help in precise face identification, detection, and alignment of facial features, so the faces are ready for proper analysis. It further uses the InceptionResnetV1 FaceNet architecture to create exact facial embeddings, focusing on the unique features of every individual. These embeddings are properly cataloged and backtracked with a gallery of known identities, which allows for fast and accurate matching, using the cosine similarity matrix.

This method cuts down the time required for manual checking, reduces the chances of errors made by people, and makes sure that identification from video footage is effective and reliable for legal proceedings.

C3 The Role of Digital Forensics in Identifying Identity Theft

Oreoluwa Ladoja, MSc, Texas Southern University, Houston, TX; Ashraf Mozayani, PharmD, Texas Southern University, Houston, TX; Jasmine Drake, PhD, Texas Southern University, Houston, TX*

Learning Objectives: Participants and attendees will understand the fundamental ideas and essential methods of digital forensics, which are used to detect identity theft, with an emphasis on situations involving juvenile cybercrime. They will gain knowledge on the role that techniques like network trace evidence, device imaging, and metadata analysis play in tracking down criminals and elucidating the effects on victims. Also, they will be able to explain useful applications of digital forensic technologies to improve evidence gathering and investigation precision by the end of this session.

Impact Statement: The forensic science community will become more proficient in using digital forensic techniques, particularly in identity theft investigation. This presentation will show how technologies may reveal juvenile offender behavior, connect actions to victims, and promote legal outcomes and will enhance performance. The session's goal is to assist practitioners in generating more precise, convincing conclusions that support victims and the legal system.

Abstract Text: This research examined the systematic application of digital forensic tools and how it is critical in effectively identifying identity theft, particularly in cases involving juvenile criminals. As cybercrime becomes more complicated, traditional investigative methods frequently fail to identify the entire scale of cybercrime (identity theft). Digital forensics provides methods for recovering deleted information, tracing IP addresses, and analyzing device metadata, providing a better understanding of criminal behavior and victim harm.

The study employs a mixed-methods approach: reviewing 16 scholarly articles published between 2019 and 2023, supported by qualitative case studies from the Office of Juvenile Justice and Delinquency Prevention (OJJDP) and quantitative data on cybercrime trends.[1-3] Findings show that digital forensic evidence such as transaction records, communication logs, and device traces can identify patterns of identity theft that might otherwise remain hidden. For example, recovered logs and deleted files have clarified offender timelines and victim lists in real cases, strengthening prosecutions and guiding restitution efforts

A major case study highlights the practical impact of digital forensics: detectives employed forensic imagery and metadata analysis to track down stolen identity data, accurately tracing how juvenile offenders accessed and used it. This led to clearer evidence, better victim identification, and more informed conclusions by prosecutors.

This paper explains that methodically incorporating digital forensic methods into identity theft investigations can improve the accuracy, depth, and dependability of results. By connecting forensic science with increasing digital risks, practitioners can better document harm, minimize recidivism among adolescents, and promote equitable outcomes for both victims and juvenile offenders.

C4 Facial Identification: Standardization, Certification, and Beyond

Steven C. Johnson, BS, Ideal Innovations, Inc., Arlington, VA; Richard W. Vorder Bruegge, PhD, ForensicVB LLC, Fredericksburg, VA; Lora Sims, Organization of Scientific Area Committees (OSAC) for Forensic Science, Arlington, VA*

Learning Objectives: Attendees will learn about existing and proposed best practices and standards that will improve facial identification as a forensic discipline that supports the digital evidence and multimedia elements of criminal investigation. There will also be information on current and proposed state and federal legislation that impacts the use of facial recognition technology and supporting facial identification services. Practitioners involved with facial identification need training, and this update will address current training programs that can facilitate skills development. Finally, the presentation will update attendees on the status of a certification program for practitioners that are working in the field across the country and around the world.

Impact Statement: It is hoped that participants will see the value in the continued utilization of facial examination and review in conjunction with the deployment of an effective facial recognition system as well as independently when available facial images are part of an investigation. Additionally, the development and deployment of a certification program will help establish the scientific rigor of the discipline and its practitioners.

Abstract Objectives: To update attendees regarding on-going developments in Facial Recognition Technology (FRT) and the Facial Identification (FI) Discipline. The presentation will cover, at a high level:

- Current published standards supporting FI
- The status of existing and pending legislation that impact Facial Recognition and FI
- Availability and effectiveness of training programs
- The American Society for Testing and Materials (ASTM) partnership and launch of a Facial Identification Certification Program for Reviewers and Examiners

Abstract: Facial Recognition (FR) and FI remain a subject of discussion across the nation and internationally. In this context, FR refers to the automated systems and algorithms utilized in multiple scenarios, while FI refers to the discipline of image-based comparisons of human facial features. Within FI, there are multiple types of comparisons, but we will focus on the reviewer level (adjudicating candidate lists from FR systems) and examiner level (forensic-expert process of comparing facial images to reach an opinion). Improving algorithms and increased education have helped reduce criticism of FRT but more work remains. In the 16 years since the creation of the Facial Identification Scientific Working Group and the subsequent establishment of the International Association for Identification (IAI) and Organization of Scientific Area Committees (OSAC) subcommittees in 2014, FI has been playing "catch up" with FRT, a technology that started making inroads into the biometrics community in the early 1990s. As we approach the latter half of this decade, these two fundamental pillars are approaching an optimal point for future accuracy, success and public acceptance. Other elements in the presentation include some of the requirements that must be met in order to apply for certification and a timeline for certification program launch.

C5 Emerging Paradigms in Forensic Facial Comparison Through Artificial Intelligence

Enrique Bermejo, PhD, Panacea Cooperative Research, Granada, Andalucia, Spain; M. Alejandra A. Guativonza, MA, University of A Coruña, A Coruña, Galicia, Spain; Oscar Ibáñez, PhD, Universidade da Coruña, A Coruña, Galicia, Spain; Antonio D. Villegas, MSc, Panacea Cooperative Research, Granada, Andalucia, Spain; Alejandro Manzanares, MSc, Panacea Cooperative Research, Granada, Andalucia, Spain; Daniel García, BSc, Universidade da Coruña, A Coruña, Galicia, Spain*

Learning Objectives: Attendees will explore how recent advances in Artificial Intelligence (AI) and emerging technologies enable a shift from traditional 2D-based forensic facial comparison methods toward a more robust 3D-driven paradigm. The presentation will demonstrate how modern approaches, such as AI-powered facial superimposition and photo-anthropometry, can overcome the historical limitations of subjectivity and low reproducibility by extracting meaningful 3D data from 2D images. Participants will gain an understanding of how these tools provide complementary and objective means of analysis, supporting more reliable, accurate, and transparent facial comparison in forensic contexts.

Impact Statement: This presentation will equip the forensic science community with advanced, AI-driven tools that enable more objective and efficient facial comparison workflows. By introducing automated quality assessment of forensic evidence, the work promotes greater consistency and transparency in analysis, reducing subjectivity in decision-making. The integration of novel methodologies supports complementary lines of inquiry, enhancing the overall robustness and reliability of forensic facial comparison practices. These contributions align with the growing demand for scientifically validated and operationally effective tools in forensic identification.

Abstract Text: Forensic Facial Comparison (FFC) has become increasingly significant as an identification technique in recent years. However, certain forensic methodologies have not fully adapted to these recent technological developments, and the reliability of different approaches within FFC remains a matter of ongoing scrutiny. For instance, international organizations, such as the Facial Identification Scientific Working Group (FISWG), discourage the use of photo-anthropometry or facial superimposition. This recommendation is based on the presence of various factors that restrict their applicability.

In this work, we present advancements that address these limitations through AI-driven methodologies. First, we explore automated techniques for analyzing the quality of evidence used in FFC to minimize biases and subjectivity. Furthermore, we will introduce the application of automated facial superimposition methods using an innovative 3D-2D paradigm, leveraging advancements in 3D scanning technologies to enhance accuracy and reproducibility. Additionally, we present a novel dataset comprising surveillance images and high-quality 3D facial scans, capturing a wide range of facial expressions, controlled conditions and in-the-wild scenarios. This dataset considers relevant aspects such as camera parameters, subject-to-camera distance, occluding objects, etc. designed to drive progress in FFC methodology.

Lastly, we present a comprehensive study analyzing the potential of photo-anthropometry through the automatic prediction of 3D Dimensions and Proportionality Indexes (DPI) from 2D images. This approach can be used to demonstrate how these tools can effectively reduce the number of possible candidates in a long list in forensic investigations, enhancing efficiency and accuracy.

C7 Advanced Methods in Image Forgery Detection: Bridging Fundamentals and Emerging Technology

Chad R. Johnson, PhD, University of Wisconsin, Stevens Point, Stevens Point, WI*

Learning Objectives: The goals of this presentation are to: 1) identify key techniques for detecting image forgeries using robust and sparse features, existing detection models, liveness detection, Partial Residual Network (PRN), Principle Component Analysis (PCA), Error Level Analysis (ELA), specular highlight analysis, and more; 2) understand the capabilities and limitations of machine learning algorithms in identifying sophisticated image manipulations. Approximate validity from my experiment will be provided; and 3) evaluate ethical considerations and best practices when analyzing digital images to maintain objectivity and integrity in forensic investigations.

Impact Statement: This presentation will significantly enhance the forensic science community by providing essential insights and practical methods for identifying image forgeries, directly addressing the evolving threats posed by advanced digital manipulation techniques. Attendees will gain actionable knowledge to improve investigative practices, ensuring greater accuracy, reliability, and fairness in criminal justice outcomes.

Abstract Text: Images have always been pivotal pieces of evidence in forensic investigations from artistic renderings to print photographs to modern-day digital images and video. It has always been possible to create image forgeries with the intent of spoiling investigations, but as technology has advanced to make photography cheaper and faster, the technology to make convincing image forgeries has advanced along with it. This brings us to where we stand today, where the risk of sophisticated image forgeries threatens the integrity of criminal justice processes. Courts have already proven somewhat trepidatious about potentially fraudulent evidence, and our ability to detect them to the satisfaction of the legal process wavers along with it. This presentation addresses current advancements and fundamental practices in image forgery detection, emphasizing both foundational forensic methodologies and innovative technological developments.

Image forgery detection techniques—including metadata analysis, digital artifact identification, and machine learning algorithms—are evaluated through case studies demonstrating their real-world application and effectiveness. In addition, I intend to share my own work in this field, where I have conducted experiments testing the efficacy of a dozen different detection techniques. The session will outline emerging challenges posed by artificial intelligence-generated content, specifically deepfakes, and propose standardized investigative practices to mitigate these risks.

Aligned with the conference theme, "Back to Basics: The Fundamentals of Forensic Science," this session emphasizes the ethical application of forensic principles, neutrality in scientific investigation, and the crucial role of human reasoning alongside technological tools. Practical guidelines and ethical considerations for practitioners dealing with digitally altered evidence will be discussed to uphold objectivity and justice.

C8 Exploring the Impact of PDF Embedding on BMP and GIF Image Integrity and Authentication: The Initial Phase for Forensic Sciences

Gregory S. Wales, DSc, Independent Researcher, Colorado Spring, CO; Gregory S. Wales, Jr., MS, United States Department of Justice, Pacifica, CA*

Learning Objectives: This session provides an overview of the exploratory challenges involved in recovering BMP and GIF images embedded within PDF documents, directly addressing research priorities set by the OSAC Visual Imaging and Technologies and Analysis (VITAL) subcommittee. The presentation details initial exploratory observations on image behavior during embedding and extraction, including format transformations, metadata loss, and structural changes resulting from common software workflows. These preliminary findings inform the design of future validation studies and contribute to the development of more reliable forensic procedures for handling embedded digital images.

Impact Statement: This research advances foundational knowledge for evaluating and ultimately validating forensic workflows involving images embedded in PDF documents. By addressing the research needs identified by OSAC VITAL, this exploratory phase provides examiners and researchers with early insights into tool behavior, potential failure modes, and sources of technical variability. The findings support the development of scientifically robust, court-defensible methodologies for digital image authentication and contribute to the enhancement of forensic standards in this emerging field.

Abstract Text: The Organization of Scientific Area Committees (OSAC) Visual Imaging and Technologies and Analysis (VITAL) subcommittee has identified a critical research need regarding the embedding of digital images in PDF documents and the implications for forensic interpretation [1]. This presentation describes the initial exploratory phase of a broader, multi-stage research program that examines image integrity, recoverability, and technical transformations across various embedding scenarios. The current phase specifically investigates BMP and GIF images embedded in PDF files.

This early-stage study examines how common embedding workflows, such as Insert Picture, Drag and Drop, and Clipboard-based insertion, as well as widely used extraction tools, affect the preservation of image characteristics. Instead of pursuing full validation, this phase maps the technical landscape by documenting format conversions, changes in color depth, metadata behavior, and structural features, including annotation-based floating images. These observations establish essential groundwork for the design of rigorous validation studies in subsequent phases.

Preliminary findings indicate that BMP images embedded in PDF documents are consistently converted across all examined workflows to compressed raster formats, such as JPG, PNG, or JP2. This conversion results in the loss of the original bit depth and metadata, regardless of whether the output format is lossy (e.g., JPG, JP2) or lossless (e.g., PNG). Extraction tools differ in their effectiveness at recovering embedded content, and certain embedding methods, particularly those based on Clipboard workflows, introduce resizing or annotation structures that complicate extraction. GIF images display similar transformation patterns, including the loss of native format and metadata. While quantitative performance metrics are not the primary focus of this phase, initial observations suggest that both tool selection and embedding method significantly influence extraction outcomes.

These results underscore the technical complexity inherent in PDF image embedding and emphasize the necessity for structured empirical validation. Subsequent phases of this research will include additional image types, such as JPG, PNG, and TIFF, and will develop formal validation methodologies consistent with OSAC VITAL priorities. By identifying foundational behaviors and potential sources of variability, this exploratory work establishes the empirical basis for developing reliable, reproducible, and court-defensible forensic workflows.

C9 The Sound of Deception: Voice and Language Markers in Emotionally Charged Lies

Sunčica Kuzmić, MASc, Forensic Science Centre Ivan Vučetić, Zagreb, Grad Zagreb, Croatia; Ivan Jerković, PhD, Faculty of Forensic Sciences, University of Split, Split, Splitsko-Dalmatinska, Croatia; Andrea Ledić, MSc, Forensic Science Centre "Ivan Vucetic" MoI Croatia, Zagreb, Grad Zagreb, Croatia*

Learning Objectives: After attending this presentation, the participants will have become familiar with acoustic markers that may indicate deceptive speech and developed an understanding of the linguistic features that differentiate between deceptive and truthful storytelling. Additionally, participants will have learned about the potential of applying AI solutions, such as Large Language Models (LLMs), for extracting linguistic variables as well as Machine Learning (ML) techniques that could be used to classify speech as deceptive or truthful.

Impact Statement: This presentation will contribute to forensic science by showcasing the ways in which deception can manifest in acoustic and linguistic traits in the Croatian language. By demonstrating how LLMs can be used to extract linguistic features from transcripts and how ML could be employed to combine acoustic and linguistic variables into a single analytical model, it will strengthen the capacity of forensic scientists to apply new technological solutions. Finally, the findings could help guide the development of voice-based deception detection systems that use objective, non-invasive methods to support investigations.

Abstract Text: Detecting deception in spoken language is a challenge in law enforcement, security, psychology, and everyday interactions. While studies have identified various acoustic and linguistic traits that may indicate deception, human judgments continue to be inconsistent and often unreliable.[1] Consequently, there is increasing interest in developing objective methods to better understand and identify deceptive communication.

This study examined the acoustic and linguistic markers of deception in spoken Croatian by analyzing narrative speech, intending to identify patterns that distinguish deceptive from truthful accounts across various emotional contexts. To this end, participants were asked to provide three types of stories: a fabricated account, a truthful story with negative emotional content, and a truthful story with positive emotional content, which were audio-recorded during the session and subsequently transcribed.

Acoustic features such as fundamental frequency (pitch), intensity (loudness), speech rate, and pause frequency were extracted with Praat and SIVE software to explore their relevance as indicators of cognitive load and stress during speech production.[2] Linguistic analysis focused on syntactic complexity, lexical choices, and the usage of personal pronouns and affective language, with linguistic features automatically quantified from Croatian transcripts using the xAI API and the Grok-3 large language model.[3]

Differences in acoustic and linguistic variables across the three conditions were then statistically examined to identify patterns associated with deception. To further explore whether these features could help distinguish deceptive from truthful speech, several machine learning classification algorithms were applied.[4] Models were trained separately on acoustic features, linguistic features, and their combination to assess the potential of a multimodal approach.

The presentation will show how emotional states and cognitive load influence acoustic and linguistic markers of deception and will discuss the potential implications of these findings for developing voice-based lie detection tools. Examples of the most informative speech features and their patterns across conditions will be highlighted to illustrate key trends.

C10 Speaker-Specific Deepfake Detection in Conversational Audio Analysis

Lucky M. Onyekwelu-Udoka, MASc, Iowa State University, Ames, IA; Yong Guan, PhD*, Iowa State University, Ames, IA*

Learning Objectives: Attendees will learn how speaker-specific deepfake detection enhances the reliability of forensic audio analysis by isolating and analyzing speech at the individual level within multi-speaker conversations. The presentation will explain how speaker embedding and diarization techniques improve detection accuracy compared to traditional methods, especially in targeted manipulation scenarios.

Impact Statement: This presentation introduces a speaker-specific deepfake detection framework that improves forensic audio analysis by isolating and verifying individual voices in multi-speaker recordings. It enhances detection accuracy, supports legal investigations, and addresses emerging threats from synthetic speech, offering a practical tool for ensuring the authenticity of conversational evidence.

Abstract Text: Speaker-specific deepfake detection in conversational audio is an emerging subfield of forensic analysis focused on identifying artificially generated or altered speech embedded within multi-speaker recordings, particularly in high-stakes contexts such as forged confessions, tampered interrogations, or impersonated witness statements that can occur in different formats like phone calls, meetings, or digital assistants. The goal is to detect such deepfakes by analyzing conversations using unique vocal traits of individual speakers, such as voiceprints, speaking style, and prosody.

Traditional detection systems that analyze entire conversations often fail when only one speaker is manipulated in a targeted attack. In contrast, speaker-specific models exploit personal vocal patterns and offer higher precision in identifying synthetic speech. These models are more robust to fine-tuning or transfer attacks that aim to bypass generic detectors by mimicking specific individuals.

Our research introduces a forensic detection framework that integrates speaker diarization, segment isolation, and deepfake detection into a unified pipeline. The system uses speaker embeddings (e.g., x-vectors, d-vectors) to isolate and verify speech segments at the speaker level. Detection models are trained using contrastive and multitask learning strategies to improve robustness and context awareness.

We used existing data sets such as ASVspoof, FakeAVCeleb, WaveFake, and the LA/DF subsets, which provide valuable benchmarks for general deepfake detection tasks.[1-4] However, these corpora are not inherently speaker-specific and often require modification or augmentation to simulate personalized attacks. To address this gap, our framework leverages a custom dataset based on publicly available speaker recordings, fine-tuned for speaker-specific analysis.

The preliminary results show that our speaker-specific detection system achieves an accuracy of up to 70%. The system also generalizes well to unseen synthesis methods and maintains robustness under background noise and domain shifts. The proposed system has a direct impact on security-sensitive applications. In voice biometrics, it enhances the authentication of traditional speakers by verifying not just identity but also authenticity. In customer support scenarios, it helps to detect impersonation attacks targeting financial or medical systems. In law enforcement and legal investigations, it provides tools to validate the integrity of wiretaps, interviews, or recorded confessions.

To support this research direction, we draw on architectural advances, including temporal modeling (e.g.,Transformers), feature-level fusion (spectral, prosodic, and phonetic), and personalized model fine-tuning. Several challenges are actively being addressed, including data scarcity for specific speakers, avoiding overfitting to known synthesis methods, achieving low-latency real-time detection, and defending against advanced adversarial or transfer-based synthesis attacks.

Future work explores multiple research directions to strengthen generalization and real-world applicability. These include code-switched and cross-lingual conversation scenario, and explainable deep-fake detection that highlights manipulated acoustic regions within the signal. Furthermore, we are investigating federated and privacy-preserving training techniques, especially relevant for the deployment of models on sensitive or proprietary voice data.

These findings reinforce the growing need for individualized forensic tools to validate the authenticity of speech in high-stakes domains such as legal testimony, law enforcement, and cybersecurity. Additional results will be presented at the conference.

C11 Navigating Moral Quandaries on the Front Lines: Lessons From 25 Years of Audio and Video Forensics With Attorneys and Experts

David Notowitz, BA, National Center for Audio and Video Forensics, Fort Lauderdale, FL*

Learning Objectives: By the end of this session, participants will be able to: (1) identify common ethical dilemmas in audio and video forensics such as conflicts between objective analysis and client pressures, drawing from real-world case examples over 25 years of practice.; (2) evaluate decision-making frameworks for navigating moral quandaries, including assessing risks to professional integrity, financial implications, and long-term business impacts; (3) apply lessons learned from intense client and expert interactions to enhance their own ethical practices, fostering greater objectivity in forensic evidence handling; and (4) discuss strategies for promoting ethical standards in the forensics community and courts with the aim of inspiring systemic improvements in expert testimony and case outcomes.

Impact Statement: This presentation could profoundly impact the forensic science community by illuminating the often-overlooked ethical challenges in audio and video forensics, drawing from 25 years of real-world experiences in high-stakes cases involving law enforcement, corporate clients, and nationally covered incidents. By sharing candid accounts of dilemmas—such as balancing objective truth with client pressures, financial incentives, and professional risks—attendees will gain actionable insights to strengthen their own ethical decision-making, reducing the potential for biased testimony that could undermine justice in criminal, civil, and federal proceedings. Furthermore, it will foster a broader dialog on elevating standards within the field, encouraging forensic experts, attorneys, and investigators to prioritize integrity over expediency. This could lead to systemic improvements such as enhanced training protocols, revised professional guidelines, and greater accountability in state bars. Ultimately, the presentation aims to inspire a new generation of practitioners to uphold objectivity, enhancing the credibility of multimedia evidence in courts and contributing to more honest outcomes across the forensic science landscape and in court.

Abstract Text: In the high-stakes realm of audio and video forensics, ethical integrity is paramount to ensuring justice in criminal, civil, and federal cases. Drawing from 25 years of firsthand experience as the founder of the National Center for Audio and Video Forensics (NCAVF), this presentation explores intense moral quandaries encountered in professional interactions with clients, attorneys, and fellow experts. Through real-world case studies—including nationally covered incidents like controversial police shootings, swimming pool drownings, and high-profile trials such as State of Colorado v. Roedema and Rosenblatt—attendees will examine dilemmas involving pressures to bias analyses for financial gain versus upholding objective truth.

The session will dissect decision-making processes, evaluating risks to professional reputation, business sustainability, and judicial outcomes. Participants will learn frameworks for navigating these challenges, strategies to maintain objectivity in evidence handling, and approaches to advocate for ethical reforms in the forensics community. As an Emmy Award-winning producer turned forensic expert appointed to the Los Angeles Superior Court Expert Witness Panel, the presenter brings authoritative insights from working for or against entities like district attorneys, public defenders, and corporations including FedEx, Amazon, McDonald's, and Southwest Airlines.

This talk aims to inspire forensic practitioners, investigators, and legal professionals to prioritize ethical standards, ultimately enhancing the credibility of multimedia evidence and fostering equitable court proceedings. By sharing lessons from the frontlines, it contributes to ongoing dialogs on professional accountability in digital forensics.

Ethics; Expert Testimony; Video Analysis

C12 An AI-Based Speech Analysis Technology for Courtroom Media Transcripts

Joseph Remy, Esq., National White Collar Crime Center, Barrington, NJ; Aakash Taneja, PhD, Stockton University, Galloway, NJ; Zachary Lord, BS, Stockton University, Ocean City, NJ; Melany Cruz, BS, Stockton University, Forked River, NJ*

Learning Objectives: After attending this presentation, attendees will understand the capabilities of the current generation of AI-enabled speech analysis technology to examine audio and video statements for purposes of forensic purposes.

Impact Statement: This presentation will have an impact on the criminal justice system by serving as a reminder that AI technology has the potential to revolutionize the examination of audio and video statements for legal purposes, but it is not yet mature enough to analyze evidence with complete confidence.

Abstract Text: The advancements in AI have transformed how audio and video are captured, processed, and analyzed across various domains. In law enforcement, audio and video data are available from sources including but not limited to body cameras, emergency calls, IoT devices, and suspect interviews. The data also sometimes involves translation from other languages to English. The prosecutors' offices require effective and efficient transcription of such crucial evidence to ensure a fair trial, which can be voluminous and time-consuming. AI-enabled speech analysis applications are available that automate transcription and extract information. Using such applications for legal purposes has its own set of challenges requiring careful attention. When evaluating AI-based speech analysis applications for legal use, it is essential to examine not only performance (e.g. accuracy, ease of use), but also operational (e.g., multi-speaker detection, language support) and legal considerations (e.g., chain of custody, security and privacy, timestamping).

This report will present a case study in AI-enabled speech analysis for legal purposes as an example of the practical application of current-generation AI tools. Specifically, this study used audio from previously transcribed cases and compared the previous transcription to the same audio data set using AI-enabled speech analysis applications.

The methodology began with the researchers first cleaning the dataset by manually removing Spanish translation tables and extracting English text, placing it outside of its original table. It was followed by removing formatting elements such as page numbers and document titles. The researchers then used the all-MiniLM-L6-v2 from the SentenceTransformer library. This model converts each line of text into a dense numerical vector representation (embedding) that captures the overall meaning of the sentence rather than just the individual words. PyTorch's cosine similarity function, which measures how similar two vectors are based on the angle that exists between them, was used to compare embeddings from each file, yielding scores ranging from 0 (no similarity) to 1 (perfect similarity). The scores were classified using Z-score analysis and categorized as "Got It Correctly" (GOTIT), "Got the Gist" (GTJ), or "Didn't Get It" (DNG). Overall, when compared to the certified transcripts, the AI-enabled speech analysis resulted in the following: GOTIT (21.17%), GTJ (44.23%), and DNG (34.59%).

These results suggest that the current generation of AI-enabled speech analysis, though perhaps financially advantageous, may not produce sufficiently reliable results for use in courtroom proceeding; but may be useful for non-essential intelligence purposes.

C13 The Forensic-AI Fusion Toolbox: A Multi-Modal Framework for the Principled Detection of Advanced Deepfakes

Zeno J. Geradts, PhD, NFI / University of Amsterdam, Den Haag, Zuid-Holland, Netherlands; Stijn Van Lierop, MSc, NFI, Den Haag, Zuid-Holland, Netherlands*

Learning Objectives: After attending this presentation, attendees will understand a novel, multi-modal framework for deepfake detection that integrates foundational forensic principles with advanced AI. They will learn how the synergistic fusion of independent detection modalities—including Photo-Response Non-Uniformity (PRNU), Electrical Network Frequency (ENF), remote Photoplethysmography (rPPG), and 3D photogrammetry—can be fused to create a more robust and resilient deepfake detection system that is more robust and resilient than any single approach applied in isolation. Furthermore, attendees will be introduced to a new workflow that leverages state-of-the-art AI classifiers for detection and Vision-Language Models (VLMs) for generating explainable, human-readable forensic reports that have to be reviewed and used by a forensic scientist.

Impact Statement: This presentation will impact the forensic science community by providing practitioners with a structured and scientifically grounded methodology to counter the threat of sophisticated deepfakes. The proposed toolbox will enhance forensic deepfake detection competence by equipping analysts with a system that integrates multiple, independent lines of evidence, reducing bias and increasing confidence in findings. This, in turn, will improve performance by enabling the creation of more robust, defensible, and transparent expert testimony suitable for legal proceedings, directly supporting the appropriate administration of justice.

Abstract Text: The proliferation of hyper-realistic deepfakes presents a critical challenge to the integrity of digital evidence, demanding a forensic response that is both technologically advanced and grounded in fundamental scientific principles. While many deepfake detection methods have been proposed, how the practitioner should integrate these methods to arrive at a conclusion remains a major challenge in the field. In alignment with the conference theme Back to Basics; we propose the Forensic-AI Fusion Toolbox, a novel framework designed to empower the practitioner through a robust, multi-modal approach to deepfake detection. Our proposition is that a synergistic fusion of disparate detection methods provides a more resilient and forensically sound defense than any single-threaded technique.

The toolbox integrates several independent and explainable analytical modules. Foundational forensic traces are established using PRNU analysis to verify camera sensor integrity and ENF analysis to confirm audio-visual temporal synchronicity. Biometric and geometric inconsistencies are identified by analyzing the spatiotemporal plausibility of physiological signals, such as heart rate patterns derived from rPPG, and by using 3D photogrammetric techniques to detect unnatural head motion and gaze behavior.

These physics-based and biological analyses are fused with a powerful AI core. This core utilizes state-of-the-art architectures, including Knowledge Injection based deepfake Detection (KID) models trained on diverse datasets (FF++, CelebDF, DFDC) for high-accuracy classification. A key innovation is the use of VLMs, not for primary detection, but as an explainability engine to translate complex AI findings into structured, human-readable reports. The outputs of all modules are synthesized by a weighted fusion engine that provides a final, context-aware probability of manipulation. This integrated framework provides the practitioner with a powerful decision-support system that is objective, explainable, and adaptable to the evolving deepfake threat. By combining physical forensics with the analytical power of modern AI, this toolbox offers a principled and effective pathway to restoring trust in digital media.

C14 A Holistic and Pragmatic Approach to Deepfake Forensics

Marco Fontani, PhD, Amped Software, Trieste, Friuli-Venezia Giulia, Italy; Blake Sawyer, BBA, Amped Software, New York City, NY; Martino Jerian, MSc, Amped Software, Trieste, Friuli-Venezia Giulia, Italy*

Learning Objectives: This presentation will: clarify the fundamental differences between authenticity and integrity verification, help attendees understand the potentiality and limitations of different approaches to deepfake analysis, and clarify that deepfake forensics goes way beyond automated deepfake detection

Impact Statement: The credibility of visual media has never faced a challenge as strong as the one brought by modern synthetic media creation technologies, especially deepfakes. This presentation aims to bring clarity to what deepfake analysis means, starting from a clear definition of integrity and authenticity analysis. We will then present the concepts of deepfake detection versus deepfake forensics. Attendees will learn that while blindly trusting black-box classifiers is not forensically sound, they may have their place as a decision support tool in a pragmatic approach to deepfake analysis. Attendees will also learn several additional techniques to reveal deepfakes in a reliable and explainable way.

Abstract Text: As synthetic media becomes increasingly sophisticated and accessible, the forensic community faces the urgent challenge of assessing the trustworthiness of digital visual content.[1] In this presentation, we propose a comprehensive and pragmatic framework for deepfake forensics, one that emphasizes the crucial distinction between authenticity and integrity verification, and encourages a multi-faceted approach that goes well beyond current trends in automated deepfake detection.

We begin by clarifying two foundational but often conflated concepts: integrity, which pertains to revealing whether a media has undergone any form of alteration after being captured, and authenticity, which instead pertains to establishing whether the media is an accurate representation of events. The core of our presentation contrasts black-box deepfake detection—typically reliant on automated classifiers—with deepfake forensics, which entails a comprehensive evaluation of a visual asset's integrity and authenticity, incorporating contextual, physical, and algorithmic evidence. We will show that automated detection tools powered by deep learning may have significant performance, but they often lack explainability and may be susceptible to adversarial manipulation.[2] As such, we caution against treating these tools as stand-alone forensic solutions.

Instead, we propose a pragmatic framework that integrates automated tools as decision-support instruments within a transparent and interpretable forensic process. This includes leveraging inconsistencies in spatio-temporal artifacts, biometric anomalies, metadata analysis, physical modeling (e.g., illumination or geometry inconsistencies), and contextual corroboration through Open-Source Intelligence (OSINT).[3] We will provide real-world examples and case studies to illustrate how this multi-layered approach offers robust and court-admissible findings.

A key takeaway for attendees will be the importance of explainability and transparency in forensic reporting. We will demonstrate how forensic investigators can document and communicate findings with scientific rigor, even when working with complex or ambiguous media. This session will equip forensic professionals with the conceptual tools to critically evaluate claims of manipulation, understand the roles and risks of current detection technologies, and develop a deeper appreciation for the methodological diversity required in deepfake forensics. By advocating for a balanced approach that bridges technical sophistication with forensic prudence, this presentation aims to help practitioners approach synthetic media in both investigative and legal contexts.

C15 Advances on Structure and Format Analysis for Media Forensics Authentication

Cole Whitecotton, MSc, University of Colorado Denver, National Center for Media Forensics, Denver, CO; Catalin Grigoras, PhD*, National Center for Media Forensics, Denver, CO*

Learning Objectives: The goal of this presentation is to disseminate important findings related to the behavior of various Apple QuickTime and MPEG-4 ISO/IEC 14496 codec libraries and software as they relate to media forensics analyses and authentication.

Impact Statement: This presentation will impact the forensic science community by providing the results of a study that impacts laboratory performance and best practices in the handling and processing of media forensics files originating from different devices, instant messaging, social media and different generative AI services.

Abstract Text: This paper presents updated results on the artifacts left by different media codecs. Lossy compressed files are common in real forensic casework, can be generated with different digital hardware, software, social media, AI services and instant messaging, and their forensic analysis and authentication can end up being crucial in judicial and extrajudicial investigations. In this study we report the structure and format particularities of original media files (e.g., Apple, Google, HTC, Huawei, LG, Motorola, Samsung, Xiaomi, ZTE mobile phones and tablets running on different operating systems), and the modifications introduced by different social media apps (e.g., TikTok, X, Facebook, YouTube), and instant messaging apps (e.g., Signal, WhatsApp). This study also reports particularities of the media files created with generative AI online tools. Extending previous studies presenting the artifacts due to different lossy compression algorithms and downloading software, the paper provides examples of the materials and the results collected in this study.

The preliminary results of this study indicate that the structures and formats of different original media files depend on the make, model, recording settings, and operating systems. Also, the structures and formats of the data downloaded from social media and AI online services depend on the downloading scheme. This paper also presents several databases built by the authors, containing original media, recorded under controlled conditions and transmitted through different social media and instant messaging files, and AI generated files as well. With these findings, the authors propose the use of different databases, updating the structure and format analysis for fast triage of the evidence files, detecting the media files that contain traces of AI, and minimizing the bias.

C16 Evaluating the Use of a Novel Expert System for Media Authentication Results Interpretation

Brandon Epstein, MS, Magnet Forensics, College Grove, TN; Bertram Lyons, MA*, Magnet Forensics, Madison, WI*

Learning Objectives: Attendees will gain an understanding of how artificial intelligence expert systems can be utilized in digital media authentication. Attendees will be able to identify the appropriate use of expert systems within digital forensics, alongside human interpreted results.

Impact Statement: This presentation will impact the forensic science community by exploring the effectiveness of a novel method to provide a succinct forensic output in media authentication examinations. As a result, attendees will be able to make informed decisions when deploying artificial intelligence expert systems in digital forensic examinations.

Abstract Text: The evolution of artificial intelligence technology has introduced hyper-realistic synthetic image and video imagery. As a result, the authentication of media evidence has become increasingly complicated. Many algorithmic approaches to media authentication have been found to be ineffective within digital forensics for variety of reasons, including the difficulty in expressing results, particularly from black-box algorithms.[1,2] Aside from the complexity of interpreting this data, practitioners also struggle with the lengthy time required to perform these examinations and sheer volume of media evidence in modern investigations.

The authors designed an artificial intelligence expert system based on several logic-based authentication tests related to video file structure, attribute similarity analysis, and other file attributes. Those tests were then organized into individual authentication pathways in order to display a concise, natural language result, similar to what a human examiner may opine.[3] The automated nature of an expert system may allow for demonstrably accurate results at scale without extensive human resources expended within authentication examinations.

This study examined the accuracy of that artificial intelligence expert system employed in to provide an "opinion" as compared to trained and proficient human examiners provided with the same data set as well as participants with no media authentication training. A diverse dataset of original, transmitted, edited, and synthetic videos' file structures, attribute similarity analysis, proprietary structural data, and metadata values were presented to all groups. The responses were then captured and evaluated for accuracy and error rates established. These results can be used to evaluate the appropriateness of deploying artificial intelligence expert systems on forensic examinations alongside human interpretations.

C17 A Quantitative Study of Frame Extraction Methods, Tools, and Their Impact on Extracted Frame Quality From High-Efficiency Video Coding Videos

Susan C. Kost, MSc, University of Colorado, Denver, Orlando, FL; Catalin Grigoras, PhD, National Center for Media Forensics, Denver, CO; Gregory S. Wales, DSc, Independent Researcher, Colorado Spring, CO; Cole Whitecotton, MSc, University of Colorado Denver, National Center for Media Forensics, Denver, CO*

Learning Objectives: This presentation will provide attendees with a data-driven analysis of how different software tools and methods affect the quality and forensic integrity of frames extracted from H.265 (High Efficiency Video Coding [HEVC]) video. Discrepancies in extracted image quality can raise concerns about the admissibility and reliability of video evidence, particularly when alterations are introduced during the extraction process, leaving stream hash values inconsistent. Attendees will learn to: 1) identify and compare common frame extraction methods (using established methods and widely available software: FFmpeg, Matlab, Adobe Media Encoder, Adobe Premiere); 2) understand how extraction methods can alter the visual and structural fidelity of frames; 3) use objective image quality metrics to assess degradation or stream hash alterations in extracted frames ; and 4) evaluate the implications of these differences for forensic analysis and courtroom admissibility

The presentation will address the research question: "Does exporting frames from HEVC video alter the original frames?" Through this inquiry, the study highlights the need for consistent standards and reliable practices in forensic video processing. The findings are intended to support improvements to the Scientific Working Group on Digital Evidence (SWGDE) recommendations and guide practitioners in selecting validated, forensically sound extraction tools.[1]

Impact Statement: This presentation will have a significant impact on the forensic science community by examining how frame extraction methods from HEVC videos, even when following established guidelines, can introduce discrepancies that compromise the forensic integrity of the extracted images. Through quantitative comparisons, the study demonstrates how different tools can subtly, yet measurably, alter visual data, raising important concerns about the reliability of HEVC video evidence. Additionally, the research explores how these discrepancies can result in mismatched stream hash values, which are intended to verify the authenticity and continuity of the original video. These findings highlight critical risks in current forensic workflows and underscore the need for validated, standards-based extraction practices for HEVC videos.

Abstract Text: The fundamental principles in digital media forensic sciences emphasize the importance of preserving the integrity of data throughout the process of recovery, handling, and processing. This thesis examines whether the image quality of frames extracted from HEVC (also known as h.265) encoded video files produces discrepancies when comparing results across software platforms. Discrepancies in the image quality of the extracted frames affect the forensic integrity of the images and raise questions about the validity of the extraction methods used for HEVC/h.265 encoded videos. These quality variations can compromise the methodology and evidence, significantly impacting forensic integrity. As digital forensic examinations can depend heavily on the accuracy and reliability of video evidence and authentication, frame extraction methods must be validated and verified as technological advances improve. Stream hashing ensures data integrity during file container conversion by generating a cryptographic hash that validates content. It verifies the raw video content remains unchanged.

In this study, video frames were extracted from the original video using various software methods from FFmpeg, MATLAB, Adobe Premiere, and Adobe Media Encoder. Stream hashing was used to verify image integrity, and SHA-256 and MD5 hash values were calculated for all extracted frames and source videos. Image subtraction and image correlation analysis revealed significant variation between extracted frames, particularly between FFmpeg and MATLAB, while Media Encoder and Premiere produced nearly identical results. Notably, discrepancies were more pronounced in flatfield test videos and in footage recorded at 60 frames per second. After transcoding to h.264 using SWGDE-recommended FFmpeg commands, stream hashes for original and decoded videos did not match, indicating that transcoding does not ensure frame-level hash consistency. These findings demonstrate the inconsistencies and limitations in current HEVC frame extraction workflows. Further research is needed to identify the causes of these discrepancies, develop standardized HEVC frame extraction methodologies, and update current forensic guidelines to account for the challenges posed by modern video compression formats

C18 Exploring Dropbox Image Downloads to iPhone Via Safari: File System vs. Camera Roll Validation Study

Gregory S. Wales, DSc, Independent Researcher, Colorado Spring, CO; Alexander Nash, MS*, National Center for Media Forensics at the University of Colorado Denver, Layton, UT; Tierney B. Moe, BS, Arapahoe County Sheriff's Office, Lone Tree, CO*

Learning Objectives: Attendees will learn how to validate the forensic integrity of digital images transferred from Dropbox to iPhones via Safari, using both cryptographic hash analysis for file containers and perceptual similarity metrics for image content. The session will equip practitioners with measurable methods to verify the integrity of evidence and assess the legal admissibility of digital workflows.

Impact Statement: This presentation will enhance the forensic science community's ability to evaluate and defend the integrity of digital evidence collected in field scenarios where specialized tools are unavailable. Clarifying the effects of iOS storage locations on forensic verification will enhance practitioner competence and performance in evidence handling, thereby supporting a robust chain of custody and ensuring admissibility in court.

Abstract Text: The increasing use of cloud storage and smart phones for digital evidence collection poses challenges to maintaining forensic integrity, especially when specialized tools are inaccessible. This study addresses a real-world scenario: images captured on one iPhone are uploaded to Dropbox and subsequently downloaded to another iPhone via Safari, either to the Files folder or the Photos application. The research question was: How does downloading images from Dropbox via Safari to an iPhone's file system versus the Photos app impact the integrity of the image file container and content?

A quantitative, quasi-experimental design was employed, involving 60 tests across three iPhones running iOS 14.2 and 14.4. Ten original images were uploaded to Dropbox and then downloaded to both storage locations. Controlled tests validated the sensitivity and accuracy of measurement tools, including Secure Hash Algorithm (SHA) 256 file container and stream hashes, as well as perceptual similarity metrics such as Pearson Correlation Coefficient (PCC), Structural Similarity (SSIM), and Multiscale Structural Similarity Index (MS-SSIM).[1-3] In this context, "image stream hashes" refers specifically to the hash of the image data, excluding any metadata associated with the container. Results showed that file container hashes remained unchanged when images were downloaded to the Files folder but were consistently altered in the Photos app, reflecting iOS-specific structural modifications. However, image stream hashes and MS-SSIM scores (1.0 in all cases) confirmed no perceptible degradation or alteration of image content.

Statistical analysis and reporting were conducted according to the President's Council of Advisors on Science and Technology **(**PCAST) recommendations for forensic validation studies.[4] The findings demonstrate that, while iOS may modify file containers in the Photos app, the actual image content remains intact, supporting the use of such workflows in forensic contexts. These results align with *Daubert* and Federal Rule of Evidence (FRE) 702 standards for evidence admissibility, providing practitioners with empirically validated guidance for digital evidence handling when conventional forensic tools are unavailable.[5,6] Future work should extend validation to additional devices, iOS versions, and cloud platforms to broaden applicability.

C19 Uncovering User Behavior: AI-Based Timeline Reconstruction From Mobile Evidence

Chen Shi, MS, Iowa State University, Austin, TX; Yong Guan, PhD, Iowa State University, Ames, IA*

Learning Objectives: By attending this presentation, participants will: (1) understand the forensic value of timeline reconstruction in mobile investigations and why it is critical for interpreting user behavior from mobile devices, (2) identify common sources of digital artifacts on Android (e.g., logs, SQLite databases, app data) that can be leveraged for timeline generation; (3) explore the role of AI and machine learning in processing, classifying, and sequencing heterogeneous event data from mobile devices; (4) examine the design of an AI-based pipeline for timeline reconstruction, including data preprocessing, model selection (e.g., Long Short-Term Memory [LSTM], Transformers), and output generation; and (5) evaluate the practical challenges and limitations of applying AI in real-world forensic scenarios, such as obfuscation, incomplete logs, and ambiguous timestamps.

Impact Statement: This presentation introduces an AI-assisted approach to reconstructing user activity timelines from Android devices, offering a new perspective on how digital evidence can be interpreted more efficiently and accurately. By combining forensic analysis with machine learning techniques, this work has the potential to significantly reduce manual workload, enhance timeline precision, and uncover patterns that may be missed through traditional methods.

Abstract Text: In digital forensic investigations, reconstructing a timeline of user activities plays an important role in uncovering user behavior and potential misconduct. However, on modern Android devices, user activity traces are fragmented across multiple data sources—such as system logs, app databases, cached files, and configuration settings, which makes the manual timeline reconstruction both labor-intensive and error-prone. This challenge is further complicated by app-specific data structures, obfuscation techniques, and incomplete or inconsistent timestamps.[1]

This work presents an AI-assisted approach for timeline reconstruction by leveraging Machine Learning (ML) techniques to process, classify, and sequence heterogeneous digital artifacts extracted from Android devices. Our proposed method treats forensic event reconstruction as a temporal sequence modeling task where logs and database records are encoded with their metadata, contextualized using language embeddings, and then processed using deep learning models.[2] The ML model is trained to recognize event patterns, infer missing links, and generate structured timelines of user actions.[3]

We explore several backbone architectures and discuss the trade-offs in model complexity, interpretability, and performance. Additionally, we introduce a lightweight preprocessing pipeline designed to convert extracted mobile data into normalized, time-aligned sequences compatible with AI-based modeling. Even in the absence of large labeled datasets, we demonstrate how zero-shot or lightly fine-tuned models can still generate meaningful event timelines with minimal supervision.[4]

Early testing of the proposed AI-assisted pipeline on sample Android log and database artifacts indicates that our approach is feasible and capable of producing coherent event sequences. Initial observations suggest that our model can effectively align the fragmented records and fill in the potential gaps in user activity. The preliminary findings provide a foundation for further experimentation with larger datasets and real-world case scenarios.

The proposed approach has the potential to significantly reduce the workload for forensic analysts, improve the accuracy and completeness of reconstructed timelines, and uncover subtle behavioral patterns that may not be obvious through manual analysis. This work contributes to the advancement of intelligent digital forensics by demonstrating how artificial intelligence can be effectively integrated into mobile evidence analysis workflows.[1,5]

C20 The Human Link in an Automated Era: Forensic Expertise in the Peritus Framework

Dineusa Maria Do Amaral, MBA, Judicial Expert for the Court of the State of Paraná, Foz do Iguaçu, Parana, Brazil; Cristiane Viana Barbpsa, MA*, UFF, Universidade Federal Fluminense, Rio De Janeiro, Brazil; Anna Beatriz Rodrigues Geranio, University Estacio de Sá, Petrópolis, Rio de Janeiro, Brazil*

Learning Objectives: Participants will understand how the automation of the digital chain of custody, using tools such as the Peritus Framework, can strengthen the reliability, traceability, and standardization of digital evidence. The presentation will also highlight the crucial role of forensic experts in bridging technical procedures and legal requirements, ensuring the acceptance and credibility of digital evidence in court.

Impact Statement: While automation contributes significantly to the standardization of forensic procedures, its effectiveness depends on the expertise and judgment of the forensic examiner. This study demonstrates how the Peritus Framework promotes transparency and auditability in the digital chain of custody while preserving the need for expert interpretation and responsibility. By addressing the capabilities and limitations of automated tools, this research provides key insights for improving forensic practices and developing protocols to ensure the admissibility and reliability of digital evidence in legal proceedings.

Introduction: The digital chain of custody is essential for validating electronic evidence, requiring mechanisms that ensure data integrity, traceability, and consistency. The Peritus Framework, developed by the Brazilian Federal Police, is a free and modular tool designed to support systematic documentation in digital forensics. This study investigates how Peritus contributes to strengthening the chain of custody and highlights the forensic expert's role in bridging technical workflows with legal standards for admissibility.

Objectives and Methods: This study aimed to evaluate Peritus in terms of its features, benefits, and limitations in supporting the digital chain of custody. The research team employed a mixed-methods approach. During the qualitative phase, the researchers reviewed technical manuals, regulatory documents, and platform content. In the quantitative phase, the team created ten simulated cases. Each case was processed using Peritus, which generated structured XML logs recording actions, parameters, timestamps, and results. A second expert independently audited each case to assess procedural clarity, traceability, and data integrity.

Results and Discussion: Peritus operates through a three-layer architecture interface, logic core, and storage, which work together to ensure consistency. Key functionalities include automatic logging with SHA-256 hashes, derivation tracking, and XML reporting. Although it does not use blockchain, the system incorporates similar principles of immutability and transparency. The system registers each forensic action in XML files that include timestamps, operators, used parameters, and resulting data, forming a technical history of the evidence. The Data Logger module ensures standardized documentation across procedures. Experts can verify file integrity by comparing generated hashes with the originals.

The tests confirmed that Peritus effectively documents every stage of the chain of custody. The second expert was able to validate all steps, demonstrating the tool's transparency and traceability. However, a notable limitation was the system's learning curve. It requires prior technical knowledge, which may be a barrier to new users. Despite this, once mastered, the system supports reproducible, auditable, and legally defensible processes.

The role of the forensic expert remains essential. Beyond executing procedures, the expert must interpret and communicate technical terms such as forensic image, hash, and integrity report in a way that legal professionals and courts can understand. This translation between technical and legal domains is critical for the acceptance of digital evidence.

Conclusion: The Peritus Framework contributes significantly to the standardization and automation of the digital chain of custody. Its XML-based logs ensure traceability and support peer review and legal validation. While the system proved effective in controlled scenarios, its broader success depends on the forensic expert's ability to operate the tool competently and translate its outputs into legally coherent reports.

Investing in training and regulatory guidance is vital. Future studies comparing Peritus with other tools and exploring new forensic applications will further advance digital forensic practices and reinforce the reliability of electronic evidence in judicial contexts.

C21 Garmin Forensics: A Study on the Device's Data Integrity and Reliability in Court

Vinicius Lima, PhD, SUNY Albany, Lafayette, IN; Akif Ozer, MS, Purdue University, West Lafayette, IN; Umit Karabiyik, PhD, George Mason University, Fairfax, VA*

Learning Objectives: The goals of this presentation are to: (1) understand the forensic potential and risks associated with data collected by wearable devices, particularly the Garmin Vivoactive 5; (2) describe the structure and function of some Flexible and Interoperable Data Transfer (FIT) files used by Garmin devices and explain how this watch design can be vulnerable to tampering; (3) demonstrate potential scenarios to manipulate smartwatch data, including both file transfers and direct edits, and the implications of such manipulation for digital forensic investigations; (4) apply forensic indicators and cross-validation techniques to detect signs of data manipulation in wearable devices; and (5) discuss court reliability of such devices from a digital forensics perspective.

Impact Statement: This study show vulnerabilities in smartwatches from Garmin devices that can be manipulated by criminals with minimal effort and/or without detectable traces. These findings challenge assumptions about the reliability of wearable device data in legal contexts. By proposing detection strategies and forensic indicators, this research equips digital forensic practitioners, legal professionals, policymakers, and researchers with tools to better evaluate the admissibility and integrity of wearable-derived evidence in criminal investigations.

Abstract Text: As digital evidence becomes increasingly central to modern criminal investigations, the integrity and reliability of data stored on personal devices must be rigorously assessed.[1] Among these devices, smartwatches (such as those developed by Garmin) are widely used for health and fitness tracking while also passively collecting potentially critical forensic data, including GPS coordinates, heart rate, and timestamped activity logs.[2] Such data have already been admitted as evidence in court to reconstruct events, verify alibis, or place individuals at specific locations.[3] In this study, we conduct a forensic examination of the Garmin Vivoactive 5 to evaluate the structure, storage, and vulnerability of its internal data. Our findings reveal the ease with which this data can be manipulated, raising serious concerns about its evidentiary reliability. Through two experimental scenarios, we demonstrate that data tampering is feasible either by transferring and re-importing files between devices or by directly modifying the internal FIT files.[4] Additionally, we show that anti-forensic techniques can be employed without triggering obvious signs of tampering, thereby compromising the trustworthiness of smartwatch-derived evidence. To assist practitioners and researchers, we propose a set of forensic indicators and cross-validation strategies to detect signs of potential manipulation. This work contributes to a deeper understanding of how wearable devices store data and highlights critical implications for their use in the litigation process.[5]

C22 iGEM: A Multi-Device Forensic Visualization Software for Geolocation and Digital Evidence Matching

Xiao Hu, MS, Purdue University, West Lafayette, IN; Akif Ozer, MS*, Purdue University, West Lafayette, IN; Marcus K. Rogers, PhD, Purdue University, West Lafayette, IN; Umit Karabiyik, PhD*, George Mason University, Fairfax, VA*

Learning Objectives: Attendees will learn how our forensic software tool, iGEM, has been developed to extract, unify, and visualize digital artifacts from iOS devices for timeline reconstruction and behavioral correlation. The presentation will demonstrate how the tool integrates fragmented geolocation and app usage data into an interactive interface, allowing investigators to uncover temporospatial patterns and cross-device relationships with minimal manual processing.

Impact Statement: This presentation will introduce a forensic visualization platform that will enable investigators to correlate and present complex digital evidence extracted from iOS devices. By providing a unified view of location data, app usage, and screen activity, the tool will help practitioners reconstruct timelines and behavioral patterns across devices. The system will support investigative clarity, improve reporting efficiency, and bridge the gap between technical analysis and courtroom communication.

Abstract Text: Digital forensic investigations involving mobile devices often face challenges in correlating fragmented data scattered across multiple file systems and databases. On iOS devices, critical artifacts such as Global Positioning System (GPS) coordinates, app usage logs, and visual screen snapshots are typically stored in separate containers, including Cache.sqlite, KnowledgeC.db, and .ktx files.[1,2] These diverse data sources, while individually useful, are difficult to cross-reference without a dedicated integration framework.

This presentation will introduce iGEM, a forensic visualization platform designed to extract, unify, and display geolocation and behavioral artifacts from iOS devices. The system has been developed to ingest full-disk iOS images and automatically parse and normalize evidence from multiple databases into a unified schema. Investigators will interact with the data through a web-based timeline interface and synchronized map view, allowing intuitive analysis of user movements, application activity, and behavioral correlations.

To demonstrate its forensic value, the presentation will walk through a simulated case involving multiple individuals whose mobile device images are processed through iGEM. The platform will simultaneously ingest and correlate artifacts from each device, enabling investigators to examine overlaps in location trails, app usage sequences, and timestamped behaviors.[3] This multi-device analysis will reveal interactions and movement patterns that could support investigative hypotheses or help clarify timelines in complex forensic scenarios.[4]

The platform's modular architecture will allow future integration of additional data types such as biometric indicators or cloud-based communications. By bridging raw digital evidence with investigative narratives, iGEM will provide forensic analysts with a practical tool for constructing coherent timelines and exposing behavior patterns that might otherwise remain hidden. Ultimately, this tool will offer the forensic community an accessible and extensible solution for temporospatial analysis of iOS device evidence.

C23 Comparing Smart Phone Geolocation Accuracy: Forensic Analysis of iOS and Android Location Artifacts

Jeff D. Rutherford, BSc, Magnet Forensics, Edmond, OK*

Learning Objectives: From this presentation, participants will learn how to rigorously validate the accuracy of geolocation data extracted from both iPhones and Android devices, with a focus on the reliability of Apple's confidence factors and Android's horizontal accuracy metrics. By applying statistical analysis and comparing Global Positioning System (GPS) points to a known reference point, participants will develop measurable skills in assessing the precision of geolocation data across both platforms, skills essential for forensic investigations and legal proceedings.

Impact Statement: This presentation enhances the forensic science community's competence by providing methodologies to validate the accuracy of geolocation data extracted from both iPhones and Android devices. It translates this competence into action by offering practical steps for forensic examiners to assess and verify the precision of GPS data from both platforms in real-world scenarios. Stakeholder outcomes are positively impacted as legal professionals and investigators gain reliable data to support or challenge evidence in court, ensuring accurate and just judicial decisions.

Abstract Text: In modern digital forensics, accurately validating geolocation data extracted from smart phones is essential, particularly in legal proceedings where the integrity of evidence is closely scrutinized. This study compares geolocation accuracy across iOS and Android devices, providing forensic practitioners and legal professionals with insights into the reliability of location data on the two dominant mobile platforms.

For iOS devices, this research analyzes Apple's "horizontalAccuracy" confidence factor, a metric indicating the estimated radius within which the actual location is expected to fall. Data from iPhones, which are stored in databases such as Cache.sqlite, includes latitude, longitude, timestamps, and horizontal accuracy values. These points are rigorously tested against known reference points to measure whether Apple's reported accuracy radii consistently encompass the actual recorded positions.

For Android devices, the study explores geolocation data primarily stored in app_semanticlocation_rawsignal_db located at /data/data/com.google.android.gms/. This data on Android devices, like their iOS counterparts, record latitude, longitude, timestamps, and horizontal accuracy values, enabling a direct comparison of geolocation accuracy between the two platforms.

The study's methodology involves extracting and decoding geolocation points from both platforms, identifying known reference locations under controlled conditions, and comparing the actual distances of the recorded locations to the positions predicted by their respective horizontal accuracy metrics. By applying this structured validation approach, the research quantifies and compares the precision and reliability of geolocation data generated by Apple and Google, evaluating systematic differences and potential biases inherent in each platform's data.

This comparative analysis provides critical insights into the strengths and limitations of each platform's geolocation accuracy, enabling forensic examiners to assess evidence reliability, construct accurate investigative timelines, and inform judicial considerations. Ultimately, this research contributes a robust cross-platform evaluation methodology, improving forensic understanding and the defensibility of smart phone-derived geolocation evidence in legal contexts.

C24 The Dark Side of Discounts: How Temu Handles Your Data

Sonali Tyagi, MS, Purdue, W Lafayette, IN; Umit Karabiyik, PhD*, George Mason University, Fairfax, VA*

Learning Objectives: After attending this session, attendees will understand how mobile e-commerce applications like Temu collect, store, and potentially expose user data across Android and iOS platforms. They will understand forensic techniques used to recover cached images, session artifacts, and search history, along with the privacy implications these findings reveal for investigations and regulatory compliance.

Impact Statement: The presentation will have a significant impact on the forensic science community by providing forensic professionals with concrete methodologies to extract user-specific artifacts from mobile commerce apps, such as Temu. This will demonstrate how cached images, search logs, and session data can support investigations. It also raises awareness of app behaviors that may bypass user expectations, prompting refinements in forensic protocols and privacy risk assessments.

Abstract Text: Nearly one-third of the world's online users, approximately 1.65 billion people, shop on their phones, and in the United States, over 76% of adults use a smart phone to make purchases.[1] Mobile shopping apps are popular because they make shopping very easy and convenient, allowing people to browse and buy at any time, anywhere.[2] Moreover, these days, mobile shopping apps make shopping more engaging by offering personalized tips and timely alerts, helping users quickly find and take advantage of deals.[3] However, to provide a better and customized experience, shopping apps often ask users to share personal details and allow access to certain phone features.[4] This process intersects with significant concerns regarding security and privacy risks associated with the collection, use, and sharing of vast amounts of user data.[5] Therefore, our study aims to identify the security and privacy risks associated with the Temu app on Android and iOS devices and report the forensically relevant findings.

Our investigation of the Temu app was conducted in accordance with the National Institute of Standards and Technology (NIST) standards for mobile device investigations and implemented the associated forensic procedures.[6] Two smart phone devices were used for this study: an Apple iPhone 7 Plus running iOS 15.7.9 and a rooted Google Pixel 5a running version 11.

Results indicate the presence of traces, as metadata and log analysis, suggest background activity and communication with external hosts, potentially for tracking or behavioral analytics purposes. However, in Android, most of the user information is encrypted, and even network communication is securely hosted on Microsoft Azure cloud with encrypted tokens. In iOS, no records of user information were found, and files that suggested such content were securely encrypted. However, like Android, the metadata that was recovered can reveal a user's search history and shopping behavior, presenting both a potential privacy concern and a valuable source of forensic evidence. The forensic analysis provided valuable insights into Temu's app behavior, cached data, user sessions, and SDK integrations.

Additionally, while using the app on a Google Pixel 5a, a few inconsistencies were identified. First, when the Temu app's inbuilt camera was used to access an image from the gallery, the app did not request camera permission, nor did it explicitly list it in the Android permission section, as per standard permission access. Despite this, the in-app interface allowed the user to open the device gallery via an embedded camera/upload function. Second, there is a persistent inconsistency with the Facebook linkage and the Temu app.

Additional findings and suggestions for future research, as well as the ethical and privacy implications of the Temu app, will be discussed.

C25 Leave a Message—Where?: A Study of Apple's Voicemail Databases

Kaylee Schoepe, MS, Epiq, Union, NJ; Chad Stedl, BS, Epiq, Eau Claire, WI; Andrew N. Crouse, BA*, Epiq, Washington, DC; Brian Smith, BS, Epiq, Bonaire, GA*

Learning Objectives: This presentation will focus on the two types of databases that voicemails can go to in iOS devices as well as the research and analysis concerning what triggers a voicemail to go into these databases. Attendees will understand the difference in what voicemail data is captured when performing an iTunes Backup extraction compared with a full filesystem extraction.

Impact Statement: This presentation is valuable to the forensic science community because voicemails can play a pivotal role in criminal and civil cases, and it is critical that examiners both capture all the data available and be able to explain where it came from and the different voicemail databases that exist on an Apple iOS mobile device.

Abstract Text: Live voicemail is a function of Apple iOS devices that was implemented in iOS version 17.[1] It provides users with a live transcription of voicemails from callers. This notifies users of the substance of an incoming voice call and allows them to decide whether they want to answer the call while reviewing the live transcription. Live voicemail is enabled by default, but users may opt to disable this function, causing voicemails to go straight to the carrier. Prior to iOS 17, voicemails were historically stored in an SQLite database called "voicemail.db." This database still exists on all modern iOS device and contains metadata about the voicemail as well as pointers to the actual Adaptive Multi-Rate (AMR) -encoded audio files containing the recording of the voicemail.[2,3] In the past, most major forensic tools were capable of parsing all voicemails from iOS collections. However, the advent of live voicemail introduced a second database called "FaceTimeMessageStore-local.sqlitedb" where voicemails are stored. This second database is used to store voicemail metadata in addition to the legacy voicemail.db. Depending on a variety of factors, voicemail data may be stored in one or both databases on modern iPhones. The focus of this study is to research what factors affect which database the voicemails will be saved to as well as to compare the differences between collection methods, including an advanced logical extraction such as an iTunes backup as well as a full file system extraction with tools such as Cellebrite and VeraKey. In researching these methods, multiple rounds of testing occurred where variables such as toggling live voicemail on/off, placing the phone in airplane mode, allowing the phone to go into low power mode, wrapping the phone in aluminum foil, and several other common occurrences were introduced.

Analysis of these results yielded that only a full file system extraction will capture both the live voicemail database and the legacy database. An advanced logical extraction, such as an iTunes backup, will only collect the legacy database. Furthermore, when variables, such as live voicemail is disabled, the phone is placed in airplane mode, or when the phone is in lower power mode, a voicemail will go to both the live voicemail database and the legacy database. However, when live voicemail is enabled, voicemails will only go to the live voicemail database. If an examiner is seeking live voicemails or does not know whether live voicemails are enabled on an iPhone, the phone should be collected using a full file system extraction versus an advanced logical extraction. The results of these changes to the voicemail databases impacts forensic examiners, requiring that they collect and review all available data on modern Apple iOS devices and also understand the factors that cause the data to be in one or both databases.

C26 Forensic Analysis and Privacy Implications of LLM Mobile Apps: A Case Study of ChatGPT, Copilot, and Gemini

Sonali Tyagi, MS, Purdue, W Lafayette, IN; Yufeng Gong, MS*, Purdue University, West Lafayette, IN; Umit Karabiyik, PhD*, George Mason University, Fairfax, VA*

Learning Objectives: After attending this session, attendees will gain insight into the forensic artifacts that can be retrieved from popular Large Language Model (LLM) mobile applications (Chatbot Generative Pre-Trained Transformer [ChatGPT], Gemini, and Copilot) across Android, iOS, and cloud platforms. They will learn how these artifacts can be helpful in forensic investigations while raising significant privacy implications.

Impact Statement: The presentation will have a significant impact on the forensic science community by providing actionable knowledge on recovering user data, conversation history, and location artifacts from LLM mobile apps, thereby enhancing evidence collection in digital forensic investigations. It also highlights critical privacy gaps, prompting the need for updated forensic protocols and ethical considerations when handling AI chatbots.

Abstract Text: Many LLMs have been developed in the past two years, gaining popularity and generating massive market revenues, such as ChatGPT by OpenAI, Bard and Gemini by Google, Copilot by Microsoft, and Large Language Model Meta AI (LLaMa) by Meta.[1,2] These days, various LLMs are utilized for diverse tasks, including translating text from one language to another, analyzing data, and analyzing sentiments, such as those employed in chatbots, as well as generating AI-based images, audio, and videos.[3,4] However, the extensive capabilities of these apps can also be misused for harmful activities.[5,6] These LLM apps can be manipulated to generate malicious code, phishing emails, and scamming content.[5-7] Additionally, they can be used by perpetrators to groom and lure innocent children.[5]

According to Statista, hackers are exploiting ChatGPT for cybercriminal activities (e.g., generating believable phishing emails and creating malware), online child sexual exploitation, and child grooming.[8,9] Due to the popularity and ease of access of these apps, people tend to use them to assist with their daily tasks. However, when downloaded on mobile phones, these apps access various types of personal data (e.g., account information, location, and device information), including browser cookies, which may be of forensic value. Considering all these potential malicious uses of LLM apps, the data collected from these apps can be helpful in forensic investigations.

Therefore, this study builds upon current literature and addresses existing gaps to further assess the significance of the forensic artifacts recovered from these LLM apps regarding privacy implications. In this study, we extended the forensic analysis of ChatGPT, Copilot, and Gemini for both Android and iOS platforms. We also analyzed Google Takeout data available for Gemini. This paper focuses on the conversation-based artifacts that can be recovered from these LLM apps for forensic investigation and examines the implications for user privacy.

The results showed that ChatGPT consistently stored plaintext user information and conversation data on both platforms, and location data on iOS only, even when location services were disabled, suggesting potential IP-based geolocation. ChatGPT does collect IP addresses, which may provide an approximate location, such as country, state, or city. Gemini, in contrast, stores minimal to no forensic artifacts on Android and iOS devices, with most user data, including complete conversation history, retrievable only via Google Takeout, which illustrates its strong reliance on cloud storage. Copilot exhibited an inverse pattern: while Android stored limited prompt data and location approximations, iOS retained detailed conversational content, including rejected queries and response metadata, in a different folder. In the first case, Copilot stored responses for the ethical prompts in fsCachedData, and in the second case, the responses for the unethical or restricted prompts were stored in Cache.db. Additionally, we could find location data for Copilot on Android but not on iOS.

Additional findings and suggestions for future research, as well as the privacy implications of AI chatbots, will be discussed.

C27 From Screen to Scene: An In-Depth Forensic Analysis on DeepSeek

Yufeng Gong, MS, Purdue University, West Lafayette, IN; Sonali Tyagi, MS*, Purdue, W Lafayette, IN; Vaishnavi Mahindra, MS*, Purdue University, West Lafayette, IN; Umit Karabiyik, PhD*, George Mason University, Fairfax, VA*

Learning Objectives: After attending this presentation, attendees will be aware of available forensic artifacts recovered from DeepSeek's mobile apps on Android and iOS. Through our detailed forensic analysis on DeepSeek's network communications, attendees can learn how to access sensitive encrypted content sent via network traffic. Additionally, attendees will recognize differences in DeepSeek's content filtering mechanisms between its international and Chinese versions. Finally, attendees will understand key privacy and security concerns associated with DeepSeek.

Impact Statement: This presentation addresses a crucial gap in the forensic investigation of emerging generative AI applications by providing a comprehensive forensic methodology and detailed artifact analysis for the rapidly adopted DeepSeek mobile application in different versions and operating systems. By systematically examining forensic-important artifacts and network communications, this research helps digital forensic practitioners obtain essential knowledge and practical techniques to effectively handle real-world investigations involving DeepSeek.

Abstract Text: As an application focusing on generative artificial intelligence, open-source LLM DeepSeek has been widely adopted by many research institutions and international companies around the world. More than 60 million active daily users have been reported on DeepSeek by QuestMobile.[1]. Given the rapid growth in the population of Deepseek's users and the fact that mobile devices gradually function as centers for users to interact with AI chatbots, it is essential to conduct thorough mobile forensics along with network forensics on the DeepSeek mobile app to discover potential evidence stored in both Android and iOS devices and provide valuable insight into its potential vulnerabilities. However, given the app's recent introduction, there is currently a lack of systematic forensic research that investigates its forensic valuable artifacts, data persistence mechanisms, and network communication patterns across platforms.

This research focused on user data and application usage, such as databases, log files, metadata, and other critical traces which revealed forensic-valuable insights for different versions of DeepSeek mobile app operating in different platforms and the data sent over the network. Our analysis can help forensic researchers and investigators fully utilize the forensic values of DeepSeek on mobile devices to have a clear view of what can be recovered and obtained.

Our investigation revealed that the DeepSeek mobile application generates recoverable artifacts across both iOS and Android platforms, including user and device information, app settings, operation logs, and chat histories. We observed distinct differences between the Chinese and international versions, particularly in censorship behavior and privacy handling. The Chinese version applies stricter content filtering and receives different responses to sensitive queries. Network analysis uncovered significant security and privacy concerns, including plaintext data leakage, persistent connections to servers operated by Chinese technology firms, and the absence of SSL pinning in the iOS version, which allowed traffic interception without additional bypass techniques. Moreover, on Android, application crashes triggered a replay of chat histories through network communication, introducing further privacy risks. Finally, despite these differences, the structure and location of key artifacts remained consistent across operating systems and regions, demonstrating stable artifact generation patterns in version 1.1.0 of the application DeepSeek.[2,3]

C28 Reading Between the Handles: How Bad Actors on Reddit and Darknet Discuss AI/LLM Misuse for CSEA

Sonali Tyagi, MS, Purdue, W Lafayette, IN; Kathryn Seigfried-Spellar, PhD*, Michigan State University, East Lansing, MI*

Learning Objectives: After attending this session, attendees will gain insight into how the platform characteristics of Reddit and Darknet forums, such as community norms, moderation policies, and perceptions of surveillance and trust, shape the discourse of bad actors surrounding Artificial Intelligence (AI) and Large Language Models (LLMs) misuse related to Child Sexual Exploitation and Abuse (CSEA). They will understand how pseudonymity, trust systems, and moderation influence deviant communication and risk behavior.

Impact Statement: The presentation will impact the forensic science community by providing critical insights into the behavioral dynamics of online bad actors, discussing AI/LLM misuse, especially for CSEA. It informs intelligence gathering strategies by highlighting where and how actionable information emerges, improving detection, monitoring, and digital evidence interpretation across Reddit and Darknet forums.

Abstract Text: LLMs have gained popularity over the past five years due to their revolutionary and advanced features, including text generation, code writing, content summarization, access to knowledge bases, conversational AI, and continuous learning.[1] However, cyber-criminals are also leveraging AI capabilities to create AI-driven cyberattacks.[2] For example, AI chatbots are being widely used for malicious purposes, including generating phishing emails and creating malware, online CSEA, and child grooming to bypass safety filters and evade detection.[3-7]

Moreover, there has been a 550% rise in deepfake videos between 2019 and 2024, with over 500,000 shared on social media in 2024 alone.[8] A study revealed that discussions about AI CSAM on darknet forums surged, with over 19,000 posts and threads referencing AI-generated abuse content in just one year.[9] Two primary spaces where these discussions may unfold are Reddit and various darknet forums. Reddit is one of the largest open-net platforms for discussion and debate, serving as a gateway to enter darknet forums.[10] Due to the anonymity and encrypted communication, the dark net is often associated with illicit activities. Therefore, by comparing Reddit and darknet forums, this study aims to understand how these environments enable or constrain deviant discourse around the misuse of AI and LLMs related to child sexual exploitation and abuse. This study examines how platform-specific features, including community norms, moderation policies, and perceptions of surveillance and interpersonal trust, impact these behaviors.

Preliminary findings show a clear divergence as the design and culture of Reddit and darknet forums create very different conditions for participation. The Reddit platform features a pseudonymous user base, karma-driven content visibility, and community-led moderation, encouraging more cautious, general, and speculative discussions. In contrast, darknet forums rely on strict gatekeeping, encryption techniques, strong anonymity, and internal trust systems allowing users to engage in detailed and explicit discussions on illicit AI use, including CSAM, deepfake creation, operational security, and evasion techniques.

Additionally, to investigate this behavior in detail, a comparative discourse analysis will be conducted on AI/LLM-related threads collected from both Reddit and a selected darknet forum. Based on identity performance, such as how often users post, the type of language they use, and the amount of personal or technical detail they share, we aim to demonstrate how the design and rules of each platform influence what bad actors are willing to disclose and how they choose to present themselves.

The results and future implications of the study's findings will be discussed.

C29 Bytes of Evidence: Examining Technology-Facilitated Abuse Against Women and Children

Neha Verma, PhD, CFSL, DFSS, MHA, India, Shimla, Himachal Pradesh, India*

Learning Objectives: Attendees of this session will gain a deeper understanding of how the nature of crimes against women and children has evolved, especially with the growing use of digital platforms. We'll explore how these shifts are not just affecting individuals but leaving lasting impacts on families and communities. Beyond just identifying these issues, the session will also focus on practical ways to help prevent such crimes from escalating—through awareness, early intervention, and the responsible use of technology. I also hope to inspire attendees to think about how they, in their own capacities, can help raise awareness and encourage others to take a stand. Whether through education, advocacy, or simply starting conversations, every small effort counts when it comes to protecting the vulnerable and building a safer society for all.

Impact Statement: In an increasingly digital world, crimes against women and children have taken new and often invisible forms, leaving victims vulnerable and justice delayed. This study recognizes the deep emotional and societal scars left by technology-facilitated abuse from online exploitation and harassment to the sharing of abusive content. Through the lens of digital forensic science, we aim not only to uncover hidden evidence but to restore voices that have been silenced. By advancing forensic tools and investigative methods, this research contributes to a justice system that is more responsive, more humane, and more equipped to protect the most vulnerable. Ultimately, this work stands as a commitment: to ensure that technology is used not to harm, but to heal and to hold accountable those who use it to exploit others.

Abstract Text: The rising number of technology-facilitated crimes targeting women and children is a reflection of a disturbing shift in the nature of abuse and exploitation in the digital era. This presentation outlines selected case studies that were initiated through tipline reports from the National Center for Missing & Exploited Children (NCMEC), with a focus on how digital forensic science played a central role in supporting investigations and achieving meaningful outcomes.

The cases presented involve offenses such as online child sexual exploitation, circulation of non-consensual intimate imagery, and cyberstalking. Each case will illustrate the complete digital forensic workflow from acquisition of digital evidence from electronic devices and cloud platforms to analysis of metadata, communication patterns, and media content using state-of-the-art tools. The forensic findings contributed to victim identification, corroboration of suspect activity, and legal proceedings.

In addition to the technical aspects, this presentation also reflects on the inter-agency collaboration required to act on NCMEC tipline data, the challenges of evidence prioritization, and the importance of rapid forensic response in time-sensitive cases involving minors. I will also briefly discuss preventive implications, including public awareness and digital safety, drawn from recurring patterns observed during examinations.

This work aims to highlight the role of digital forensic science not only in reactive investigations but also in proactive protection of vulnerable populations. It underscores the responsibility of forensic professionals to stay adaptive, ethically grounded, and aligned with the evolving digital threat landscape.

C30 Improving CyberTipline Processing: Leveraging Machine Learning and OSINT for Enhanced ICAC Response

Nina Matulis, MS, Purdue University, Lafayette IN PD, West Lafayette IN, IN; Marcus K. Rogers, PhD, Purdue University, West Lafayette, IN*

Learning Objectives: By the end of this presentation, attendees will be able to: (1) identify common inefficiencies in the current workflow for processing CyberTipline reports submitted to the National Center for Missing & Exploited Children (NCMEC), including sources of delay, misclassification, and false positives encountered by state and local Internet Crimes Against Children (ICAC) units; (2) evaluate the operational impact of false positives in NCMEC CyberTipline reports using preliminary data collected through structured survey instruments distributed to ICAC investigators; and (3) assess the feasibility and potential value of integrating machine learning and Open-Source Intelligence (OSINT) -based triage tools—such as a decision-tree model—to serve as an intermediary layer between NCMEC, state law enforcement, and local agencies, improving case prioritization and resource allocation.

Impact Statement: This presentation offers a foundational feasibility analysis of inefficiencies in CyberTipline processing, identifying key pain points experienced by ICAC investigators at the state and local levels. By empirically documenting false positives, misclassifications, and delays, this research provides the first structured insight into how these issues hinder timely response and effective case triage. The study explores the potential of integrating machine learning and OSINT tools to flag low-priority or mis-routed tips before they reach investigators, ultimately reducing backlog and improving prioritization. The findings will inform scalable, data-driven interventions that enhance collaboration between NCMEC and law enforcement, with long-term implications for victim identification timelines, investigative resource allocation, and digital forensics support in child exploitation cases.

Abstract Text: The investigation sof ICAC relies heavily on CyberTipline reports submitted to the NCMEC. According to NCMEC's 2024 Impact Report, "the CyberTipline received 20.5 million reports related to 29.2 million incidents of suspected child sexual exploitation."[1] These CyberTips—originating from electronic service providers or user-submitted complaints—are forwarded to state-level law enforcement agencies, which then determine jurisdictional responsibility and route the information to local agencies.[2] While this tiered process facilitates nationwide coordination, it introduces several points of friction that may delay response times or introduce errors.

Anecdotal evidence and professional experience in local law enforcement have highlighted recurring issues in CyberTip processing. These include significant time lags between the initial receipt by NCMEC and final assignment to the appropriate local agency, misclassification of report urgency, and receipt of tips that fall outside of ICAC criteria.[3] Such "false positives" within CyberTipline reports include, but are not limited to, non-CSAM media, consensual teen sexting, jurisdictional mismatches, poor quality or insufficient information, or cases involving compromised social media accounts.[3]

This presentation proposes a feasibility study to determine the prevalence and operational burden of these issues at the state and local levels. Following survey methodologies used in prior ICAC research, a structured instrument will be disseminated to ICAC investigators and CyberTipline coordinators across jurisdictions.[4] The research seeks to quantify: (1) average turnaround times in the current workflow; (2) frequency and types of false positives; and (3) perceived gaps that could be addressed by automation or OSINT-driven triage.

The long-term goal is to assess whether a Machine Learning (ML) -supported decision-tree model could serve as an intermediary layer between NCMEC, state law enforcement, and local jurisdictions, as similar metadata-based ML frameworks have shown promise in CSAM detection contexts.[5] Such a model would draw on social media and OSINT to flag indicators of false positives before expending investigative resources. For example, a flagged social media account could be checked in real time for signs of being compromised or assessed for age-consensual interactions, thereby reducing investigative backlog and improving prioritization.

By outlining the proposed methodology and its potential applications, this presentation highlights opportunities to optimize CyberTipline workflows and improve investigative efficiency. Importantly, preliminary feedback from ICAC practitioners will be incorporated into this presentation, offering early insights into both the scope of the problem and the practicality of technology-driven interventions.

C31 Exploring the Use, Challenges, and Opportunities of Generative AI in Digital Forensics

Vir V. Phoha, PhD, Syracuse University, Syracuse, NY*

Learning Objectives: Attendees will learn current research trends and the state of the art in the use of generative AI in digital forensics; limitations of AI; and how to make meaningful inferences using AI in forensics analyses. They will understand the capabilities and limitations of generative AI in forensics analysis.

Impact Statement: This work will open up the field of AI applications to forensics analysis for academicians, researchers, and practitioners. They can then build upon this work to make insightful interpretations of AI-generated forensic reports and inferences. This work fills a critical need for a treatise on the use of generative AI for research, practice, and future directions of generative AI in digital forensics.

Abstract Text: The rapid advances of digital technologies have significantly broadened the scope and complexity of digital forensic investigations.[1,2] As cybercrimes become sophisticated and data volumes grow, traditional forensic methods often struggle to keep pace. In this context, generative Artificial Intelligence (AI), which includes models such as Generative Adversarial Networks (GANs), Variational Autoencoders (VAEs), and Large Language Models (LLMs), offers transformative potential for enhancing digital forensic capabilities. This work examines the intersection of generative AI and digital forensics, exploring how these technologies can enhance evidence analysis, reconstruction, and interpretation.

Digital forensics has recently started seeing integration of generative AI.[2-4] However, we found little to no integration of language models such as image models, Image GPT-3 into Forensics applications.[5] Our major contribution in this work is to fill the gap in the general literature on AI applications to digital forensics and provide a roadmap of generative AI's use in digital forensics.

In particular, we address how generative AI can augment forensic workflows. These workflows include the reconstruction of corrupted or incomplete digital evidence, detection and analysis of deepfakes and synthetic media, automated malware deobfuscation, and the generation of forensic narratives from large volumes of textual data and image data. We present case studies that show the efficacy of generative AI in real-world forensic case analysis.[6]

We present challenges of the integration of generative AI into digital forensics and discuss possible solutions.[3,7,8] The black-box nature of many generative models raises concerns about the transparency of forensic findings. We examine issues related to model accuracy, explainability, and the risk of false positives.[9] We elaborate on the legal and ethical implications of using AI-generated evidence, particularly in judicial contexts.[5,10] We also address the dual-use nature of generative AI, noting its potential to be exploited by malicious actors to create deceptive content or evade detection.

Looking ahead, we propose a set of future directions to guide research and practice in this emerging field. These include the development of hybrid forensic frameworks that combine symbolic reasoning with generative modeling, the creation of standardized benchmarks for evaluating AI-driven forensic tools, and the design of collaborative systems that enhance human-AI interaction. We emphasize the need for robust policy and governance structures to ensure the responsible use of generative AI in forensic contexts.

C32 Can AI Explain Fraud? Explainable AI for Document Fraud Detection in Digital Forensics

Yujin Lee, BEng, Purdue University, West Lafayette, IN; Umit Karabiyik, PhD, George Mason University, Fairfax, VA; Marcus K. Rogers, PhD, Purdue University, West Lafayette, IN*

Learning Objectives: After attending this presentation, attendees will understand the importance of explainability in the application of Artificial Intelligence (AI) to digital forensic investigations. This presentation will explain how AI decision-making processes can be visualized and interpreted through Explainable AI (XAI) approaches, such as SHapley Additive exPlanations (SHAP), using a hypothetical case of identity fraud detection.

Impact Statement: This presentation explores how explainability can be applied in digital forensic workflows by examining AI-assisted identity document fraud detection. Through this hypothetical case, it offers insights into incorporating XAI into forensic processes and contributes to strengthening the community's ability to apply AI in a transparent and trustworthy manner.

Abstract Text: Artificial intelligence (AI) is increasingly applied in digital forensic investigations. AI models have been used to support tasks such as document forgery detection, image analysis, and large-scale data classification. These methods assist investigators by automating repetitive processes and identifying patterns that may not be easily observable through manual inspection. However, due to the black-box nature of many AI models, it can be challenging in legal settings, where understanding and justifying model outputs may be required.[1] This lack of transparency has raised concerns in domains where the justification of results is required for legal purposes.[2]

Explainable artificial intelligence (XAI) has been introcduced to address these challenges. XAI aims to clarify the internal mechanisms of AI models by identifying the factors that influence a specific prediction. By providing human-interpretable explanations using XAI, AI models can reveal the features influencing their decisions, thereby improving transparency and legal trust in digital forensic contexts.[3]

In this study, we use a large-scale, research-use synthetic dataset of identity documents, known as the IDNet Dataset.[4] We developed an AI model to determine the authenticity of documents and applied the SHAP to visualize the key features influencing the model's predictions.[5] These visualizations help investigators and analysts understand the AI's decision logic and support them in communicating results effectively in investigative reports or courtroom settings.

C33 Improving Learner Resilience to Online Fraud Through Immersive Roleplaying Experiences: A Transformative Learning Approach

Tatiana Ringenberg, PhD, Purdue University, West Lafayette, IN; Paul Thomas, PhD, Purdue Unviersity, West Lafayette, IN; Alejandra J. Magana, PhD, Purdue University, West Lafayette, IN*

Learning Objectives: Attendees will learn an effective, theory-driven approach to building real-time roleplaying simulations that enable digital forensics learners, particularly in identifying persuasion and manipulation tactics associated with online fraud.

Impact Statement: This presentation will introduce digital forensics educators and law enforcement training designers to a theory-driven lens for developing structured and immersive roleplaying education modules that encourage learners to: (1) understand and dynamically respond to emerging online threats, and (2) grow their skillset by reflecting on their own performance based on real-time feedback. By fostering problem-solving, self-awareness, and adaptability, this approach can support learning across a wide range of digital forensics topics.

Abstract Text: Online fraud continues to be a growing threat, with Federal Bureau of Investigation Internet Crime Complaint Center (IC3) reporting a total loss of $50.5 billion in 2024 from a total of 859,532 complaint reports.[1] These attacks have also evolved in sociotechnical complexity. Scammers are now leveraging AI-powered tools to create highly realistic deepfake images and automate attacks using generative models.[2,3] These technologies have become so accessible that even inexperienced fraudsters can exploit users with ease. From a social engineering standpoint, scammers are developing increasingly complex pretexts and approaches that blur the lines between various scams, such as romance scams and cryptocurrency scams, to create more convincing narratives and long-term deception strategies.[4]

Although the technologies and scenarios used in online fraud are evolving and becoming increasingly difficult for users to identify, the underlying persuasion and manipulation mechanisms used to gain the user's trust and compliance remain largely the same. Teaching learners to detect these strategies as attacks unfold is crucial to helping them to identify online fraud risks targeted at themselves and others. However, current methods for teaching online fraud education often do not incorporate activities that allow learners to practice identifying and responding to online fraud cues in real-time while the scammer adapts and adjusts their approach. Further, existing educational interventions often do not include iteration, helping the learner to learn through practice and improve their performance.

This presentation introduces a transformative learning approach to digital forensics education, using in-class activities that actively immerse students in attacker and defender roles focused on online fraud.[5] Activities include social influence board games mapped to digital persuasion techniques, real-time roleplaying involving AI chatbots to simulate live scam and defense scenarios, and analysis tasks where students diagnose manipulation strategies and formulate responses. These interventions go beyond traditional lecture and static content by requiring students to integrate persuasion theory, reflect on experiences, and dynamically adapt their tactics. Preliminary results suggest this method leads to greater engagement and deeper conceptual mastery. The presentation outlines example activities, assessment methods, evidence of outcomes, ethical considerations for implementation, and recommendations for adapting such activities beyond the classroom.

C34 Weighted Anomaly Detection and Cross-Chain Arbitrage Analysis: A Blockchain Forensics Framework

Xiao Hu, MS, Purdue University, West Lafayette, IN; Umit Karabiyik, PhD*, George Mason University, Fairfax, VA*

Learning Objectives: By attending this presentation, attendees will learn how anomaly detection methods can be adapted for forensic analysis of cryptocurrency transactions. This presentation will help attendees recognize the investigative challenges introduced by cross-chain activity and understand how forensic tools can prioritize suspicious transactions for further review. It will also demonstrate how adaptive techniques can reduce manual workload and support timely decision-making in digital investigations.

Impact Statement: This presentation enhances the forensic science community's ability to identify and prioritize suspicious transactions involving digital currencies by introducing an adaptive, transaction-level analysis framework. It improves competence in interpreting irregular blockchain behaviors that may indicate concealment or manipulation and supports the practical application of data-driven tools in fast-evolving digital environments. The framework promotes efficient triage and investigative focus, offering forensic professionals a timely, scalable method to respond to financial crime in blockchain contexts.

Abstract Text: The rapid evolution of blockchain technology has transformed digital finance and introduced new forensic challenges. While many forensic efforts focus on analyzing transactions within a single cryptocurrency network, recent trends show increased use of cross-chain mechanisms to obscure financial activity and avoid detection.[1,2] These behaviors complicate investigations by dispersing transactional traces and introducing greater variability, especially when timing, fee structures, and profit flows are manipulated to resemble legitimate activity.

This presentation introduces a forensic framework designed to detect suspicious patterns across cross-chain cryptocurrency transactions. Rather than attempting to label transactions as explicitly illicit, the framework identifies and prioritizes statistically unusual behaviors for investigative review.[3] It leverages adaptive statistical modeling to compute dynamic thresholds that reflect recent transactional trends. Unsupervised anomaly detection techniques, such as Isolation Forest and similar models, are explored for their ability to detect irregular patterns in complex datasets without requiring fixed rules or prior categorization.[4] The methodology includes key steps such as preprocessing raw transaction data, constructing weighted forensic indicators, performing time-based cross-chain pairing, and ranking transactions by anomaly score. Designed with investigative efficiency in mind, this approach helps reduce the volume of transactions requiring manual inspection while retaining those most likely to warrant further analysis. In practical contexts where clear ground truth is unavailable, the framework supports flexible evaluation strategies to assist forensic analysts in validating detection performance.

Importantly, this work responds to growing recognition within the forensic industry of the challenges posed by cryptocurrency-based financial crime. For example, Magnet Forensics' recent collaboration with blockchain intelligence company TRM Labs highlights an urgent shift toward building better tools for digital asset investigations.[5] This presentation contributes an academic and transparent response to that need, offering an adaptable and reproducible forensic framework to support more focused and evidence-informed investigations in blockchain environments.

C35 Intent in Isolation: Forensics of Echo Chamber Activity

Vaishnavi Mahindra, MS, Purdue University, West Lafayette, IN; Marcus K. Rogers, PhD, Purdue University, West Lafayette, IN*

Learning Objectives: After attending this session, attendees will gain a deeper understanding of forensic techniques and methods used to analyze cases where online posts in social media echo chambers may be used as collateral evidence.

Impact Statement: The presentation will have a significant effect on the forensic science community by highlighting the special considerations required when assessing cases involving online echo chambers and violent rhetoric. This includes the relevance of online posts in forensic investigations, current challenges, and the selection of forensically sound methods in criminal cases.

Abstract Text: The emergence of social media sites and forums dedicated to specific topics has expanded digital artifacts of forensic value from direct communication between persons of interest to larger communities. Investigators may be required to assess public posts, forum histories, followed groups, and manifestos.[1] Incorporating social media data is a relatively recent practice, with use cases in forensic mental health assessments.[2] Social media data may assist in understanding connections to ideologies or other accounts and incidents.[3] However, forensic practitioners need to exercise caution when collecting or assessing such artifacts. Some issues with trust in interpreting social media data include the possibility of curating a narrative by selectively choosing posts and interpreting context.[4]

Particularly, data gathered from users who may have had ideological motivations to commit crimes may also express these views or the formation of these opinions online. Echo chambers and extremist groups are pockets of social media sites that form a community of like-minded users with a predominant opinion and little room for alternative perspectives.[5] Research shows that ideologically motivated violence is more methodical and lethal than revenge-seeking or reactionary violence.[6] Especially in the case of lone actors, this ideology and planning are often leaked months or years in advance, and other individuals are usually aware of the individual's views or intent to commit violence.[4,7] Virtual communities are increasingly avenues to express these intents, with a high area of interest in forensic linguistic analysis and social network analysis as methods to extract details about the crime.[8,9]

This presentation examines current methods for evaluating individual activity in social media groups perceived as echo chambers. Relevant case studies are presented, along with the possible pitfalls and costs associated with utilizing social media data for forensic investigative purposes. The Charleston church shooting and the Isla Vista shooting investigations are primary examples of such case studies.[1,8] Identification and context recognition of echo chambers or ideological groups are crucial for weighing the intent of engagement, as well as determining incitement. This context is also valuable for greater accuracy in evaluating motivation. A summary of research querying forensic clinicians shows suggested practice guidelines, future research directions, and challenges as described by practitioners.[2,4]

C36 Scalpel3: A New High-Performance Carving Architecture for Recovering Fragmented Files

Golden G. Richard, III, PhD, Louisiana State University, Baton Rouge, LA; James Ghawaly, PhD, Louisiana State University, Baton Rouge, LA; Karley Waguespack, MS, Louisiana State University, Baton Rouge, LA*

Learning Objectives: After attending this presentation, participants will understand the challenges of recovering fragmented data from storage devices such as hard drives, flash drives, and memory cards. Most existing data carving tools, including earlier versions of Scalpel, attempt to recover only unfragmented files. This presentation explores why earlier efforts to develop tools for recovery of fragmented data have largely failed and how the recently developed Scalpel3 architecture overcomes many of the challenges in fragmented data recovery.

Impact Statement: This presentation will impact the forensics community by introducing a new architecture for fragmented data recovery, which achieves high performance on modern hardware while allowing recovery techniques for new file types to be developed without exposing developers to complex multi-threading and synchronization issues. Support for new file types is introduced by writing single-threaded code, and the Scalpel3 back end then transparently accelerates data recovery. Notably, the Scalpel3 toolchain allows easy integration of other tools into complex workflows to maximize flexibility as well as performance.

Abstract Text: Data carving is an important recovery technique to retrieve damaged or deleted files by identifying file-type-specific patterns to locate, reconstruct, and extract files from a variety of types of storage media. Importantly, file carving does not typically rely on filesystem metadata, so it can be applied to badly damaged media. Data carving is useful to support digital forensics tasks as well as broader "digital exploration" activities to identify data of interest on storage devices of unknown provenance.

This presentation describes the design and development of Scalpel3, a new high-performance, open-source data carving architecture. Unlike most existing tools, which focus primarily on recovery of contiguous files, Scalpel3 is the first carving tool capable of efficiently recovering both fragmented and unfragmented files at scale. This is achieved through a combination of aggressive performance optimizations targeting modern hardware, intelligent heuristics, and a modular architecture.

Scalpel3 offers fine-grained control over the data carving process, allowing investigators and developers to tailor recovery strategies to specific file types and recovery goals. Unlike first-generation header/footer-based carving tools, support for new file types in Scalpel3 will typically involve writing code. To make this process easier, Scalpel3 isolates developers from multithreading and synchronization, which are used heavily in the Scalpel3 backend to increase performance. Instead, developers write single-threaded functions that embody thoughtful methods for identifying files and file fragments, and these are accelerated automatically by the backend. This is in sharp contrast to earlier strategies for testing new data recovery techniques, which often involved the use of "throwaway," standalone code in slow languages like Python, which severely limited evaluation of the strategies against realistic data sets.

Digital Forensics; Data Recovery; File Carving

C37 A Research-Focused Framework for Empirical Method Validation in Digital and Multimedia Evidence

Gregory S. Wales, DSc, Independent Researcher, Colorado Springs, CO*

Learning Objectives: Attendees will learn how to apply a stepwise, research-focused framework for empirically validating foundational methods in digital and multimedia evidence. They will gain strategies for statistical planning, error research, and transparent reporting, all aligned with current scientific and legal standards. This presentation reinforces the fundamental principles of responsible, ethical, and just forensic practice.

Impact Statement: This presentation enhances the forensic science community's capacity to conduct scientifically rigorous and ethically grounded validation studies of foundational digital and multimedia methods. By operationalizing best practices and bridging the gap between policy and practice, the framework empowers researchers and method developers to improve the reliability, transparency, and admissibility of forensic evidence.

Abstract Text: As technology continues to evolve, the enduring fundamentals of forensic science—scientific rigor, transparency, and ethical responsibility—have never been more essential. Yet despite decades of guidance from scientific and legal bodies, digital and multimedia forensics still lack a detailed, implementable framework for empirically validating its foundational methods. From the perspective of a researcher with practical field experience, this gap represents more than a theoretical concern; it leaves method developers and practitioners without clear guidance for meeting today's heightened expectations. In particular, recent amendments to Federal Rule of Evidence 702 and increased scrutiny in high-profile court cases demand documented error rates, reproducibility, and methodological transparency as prerequisites for admissibility.[1-5]

This presentation introduces a comprehensive, stepwise framework that enables rigorous, transparent method validation aligned with both scientific and legal standards. The framework integrates: (1) iterative statistical planning, from initial power analysis to high-confidence simulations; (2) custom dataset development to ensure contextual relevance and ground truth control; (3) pilot testing for calibration and feasibility assessment before full-scale studies; (4) empirical error mapping and mitigation, beyond mere identification into refinement; (5) structured community engagement and open-source transparency, supporting peer review and reproducibility; and (6) legal alignment with *Daubert* criteria and FRE 702, including clear communication of uncertainty through Likelihood Ratios (LR/LLR), Confidence Intervals (CI), and Credible Limits (CL).

Empirical validation studies following this framework minimally report key performance metrics, accuracy, specificity, sensitivity (recall), precision, false positive and false negative rates, and F1 score to comprehensively quantify error rates and method reliability. These metrics are standard in forensic validation, directly address the President's Council of Advisors on Science and Technology (PCAST) and *Daubert* requirements for known error rates, and support both scientific credibility and legal admissibility

Applied to foundational methods, this approach supports validation efforts that are statistically robust, legally defensible, and adaptable to evolving technologies. It provides a practical roadmap for documenting error sources, refining techniques through empirical testing, and producing studies that advance both scientific credibility and courtroom reliability.

By returning to the basics of empirical validation and transparent reporting, this framework reinforces the ethical and scientific foundations of forensic science and supports the just application of digital evidence in modern legal systems.[1-5]

C38 Applied Gamification Research in Digital Forensics Higher Education for Knowledge and Skill Retention

Yansi Keim, PhD, State University of New York at Albany, Albany, NY; Marcus K. Rogers, PhD, Purdue University, West Lafayette, IN*

Learning Objectives: After attending this session, attendees (such as faculty, practitioners, and students) will have a better understanding of best practices in applied gamification (via Capture The Flag [CTF] competitions) in digital forensics higher education for assessing knowledge and skill retention among undergraduates. The audience will take away strategic gamified methods that can be implemented in their classroom or professional training settings.

Impact Statement: This presentation will impact the forensic science community by introducing a scalable, evidence-based instructional model that directly addresses the community's need for professionals who are not only theoretically proficient but also practically skilled in digital evidence handling, analysis, and reporting.

Abstract Text: This presentation introduces a first-of-its-kind hybrid higher education model in digital forensics that integrates CTF competitions with an accredited cybersecurity curriculum, guided by the National Institute of Standards and Technology (NIST) National Initiative for Cybersecurity Education framework (NICE).[1,2]

The study provides a replicable blueprint for integrating gamified learning into forensic science education. The technical contributions—including a hardened CTF infrastructure, beta-tested challenge design, and detailed NICE mapping—can be adopted by other institutions seeking to modernize their digital forensics programs.[3,4]

The research involved a controlled experimental design with senior cybersecurity majors randomly assigned to either a test group (curriculum + CTF) or a control group (curriculum-only). A 21-item scenario-based pre- and post-test instrument, aligned with the NICE Digital Forensics Work Role (PD-WRL-002), was used to assess knowledge and skills. The results of a one-way Analysis of Covariance (ANCOVA) revealed a statistically significant improvement in the test group's post-test scores ($F(1, 23) = 33.096$, $p < .001$), with a large effect size ($r = .51$), indicating that 51% of the variance in learning outcomes could be attributed to the hybrid model intervention.[5]

The CTF component was designed using a rigorous four-phase methodology—planning, implementation, feedback, and evaluation—grounded in behaviorism, cognitivism, and constructivism learning theories. Twenty-one CTF challenges were developed and mapped to 46% of NICE Tasks, 46% of NICE Knowledge, and 57% of NICE Skills in digital forensics. Participants also completed a post-CTF alignment survey, with results showing strong perceived alignment between the CTF tasks and NICE framework components.[4]

D2 Forensic Reconstruction of a Fatal Stair-Related Fall Using Postmortem CT, Photogrammetry, and Virtual Reality: A Case Report

Haruki Fukuda, MD, PhD, Department of Legal Medicine, Gunma University, Graduate School of Medicine, Maebashi, Gumma, Japan; Tadashi Hosoya, MD, PhD, Department of Legal Medicine, Gunma University, Graduate School of Medicine, Maebashi, Gumma, Japan; Hiroyuki Tokue, MD, PhD, Department of Diagnostic Radiology and Nuclear Medicine, Graduate School of Medicine, Gunma University, Maebashi, Gumma, Japan*

Learning Objectives: Attendees will: (1) learn the process of generating 3D surface models from photogrammetry and integrating them with Computed Tomography (CT) data; (2) explore the application of Virtual Reality (VR) to enhance the visualization of injury mechanisms and their relationship to environmental structures; and (3) evaluate the benefits and limitations of combining Postmortem Computed Tomography (PMCT), photogrammetry, and VR in forensic death investigations.

Impact Statement: This presentation will enhance the competence of forensic professionals by demonstrating a practical workflow that integrates PMCT, photogrammetry, and VR for scene reconstruction. By applying these tools, practitioners can improve the accuracy and clarity of injury interpretation, ultimately strengthening forensic documentation and communication with legal stakeholders.

Abstract Text: Three-dimensional (3D) documentation is increasingly being utilized in forensic investigations to record injuries and reconstruct crime scenes accurately.[1] Although photogrammetry offers a low-cost and accessible method for capturing surface details, its integration with PMCT data and VR can further enhance spatial understanding.

In this case study, we report a fatal case of a stair-related fall of a man in his 70s, in which we visualized the injuries by combining PMCT data with surface models of the body and the staircase.[2] A 3D model of the bones was created from the PMCT data using OsiriX, whereas surface models of the body and staircase were generated using photogrammetry. The reconstructed scene was visualized in VR using Unreal Engine and a MetaQuest 3 headset. The reconstructed scene clearly demonstrated the spatial relationship between the stair edges and injury sites, such as the occipital region, midthoracic spine, and sacrum. The vertical distances between the injuries closely matched the staircase step depth, supporting the interpretation of stair-related falls.

This method provides an intuitive and immersive understanding of injury mechanisms. Our approach demonstrates the feasibility and utility of integrating CT, photogrammetry, and VR in forensic death investigations, offering enhanced documentation and visualization that can benefit not only forensic experts but also legal professionals and juries.

D3 A Study on an Analysis Methodology for Crowd Crush Accidents

Kyeongmin Lee, MEng, National Forensic Service, Wonju, Kangwon-do, Republic of Korea; Chan-Seong Park, PhD, National Forensic Service, Wonju-si, Kangwon-do, Republic of Korea*

Learning Objectives: Through this presentation, attendees will learn techniques to estimate time-dependent changes in crowd density during analyses of crowd crush accidents as well as methods to reproduce the process of crowd collapse and the influence of topographical factors.

Impact Statement: This presentation introduces a method to estimate real-time crowd density using AI-based video analysis and a technique for reproducing the progression of crowd collapse caused by physical factors such as road structures using a multibody simulation (PC-Crash). The proposed approach is expected to contribute to causal analysis in various types of crowd crush accidents in the future.

Abstract Text: The analysis of crowd crush accidents requires an understanding of time-dependent crowd density as well as the causes and conditions at the initial point of collapse. Time-series crowd density data allow for a comprehensive interpretation of the incident when compared with reports and emergency dispatch records. Furthermore, it is important to verify through reconstruction how physical factors such as road structure at the collapse initiation point influence the overall progression of crowd collapse. Therefore, this presentation introduces a method to analyze crowd density in video using a YOLOv8-based object detection model, along with a reconstruction technique using PC-Crash.

Crowd density was calculated by detecting crowd objects (such as heads) in the video using a YOLOv8 model trained on a large image dataset and by estimating the number of objects in a defined area. Based on this, a program was developed to calculate crowd density in real time for the input video. The program was applied to various cases and successfully computed crowd density changes in actual accidents.

The influence of physical factors such as road structures on crowd flow at the initial point of collapse was reproduced using a multibody model. Due to the characteristics of crowd flow, more than 1,000 multibody elements had to be modeled. An automatic configuration method was developed, and after its effectiveness was verified, it was applied to an actual case. The terrain of the site was defined using boundary conditions based on point cloud data obtained through 3D scanning. In the actual case, the point where the collapse began was located at the section where the road slope started to change, and both sides of the road were initially blocked by structures, with one side partially open. These structural features of the road were modeled as rigid bodies based on the scanned data.

The results of the simulation revealed that the behavior of the multibody model corresponded to the crowd flow observed in the actual incident footage, confirming that physical factors such as road structures could influence the onset of collapse. In addition, the load applied to each multibody element during the collapse process was calculated. According to previous studies, a static load of 300–600 kg applied to the chest can inhibit lung expansion and pose a fatal risk of asphyxiation.[1] The results of the simulation confirmed that some multibody elements experienced loads exceeding 300 kgf.

Based on the overall findings, the program developed using the YOLOv8 model successfully estimated real-time crowd density. Furthermore, the multibody simulation combined with scanned data effectively reproduced the influence of physical factors such as road structures on crowd flow through modeling. These results suggest that the proposed method can be widely applied in future investigations of various crowd crush accidents.

D4 Built to Harm? Forensic Perspectives on Design-Induced Suicide and Self-Harm in Detention Facilities

Mohsen Ghoreishi, MA, KOHAN, San Francisco, CA*

Learning Objectives: The goals of this presentation are to: (1) identify common architectural and construction features in detention facilities that can become mechanisms for self-harm or suicide; (2) analyze forensic case studies where poor design directly or indirectly contributed to inmate suicide attempts or deaths; (3) apply trauma-informed design strategies that align with correctional standards and behavioral health best practices; (4) evaluate post-incident forensic procedures, including ligature point documentation, scene reconstruction, and liability assessment; and (5) recommend design improvements that reduce self-harm opportunities while maintaining safety, surveillance, and institutional control

Impact Statement: This session challenges designers, forensic professionals, and correctional administrators to recognize that building design is not behaviorally neutral. When detention facilities are not thoughtfully designed, they may unintentionally provide tools or conditions for self-harm and suicide. By presenting forensic evidence from real incidents, this session highlights how built-in risks can be mitigated through detail-driven, human-centered strategies. The impact extends beyond reduced incidents—it strengthens compliance with legal standards of care, reduces liability exposure, and supports the ethical treatment of vulnerable populations in custody.

Abstract Text: Detention centers present an exceptionally high-risk environment for suicide and self-harm, with architectural and construction details often playing a critical yet overlooked role in these incidents. This presentation explores the forensic analysis of a suicide and self-harm case within correctional facilities, revealing how design choices can either mitigate or exacerbate behavioral risk.

Through the examination of forensic investigations, the session identifies recurring spatial and constructional risk factors: ligature points, unsupervised zones, inaccessible observation angles, and inappropriate material choices. Case studies illustrate how minor oversights such as exposed fasteners, misplaced vents, or poorly detailed bunk edges can become mechanisms for harm. In many instances, these features contradict current correctional design standards or fail to anticipate behavioral outcomes under psychological distress.

The presentation further examines the balance between security, humane treatment, and operational functionality, outlining how trauma-informed design and suicide prevention principles can be embedded into architecture and construction without compromising control. Emphasis will be placed on the forensic methodologies used to assess risk after incidents, including site documentation, failure analysis, and behavioral context review.

This session is designed for forensic experts, correctional architects, legal professionals, and mental health consultants engaged in facility design or litigation. It provides not only post-incident insights but also proactive strategies to reduce harm, align with evolving standards of care, and improve overall custodial environments.

D5 The Fluid Dynamics of Intravitreal Injections as It Relates to Needle Design

Amanda Felstow, Wayne State University, Detroit, MI; Cynthia Bir, PhD, Wayne State University, Detroit, MI; Andrew Davis, MPH, Wayne State University, Detroit, MI; Brittany Hodges, MD, Wayne State University, Detroit, MI; Kavon Rahmani, BSc, Wayne State University, Detroit, MI; Pradeepa Yoganathan, MD, Wayne State University, Detroit, MI*

Learning Objectives: In this presentation, attendees will learn about the circumstances surrounding poor outcomes related to Intravitreal Injections (IVIs) and the effects of needle design on fluid flow behavior.

Impact Statement: This presentation will impact the forensic community by providing methodologies to understand how minute differences in medical devices might lead to varied engineering outcomes and ultimately clinical complications.

Abstract Text: IVIs are a critical and widely used treatment modality for managing a range of retinal pathologies, including age-related macular degeneration, diabetic retinopathy, and retinal vein occlusions.[1] Despite their clinical efficacy, the biomechanical and fluid dynamic consequences of IVIs remain poorly characterized, particularly with respect to how specific injection parameters influence intraocular conditions. Rapid Intraocular Pressure (IOP) spikes and high-velocity fluid jets during injection can introduce potential risks such as transient vision loss, vitreoretinal traction, mechanical stress on delicate retinal tissues, and heightened discomfort—risks that are especially pronounced in eyes with pre-existing conditions like glaucoma or retinal thinning.[2]

This study employs a silicone eye model, which closely approximates the human eye in size, to systematically evaluate the effects of syringe design on fluid flow behavior. A high-speed camera was used to capture the injection event. A pump was used to establish a standardized rate of injection based on clinical practice. Food coloring was added to the fluid in the syringe to allow for fluid dynamics to be captured. Various needles were evaluated to determine how both beveling and overall design affected the fluid dynamics. Results will be presented discussing how the fluid dynamics change and the potential for injury.

D6 Spectral Characterization and AI Modeling of Human Decomposition-Impacted Soils Over the Period of One Year

Koushik Sanjay Saravana Kumar, University of Knoxville, Tennessee, Spring Hill, Tn; Lois S. Taylor, PhD, University of Tennessee, Knoxville, TN; Jennifer DeBruyn, PhD, University of Tennessee, Knoxville, TN; Sathish Samiappan, PhD, University of Tennessee at Knoxville, Knoxville, TN*

Learning Objectives: After attending this presentation, the attendees will gain an understanding of the use of hyperspectral remote sensing and Artificial Intelligence (AI) -based modeling for evaluating properties of human decomposition-impacted soils and how this technology potentially can be used to identify soil samples associated with human remains.

Impact Statement: This work improves our understanding of how hyperspectral remote sensing and AI modeling can help non-invasively identify areas in which decomposition has occurred through novel spectroscopic and AI-based approaches.

Abstract Text: Spectroscopy is a remote sensing technique that records the amount of light being reflected in ultraviolet, visible, and infrared wavelength regions. This rich hyperspectral data is shown to be useful to determine properties of soil. Soil disturbance resulting from human decomposition alters multiple properties (e.g., pH, conductivity, nitrogen, etc.) and, therefore, the use of spectroscopic techniques can help differentiate between areas of soil that have been exposed to decomposition and identify locations for further testing.[1]

The goals of this study are to: (1) identify regions of soil reflectance within hyperspectral data that distinguish human decomposition-impacted samples from background soils; and (2) develop, implement, and test One-Dimensional Convolutional Neural Network (1D CNN) AI models to distinguish the hyperspectral signatures of impacted from background soils. A year-long human decomposition study was conducted at the University of Tennessee's Anthropology Research Facility, Knoxville, TN where three human subjects (donors) were placed in direct contact with soil and allowed to decompose naturally for one year. Soils had not previously been used for decomposition experiments. Soil sampling to a depth of 1 cm was performed at 20 time points from underneath donors as well as from background areas located 3 m away from the donors.[2] Samples were oven-dried at 105ºC for 72 hours to remove water and grounded to a fine powder. Soils were placed in a white paper cup, and five radiometric scans were taken per sample by mixing them prior to each scan to capture variability due to sample heterogeneity. Spectral reflectance data were acquired using a PSR+ spectroradiometer (Spectral Evolution, Inc.) in the spectral range of 350–2,500nm. A soil contact probe and DARWin LT data acquisition software was used to acquire and radiometrically calibrate the data respectively.

After preprocessing the spectral data, a thorough analysis was done by graphing the signatures of human-decomposed and background soils over different time periods, different donors, and different variations of the same sample. A 1D CNN was built and trained using part of the samples from all three donors. Then, the same model was used to test its sensitivity to unseen samples where training, validation, and testing datasets were strictly confined to data from a particular donor. The model performances for these experiments were assessed using the following metrics: overall classification accuracy, confusion matrix, precision, recall, F1-score, Cohen's Kappa, and class accuracies.

Our preliminary experiments with 1D CNN show classification accuracy of 98%, precision of 99%, recall of 97%, F1-score of 98%, Cohen's Kappa of 0.96. Results from four combinations of sensitivity study show a best accuracy of 97% and worst of 78%. Fairly high accuracy for the sensitivity experiments shows that the 1D CNN models are well generalized. From graph analysis, noticeable changes in reflectance around 2,250–2,400nm for the human decomposition-impacted soils are evident during the active decomposition phase. However, those patterns start to appear like background over time. Our results indicate that hyperspectral remote sensing and AI modeling could be a useful tool for non-invasive identification of soils exposed to decomposing human remains.

D7 The Use of Postmortem Computed Tomography in the Identification of Bodies: A Newly Emerging Technique to Complement Traditional Methods

Maiko Yoshida, MD, PhD, Chiba University, Chiba, Chiba, Japan; Yohsuke Makino, MD, PhD, The University of Tokyo, Bunkyo-ku, Tokyo, Japan; Yukiko Uemura, MD, The University of Tokyo, Bunkyo-ku, Tokyo, Japan; Ayaka Sakuma, PhD, Chiba University, Chiba, Chiba, Japan; Hirotaro Iwase, MD, PhD, Chiba University, Chiba, Chiba, Japan*

Learning Objectives: The attendees will be informed about a newly emerging method using Postmortem Computed Tomography (PMCT) to identify unknown bodies by comparing them with the antemortem images of the presumed persons.

Impact Statement: This new technique will provide an opportunity to decrease the bodies that cannot be identified by conventional methods such as DNA, fingerprinting, and dental records.

Background and Purpose: Many identification methods have been widely described in the literature, mainly in disaster and humanitarian contexts. In recent years, there has been a movement to use PMCT in the Disaster Victim Identification (DVI) process. Several reports have been published using this technique in real disasters. However, there has been limited reporting of the identification methods used in domestic medicolegal death investigation contexts. Identification of unidentified bodies during peacetime in Japan is generally performed using traditional methods such as dental records, fingerprints, or DNA analysis. However, there remain bodies in which these methods are not effective. This study aimed to evaluate the identification methods using PMCT utilized at our institution.

Method: The police ordered our institution to identify 50 bodies from January 2021 to January 2024, using images. In all cases, the dental and fingerprint methods were unavailable. DNA was planned in several cases. In all cases, there were presumed persons, and the police provided antemortem images taken at various hospitals or clinics. Two certified radiologists with experience in interpreting PMCT performed image interpretation, comparing antemortem images with PMCT taken before autopsy. A 64-row detector CT was used to PMCT (Supria Grande, Fujifilm Healthcare Co. Ltd.). PMCT were reconstructed on a workstation (Vincent, Fuji Film) to create appropriate images for comparison with the antemortem images.

Results: A total of 50 cases were judged (age 36~94, average 70.7 ± SD 12.9, female 14, male 36). Thirty cases were severely decomposed, nine were skeletal remains, eight were severely burned, and three were mummified. Forty-five cases were identified by residents at the site where the remains were found, and five cases were found outside of private homes, with all cases showing possessions that suggested the identity of the deceased. In all cases, dental records and fingerprints could not be matched. DNA matching was planned in some cases. Forty-four cases were compared using CT scans of the head or other areas. Four cases were compared using only head Magnetic Resonance Imaging (MRI), one case using lumbar spine MRI and plain X-rays, and one case using only copies of plain X-rays of the knee joint. In 49 cases, the bodies were identified as the same person as the presumed identity.

Conclusion: Identification using antemortem images and PMCT is powerful and frequently successful, particularly when the presumed person is known. This method is beneficial when other traditional methods, such as dental records, fingerprints, and DNA analysis, are unavailable. In the future, we aim to apply this method in a disaster setting.

D8 Building the Artificial Intelligence Infrastructure for Forensics

Mihir Joshi, BS, UCLA, Los Angeles, CA; Vikas Kakar*, The Ohio State University, Columbus, OH; Maneesha Pandey, MD, The Forensic Pathologists LLC, Toledo, OH; Avneesh Pradhan, MS*, Ohio State University, Plain City, OH*

Learning Objectives: Attendees will learn how AI can be responsibly and effectively integrated into forensic workflows—beginning with autopsy documentation—to reduce administrative burden, enhance consistency, and reinforce rather than replace expert judgment. This presentation will explore validated use cases and offer a vision for expanding AI tooling across forensic domains while upholding scientific integrity.

Impact Statement: This presentation will impact the forensic science community by demonstrating how domain-informed, practitioner-led AI systems can streamline documentation, promote interdepartmental standardization, and improve stakeholder outcomes without compromising the fundamentals of forensic science.

Abstract Text: Across the country, forensic professionals are expected to manage rising caseloads using outdated, fragmented systems, often resulting in hours lost to documentation, coordination, and manual quality checks. Despite a growing national interest in AI, very little of that progress has reached the autopsy suite, the death scene, or the forensic laboratory. The risks of deploying AI in high-stakes domains are well known: hallucinated outputs, opaque decision-making, and misplaced trust. But the opportunity is equally real—if we build the right systems with the right constraints.

Over the past year, our interdisciplinary team has worked directly with forensic pathologists across several United States counties to explore how AI-enabled tools can support—not supplant—core documentation workflows. Instead of building monolithic, black-box systems, we focused on designing smaller, reliable tools that reduce redundant effort, help standardize formatting and structure, and integrate naturally into existing practices. These tools have now been used in over 300 real autopsy cases to generate structured, jurisdiction-specific reports from dictated or typed findings.

The tools were built in close collaboration with practicing forensic professionals, shaped by observation, feedback, and hands-on testing. Rather than dictate how work should be done, they are designed to adapt to individual preferences and institutional norms. Users retained full control over how reports were generated, reviewed, and finalized—and initial feedback suggests the tools helped reduce time spent on clerical tasks while improving report consistency and completeness.

While these initial deployments focused on autopsy documentation, the broader vision is much more expansive. We are actively working with county offices and investigators to build and validate tools that can support scene triage, case progress tracking, and evidence intake—all with an emphasis on transparency, auditability, and practitioner involvement. Early prototypes aim to assist investigators in creating structured narratives and tracking case flow from intake to disposition.

Looking ahead, we are beginning exploratory work to apply these same principles to the forensic laboratory, particularly in areas such as toxicology reporting, evidence cataloging, and internal Quality Assurance (QA) processes. As with our current approach, these tools are not intended to make conclusions, but rather to assist with the administrative and documentation burdens that often slow down high-quality forensic work.

This session shares insights from real-world deployments, highlights design considerations that helped foster trust and adoption, and outlines a roadmap for how AI tools can respectfully and responsibly enhance the entire forensic workflow. Rather than speculate on what AI may someday do for forensic science, this presentation focuses on what it's doing right now—in real cases, with real practitioners, under real-world constraints.

This is not about replacing expertise. It's about building tools that respect it.

D9 Computational Linguistic Analysis in Financial Fraud Investigations

David P. Weber, DBA, Salisbury University, Salisbury, MD; Ruwan Adikaram, PhD, Salisbury University, Salisbury, MD; Carole E. Chaski, PhD, Institute for Linguistic Evidence, Georgetown, DE*

Learning Objectives: After attending this presentation, attendees will be aware of language-based methods for detecting corporate anomalies related to possible financial fraud in Management Discussion and Analysis (MD&A) sections of publicly-traded corporations' legally mandated annual reports (United States Securities and Exchange Commission [SEC] Form 10-Ks). These language-based methods complement forensic accounting examinations of these 10-Ks for financial statement fraud.

Impact Statement: The forensic science community will be impacted through gaining awareness of language-based methods for detecting corporate anomalies related to financial fraud. Further, the feasibility of using these detection methods includes factors such as required data quantity and the reliability of event prediction.

Abstract Text: Fraud is an act of deception resulting in financial gain for the deceiver.[1] Fraud is broadly defined to include a variety of misconduct, including management fraud, which usually perpetrates fraud against shareholders or other third parties.[2,3] In each financial fraud, a key element is deception.

This central role of deception in financial fraud motivates the research presented in this talk, which focuses on linguistic methods for detecting fraud as a complement to forensic accounting. The value of linguistic analysis for detecting financial fraud is established, but the results for classifying or predicting financial fraud from executive statements has been mixed, with some reports of close to 70% accuracy and other reports over 90% accuracy.[4-8] None of the linguistic features used in previous studies are known to correlate well with language-based deception detection and most of the classifiers used in the previous studies are not robust enough for forensic use, including in civil or criminal cases.[9]

As required by the United States SEC, public corporations are required to file annual reports with the SEC, which are called 10-Ks. These 10-Ks are legally required to include a Management Discussion and Analysis (MD&A) section. One commentary states that "the MD&A section of a 10-K primarily uses words to explain a financial position instead of numbers. Therefore, management can use language that it feels is appropriate to manipulate financial performance or its expectations. Whereas financial reporting is governed by generally accepted accounting principles (GAAP), a company has the flexibility to represent itself as it sees fit in the Management's Discussion and Analysis (MD&A) section."[10] Thus, MD&A statements are potential communications where deception, a key element of fraud, can occur and be detected.

In this study, MD&A data is collected from the Wharton Research Data Services.[11] Using this MD&A data, an "event study" can be performed (i.e., the data can be collected and analyzed for determining if and under what conditions an event of interest has occurred).[11] The data is from publicly traded firms who have a change in stock price at four levels over a period of ten years. The change in stock price is stratified to four levels: minimum (3%); material (5%); severe (10%); and catastrophic (15-20% drop) often associated with fraud, class actions, or SEC investigations or enforcement actions. Data collection is complicated by bull or bear market cycles, the COVID crash, and Fed changes. Data analysis is both linguistic and statistical. The linguistic and statistical analysis focus on features in previous studies, such as stylometric, lexical, vector linguistic analysis, and statistical or machine learning classifiers of various types. Further, the linguistic and statistical analysis adds to the discussion of fraud detection in MD&A by including syntactic and discursive features of language that are known to correlate with deception, and statistical classifiers that are robust for forensic use by providing error rates after cross-validation.

D10 From Variation to Verification: A Basic Forensic Method for Identifying Single vs. Multiple Authors of Anonymous Letters

Jelena Tabak, MA, Faculty of Humanities and Social Sciences, University of Zagreb, Split, Splitsko-Dalmatinska, Croatia; Andrea Ledić, MSc, Forensic Science Centre "Ivan Vucetic" MoI Croatia, Zagreb, Grad Zagreb, Croatia; Ivan Jerković, PhD, Faculty of Forensic Sciences, University of Split, Split, Splitsko-Dalmatinska, Croatia*

Learning Objectives: Attendees will learn how intra-authorial variation from a verified corpus can benchmark authorship in anonymous texts. They will gain insight into how combining qualitative linguistic analysis with quantitative clustering techniques (Principle Component Analysis [PCA]) can support or challenge hypotheses of single versus multiple authorship in forensic cases.[1-3]

Impact Statement: This presentation introduces a replicable methodology that strengthens forensic authorship analysis through cross-validation, particularly in under-researched language contexts such as Croatian.[4] It also presents a recent forensic approach that uses forensic handwriting examination to verify the likelihood of single or multiple authorship in anonymous letters, alongside qualitative stylistic and quantitative stylometric analysis.[1,2,4,5] Central to this approach is the use of intra-authorial variation from a verified corpus as a benchmark for comparison, a method not previously applied in Croatian forensic linguistic practice.

Abstract Text: The case study involves two corpora of anonymous threatening letters sent to high-profile political figures. The first corpus (Q set) consists of 15 typed letters, and the research aimed to determine whether the Q corpus was the work of a single author or multiple contributors within a shared community of practice.[6] Initial qualitative and quantitative analysis of the Q corpus revealed internal consistency but with apparent idiolectal variation, or suggesting the possibility of multiple authors, which can also arise from shared norms within a sociolinguistic group.[1,3,6]

The second (C set) includes 13 handwritten letters previously confirmed through forensic handwriting examination to have been authored by a single individual.[3] Both corpora matched for genre, topic, period, and ideological context.[7,8]

Style markers were divided into two categories: *universal markers* (such as sentence length or type-token ratio), deducible from both corpora, and *distinctive markers*, letter-specific syntactic and morphological patterns.[1] Universal markers were encoded numerically and analyzed using PCA and hierarchical clustering. While the C set displayed measurable intra-authorial variation, all Q documents fell within the stylistic variation range of the C set when projected into the same PCA space. Additional Euclidean distance analysis supported these findings: intra-group distances were 3.06 for C and 2.05 for Q, while inter-group distance averaged 3.25.

These results indicate that the observed differences within the Q corpus are more likely due to stylistic flexibility than multiple authorship. Binary tracking of distinctive markers further reinforced the internal consistency of each corpus, in favor of single authorship. The convergence of linguistic and handwriting examination evidence, cross-validated with ISO standards and microscope-supported techniques, strongly supports the single authorship hypothesis for the Q set.[9,10]

This case illustrates the forensic power of authorial benchmarks based on intra-authorial variation and shows how they enhance the reliability and feasibility of both qualitative analysis and statistical thresholds. It also demonstrates the necessity of defensible, replicable methodologies and protocols in forensic authorship analysis.[2]

D11 Exploring Runtime Evolution in Android: A Cross-Version Analysis and Its Implications for Memory Forensics

Babangida Bappah, Louisiana State University, Baton Rouge, Louisiana, LA; Aisha Ali-Gombe, PhD, Louisiana State University, Baton Rouge, LA; Lauren G. Bristol, BS, Louisiana State University, Baton Rouge, LA; Lamine Noureddine, PhD, Louisiana State University, Baton Rouge, LA; Sideeq Bello, BSc, Louisiana State University, Baton Rouge, LA; Umar Farooq, PhD, Louisiana State University, Baton Rouge, LA*

Learning Objectives: The audience will learn about the systematic evolution of Android Runtime (ART) structures across versions 9–14 and how these changes fundamentally impact the reliability of memory forensic tools. Additionally, the presentation will provide a detailed analysis of structural modifications in critical forensic components, including Runtime, Thread, and Heap structures, demonstrating how over 73% of structure members undergo positional changes that break traditional forensic approaches.

Impact Statement: From a digital forensics standpoint, this research directly addresses the growing fragility of Android memory forensic tools by providing empirical evidence of structural evolution patterns and proposing adaptive methodologies. The publicly available structure repository and recommended hybrid approaches will enable the forensic community to develop more resilient tools capable of maintaining evidence recovery capabilities despite Android's rapid architectural changes.

Abstract Text: Userland memory forensics has become a critical component of smart phone investigations and incident response, enabling the recovery of volatile evidence such as deleted messages from end-to-end encrypted apps and cryptocurrency transactions. However, these forensics tools, particularly on Android, face significant challenges in adapting to different versions and maintaining reliability over time due to the constant evolution of low-level structures critical for evidence recovery and reconstruction. Structural changes, ranging from simple offset modifications to complete architectural redesigns, pose substantial maintenance and adaptability issues for forensic tools that rely on precise structure interpretation. Thus, this paper presents the first systematic study of ART structural evolution and its implications for memory forensics.

We conducted an empirical analysis of critical Android runtime structures, examining their evolution across six versions for four different architectures. Our findings reveal that over 73.2% of structure members underwent positional changes, significantly affecting the adaptability and reliability of memory forensic tools. Further analysis of core components such as Runtime, Thread, and Heap structures highlights distinct evolution patterns and their impact on critical forensic operations, including thread state enumeration, memory mapping, and object reconstruction. These results demonstrate that traditional approaches relying on static structure definitions and symbol-based methods, while historically reliable, are increasingly unsustainable on their own. We recommend that memory forensic tools in general and Android in particular evolve toward hybrid approaches that retain the validation strength of symbolic methods while integrating automated structure inference, version-aware parsing, and redundant analysis strategies. These adaptations are essential for sustaining effective and trustworthy forensic capabilities amid rapidly evolving runtime environments.

D12 Thoracic Aorta Injuries in Fatal Motor Vehicle Crashes: A Pilot Study and Comparative Mechanism Analysis

Angela L. Harden, PhD, Injury Biomechanics Research Center, Columbus, OH; Delaney Edwards, MA, The Ohio State University, Columbus, OH; Mary E. Cole, PhD, The Ohio State University, Columbus, OH; Brian T. Bautsch, MBA, American Honda Motor Co., Inc., Torrance, CA; Lauren Cardoni, MS, Burgess & Niple, Columbus, OH; John H. Bolte, IV, PhD, Biomechanics & Injury Analysts, Dublin, OH*

Learning Objectives: Attendees will learn how Traumatic Aortic Injury (TAI) presents in modern fatal motor vehicle crashes and how injury patterns correspond to crash dynamics, restraint use, and vehicle compatibility. They will be able to identify key biomechanical mechanisms associated with TAI and evaluate how these mechanisms persist despite advances in safety systems.

Impact Statement: This presentation will reinforce foundational biomechanical principles relevant to fatal crash reconstruction and forensic pathology, increasing attendees' abilities to recognize and interpret thoracic aorta injuries. When scaled to larger datasets, this type of analysis could also improve post-crash care by identifying injury patterns that require rapid recognition and intervention.

Abstract Text: Blunt traumatic Injuries Of The Thoracic Aorta Are A Rare But Highly Lethal Injury Most Often Associated With High-Energy motor vehicle crashes (MVCs). Despite advances in vehicle safety systems, the persistence of TAI in fatal crashes raises important forensic and engineering questions about injury mechanisms and occupant risk factors. This study revisits core biomechanical concepts to determine whether historical mechanisms of TAI remain relevant in contemporary crash contexts.

This retrospective pilot study examined 24 fatal MVCs involving confirmed TAI, with data collected from Ohio crash reports and the corresponding autopsy reports. Variables included crash type, sequence of events, posted speed, occupant demographics, restraint and airbag usage, and vehicle-to-vehicle compatibility.

Frontal crashes accounted for 79% of cases, with 67% of fatalities in the striking vehicle. The most frequent elements of the sequence of events included running off the road either left or right (42%), motor vehicle in transport (collision with another moving vehicle) (36%), collision with a fixed object (29%), crossing the center line or median (25%), and overturn/rollover (21%). While 46% of cases occurred in 55 mph zones, 17% occurred in 35 mph zones, indicating that high-energy trauma may occur even at moderate posted speeds. Although all vehicles deployed airbags, 71% of fatalities were unrestrained, and 79% were not ejected. Additionally, 67% of incidents involved a passenger car interacting with a larger vehicle. Fatalities were predominantly male (67%) and under 40 years of age. No pre-existing cardiovascular disease was observed in 71% of the fatalities, supporting trauma, not comorbidity, as the primary driver of TAI.

These findings are consistent with long-established injury mechanisms such as rapid deceleration, chest compression, and the osseous pinch model.[1-3] However, the presence of TAI in restrained occupants and in moderate-speed environments raises new questions about safety system efficacy and vehicle compatibility in modern crashes. This study affirms the need to integrate autopsy evidence with crash dynamics to improve forensic interpretations and inform biomechanical models of injury causation.

D13 Evaluating Thoracic Deflection and Injury Risk From Seatbelt Pretensioners in Small Female Occupants

John H. Bolte, IV, PhD, Biomechanics & Injury Analysts, Dublin, OH; Allison Guettler, PhD, The Ohio State University, Pickerington, OH; Amanda M. Agnew, PhD, The Ohio State University, Columbus, OH; Yun-Seok Kang, PhD, The Ohio State University, Columbus, OH*

Learning Objectives: After attending this presentation, participants will gain an appreciation for interdisciplinary research in skeletal trauma analysis, with a specific focus on potential injuries to small-statured females in frontal crashes from seatbelt pretensioner systems. They will learn how to apply experimentally driven biomechanical methods to validate skeletal trauma for forensic engineering applications and understand the critical role of experimental data in elucidating the injury mechanisms underlying an occupant's injuries.

Impact Statement: This research provides critical biomechanical data defining a non-injurious thoracic load case for small, elderly female occupants exposed to seatbelt pretensioner loading in frontal crashes. By demonstrating that pretensioners alone produced low thoracic deflections without rib fractures, and that injuries occurred only when combined with additional lateral loading, these findings help ensure that emerging small female safety tools do not overpredict thoracic injury risk. The results directly inform injury criteria development, forensic analysis, and the design of restraint systems that protect vulnerable occupants without introducing unintended injury mechanisms.

Abstract Text: Seatbelt pretensioners have been a standard element of vehicle restraint systems for over 50 years. Designed to remove slack from the seatbelt during the initial milliseconds of a crash, they improve occupant kinematics, reduce forward excursion, and enhance airbag performance. Although their benefits are well established, documentation of thoracic injuries directly caused by pretensioner activation is limited. Recent epidemiological data suggest such injuries are rare, with an estimated 0.3% risk of AIS2+ thoracic injury in low-severity crashes.[1,2] As small female Anthropomorphic Test Devices (ATDs) and human body models are developed, it is important that they do not overpredict injury risk from pretensioner loading alone.

This study aimed to quantify thoracic loading from pretensioners in small, elderly female occupants and define a non-injurious load case to inform safety tool development and injury assessment. Two experimental programs were conducted using 5th percentile female Postmortem Human Subjects (PMHSs). The first involved ten near-side sled tests with realistic vehicle boundary conditions, including a production driver's seat, standard three-point belt with pretensioner, and either a production or experimental c-shaped side airbag. The second consisted of three laboratory-based static deployments of the same pretensioner in a custom fixture replicating the sled geometry and belt path.

All PMHSs were positioned in a natural driving posture. Instrumentation included four seatbelt load cells to measure shoulder belt forces, chest bands at the axillary and xiphoid process to measure Anterior–Posterior (A/P) thoracic deflection, and 28 strain gauges to detect rib fracture timing. Laboratory test belt loads were tuned to match sled test loads for direct comparison.

Across all 13 tests, pretensioner-only loading generated mean peak A/P thoracic deflections of 18 ± 4 mm and shoulder belt forces averaging 1020 ± 150 N, with no rib fractures observed. Rib fractures occurred only in four combined-loading cases where pretensioner activation coincided with lateral thoracic loading from side airbag deployment. These findings indicate that pretensioners alone produce thoracic loading levels well below injurious thresholds for small, elderly females, and that fracture risk arises primarily from combined loading conditions rather than pretensioner activation alone.

This research provides an experimentally derived non-injurious thoracic load case for small, elderly female occupants. These data are directly applicable to refining thoracic injury criteria for small female ATDs and computational models, supporting more accurate injury risk predictions. The findings also have value for forensic injury analysis, ensuring injury causation assessments properly distinguish between pretensioner-only and combined-loading mechanisms. Additionally, the results inform restraint system design and regulatory evaluation, helping to maintain the proven benefits of pretensioners while minimizing unintended injury risk to vulnerable occupants.

D14 Seeing Beyond the Surface: Structured-Light 3D Scanning in a Prison Suicide by Hanging

Simona Calabrese, MD, Unime, Messina, Sicilia, Italy; Alessandro N. Nicolosi, MD*, Unime, Messina, Sicilia, Italy; Daniela Sapienza, PhD, Unime, Messina, Sicilia, Italy; Filippo Cucinotta, PhD, Unime, Messina, Sicilia, Italy; Fabio Salmeri, PhD, Unime, Messina, Sicilia, Italy; Cristina Mondello, PhD, University of Messina, Messina, Sicilia, Italy*

Learning Objectives: This research aims to share knowledge among forensic practitioners and pathologists regarding the practical integration of Structured-Light Scanning (SLS) with autopsy findings. The objective is to demonstrate how this technology can document complex forensic evidence—such as ligature marks—with high fidelity, reproducibility, and without modifying routine procedures. By illustrating its use in a real forensic case, the study provides a transferable workflow that combines accessible hardware with open-source analytical tools.

Impact Statement: The use of SLS in forensic pathology marks a valuable step forward in recording the pattern surface of injuries and the detailed features of lesions. Its ability to quickly capture highly accurate, color-rich 3D images adds both scientific depth and evidentiary strength to postmortem documentation. This case proves how digital 3D reconstruction can strengthen the objectivity and clarity of forensic fit match reports in support of comparative analyses and provide robust visual evidence in medicolegal contexts.

Abstract Text: The use of SLS has provided multiple advantages for the collection and preservation of evidence and in court presentations. Its use has been widely explored for collecting impression and trace evidence such as blood pattern analysis, and crime scene reconstruction.[1] Structured-light scanners project a series of coded luminous patterns onto the target surface, typically consisting of stripes or geometric grids. These patterns, deforming on the object's or body's surface, are detected by two integrated stereoscopic cameras within the scanner, allowing the calculation of spatial coordinates of points through a triangulation process.[2-4] This technique achieves exceptionally high resolution and precision, making it ideal for documenting fine details such as ligature marks from hanging, an entry wound in a gunshot, or other forensic lesions.

In the forensic case presented, structured-light scanner Creality CR-Scan 01 was integrated with the autopsy findings of an individual deceased in a prison cell. The body was discovered by the forensic medical officer lying near a noose made from braided white bed sheets. A ligature mark was evident on the neck, oriented obliquely from left to right and more prominent anteriorly, consistent with typical suicidal hanging. Both visual inspection and 3D scanning confirmed the compatibility between the neck sulcus and the structure of the improvised rope. The scanner was manually moved around the cervical-thoracic region, maintaining an average operational distance of approximately 60 cm and the rope used in the suicide was also acquired in three dimensions. Each acquisition was completed in less than three minutes and produced raw point clouds consisting of about four million points each, both integrated with texture. Acquiring texture allows the coloring of points in the generated cloud, enhancing realism and facilitating visual identification of relevant details.[5]

The generated point cloud was initially processed with the proprietary CR-Studio software, allowing initial cleaning of the cloud, automatically removing anomalous points, and reconstructing the three-dimensional surface through advanced triangulation.[6] This procedure generated preliminary STL files, subsequently imported into CloudCompare (v.2.13) for further refinement. In CloudCompare, an open-source software widely used for advanced 3D processing, manual selection and removal of irrelevant portions of the models (such as table elements and other supports) were carried out.[7] Furthermore, CloudCompare allowed precise dimensional measurements directly on the final three-dimensional models, significantly aiding subsequent forensic analyses and interpretations.

In conclusion, this workflow has proven to be particularly effective, rapid, and easily integrated into standard autopsy procedures in performing fit-match analyses between cause/effect and injury, and between injuries and forensic dynamics, in order to demonstrate compatibility with the criminal/suicidal action.

D15 Multi-Modal Deep Learning for Bruise Age Estimation: Enhancing Forensic Reliability Through Integrated Visual and Contextual Data

Mehrdad Ghyabi, PhD, George Mason University, Fairfax, VA; Katherine N. Scafide, PhD, George Mason University, Fairfax, VA; David Lattanzi, PhD, George Mason University, Fairfax, VA*

Learning Objectives: After attending this presentation, attendees will understand how a multi-modal deep learning framework is used to integrate visual and structured textual data for objective bruise age estimation. They will learn about the application of Convolutional Neural Networks (CNNs) for image feature extraction and pretrained text embeddings for processing participant-specific metadata and the anticipated benefits of feature-level fusion for personalized predictions in forensic and medical diagnostics.

Impact Statement: This proposed research aims to impact the forensic science community by offering a more objective and data-rich alternative to traditional subjective bruise aging assessments, thereby enhancing the reliability of forensic evidence. By reducing inherent human error and effectively accounting for individual physiological variability in healing, this technology aims to promote the responsible, ethical, and just use of technology in the forensic sciences.

Abstract Text: Estimating bruise age on living individuals remains a challenge in forensic science and medical diagnostics, as current methods rely heavily on subjective visual assessments and rarely account for significant inter-individual variability in healing. Unlike forensic pathologists, who can use gross and histological analysis on deceased individuals to aid bruise dating, practitioners working with living populations have limited tools. To address this gap, we developed a novel multimodal deep learning model that integrates visual image data with structured textual data representing participant-specific physiological attributes, with the aim of delivering more accurate and personalized bruise age predictions.

Our study leverages a dataset of over 32,000 high-resolution bruise images collected under controlled conditions from living participants, along with rich metadata including age, skin tone, body fat, and other physiological characteristics. CNNs were employed to extract features from the images, while participant attributes were transformed into natural language-like input and embedded using a BERT-based model to capture individual healing variability. These two data streams were fused at the feature level into a unified vector and used to train the final model for bruise age prediction.

This integrative approach enables the model to capture complex interactions between visual bruise characteristics and the underlying physiological context of the individual, substantially improving prediction accuracy. Results from the evaluation of this model will be presented, and ongoing work includes testing the model's robustness on images of naturally occurring bruises to assess its generalizability in real-world forensic and clinical settings.[1-7]

D16 A Forensic Investigation of Hydrogen-Driven Blasts in Galvanized Sprinkler Systems

Songhie An, PhD, National Forensic Service, Seoul Institute, Department of Forensic Chemistry, Seoul, Seoul-t'ukpyolsi, Republic of Korea;*
Sungwan Park, MASc, National Forensic Service, Seoul Institute, Department of Engineering, Seoul, Seoul-t'ukpyolsi, Republic of Korea;
Wooyong Park, MSc, Department of Chemistry, National Forensic Service, Republic of Korea, Wonju-si, Kangwon-do, Republic of Korea

Learning Objectives: After reviewing the poster, attendees will be able to: (1) recognize hidden hydrogen hazards: identify visual and operational clues—such as white zinc scale, unexpected pressure rises, and drain-tank gas pockets—that point to hydrogen involvement in sprinkler incidents; (2) explain the corrosion mechanism: describe how zinc oxidation in stagnant, oxygen-rich water generates hydrogen gas and why closed-pipe geometry lets the gas accumulate to dangerous levels; and (3) apply prevention and mitigation strategies: list practical measures (venting high points, relocating ignition sources, using non-zinc materials, routine head-space monitoring) that reduce hydrogen-explosion risk in both existing and new sprinkler systems. Together, these objectives equip the audience to diagnose, evaluate, and control hydrogen-related hazards in fire-protection networks.

Impact Statement: This presentation shows that slow zinc-water corrosion inside galvanized wet-pipe sprinklers can accumulate hydrogen to explosive levels—an overlooked cause of several documented building fires. By presenting the chemical data and field evidence in this poster, we highlight a public-safety issue that extends beyond traditional crime reconstruction. The results underpin practical inspection checkpoints, code updates, and broader searches for "trivial" chemistry that pose hidden risks in other infrastructure, positioning forensic chemistry as a proactive safeguard against future casualties and property loss.

Abstract Text: Galvanized wet-pipe sprinkler systems dominate fire-suppression infrastructure in Korea, where a thin zinc coating is applied to steel mains to inhibit corrosion. Under stagnant conditions, however, zinc undergoes a slow electrochemical reaction with oxygenated water, producing zinc-hydroxide scale and liberating hydrogen gas (H_2). Because the pipe network is normally closed, the evolved gas cannot dissipate, allowing head-space concentrations to rise silently until they approach the lower flammability limit. If the mains are drained suddenly into a collection tank that houses an unclassified ignition source, the accumulated H_2 can trigger a powerful explosion. Although several documented sprinkler blasts have been traced to this mechanism, current Korean fire-safety codes do not address hydrogen generation in wet systems, and the hazard remains largely unrecognized by installers and inspectors.

This study investigates the conditions under which H_2 forms and accumulates in galvanized sprinkler pipes and translates the findings into practical risk-reduction measures. Laboratory immersion tests of zinc disks (mimicking sprinkler pipes) were conducted; gas chromatography tracked head-space H_2, while Scanning Electron Microscopy with Energy-Dispersive X-ray Spectroscopy (SEM/EDS) characterized the corrosion products. Furthermore, samples were additionally collected from actual incident sites, which supplied real-world data on pipe scale, and water chemistry. The combined results show that as little as four weeks of stagnation at 25 °C can yield significant amounts of hydrogen gas. These observations underscore the urgent need for proactive, evidence-based safeguards. We hope that our findings will support the development of worldwide mitigation strategies that close this critical safety gap and prevent future hydrogen-driven fires and explosions in sprinkler networks.[1]

D17 Multidimensional Scaling of Hybrid Similarity Search Match Factors for Fentanyl Analogs

Melinda A. Kleczynski, PhD, Georgetown University, Chevy Chase, MD; Arun S. Moorthy, PhD, Trent University, Peterborough, Ontario, Canada; Anthony Kearsley, PhD*, National Institute of Standards and Technology, Jessup, MD*

Learning Objectives: After visiting the poster, attendees will have a general understanding of Multidimensional Scaling (MDS), improving their ability to interpret MDS representations in the research literature. Attendees with an interest in mass spectral datasets will be aware of some technical issues that may arise when utilizing the successful HSS Match Factor to produce MDS plots, as well as guidance for how to address these issues.

Impact Statement: We address challenges in the visualization and interpretation of mass spectral datasets. Our current application is the analysis of fentanyl analog datasets, but these techniques are applicable to a range of mass spectral libraries.

Abstract Text: MDS has successfully enabled visualization and error checking of mass spectral datasets. MDS is a mathematical/statistical technique that inputs pairwise dissimilarities between objects and uses iterative optimization to find a configuration of points whose pairwise distances approximate the given dissimilarities. In our application, the objects are fentanyl analog mass spectra. There are various choices for computing dissimilarities, including utilizing Hybrid Similarity Search (HSS) Match Factors.[1] Given a collection of match factors, we use MDS to produce a 2-dimensional plot whose points correspond to the mass spectra of interest.

HSS excels at detecting similarity of substances that differ by one modification, but is not designed to handle multiple modifications. These properties of the HSS can produce undesirable effects in MDS representations of larger datasets, such as mass spectra with strong match factors being mapped to distant points on the plot. This behavior is pronounced in MDS of comprehensive fentanyl analog datasets, fueled by the presence of many different types of modifications. Consequently, it is difficult to interpret MDS representations of HSS Match Factors of fentanyl analogs. We discuss our preliminary work investigating these phenomena and proposed adjustments to the typical MDS pipeline. We hope these techniques will aid in the analysis of mass spectra of seized drugs and other substances.

D18 Officer Confusion Leads to Improper Conclusions in a Fatal Head-On Accident

Darren H. Franck, MSME, Advanced Engineering Associates, Inc., Charleston, WV; Harold H. Franck, MSEE, Advanced Engineering Associates, Inc., Charleston, WV*

Learning Objectives: Attendees will be presented with investigation methods to assist in correctly identifying at-fault parties in a multi-vehicle collision. These methods include road surveying, mapping of tire marks and gauges, interrogation of air bag modules, interpretation of crash data, and analysis methods based on the laws of physics.

Impact Statement: This presentation will impact the forensic science community by emphasizing the importance of a close examination of the physical evidence and the fallibility of witness statements.

Abstract Text: This case involves five vehicles traveling on a two-lane road in Wayne County, WV. Four vehicles were traveling in the northbound lanes on US Route 52 during daylight hours in April 2022. A Ford SUV was traveling south on this road and was involved in a sideswipe collision with Chevrolet SUV traveling north. Following this impact, the Ford SUV was involved in a frontal offset collision with a Toyota sedan. Due to the nature of the collision, both vehicles entered into a counterclockwise yaw rotation. The Ford came to rest with an easterly heading in the northbound lane of travel. The Toyota was driven off the east side of the road and came to rest in a grassy field with a westerly heading. This collision resulted in fatal injuries to the driver of the Toyota.

Following the head-on collision, a northbound Kia SUV and a northbound Ford ambulance were involved in minor collisions with the Ford and Toyota. Conflicting statements were provided by the drivers of the Chevrolet, Kia, and Ford ambulance. Moreover, the officer's expressed confusion as to the headings of the Ford SUV and Toyota sedan that were involved in the head-on collision. This confusion was reflected in a recorded statement with the driver of the Ford SUV. Despite the officer's uncertainty, blame was placed on the deceased driver of the Toyota sedan for traveling left of center.

The rest positions of the subject vehicles did not support the police report. A momentum analysis indicated that the head-on collision would have had to have occurred within the northbound lane. Moreover, the physical evidence involved gouging and tire marks from the collision that were fully within the northbound lane. These thoughts were confirmed by interrogation of the air bag modules for the respective vehicles. The data indicates a slight, rightward steer angle for the Toyota in the seconds prior to the collision, which matched the gentle horizontal curve for the northbound lane before the point of impact. The Toyota was then steered significantly to the right and the brakes were applied one-half second prior to the collision. The speed of the Toyota prior to applying the brakes did not exceed the posted speed limit of 55 mph.

Conversely, the driver of the Ford SUV did not apply the brakes prior to the collision and maintained a constant speed of 47 mph. The Ford SUV maintained a slight, leftward steer angle until about 200 feet from the point of impact. This gentle steer matched the horizontal curve in the road for southbound travel. While the road straightened near the area of impact, the leftward steer angle of the Ford SUV increased until one-half second prior to impact. The driver of the Ford SUV then attempted to steer right just prior to impact.

This investigation resulted in correctly identifying the at-fault party in this collision. The emphasis on independent, physical evidence allowed for a proper result in this case where the victim could no longer speak in his defense.

D19 Sun Altitude and Azimuth Causes a Fatal Crash With a Flatbed Trailer

Kurt D. Weiss, MSME, Case Study Collision Science LLC, Santa Barbara, CA*

Learning Objectives: This presentation will demonstrate a traffic collision reconstruction using event data recorder pre-crash data to analyze vehicle approach speed and insight into driver behavior at the time of the collision. The sun altitude and azimuth research revealed a substantive cause in this collision.

Impact Statement: This presentation will assist the forensic community by demonstrating how a comprehensive traffic collision reconstruction, using event data record pre-crash data and sun data, can reveal the substantive cause of a fatal collision.

Abstract Text: The driver of a Pontiac Firebird was heading eastbound on a city street with a posted regulatory speed limit of 35 mph. His adolescent daughter occupied the right front seat. This street has four lanes, two each direction, and a dedicated left turn lanes. A north/south side street forms a T-intersection to the south, with a posted stop sign and stop line.

Construction of a large apartment complex on the north side opposite the T-intersection had started the year before. Pursuant to a revocable encroachment permit granted to the construction company, traffic cones were placed along the parking lane to accommodate transporting equipment from an adjacent site to the build site. Working hours were specified as Monday through Friday, 8:00 a.m. to 4:30 p.m. On this day, flagmen had stopped westbound traffic to accommodate a tractor-trailer on the side street backing northbound into the build site. As the trailer crossed the eastbound lanes, the Pontiac impacted the trailer. The collision occurred outside the permitted working hours at 7:39 a.m. Later it was determined the encroachment permit had expired 84 days earlier.

The unloaded flatbed trailer's loadbearing center flange caught the Pontiac's hood as the vehicle continued underneath. The windshield offered little resistance and folded backward as the T-tops buckled. The Pontiac squatted to fit, but surrendered under the immense applied force. The underride damage extended approximately 10½-feet back to the Pontiac's B-pillar.

The driver's head was aligned with the trailer's loading deck, and he subsequently suffered fatal craniocerebral injuries, including penetration by a metal hook on the trailer used to secure cargo. Miraculously, the daughter survived without significant injuries.

The Pontiac Airbag Control Module (ACM) was imaged, and two event records were obtained: a deployment event and an unrelated non-deployment event. The ACM-indicated pre-crash speed was corrected for oversized tires and showed the vehicle was traveling at a maximum speed of 36.7 mph, well within acceptable speedometer error. The pre-crash data also revealed a possible delayed reaction to the immediate hazard. Despite having more than 500-feet of forward visibility, the driver lifted his foot from the accelerator pedal, and then applied the brakes between two seconds and one second before impact.

The sun's altitude and azimuth of approximately 8.4 degrees above the horizon, and 90.8 degrees east of north, respectively, was explored as a potential contributing factor. The incident azimuth angle was found to align with the eastbound lane. Therefore, plaintiff's counsel argued the sun's altitude and azimuth caused the driver's temporary blindness, delaying his brake application.[1]

The toxicological report revealed the presence of benzoylecgonine, 11-hydroxy delta-9, delta-9 carboxy and delta-9 THC. Therefore, law enforcement investigators concluded the primary collision factor was driving under the influence.

The lawsuit reached a settled with the building company who enacted the encroachment permit.

D20 Heavy Truck Cab Integrity and the Swedish Test

Christopher Clarke, PE, BS, SAFE, Goleta, CA; Brian Herbst, PE, BS, SAFE, Goleta, CA*

Learning Objectives: This presentation reviews standardized heavy truck cab integrity testing methods. In addition, an analysis of real-world heavy truck accidents that resulted in intrusion into the cab structure is presented. Finally, a set of Swedish cab integrity testing will be presented and analyzed.

Impact Statement: This presentation will explore standardized methodologies for heavy truck cab integrity testing, present real-world heavy truck accidents challenging cab integrity, and evaluate cab performance in the Swedish impact test.

Abstract Text: Cab structure integrity is essential for heavy truck occupant protection. However, the testing methods used by manufacturers don't represent real world crash severity. The first cab integrity standard, known as the Swedish test, has been used since 1959. The three-part test represents rollover, impact with an object such as a tree, and cargo sliding forward.[1] The roof is loaded to 33,000 pounds, a cylindrical pendulum strikes the top corner of the cab, and a flat pendulum strikes the rear wall. Deformation generated in Swedish testing is often less than observed in real-world crashes such as 180 degree rollovers, but it remains the most demanding standardized test. In 1974, the United Nations Economic Commission for Europe (UNECE) implemented the R29 cab integrity test consisting of frontal impact, roof loading, and rear loading. However, R29 is much less demanding than the Swedish standard.

In 1986, the National Highway Traffic Safety Administration (NHTSA) identified heavy truck rollover as a safety priority, estimated adopting the Swedish standard would double cab strength, and recommended developing improved cab structures.[2]. In response, the SAE set out to develop a test representing rollover. Field accident evaluations, Finite Element Analysis (FEA) simulations, and physical testing were carried out. Peterbilt 359 trucks, introduced in the 1960s and long out of production by this time, were used for the testing run to develop the new test standard. This work indicated cabs would see loads up to 55,000 pounds and energy levels over 40,000 foot pounds during rollovers.[3,4] However, the Society of Automotive Engineers (SAE) did not adopt these force and energy levels. Instead, SAE J2422 specifies a 13,000 foot pound sled impact to represent tipover, followed by a roof load roof load of 22,000 pounds to represent inversion. These parameters were sufficiently reduced from those of real-world rollovers that the Peterbilt 359 and most if not all contemporary cabs could pass without any structural improvements.

A case study was analyzed involving a truck that was not designed for any cab integrity standards. The subject truck crashed into a tree that had fallen across a highway. The upper portion of the cab interacted with a horizontally oriented tree limb, generating an impact configuration similar to that of the Swedish frontal impact. The impact broke the tree limb, and the truck continued past the tree and gradually slowed to rest. Although the impact caused a negligible delta-V, it resulted in significant intrusion into the occupant survival space, which in turn resulted in fatal injuries for the driver.

A set of Swedish frontal cab impact tests was conducted to evaluate the performance of the case study cab and an improved cab design from the same manufacturer that was designed for the Swedish test. The damage patterns were consistent with the case study cab and demonstrated that designing to the Swedish standard achieves a significant reduction of intrusion compared to a cab that is not designed to the standard. It was determined that had the subject truck been equipped with this improved cab design, the fatal intrusion injuries sustained by the driver in the case study accident would have been prevented.

D21 The Fine Points of the Interrelationship Between Vehicle Dynamics and Occupant Kinetics in Frontal Motor Vehicle Accidents (MVAs)

David J. Porta, PhD, Corporeal Consulting, LLC, Louisville, KY*

Learning Objectives: After attending this presentation, attendees will be reminded of the factors that determine how occupant motion, and thus resultant potential for injury production within a crashing vehicle, is dependent on bullet vehicle velocity, restraint usage, pretensioner activation, interior component layout, angle of impact, principal direction of force, level of under- or override, etc. Target vehicle factors are similar but also include exterior profile in the area of impact. A specific crash will be examined to demonstrate how vehicle profile can affect occupant kinetics.

Impact Statement: Forensic accident reconstructionists will benefit from this presentation by reviewing how vehicle motions affect occupant motions. This will enhance the performance of injury analysis in the motor vehicle crash environment, especially when questions of restraint usage arise.

Abstract Text: Frontal collisions comprise the majority of serious roadway crashes. Often, forensic analyses include the assessment of roadway characteristics, vehicle components, crash dynamics, and occupant motions in relation to injuries. In a typical moderate- to high-speed collision, the front end of the involved vehicle will be forced downward, often resulting in pavement gouge marks from the diving frame components. At the same time, the rear of the vehicle will often ramp upward. This affects the trajectory of occupants and thus their interaction with interior components like the steering wheel and airbags. Unrestrained occupants in violent frontal collisions often move such that their heads impact the windshield—even when an airbag deploys in their path. However, a particular target vehicle shape can alter the bullet vehicle motion and subsequent occupant motion. In this case, a claim of proper restraint usage may seem warranted due to the lack of windshield interaction. But a clear understanding of the role of target vehicle profile will show why the head did not travel along the typical path for an unrestrained occupant. This will be demonstrated with images from actual crashes and videos from experimental crash tests.

In conclusion, target vehicle shape in the area of impact can affect occupant motion in the bullet vehicle.

D22 The Detection and Forensic Documentation of Clandestine Pollutant Discharges in Federal Watercourses in Brazil

David Domingues Pavanelli, PhD, Brazilian Federal Police, São Paulo, Sao Paulo, Brazil*

Learning Objectives: By attending this presentation, participants will be able to: (1) identify the multidisciplinary requirements for detecting clandestine pollutant discharges in federal watercourses, including environmental toxicology, sampling protocols, and rapid-response logistics; (2) describe best practices for planning and executing forensic field operations aimed at documenting environmental crimes, with an emphasis on real-time data collection and preservation; (3) recognize the importance of collaboration between criminal forensic experts, environmental oversight bodies, and public safety agencies to ensure investigative success; (4) evaluate case-specific strategies employed by the Brazilian Federal Police in the successful interruption and documentation of illegal industrial discharge; and (5) apply key operational insights—such as team composition, training regimens, equipment selection, and procedural rehearsals—to their own forensic investigations of environmental offenses.

Impact Statement: This presentation will broaden the forensic science community's understanding of environmental crime investigations, particularly in the context of water pollution enforcement. The case study emphasizes the value of specialized training and rapid execution in documenting transient criminal acts like illegal effluent discharge—skills that are increasingly critical in environmental forensics worldwide.

Abstract Text: In Brazilian legislation, water pollution is classified as an environmental crime. When such violations occur in federal rivers, the investigation falls under the jurisdiction of the Brazilian Federal Police, with forensic criminal experts playing a central role in both evidentiary documentation and attribution of responsibility.

Detecting illicit discharges into water bodies poses considerable challenges, requiring a multifaceted and well-coordinated approach. This includes preliminary field reconnaissance to identify potential discharge locations, toxicological profiling of suspected pollutants, prior study of the receiving watercourse, deployment of trained personnel for environmental sample collection, and the use of appropriate chemical detectors and Personal Protective Equipment (PPE) as well as proper materials and protocols for sample preservation. Crucially, the success of such operations depends on rapid access to the discharge site, as clandestine releases may be halted abruptly.

This case study describes the successful detection of illegal pollutant discharge by a textile company long under investigation by environmental oversight agencies. The discharge was interrupted at the outset of the operation, and the swift execution of well-rehearsed forensic procedures by Federal Police experts proved critical to the outcome.

The report underscores the complexity involved in documenting clandestine environmental crimes and highlights that operational success stems from collaborative efforts with environmental and public security agencies, strategic team composition and training, the use of specialized equipment, professional engagement, and rigorous procedural planning and rehearsal.

D23 Forensic Identification and Discrimination of Biological Fluids Via Hyperspectral Imaging and Chemometric Analysis

Alberto Mazzoleni, MSc, DataBloom Srl, Department of Chemistry, University of Turin, Turin, Piemonte, Italy; Eugenio alladio, PhD, Department of Chemistry, University of Turin, Torino, Piemonte, Italy; Giovanni Solarino, MSc, Department of Chemistry, University of Turin, Turin, Piemonte, Italy*

Learning Objectives: After attending this presentation, attendees will: (1) understand the principles of Hyperspectral Imaging (HSI) and its forensic applications in biological fluid analysis; (2) learn how chemometric tools enhance the discrimination between different types of biological fluids; and (3) learn how to evaluate the potential and limitations of HSI-chemometric methods in operational forensic casework.

Impact Statement: This presentation introduces an innovative approach to the identification and discrimination of biological fluids using HSI combined with chemometric analysis. By offering a non-destructive, rapid, and objective method, this work has the potential to improve the accuracy and efficiency of biological trace analysis in forensic investigations.

Abstract Text: The detection of biological fluids at crime scenes is a fundamental aspect of forensic investigations as it enables both the identification of individuals involved and the reconstruction of event dynamics. Traditional techniques for locating biological traces, such as forensic Alternate Light Sources (ALS), often suffer from limited sensitivity and specificity. This underscores the need for alternative, non-destructive, and more selective approaches.

This study investigates the potential of a multiblock analytical platform based on hyperspectral imaging (IRIS, XGLab SRL–Bruker Nano Analytics), which simultaneously acquires X-Ray Fluorescence (XRF, 1–40 keV), Visible and Near-Infrared (VNIR, 380–1100 nm), and Short-Wave Infrared (SWIR, 1100–2500 nm) reflectance spectra.[1] To fully exploit the complementary information provided by these spectral ranges, the multimodal datasets were processed using chemometric methods, specifically Principal Component Analysis (PCA) and Multivariate Curve Resolution-Alternating Least Squares (MCR-ALS).[2] These were applied both separately to individual data blocks and jointly using a low-level data fusion strategy.

Biological fluids—blood, urine, semen, and saliva—from multiple donors were deposited on wooden substrates and analyzed at various time points post-deposition. The study pursued two main objectives: (1) to detect and precisely localize biological traces on complex surfaces, and (2) to differentiate between fluid types. The chemometric approach proved highly effective in generating chemically informative maps for both detection and identification. Notably, low-level data fusion significantly enhanced the discrimination capability, particularly for fluids with similar spectral and elemental profiles such as urine and saliva.

D24 Robust Linking Estimation in the Graded Response Model With Contaminated Ability Distributions

Ibrahim Almansour, MS, University of Central Florida, Maitland, FL; Larry Tang, PhD, University of Central Florida, Orlando, FL*

Learning Objectives: Participants will be able to: (1) describe the limitations of Ordinary Least Squares (OLS) equating under contaminated ability distributions; (2) apply Quantile Regression (QR) methods to link item parameters in Graded Response Models (GRM); and (3) interpret simulation results comparing bias and standard error between OLS and QR approaches

Impact Statement: This presentation introduces a robust equating framework using QR that reduces bias when ability distributions deviate from normality. For forensic psychological assessments and credentialing exams, these methods can improve the validity of score comparisons across test forms, leading to fairer and more defensible evaluations in forensic contexts.

Abstract Text: The GRM, a widely used extension of Item Response Theory (IRT) for analyzing ordered categorical data, faces challenges in linking test scores when the underlying ability distributions deviate from normality. Traditional linking methods, which assume that the distribution of latent traits follows a normal distribution, often suffer from bias and inefficiency in the presence of skewness or outliers. This study introduces QR, Composite Quantile Regression (CQR), and Weighted Composite Quantile Regression (WCQR) as robust alternatives for estimating linking coefficients under such non-normal conditions. These quantile-based methods allow flexible modeling across various points of the conditional distribution, effectively mitigating the influence of extreme values.

Through extensive simulation studies and real-data analyses on educational assessments, we demonstrate that QR, CQR, and WCQR consistently reduce bias and improve standard error estimation compared to traditional moment-based methods, often matching or exceeding characteristic curve approaches. Although our empirical data come from academic testing contexts, the robust performance of quantile-based linking methods suggests clear applicability for high-stakes and forensic credentialing examinations—where fairness and defensibility of score comparisons are paramount. These findings establish quantile-based regression as a powerful framework for accurate and equitable linking under irregular latent trait distributions, informing future development of forensic proficiency tests and standardized certification processes.[1-11]

D25 Aerosols With Addresses: A Method for Testing Aerosol Dispersion in Variable Environments

Catherine G. Reyes, PhD, Lawrence Livermore National Laboratory, Livermore, CA*

Learning Objectives: In attending this presentation, audience members from traditional forensic science fields will be introduced to the novel concept of using biological surrogates with uniquely tagged DNA oligomers for tracking the spread of aerosols throughout an area. Originally emerging as a mitigation tool for estimating the potential breadth that bio-aerosol warfare agents may have if adversarially employed, this method of aerosol tracking has potential for use in other contexts where particle or other forms of trace material tracking and/or tagging may be of interest for the forensics community.

Impact Statement: This presentation will impact the forensic science community by serving as a discussion point, and potential interest area for cross-collaboration, by introducing the idea that other materials science and engineering-based innovations and methodologies used for biosurveillance (for example) may be also used to help solve issues encountered in the forensics fields, particularly when it comes to identification, estimation, or re-creation of events.

Abstract Text: DNA tagged reagents for aerosol experiments (DNATrax) are harmless biological aerosol simulant materials designed to mimic bacterial spores. DNATrax, which uses a food-safe sugar (maltodextrin) as the carrier for short (~100 base pair) synthetic DNA oligomers, has been implemented to study the spread of biological agents in both indoor and urban environments through aerosol studies. The particle sizes range from one to a few micrometers, to model the size of single and aggregated *Bacillus* spores, also allowing for a wide distribution of dispersal. The DNA incorporated into the sugar carriers, which essentially act as "barcode addresses" for the particles, can be amplified by Polymerase Chain Reaction (PCR) and, therefore, be detected with high sensitivity, allowing us to see how simultaneous dispersals can also spread. In the past, DNATrax has been safely released in public populated areas to study how biological particles may spread in government buildings and underground subways.[1-5]

In this presentation, the original DNATrax concept will be presented as well as more recent findings demonstrating that other food-safe carriers for "bar codes" can be reliably synthesized, which can be applicable for various environments (e.g., to model breath droplet dispersal in the context of COVID and to understand particle spread in humid/wet environments). Though conceived as a tool for biosurveillance, the methodology of uniquely identifying particle distribution and spread throughout an area has potential to be useful for forensic applications where the identification of aerosol, particulate, and disparate trace materials/residues and their spread may be necessary.

D26 The Aberrant Behavior of Gas Appliances That Incorporate Flame Arrestors Being Indicative of Fugitive Fuel Gas Intrusion by Soil Migration

Tim G. Dunn, MS, Dunn Laboratories, Roswell, GA*

Learning Objectives: While today's gas water heaters incorporate flame arrestors to protect against flammable vapor ignition, uncontrolled firing can be a predictive of fugitive natural gas or propane intrusion migrating from a buried gas line. Disguised as a water heater problem such as prolonged firing, extremely hot water, or burner shut down, there can be more dangerous issues that need careful consideration. Two examples, with visuals, will be presented.

Impact Statement: Given the safety design, the obvious appearance of a water heater malfunction, the investigation should go further to thoroughly evaluate other issues with regard to the integrity of the gas piping system.

Abstract Text: I have investigated both natural gas and propane explosions where the source was a piping leak underground, outside the residence. This fugitive fuel gas has migrated into the residence, where it has been drafted into the gas-fired water heater through its flame arrestor. The added fuel can certainly overfire the appliance, causing extremely hot water, and ultimately result in the actuation of the temperature-pressure relief valve, or burner shut down, by the thermal cut off switch tripping out.

Two such examples will be discussed, including a video of the flames being emitted directly from the flame arrestor mesh. The investigator should understand the design and behavior of the domestic water heater. I will discuss the history of the domestic gas water heater and its design, the reason for the flame arrestor, and its limitations. References will be made to my photographs and video (if possible to play). During shutdown of the water heater, the gas intrusion can result in dangerous accumulation inside the residence. I will go through my methodology in leak testing the complete gas system, including the piping, and systematic testing of the water heater components as well as explore the means of intrusion of the flammable gas.

D27 Lessons From the Wreckage: Forensic Architecture and Construction Failures Every Professional Should Understand

Mohsen Ghoreishi, MA, KOHAN, San Francisco, CA*

Learning Objectives: By the end of this session, participants will be able to: (1) identify common causes of construction failures related to material selection, poor detailing, or deviations from design intent through real-world forensic case studies; (2) differentiate between forensic architecture and forensic construction and explain the distinct roles they play in diagnosing building performance issues; (3) apply proactive risk mitigation strategies such as enhanced Quality Assurance/Quality Control (QA/QC) processes, submittal review, and field coordination to reduce the likelihood of costly construction errors; and (4) evaluate lessons learned from failed projects and incorporate best practices into future design and construction workflows to improve building safety, performance, and compliance.

Impact Statement: This presentation empowers industry professionals to recognize the hidden risks that often go unnoticed until it's too late. By dissecting real forensic failures, attendees will gain a deeper understanding of how decisions made in design, engineering, and construction affect building performance and legal liability. These insights equip participants to build not only safer and more resilient structures but also stronger professional accountability across project teams. The lessons shared have the potential to save millions in repair costs, preserve reputations, and, most importantly, protect lives. This is not just about looking back at what failed, it's about building forward better.

Abstract Text: Construction failures are rarely the result of a single error. Instead, they are often the consequence of compounded missteps, missed details in the design phase, communication breakdowns between disciplines, improper material selection, or deviations from the original construction intent. This presentation explores how and why things go wrong in the built environment by examining real-world forensic investigations where the consequences were costly, dangerous, and entirely preventable.

This presentation introduces attendees to the critical distinctions between forensic architecture and forensic construction, offering a framework for understanding the root causes of project failure. While forensic architecture focuses on the intent and technical adequacy of the design, forensic construction investigates how that design was executed in the field, looking at workmanship, sequencing, material compliance, and more. Together, these disciplines help uncover the truth behind structural collapses, envelope failures, and systemic construction defects.

Through detailed case studies, including the demolition of a 60,000 square-foot second floor due to improper concrete mix selection, participants will see firsthand how overlooking a single submittal or bypassing material verification can result in catastrophic structural overloads. These examples will demonstrate not only the technical breakdowns but also the procedural failures that allowed them to occur.

Participants will leave with a set of practical takeaways: how to implement proactive quality assurance protocols, the importance of coordinating across trades during design and preconstruction, and the value of verifying field conditions against assumptions made in the drawings. Emphasis will also be placed on legal and professional responsibility, particularly where accountability becomes critical during dispute resolution and claims.

Whether you are a builder, architect, owner's representative, legal counsel, or project manager, this session provides an essential perspective into the vulnerabilities of the building process and how to strengthen them. By examining failures not as isolated incidents but as learning opportunities, we can build smarter, safer, and more enduring structures.

D29 Hydrogen Explosion in Sprinkler Pipes: A Forensic Chemical Analysis

Songhie An, PhD, National Forensic Service, Seoul Institute, Department of Forensic Chemistry, Seoul, Seoul-t'ukpyolsi, Republic of Korea;*
Sungwan Park, MASc, National Forensic Service, Seoul Institute, Department of Engineering, Seoul, Seoul-t'ukpyolsi, Republic of Korea;
Wooyong Park, MSc, Department of Chemistry, National Forensic Service, Republic of Korea, Wonju-si, Kangwon-do, Republic of Korea

Learning Objectives: After the presentation, the audience will be able to: (1) recognize hidden hydrogen hazards, (2) explain the corrosion mechanism, (3) assess explosion potential quantitatively, and (4) apply prevention and mitigation strategies. These objectives equip attendees to diagnose, evaluate, and control hydrogen-related explosion risks in fire-protection systems.

Impact Statement: This presentation alerts the forensic science community to a poorly recognized hazard: slow, normally benign zinc-water reactions inside wet sprinkler systems can generate explosive hydrogen concentrations, leading to documented building fires. By uncovering this overlooked hazard and outlining preventive measures, the research expands forensic science beyond crime reconstruction to proactive public safety. The findings can inform inspection protocols, update building codes, and inspire similar investigations of "trivial" chemistries in other critical infrastructures. The study therefore positions forensic chemistry not only as a tool for post-incident attribution but also as a proactive discipline that prevents future casualties and property loss.

Abstract Text: Galvanized steel is routinely specified for wet-pipe sprinkler systems because its zinc coating suppresses corrosion; yet the same coating can create an overlooked explosion hazard. When water stagnates in the pipework, zinc undergoes redox corrosion and liberates Hydrogen gas (H_2). Recent European and Asian case reports describe pressure build-ups, pipe ruptures, flash fires, and full explosions attributable to this mechanism. The present study re-examines two Korean incidents in which violent blasts occurred within minutes of draining the mains into a collection tank.

Post-incident inspections showed that H_2 had accumulated at high points in the network and migrated into the tank head-space. Metallurgical evidence and further investigation indicate that an electrical contact from the water level control device provided the ignition source while adjusting the water level.[1] Although the installation was assumed to be inert, its internal chemistry rendered it intrinsically vulnerable: hydrogen is flammable over a broad range (4–75 vol %) and ignites at ~0.02 mJ—several orders of magnitude below the energy released by ordinary switch contacts. Once ignited, the confined mixture produced an abrupt pressure surge capable of lifting the tank lid, distorting adjacent pipework and endangering personnel.

A qualitative review of pipe scale, water chemistry, and maintenance logs identified three coupled drivers: (1) continuous zinc–water corrosion in mildly alkaline, oxygen-rich water; (2) periodic drainage that transfers trapped gas en masse to the tank; and (3) non-rated electrical devices located inside the potential gas pocket.[2] Building on international guidance, we outline a tiered safety strategy for legacy and new systems covering design, operation, and inspection. Implementing these controls can eliminate hydrogen accumulation without compromising the corrosion resistance for which galvanized piping is valued.

D30 A Mechanical and Metallurgical Investigation of Cracks Within a Pipeline Repair

Bart B. Kemper, PE, Kemper Engineering Services, Baton Rouge, LA*

Learning Objectives: Cracks in a pipeline are a failure well understood in the field. The impact of a crack in a pipeline can range from lost product to a catastrophic explosion, leading to the development of codes and standards to address the issue. What has not been addressed well is when a crack occurs within a repaired section and leads to a loss of containment. This paper examines the techniques used to investigate a leak within a repair sleeve to include the Verification, Validation, and Uncertainty Quantification (VVUQ) to support the findings.

Impact Statement: Attendees will gain knowledge of the use of Finite Element Analysis (FEA) within the context of pipeline repair. There will be a focus on the VVUQ process and how VVUQ is part of the due diligence for applying engineering simulations, including in a forensic investigation.

Abstract Text: Pipelines are vital to national infrastructure. They transport our drinking water, our fuel supply, and other critical fluids. Almost all of our piping and pipeline falls under engineering codes and standards, setting the bar for what is acceptable design practice.[1] Once a crack gets to a critical length, the pressure will cause the crack to become unstable and rapidly propagate. Once started, the crack "unzips" the pipe until the leak rate drops the pressure, and resulting hoop stress, to a stable point.[2] An example of this is the 2010 pipeline failure in Marshall, MI.[3]

The Type A sleeve is also used for dents in pipelines. A dent that occurs when unpressurized, such as during construction, can flex outward while under pressure. This can set up local stresses and create a leak Dents are mitigated by squeeze-fitting a sleeve around the dent, then filling the dent with a hardening material like Bondo to prevent flexure.[4] The sleeve takes up the pressure-induced load, reducing the stress in the pipeline. The challenge is if a crack develops within the repair section. The reinforcing nature of the sleeve reducing pipeline hoop stress is not something accounted for in the codes and standards. This changes the critical values for crack length, which in turn changes the repair criteria.[5,6] Simply applying the code-specified procedures instead of understanding the theory can result in faulty forensic conclusions.[7] Using FEA is a valid way to address complex geometries. The FEA results verified the crack will not propagate due to the sleeve-pipewall interactions, leaving corrosion and pressure fluctuations as the remaining drivers.

Forensic engineering relies more on engineering codes and calculations, whereas forensic science tends to rely more on testing and experimentation.[8] However, FEA has its own challenges in ensuring the models and boundary conditions are valid for the physical problem and the questions being asked. The process of VVUQ provides the means to demonstrate the degree to which the model and its results can be trusted.[9,10] VVUQ has long been the standard of care for using simulations in engineering outside of codes and standards, such as novel spacecraft. VVUQ is increasingly used to support the use of FEA and other simulations for designs based on codes and standards.[11] This is also the standard of care to satisfy Federal Rules of Evidence 702 to demonstrate the expert's opinion, based on the FEA results, "reflects a reliable application of the principles and methods to the facts of the case."[12] Using VVUQ can be key to using code-driven assumptions such as geometry and materials as a starting point and then modeling the real-life deviations to determine the root cause in a manner that satisfies Rule 702.

E1 Forensic Nursing in India: The Importance of Introducing Forensic Nursing in an Indian Scenario

Sangeeta Shokeen, MSc, AIIMS Delhi, Delhi, India*

Learning Objectives: From a global health perspective, forensic nursing in India addresses violence, abuse, and trauma across cultures and borders. It will promote standardization of care of victims of violence and abuse and facilitate international collaboration, sharing best practices and research to address global health issues. It provides a holistic approach to violence abuse cases and will ultimately improve patient care by promoting justice and accountability. This presentation will familiarize attendess with the scope of forensic nursing practice in India by discussing challenges and opportunities.

Impact Statement: This presentation will impact the forensic science community via: (1) competence/ability—forensic nurses are competent in evidence collection and preservation in a way admissible in court. They know human body anatomy and physiology very deeply and it will help in forensic science investigations. They can provide trauma care to victims, do wound analysis, forensic assessment, and counselling effectively; (2) concerning their performance—forensic nurses promote streamlined evidence collection process, improve collaboration with law enforcement, forensic scientists, doctors, and other stakeholders, and enhance court testimony by providing expert testimony in court; and (3) patient stakeholders outcomes—forensic nurses improve patient care, increase access to justice, and enhance patient safety.

Abstract Text: The most modern idea in forensic services is forensic nursing, which has only lately been implemented in India. This idea unites resources from criminal justice, forensic science, and health care with a shared concern for the suffering of crime victims, accused people, and their families. Nursing professionals and nursing students are currently bursting with excitement about becoming forensic nurse examiners. Police organizations and forensic medical specialists will directly benefit from this advancement. With competent forensic nursing colleagues, forensic pathologists and Forensic Medical Examiners (FMEs) will be able to carry out their professional responsibilities more effectively. Direct services from forensic nursing specialists, who are specially trained to work with people who are traumatized by crime or who have been falsely accused of crimes, will be beneficial to society. Experts in building relationships with these particular clientele, forensic nurse examiners are able to effortlessly clarify legal needs and complexities. Better forensic nurses are those who can conduct sympathetic, in-language interviews with patients.

In India, the demand for forensic nursing services has been steadily increasing, driven by factors such as rising awareness of legal rights, changes in legislation, and heightened public consciousness about issues related to violence and victimization and, most importantly, the increased rate of crime creates opportunities for more forensic professionals in which the role of nurses are of great value due to their strong affinity toward wrong and illegally manipulated things. Additionally, they are the pillars of every health care institutions.

This abstract provides a brief overview of the topic, including its relevance, current status, challenges, and potential future directions, while also hinting at the key findings and recommendations of the paper.

E2 System-Wide Education for Adult Sexual Assault Response: Integrating Emergency and Inpatient Teams to Improve Care and Forensic Readiness

Jamie Ferrell, MBA, Memorial Hermann Health System, Katy, TX; Christie Dawson, MSN, Memorial Hermann Cypress Hospital, Cypress, TX; Amber Sneed, MD, Memorial Hermann, Houston, TX*

Learning Objectives: The goals of this presentation are to: (1) identify key components of a trauma-informed, multidisciplinary approach to adult sexual assault care across emergency and inpatient settings; (2) describe system-wide strategies to improve forensic readiness and reduce missed opportunities for evidence collection; and (3) apply practical tools for interdepartmental collaboration, documentation, and legal compliance in the care of sexual assault survivors.

Impact Statement: This initiative strengthens cross-disciplinary expertise in identifying, documenting, and legally supporting adult sexual assault survivors across both emergency and inpatient settings. By embedding forensic principles into the workflows of departments, including hospital medicine, labor and delivery, risk management, and social work, it ensures trauma-informed, legally sound care is delivered consistently throughout the continuum of care. The program enhances the forensic science community's ability to preserve evidence integrity, reduce documentation errors, and improve both survivor well-being and justice outcomes through unified, system-wide practices.

Abstract Text: Adult survivors of sexual assault often navigate fragmented health care systems that can delay care, jeopardize forensic evidence collection, and compromise both legal and health outcomes.[1,2] This presentation describes the design, implementation, and impact of a hospital-wide educational initiative aimed at aligning the multidisciplinary response to adult sexual assault across both emergency and inpatient care settings.

Spearheaded by Forensic Nursing Services leadership in collaboration with physician champions, the initiative was strongly supported by hospital administration, including the Chief Nursing Officer (CNO), Emergency Department (ED) medical director, ED clinical managers, risk management, hospitalist teams, social work, and labor and delivery. The program emphasizes trauma-informed principles, rapid forensic readiness, and system-level accountability to ensure survivors receive timely, respectful, and competent care at every point of entry—whether through the ED, inpatient units, or obstetric services.[3]

Key components include standardized training in trauma-informed triage, medical screening, forensic medical examination with appropriate documentation, chain-of-custody protocols, evidence-based medical management (including Sexually Transmitted Infection [STI] prophylaxis and emergency contraception), and sensitive, victim-centered communication.[4] The training also addresses interdepartmental handoffs, mandatory reporting, and the legal implications of documentation and forensic care. Special attention is given to inpatient staff—often overlooked in traditional forensic training—including hospitalists, labor and delivery nurses, risk managers, and case managers, ensuring readiness across the continuum of care.

This initiative addresses provider knowledge gaps and institutional barriers that contribute to missed forensic opportunities, re-traumatization, and legal vulnerabilities. By embedding forensic principles into both emergency and inpatient workflows, this program enhances clinical and forensic outcomes while fostering collaboration between healthcare and legal systems. Attendees will leave with strategies for system-wide implementation, tools to promote forensic readiness, and lessons learned from real-world experience.

E3 Female Genital Mutilation Among Asylum Seekers in Montpellier, France: A Medicolegal Estate and Literature Review

Quentin Rébillard, MD, Forensic Medicine Department, EPDFM, CHU of Montpellier, Montpellier University, Montpellier, France., Montpellier, Languedoc-Roussillon, France; Fanchon Herman, MSc, Clinical Research and Epidemiology Section, Montpellier University Hospital, Montpellier, France., Montpellier, Languedoc-Roussillon, France; Eric Baccino, MD, PhD, Forensic Medicine Department, EPDFM, CHU of Montpellier, Montpellier University, Montpellier, France., Montpellier, Languedoc-Roussillon, France; Laurent Martrille, MD, PhD, Forensic Medicine Department, EPDFM, CHU of Montpellier, Montpellier University, Montpellier, France., Montpellier, Languedoc-Roussillon, France; Stavroula Papadodima, MD, PhD, Department of Forensic Medicine and Toxicology, School of Medicine, National and Kapodistrian University of Athens, Greece., Athens, Attiki, Greece*

Learning Objectives: Attendees will learn to identify the profiles of affected women, contextualize their migratory paths, and recognize the value of clinical and psychosocial evaluations as essential tools in assessing trauma and guiding protection and care strategies. They will also learn the importance of a medicolegal approach in the examination of excision victims in order to provide an exhaustive evaluation.

Impact Statement: This study provides insight into the lived realities of the vulnerable population of asylum seekers and underlines the need for specialized and multidisciplinary care. Our study contributes to the development of tailored medicolegal approaches and long-term support strategies for victims of Female Genital Mutilation (FGM) in the context of asylum.

Abstract Text: FGM represents both a violation of the rights of women and girls and a significant global public health issue. By 2024, more than 200 million people were estimated to be living with the consequences of FGM. With increasing migration flows, this issue has expanded beyond the borders of Africa and the Middle East to become a widespread concern affecting women's health and rights internationally. It has also become a growing basis for asylum claims, with a notable rise in cases.

We conducted a retrospective study of all cases examined at the legal medicine unit of Montpellier University Hospital. We analyzed 150 medicolegal reports of women examined between 2014 and 2023 who declared having undergone FGM or having fled their country to avoid it.

Guinean nationality was the most represented among the sample (40.27%), followed by Nigerian (21.48%) and Ivorian women (17.45%). Guinea also had the highest proportion of completed excisions, while Nigerian and Ivorian women were more often able to escape prior to mutilation. The most commonly observed FGM type was Type 2b according to the World Health Organization (WHO) anatomical classification, involving lesions of the labia minora and clitoris (56.52%), followed by Type 1b, involving the clitoral glans and prepuce (16.52%). Most women reported having undergone FGM before the age of 13. Among the women examined, 46.85% presented with somatic sequelae and 82.46% reported psychological consequences. Our data, which are concordant with the data of other Europeans countries but also with American data, also reveal an increasing number of consultations over time, rising from 4 cases in 2014 to 33 in 2023.

FGM remains a deeply entrenched issue that intersects with social, cultural, medical, and legal domains. Through this nine-year analysis, we were able to outline the profile of female asylum seekers examined at UMJ Montpellier who were affected by FGM or who fled in order to avoid it.

This study reaffirms the importance of clinical observation and medicolegal evaluation as foundational tools in understanding trauma and providing care to vulnerable populations.[1-6]

E5 The Shadow of Gynecological Violence in the Health Management of Survivors of Sexual Assault

Sarah Gino, MD, Department of Health Sciences, University of Eastern Piedmont, Novara, Piemonte, Italy; Elena Rubini, PhD, CRIMEDIM, Center for Research and Training in Disaster Medicine, Humanitarian Aid and Global Health, University of Eastern Piedmont, Novara, Piemonte, Italy*

Learning Objectives: Through this presentation, participants will learn about the risk of gynecological violence during clinical and forensic medical examinations for women who have survived sexual abuse.

Impact Statement: The forensic science community will be informed about the actions to be taken during the medical and forensic care of female victims of sexual violence, with the aim of avoiding any form of gynecological violence. In particular, it is necessary to:

- Create a "safe" area for the reception and care of patients, to ensure privacy
- Have dedicated and qualified health care personnel, ideally female
- Avoid multiple clinical and forensic examinations, ensuring that they are guided by the survivor's account
- Perform head-to-toe examinations without full undressing of the patient
- Consider consent as a therapeutic and ethical choice to restore dignity and respect

Abstract Text: Sexual violence has been defined as "any sexual act, attempt to obtain a sexual act, or other act directed against a person's sexuality using coercion, by any person regardless of their relationship to the victim, in any setting."[1] It constitutes a violation of the sexual and reproductive health and rights of individuals and has a profound impact on the victim's health, causing morbidity, disability, and mortality in the short and long term.[2,3] This complex trauma requires a multidisciplinary health care approach, as the needs of victims go beyond clinical and psychological care and include forensic aspects for legal support and the protection of their rights.[4,5]

Emergency department staff are often the first point of contact and have a dual responsibility: (1) to provide essential physical and psychological care, and (2) to manage forensic procedures by documenting the event, performing clinical-forensic examinations, recording injuries, and collecting biological evidence. During this medical process, patients are at risk of obstetrical-gynecological violence, defined as "any act perceived as sexist or disrespectful of human dignity during gynecological examinations."[6] This includes violations of privacy, derogatory behavior, misogynistic comments, and inadequate information about treatments or health care pathways.

Health care facilities must establish clear protocols for gynecological examinations and procedures for survivors of sexual violence. Despite difficult working conditions, it is essential to promote empathy and trust between personnel and victims. It is essential to minimize the presence of non-essential staff and create a safe environment enabling the survivor to express herself without fear of being judged and to ensure her dignity and privacy are respected. Health care facilities should have dedicated staff with the time and capacity to fully support survivors.

Another key point is the importance of training for health care personnel to avoid subjecting survivors to multiple medical and forensic examinations. The purpose of the examination is to assess the woman's state of health and document the injuries and their consequences. Clinical and forensic aspects must be assessed simultaneously, based on the patient's description of the violence, thus avoiding further violation of the body. Medical staff should conduct a thorough head-to-toe examination, ensuring that the patient is never fully undressed, following World Health Organization (WHO) recommendations, to minimize discomfort and protect the patient's dignity. They should also be able to interpret non-verbal cues and refrain from judging the survivor.

Obtaining consent for clinical-forensic interventions is particularly important for victims of sexual violence. Informed consent for any diagnostic or therapeutic treatment is a legal requirement. In the context of violence, consent becomes not only a duty but also a therapeutic and ethical choice to restore the integrity, dignity, and respect of a violated body and to avoid gynecological violence.

In conclusion, for sexually abused women, the lack of a dedicated path in health facilities and of decision-making power, not having the possibility to choose the gender of the health personnel managing their case, and the possible judgment expressed by health staff through verbal or non-verbal language can constitute a further form of violence.

E6 Preliminary Findings: Focus Group Insights and Perspectives of Forensic Nurses (SANE) Attending STARS SANE Education

Jacqueline C. Callari Robinson, RN, University of Wisconsin, Vineyard Haven, MA*

Learning Objectives: After participating in this activity, attendees will report increased knowledge: (1) about nurses' motivation and possible sustainability for nurses who attend culturally focused Sexual Assault Nurse Examiner (SANE) training; (2) why SANE training programs should include elicit expectations of future SANE nurses so their training needs are met; and (3) barriers nurses face in developing and sustaining forensic nursing (SANE) programs and gaps in SANE nursing care and training.

Impact Statement: There is an urgent need to increase the number of trained and certified SANEs in both rural and urban communities. The purpose of our study was to understand future forensic nurses' (SANE) intentions and attitudes after participating in our Successful Training and Retention of SANEs (STARS) program at the University of Wisconsin, Milwaukee (UWM).

Abstract Text: The purpose of this 30-minute presentation is to share preliminary insights in the understanding of future forensic nurse' (SANE) intentions and attitudes when seeking out and attending the STARS training at the UWM. Through focus group interviews, we sought to gather qualitative insights, in-depth opinions, perceptions, and experiences from nurses attending our training. As scholars, our intention is to uncover underlying motivations, identify common themes, and explore different perspectives through open discussion and interaction with nurses who attended the STARS training. Another goal of the focus group interviews is to continuously reflect and generate new ideas to improve our curriculum.

The STARS program provides specialized trauma-informed training required to adequately address survivors' holistic health care needs. Additionally, our STARs program includes specific content about the care of underserved populations that disproportionately experience violence but also encounter the greatest barriers to health care. The UWM ongoing work with underserved populations (including Black, Indigenous, and People Of Color [BIPOC], and lesbian, gay, bisexual, transgender, two-spirit, and queer persons [LGBTQ/Two Spirit]), and review of the literature, has unveiled both the lack of available SANEs and the inability of our partner health care systems to effectively meet the current health care needs of Sexual Assault (SA) and Domestic Violence (DV) survivors. We provide training for forensic care nursing in an academic setting at the UWM School of Nursing (SON), in partnership with culturally specific health care and social service agencies serving SA and DV survivors representing underserved populations.

Results identified motivations and themes of why nurses attended the STARS training. [1-3]

E7 Silent Indicators: STI Positivity in Prepubescent Children With Minimal Disclosure During Sexual Assault/ Abuse Evaluations

Sally Henin, MD, Memorial Hermann Health System, Houston, TX; Jamie Ferrell, MBA, Memorial Hermann Health System, Katy, TX*

Learning Objectives: The goals of this presentation are to: (1) analyze the prevalence and types of Sexually Transmitted Infections (STIs) identified in prepubescent children undergoing sexual abuse evaluations, with a focus on cases involving minimal or no disclosure; (2) justify the role of routine, site-specific STI testing in pediatric medical forensic examinations, regardless of verbal disclosure or observable physical symptoms; (3) evaluate the implications of STI findings in non-disclosing or minimally symptomatic children for purposes of documentation, mandated reporting, and multidisciplinary team coordination; and (4) apply current research and guidelines to update clinical protocols and enhance decision-making in the evaluation and care of prepubescent children suspected of sexual abuse

Impact Statement: This presentation challenges assumptions about the necessity of verbal disclosure or physical findings in pediatric sexual abuse evaluations by highlighting cases of STI positivity in prepubescent children with minimal or no disclosure. The findings underscore the critical role forensic nurses play in recognizing silent indicators of abuse, advocating for comprehensive testing, and ensuring appropriate medical and legal responses. This work advances the practice of forensic nursing by reinforcing trauma-informed, evidence-based approaches that prioritize the child's well-being even when the history is limited or unclear.

Abstract Text: STIs in prepubescent children are rare in the general pediatric population but are considered highly specific indicators of sexual abuse when perinatal and non-abuse-related exposures have been excluded, although guidelines recommend *considering* STI testing in preverbal children and children who cannot verbalize details of the assault.[1,2] STI testing practices vary based on caregiver concerns or physical findings. This reliance on subjective or external factors may lead to under-diagnosis in children who are asymptomatic or unable to verbalize abuse due to developmental stage, trauma, or fear.[3]

A review of the literature supports consideration of universal testing in children being evaluated for abuse. One study shows of 536 children ages 0-13 years where STI testing was performed, *C. trachomatis* was detected in 15 (3.1%), *N. gonorrhoeae* in 16 (3.3%), and *T. vaginalis* was identified in 5 (5.9%).[4] Another study of 675 children under 14 revealed that limiting testing to only sites disclosed would have missed infections. Of the 11 patients who tested positive for gonorrhea and/or chlamydia, 9 had anatomical sites of infection that did not match their reported contact history. Notably, none of the four patients with rectal-only infections disclosed a history of anal contact. Overall, five infections would have gone undiagnosed if testing had been restricted to disclosed sites of sexual contact.[5] Yet another study of children 0-17 years of age shows that of 1,319 patients tested, 120 were found to have at least one infection. *Chlamydia trachomatis* was identified in 104 patients and *Neisseria gonorrhoeae* in 33. Fifty-one patients had positive anal tests and 24 had positive oral tests. Most patients with a positive anal (59%) or oral (77%) test did not report genital contact with that site, underscoring limitations of relying on disclosure alone to guide testing.[6]

This presentation examines routine STI testing and outcomes among prepubescent children evaluated for concerns of sexual abuse at a large urban pediatric emergency department with a pediatric forensic nursing program. The analysis focused on patients with minimal or no verbal disclosure and non-specific or absent physical findings. Notably, a subset of patients tested positive for STIs on urine, rectal, and/or pharyngeal specimens despite lacking detailed disclosures or definitive anogenital findings. These results highlight the need for continued emphasis on *routine* STI screening in prepubescent children evaluated for sexual abuse, regardless of disclosure status or physical symptoms.

These findings have direct implications for forensic nurses who play a critical role in conducting trauma-informed, evidence-based evaluations, ensuring thorough documentation, and advocating for appropriate medical and psychosocial care. The presence of "silent indicators," such as laboratory-confirmed STIs in non-disclosing children, reinforces the importance of a proactive, standardized approach to testing and follow-up. This presentation will equip forensic nursing professionals with current evidence to support more inclusive STI screening practices and foster stronger multidisciplinary collaboration. It underscores the potential for missed diagnoses in this vulnerable population and highlights the need for protocols that prioritize the child's well-being with routine STI testing at all three anatomical sites, regardless of verbal disclosure or exam findings.

E8 Victims' Perspectives on Optional Forensic Testing of Non-Report Sexual Assault Kits

Rachael Goodman-Williams, PhD, American University, Washington DC,*

Learning Objectives: Attendees will learn the range and relative frequency of forensic testing options for non-report sexual assault kits in the United States. They will also learn about perspectives on these options shared by sexual assault victims who utilized alternative reporting options after a sexual assault. Finally, they will learn about considerations relevant to the expansion of such options in their communities.

Impact Statement: Forensic testing options for non-report sexual assault kits are expanding across the United States. It is important that forensic science professionals have an understanding of what this option entails, its potential benefits to survivors, and its potential drawbacks as well. Changes to this policy should be made with victims' voices included in the conversation, and this presentation contributes to this need by sharing results from qualitative interviews with sexual assault victims who have engaged with alternative reporting options.

Abstract Text: The non-report sexual assault kit option has been widely available since the Violence Against Women Act Reauthorization of 2005. Though there is variation from state to state on what this option entails, it generally offers victims the opportunity to have a sexual assault kit collected and held anonymously for a predetermined length of time, during which the victim may decide to "convert" their kit by releasing it to police for potential forensic testing and investigation.[1] Rates of kit conversion remain low, however, with the few studies that have documented rates of kit conversion typically finding rates of 5%–10%.[2,3]

Some states have expanded their alternative reporting options to provide victims the option of releasing their sexual assault kit for forensic testing prior to making a police report. This presentation shares findings from interviews conducted with sexual assault victims who had a non-report sexual assault kit collected or utilized other alternative reporting options, specifically focusing on their opinions regarding optional forensic testing of sexual assault kits prior to police reporting. Overall, opinions were supportive of optional forensic testing and reasons for this support will be discussed. The presenter will also highlight areas of concern and consideration for communities looking to expand the forensic testing options available to non-reporting victims.

E9 A Patient-Centered Forensic Nursing Model of Care for Victims of Law Enforcement Violence

Maija Anderson, DNP, Morgan State University, Baltimore, MD; Jacqueline C. Callari Robinson, RN, University of Wisconsin, Vineyard Haven, MA; Jocelyn C. Anderson, PhD, UAMS, Little Rock, AR; Erin N. Pollitt, MS, District of Columbia Forensic Nurse Examiners, Millersville, MD*

Learning Objectives: This presentation will encompass:
- Law Enforcement Violence (LEV) = Public Health Crisis (American Public Health Association, 2018)
- Disproportionately affects Black, Indigenous, communities of color and lower socioeconomic status (Edwards et al, 2019)
- Victims lack consistent, trauma-informed care
- Gaps in forensic protocols for LEV cases

Impact Statement: According to the American Association of Public Health (2018,) law enforcement violence is a public health issue that is structurally mediated by the current systems and policies resulting in the adverse physical and physiological health outcomes of marginalized communities and populations.

Abstract Text: Public debate and concern of the use of police force are not recent to the American conscience with Law Enforcement Violence (LEV) being recognized as a crucial public health issue, with the potential for poor health outcomes.[1] The victimization of residents of neighborhoods with high rates of law enforcement use of force are at increased risk for diabetes and obesity.[2] Besides the obvious, injury and death, LEV affects individuals and communities' ability to achieve short- and long-term positive health outcomes and exacerbates physical and mental health concerns in already marginalized populations.[3-5]

The role of forensic nurses in caring for victims of violence is a crucial one that affords them access to victims of LEV during times of crisis. Forensic nurses provide direct patient care to individuals, families, communities, and systems that have experienced violence or trauma.[6] Restorative justice principles are the underpinnings of this care. Attitudes, beliefs, and knowledge about police violence toward civilians and acceptance of this form of violence can shape the public response, consequently having a negative influence on victims' physical, emotional, and psychological health.

Forensic nurses advocate for health care justice by providing leadership and support in changing attitudes, policies, and health practices to promote healing to victims of violence. For survivors of violence, positive intervention with police and health care could make the difference between life and death.[7] Forensic nursing care of victims of police violence should be addressed at the local, state, and federal level. Systematic changes need to be made in access to forensic nursing care for victims of this type of violence. We are proposing a Patient-Centered Forensic Nursing Model for the victims and patients who experience police violence. We are interested in the exploration of how restorative justice partnership with the criminal justice system in the provision of the Patient Centered Forensic Nursing Care Model for the Healthcare Response will support equity in health care and its impact on victim/patient and community outcomes.

E10 Smarter Than the Science: The History of Service Dogs

Janean M. Fossum, BS, Forensic Consultant, Eugene, OR*

Learning Objectives: After attending this presentation, attendees will understand: (1) the history of service dogs , (2) how service dogs are utilized in forensics, and (3) the importance of service dogs for the law enforcement and forensic work

Impact Statement: After this session, attendees will have a better understanding of the history of service dogs, from our K9 officer to serving individuals with disabilities, how they are utilized in our courtrooms and hospitals and for emotional support for Post-Traumatic Stress Disorder (PTSD) survivors.

Abstract Text: The use of trained service dogs has a long and diverse history and were initially utilized in the military as guard and surveillance dogs. The obvious benefits provided by the dogs were expanded on and fine-tuned to suit the service needed. These dogs, trained for many different tasks depending on the circumstances and partnering with a trained handler, are used for bomb sniffing, a variety of rescue tasks, search, and patrolling.

Service dogs for those with physical, cognitive, or emotional disabilities may be the most visible service seen. Dogs are utilized for safely leading the blind and deaf in their daily lives. Service dogs are also trained to sense seizures in persons and detect abnormal blood glucose, among other medical conditions such as cancer detection.

Most recently and greatly impacting the forensic practice are the service dogs trained to provide protection and comfort to those seriously traumatized. The Post-Traumatic Stress Disorder (PTSD) dog provide service to a wide spectrum from young children of trauma and abuse to men and women coming home victimized by war. For those traumatized, whether it is an encounter in the courtroom, a visit to the child advocacy center, or living in the home with the traumatized person, the impact is always positive and has tremendous results.

After attending this presentation, attendees will understand the principal uses of service dogs, including a historical review, distinguishing features that allow them superior abilities, and the multiple services they provide in forensic practice.

E11 Mixed Method Assessment of Trauma-Informed Care Decision-Making and Incorporation Into Forensic Nursing Practice

Laurie Charles, DNP, Texas A&M University, Center of Excellence in Forensic Nursing, Bryan, TX*

Learning Objectives: After this presentation, attendees will be able to: (1) describe six principles of trauma-informed care, (2) recall correlations between years of forensic nursing experience and implementation of trauma-informed care, and (3) express ways to address barriers to providing trauma-informed care.

Impact Statement: This presentation highlights the importance of trauma-informed care practices when treating patients who report experiencing sexual assault and how forensic nurses incorporate said practices into their clinical practice.

Abstract Text: Sexual violence may create profound and enduring health consequences, necessitating trauma-informed, person-centered care by specialized health care providers such as forensic nurses. This Doctor of Nursing Practice (DNP) project evaluated the effectiveness of a two-part continuing education program—an asynchronous classroom Sexual Assault Nurse Examiner (SANE) education course followed by a hands-on simulation—designed to prepare novice forensic nurses to integrate Trauma-Informed Care (TIC) into their clinical practice.

Using a mixed-methods approach, the author assessed self-reported knowledge, attitudes, competence, practice, and perceived barriers related to TIC through the *Trauma-Informed Care Provider Survey – Version 2.01*, followed by sampling individual virtual interviews. The sample (*n*=98) consisted of registered nurses and Advanced Practice Registered Nurses (APRNs) from diverse practice settings. The survey findings indicated moderate to high levels of TIC knowledge and opinions. Increased TIC competence and reduced perceived care barriers correlated with greater forensic experience and numbers of patient interactions. Interview themes aligned with the Substance Abuse and Mental Health Services Administration (SAMHSA) six principles of TIC2, emphasizing the importance of consent, trust, empowerment, and language sensitivity. This project underscores the importance of classroom education followed by structured, experiential learning simulations to equip forensic nurses for ethical, effective care of individuals affected by sexual violence.

E12 The Intersection and Implications of Strangulation in Consensual Sexual Encounters and Sexual Assault Cases

Alyssa Lark, BSN, University of Utah, Hanover, MD; Julie L. Valentine, PhD, University of Utah, Hanover, MD*

Learning Objectives: At the end of this presentation learners will be able to: (1) define sexual strangulation and explain its increasing prevalence in consensual sexual encounters, pornography, and sexual assault cases, (2) identify the health risks associated with non-fatal strangulation, including both acute and long-term physical and psychological outcomes, (3) evaluate how misinformation and normalization of sexual strangulation in media and pornography contribute to public health concerns and legal complexities, (4) discuss the legal ambiguity surrounding consent to strangulation during sexual activity and its implications for sexual assault and Intimate Partner Violence (IPV) investigations, and (5) analyze the intersection of strangulation in both consensual and non-consensual contexts and its impact on survivors and legal proceedings.

Impact Statement: This literature review and forthcoming chart analysis provide a timely examination of the rising prevalence and normalization of sexual strangulation, particularly within consensual sexual encounters and portrayals in pornography. The study underscores the severe health consequences and legal challenges posed by non-fatal strangulation, which is increasingly reported by women as occurring without prior consent. By highlighting the blurred lines between consent and harm, this research contributes critical knowledge to responders across health care, forensic, and legal systems. It also identifies urgent gaps in public understanding, professional training, and systemic response—ultimately aiming to strengthen protections for survivors of sexual violence and inform future public health and policy interventions.

Background: Under the cloak of colloquial pseudonyms such as breath-play, sexual choking, and erotic asphyxiation, rates of strangulation during sex have risen significantly in recent years worldwide in multiple developed countries.[1] Sexual strangulation is often advertised across social media platforms as harmless and in pornography as desirable. Misinformation surrounding sexual strangulation has contributed to adverse health outcomes, including fatalities. Normalization of sexual strangulation has further complicated the legal response to sexual assault, IPV, and homicide cases.[2] This literature review addresses the rise and normalization of non-fatal strangulation during sex and pornography, the health and legal implications, and the question of consent to strangulation. The intersection of strangulation in consensual sexual encounters and in sexual assault cases is also explored and discussed.

Methods: A literature review was conducted, and articles were retrieved from CINAHL and PubMed to determine the prevalence of non-fatal strangulation during consensual sexual encounters and in pornography, the health and legal implications, and the uncertainty regarding consent to strangulation. Additionally, a retrospective chart review will be conducted to determine rates of strangulation in reported sexual assault cases in a Mountain West area of the United States with data analysis completed by October 2025.

Results: Though sexual strangulation purportedly occurs most often in a consensual context, women report experiencing strangulation without prior consent.[1] Researchers have found concerning associations with mental health effects after studying the specific context of sexual strangulation. Strangulation experienced in other contexts, such as IPV, has been established to cause devastating health outcomes: paralysis, acute and chronic fear, suicidality, post-traumatic stress disorder, and cognitive deficits.[2] Sexual strangulation is currently the most common form of strangulation, and thus, the health risks present a serious public health problem.

Conclusions: This review elucidates key findings related to the intersection of strangulation in consensual sexual encounters and in sexual assault cases, providing responders to gender-based violence critical information regarding this increasingly common problem. The review also provides areas for improvement in the response to gender-based violence, specifically when strangulation is involved.

E13 The Role of Medical Records in Cases of Medical and Nursing Liability

Luca Calanna, MD, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Matteo Antonio Sacco, MD*, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Alessandro Pasquale Tarallo, MD*, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Maria Cristina Verrina, MD, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Aurora Princi, MD, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Gioele Grimaldi, MD, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Maria Daniela Monterossi, MD, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Mariachiara Militi, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Isabella Aquila, MD, PhD*, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy*

Learning Objectives: After attending this presentation, attendees will clearly understand the critical role that accurate and comprehensive medical records play in the forensic evaluation of alleged cases of health care malpractice.

Impact Statement: This presentation will impact the forensic science community by demonstrating how clinical documentation serves as an indispensable tool in reconstructing diagnostic and therapeutic processes and in determining the appropriateness of health care conduct in legal settings.

Introduction: Health care malpractice remains a pressing concern in the Italian health care system, with a notable rise in complaints over the past decade that has contributed to significant financial and professional consequences. Within this context, the medical record—defined under Italian law as a public act documenting patient care—plays a pivotal role in medicolegal investigations concerning professional liability. The enactment of the Gelli-Bianco Law reinforced the legal and practical relevance of clinical documentation by establishing that health care professionals' liability must also be assessed based on adherence to good clinical practices and to evidence-based guidelines. While guidelines in the United States are often admitted as procedural evidence in court, in Italy, they function more as a legal benchmark for evaluating the qualification and appropriateness of clinical decisions. The quality of the medical record is frequently the decisive factor in malpractice cases, representing the principal source of information for reconstructing the diagnostic and therapeutic pathway and for judging the clinical reasoning behind medical choices.

Objective: This study aims to analyze the correlation between the quality of clinical documentation and the outcomes of malpractice claims examined at the Institute of Legal Medicine of the University "Magna Graecia" of Catanzaro, proposing practical strategies to improve documentation and reduce litigation.

Materials and Methods: A retrospective monocentric study was carried out using a standardized assessment form specifically developed for this purpose. The criteria were based on national and international definitions of high-quality documentation. The evaluation considered the completeness of records, including the presence of all mandatory documents, traceability of clinical decisions, comprehensive patient history, proper registration of diagnostic exams and administered therapies. It also examined the clinical appropriateness of the documented care, assessing adherence to clinical guidelines, justification of therapeutic strategies, informed consent practices, management of adverse events, and continuity of care. Finally, it evaluated regulatory compliance, such as timely entries, the presence of required signatures and stamps, legibility, legally compliant corrections, and proper archiving.

Results and Discussion: The study revealed significant weaknesses in clinical documentation in most of the analyzed cases. Key deficiencies included inadequate or missing informed consent, poor documentation of clinical decision-making, and insufficient recording of adverse events. Among these, the absence or inadequacy of informed consent emerged as the strongest predictor of negative medicolegal outcomes, followed by the inability to trace diagnostic or therapeutic decisions, inappropriate handling of complications, and incomplete documentation of test results.

Conclusions: The findings highlight the decisive importance of clinical documentation quality in medicolegal evaluations of health care malpractice. Improving record-keeping practices is essential not only for legal protection but also for enhancing the overall quality and safety of health care. Implementation of standardized documentation protocols, continued professional training, routine clinical audits, and strengthening of digital record systems are recommended strategies to achieve this goal.

E14 The Science of Strangulation: What We Know, What We Assume, and What Still Isn't Proven

Tara Godoy, MBA, Godoy Medical Forensics, Grants Pass, OR; Merriam Young, MS, RN, Godoy Medical Forensics, Inc., Santa Cruz, CA*

Learning Objectives: The goals of this presentation are to: (1) identify the primary scientific studies that form the basis of common expert testimony in strangulation cases, (2) critically assess the strength, limitations, and applicability of the existing research on timing, loss of consciousness, and injury patterns, (3) explain the gap between scientific evidence and commonly accepted assumptions in forensic testimony regarding strangulation, and (4) discuss how uncertainties in the literature should be ethically and accurately communicated in court.

Impact Statement: This presentation will challenge forensic professionals to critically evaluate the scientific foundations of commonly accepted opinions in strangulation cases. By dissecting the limitations and variability in existing research, attendees will be better equipped to distinguish between evidence-based conclusions and unsupported assumptions. This will enhance both the scientific integrity of expert testimony and the pursuit of just outcomes in the legal system.

Abstract Text: Strangulation is increasingly recognized in both clinical and legal contexts as a serious and potentially lethal form of interpersonal violence, yet many commonly accepted forensic claims about its effects lack solid grounding in scientific literature. This presentation critically examines the foundational science used by forensic experts to explain physiological responses to strangulation—such as time to unconsciousness, presence or absence of injury, mechanisms of death, and long-term neuropsychological impact.

Drawing from a broad review of the literature, including case studies, experimental data, and retrospective analyses, this session will explore the extent to which expert testimony is supported—or contradicted—by actual scientific evidence. Attendees will be guided through key concepts related to hypoxic-ischemic brain injury, vascular occlusion, capillary rupture, and the neurological and psychological outcomes associated with non-fatal strangulation. Attention will also be given to common gaps or inconsistencies in current testimony practices, particularly when experts extrapolate from limited or outdated studies.

The goal of this presentation is not to invalidate expert testimony, but to encourage a more critical, evidence-based approach to forming and communicating opinions in court. Special emphasis will be placed on distinguishing between what is well-supported, what is theoretically plausible but not empirically established, and what falls outside the boundaries of defensible forensic opinion.

This session is appropriate for forensic nurses, physicians, psychologists, legal professionals, and anyone involved in the evaluation or litigation of strangulation-related cases. Participants will leave with a more nuanced understanding of the science behind strangulation and a framework for applying this knowledge responsibly in forensic contexts.

Strangulation; Expert Testimony; Forensic Science

E15 A Forensic Examination of Paper Medical Records

Linton Aphzal Mohammed, PhD, Forensic Science Consultants, Inc., Poway, CA*

Learning Objectives: This presentation will introduce forensic nurses to methods and techniques used by Forensic Document Examiners (FDEs) in the exemption of paper medical records. The authenticity of signatures and handwriting, alterations, and the sequence of entries in a medical record are some examples of the questioned posed to FDEs. This presentation will provide suggestions to forensic nurses on how to preserve medical records and reduce the chances of alterations.

Impact Statement: This presentation aims to provide forensic nurses with information on the preparation, care, and preservation of medical records. Good record management can reduce the possibilities of file manipulation, which, if not detected, can lead to unjust outcomes.

Abstract Text: FDEs conduct examinations of documents to determine their authenticity, source, age, or content. FDEs examine a wide gamut of casework ranging from signatures to complex multi-faceted cases that require the use of several examination techniques. Medical records examinations are usually multi-faceted.

The examination of paper medical records can include the examination of signatures and handwriting of patients and medical staff to determine who signed a record, or who inserted an entry. The other question that is asked is when the signature or handwritten entry was put in the record. Other examinations involve the sequencing of entries, ink comparisons, and indented impressions to determine whether the file has been altered by adding or removing entries, or whether there has been page substitution(s).

While the examination may be about a certain entry or day in a record, the FDE usually has to examine the entire file, including the front and back covers. While limited examinations can be conducted with copies of the file, the original file should be examined ideally.

The testing is mainly considered to be non-destructive. However, dating of inks and paper does involve chemical testing which required removal of ink and paper samples. The entries are usually still legible afterwards, but it is important that high quality copies be made of the record before chemical testing is conducted. Ink and paper testing is conducted by specialists in these fields. FDEs do not normally conduct these examinations.

This presentation will walk the attendees through the process by which a paper medical record is examined, and the instrumentation and techniques that are required. Answers that the FDE can and cannot provide will be discussed. It is important to note that although there may be alterations in the record, these may not be evidence of malpractice, as there may be a perfectly sound explanation for why and when the changes were made. Precautions that Forensic Nurses should take will be suggested.[1-3]

E16 Exploring the Use of Positive Deviance in Forensic Nursing

Jodie C. Gary, PhD, Texas A&M University, Bryan, TX; Laurie Charles, DNP, Texas A&M University, Center of Excellence in Forensic Nursing, Bryan, TX*

Learning Objectives: By attending this presentation, attendees will be able to define and contextualize Positive Deviance (PD) within nursing practice and consider implications for forensic nursing practice.

Impact Statement: The presentation will impact the forensic science community by identifying implications of PD findings for forensic nursing policy and practice. This includes how exceptional care strategies can inform improvements in patient outcomes and system-level changes.

Introduction and Background: PD is an "intentional act of breaking rules in order to serve the greater good".[1] PD in nursing is intentional and honorable behavior that departs or differs from an established norm and contains elements of innovation, creativity, and/or adaptability; it also involves risk for the nurse.[1] Nurses who use PD practice differently and more effectively to provide patient-centered care.[2] Although professional nursing standards guide patient care and lay the groundwork for best practices, they are not enough to guide many nursing decisions that involve multiple levels of uncertainty and risk in their practice; therefore, nurses may need to respond resourcefully to meet immediate patient needs and may employ the concept of PD to help guide those actions.[1] Forensic Nurses (FNs) may experience role conflict when lines are blurred between "advocacy" and "caring."[3] There is a lack of understanding of behaviors and strategies used by FNs when barriers to providing person-centered care are encountered.

We hypothesized that FNs use PD behaviors and strategies to provide person-centered, trauma-informed care and may be working around ineffective or outdated policies.

Purpose: A three-phase project seeks to understand if, and what, PD behaviors and strategies are used by FNs. Next steps would immediately consider further investigation into policy implications and lessons learned while addressing these patient care issues that led to PD behaviors and strategies. This presentation will report phase one.

Methods: The project explores the concept of PD among FNs in three phases. Phase 1 conducts a narrative literature review to synthesize evidence regarding the use of the PD in the delivery of forensic nursing care. In consultation with a medical librarian, a pragmatic approach worked forward from Gary's definition of PD in nursing and backward from contemporary sources of information extracted from published health, education, and nursing literature.[1,2] A narrative review allows inclusion of a wide variety of studies to provide an overall summary, with interpretation and critique.[4] Narrative reviews also provide insights into advancing the field or current evidence viewed from different or unusual perspectives.[5] Phase 1 will yield FN literature related to PD concepts and aid in the development of open-ended survey questions for FNs to provide accounts of care experiences.

Results: The narrative review (Phase 1) is in progress and results will be complete for this presentation.

Impact/Outcomes: This project is vital to advancing nursing science as lifelong health sequelae may be extensive for those who experience sexual assault.[6] It is critical that persons who experience sexual assault are treated by educated FNs to improve patient outcomes and possibly prevent negative health sequelae. A national nursing and FN shortage means that many Americans, and more specifically Texans, do not have local access to specialized FNs care.[7-9] Care by FNs improves patient outcomes.[10,11] This inquiry aims to identify and amplify assets to enhance quality, reduce errors, and improve patient outcomes by identifying lessons from those who exhibit exceptional practices and implement successful strategies in their practice.[12]

E17 Following in the Footsteps of Virginia Lynch: The Attitudes of Israeli Emergency Department Nurses Toward the Role of Forensic Nurses

Orli Grinstein-Cohen, PhD, Ben-Gurion University of the Negev, Beer Sheva South District, HaDarom, Israel; Sivan Cukerman-Hgag,, MN, Ben-Gurion University of the Negev, Beer Sheva South District, HaDarom, Israel*

Learning Objectives: Forensic nursing is not yet a specialization in Israeli Emergency Departments (EDs). We studied ED nurses' frequency of performing forensic procedures and the importance they attributed to forensic procedures before the specialization is introduced to the ED.

Impact Statement: Israel is about to introduce forensic nursing as a specialization. This lecture shows the frequency of performing forensic procedures in the ED and staff attitudes to forensic nursing prior to the introduction of the specialization

Background: Forensic nurses provide specialized nursing care to diverse groups affected by criminal incidents (victims, witnesses, suspects, and perpetrators), their families, and communities impacted globally by trauma and violence. Examples of forensic patients include individuals involved in road accidents, child/elder abuse or neglect, domestic violence, sexual assaults, gunshot and sharp instrument injuries, and any injuries or deaths associated with legal implications. Training programs for forensic nursing exist in over 30 countries worldwide (including Iran), yet not in Israel. Nurses working in EDs frequently encounter potential forensic patients daily, dealing regularly with trauma and violence victims.

Objective: To describe the current situation in Israeli EDs, examining the frequency of forensic actions performed by nursing staff, their perceived importance, and related socio-demographic and professional factors.

Methods: A cross-sectional descriptive study sampled 438 nurses working in EDs across Israel. Using an online questionnaire, participants provided demographic and professional data, frequency of performing forensic procedures, and the perceived importance of performing these procedures in their daily practice. Data were analyzed using statistical models, Pearson correlations, independent-samples t-tests, one-way Analysis of Variance (ANOVA), and hierarchical linear regression analysis using IBM SPSS Statistics version 29 with the PROCESS add-on (Model 1; Hayes, 2022) to explore interactions. The study's hypotheses were tested at a two-tailed significance level of 5%.

Results: The study included 438 ED nurses across Israel, aged 23 to 76 years (M = 39.66, SD = 8.83), with an average professional experience of 10.75 years (SD = 39.66, Range = 0.4 - 43). Results indicated a relatively low frequency of performing forensic procedures (M = 2.26, SD = 0.54). However, the perceived importance of performing these procedures was relatively high (M = 4.01, SD = 0.64). Significant relationships were found between socio-demographic characteristics (age and educational level) and the perceived importance, with older nurses and those holding master's degrees attributing higher importance compared to younger nurses and those with registered nurse diplomas or bachelor's degrees. Professional characteristics, including years of experience and willingness to receive forensic nursing training, were also significantly related to perceived importance; more experienced nurses and those willing to undertake forensic nursing training reported higher importance ratings. The hierarchical linear regression model showed that educational level, willingness to receive forensic nursing training, and frequency of procedure performance significantly contributed uniquely to the explained variance. Furthermore, the frequency of performing forensic procedures moderated the relationship between the willingness to undergo forensic nursing training and the perceived importance of performing these procedures.

Discussion and Recommendations: The low frequency of forensic actions likely results from limited knowledge, training, protocols, and specialized equipment. However, high perceived importance may be due to increasing trauma and violence in Israel and recent critical events. These findings should guide policymakers in establishing forensic nursing roles, developing appropriate training programs during nursing education and practice, and expanding research to representative samples.

E18 Violence Against Health Care Workers in a University Referral Hospital in Northwestern Italy

Federica Collini, MD, University of Eastern Piedmont, Milan, Lombardia, Italy; Silvia Rampi, MN, AOU Maggiore della Carità di Novara, Novara, Piemonte, Italy; Martina Barrea, BS, AOU MAggiore della Carità di Novara, Novara, Piemonte, Italy*

Learning Objectives: After attending this presentation, attendees will understand that the increasing number of aggressions toward health care workers is having a growing global impact on the effectiveness of health care. Recent literature shows an ever-increasing interest in this topic, so much so that it has been defined as an "epidemic" phenomenon, as well as a risk factor for pathologies such as burnout and Post-Traumatic Stress Disorder (PTSD).[1] Globally, nearly one-third of workplace violence occurs in the health sector.[2] There are laws in several states aimed at the prevention of violence against health care workers and health establishments, but conviction rates are very low.[3,4] At the end of 2024, Italy introduced a new decree law concerning Urgent Measures to Combat Violence Against Health Care Professionals in the Performance of Their Functions.[5]

Impact Statement: Starting with case analysis, after illustrating that violence against health care workers is increasingly a strategy of modern warfare, with devastating short- and long-term impacts on health staff, patients, and the health system as a whole, this presentation will impact the forensic science community by analyzing the growing relevance that institutions are giving to this topic in Italy, especially after the recent law against violence against health workers came into force (D.L. 137/2024).[5,6] No previous Italian sample study has yet ever been published on this topic after the new law. The study conducted an analysis of the case history of a referral University Hospital in Northwestern Italy (Novara) from 2016 to June 2025, which grew exponentially, highlighting the growing need to address this important issue more actively, with improvement measures.

Abstract Text: This study, focusing on Italian national and local protocols for violence against health- are workers, analyzed the effectiveness of monitoring of violence reports by health care workers between January 2016 and June 2025 at the Hospital "Maggiore della Carità" of Novara in Northwest Italy, highlighting that the importance of respect and professionalism is pivotal.[7,8] Demographic data (sex, age, profession, role) of the victims and of the attacker (when available), the day (weekday or holiday, morning/afternoon/night) of the aggression, the place (which Unit of the hospital), and the type of the aggression (verbal or physical) were collected for each case. A descriptive statistical analysis of the data obtained was then carried out.

A total of 142 reports were analyzed in which health care workers had experienced physical or verbal violence; only 17 events (11.9%) were registered between 2016 and 2022, while most of them were recorded since 2023. Most of the aggressions were verbal ones (64,5%), but many of them (22%) resulted in physical assaults. About the half of the events happened in the Emergency Care Unit, and 65,6% of the victims were female, considering that about one-third of the violence events has involved more than one worker. The most involved age was between 30–39 years, and the most attacked professional figure was the nurse, followed by the medical doctor, midwives, health care workers, and security guards. Most aggressions happened during the working days, in the afternoon, only 15% occurred at night. In 55% of cases, the aggressor was male. All the reports had been uploaded on the Information System for Monitoring Errors in Healthcare (SIMES) of the Piedmont Region. The staff involved was contacted to provide psychological support, especially in the most serious events. The Clinical Risk Unit conducted targeted meetings in the facilities most prone to assaults to assess recurring critical issues and define appropriate measures with workers to minimize the risk of assault. Residential company training courses were launched for all health care professionals on the management of conflictual situations with patients and other users, aimed at reducing workplace risks associated with conditions that generate violence against health care workers. The Surveillance service was strengthened, particularly in the Emergency Department, with the addition of a video surveillance system available to the Judicial Authorities. The presence of Association volunteers to listen to and comfort patients was increased. Information for operators regarding the contacts for authorities and emergency numbers to be used in case of an assault was published on the website and distributed internally.

The aforementioned improvement actions implemented during 2024 have led to greater awareness and sensitization among health care professionals, resulting in a more than doubled number of reports compared to the previous year (2023). Also, in light of recent legislation on the prevention of acts of violence against operators, a meeting is being scheduled with the Novara Public Prosecutor's Office to define an intervention protocol to be operationally agreed upon with the police.

E19 The Impact of Italian Regional Guidelines on the Use of Safety Devices That Limit Patient Movement in Hospitals on Falls, Physical Restrictions, and Their Consequences: A Retrospective Study

Federica Collini, MD, University of Eastern Piedmont, Milan, Lombardia, Italy; Silvia Rampi, MN, AOU Maggiore della Carità di Novara, Novara, Piemonte, Italy; Martina Barrea, BS, AOU Maggiore della Carità di Novara, Novara, Piemonte, Italy*

Learning Objectives: After attending this presentation, attendees will have greater awareness of the efforts that Italian institutions are making to try to prevent psychological and physical injuries to hospitalized patients, trying to find the right balance between physical restraint procedures and the prevention of consequences on patients' health, including falls to the ground.

Impact Statement: Starting with case analyses of Novara's University Hospital, after illustrating the correct definitions of restraint devices and the various types, this presentation will impact the forensic science community by focusing on the fact that the use of physical restraints in patients is a common practice in many countries, but there is often an abuse of physical restraint devices due to the ignorance regarding their real need for prescription and use. This presentation is aimed at limiting injuries and negative consequences due to an improper use of physical restraint procedures on hospitalized patients as much as possible by highlighting the pivotal role of improving educational programs dedicated to this issue.

Abstract Text: This study, focusing on Italian protocols for regional guidelines on the use of safety devices that limit patient movement in hospital published in November 2022, analyzed the actual situation at a University Referral Hospital in North-Western Italy (Novara) since 2024, and aims to examine its effects on the rates of falls, injurious falls, and physical restraint use.[1]

The health care professionals consider restraint as very important in preventing safety problems, but the definition and applicability of restraint devices has evolved over the years, often resulting in abuse rather than appropriate use, thus increasing the risk of potential patient injury.[2,3] In fact, restraint is not a therapeutic measure and has no preventive, curative, or rehabilitative purpose. There is no scientific evidence that the use of physical or pharmacological restraints protects patients from falls. Mechanical restraints, however, can cause adverse psychological and physical effects, both direct and indirect. Therefore, physical restraint should be used only when strictly necessary, supported by a medical prescription, and only after adopting every possible alternative care strategy, including relational and environmental interventions and the involvement of the patient, where possible, and their family.[4]

From January 2019 to July 2025, the University Referral Hospital "Maggiore della Carità" in Novara registered a total of 2,367 cases of falls (a mean of 359 per year), of which only 65 (2.75%) had serious consequences (as fractures, cerebral hemorrhages, or death). Only after regional directives, the hospital has also started to record cases of physical restraint: 286 in 2024 and 209 in 2025 (January–July). Falls in hospital were 319 in 2024 (19 with serious consequences) and 202 in 2025, within July (13 with serious consequences). Monitoring these data could be useful for future considerations about the appropriateness and effectiveness of restraint measures on the prevention of falls. Bed rails, belts, wristbands, and anklets have been reported as the most frequently used restraints in bed; chairs with a table and belts are the most frequently reported restraints in a chair. It is evident that physical restraints in most cases are used as safety measures; the main reason is the prevention of falls. Predictors for the use of physical restraints are poor mobility, impaired cognitive status, and high dependency of the patient and the risk of falls.

In order to improve the quality of care, it is essential to identify the factors that can have an effect on the application of physical restraint. Restraint use is sometimes wrongly related only to organizational characteristics. As many adverse effects of restraint use have been reported in the literature, like falls, pressure sores, depression, aggression, and death, they should not be considered as an adequate measure for the prevention of falls.

Educational programs are of fundamental importance, but to be more effective in reducing the use of physical restraint, they should address commonly held views on rationale for restraint use and be accompanied by institutional policies promoting a restraint-free environment.[5-7]

F1 A Five-Year Review of Fire Scene Fatalities at the West Tennessee Regional Forensic Center

Sydney Carr, BS, West Tennessee Regional Forensic Center, Memphis, TN; Ibrahim Ortanca, MD, West Tennessee Regional Forensic Center, Memphis, TN*

Learning Objectives: Attendees will examine the prevalence, manner, and characteristics of fire scene fatalities in West Tennessee and recognize common patterns and key differences between fire-related deaths and deaths due to other factors. Attendees will be able to distinguish demographic and situational patterns that differentiate deaths directly caused by fire from non-fire-related deaths with postmortem fire involvement. These patterns and distinctions can help pathologists and investigators seek additional information to ensure a complete and accurate case evaluation.

Impact Statement: This presentation will impact the forensic science community by distinguishing true fire fatalities from deaths involving postmortem fire exposure, a differentiation that is essential for accurate cause and manner-of-death determinations. By identifying demographic, situational, and seasonal trends as well as the high prevalence of homicides among non-fire-related deaths, the findings of this study enhance the ability of forensic pathologists and investigators to recognize patterns that may otherwise be overlooked. The results underscore the importance of integrating thorough scene investigation with autopsy findings to prevent misclassification of death.

Abstract Text: Tennessee's fire mortality rate is 24.7 deaths per million population, notably higher than the national average of 13.1.[1] The West Tennessee Regional Forensic Center (WTRFC), located in the largest and most populous county of Tennessee, investigates all fire-related deaths within its jurisdiction.

The presence of a decedent at a fire scene does not necessarily mean that the individual died from fire-related injuries. Fires may be intentionally set to conceal a homicide or may occur coincidentally with unrelated causes of death, such as overdose or natural disease.[2] This study examines the prevalence, manner, and characteristics of deaths at fire scenes investigated by the WTRFC over a 5-year period.

A retrospective review of 7,942 postmortem autopsy records from January 1, 2020, to December 31, 2024, was conducted. The WTRFC case management system was queried using the terms "thermal," "carbon monoxide," "charred," and "inhalation." Cases without a flame-producing fire were excluded.

Of the 218 initially identified cases, 29 were excluded due to the absence of a flame-producing fire, including 23 deaths from carbon monoxide toxicity from vehicle exhaust or malfunctioning appliances and 6 deaths from water scalding or contact burns. The remaining 189 cases included 163 (86%) fire deaths and 26 (14%) non-fire related deaths. Statistics for each population were analyzed separately and compared.

Fire deaths were overwhelmingly classified as accidental (90%), followed by undetermined (6%), suicide (2%), and homicide (2%). In contrast, 88% of non-fire related deaths were homicides, with the majority (n=15) resulting from gunshot wounds, and the remaining 12% were accidental.

Males were more frequently represented in both groups, but were disproportionately higher in the non-fire-related group (67% vs. 85%). Fire-related deaths were most common in individuals aged 60–79, while non-fire-related deaths were most common in those aged 30–49.

Scene location also differed by group. Most fire deaths occurred in structural fires (74%), followed by motor vehicle fires (20%) and outdoor fires (6%). Conversely, non-fire-related deaths were most frequently found in motor vehicle fires (69%), followed by structural (19%) and outdoor (12%) settings. Seasonal analysis showed that fire deaths peaked in winter (42%) and declined through fall (24%), spring (21%), and summer (13%) while non-fire-related deaths had no seasonal trend.

Although initial scene findings may appear similar between fire-related and non-fire-related deaths, this study highlights distinct patterns and statistical differences between the two. Recognizing these differences, alongside thorough autopsy and fire scene investigation, can help forensic pathologists and investigators obtain critical information and ensure accurate cause and manner-of-death determinations.

F2 A Peculiar Case of Complex Suicide by Hanging With Hesitation Marks From Incised Wounds

Gianmarco Sirago, MD, Università degli Studi di Bari "A.Moro", Bari, Puglia, Italy; Susanna Sabato, MD, University of Bari "Aldo Moro", Medical-Legal Section of Policlinico di Bari, Bari, Puglia, Italy; Annachiara Vinci, MD, University of Bari "Aldo Moro", Medical-Legal Section of Policlinico di Bari, Bari, Puglia, Italy; Biagio Solarino, MD, PhD, Università degli Studi di Bari Aldo Moro, Bari, Puglia, Italy; Paolo Visci, University of Bari "Aldo Moro", Medical-Legal Section of Policlinico di Bari, Bari, Puglia, Italy; Davide Ferorelli, MD, University of Bari "Aldo Moro", Bari, Puglia, Italy*

Learning Objectives: By the end of this presentation, attendees will be able to define and differentiate the concept of complex suicide from other suicidal behaviors, gaining a deeper understanding of its epidemiological relevance. They will learn to identify the forensic characteristics of hesitation marks and other sharp-force injuries typically observed in cases of complex suicide and to analyze autopsy findings in order to distinguish between primary and secondary suicidal methods while correlating them with evidence collected during scene investigation. Furthermore, participants will evaluate the significance of household items as means of suicide and their implications for forensic analysis. Finally, they will discuss the role of multidisciplinary suicide prevention strategies, focusing on the integration of mental health support, community awareness, and early intervention to effectively reduce suicide risk.

Impact Statement: This presentation will impact the forensic science community by providing an in-depth analysis of a rare case of complex suicide, highlighting the importance of integrating scene findings with autopsy evidence to accurately reconstruct the sequence of events. By illustrating the forensic significance of hesitation marks, cranial injuries, and the use of multiple methods, it will enhance the understanding and interpretation of complex injury patterns. Moreover, the discussion on easily accessible means of suicide and the broader implications for prevention will foster a multidisciplinary perspective, encouraging forensic professionals to collaborate more closely with mental health experts and public health authorities. Ultimately, this case study underscores the need for continuous education and research to improve both forensic investigations and preventive strategies in the context of suicide.

Abstract Text: Suicide is a pressing social and public health issue that involves over 700,000 deaths per year and ranking as the fourth leading cause of death among young adults worldwide.[1,2] The term "complex suicide" refers to the use of more than one suicidal method to achieve the fatal outcome. Commonly, this includes incised wounds located on the wrists or the volar surface of the arms, known as "hesitation marks." These injuries often present as multiple, parallel cuts of varying depth, reflecting repeated attempts caused by pain or uncertainty before fully penetrating the skin.[3] While hesitation marks are often located near or overlapping a fatal sharp-force injury, they may also appear in areas distant from the lethal wound. The most common sites for hesitation marks include the neck, the left side of the chest, and the wrists. On the upper limbs, they are generally observed on the flexor surfaces and the radial side of the forearm.[4]

We report the case of a 55-year-old man who committed suicide by hanging in his home. Further investigation revealed multiple incised wounds on the fronto-parietal region of the head. On-site examination led to the recovery of a blood-stained axe, with blood traces predominantly on the handle and blade, the latter also bearing hair fragments.

External examination highlighted, in the fronto-parietal region, a complex of seven linear parallel wounds, oriented anteroposteriorly, with infiltrated and lacerated margins exposing the underlying tissues. Additionally, an oblique parchment-like ligature mark was observed on the cervical region. Autopsy confirmed hemorrhagic infiltration of the subcutaneous tissues and galea capitis at the site of the head injuries, along with five linear, parallel bone incisions of variable length and depth, not involving the full thickness of the cranial bone. The characteristics of the cranial injury pattern and the extent of bloodstaining with hair on the cutting surface of the axe blade were consistent with the action of the recovered weapon.

Further autopsy findings included bilateral hemorrhagic infiltration of the thyrohyoid muscle, multiple transverse lacerations of the carotid artery intima, and fracture of the right greater horn of the hyoid bone with associated hemorrhagic infiltration.

The individual had access to easily available household items, such as an axe and a rope. This case underscores the critical need for suicide prevention strategies that extend beyond the sole limitation of access to lethal means. Effective prevention requires a comprehensive, multidisciplinary approach integrating mental health support, early identification of risk factors, community awareness, and timely intervention. By addressing the psychological, social, and environmental determinants of suicidal behavior, healthcare systems can better mitigate risk and improve outcomes. This emphasizes the importance of collaborative efforts between clinicians, public health authorities, and social services to develop proactive and holistic prevention programs.

F3 A Qualitative NMR and Histological Analysis of Adipocere Formation in Different Aqueous Environments Using *Sus Scrofa* Models

Mia M. Sorrentino, MS, John Jay College of Criminal Justice, Freeport, NY; Angelique Corthals, DPhil, CUNY John Jay College, East Setauket, NY*

Learning Objectives: Audience members will learn what adipocere is, its main components, and how different environmental factors such as salinity, temperature, and exposure can impact the physical and chemical characteristics of grave wax. Audience members will see how different stages of decomposition impacts the cellular structural integrity of tissues through the histological preparation of samples taken during period collections.

Impact Statement: Research aims to fill in the large gaps concerning adipocere formation in the forensic science community, specifically, its formation in aqueous environments and the histological aspects of tissues undergoing the formation process. This study aims to view distinct structural changes within the tissue as adipocere formation advances.

Abstract Text: Adipocere is a wax-like crust that has the potential to form over corpses in moist, humid, and anaerobic environments, preserving them in a process similar to that of mummification.[1] The substance can be identified within 3-6 months postmortem and is characterized by the ratio of saturated fatty acids to unsaturated fatty acids.[2,3] Palmitic acid and stearic acid are the most abundant in comparison to myristic and oleic acids.[2] The goal of this study was to investigate factors affecting adipocere formation in different aqueous environments. Pork belly samples were submerged in water samples collected from different places around New York City and Long Island. Some samples were allowed direct exposure to the environment where others were wrapped in a plastic bag to simulate a forensic scenario. After 6 months of collection, samples with direct exposure were in an intermediate stage of adipocere formation, whereas bagged samples were at a stage of decomposition. Fats were extracted using a modified Folch's method.[4] NMR spectra were consistent with the spectra of the three acids. Spectra from environments with high salinities did not appear to have formed adipocere, and could have possibly formed a different postmortem product.[5] Histological analysis of adipocere samples yielded a change from tightly packed tissue to a spacious lattice network of adipose and oxidized fats where the decomposing samples mostly contained stretched sinew and slowly decomposing muscle.

F4 A Rare Case of Suicidal Strangulation: Diagnostic Challenges in Forensic Practice

Alessandro Ghamlouch, MD, Sapienza, University of Rome, Rome, Lazio, Italy; Gaia De Angelis, MD, Sapienza, University of Rome, Rome, Lazio, Italy; Gabriele Napoletano, PhD, Sapienza, University of Rome, Rome, Lazio, Italy; Biancamaria Treves, MD, Sapienza, University of Rome, Rome, Lazio, Italy; Maura Racciatti, MD, Sapienza, University of Rome, Rome, Lazio, Italy; Fabio Del Duca, MD, Tor Vergata University, Rome, Lazio, Italy*

Learning Objectives: Attendees will learn how to distinguish suicidal from homicidal ligature strangulation through forensic analysis. They will gain practical skills in interpreting autopsy, histological, and scene findings to accurately determine the manner of death in challenging asphyxia cases.

Impact Statement: This presentation will strengthen forensic competence and performance by providing clear criteria for identifying suicidal ligature strangulation, leading to more accurate cause-of-death determinations and improved medicolegal outcomes.

Introduction: Asphyxia is a pathological condition characterized by the failure of adequate oxygen supply to tissues, leading to disruption of normal cellular respiration.[1] Strangulation, a form of asphyxia resulting from external compression of the neck structures, is most frequently associated with homicide.[2] However, suicidal ligature strangulation remains a rare and diagnostically challenging occurrence. Differentiating suicidal from homicidal cases demands a thorough medico-legal and forensic approach, given the overlapping mechanisms of death, which may include vascular occlusion, airway obstruction, and vagal inhibition.[3]

Case Report: We present a rare case of suicidal ligature strangulation in a 50-year-old male found deceased in his home. The decedent was discovered lying supine on his bed with a belt tightly fastened around his neck. External examination revealed abundant fixed post-mortem lividity, particularly in the posterior body regions and anteriorly up to the axillary lines, as well as on the face and neck. Petechial hemorrhages were noted on the chin, palpebral, and conjunctival regions. A well-demarcated horizontal ligature mark, approximately 3.5 cm in width, was observed in the cervical area, most pronounced in the right lateral region. A brown-violet ecchymotic-abrasive lesion corresponding to the metallic components of the belt buckle was present anterolaterally on the neck.

Internal examination showed marked polyvisceral congestion and pulmonary edema. No defensive wounds or injuries suggestive of a struggle were identified. Histological analysis of skin samples from the ligature site revealed significant vascular ectasia, congestion, epidermal thinning, and keratinocyte degeneration. In the ecchymotic-abrasive area, loss of the epidermis and dermal homogenization were observed, with minimal erythrocyte extravasation. The underlying subcutaneous tissue was unaffected.

Discussion: The cause of death was determined to be suicidal ligature strangulation with a belt. No alternative cause of death was identified, and the autopsy findings were corroborated by the presence of a farewell note found at the scene.[4] This case highlights the importance of integrating autopsy findings, histopathology, and circumstantial evidence in establishing the manner of death.[5] Suicidal strangulation, although rare, must be considered in differential diagnoses, and its confirmation requires close collaboration between forensic pathologists and investigative authorities.[6]

F5 A Retrospective Analysis of the Clark County Office of the Coroner/Medical Examiner Pediatric Homicides (1991–2024)

Laura L. Jordan, MA, University of Nevada Las Vegas, Las Vegas, NE; Candace C. Caterer, Clark County Office of the Coroner/Medical Examiner, Las Vegas, NE; Jennifer F. Byrnes, PhD, University of Nevada, Las Vegas, Las Vegas, NE; Melanie Rouse, MA, Clark County Office of the Coroner/Medical Examiner, Las Vegas, NE; Nathan Shaller, MD, Clark County Office of the Coroner/Medical Examiner, Las Vegas, NE*

Learning Objectives: After attending this presentation, attendees will become more knowledgeable about pediatric homicide trends and observations within local and national contexts, understanding how disparities may contextualize the data presented.

Impact Statement: This presentation will benefit the forensic science community by presenting pediatric homicide data demonstrating demographic disparities and providing critical insights into elusive, yet pervasive, mortality risk factors evident across local and national contexts.

Abstract Text: According to the CDC, homicide is a leading manner of death among U.S. children.[1,2] While national data indicates an overall decline in pediatric homicide, this may not be true locally.[3] National programs like Child Protective Services, the Administration for Children and Families, and local programs like Nevada's Child Death Review Teams (CDRT) aim to analyze child mortality. This study examined 279 pediatric homicide cases (ages 0-12) from the Clark County Office of the Coroner/Medical Examiner (CCOCME) between 1991 and 2024 to compare local to national trends, using the Web-based Injury Statistics Query and Reporting System (WISQARS) database for context (3). National data (1999-2020; 38,362 children aged 0-17 years) showed higher homicide rates for males, especially in late adolescence. From 2012-2014, Black children had the highest rates, with disparities widening for Black and Hispanic children while declining for Asian, Pacific Islander, and White children.[2]

Locally, there were 184 males (65.9%) and 95 females (34.1%). The mean age at death was 3.09 years (SD = 2.62), with infants (0-11 months) being the most common age cohort (36.9%, n=103). Black females were disproportionately higher than their male counterparts (38.9% vs. 31.5%). Conversely, Hispanic males were more represented than females (24.5% vs. 17.9%). White female and male groups were almost equal (34.7% vs. 34.2%). Highest frequencies by race and age cohort were: White children 0-11 months (38.8%, n=40), Black children 1-3 years (38.3%, n=31), Black children 3-7 years (39.1%, n=25), and Hispanic children 8-12 years (35.5%, n=11). Blunt force trauma was the primary cause of death (COD) (59.1%, n=165), followed by sharp force trauma (12.5%, n=35) and gunshot wounds (12.2%, n=34). Males accounted for 72.1% (n=119) of blunt force trauma cases. It was also the most common COD for infants (0-11 months) at 68.9% (n=71). White children had the highest frequency of blunt force trauma deaths (64.6%, n=62). Black males aged 0-7 predominantly died from blunt force trauma (76.4%, n=42), shifting to gunshot wounds for those 8-12 (66.7%, n=2). Black females showed the highest frequencies of sharp force trauma and asphyxiation (40.5%, n=15). Southern Nevada's crude pediatric homicide mortality rate (2001-2023) was 0.42 per 100,000, lower than the WISQARS national average of 1.54 per 100,000 for children aged 0-12 years. However, Clark County showed an unstable but steady increase in child and infant mortality rates with population growth.

These findings indicate significant racial and age-related disparities, likely influenced by economic, environmental, and demographic inequalities. This data supports local governmental agencies in refining public health outreach and programs, and aids forensic science in interpreting risk factors within vulnerable groups. Future research will evaluate national initiatives and pinpoint community-level determinants to address systemic inequities in public health infrastructures.

F6 The Characteristics and Resistance of Paper Money in Gunshot Wounds: A Case Report and Experimental Study

Massimo Musardo, LLB, Italian Finance Police, Catanzaro, Calabria, Italy; Matteo Antonio Sacco, MD, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Saverio Gualtieri, MD, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy;Alessandro Pasquale Tarallo, MD, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Maria Cristina Verrina, MD, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Denise Errigo, LLM, Magna Graecia University of Catanzaro, Crotone, Calabria, Italy; Claudia Catia De Pasquale, MSc*, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Roberto Raffaele, MSc*, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Isabella Aquila, MD, PhD*, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy*

Learning Objectives: After attending this presentation, participants will understand the morphological and physical characteristics of paper money when involved in gunshot wounds and its potential forensic significance.

Impact Statement: This presentation will impact the forensic science community by demonstrating the role of resistance of paper money to determine the distance of the shot, the type of caliber and weapon used, and the dynamics of the impact in cases of gunshot wounds.

Abstract Text: A fundamental characteristic of paper used in banknote production is its reliance on cotton as the primary material, a choice rooted in decades of proven performance and trust by central banks worldwide. This cotton-based substrate imparts a distinctive tactile sensation, recognizable sound, and visual appearance that collectively foster public confidence and facilitate authentication by machines and human users. The physical and chemical properties of cotton paper make it amenable to the integration of advanced security features, such as watermarks, security threads, and foils, all of which can be embedded or attached during manufacturing to thwart counterfeiting attempts. Banknotes are constantly subjected to mechanical stresses as they pass from hand to hand, leading to defects such as tears, folds, crumples, and ink wear, which compromise structural integrity and aesthetic appeal.

We report the case of a firearm homicide in which fragments of paper money were found inside the chest, where the gunshot wounds had occurred, around the bullets that had penetrated the body. Visual analysis of the intact fragments revealed the type of paper money. Before the murder, the banknotes were inside the upper right pocket of the victim's work overalls. The question arose as to how resistant a banknote could be to the force exerted by a bullet, sufficient to be transported inside the human body. For this reason, the Institute of Forensic Medicine at the University of Catanzaro initiated a scientific collaboration with the Bank of Italy.

To address these challenges effectively, central banks and manufacturers must invest in research and adopt advanced materials to withstand the diverse and demanding conditions of global circulation.

Paper money is composed of a blend of cotton fibers and other substances that give it strength and durability. Furthermore, paper money has a specific thickness and weight that can affect its resistance to stress. Humidity and environmental conditions also affect resistance. Forensic analysis has shown that when a bullet passes through paper money, it can cause lacerations, deformation, compression, and loss of structural integrity. Experimental analysis of paper money using firearms provides objective data on damage caused by shots fired. This also provides insight into the distance of the shot, the caliber and weapon used, and the impact dynamics.

In our case, the impact of the 357 Magnum bullet likely caused lacerations in the banknotes, while chest humidity may have weakened the structure and promoted tearing. The variables in this assessment are related to environmental conditions and the type of damaged banknote. It is essential to perform laboratory analyses on samples and request the paper's technical data sheet. Ultimately, this analysis could offer new insights into gunshot wounds and could be a valid, repeatable and reproducible tool for evaluating these dynamics. The combination of ballistics and paper money analysis is a unique and fascinating topic.

F7 A Chronological Evolution of Volatile Organic Compounds (VOCs) From Burned Human Remains Analogs

Daigoro Greco, BS, Florida International University, Miami, FL; Lauryn DeGreeff, PhD, Florida International University, Miami, FL*

Learning Objectives: AAFS attendees will learn about the evolution of VOCs during the controlled combustion of human-analog tissues. Specific details will include techniques and methodologies employed to capture and characterize changing volatile chemical profiles, the impact of thermal degradation on odor sources, and the implications and complications of burned remains on forensic investigations.

Impact Statement: This research directly expands the limited area of characterization and analysis of burned human remains, creates a list of burn-stage specific volatile biomarkers, and aims to improve interpretation of fire damage to tissue and provide supporting findings for canine training in fire-related disasters.

Abstract Text: Combustion and pyrolysis of human remains are driven by a complex system of physical changes and chemical reactions. This destructive and deeply transformative cascade of reactions remains largely under investigated and poorly understood by the forensic community, with both early and contemporaneous forensic literature on fire revolving around crime scene reconstruction (fire propagation, structural damage, and detection of accelerants and ignitable liquids); and the small portion involving human remains largely focuses on replication of specific scenarios, end-stage effects of combustion, or detection of contaminants.[1-6] The limited literature on the topic, and often only tangential focus on burned organic samples, carry severe ramifications for post-fire analysis of human remains, cadaver dog deployment to fire scenes, and even cadaver dogs training. As such, this research is a novel and uniquely focused approach to the study of human remains combustion by adopting a systematic monitoring of the full progression of volatile organic compound (VOCs) generated during a controlled, multi-stage thermal degradation process of human remains analogues. To characterize the changes occurring in the VOC profile as a function of combustion processes, fresh samples of porcine flesh (a commonly used human surrogate for medical and forensic applications[7]), were incinerated in an electric laboratory furnace under controlled thermal conditions designed to eliminated interferants and the need for accelerants. By allowing each sample to burn for a set amount of time (with successive runs increasing the duration of heat exposure), it was possible to create a chronological trajectory of the thermal degradation process across four macro stages: singeing, flaming, charring, and calcination. Upon reaching the allotted time in the furnace, each sample was quickly removed from the heat and sealed in a 16 oz canning jar. Odorants in the headspace were sampled using 50/30 µm DVB/CAR/PDMS SPME fibers and analyzed via direct injection into a gas chromatography/mass spectrometry (GC/MS) instrument equipped with a volatiles-dedicated column.

Preliminary data obtained during method optimization revealed both the degree of permanence of key volatile biomarkers, as well as promising differences in the compounds found at each of burning stage. The hypothesized trend correlating higher temperatures with the irreversible loss of molecular products has already been observed and the finalized collection of individual chromatograms is expected to produce a full transitional profile for burn-related VOCs. The characterization of a VOCs timeline comprised of chromatographic fingerprints of defined pyrolytic degradation stages and the identification thermally stable and labile combustion biomarkers will have a direct impact in both theoretical and applied forensic science. Not only will these findings provide a much-needed expansion and shift in focus for the scientific literature, but the proposed molecular timeline and relative volatile biomarkers for burned human remains could aid forensic investigators in more accurately establishing length and degree of flame exposure and to quickly screen and identify biological remains on disaster scenes. Lastly, any insight obtained from this study would greatly benefit HRD canine handlers looking to incorporate or strengthen their fire scene training and effectiveness during deployment.

F8 Concurrent Crises: Modeling the Pandemic's Impact on Accidental Poisoning Deaths and the Medical Examiner and Coroner System Burden

Molly E. Pierson, MPH, Celia Scott Weatherhead School of Public Health & Tropical Medicine at Tulane University, New Orleans, LA*

Learning Objectives: The goals of this presentation are to: (1) identify patterns of disruption in accidental poisoning mortality trends across all 50 states in the United States during the COVID-19 pandemic using segmented regression analysis. Attendees will learn how mortality trends changed at the state level and how to interpret level and slope shifts using simple statistical outputs; (2) evaluate the operational implications of pandemic-period mortality surges on Medical Examiner and Coroner (ME/C) systems. Attendees will understand how increased poisoning deaths impacted ME/C caseloads, staffing needs, and investigative demands—especially in states with the most significant disruptions; and (3) assess the need for scalable, resilient ME/C infrastructure capable of maintaining core functions during periods of concurrent public health crises. Attendees will be able to describe how systemic stressors like the pandemic highlight structural vulnerabilities in death investigation systems and apply this insight to preparedness planning.

Impact Statement: This presentation provides the medicolegal community with comprehensive data-driven assessments of how the COVID-19 pandemic disrupted accidental poisoning (substance toxicity) trends across all 50 states in the United States and magnified operational strain on ME/C systems. By linking statistical findings to operational challenges, this research emphasizes the need for death investigation infrastructure that is capable of weathering concurrent periods of elevated mortality. Attendees will gain strategic takeaways to inform future planning, workforce preparedness, and policy advocacy aimed at strengthening medical examiners and coroners nationwide.

Background: The Covid-19 pandemic exacerbated systemic vulnerabilities and highlighted operational capacity limitations for medical examiners and coroners throughout the United States of America. The medicolegal landscape, already burdened by rising trends in accidental poisoning deaths due to the opioid crisis, was operating under chronic resource limitations, workforce shortages, and escalating caseloads even before the onset of the Covid-19 pandemic. This study examines whether the pandemic period represented a structural break in state-level trends of accidental poisoning deaths, necessitating the absorption of concurrent periods of elevated mortality.

Methods: Segmented linear regression models were constructed in SPSS for all 50 U.S. states using accidental poisoning mortality data from 2010–2023. Substance toxicity deaths were defined as accidental poisoning deaths (ICD-10 X40–X49) via CDC WONDER. Each model included a pre-pandemic time trend and a pandemic period indicator (beginning in 2020) to assess for significant level changes. In addition, traditional interrupted time series models incorporating post-2020 slope terms were applied to both accidental poisoning and intentional self-poisoning deaths (ICD-10 X60–X69) to evaluate whether the pandemic period corresponded to structural changes in poisoning mortality trajectories. Collinearity diagnostics confirmed stability between time and intervention terms. Model outputs were evaluated for both statistical fit and the epidemiologic patterning of disruption across states.

Results: Forty-three states exhibited a statistically significant level increase in accidental poisoning deaths coinciding with the onset of the pandemic ($p < .05$), consistent with an abrupt mortality surge beyond baseline trends. Only three states, Nevada, Oklahoma, and Washington, demonstrated statistically significant slope changes, suggesting altered post-2020 trajectories. Interrupted time series analyses demonstrated heterogeneous state patterns for both accidental and intentional self-poisoning, with some states exhibiting level changes, others slope changes, and others no statistically significant break, consistent with disruption in poisoning mortality patterns during the pandemic period. Model fit was strong ($R^2 > .85$) in the majority of states, and no collinearity issues were detected. While deaths increased broadly, the timing and magnitude varied, highlighting differential capacity across ME/C systems to detect, certify, and report poisoning deaths under pressure.

Conclusion: The Covid-19 pandemic period was a nationwide systemic stressor that prompted a dramatic increase in accidental poisoning deaths across most states and amplified the workload of many medical examiner and coroner offices. This upturn coincided with pre-existing operational challenges including staffing shortages, rising caseloads, and compromised infrastructure. These findings highlight the need for scalable, sufficiently resourced medical examiner and coroner systems capable of maintaining daily operations amidst concurrent surges and stressors.

F9 Dealing With Death: Perspectives From Forensic Personnel

Rebecca Platt, BA, BS, University of Tennessee, Knoxville, Knoxville, TN*

Learning Objectives: After attending this presentation, attendees will learn about the various strategies used by medicolegal investigators and medical examiners to cope with their death-related work as well as the influence of their careers on their worldviews.

Impact Statement: This presentation will impact the forensic science community by fostering a deeper and more nuanced understanding of the emotional labor involved in death investigation. It will also highlight the need to address workplace dissatisfaction and the need for integrated mental health support, ultimately promoting the development of more comprehensive well-being initiatives across the forensic science profession.

Abstract Text: Studies show that forensic personnel are at risk for developing conditions such as post-traumatic stress disorder (PTSD), acute stress disorder (ASD), and symptoms of depression, and that these individuals have different psychological reactions to different manners of death.[1,2] However, there is a lack of research into the methods used by these individuals to process their work and cope with consistent exposure to the dead. The current study attempts to fill this gap by fulfilling three main goals: (1) identifying coping mechanisms utilized by medicolegal death investigators and medical examiners, (2) identifying trends in those strategies, and (3) evaluating the impact of their work on an individual's worldview.

Eight individuals working in four states (New York, Connecticut, Arizona, and Nevada) were contacted via email and asked to complete a brief online survey through Microsoft Forms and a follow-up interview over Zoom. Two medicolegal investigators and two medical examiners—one of each working in Connecticut and Arizona—completed the survey and were interviewed. Two additional individuals, both working as medicolegal investigators in Connecticut, received the survey from a colleague and submitted responses but did not participate in interviews. All but one participant had been working in their field for a minimum of ten years, with none working for more than thirty. Participants reported working on a large number of cases each year, with the minimum being 250 cases and the maximum being 1,000 cases. The types of cases that elicited an emotional response differed between participants, as did the coping mechanisms they employed. Despite these differences, each described strategies with common foundations in a strong separation between their professional and personal lives, a reliance on their training and education, and the use of humor to build and maintain relationships with their colleagues. Many also described using their work to subvert social issues and prejudices as well as advocate for a more equal and independent death investigation system. Participants also shared some dissatisfaction with their workplaces and felt that there was a lack of effective support systems in place to help them when their own coping mechanisms were insufficient. These findings were not shown in previous research but were expressed in memoirs written by a forensic pathologist and medicolegal death investigators, and in an interview given by an individual working to identify disaster victims.[3-6]

Future research should further explore the reasons for discontent in the workplace and expand the pool of participants to include not only more individuals, but those working on different aspects of death investigation (e.g. law enforcement officers, crime scene investigators, forensic anthropologists) as well as those with less experience in their field. The addition of a trained mental health professional to the study would also have immeasurable benefits and could lead to the development of more effective programs to assist forensic personnel in processing their work.

F10 Death at Climax: A Case of Aneurysmal Subarachnoid Hemorrhage During Sexual Intercourse

Pawan Kumar, MD, AIIMS New Delhi, Delhi, India; Abhishek Yadav, MD, AIIMS New Delhi, Delhi, India*

Learning Objectives: Attendees will: (1) understand the pathophysiology and risk factors of aneurysmal Subarachnoid Hemorrhage (aSAH), particularly in the context of physical exertion during sexual activity; (2) recognize the clinical and forensic significance of sudden death during or after sexual intercourse; and (3) identify autopsy and radiological findings associated with aneurysmal subarachnoid hemorrhage.

Impact Statement: This case highlights the rare but significant association between sexual activity and fatal aSAH, emphasizing the need for clinicians and forensic experts to consider cerebrovascular catastrophes in sudden deaths occurring during or after intercourse. By presenting detailed clinical, autopsy, and medicolegal findings, this report enhances understanding of the pathophysiological stressors involved, aids in accurate determination of cause and manner of death, and underscores the importance of thorough forensic evaluation in cases with potential legal, social, or familial implications.

Background: Subarachnoid hemorrhage (SAH) is a critical neurological emergency, commonly caused by rupture of an intracranial aneurysm. While several physiological stressors are known to precipitate SAH, sexual activity is an uncommon but recognized trigger due to the sudden increase in blood pressure and intracranial pressure during orgasm.

Case Presentation: We report the sudden death of a 30-year-old previously healthy female during consensual sexual intercourse. According to the partner's account, at the point of imminent orgasm, she complained of a headache with breathlessness, following which she became unconscious. Emergency medical services were called, but she was unresponsive on arrival and declared dead at the hospital. A medicolegal autopsy was conducted to determine the cause of death. External examination revealed no signs of trauma or foul play. Internal examination revealed extensive subarachnoid hemorrhage predominantly around the circle of Willis. A ruptured saccular aneurysm was identified at the anterior communicating artery. The cause of death was concluded as a spontaneous rupture of a cerebral aneurysm leading to fatal SAH.

Discussion: The significance of sexual engagement as an uncommon trigger for aneurysmal rupture is highlighted by this instance. In vulnerable people, the physiological alterations brought on by arousal and orgasm, such as an abrupt rise in systemic blood pressure, may raise the chance of aneurysm rupture. Even though they are uncommon, these cases are important in forensic pathology and need to be thoroughly examined to rule out accidental or homicidal reasons.

Conclusion: Sudden death during sexual activity, though rare, can be due to spontaneous SAH from a ruptured intracranial aneurysm. This case underlines the importance of considering natural causes in unexpected deaths during intercourse and contributes to the limited literature on this phenomenon.[1-3]

F11 Drug Overdose Deaths in Knox County, Tennessee, Adults 65 and Over: A Retrospective Study

Christie-Anne Estrada, MD, University of Tennessee Medical Center, Knoxville, TN; Darinka Mileusnic-Polchan, MD, PhD, Knox County Regional Forensic Center, Knoxville, TN*

Learning Objectives: The goals of this presentation are to: (1) identify trends in accidental overdose drug deaths in Knox County, TN, residents by age; (2) achieve a basic understanding of how to use chi square and cross-tabulation analysis on patient demographic data; and (3) reflect on how this method can be repurposed and broadened to be used in other counties.

Impact Statement: This project illustrates how forensic data can provide an objective and impactful public health service by identifying and tracking trends that can be reflective of greater national and/or local issues using deidentified patient data and readily accessible statistical analysis.

Abstract Text: In the United States, accidents are the third-leading cause of death, with drug overdose making up a significant portion. For Americans aged 18 to 44, it is the number one cause of death. The most recent available data show Tennessee as the third-highest state in the nation for drug overdose deaths per capita.[1,2] Targeted campaigns and awareness regarding drug overdose have helped decrease mortality rates over the years, with preliminary data showing a significant decrease in deaths since 2020.[3] While this news is encouraging, this retrospective study in accidental overdose deaths in Knox County used cross-tabulation and chi-square analysis to uncover an alarming trend; overdose deaths in individuals over the age of 65 have increased. Further investigation into the drug type and frequency shows, most notably, that fentanyl was found in over half of individuals in this age group. Our data also highlights an increased prevalence in drugs such as cocaine and xylazine in this age group and a decreased prevalence of prescription opioids and heroin. This population, although not traditionally thought of as having high risk for drug abuse, are uniquely susceptible to their toxic and many times fatal effects. This study showcases how forensic data can be used to identify at-risk populations and provide information on specific trends for future targeted preventative and substance misuse programs.

F12 Drug Trends and Novel Psychoactive Substances Identified Through Forensic Casework in the District of Columbia

Marsha Cox, BS, DC Department of Forensic Sciences, Washington, DC; Alexander San Nicolas, MSFS*, Indiana State Department of Toxicology, Indianapolis, IN*

Learning Objectives: Attendees will learn how forensic chemistry casework reveals evolving drug trends, including the detection of Novel Psychoactive Substances (NPS). Participants will understand how these insights support law enforcement and inform laboratory practices such as method validation and reference library expansion.

Impact Statement: This presentation will highlight real-world drug trends identified through the analysis of seized drugs in the District of Columbia. By reviewing current and past data/patterns, the presentation will provide valuable insights for public health officials, law enforcement, and forensic professionals. These findings will inform laboratory practices, support evidence-based policy decisions, and contribute to a more proactive response to emerging drug threats in the region.

Abstract Text: The ongoing evolution of illicit drugs presents a significant challenge for forensic science laboratories tasked with identifying and monitoring emerging substances. In recent years, the increase of novel psychoactive substances (NPS), synthetic opioids, designer benzodiazepines, and adulterated drug mixtures has significantly impacted public health and law enforcement efforts. This poster presents an in-depth analysis of drug trends identified through routine casework at our forensic chemistry laboratory, which services local law enforcement agencies within our jurisdiction.

Seized drug evidence submitted to our laboratory is analyzed using a combination of analytical techniques such as Gas Chromatography-Mass Spectrometry (GC-MS), Gas Chromatography with Flame Ionization Detection (GC-FID), and Fourier Transform Infrared Spectroscopy (FTIR). These analytical techniques detect and confirm controlled substances, cutting agents, and novel compounds encountered in casework. Through retrospective data mining and real-time monitoring of case submissions, we have documented the appearance of emerging synthetic drugs and fluctuations in the prevalence of commonly abused substances, such as fentanyl analogs, synthetic cannabinoids, and substituted cathinones.

This work highlights the importance of regularly updating laboratory methods, expanding spectral reference libraries, and validating analytical protocols to ensure accurate identification and minimize the risk of false negatives. Staying informed about current trends also ensures that scientific testimony remains relevant and credible, while helping laboratories anticipate legal challenges related to new or controversial substances.

The results of our casework analysis support investigative efforts related to drug trafficking and distribution patterns.

This presentation will provide attendees with an overview of current drug trends observed in our jurisdiction, offer practical recommendations for integrating drug monitoring into routine casework, and demonstrate how forensic laboratories can serve as critical intelligence hubs in the broader fight against drug-related harm.

F13 Evaluating the Quality and Quantity of Detail of Latent Prints on Buried Objects

Angela Gonzalez Bueno, BS, Forensic Science Institute- University of Central Oklahoma, Edmond, OK; Cait Porterfield, MS, Forensic Science Institute, University of Central Oklahoma, Edmond, OK*

Learning Objectives: After attending this presentation, attendees will understand the fundamental principles of fingerprints, the composition of fingerprints, the various factors that affect the degradation rate of fingerprints, and how the quality and quantity of detail of fingerprints degrade when exposed to extreme environmental conditions. Attendees will also understand how burial scene conditions, such as the soil's temperature, pH, and moisture level, pose unique threats to fingerprints.

Impact Statement: This presentation will impact the forensic science community by expanding the evidentiary scope of clandestine graves and optimizing latent print recovery techniques at burial sites. The presentation can also provide insight into how latent prints behave in a burial scene, specifically showing any correlation between the soil's temperature, moisture level, or pH and the quantity and quality of detail in the latent prints.

Abstract Text: Fingerprints are fragile and degrade over time, which creates the loss of quality and quantity of detail in the print. This degradation hinders the analysis process, as the ability to visualize the features in the print is lost. Factors such as the substrate type, time, and environmental conditions have been shown to affect the degradation rate of fingerprints.[1] Research has also examined how harsh environmental conditions, such as fire and underwater scenes, further affect the quality of prints over time. Ultimately, studies have shown that latent fingerprints can still be recovered and developed even after exposure to fire and underwater scenes.[2-6] This implies that such prints could also withstand other extreme conditions, such as those encountered in burial environments. Nevertheless, limited research has been conducted that focuses on understanding how fingerprints behave in burial scenes. As burial is a common disposal method, it is critical to understand how the quality and quantity of detail of fingerprints is affected by these scene conditions.

This project aimed to determine how long latent prints can survive being buried underground while maintaining sufficient quality and quantity of detail for analysis. Multiple latent prints were deposited on knives, pieces of duct tape, dollar bills, and brass cartridge cases; then buried in soil at the same depth for 6 months. One of each item was recovered every day for the first week, then every week for the remainder of the 6 months. At each recovery, the soil's temperature, pH, and moisture level were documented. The prints were also developed using the recommended processing method and analyzed using various statistical tests. This resulted in the development and analysis of 120 items and 360 prints.

F14 The Experimental Evaluation of the Wounding Potential of a Nail Clipper: A Compatibility Study Between an Atypical Tool and Medicolegal Lesions

Matteo Antonio Sacco, MD, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Roberto Raffaele, MSc*, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Isabella Aquila, MD, PhD*, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy*

Learning Objectives: After attending this presentation, attendees will understand the experimental forensic methods applicable to trauma assessment involving atypical everyday objects, including their diagnostic utility and medicolegal implications.

Impact Statement: This presentation will impact the forensic science community by highlighting the importance of standardized experimental approaches for the objective characterization of the wounding potential of household items.

Introduction: The offensive use of common objects is a growing concern in forensic medicine, as items not designed for aggression can nonetheless cause injuries of varying severity, potentially life-threatening. Among these, the nail clipper—a small, hygienic tool—may acquire significant wounding potential when used with intentional force and technique that exploit its metallic structure. The lack of experimental studies on the offensive capabilities of such atypical instruments underscores the need for objective trauma characterization to support the clinical-forensic interpretation of wounds. This study aims to experimentally demonstrate the wounding capacity of a nail clipper by reproducing incised injuries on a standardized simulation substrate and comparing them morphologically to the injuries observed in a real forensic case.

Case Report: The case concerned a male individual hospitalized as an emergency following an assault involving a small bladed object. The forensic examination conducted shortly after the incident revealed a left lateral cervical wound with second-degree abrasion and a small pneumothorax, two stab-like injuries on the left hemithorax, one on the left flank, two posterior lesions in the left scapular and right paravertebral regions, and an abrasion on the left antecubital fossa. Due to the vital location of the wounds and potential hemorrhagic risk, the initial prognosis was reserved. Upon clinical stabilization, a final prognosis of 15 days was given. The wounds exhibited sharp, clean margins and variable depth, consistent with a small pointed and cutting instrument.

Materials and Methods: An experimental study was conducted using a standard metal nail clipper with a 4.5 cm cutting blade, matching the dimensions and morphology of the object seized in the case. The simulation employed a high-density paperboard substrate (3 mm thick), selected for its consistent resistance to cutting. Multiple strikes were inflicted, varying both the angle of impact (45° to 90°) and the manually applied force, to reproduce a representative range of injury patterns. Each lesion was documented with digital photography under natural light, using a millimeter scale for accurate measurement of length, width, and wound edge characteristics. These parameters were then compared with the clinical-forensic wound data.

Results: Experimental incisions on the paperboard produced both linear and curved wounds with regular margins and depth proportional to the applied force. A 45° angle yielded oblique lesions with slightly frayed edges, while 90° strikes resulted in perpendicular, clean-edged wounds. Lesion lengths ranged from 0.8 to 2.5 cm, with average widths between 0.4 and 1.1 cm. Morphometric and photographic analysis revealed high morphological congruence with the clinical wounds in terms of shape, dimensions, and edge characteristics. Direct comparison between laboratory and clinical images confirmed strong traumatic compatibility between the experimental tool and the injuries observed in the patient.

Discussion: This study objectively demonstrated the wounding potential of a nail clipper, generally perceived as harmless. When applied with sufficient force and favorable angle, it can produce penetrating injuries of potentially serious nature. From a forensic perspective, the findings support classifying the nail clipper as an atypical yet effective improvised weapon.

F15 A Fatal Bilateral Jugular Vein Lesion From Multiple Sharp-Force Injuries: An Unusual Case Involving Atypical Weapons

Gianmarco Sirago, MD, Università degli Studi di Bari "A.Moro", Bari, Puglia, Italy; Natalia Sebastiani, MD, University of Bari "Aldo Moro", Medical-Legal Section of Policlinico di Bari, Bari, Puglia, Italy; Paolo Visci, University of Bari "Aldo Moro", Medical-Legal Section of Policlinico di Bari, Bari, Puglia, Italy; Davide Ferorelli, MD, University of Bari "Aldo Moro," Medical-Legal Section of Policlinico di Bari, Bari, Puglia, Italy; Annachiara Vinci, MD, University of Bari "Aldo Moro", Medical-Legal Section of Policlinico di Bari, Bari, Puglia, Italy; Alessandro Dell'Erba, MD, PhD, University of Bari "Aldo Moro", Bari, Puglia, Italy*

Learning Objectives: After attending this presentation, attendees will be able to: (1) recognize the forensic significance of small bilateral venous injuries in the neck and their potential for rapid lethality despite extensive surrounding trauma; (2) identify injury patterns consistent with multi-weapon assaults and overkill scenarios, including heterogeneous sharp- and blunt-force lesions; (3) apply a stepwise autopsy approach to complex homicide cases, with emphasis on meticulous cervical vascular dissection to accurately determine cause of death; and (4) correlate crime scene findings, wound morphology, and microanatomical autopsy results to reconstruct the sequence of assault in multi-injury cases.

Impact Statement: This case illustrates a rare case of paradoxical lethality in an overkill homicide, where a victim with 85 sharp- and blunt-force injuries died from two minute bilateral internal jugular vein lesions. Despite the overwhelming number of visually dramatic but non-lethal wounds, rapid exsanguination from these minor venous injuries proved fatal. By integrating meticulous autopsy techniques, detailed cervical vascular dissection, wound pattern analysis, and crime scene reconstruction, this case enhances the forensic community's ability to correctly identify the true mechanism of death in complex multi-weapon assaults, minimizes the risk of misattribution in overkill scenarios, and contributes to the refinement of homicide investigation protocols in forensic pathology.

Abstract Text: Homicides involving extensive sharp-force trauma are well documented in forensic literature; however, cases combining overkill patterns, the use of multiple improvised weapons, and lethality caused by minor venous injuries are exceedingly rare.[1] We present an unusual forensic case of a 63-year-old male found deceased in his residence with 85 sharp- and blunt-force injuries inflicted using multiple atypical weapons, including a deformed two-pronged kitchen fork and scissors.

On January 8, 2025, the victim was discovered prone in a pool of blood in the living room of his apartment in Santo Spirito, Bari. The crime scene investigation revealed minimal arterial blood spatter despite the extraordinary number of wounds. External examination and complete autopsy identified widespread lesions affecting the head, neck, trunk, and upper limbs, combined with multiple blunt-force impacts to the craniofacial region. Injury patterns and wound orientation indicated that the victim was assaulted in three phases: an initial attempt to occlude the mouth manually, followed by blunt-force strikes to the head, and finally a prolonged assault with sharp weapons while the victim lay prone, with the assailant positioned above him.

Despite the multiplicity and severity of injuries, death was determined to result from hemorrhagic shock primarily due to bilateral lesions of the internal jugular veins. Both fatal wounds were small—approximately 0.5–1 cm in external dimension—yet they caused rapid exsanguination from venous structures supplying the craniofacial circulation, a mechanism previously described in rare forensic cases.[2] The autopsy demonstrated abundant venous pooling without the high-pressure arterial spray typically associated with massive neck trauma, consistent with venous source bleeding. Histological and scene findings corroborated rapid blood loss and absence of defensive or escape activity following the critical injuries.

This case is original in several aspects: the simultaneous use of multiple improvised cutting instruments creating heterogeneous wound patterns; the overwhelming number of injuries giving an impression of massive trauma; and the paradoxical lethality of two minor venous lesions compared to the extensive but non-fatal surrounding wounds. It underscores the critical need for meticulous stepwise autopsy technique, including careful dissection of cervical vascular structures, to correctly identify the actual mechanism of death in complex overkill scenarios.

The findings emphasize that small venous injuries in the neck can be rapidly fatal, especially when bilateral and in the context of restrained or incapacitated victims. This report contributes to forensic literature on multi-weapon assaults and illustrates the importance of correlating scene reconstruction, injury morphology, and microanatomical dissection to avoid misattribution of cause of death in cases with extensive trauma.

F16 A Fatal Tracheal Impalement Injury: An Accidental Fall From a Height or Suicidal Event? A Case Report and Review of the Literature

Tindara Biondo, MD, Messina University, Messina, Sicilia, Italy; Gennaro Baldino, MD, PhD*, Messina University, Messina, Sicilia, Italy; Giorgia Burrascano, MD, Messina University, Messina, Sicilia, Italy; Pietro Tarzia, MD, Asp Reggio Calabria, Roccella Jonica, Calabria, Italy; Elvira Ventura Spagnolo, MD, Messina University, Biomorf Department, Medico legal section, Messina, Sicilia, Italy; Marija Caplinskiene, MD, Nicholas Romeris University of Vilnius, State Forensic Medicine Service, Vilnius, Vilnius, Vilniaus Apskritis, Lithuania*

Learning Objectives: Following this presentation, attendees will have gained a comprehensive understanding of impalement-related deaths and their mechanisms. Emphasis will be placed on the value of a multidisciplinary approach to case analysis

Impact Statement: This presentation contributes to the forensic science community by underscoring the importance of meticulous crime scene inspection and a multidisciplinary forensic approach to the body, raising critical questions concerning the accidental versus suicidal nature of impalement events as well as implications for occupational safety and prevention. A comparative evaluation with current literature enhances the discussion and informs forensic practice.

Introduction. Site inspections represent the initial and irreplicable step in corpse recovery. The involvement of a forensic pathologist in the early phases of investigation is crucial to ensure accurate collection of evidence and data. Impalement fatalities are rare in medico-legal practice.[1] A literature review was conducted to explore the spectrum of injuries and scenarios that may lead to fatal or near-fatal impalement.[2]

Case Report. A 57-year-old male construction worker was found deceased at the base of a scaffold, exhibiting a penetrating injury to the anterior neck. Forensic examination of the scene revealed an iron stake, typically a plant support, with blood on its upper end, morphologically consistent with the neck wound. Autopsy, histological, toxicological, and instrumental analyses determined the cause of death to be passive impalement trauma to the anterior neck, resulting in tracheal rupture. Surveillance footage corroborated the accidental fall from the scaffold and the immediate, self-removal of the iron stake post-injury. Toxicology revealed blood alcohol positivity.

Conclusion. This case highlights the diagnostic complexity of passive impalement trauma, as illustrated through comparative analysis and supported by existing medical literature. It emphasizes the critical role of forensic crime scene reconstruction in differentiating accidental events from suicidal acts. The multidisciplinary integration of pathology, toxicology, and video analysis proved essential in elucidating the sequence of events and determining the cause of death. Furthermore, the findings underscore the importance of stringent workplace safety measures and reinforce the value of interprofessional collaboration in forensic investigations.

F17 Forensic Age Estimation With Artificial Intelligence: An Experimental Study for the Identification of Underage Victims

Matteo Antonio Sacco, MD, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Alessandro Pasquale Tarallo, MD*, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Saverio Gualtieri, MD, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Aurora Princi, MD*, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Roberto Raffaele, MSc*, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Claudia Catia De Pasquale, MSc, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy;Andrea Costa, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Isabella Aquila, MD, PhD*, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy;*

Learning Objectives: After attending this presentation, participants will clearly understand the critical importance of accessible technological tools for the accurate automatic recognition of underage victims in online content.

Impact Statement: This presentation will impact the forensic science community by demonstrating the need to make reliable and publicly available AI tools accessible for the protection of minors.

Abstract Text: The identification of child sexual abuse material (CSAM) represents one of the most complex and urgent challenges in modern digital forensic science. The increasing digitalization and uncontrolled spread of online content have led to a significant rise in CSAM. One of the most critical aspects is the accurate estimation of the victim's age, a key element not only for the legal classification of the material but also for the effectiveness of investigations and the concrete protection of minors.

Visual age estimation, traditionally performed by experts through observation of physical traits and bodily development, is still the most used method. However, it presents significant limitations, including high inter-observer variability, cognitive bias, and the psychological burden on even highly trained professionals. In this context, the integration of artificial intelligence (AI) tools into digital forensics offers a valuable opportunity. Convolutional neural networks (CNNs) have demonstrated excellent performance in automatic age estimation from facial images, with reported mean absolute errors (MAE) ranging from 2.93 to 6.69 years and accuracy levels exceeding 99% in dento-maxillofacial radiographs. Recent studies also show that the use of these systems reduces analysis time by up to 93%, with facial recognition precision surpassing 70%.[1-6] Further promising results come from Grubl et al., who achieved an MAE of 1.79 years in subjects aged 10 to 15 using the Deep EXpectation (DEX) algorithm on the IMDB-WIKI dataset.

The present study aimed to experimentally evaluate the effectiveness of the Face++ API algorithm in recognizing age in underage individuals. A total of 112 images were initially selected from the UTKFace dataset, evenly divided between minors (3–17 years) and adults (18–90 years). After a selection process based on image quality (including only clearly visible and correctly framed faces), 94 images were included in the final analysis: 55 minors and 39 adults. Images were chosen based on strict quality criteria (good facial visibility, frontal or semi-frontal framing, and confirmed chronological age). Data analysis showed that the algorithm correctly identified 50 out of 55 underage individuals, and 36 out of 39 adults. This yielded an overall accuracy of 91.5%. The sensitivity of the test (its ability to correctly detect minors) was 90.9%, while the specificity (its ability to correctly identify adults) was 92.3%. These values indicate a good level of reliability for automated age categorization, with room for improvement through optimization of training datasets. Further analysis is underway to assess statistical agreement using Cohen's kappa coefficient and to estimate confidence intervals.

AI-based technologies offer promising perspectives for automatic age recognition in digital forensic contexts, particularly in handling child sexual abuse materials. The accuracy observed in our study suggests that such tools may serve as valuable support in investigations, enhancing child protection and operational efficiency. However, to achieve real-world impact, these technologies must be systematically implemented and made accessible to forensic professionals in public and judicial settings.

F18 Forensic Aspects of "Incaprettamento"

Saverio Gualtieri, MD, Department of Medical and Surgical Sciences, Magna Graecia Un1iversity of Catanzaro, Catanzaro, Calabria, Italy; Matteo Antonio Sacco, MD*, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Alessandro Pasquale Tarallo, MD, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Mattia Solano, MD*, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Pietro Tarzia, MD*, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Savino Franco, MD, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Isabella Aquila, MD, PhD*, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy*

Learning Objectives: After attending this presentation, attendees will understand the forensic features, execution techniques, and symbolic meaning of "incaprettamento," with particular focus on its impact on forensic investigations and reconstruction of the cause and manner of death.

Impact Statement: This presentation will impact the forensic sciences community by demonstrating the relevance of integrated analysis of autopsy findings and ligature patterns in cases of incaprettamento, contributing to a better interpretation of ritual homicides and raising awareness of the risks of positional asphyxia in both criminal and non-criminal settings.

Introduction: Incaprettamento is a ritualistic homicide method historically linked to the Calabrian 'Ndrangheta, characterized by binding techniques that induce positional asphyxia while conveying a symbolic message of humiliation, control, and punishment for betrayal. This execution style often includes a signature positioning of the body and specific ligature methods with deep criminological and cultural significance. Several published forensic reports document such cases, revealing recurring patterns of brutality and symbolism.

Materials and Methods: A systematic literature review was conducted using the PubMed database with the keywords "incaprettamento and death" and "hogtie and death." Six articles describing forensic cases of incaprettamento were selected and analyzed, focusing on medicolegal and criminological characteristics.

Results: Published cases describe victims immobilized in a prone position, with wrists and ankles tied behind the back and a cord often connecting the limbs to the neck, causing positional asphyxia. In some cases, the body was wrapped in tape or placed in sacks. Autopsy findings frequently included abrasions and ligature marks on the neck, wrists, ankles, and torso; fractures of cervical structures (thyroid cartilage, hyoid bone, cricoid); and typical asphyxial signs (petechiae, visceral congestion, pulmonary edema). Some cases showed postmortem mutilation (e.g., penile amputation), simulation of honor crimes, and varied ligature materials. Victims were predominantly adults, including transgender individuals. Ritualistic elements were recurrent at the crime scene.

Discussion: Accurate recognition of ligature configurations and autopsy evidence is essential to differentiate this practice from other mechanical asphyxia or simulated suicidal events. Determining the vitality of injuries—via both gross and histological examination—is crucial in distinguishing antemortem trauma from postmortem alterations. This study contributes to the forensic understanding of incaprettamento, outlining injury patterns and providing objective elements for postmortem assessment. Additionally, it enhances insight into the criminological context of such executions, emphasizing their symbolic and punitive roles. However, the literature suffers from limitations: the number of documented cases remains low, and clandestine circumstances or crime scene tampering may lead to significant underreporting. These challenges underscore the need for broader data sharing and further investigation within the forensic field.

Conclusion: Incaprettamento constitutes a ritualistic homicide practice marked by symbolic execution methods and consistent forensic patterns, reflecting organized crime's control and brutality. Forensic practitioners must be familiar with its distinctive dynamics to accurately interpret autopsy findings and reconstruct the sequence of events. Interdisciplinary collaboration and systematic data collection are essential for advancing diagnostic precision and forensic awareness.[1-4]

F19 From Autopsy to Action: Leveraging Medicolegal Data to Prevent Overdose Deaths in Correctional Facilities

Ava S. Lewandowski, BA, UAMS College of Medicine, Little Rock, AK; Theodore T. Brown, MD, Arkansas State Crime Laboratory, Little Rock, AK*

Learning Objectives: After attending this presentation, participants will have a better understanding of how overdose mortality data from Arkansas correctional facilities can be used to inform strategies that prevent drug-related deaths.

Impact Statement: This presentation will impact the forensic science community by demonstrating how data-driven insights into overdose deaths can drive positive change in correctional systems. By identifying opportunities in prevention and care, it supports strategies to improve inmate well-being, enhance staff readiness, and promote long-term recovery and rehabilitation.

Abstract Text: Since March 2022, the Arkansas Department of Corrections (ADC) has reported 64 drug overdose and overdose-related deaths, accounting for 34% of all ADC deaths referred for autopsy by the Arkansas State Crime Laboratory. This data represents an opportunity to save lives, support recovery, and promote safer correctional environments.

Through a comprehensive review of available medicolegal death investigations and autopsy reports, this project identifies key areas where improved care, surveillance, and intervention could significantly reduce overdose-related fatalities. Among the 64 decedents, 89% were male and 11% female, with an average age of 43.6 years. Racially, 41.9% were African American/Black and 58% were White. Over half of the cases (53.6%) involved synthetic cannabinoids, followed by methamphetamine (21.8%) and fentanyl (14.5%), often appearing in combination.

Notably, 78.4% of individuals with documented medical histories had a known substance use disorder (SUD), underscoring a significant opportunity to expand access to medication-assisted treatment (MAT) and deliver more proactive, person-centered care. In 50% of cases, drug paraphernalia was found either on the scene or within the body, pointing to practical opportunities for enhancing contraband detection strategies. Additionally, 45.3% of cases included video evidence or eyewitness testimony, signaling the potential value of technology-assisted monitoring to strengthen response times and oversight.

To further advance prevention efforts, medical examiner and coroner offices can play a critical role by collaborating with correctional facilities to share timely data on emerging drug trends, such as through a drug overdose dashboard. Medical examiner and coroner offices should also consider establishing dedicated death review teams, in partnership with correctional facility personnel, to systematically examine correctional facility fatalities, including drug overdoses, to determine root causes and identify actionable system-level gaps. These multidisciplinary teams can help clarify what medicolegal death information would be most useful to improve both surveillance and clinical care. Through stronger interagency partnerships, better use of forensic data, and coordinated interventions, correctional systems can improve health outcomes, reduce mortality, and enhance the safety and dignity of incarcerated individuals.

F20 From Scene to Autopsy: Foundational Forensic Methods for the Suicide–Homicide Distinction

Gabriella Maisetta, MD, Università di Pisa, Pisa, Toscana, Italy; Rebecca Pieretti, MD*, University of Pisa, Lucca, Toscana, Italy; Marco Di Paolo, MD, PhD, University of Pisa, Pisa, Toscana, Italy; Federica Spina, MD, Università di Pisa, Pisa, Toscana, Italy; Matteo Leoni, MD, Università di Pisa, Pisa, Toscana, Italy; Chiara Ariani, MD, University of Pisa, Marliana, Toscana, Italy*

Learning Objectives: Attendees will explore how a structured approach combining wound morphology, environmental context, and microscopic tissue evaluation contributes to evidence-based differentiation between suicide and homicide. This presentation will provide measurable skills in correlating scene context, injury morphology, and vitality testing to reconstruct complex death dynamics with forensic reliability.

Impact Statement: This presentation will enhance forensic practitioners' ability to apply foundational investigative methods in cases involving multiple trauma modalities. By strengthening the link between autopsy findings and scene interpretation, attendees will improve performance in distinguishing manner of death, reducing classification errors, and supporting justice system integrity.

Abstract Text: A 60-year-old male with a documented history of chronic spinal pain and depressive symptoms was found deceased in a prone position in a residential parking lot, directly beneath the balcony of his second-floor apartment. The body was lying approximately 1.75 meters from the building wall, over a large pool of blood. The decedent was wearing only undergarments. External examination revealed multiple blunt injuries, including facial abrasions and contusions, as well as exposed fractures of both lower limbs. A segment of small bowel was eviscerated from an abdominal wound, suggesting sharp force trauma.

Upon rotation of the body into a supine position, six incised wounds became visible: four on the anterior thorax, one on the left cervical region, and one abdominal lesion with bowel protrusion. The wound morphology—superficial-to-deep track, accessible anatomical locations, regular edges, and consistent directionality—supported the hypothesis of self-infliction. As confirmed by autopsy, none of the lesions involved major vascular structures or showed characteristics of hesitation or defense wounds. Histological analysis demonstrated clear ante-mortem vitality in all sharp injuries, including granulation tissue and hemorrhagic infiltration at the bowel margins, suggesting that the abdominal lesion, although dramatic in appearance, was not acutely fatal.

The injuries resulting from the fall included cranial fractures with subarachnoid hemorrhage, multiple rib fractures, and bilateral exposed fractures of the lower limbs. Histological examination confirmed that these traumatic lesions were also sustained during life. This indicated that the fall from height occurred after the self-inflicted wounds, and that the decedent was alive at the moment of impact.

The investigation highlighted the necessity of integrating autopsy findings with systematic crime scene analysis. The living room—whose door was reportedly locked from the inside, according to the decedent's wife—contained extensive blood evidence in passive drip, transfer, and swipe patterns, indicating movement and prolonged presence of the victim after bleeding began. A kitchen knife with a 16 cm single-edged blade, consistent with the incised injuries, was recovered on a table near an open box of prescribed Oramorph. The victim's clothing was found nearby, clean, neatly folded, and without tears or bloodstains, suggesting a deliberate and voluntary disrobing before the injuries were inflicted.

No signs of struggle or forced entry were identified. The presence of blood on the balcony floor and railing, coupled with the final body location and absence of evidence of third-party involvement or external coercion, reinforced the hypothesis of a suicidal act by jumping.

This case exemplifies the critical importance of combining fundamental forensic disciplines—scene reconstruction, injury pattern recognition, behavioral context, and histological testing—to accurately reconstruct complex death scenarios. By adhering to core principles and maintaining an objective, methodical approach, it was possible to exclude homicidal violence and support a scientifically grounded conclusion of suicide. The case reinforces the indispensable role of basic forensic competencies in ensuring both investigative reliability and judicial accuracy.

F21 High-Energy Blunt Force Trauma: Massive Craniofacial Disruption From a Tire Projection

Fabio Del Duca, MD, PhD, Tor Vergata University of Rome, Rome, Lazio, Italy; Alessandro Ghamlouch, MD, Sapienza, University of Rome, Rome, Lazio, Italy; Biancamaria Treves, MD, Sapienza, University of Rome, Rome, Lazio, Italy; Gaia De Angelis, MD, Sapienza, University of Rome, Rome, Lazio, Italy; Maura Racciatti, MD, Sapienza, University of Rome, ROME, Lazio, Italy; Vittoria Zammar, MD, Universita di Genova, Rocca di papa, Lazio, Italy*

Learning Objectives: Attendees will learn to apply fundamental principles of forensic analysis to evaluate complex, high-energy blunt force trauma. They will gain practical skills in interpreting patterned lesions and leveraging circumstantial evidence to accurately determine injury mechanisms, even in highly challenging cases.

Impact Statement: This presentation will enhance forensic competence and performance by providing a clear methodological framework for analyzing atypical blunt force trauma cases. This approach will lead to more accurate injury assessments, support more robust medicolegal investigations, and ultimately contribute to improved accountability, justice, and workplace safety.

Introduction: Forensic science, at its core, rests upon universally recognized principles which are fundamental for meticulous investigation and interpretation. However, when confronted with extreme complexity, such as high-energy blunt force trauma, these cases deeply challenge conventional assessment. Such scenarios emphasize the imperative for forensic practitioners to embark on a rigorous return to fundamental principles, thereby rebuilding and reinforcing the very foundations of injury analysis.

Case Report: We here report a case of a 57-year-old male who suffered massive craniofacial trauma from the violent projection of a tire during an industrial inflation procedure. The trauma manifested as a distinct patterned lesion, precisely molding the contours of the impacting object with distinctive rounded margins. Our analysis of these unique lesions aims to lay solid foundations for a strong approach to forensic injury evaluation and future practice.

Discussion: This case is more than a tragic occupational fatality; it stands as an important touchstone. It compellingly demonstrates why methodical adherence to fundamental scientific principles, driven by the individual forensic practitioner, is non-negotiable when analyzing atypical, high-energy mechanisms. This incident offers valuable insights into the specific biomechanics of blunt force trauma. Moreover, it also highlights the practitioner's indispensable role in ethical, thorough, and precise medico-legal investigation. This ethical duty is key, as the integrity of forensic application directly impacts accountability, workplace safety, and prevents the systemic failures that could lead to injustice. This presentation serves as a powerful call to empower and recognize the individual experts who tirelessly uphold the integrity of forensic foundations.

F22 The Incidentally Detected 46, XY Disorder of Sex Development in Short Tandem Repeat Analysis

Sojung Lim, MD, Seoul National University, Seoul, Seoul-t'ukpyolsi, Republic of Korea; Sohee Cho, PhD, Seoul National University, Seoul, Seoul-t'ukpyolsi, Republic of Korea; Soong Deok Lee, MD, PhD, Seoul National University, Seoul, Seoul-t'ukpyolsi, Republic of Korea*

Learning Objectives: Through this presentation, attendees will understand that the biological sex determined by Short Tandem Repeat (STR) analysis may differ from the perceived gender. Sex-specific markers in STR analysis may reveal incidental findings related to sex development. This presentation will provide an insight of the associated ethical issues and medical implications. It will also highlight how such results may be misleading in forensic investigations.

Impact Statement: By raising awareness of the limitations of sex profiling, this presentation will enhance the ability of forensic professionals to critically evaluate STR-based sex determination results. It will also provide an opportunity to discuss ethical concerns related to incidental findings in forensic practice.

Abstract Text: Short tandem repeat (STR) analysis is the most widely used method in the field of forensic genetics. Sex determination is performed by including markers such as amelogenin, Y-STR, and Y indel. While autosomal STR markers do not reveal health-related information, sex determination markers can incidentally uncover sex chromosome abnormalities or disorders of sex development (DSDs).[1]

Here, we present a case of 46, XY DSD incidentally identified during kinship testing. The subject was a 73-year-old woman. However, both AMELX and AMELY alleles were detected with similar peak heights on STR analysis. DYS391 and Y indel loci were also detected. In addition, Y-STR analysis showed a complete profile, and all loci were hemizygous on X-STR analysis. The subject reported a lifelong history of primary amenorrhea and had no biological offspring. After obtaining informed consent, targeted sequencing for 63 genes associated with DSD was performed. *AR* c.2173+1G >A splicing variant was detected, suggesting a possibility of androgen insensitivity syndrome.

As demonstrated in our case, discrepancies may arise between the sex inferred from STR analysis and the phenotypic or perceived gender. This may be a result of AMELY deletion or mutations at the primer binding site of the amleogenin locus, in which retesting with a different STR kit or performing additional X-STR and Y-STR analyses can resolve the discrepancy.[2] On the other hand, it can be the result of a true DSD. In such cases, sequencing of DSD-related genes, such as *AR* and *SRY*, can help identify the underlying cause. Referral to a specialized medical center may also be warranted because the risk of developing a gonadal malignancy is increased in DSD.[3,4] Nonetheless, the disclosure of incidental findings can raise serious privacy issues, and it needs careful ethical consideration.[5] Furthermore, forensic professionals should be aware of the inaccuracies of sex profiling, since the results may be potentially misleading in investigative contexts.

F23 Investigating and Analyzing After a Fatal Fall From Heights

Isabelle Sec, MD, Institut Médico-Légal, Bordeaux, Aquitaine, France; Patrick Joffrin, IFSTTAR, Bron, Rhone-Alpes, France; Bertrand Ludes, PhD, Institut Médico-Légal, Paris, Ile-de-France, France*

Learning Objectives: After attending this presentation, you will understand how the layout of the premises and measurements of the crime scene were essential to analyzing a fall and providing answers.

Impact Statement: This presentation will impact the forensic science community by showing the importance of physical equations, theoretical trajectories, the investigation data, and various statements.

Abstract Text: Falls from heights, including balconies, do not generally pose any medical difficulties when investigating the causes of death. However, determining the forensic circumstances surrounding the fall requires in-depth expertise.

The medical examiner is often called upon to answer numerous questions concerning the circumstances of the fall: did the victim jump alone, for example, by climbing out of a window or over a balcony, fall accidentally, or was pushed? These forensic cases are particularly difficult, and it seems that an autopsy is the first essential step, particularly to look for injuries in the areas where the victim may have grabbed or held on. The toxicological analysis completes these forensic findings and investigates for alcohol consumption or drug use. Indeed, alcohol consumption increases balance disorders, decreases reflexes and coordination, and consequently, the risk of falls and serious injuries. In addition, drinking causes people to make irresponsible decisions, have memory lapses.

Then, in a second step, the expert may be appointed as part of a judicial investigation to rule on the statements of a person under investigation. He or she may also be assisted by a co-expert specializing in biomechanics or accidentology to describe the "anatomy of the fall."

Illustrated by a case report, determining the medico-legal circumstances of the fall first required an analysis of all the procedural documents, including the findings on the crime scene, such as photographic albums and plans, as well as various witness statements. In this case, violence was inflicted on the victim before and after the fall, which the defendant admitted, but he denied causing the fall.

We will see how the layout of the premises and measurements of the crime scene were essential in providing answers. The forensic pathologist used a biomechanical engineer to analyze the fall, using physical equations, and to compare the theoretical trajectories with the measurements made when the body was discovered.

Findings in cases involving falls from a great height are essential. In certain complex cases, it is important to revisit the "fall equation" by consulting a biomechanics or accidentology expert and comparing these raw results with the investigation data and various statements.

F24 Investigating the Effects of Substrate Color on the Detection of Ruhemann's Purple Using Confocal Raman Microscopy

Daye Kim, MFS, Sam Houston State University, Huntsville, TX; Jorn Yu, PhD, Sam Houston State University, Huntsville, TX; Geraldine Monjardez, PhD, Sam Houston State University, Huntsville, TX*

Learning Objectives: After attending this presentation, attendees will gain greater understanding of the impact of substrate color on the visualization of Ruhemann's purple, the chromogenic product of the ninhydrin reaction, in latent fingerprints and bloodstains using confocal Raman microscopy. The audience will learn that confocal Raman microscopy enables the detection of molecular signatures of biological residues even after ninhydrin application, highlighting its potential for non-destructive forensic analysis of Ruhemann's purple on colored paper substrates.

Impact Statement: This presentation highlights the capability of confocal Raman microscopy as a mostly non-destructive and highly sensitive technique for detecting both fingerprint residues and trace biological materials such as blood, even after the application of chemical enhancement reagents like ninhydrin. The ability to recover molecular-level information from colored substrates enhances the applicability of this technique to latent print detection, particularly in complex real-world scenarios where fingerprints are commonly deposited on non-white surfaces. This approach has the potential to enhance the probative value of latent print evidence by providing optimized detection parameters and minimally invasive protocols in forensic investigations.

Abstract Text: While latent fingerprints detection and visualization involve pattern recognition and are influenced by subjective interpretation, they continue to be a cornerstone in forensic science. Visualizing latent fingerprints is an essential skill for both crime scene investigators and latent fingerprint examiners. Successful development depends largely on understanding the chemical makeup of the fingerprint residue and the nature of the substrate on which it is deposited. Ninhydrin, the most commonly used chemical reagent, reacts with amino acid residues present in latent fingerprints and blood traces, producing Ruhemann's purple (RP), a chromogenic compound that aids in the visualization of latent patterns on porous substrates such as paper. Although RP is widely used in forensic processing, the impact of substrate color on its detection using spectroscopic methods has not been thoroughly examined. This study therefore investigates the influence of background substrate color on the detectability of RP and associated biological residues using confocal Raman microscopy, a mainly non-destructive and chemically specific analytical technique.

To examine the detection and interference of the substrate colors, samples were deposited on white and five different colored paper substrates. The colors were selected based on the lack of contrast between the paper background and the RP, as observed by the naked eye. Raman spectra were collected using 532 nm and 785 nm excitation laser wavelengths, 10 seconds exposure time, less than 10% of laser power, and 3 accumulations for each spot to detect RP, fingerprint residues, and blood components. The laser power varied depending on the laser wavelength and the color of the paper substrates.

RP was consistently identified across all paper colors, with prominent peaks observed at 662 and 792 cm^{-1}, corresponding to characteristic carbonyl vibrational modes. Hemoglobin-specific Raman bands were also detected in samples containing blood. Moreover, no significant spectral interference from background paper color was observed, confirming that substrate color does not inhibit Raman scattering signals of RP.

These findings underscore the potential of Raman microscopy for application on latent prints, particularly on colored substrates. By demonstrating color-independent detection, this study supports the integration of spectroscopy into latent print workflows. Moreover, this approach may provide additional contextual information by detecting biological components within target samples. Overall, the results demonstrate that Raman microscopy is a non-destructive and highly sensitive technique for identifying both fingerprint residues and trace biological materials such as blood, even after chemical enhancement with ninhydrin.

In summary, Raman microscopy enables reliable detection of latent fingerprints and biological residues regardless of substrate color, highlighting its value in forensic analysis of latent prints.

F25 It Went Under My Skin: Assessing Tattoo Persistence Under Postmortem Conditions

Jade Ryan, MSc, Liverpool John Moores University, Liverpool, England, United Kingdom; Matteo Borrini, PhD, Liverpool John Moores University, Liverpool, England, United Kingdom*

Learning Objectives: After attending this presentation, attendees will be able to evaluate the effects of postmortem changes on tattoo preservation and the potentials offered by alternative light sources to enhance their detection and documentation in forensic cases.

Impact Statement: This presentation will impact the forensic science community by enhancing competence in understanding tattoo degradation under varied postmortem conditions, improving the practical application of alternative light sources for accurate tattoo visualization, and ultimately strengthening the reliability of tattoo-based identification in forensic investigations, supporting more effective victim identification, particularly in mass fatalities and migrant deaths.

Abstract Text: Tattoos are widely recognized as valuable secondary identifiers in forensic investigations, particularly in Disaster Victim Identification and cases involving missing persons, such as migrant deaths.[1] Despite their increasing use, there is a significant lack of empirical research into how tattoos degrade under postmortem conditions—particularly desiccation and aquatic environments—which may compromise their visualization, documentation and reliability in forensic identification.

This study examined morphometric and visual changes in tattoos during desiccation and evaluated the efficacy of various alternative light sources (ALS) for enhancing tattoo visibility. Seventeen pig (*Sus scrofa*) skin samples were tattooed by a professional artist using seven commercially available ink colors and a homemade ash-based ink, simulating inks commonly found in traditional and correctional settings. For each color, two samples were tattooed with five geometric symbols (circle, solid circle, cross, grid, hank). Samples underwent desiccation on silica gel in a controlled environment (laboratory oven at 40°C) for seven weeks. One sample per pair was covered with horse blood to simulate presence of wounds and bleeding. Morphometric changes were measured weekly using digital calipers, and statistically analyzed using a two-way mixed ANOVA.

Additionally, one sample underwent artificial mummification using natron to mimic ancient preservation techniques, and another was submerged in spring water at room temperature; these were examined only on the seventh week.

Results demonstrated a statistically significant reduction in tattoo size between weeks one and two ($p < .001$), after which changes stabilized. All dimensional changes were under 1 mm and visually imperceptible, suggesting minimal impact on identification for forensic use. Most ink showed negligible color change; however, lighter inks (red, yellow, orange) appeared slightly darker or muted, likely due to skin pigmentation alterations during desiccation.

For the documentation of the tattoos, ALS testing included visible light wavelengths (red, violet, cyan, royal blue), longwave and shortwave ultraviolet, and infrared. Infrared was most effective in visualizing tattoos covered by blood, particularly those with darker pigments, whereas visible and UV light offered limited enhancement.

In contrast, tattoos on the water-submerged sample visually deteriorated and vanished during gentle drying; no ALS revealed residual ink or needle impressions, underscoring the need for further research on aquatic tattoo taphonomy, particularly in consideration of the cases that can involve migrant deaths in the sea.

The authors present a controlled investigation of tattoo degradation under desiccation and aquatic conditions. Findings confirm that while desiccation minimally affects tattoo visibility, aquatic environments may cause complete loss of tattoo evidence. The results highlight the forensic value of infrared ALS in recovering taphonomically altered tattoos and emphasize the need for continued research on postmortem tattoo persistence across diverse environmental scenarios. These insights advance tattoo-based identification protocols and reinforce the significance of dermal evidence in forensic science.

F26 Knife Crimes Then and Now: Forensic Lessons From the Murder of Martha Tabram

Matteo Borrini, PhD, Liverpool John Moores University, Liverpool, England, United Kingdom*

Learning Objectives: After attending this presentation, attendees will understand the importance of a holistic, multidisciplinary approach to knife-crime investigations and the main challenges that can interfere with accurate reconstructions, including the limitations of wound morphology on soft tissues and the need to integrate bloodstain-pattern analysis in crime scene evaluation.

Impact Statement: This presentation will impact the forensic science community by using the historical Martha Tabram case, the possible first murder of Jack the Ripper, to highlight the importance of a holistic, multidisciplinary approach to knife-crime investigations. By integrating bloodstain pattern analysis, clothing damage assessment, and cut-mark examination, the case illustrates how comprehensive methods can enhance the accuracy and reliability of modern sharp-force homicide reconstructions.

Abstract Text: Martha Tabram was murdered with multiple stab wounds in the early hours of August 7, 1888, on a landing of the George Yard Buildings in London, UK.[1] Although traditionally listed among the "Whitechapel murders," she is not counted among the canonical five victims attributed to Jack the Ripper. Nonetheless, many historians and criminologists consider Tabram a potential first victim of the notorious killer. This historical case highlights critical challenges and best practices in the investigation of sharp force homicides that remain deeply relevant to contemporary forensic science.

First, the case review underscores the necessity of processing the crime scene as a multifactorial system. While systematic documentation of the body's position is fundamental, it represents only a single aspect of scene analysis. Equally crucial is the presence and analysis of bloodstains (BPA), which can provide essential information for reconstructing the dynamics of the crime, including the relative positions and postures of victim and assailant, their movements during the event, the direction and angle of the blows.

A particularly controversial aspect of the Tabram case concerns the number and type of weapons employed. Contemporary forensic opinions suggested both a bayonet and a smaller knife. Modern forensic standards caution against relying solely on wound morphology to deduce weapon characteristics. Martha Tabram sustained both superficial and deep lesions, including punctures and cuts, and in various parts of the body, aspects that can produce different wound morphologies mimicking the use of multiple implements. Furthermore, specific aggressor's behaviors or intentions (e.g. slicing the throat or picquerism) can result in a different handling of the tool and wound morphology.

Thus, in the investigation of sharp-force homicides, wounds must be assessed holistically alongside bloodstains and clothing patterns to accurately reconstruct crime dynamics and weapon type.

The Tabram case also exemplifies the importance of comprehensively interpreting the autopsy findings, taking into account all anomalies on the body (e.g. bruises or wounds associated with different forms of assault) to evaluate their possible forensic relevance and the sequence of events.

Another critical lesson gained from this case is the potentially misleading impact of soft tissues on interpreting sharp force injuries. To address this, investigators should prioritize analysis of cut marks on rigid (bone) or semi-rigid (cartilage) structures, which better preserve blade characteristics.[2] Integrating anthropological expertise and fostering multidisciplinary collaboration further enhances the reliability of evidence interpretation and the overall reconstruction of the crime.

In conclusion, the murder of Martha Tabram illustrates enduring forensic imperatives in sharp-force homicide investigation. Her case underscores the necessity of comprehensive scene documentation, BPA-based reconstruction, contextual interpretation of wounds, and a cautious, standardized analysis of cut marks to improve the accuracy of modern forensic investigations in knife crimes.

F27 An LC/MS/MS Analysis of Benzodiazepines in Sewage From Six Metropolitan Areas in the Southeastern United States

Kyle Bledsoe, BS, The University of Mississippi, Memphis, TN; Iram Shahzadi, ElSohly Laboratories Incorporated, Oxford, MS; Katherine Bollinger, APM, Research Triangle Institute, Durham, NC; Mahmoud ElSohly, PhD, University of Mississippi, Oxford, MS; Murrell Godfrey, PhD, University of Mississippi, Oxford, MS; Waseem Gul, PhD, ElSohly Laboratories Incorporated, Oxford, MS*

Learning Objectives: Attendees will learn about the latest methods used in Sewage-Based Epidemiological (SBE) research as it relates to the detection of drug residues. This presentation will inform attendees of the unique trends in benzodiazepine consumption in the Southeastern Region of the United States. This presentation will inform or reinforce the importance and utility of sewage-based epidemiology as an increasingly useful non-invasive, non-incriminating means of community-level surveillance of public health indicators.

Impact Statement: This project is the first comprehensive, regional SBE study to focus on the Southeastern United States. As such, this is an important addition to the application of SBE for drug surveillance toward the betterment of scientific understanding of the correlation between geographical areas and drug consumption.

Abstract Text: Abuse of benzodiazepines presents an increasing public health and forensic concern that can have severe societal consequences, as their use can lead to profound loss of motor functions, and anterograde amnesia—negative side effects which lead to increased instances of motor-vehicle accidents, overdosing, and date-rape incidents, respectively.[1-5] This study was conducted to develop, validate, and establish new methods of analysis of benzodiazepine drug residues in sewage to track the development of benzodiazepine abuse. Here, 8 common Benzodiazepine residues (i.e. flurazepam, 7-NH_2-flunitrazepam (7-NH_2-FLUN), α-OH-alprazolam (α-OH-ALPRAZ), alprazolam (ALPRAZ), oxazepam (OXAZ), Temazepam (TEMAZ), Nordazepam (NORD), and 2-OH-ethyl-flurazepam) were probed for in wastewater samples collected from six metropolitan areas across the Southeastern Region of the U.S. (including Birmingham, AL; Baton Rouge, LA; New Orleans, LA; Jackson, MS; Oxford, MS; and Memphis, TN) using UHPLC coupled to triple quadrupole (QqQ) mass spectrometry. Of the 8 drug residues sought, 4 (alprazolam, α-OH-alprazolam, Nordazepam, and Temazepam) were detected in quantifiable amounts. According to calculations based upon average dosages of each drug, alprazolam is the most prominent drug in each location except in the college town of Oxford, MS. This paper details the first sewage-based epidemiological study on benzodiazepine usage trends in the Southeastern Region of the U.S.

F28 Lethal Heat—The Deadly Impact of Rising Global Temperatures: A Case Study

Monica La Greca, APM, Sapienza, Università di Roma, Roma, Lazio, Italy; Gianluca N. Piras, MD, Local Health Authority, Belluno, Italy, Belluno, Veneto, Italy; Benedetta Baldari, PhD, Sapienza University, Roma, Lazio, Italy*

Learning Objectives: Attendees will learn the difference in defining deaths caused by extreme temperatures and how to incorporate this diagnostic element into the differential formulation of the cause of death. Participants will understand how immunohistochemical investigations can be a valuable aid in determining the causes of death in cases of heatstroke, although caution is required due to the non-specific nature of both macroscopic and microscopic autopsy findings.

Impact Statement: Our work lays the foundation for not overlooking the suspicion of heatstroke-related death, which must be considered as the climate crisis caused by global warming. The case study illustrates the techniques to be applied to support the suspicion of heatstroke-related death, which should be just hypothesized in the elderly population, despite the limited evidence in the literature, due to the comorbidities often present in this age group.

Abstract Text: Although climate change has different repercussions depending on the geographical area considered, the overall risk of heatstroke-related death has been increasing in recent years. The World Health Organization has estimated that in the past two decades, at least half a million deaths were associated with heatwaves—half of them in Asia and one-third in Europe.[1,2]

Generally, literature on heatstroke-related deaths focuses on the pediatric population, either in domestic settings or inside vehicles where children are unintentionally left by their parents.[3,4] Cases involving heatstroke deaths among the elderly are much rarer: although this age group is equally vulnerable to extreme temperatures, the frequent presence of other comorbidities often overshadows the hypothesis of death due to heat exposure. Moreover, work-related deaths due to heat stroke or extreme temperatures are even less addressed in the existing literature. Indeed, heatstroke deaths are considered a diagnosis of exclusion, as true hyperthermia requires the measurement of body temperature before death occurs, and must be confirmed as exceeding 40.6°C.[5]

Our work aims to present the case of a worker who died from heatstroke within his shift. The case study concerns a male subject, aged 68, who presented to the Emergency Department with non-specific symptoms, after suffering a sudden loss of consciousness while at work. Despite appropriate medical intervention, the patient died shortly after hospital admission; death occurred so rapidly that it was not possible to measure the body temperature. An autopsy was requested by the competent Judicial Authority, and a complete postmortem examination was carried out. Macroscopic findings showed visceral petechiae involving the heart, the lungs, and the diaphragm, in the context of three-vessel coronary artery disease; histological examinations revealed acute pulmonary emphysema, which is typically associated with violent mechanical asphyxia. Toxicological analyses were negative.

In our case, the expression of Heat Shock Proteins (HSPs) was detected in skin tissue, potentially indicating that the man had been exposed to extremely high temperatures while still alive, as well as brain, liver and kidney. This immunohistochemical finding—alongside circumstantial evidence, autopsy results, and toxicological analyses—contributed to establishing the cause of death.[6-8]

Our study confirms that the forensic diagnosis of heat-related deaths relies on a combination of multiple sources: circumstantial information, autopsy examination, and toxicology testing. These data are often non-specific and, in many cases, not entirely available, increasing the risk of underdiagnosing this type of death. Given that the diagnosis remains one of exclusion, it is crucial to collect all relevant information meticulously.

In particularly complex cases such as ours, an in-depth investigation of the decedent's clinical history becomes essential. Moreover, immunohistochemical analysis proves to be a valuable tool in suspected heatstroke deaths, where no pathognomonic signs are present to enable a straightforward diagnosis.

As demonstrated in our case, both the subject's medical history and contextual information can offer critical insight into the dynamics of death. When heatstroke is suspected and no alternative causes of death are identified, immunohistochemical testing for specific proteins—such as HSPs—may provide additional diagnostic support, especially if of forensic relevance.

F29 Medicolegal Death Investigation and the Use of Digital Latent Print Analysis in Establishing Positive Identification on Complex, High Profile, and Time-Sensitive Cases

Caroline G. Hanau, MS, Tippecanoe County Coroner's Office, Lafayette, IN; Aubrey Bryak, MDI*, Tippecanoe County Coroner's Office, Lafayette, IN; Carrie Costello, MS, Tippecanoe Coroner Office, Lafayette, IN*

Learning Objectives: After observing this poster presentation, attendees will understand the importance and benefit of utilizing digital latent print analysis in medicolegal death investigations to establish positive identification of the deceased. This poster will highlight and provide real case examples where positive identification was established via digital latent print analysis when other methods were not reasonable or possible.

Impact Statement: This poster presentation will impact the forensic science community by demonstrating how important, useful, and quick, digital latent print analysis can be in establishing positive identification of a decedent when other methods such as DNA comparison and visual identification are not possible. This poster will show how easy it is to take and submit fingerprint photographs for comparison without the need for ink or expensive fingerprinting devices, therefore saving time, money, and resources.

Abstract Text: The Tippecanoe County Coroner's Office, located in Lafayette, IN, follows strict Indiana laws regarding the identification of deceased individuals per IC 36-2-14-6.5. When attempting to establish a positive identification in each medicolegal death investigation there are problems that can arise. In situations where the decedent's cause of death has left them badly burned, injured, or decomposed beyond recognition, establishing positive identification can be challenging. In other cases, the deceased individual may be viewable, but there is no known presumptive identification and therefore no known presumptive next of kin to try and establish a visual identification. Although positive identification via DNA can be an option, this method often does not have a quick turnaround time. Therefore, when dealing with complex, high profile, and time sensitive cases, utilizing digital latent print analysis to establish a positive identification has proven the most effective method.

When utilizing digital latent print analysis for positive identification, an adequate digital print first needs to be obtained where impressions suitable for comparison purposes are preserved by digital imaging. Once the digital print is obtained, the image is then emailed to the Indiana State Police Lab along with the submission paperwork, and the print is analyzed. The submitted print is compared to any exemplars obtained from the Indiana State Police Archive, and any exemplars obtained as a result of searches in the Indiana State Police Automated Fingerprint Identification System (AFIS) and the Next Generation Identification System (NGI).[1] Conclusions are based upon the friction ridge skin depicted in the exemplars compared to the submitted images, with comparisons being completed using the Analysis, Comparison, Evaluation, and Verification (ACE-V) methodology.

Multiple case examples that show the state and condition of the deceased, along with the digital photographic prints that successfully established a positive identification on each case, will be presented. Examples include fatal fire victims, severely decomposed and/or skeletonized remains, and traumatic injury deaths such as motor vehicle crashes and gunshot wounds. Even in cases where only half a print was visible, or the decedent's finger was covered in soot, a positive identification was able to be obtained via digital latent print analysis.

This poster presentation exemplifies the importance and effectiveness of obtaining positive identification through the use of digital latent print analysis, while highlighting the skills used by medicolegal death investigators to obtain quality digital prints. When using this method to positively identify the deceased, identification can sometimes be established in mere hours. Unlike establishing positive ID through DNA, digital fingerprint analysis does not require a physical sample to be transported and submitted to the lab. Without the use of digital latent print analysis, positive identification of deceased individuals could take a lot more time, require more resources, and be a lot more challenging.

F30 Observing United Kingdom Cadaver Dog Performance in Aquatic Environments Through UK-K9: A Basis for Global Search and Recovery Training Comparisons

Ellen R. Shakeshaft, MSc, LJMU, Liverpool, England, United Kingdom*

Learning Objectives: Attendees will gain a foundational understanding of the principles behind cadaver dog scent detection in aquatic environments, focusing on how environmental factors such as temperature, water movement, and wind can affect Volatile Organic Compound (VOC) dispersal and canine accuracy. Through observational data collected from UK-K9, a National Association of Security Dog Users (NASDU) -accredited training provider, the presentation will explore real-world training practices used in the United Kingdom and compare them to established American and international methodologies. By returning to the basics of scent theory and canine behavior in complex aquatic scenarios, the session will highlight both the potential and limitations of current practices. Attendees will also be introduced to existing gaps in academic research and practical application, reinforcing the need for further study and the development of standardized, evidence-based protocols to improve the reliability of cadaver dog deployment in water-based forensic recovery operations.

Impact Statement: This presentation will impact the forensic science community by addressing a critical gap in the understanding and application of cadaver dog use in aquatic recovery scenarios. By providing observational data from United Kingdom-based training practices and comparing them to existing American methodologies, this research supports a return to foundational principles of scent detection while advancing discussions around environmental influences on canine accuracy. The findings aim to encourage cross-disciplinary collaboration, inform future controlled studies, and contribute to the development of standardized guidelines for aquatic cadaver dog deployment. Ultimately, this work has the potential to enhance the reliability, consistency, and effectiveness of water-based search and recovery operations in forensic contexts.

Abstract Text: Accidental and intentional drowning accounts for approximately 600 deaths each year in the United Kingdom, with recent data from the National Water Safety Forum's Water Incident Database (WAID) indicating that 44% of accidental drowning victims had no intention of entering the water.[1] Given the UK's diverse waterways, cadaver detection dogs (CDDs), also known as human remains detection dogs (HRDDs), play an increasingly critical role in search and recovery operations. While CDD effectiveness on land is supported by published literature and practical recoveries, their use in aquatic environments is far less understood.[2] Nonetheless, UK-based specialist teams, such as UK-K9, report that a significant proportion of their real-world cases involve aquatic scenes.

Detecting human remains in water presents unique challenges, particularly the altered dispersal of volatile organic compounds (VOCs) due to external factors such as temperature, water flow, current, windspeed, and microbial activity.[3] These variables not only influence training and operational effectiveness but also raise questions about how decomposition scent is perceived and signalled by dogs in aquatic environments. Academic literature currently lacks comprehensive research on aquatic cadaver detection, with most studies focusing on land-based decomposition and VOCs in air, rather than water.[4] Furthermore, few peer-reviewed studies explore how environmental factors influence canine accuracy in water. Reports from UK-K9 suggest that even live scent trailing dogs, not formally trained as CDDs, have successfully indicated submerged remains—suggesting a potential, yet poorly understood, overlap in the scent profiles released during early decomposition. This gap highlights the need to explore how scent is interpreted and acted upon by working dogs in aquatic conditions.

This ongoing pilot study aims to address some of these gaps by closely observing cadaver dog training within UK-K9, a NASDU-accredited (National Association of Security Dog Users) training provider. UK-K9 delivers training in both canine and handler development. Observational data—including ambient temperature, water temperature, wind speed, soak time, age of remains, and training hours—was collected over three months across multiple seasons during water-based training sessions. Dogs are initially trained to recognize decomposition scent using pig remains on land, then progress to water training using similar materials submerged at varying depths (bank, surface, and submerged) and soak times (from 20 minutes to several days). Crucially, no intervention was made in the training process, preserving UK-K9's existing protocols and accreditation.

During aquatic sessions, researchers recorded environmental data, number of alerts, whether they were positive, and dog behavior in relation to known bait locations in both freshwater and saltwater conditions. Early findings suggest that environmental context and scent conditioning could drastically influence detection outcomes. By examining real-world training scenarios without altering established methods, this research aims to inform future controlled studies and contribute to the development of standardized guidelines for aquatic cadaver detection. Ultimately, the study seeks to support the reliability and accuracy of CDD deployment in water-based forensic searches and act as a basis for application to international scenarios.

F31 One Car, Two Methods for Self-Harm—An Unplanned Complex Suicide: A Case Report

Giovanni Pollice, MD, Università di Foggia, Foggia, Puglia, Italy; Andrea Cioffi, MD, University of Foggia, Foggia, Puglia, Italy; Luigi Cipolloni, MD, PhD, University of Foggia, Foggia, Puglia, Italy; Camilla Cecannecchia, MD, University of Foggia, Foggia, Puglia, Italy; Roberta Bibbò, MD, Università degli Studi di Foggia, Foggia, Puglia, Italy; Chiara Fabrello, MD, Università degli Studi di Foggia, Foggia, Puglia, Italy*

Learning Objectives: This presentation aims to explain a multidisciplinary approach to a complex, unplanned suicide case. To assist judicial authorities and police investigations in accurately classifying the crime, the involvement of toxicologists and forensic pathologists is crucial. In this context, the forensic pathologist's role is vital in identifying the causes of death and distinguishing between suicide, accidental death, and homicide.

Impact Statement: In planned complex suicides, death is guaranteed by the simultaneous use of two predetermined methods. Conversely, in unplanned complex suicides, an additional improvised method may be used if the first method fails, as long as the person remains conscious and capable of acting. This presentation aims to significantly support the forensic science community by providing essential guidance for handling similar forensic cases.

Abstract Text: A 65-year-old woman, who had been missing for approximately two days, was found deceased within an agricultural area near her vehicle. The terrain was steep and located beneath a paved road, featuring numerous tire tracks. The woman's car was discovered tipped over in a ditch on the property. The body was positioned curled up between the front left door and the compartment of the vehicle, with her feet touching the ground and the driver's side seatbelt wrapped around her neck. Inside the car, there were a packet of cigarettes, a handbag, and a mobile phone. The external examination revealed several abrasions on the chin area, dried blood near the ears, and a mark of compression on the neck. The forensic pathologist performed a complete autopsy alongside histological, immunohistochemical, and toxicological examinations.

The autopsy revealed pulmonary congestion and edema, as well as visceral stasis. There was a fracture of the thyroid cornu of the larynx, without fractures in other areas of the body. There was an area of hemorrhage in the abdominal adipose tissue, without any injury to the abdominal organs. Histological and immunohistochemical analyses confirmed the presence of pulmonary edema with hemorrhages and the viability of the lesion at the laryngeal level. Toxicological examinations revealed the absence of substances of abuse in the analyzed biological fluids.

The forensic pathologist, combining the autoptic findings, the subsequent analyses, and the evidence of the crime scene investigation, established the cause of death as mechanical asphyxiation by suicidal hanging.

From an analysis of the crime scene and the presence of previous injuries, the coroner determined that the woman attempted to drive her car into the ditch, but, having failed in her attempt at self-preservation, she hanged herself with her seat belt.

These results indicate that a methodological framework incorporating a forensic pathologist, a toxicologist, and a coroner is crucial in such cases. This collaborative effort effectively determines the cause and manner of death.[1-6]

F32 Overkill Behind Closed Doors: A Case Series and Review of the Literature of Familiar Homicides

Domenico Abramo, MD, Messina University, Messina, Sicilia, Italy; Cataldo Raffino, MD, INAIL, Enna, Sicilia, Italy; Gennaro Baldino, MD, PhD*, Messina University, Messina, Sicilia, Italy; Giorgia Burrascano, MD, Messina University, Messina, Sicilia, Italy; Elvira Ventura Spagnolo, MD, Messina University, Biomorf Department, Medico legal section, Messina, Sicilia, Italy; Tindara Biondo, MD, Messina University, Messina, Sicilia, Italy*

Learning Objectives: After attending this presentation, participants will understand the critical importance of a comprehensive, multidisciplinary forensic evaluation, not only to reconstruct the dynamics of a homicidal event, but also to interpret its underlying criminal, relational, and psychiatric dimensions.

Impact Statement: This presentation will impact the forensic science community by illustrating a series of overkill cases that occurred in a family context. It emphasizes the necessity of multidisciplinary investigative strategies to understand and resolve such complex cases.

Abstract Text: In forensic science, the term overkill refers to a particular homicidal modality characterized by the excessive and disproportionate application of violence beyond what is required to cause death.[1] Although overkill represents a minority of total homicide cases, it is gaining increased relevance, particularly in domestic and familial contexts, where the lethal aggression often carries symbolic and/or psychopathological significance.[2] A five year, between 2021 and 2025, retrospective analysis was conducted on judicial cases examined at the Institute of Legal Medicine of Messina. Eight episodes were identified and classified as overkill based on the offenders' modus operandi, all of which occurred in domestic or familial settings. In the eleven victims (7 females, 4 males), injuries were predominantly located on the head, neck, and chest. Defensive wounds - both active and passive - were documented in all cases. Notably, one case included postmortem injuries associated with the concealment of the corpse by means of carbonization. Comprehensive forensic investigations, including crime scene reconstruction, blood pattern analysis, circumstantial evidence, PMCT, autopsy, histological, and toxicological examination, were coupled with a multidisciplinary approach involving an engineering specialist. This strategy enabled case resolution and facilitated a reconstruction of the dynamics and modalities of the homicides, highlighting the cruelty and supporting evidence of extreme violence. A multidisciplinary approach, incorporating forensic engineering expertise, enabled dynamic reconstruction and clarified the operational mechanics of each homicide.

The pathological and anatomical findings align with patterns observed in current literature, particularly regarding the regions most affected, weapon typologies, and associated psychiatric factors. This study reinforces the necessity of a standardized, multi-tiered investigative protocol tailored specifically to the complex nature of *overkill* homicides. Such rigor ensures not only the resolution of individual cases but also a broader understanding of violence escalation mechanisms in the domestic sphere.

F33 Porcine Decomposition Rates as an Estimate for Human Postmortem Interval in the High Desert Ecosystem of Northern Arizona

Hillary L. Eaton, PhD, Embry-Riddle Aeronautical University, Prescott, AZ; Makenzi M. Patterson, BSc, Embry-Riddle Aeronautical University, Prescott, AZ; Nina K. Gowell, BSc, Embry-Riddle Aeronautical University, Prescott, AZ; Brooke Holt-Eddington, BSc, Embry-Riddle Aeronautical University, Daytona Beach, FL; Megan Cramer, Embry-Riddle Aeronautical University, Daytona Beach, FL*

Learning Objectives: Attendees to this presentation will understand key environmental elements of porcine decomposition rates in Arizona's high desert ecosystem in comparison to the more intensely studied low desert ecosystem.

Impact Statement: This presentation will impact the forensic science community by providing fundamental applied scientific data as the first study of this nature to be conducted in Arizona's high desert, which can provide valuable information on Postmortem Interval (PMI) estimation in the region.

Abstract Text: The rate of decomposition of human remains is variable depending on the ecosystem in which the body is located. Arizona's Sonoran Desert, a low desert ecosystem, has been a site of interest for prior decomposition studies due to the large number of remains found in the area. Understanding the rates of decomposition in the high desert ecosystem could benefit forensic scientists when determining post-mortem interval (PMI) of a decedent. Due to northern Arizona's unique high desert elevation and weather patterns, and lack of available data, the standard rate of decomposition in this region is unknown.

In this study, air temperature, air humidity, soil temperature, soil moisture, soil pH, UVA/UVB rays, luminous flex per unit area (LUX), and pictures were recorded once daily from two deceased, clothed 100-pound female domestic pigs (*Sus scrofa domesticus*), one with full exposure to sun and the other placed in shade, in mid-February. Entomological techniques to collect and identify insects via bright-field microscopy included four pitfall traps, one near each pig's head, and one near their torso.

Current results show the cooler temperatures and lower humidity (average 22.2°C and 23.4%, respectively), prolonged the rate of decomposition for both pigs, compared to the hotter climate in southern Arizona. Soil pH and moisture varied little throughout the study. The main environmental variables were air temperature, humidity, and insect activity. Snow events in weeks 1 and 3 paused the decay process until thawing occurred. Increases in air humidity and soil moisture with rain events from weeks 3.5-4 accelerated decomposition to early stages with bloating and abdominal rupture. After 6 weeks, both pigs demonstrated advanced decomposition. Skeletonization with areas of mummified tissues occurred between 12-16 weeks, when the air temperatures were 26-35°C, and air humidity averaged 26%. The shade pig showed slower overall decomposition with cooler temperatures by a maximum of -15°C difference.

Most insect activity was Diptera *Calliphoridae* (blow flies), which began on day six, but increased on day nine. Other noted insect activity was Hymenoptera *Formicidae* (desert ants) and Coleoptera *Carabidae* (ground beetles). Maggot activity began on day 22, with stage 3 larvae in the shade pig's eyes, and stage 1 and 2 in the sun and shade pigs' mouths. Stage 3 larvae disappeared by day 25, and larval activity remained at stages 1 and 2 until tissue mummification occurred in weeks 12-16.

This study's results show typical insect diversity for Arizona, but results obtained over six months demonstrate the typical rate of decomposition and entomological activity estimated from low desert areas of Arizona, is delayed in the high desert ecosystem due to the colder temperatures between –2.2- and 10°C, experienced through the end of winter and into spring. Because numerous changes occur as decomposition progresses, the estimation of PMI becomes less reliable, and understanding conditions of each unique ecosystem becomes paramount. Continuous changes in the weather, entomology, and physical conditions of the pigs will be monitored until extreme decomposition occurs. This study will provide important data and information for PMI estimation in our unique high desert ecosystem.

F34 A Preliminary Analysis on Deaths in the LGBTQ Population in Jefferson County, Alabama

Elizabeth K. Lee, BA, The University of Alabama at Birmingham, Birmingham, AL; Brandi C. McCleskey, MD, UAB Heersink School of Medicine, Birmingham, AL*

Learning Objectives: The learning objectives are to: (1) understand descriptive statistics involving deaths in the LGBTQ population in Jefferson County, AL, and (2) understand statistics regarding natural deaths in the LGBTQ population in Jefferson County, AL.

Impact Statement: After this presentation, the audience will have a better understanding of deaths within a marginalized and vulnerable population in Jefferson County, AL, and a better understanding of natural deaths in this population.

Introduction: Members of the LGBTQ community experience a disproportionate amount of violence, suicide, unemployment and poverty, placing them at higher risks of experiencing early deaths.[1-5] Additionally, people in the LGBTQ population often delay seeking healthcare due to perceived or experienced discrimination within the healthcare system, placing them at higher risk of experiencing death due to complications from natural diseases[3,5] This information could be vital to the death investigation, providing insight that could assist with understanding the specific mortalities members of the LGBTQ population face.[1,2] Therefore, the aim of this project is to conduct preliminary analysis on deaths in the LGBTQ population in Jefferson County, and to extend this analysis to natural deaths.

Methods: The Jefferson County Coroner/Medical Examiner's Office (JCCMEO) Case Management Database was used to find decedents who were part of the LGBTQ population starting in the year 2011.[6] Broad inclusion criteria were applied including review of narrative histories as well as association with same sex partners. Statistical analyses were completed using Microsoft Excel.

Results: 44 decedents were identified as part of the LGBTQ community. Age was not significantly different between the LGBTQ population ($M = 42.3$, $SD = 15.1$) and other assumed cases ($n = 13{,}584$, $M = 45.2$, $SD = 18.6$), $t(13{,}630) = -1.27$, $p = .21$. The most common manner of death in the LGBTQ population was accidental (36.4%, $n = 16$), and the second most common manner of death was suicide (27.3%, $n = 12$). The most common manner of death in the general population was also accidental (45.3%, $n = 6166$), but the second most common manner was natural (26.4%, $n = 3587$). A chi-square test of independence revealed a significant association between identifying as LGBTQ and manner of death, $X^2(4) = 20.4$, $p = < .001$, as well as a significant association between identifying as LGBTQ and means of death, $X^2(126) = 64360.1$, $p = < .001$.

There were 9 natural deaths in the LGBTQ population. There was no significant difference in the age of natural deaths for members of the LGBTQ population ($M = 49.6$, $SD = 15.8$) and other assumed cases ($n = 3{,}587$, $M = 56.4$, $SD = 15.7$), $t(3{,}594) = -1.29$, $p = .19$. The most common means of death was cardiovascular disease (66.7% $n = 6$), but there was no significant association between the LGBTQ population and means of natural deaths, $X^2(1) = .54$, $p = .46$.

Discussion: It appears that people of the LGBTQ population are dying at the same age as the general population, but for seemingly different reasons. More of the LGBTQ population appears to die from suicide, supporting previous research in the field[1]. Natural deaths in the LGBTQ population appear to have no significant differences with the general population, and it is pertinent for providers to address cardiovascular disease risk in this population. Limitations of the study include a small sample size and under-reporting sexual orientation and gender identity. However, preliminary analyses show differences in this population that warrant further investigation.

F35 Regional Poisoning Patterns in Pakistan: A Forensic Study on Organophosphates, Aluminium Phosphide, and Paraphenylenediamine in Suicidal Deaths (2008–2023)

Hafiz Faisal Usman, MS, Codex & Co. Intellectual Property, Lahore, Punjab, Pakistan; Yusra Iqbal, FCPath, The Children's Hospital, Lahore, Pakistan, Lahore, Punjab, Pakistan; Shah Nawaz Shakeeb, LLM, Codex & Co. Intellectual Property, Lahore, Punjab, Pakistan*

Learning Objectives: This study allows the attendees to learn about the trends and demographic data of suicidal poisons used by the youth in Pakistan from 2008 to 2023. Young females of low socio-economic regions are more vulnerable to local poisons like organophosphates (spray poison), aluminum phosphide (wheat pills), and paraphenylenediamine (kala pathar).

Impact Statement: This presentation will identify a potential gap for proficiency testing providers, highlighting a real-time need to include local poisons in proficiency panels, particularly for South Asian countries. Regarding toxicology, researchers are required to develop new analytical methods for the identification and confirmation of local poisons in a variety of biological samples.

Background: Pakistan is an agricultural country where organophosphates (OPs, also known as spray poison) are frequently used by farmers to protect different crops like wheat, rice, cotton, and vegetables from pests and insects.[1,8] While Aluminum Phosphide (ALP, locally known as "wheat pills") is widely used as a fumigant for wheat and rice storage.[19,20] Paraphenylenediamine (PPD or local name Kala Pathar) is another chemical that is a component of hair dye. It is commonly available as Black Henna in Pakistan.[23,24] All these chemicals are cheap and available, so they are frequently misused by youth as self-harm poisoning agents.

Method and Results: In this study, data on suicidal poisoning cases were collected from tertiary care hospitals and poison centers in thirty-four districts of Pakistan (a systematic review of thirty-four national and international articles published from 2008 to 2023).[1-33] A total of 9,763 cases of OP poisoning were received. Among these, 62% belong to females, and 97% of all cases occurred in individuals aged 13–35 years. Urban Sindh reported the highest incidence (90.5%). Notably, 70.5% of cases were linked to suicide. The average mortality rate was 16.5%. Clinically, the most common symptoms included excessive salivation, vomiting, diarrhea, muscle twitching, and bradycardia.[2-17]

Out of 967 reported ALP poisoning cases, 58% involved females, with 91% of all cases occurring among individuals aged under 30 years. Central Punjab reported the highest incidence (37%), followed by Northern Khyber Pakhtunkhwa (30.5%). Alarmingly, 90.5% of the cases were linked to suicide. The overall mortality rate was 69%, with Kharian and Sargodha in Punjab exhibiting especially high fatality rates of 87% and 83%, respectively. Clinically, the most common symptoms were vomiting, nausea, and abdominal pain (91%). Pathological findings in 87% of cases included multi-organ congestion, edema, and necrosis.[18-22]

A total of 4103 patients of PPD poisoning were reported; 67.5% were females, indicating a disproportionate prevalence among women. The majority of cases (81%) fell within the age range of 20 to 30 years, highlighting the vulnerability of young adults to PPD poisoning. Geographically, South Punjab accounted for 51% of cases, followed by Interior Sindh with 32.5%. Suicide emerged as the primary intention behind PPD poisoning, constituting 87.5% of cases. The overall mortality rate attributed to PPD poisoning was 29%, signifying its lethal potential 23-34.

Conclusion: OPs, ALP, and PPD are readily available and inexpensive chemicals in local markets of Pakistan that pose a grave threat to public health, particularly among the youth. Urgent regulatory measures are warranted to ban or control these local poisons. Moreover, the majority of cases hailed from rural and low socio-economic backgrounds, with more than 90% of female patients. Additionally, concerted efforts from human rights organizations are imperative to address the underlying socioeconomic factors driving suicidal behavior, particularly among young females. This study contributes valuable insights into the emerging trend of local fatal poisons in developing countries like Pakistan, paving the way for further research, development, and standard guidelines for toxicological analysis and interpretation of these poisons.

F36 Sample Demographics, Injury Patterns, and the Influence of Ocean Currents on the Movement of Bodies of Golden Gate Bridge Jumper Cases

Samantha R. Robinson, BS, California State University, Chico, Chico, CA; Jazmin Borrayo, BA, California State University, Chico, Chico, CA; Eric J. Bartelink, PhD, California State University, Chico, Chico, CA*

Learning Objectives: After viewing this presentation, attendees will understand demographic patterns, mortality rates, and injury patterns in bridge jumper fatality cases. In addition, attendees will better understand how ocean currents influence the fluvial transport of bodies of fatal jumping cases linked to the Golden Gate Bridge.

Impact Statement: This presentation will impact the forensic community by providing awareness of the demographics of fatal jumping cases, skeletal injuries sustained from high-velocity water impacts, and how these data may inform on unidentified remains cases found along the Pacific Coast. It will also provide information on how ocean currents influence fluvial transport rates and distribution patterns of Golden Gate Bridge jumper cases.

Abstract Text: The Golden Gate Bridge (GGB) is a 1.7-mile-long suspension bridge that connects the city of San Francisco to the Marin County Headlands and spans the one-mile stretch of the mouth of San Francisco Bay. The GGB is 746 feet tall and 90 feet wide, with a deck-to-ocean distance of 220 feet. Since 1937, approximately 2000 people have jumped from the GGB, with a 98% mortality rate. Most individuals jumped from the bay side of the bridge because the Pacific Ocean side is mainly open to bicycle traffic. In 2024, a deterrent system was completed, consisting of a steel net extending 20 feet out and below on both sides. This barrier should dramatically reduce fatalities.

Approximately 85% of cases are Bay Area residents, with 9% residing in other parts of California, and 6% from other U.S. states.[1] The GGB case demographic is skewed toward males (74.2%) of Euro-American descent (80.3%), who are between 25-64 years of age (80%).[2] Between 1990 and 2005, suicides accounted for ~18% of all deaths in Marin County (vs. 1.4% nationally), with 39% involving GGB jumping cases.[2]

The fall takes four seconds at a maximum speed of 75 miles per hour and results in significant injuries. GGB cases dating from 1976-1991 revealed that most impacts were horizontal, with 77% of deaths due to multiple traumatic injuries, 9% to multiple traumatic injuries with drowning, and 7% to drowning with nonfatal injuries.[3] Most fatalities included crushing rib fractures/flail chest, and injuries to the heart, large vessels, and lungs. Skeletal injuries, especially fractures to the spine, thorax, and pelvis, were most common in both non-survivors and survivors.[4] Most witnessed jumps result in successful decedent recovery by the Coast Guard or bodies washed ashore in Marin County and occasionally on the Pacific Ocean side of the San Francisco Peninsula. However, hundreds of decedents have never been recovered. The recognition of skeletal injury patterns in unidentified remains found along the adjacent coast may provide investigative leads toward identity, and cause and manner of death.

Through reviewing cases from the National Missing and Unidentified Persons System (NamUs) and considering the currents of the San Francisco Bay area, an understanding can be gained of where to potentially locate human remains and to predict whether unidentified remains likely originated from the GGB. NamUs includes 75 missing persons cases that are likely GGB fatalities (83% male vs. 17% female, mean age = 30±9.6 years). This is based on contextual information, witnessed jumps, personal effects, notes, and vehicles left in the GGB parking lots. In addition, NamUs lists 28 unidentified human remains cases found on the coasts of Marin, San Francisco, and San Mateo Counties, all areas where confirmed GGB jumping cases have been recovered. As part of this preliminary study, we highlight a case study where a shoe associated with an unidentified individual was found with paint transfer consistent with the paint color of the GGB, which in conjunction with other lines of evidence, potentially link the individual to the bridge as a jumping victim.

F37 Sugar Land 95: Ethical Considerations Using Forensic Investigative Genetic Genealogy to Identify Historic Remains

Samantha D. Hofland, MA, University of Montana and Principal Research Group, Missoula, MT; Meradeth H. Snow, PhD, University of Montana, Missoula, MT; Catrina Whitley, PhD, Principal Research Group, Midlothian, TX; Helen Graham, EdD, Principal Research Group, Missouri City, TX; Abigail E. Fisher, PhD, Principal Research Group, Dallas, TX; Rita Simonetta, BA, Principal Research Group, Boerne, TX*

Learning Objectives: Attendees will learn about the process of using Forensic Investigative Genetic Genealogy (FIGG) to identify historic remains and the ethical considerations of this research. The presentation will not only benefit those working on historic cases but also provide insight and forethought into the ramification of this forensic research in the future.

Impact Statement: This presentation supports forensic professionals by providing insight into the ethical dilemmas that practitioners often encounter with historical Unidentified Human Remains (UHRs) and how to effectively maneuver them.

Abstract Text: The Sugar Land 95 are individuals who died from inhumane treatment experienced during the convict-leasing era in the United States. Convict-leasing was developed in response to the ratification of the 13th amendment, which abolished slavery except in the case of incarcerated individuals. This amendment along with Jim Crow laws and Black Codes, led to the re-enslavement of African Americans.[1,2] The conditions of this return to bondage were horrific, and many of the Sugar Land 95 died from disease, injury, and malnourishment.

The remains of the Sugar Land 95 were disinterred in 2018 and underwent anthropological analysis to assess trauma, pathology, taphonomy, and to generate a biological profile. The results of this analysis were compared to the historical records of the individuals known to have died at the plantation convict camp.[1,2] This helped to create hypotheses about the identities of some of the individuals. Principal Research Group and the Snow Molecular Anthropology Laboratory have begun the process of identification using forensic investigative genetic genealogy (FIGG).

Due to the historic and generational trauma caused by the loss of family members to the convict-leasing system and today's prison system, the process of identification can be emotional and difficult. The goal is always to provide answers and to avoid re-traumatizing the living descendants and maintaining the dignity of the deceased. However, the nature of this work always has the possibility of revealing hard truths and the potential for unintended consequences in regard to privacy.

This presentation will provide insight and a unique perspective on the effects of completing historic identification research with living individuals based on our experiences. We will address possible pitfalls as well as best practices in completing FIGG identification on historic populations, with specific attention to ramifications experienced by the descendants today.

F38 Taphonomic Surface Changes: A New Frontier in Grave Detection?

Mike Walters, MSc, Cranfield University, Reading, England, United Kingdom; David Errickson, PhD, Cranfield Forensic Institute, Cranfield University, Shrivenham, England, United Kingdom; Roland Wessling, MSc, Cranfield Forensic Institute, Cranfield, England, United Kingdom*

Learning Objectives: The learning objectives of this presentation are to: (1) reach a new understanding of grave dynamics; (2) understand the role of soil type and characteristics in taphonomic surface changes; and (3) realize the potential for a new method of search.

Impact Statement: The presentation will impact the forensic science community twofold. Theoretically, the presentation offers new insights into the complexities of burial and its demonstration in the soil surface. Practically, the presentation highlights the potential of a new method of search for illicit burials.

Abstract Text: The ability to detect graves quickly, efficiently and cost effectively is important both for law enforcement and for the closure of grieving families, however too often this objective is limited by traditional methods of search**,** such as field walking or geophysics. Alternative approaches using imaging techniques can better focus (or identify) the smaller taphonomic changes in the landscape as a result of the decomposition occurring below. To address this knowledge gap, five cylinders of pork mince, five pig legs and five pig carcasses were buried and scanned weekly using terrestrial laser scanning (TLS) and photogrammetry. Further, burials were overflown by a drone monthly at multiple altitudes. This allowed assessment of taphonomic surface changes in the greater landscape to be considered and the vanishing point established. In turn, this establishes parameters for future drone enabled search. Overall, the study supported the use of surface scanning in grave detection, with burials showing detectable differences between burials and controls across all methods used. Further, the shape of the buried material could be inferred from the surface changes shown, suggesting greater complexity in grave dynamics than previously thought. This contributes to the growing body of grave detection literature and offers promising avenues for further research.

F39 The Temporal and Environmental DNA (eDNA) Effects on Microbial Composition of Latent Fingerprints

Emily Kenoyer, BS, University of New Haven, New Haven, CT; Josep De Alcaraz-Fossoul,PhD, University of New Haven, West Haven, CT*

Learning Objectives: This presentation explores the potential impact of environmental DNA (eDNA) on Latent Fingerprint (LF) microbiota over time. By exposing LFs to varying conditions of temperature, light, environmental exposure, and human activity, differences in microbial compositions over time will be explained to estimate eDNA's impact on resident LF microbiota.

Impact Statement: This presentation will impact the forensic science community by demonstrating the influence of eDNA as a potential contaminant in LF microbial analyses. As an emerging forensic technique, human microbiome analyses have already been utilized for several forensic purposes such as identification and time-since-death studies. This experiment contributes to the development of LF knowledge, ensuring the continued credibility of microbiome evidence in forensic investigations.

Abstract Text: Latent fingerprints (LF) are an established and important type of forensic evidence that rely on friction ridge patterns for human identification. Additionally, LFs host a community of microbes that are potentially influenced by various external factors, including temperature and human activity. LF microbiota has several forensic applications, such as aiding in the identification of individuals and estimating postmortem intervals (PMI), but the influence of environmental DNA (eDNA) is still poorly characterized.[1-3]

When organisms interact with their surroundings, they leave behind eDNA or small genetic traces that can be released in several ways, including sloughed-off skin cells, saliva, sperm, blood, urine, leaves, pollen, spores, and even whole organisms such as microbes.[4] Therefore, the accuracy of such LF microbiome-based analyses may be compromised by eDNA inadvertently deposited onto surfaces through human activity or environmental exposure. This study investigates how varying levels of human traffic and environmental exposure influence the resident microbiota of LFs, specifically focusing on the extent to which eDNA interferes with specific time-dependent LF microbial signatures.

In this project, LFs of the right hand's thumb and index were deposited on glass microscope slides in duplicate from three donors and placed in four environmental conditions with varying temperatures, light, environment exposure, and human activity. LFs were compared under these conditions: indoor low human activity enclosed with no light; indoor low human activity open and exposed to light; indoor high human activity open and exposed to light; and outdoor open and exposed to light. Analysis of LFs was performed at 24 hours, 3 days, and 30 days post-deposition. Microbial community profiling was conducted via Next-Generation Sequencing (NGS) of the 16S rRNA gene, focusing on the bacterial component of the LF microbiome. Upon completion of the 16S rRNA gene sequencing, microbial community compositions were assessed at the family taxonomic rank for the quantification of temporal effects and the impact of environmental DNA (eDNA) on the observed microbial profiles.

Preliminary results indicated that both temporal progression and environmental exposure influenced the composition of LF microbiota per location and time point. Across all tested conditions, microbial abundance and diversity generally increased with time, suggesting that time was an influencing factor of the LF microbiota. This effect was particularly pronounced in the outdoor condition, where exposure to environmental factors appeared to drive a substantial rise in microbial diversity over time compared to the indoor environments. Furthermore, when comparing the two indoor low human activity conditions, one enclosed and one open, findings revealed that the exposed condition experienced more microbial shifts and a greater increase in bacterial populations over time. These findings suggested that environmental conditions, and the eDNA associated with them, had an impact on LF microbial communities over time and should be accounted for in microbial analyses.

F40 The Humanitarian and Human Rights Resource Center (HHRRC): Ten Years of Serving the Academy and the Global Community

Dawnie Steadman, PhD, University of Tennessee, Knoxville, TN*

Learning Objectives: In this presentation, participants will learn about learn about the HHRRC structure, programs, and awards as well as the impacts HHRRC grants have made over the past ten years. Participants will also learn about current humanitarian and human rights needs and how forensic scientists from all disciplines can play a part in global investigations.

Impact Statement: This presentation will impact the forensic science community by providing not only data and first-hand testimonials of how HHRRC funding and actions have moved humanitarian and human rights investigations and research forward but also examine the expanding role of forensic science in a rapidly changing world of humanitarian needs. Forensic scientists of all disciplines can have a role in conducting research and/or mitigating global human rights abuses and humanitarian actions.

Abstract Text: Entering its second decade of service, the Humanitarian and Human Rights Resource Center (HHRRC) seeks to utilize the assets of the American Academy of Forensic Sciences (AAFS) to promote the application of contemporary forensic science principles to global humanitarian and/or human rights projects. Human rights abuses include forced disappearance, extrajudicial killings, torture, human trafficking, genocide, mental health harm, biological and chemical weapons, and sexual, racial and gender-based violence.[1] Humanitarian crises can include environmental catastrophes, forced migration, famine, post-conflict recovery of the dead, epidemics, and structural failures.[2].

While forensic anthropology, archaeology, radiology, dentistry and pathology have historically been integral to identify victims of humanitarian crises and human rights abuses, forensic science involvement must expand to meet global needs in a rapidly changing world. For instance, digital expertise is needed to evaluate audio and/or video footage to determine authenticity or enhance images to identify perpetrators and victims, while document examiners are needed to evaluate the authenticity of signatures and documents (e.g., falsifying death certificates). Each section of AAFS is relevant to addressing human rights abuses and taking humanitarian forensic action.

One goal of the HHRRC is to provide resources to investigative organizations. Early efforts focused on compiling laboratory standards and protocols for a variety of forensic disciplines that were made available to laboratories world-wide. Educational resources about SARS-CoV-2 (Covid-19) were compiled and placed on the website in 2020. HHRRC also provides outreach to the Academy, including AAFS workshops, informing members of international agencies that need forensic experts.

One of the most important functions of the HHRRC is to fund projects that advance forensic science in human rights. Since 2016, HHRRC has overseen $800,000 in funding to 61 investigations, training and research projects operating in 30 countries, including the global South. The 61 projects are categorized into research (43%), capacity building/training (28%) and specific actions on the ground (29%). Research that applies forensic science to support humanitarian and human rights investigations include stable isotopes, remote sensing to find mass graves, skeletal and dental identification techniques, fingerprint enhancement, and chemical warfare signatures in hair. Examples of capacity building include training pathologists to recognize the signatures of torture and supporting investigative infrastructure, such as digitization and database management. Finally, HHRRC directly supports practitioners conducting forensic action on the ground, including exhumations of mass graves and identifying missing migrants. To help connect AAFS with international research or investigative needs, all proposals must include an AAFS member as a PI or consultant. Funding has graciously been provided by the AAFS, National Institute of Justice, RTI International, and currently the Forensic Sciences Foundation (FSF).

Finally, the HHRRC presents the Clyde Snow Award annually to an individual or organization who has demonstrated an enduring contribution to applying forensic science to humanitarian or human rights contexts. Eight Clyde Snow Awards have been provided to date.

As the landscape of conflict, disasters and political violence shifts, forensic scientists should become more aware of how their professional skills can be applied to help relieve human suffering around the world.

F41 Medicolegal Death Investigation—Then and Now: Advancements Over the Past 15 Years

David E. Kintz, Jr., BS, Park County Coroner's Office, Fairplay, CO*

Learning Objectives: This presentation will aim to empower local jurisdictions by looking back at the way things were done not so long ago and how far we have come in a short time. It will hopefully motivate those still using antiquated technology to look at the current standard. I plan to address technology such as cameras, cots, and fingerprinting in addition to trainings, methods (Global Positioning System [GPS]), and certifications. I will also address accreditation.

Impact Statement: The impact of this presentation will be to educate those leaders of local coroner/medical examiner offices to keep moving forward and advancing their profession. This includes seeking out the latest technology, techniques, and the science behind them. Many offices have been ingrained in the same ways while others at the front of curve. My goal is to excite all jurisdictions to be a leader in forensic science.

Abstract Text: Many times, the old adage of "if it ain't broke don't fix it" gets in the way of advancing our field. I aim to motivate past that thinking. Technology, techniques and mind set have changed significantly in the last 15 years and I aim to highlight those changes.

Advancing technology, procedures, mindset, training, techniques are absolutely paramount to keeping Medicolegal Death Investigation sharp on each scene. In this presentation I will show technology that was used not too long ago in comparison to current technology via photos. I also will present what was recently accepted at top tier training compared to many topics today. I will also compare the sciences we use. I will compare 15 years of DNA changes which will include to the rise of Forensic Genetic Genealogy. I will address the old way of hunting down fingerprints state by state as compared to the current consolidation by the FBI.

I will talk about a few specific products such as Polaroid but just in the sense of things that used to be the standard. I will show pictures of my current equipment and when applicable a picture of similar products. I intend this talk to humorous with the intention of really making people think about advancing their jurisdictions without preaching to them. I will reference my testimony to the National Academy of Sciences Death in Custody committee in 2024.

F42 The Basics of Medicolegal Death Investigation Systems Across the United States

Kelly Keyes, BS, RTI International, Yorba Linda, CA*

Learning Objectives: After attending this presentation, attendees will have a better understanding of how use of titles like medical examiner and coroner vary among Medicolegal Death Investigation (MDI) systems across the country, how prerequisites, qualifications, and jurisdictional processes differ, and how care should be taken to understand these titles relative to specific jurisdictions.

Impact Statement: The presentation will impact the forensic science community by creating greater awareness of the differences between MDI systems to include understanding variability in common roles, like coroner, medical examiner, forensic pathologist, and medicolegal death investigator, and how these terms are not used universally throughout the United States, forming an awareness that assumptions about a title, such as assuming all medical examiners are physicians, may lead to false assumptions.

Abstract Text: It is important for forensic practitioners, including legal teams, to understand the backgrounds and qualifications of colleagues they may interact with through casework. Normally, practitioners understand the titles and qualifications of those they regularly interact with, but these same inferences about those in other jurisdiction can lead to problems and create confusion. This is particularly important in medicolegal death investigation (MDI) systems, which have an incredible amount of diversity among them, and to assume that someone holding the title medical examiner is a physician, that someone holding the title Coroner is elected or lacks rigorous qualifications, or to assume someone performing autopsies is a medical examiner, can lead to false assumptions. Many in society think the terms medical examiner and forensic pathologist are synonymous, and this isn't the case across the US.

There are over 2,000 MDI systems across the United States, including approximately 1,600 Coroner offices and 400 Medical Examiner offices, and a few offices Coroner-Medical Examiner systems.[1,2] The one thing that is generally consistent is that the head of a coroner's office is called a Coroner and the head of a medical examiner's office is titled a Medical Examiner, beyond that little can be inferred. The prerequisites, qualifications and jurisdictional processes for the heads of offices of these systems can vary greatly with many variations in-between. Some MDI systems are required to be headed by a forensic pathologist, some by an official with minimum qualifications, and others may be required to be a physician, but not a forensic pathologist. Others may serve in a combined role, either officially or not, with another government role (like a Sheriff-Coroner or Prosecutor-Coroner). Some are elected, others are appointed. Additionally, there are over 200 counties in Texas in which MDIs are not conducted by someone with either of these titles, but rather by Justices of the Peace. Thus, because an office, or the head of that office, has a certain title, conclusions cannot be drawn about the organization of the office or qualifications of the person in charge.

This presentation will cover many of the statutory variances among MDI systems, such as that in Wisconsin the main statutory difference between medical examiners and coroners is that one is appointed and the other elected, thus in many Wisconsin counties Medical Examiners may not be physicians. In several states county appointed medical examiners are required to be physicians, but not forensic pathologists, and may have no training in medicolegal death investigation or forensic work, and in others places a coroner may be required to be a physician and may even be a forensic pathologist who is elected to their role. An overview of the many differences among systems, to include titles (coroner, medical examiner) and roles (forensic pathologist, medicolegal death investigator) and requirements will be covered.

F43 Is the Extent of Decomposition Consistent With Other Scene Observations? A Synthesis of 82 Cases on O‘ahu, Hawai‘i

David O. Carter, PhD, TABFE, International Taphonomy Applications LLC, Ventura, CA; Katherine Bratt, BS, Honolulu Department of the Medical Examiner, Honolulu, HI; Charlotte A. Carter, MS, Medical Examiner's Office, County of Ventura, Ventura, CA; Chelsie KR Mangca-Valdez, MFS, City and County of Honolulu Department of the Medical Examiner, Honolulu, HI; Alexis J.L. Peterson, BS, City and County of Honolulu Department of the Medical Examiner, Honolulu, HI; Philip C. Verso, BA, City and County of Honolulu Department of the Medical Examiner, Honolulu, HI*

Learning Objectives: Attendees can expect to acquire an understanding of indoor decomposition cases involving adult decedents without visible trauma. They will learn about common postmortem changes, including the quantification and sequence of decomposition processes in the city and county of Honolulu, Hawai’i.

Impact Statement: This presentation will impact the forensic science community by demonstrating that the quantification of decompositional changes can be used to establish a fundamental understanding of decomposition within a jurisdiction. Decompositional changes have a significant positive relationship with time, and this relationship has the potential to help investigative personnel determine if the extent of decomposition is consistent with other findings. These findings have the potential to be able to provide a more comprehensive overview of scene observations to the recently bereaved.

Abstract Text: One component of medicolegal death investigation is information gathering. Investigative personnel acquire many types of information and, while doing so, must determine if they are consistent with each other. Investigations involving decomposing remains, commonly called decomposition cases, need to determine if decomposition is consistent with other scene observations. One aspect of this is temporal; it is important to determine if decomposition is consistent with when the decedent was last known to be alive. The quantification of decomposition processes (decomposition scores) is widely used to evaluate relationships between decomposition and time but existing scoring methods were developed primarily for outdoor cases.[1-3] Because of this, we developed a scoring method to identify indoor decomposition trends within the City & County of Honolulu.[4] The long-term goal of this research is to provide a reliable means to determine if decomposition is consistent with other investigative findings. To initiate progress toward this goal, 318 decomposition cases within the City & County of Honolulu were assessed to establish a fundamental understanding of decompositional changes.

Cases were analyzed retrospectively using scene photographs and the extent of decomposition was quantified using Indoor Taphonomy Score (ITS).[4] Of the 318 cases, 82 shared four characteristics, including (1) adult decedent, (2) no visible trauma, (3) indoor location, and (4) a reliable postmortem interval (PMI). These 82 cases are the focus of this presentation. Also investigated were the effect of season (spring, summer, autumn, winter), clothing (fully clothed, partially clothed, nude), location of decedent (bathtub, bed, chair, sofa, floor), and insect activity (present, absent). Spearman correlation coefficient (r) and linear regression (r2) were generated using Prism 10.5.0 for macOS 15.5 (GraphPad Software, La Jolla, CA, USA) to investigate the relationship between ITS and PMI. Research was approved by Chaminade University of Honolulu Institutional Review Board (IRB00007927).

The 82 cases with reliable PMI were investigated during every season but mostly during the winter (33%) and autumn (29%), with summer (21%) followed by spring (17%). Manner of death included Natural (74%), Accident (18%), Undetermined (5%), and Suicide (2%). Most decedents were partially clothed (63%), while 21% were fully clothed and 16% were nude. More than half of the decedents were discovered on the floor (54%). Other substrates included bed (31%), sofa (12%), chair (2%), and bathtub (1%). Insects were observed at 26% of scenes beginning at one day postmortem.

A significant positive ($P < 0.001$, $r = 0.777$, $r^2 = 0.604$) relationship was observed between ITS and PMI. Decompositional changes occurred rapidly from zero to six days postmortem whereas ITS remained relatively stable from six to ten days postmortem. This decomposition pattern is consistent with many studies in warm, humid locations.[5] Significant effects of clothing, insect activity, location, and season were not observed. We conclude that quantifying decomposition has started to provide a fundamental understanding of decompositional changes within our jurisdiction. Furthermore, the statistical strength of the relationship between ITS and PMI supports further data collection to improve the understanding of decomposition and related variables.

F44 Medicolegal Recognition of Autoerotic Deaths in a Ubiquitous Digital Age

Brett E. Harding, MBA, Ada County Coroner's Office, Meridian, ID; Christina E. Di Loreto, MD, Ada County Coroner's Office, Meridian, ID; Jessica E. Macdonald, MA, Ada County Coroner's Office, Meridian, ID; Carolina E. Ramos, BS, Ada County Coroner's Office, Meridian, ID; Shelly E. Pearlman, Ada County Coroner's Office, Meridian, ID*

Learning Objectives: This presentation will reveal needed modifications of the longstanding tenets for recognizing and identifying autoerotic deaths with the advent of society's ubiquitous digital media access. This presentation will discuss the persistent myths surrounding principles of autoerotic death recognition as well as demonstrate the value of the utilization of a multidisciplinary process in medicolegal death investigations. The public's nearly instantaneous access to digital technology, its limitless media content, and how it may contribute to these types of deaths will also be explored.

Impact Statement: The impact of the presentation on the medicolegal community may be significant. The observations and cases presented will illustrate the need for change in forensic medicolegal standards used to recognize autoerotic deaths and stress the necessity in utilizing multidisciplinary methods for accurate investigational outcomes. By understanding and utilizing improved methods, the medicolegal investigation will also be able to contribute to a more accurate classification of the manner of death.

Abstract Text: This presentation will reveal modifications of the longstanding tenets for recognizing and identifying autoerotic deaths with the advent of society's ubiquitous digital media access. It will discuss the persistent myths surrounding principles of autoerotic death recognition as well as demonstrate the value of the utilization of a multidisciplinary process in medicolegal death investigations. The public's nearly instantaneous access to digital technology and its limitless media content will also be explored. The presentation will explain how the use of various tools and techniques, such as social media mining and the psychology autopsy procedure, can illuminate information and the potential motivating factors that resulted in death.

Persons involved in the practice of medicolegal death investigation are obligated to complete a thorough, accurate investigation of all deaths. This requirement necessitates a perpetual environment of continuing education to stay abreast of advancements in an ever-evolving field. An investigator indifferent to science-based changes in medicolegal death investigation not only risks drawing inaccurate conclusions but may also raise ethical questions regarding their professional dedication to due diligence.

Autoerotic deaths are an extreme paraphilic behavior wherein individuals induce sexual gratification during self-stimulated sexual activities, often by the utilization of an apparatus to achieve the desired effect.[1]

The diagnosis of an autoerotic death has traditionally rested on multiple, widely accepted inclusionary factors. These rules denote that all autoerotic deaths are related to asphyxia, demonstrate evidence of masturbation, and have pornography present at the scene of the death. Not only are these tenets widely accepted by medicolegal professionals, but they are also listed among the myths of autoerotic death diagnosis.[2]

Autoerotic death investigations have mainly concentrated on asphyxial deaths involving hanging or other ligature methods due to their prevalence in such deaths.[3] However, autoerotic stimulation is achievable with the utilization of various methods that may also result in death. Additional methods, such as those utilizing electricity, compression or submersion satisfy the autoerotic designation but may not get recognized as such by the medicolegal professional.

The medicolegal cases presented will highlight the need for change in forensic medicolegal standards used to recognize autoerotic deaths and stress the necessity in utilizing multidisciplinary methods for accurate investigational outcomes.

F45 A Forensic Analysis of an 820-Foot Fall Into Water: Deceleration Trauma Patterns

Benjamin Charroy, MD, Rouen University Hospital, Rouen, Haute-Normandie, France; Camille Launoy, MD, Rouen University Hospital, Rouen, Haute-Normandie, France; Gilles P. Tournel, MD, PhD, CHU de Rouen, Rouen, Haute-Normandie, France; Idriss-Marly M'bama, MD, Rouen University Hospital, Rouen, Haute-Normandie, France; Florence Vincent, MD, Rouen University Hospital, Rouen, Haute-Normandie, France; Erwan Le Garff, PhD, CH Boulogne sur Mer, CHU Rouen, Boulogne sur Mer, Nord-Pas-de-Calais, France*

Learning Objectives: Attendees will recognize the unique injury patterns in extreme-altitude aquatic falls, particularly the disparity between severe internal trauma and external preservation. They will learn the value of combined Computed Tomography (CT) -autopsy analysis in documenting deceleration injuries that may escape routine examination.

Impact Statement: This case establishes the first biomechanical marker for aquatic deceleration trauma reconstruction through helmet avulsion analysis, while providing empirical validation of Snyder's survival thresholds and Kenedi's psychiatric patterns in aviation-related fatalities.[1,2]

Case Report: A 5'11" male with documented psychiatric history (including prior suicide attempts) died from traumatic injuries sustained during an 820-ft (250 m) free-fall from an autogyro into seawater. The violent detachment of the victim's jet helmet upon impact created a distinctive circumferential scalp avulsion with complete periosteal stripping, demonstrating the extreme shear forces generated during water entry. Postmortem imaging revealed multiple characteristic injuries: comminuted occipital fracture with bilateral orbital roof fractures, spinal canal pneumorrhachis at C6-C7 and T2-T3 levels, flail chest with rib displacement, and complex pelvic fractures. Notably, the complete sparing of lower limb fractures contrasted sharply with the severe axial skeleton damage. Autopsy confirmed massive hemothorax (406 mL) and visceral lacerations (lungs, liver) consistent with deceleration trauma.

Discussion: Three key findings emerge from this case. First, the helmet avulsion pattern - with its complete periosteal detachment and clean wound margins - suggest a back-first entry into water. Second, the injury distribution (severe axial trauma with preserved appendicular structures) perfectly illustrates Snyder's hydraulic burst mechanism in aquatic impacts, where water's rapid energy dissipation protects peripheral structures while concentrating force on the torso.[1] Third, the case aligns with Kenedi's epidemiological data on aviation suicides, particularly regarding the 47% incidence of substance involvement (alcohol consumption was reported pre-flight) and the recurrence pattern in individuals with prior suicide attempts.[2] The extreme fall height (820 ft) significantly exceeds Snyder's documented 186-ft survival limit for feet-first water impacts, confirming the unsurvivable nature of such trauma.

Conclusion: This case provides compelling validation of Snyder's biomechanical models for high-velocity aquatic impacts while demonstrating the forensic utility of equipment analysis in aviation fatalities. The helmet avulsion serves as a novel, biomechanically-specific marker for impact reconstruction. These findings underscore the critical importance of integrated CT-autopsy examination in aquatic deaths and the need to consider Kenedi's psychiatric recurrence patterns when investigating aviation-related fatalities.

F46 A Multicentric Study on Forensic Investigation of Blunt Force Versus Fall-Induced Head Trauma: A Multidisciplinary Methodological Proposal

Gennaro Baldino, MD, PhD, Messina University, Messina, Sicilia, Italy; Giovanni Cecchetto, MD, Pavia University, Legal Medicine Section, Pavia, Lombardia, Italy; Paolo Fais, MD, Alma Mater Studiorum, Bologna University, Legal Medicne Section, Bologna, Emilia-Romagna, Italy; Elvira Ventura spagnolo, MD*, Messina University, Biomorf Department, Medico legal section, Messina, Sicilia, Italy; Margherita Neri, PhD, University of Ferrara, Ferrara, Emilia-Romagna, Italy; Antonio Oliva, MD, Catholic University of Rome, Rome, Lazio, Italy*

Learning Objectives: After this presentation, attendees will have gained insights into the forensic techniques and data collection strategies essential at the scene investigation, autopsy, and laboratory analysis phases to learn how to identify key indicators that differentiate cranial injuries resulting from blunt force trauma versus those from falls.

Impact Statement: This presentation offers substantial contributions to the forensic science community by emphasizing the critical need to integrate diverse investigative methods. It promotes the refinement of forensic protocols and the establishment of standardized approaches for analyzing cranial trauma in ambiguous death scenarios. An innovative operational protocol is proposed to guide forensic pathologists in evaluating such cases with greater accuracy and consistency

Introduction. Blunt force trauma analysis remains one of the most challenging aspects of forensic pathology, especially when distinguishing between injuries induced by direct impact and those caused by accidental falls.[1] These distinctions are vital for correctly reconstructing incident dynamics in violent assaults, homicides, or unexplained deaths. Injuries vary considerably in distribution, severity, and morphology, depending on the type of surface, force direction, and energy of impact. A thorough evaluation incorporating clinical, radiological, and forensic methodologies is necessary to draw reliable conclusions. Computed tomography (CT) is instrumental in identifying patterns that suggest inflicted trauma versus accidental origin.[2] Special attention must be given to elderly decedents, whose vulnerability due to preexisting conditions (e.g., osteoporosis, vascular fragility) can amplify injury severity even from low-energy mechanisms.

Materials and Methods. Following a systematic literature review, a retrospective study was conducted on autopsy data from cases between 2016 and 2025 collected from multiple Italian forensic institutions. In the first phase, human reviewers analyzed the medical-legal focusing on cases in which head trauma from a fall or blunt force was listed as a cause of death. In the second phase, a retrospective machine learning analysis was conducted on the electronic case records of deceased individuals during the same period to identify associated risk factors. Epidemiological data (age, sex), clinical history, circumstantial details (e.g., location of discovery, history of domestic violence, prior trauma reports), and forensic findings (radiological imaging, external inspection, autopsy, histological and toxicological analyses) were evaluated. Machine learning models were then applied to identify predictive patterns.

Conclusion. Through this multidisciplinary approach, distinct lesion patterns were identified, correlating with the dynamics of the fatal event. These findings have been synthesized into a novel operational protocol intended to assist forensic pathologists in differentiating cranial trauma origins, supporting case analysis with greater precision and objectivity. This protocol may serve as tool for future forensic standards in trauma analysis.

F47 Standards Development Activities in Medicolegal Death Investigation, Including Disaster Victim Identification

Kelly Keyes, BS, RTI International, Yorba Linda, CA; Michelle Rippy, EdD, California State University East Bay, Hayward, CA*

Learning Objectives: After attending this presentation, attendees will have a better understanding of the process for standards development in medicolegal death investigation. The presentation will also highlight the status of discipline-specific standards pertinent to the field of medicolegal death investigation, including disaster victim identification. This presentation will cover documents both at the Organization of Scientific Area Committees (OSAC) and the Academy Standards Board (ASB).

Impact Statement: The presentation will impact the forensic science community by creating greater awareness of standards development activities pertinent to medicolegal death investigation, including disaster victim identification. It will also increase awareness regarding training, tools, and resources that support implementation, compliance monitoring, and broader understanding.

Abstract Text: Organization of Scientific Area Committees (OSAC) for Forensic Science was created to strengthen the nation's use of forensic science by promoting the use of discipline-specific forensic science standards, to strengthen the basics upon which the work we do is based. To this end, the OSAC drafts proposed standards and best practice recommendations that are forwarded to standards developing organizations (SDOs), like the Academy Standards Board (ASB) that further develop and publish them but may also generate their own standards. The OSAC also reviews standards and recognizes them on the OSAC Registry, which serves as a central repository of high quality, consensus-based, technically sound standards.

During this presentation, updates related to standards development in medicolegal death investigation, to include disaster victim identification, will be discussed. In the last year there have been a number of new standards that have been finalized, including standards on interactions with organ and tissue procurement agencies (ANSI/ASB Standard 202), communication with next of kin (ANSI/ASB Best Practice Recommendation 209), and terminology (ANSI/ASB Technical Report 151). Additional documents are in the process, including those on response to death locations and incidents scenes (ASB Best Practice Recommendation193), conducting external evaluations at scene (OSAC 2025-N-0008), resources for MDI authorities (OSAC), in custody deaths (OSAC), and components of an MDI report (OSAC). Also in progress are documents related to mass fatalities on data management (ASB Best Practice Recommendation 005), identification (OSAC 2022-S-0022), family engagement (ASB Best Practice Recommendation 213), media communications (ASB Best Practice Recommendation 181), victim accounting (ASB Best Practice Recommendation 182), incident management (ASB Best Practice Recommendation 206), and fingerprints.

Additionally existing standards will be discussed, including ANSI/ASB Standard 125, Organizational and Foundational Standard for Medicolegal Death Investigation. 2021. 1st. Ed.; ANSI/ASB Best Practice Recommendation 007, Postmortem Impression Submission Strategy for Comprehensive Searches of Essential Automated Fingerprint Identification System Databases. 2018. 1st. Ed; ANSI/ASB Best Practice Recommendation 008, Mass Fatality Scene Processing: Best Practice Recommendations for the Medicolegal Authority. 2021. 1st. Ed.; ANSI/ASB Best Practice Recommendation 009, Best Practice Recommendations for the Examination of Human Remains by Forensic Pathologists in the Disaster Victim Identification Context. 2019. 1st. Ed.; ANSI/ASB Best Practice Recommendation 010, Forensic Anthropology in Disaster Victim Identification: Best Practice Recommendations for the Medicolegal Authority. 2018. 1st. Ed.; ANSI/ASB Best Practice Recommendation 094, Postmortem Impression Recovery: Guidance and Best Practices for Disaster Victim Identification. 2021. 1st. Ed.; ANSI/ASB Best Practice Recommendation 108, Forensic Odontology in Disaster Victim Identification: Best Practice Recommendations for the Medicolegal Authority. 2021. 1st.

Opportunities for supplemental training related to discipline-specific standards will be presented, as well as additional resources and tools to assist with implementation. Opportunities to be involved in the process of developing these documents will also be discussed.

F48 Suicide Via Sodium Nitrite Ingestion: Trends in Multnomah County, Oregon, 2018–2025

Jessica Crowson, MFS, Multnomah County Medical Examiner's Office/ University of New Haven, Portland, OR; Jaxson D. Haug, MA, Multnomah County Medical Examiner's Office/ Southern Methodist University, Portland, OR*

Learning Objectives: The goal of this presentation is to recognize evidence in sodium nitrite suicides, including the following: understanding potential scene findings, recognizing common/less common postmortem observations, considering associated risk factors, and knowing questions to follow-up on with family and/or within medical records.

Impact Statement: After attending this medicolegal presentation, attendees will gain knowledge of some common findings in suicides where sodium nitrite was confirmed as the mechanism of death. This presentation is an effort to share information to working forces such as law enforcement, hospital staff, death investigators, or other relevant forensic agencies to recognize evidence in these types of investigations.

Abstract Text: After attending this medicolegal presentation, attendees will gain knowledge of some common findings in suicides where sodium nitrite was confirmed as the mechanism of death.[1] This contemporary dialog will discuss demographic factors among decedents, potential postmortem observations, and common evidence on scene in these types of deaths.

Sodium nitrite, a chemical used as a cured meat preservative, as well as, a metal treatment/finishing product, has become a more common substance utilized in suicide deaths. While there is evidence of sodium nitrite ingestion being confirmed in a death as far back as over 40 years ago, recent literature and cases appear to indicate a higher prevalence of such in the last 5-10 years.[1]

Sodium nitrite appears to easily be purchased online or directly at sporting goods stores. This review will pertain to a group of investigations in Multnomah County, Oregon from the last 8 years, where sodium nitrite was confirmed as the proximate cause of death. This dialogue will further include discussions on the following topics: how sodium nitrite was purchased, media sources where instructions were provided pertaining to its use as a suicidal agent, common (and less common) postmortem observations, associated risk factors, and commonalities noted within investigative findings.

This presentation is an effort to share information to law enforcement/hospital staff/death investigators to assist in recognizing evidence in these types of medicolegal investigations.

F49 Lie Detection, Polygraph Testing, Credibility Assessment: Forensic History, Current Status, and Future Developments

Frank S. Horvath, PhD, Michigan State University, Chapin, SC*

Learning Objectives: In this presentation, attendees will learn the role that "lie detection" played in its early years in the forensic sciences and of major developments since that time that have influenced and limited the practice and the perspective of that forensic technique. Attention will also be given to factors that impede current and future forensic usages of what is now referred to as Credibility Assessment.

Impact Statement: This presentation will show how the commercialization of "polygraph testing," socio-political developments, international growth, emerging "lie detection" instruments, and seemingly neutral scientific assessments have influenced usage of forensic Credibility Assessment.

Abstract Text: In this presentation attendees will learn of the role that "lie detection" played in its early years in the forensic sciences and of major developments since that time that have influenced and limited the practice and the perspective of that forensic technique. Attention will also be given to factors that impede current and future forensic usages of what is now referred to as Credibility Assessment.

1923. That was the year DC Circuit Judge Josiah Van Orsdel denied admissibility of a "lie detector" result offered by Dr. William Moulton Marston in support of the accused murderer James Alphonso Frye.[1] Marston's "test", the "systolic blood pressure deception test," was an early example of what was known as "lie detection" and over time referred to as polygraph testing and today more generally as credibility assessment. The "Frye rule" resulting from the Van Orsdel court decision governed the admissibility of scientific forensic evidence for more than seven decades until 1993 when the *Daubert v. Merrell Dow Pharmaceuticals, Inc.* decision replaced it. Today, polygraph testing evidence is still not generally admissible even though over that time span other forms of forensic evidence, some newly developed (e.g., DNA), are regularly admitted in court.

Legal developments regarding "lie detection," however, have not been as influential as other factors in limiting usage. In this presentation these other things will be discussed. These include the commercialization of "polygraph testing," socio-political developments, international growth, emerging "lie detection" instruments and seemingly neutral scientific assessments. Moreover, factors related to how those who engage in polygraph testing continue to influence forensic usage will be discussed. In this presentation I will show how together these factors indicate what is needed in order to encourage more widespread and more judicious use of Credibility Assessment in forensic and investigatory circumstances.

F50 A Digital Forensic Phone Download Solves a Homicide Case: "I'll Help You After I Watch You Die!"

Aubrey Bryak, MDI, Tippecanoe County Coroner's Office, Lafayette, IN; Caroline G. Hanau, MS*, Tippecanoe County Coroner's Office, Lafayette, IN; Carrie Costello, MS, Tippecanoe Coroner Office, Lafayette, IN*

Learning Objectives: After attending this presentation, attendees will understand the crucial role of digital forensic technology in solving homicide cases. The presentation will also demonstrate the importance and vital role the digital forensic examiner plays in the investigation process. Without the science of digital forensics, and without the digital forensic examiner who implements the science, many investigations would potentially go unsolved.

Impact Statement: This presentation will impact the forensic science community by demonstrating how going back to the basics in forensic science is imperative in the investigative process and, more specifically, how digital forensic technology was the main component in solving a brutal homicide case. This presentation highlights not only the important role of the digital forensic examiner and their utilization of digital forensic science to help solve the case, but also the hard work and dedication of all the players involved. It proves the importance of a thorough investigation and analysis being done by dedicated individuals, and the fact that forensic science does not work on its own without the people who implement it.

Abstract Text: On August 8, 2017, at 0054 hours, the Tippecanoe County Sheriff's Department responded to a shooting that occurred at 4021 East 500 South, Lafayette, Indiana 47909. The caller, Patrick Elliot, stated his wife, Donita Elliot, attempted to attack him with a knife, and he shot her. Donita was transported to a local hospital, where she was pronounced dead later that morning. While Patrick claimed self-defense, Patrick and Donita's phones were collected for data retrieval and analysis. A gun was located in the kitchen drawer right below where the kitchen knives were located on the counter, and one knife was missing from the block. A knife matching the set was located on the floor in the living room, near where Donita's body had been lying when first responders arrived at the scene.

On August 11, 2017, the digital forensic examiner performed a download on Patrick's cell phone, which uncovered a video recording from August 8, 2017. The file was 5 minutes long, and only recorded audio. The events leading up to and throughout the shooting could be heard on the recording. The forensic examiner listened to the recording several times and was able to identify the male's voice as Patrick and the female's as Donita. At one point in the video, Donita was heard begging Patrick for help and in response to that, Patrick was heard saying "I'll help you after I watch you die!". Patrick already had an appointment to go into the Sheriff's Office on August 14, for a follow-up interview, and it was decided that at that time, detectives would confront Patrick with the audio recording from the phone. When Patrick came in for the interview, detectives played the recording and were ultimately able to obtain a confession that he planted the knife. Following the interview, Patrick was subsequently arrested for the murder of his wife.

After Patrick confessed to killing his wife in self-defense, the case went to trial. On July 18, 2019, a jury ruled the killing was murder and Patrick was convicted of the murder, a felony, along with false informing, a class A misdemeanor. Patrick was ultimately sentenced to an aggregate term of seventy-five years, executed in the Indiana Department of Corrections. On July 17, 2020, Patrick appealed his conviction and lost, and his sentence was affirmed.

This case is different from other digital forensic cases because Patrick recorded audio of himself shooting Donita and that audio was recovered from his phone within 72 hours. This exemplifies the importance of the forensic examiner and their role in the implementation of forensic science. Without the forensic download that was completed on the phone and the information that was obtained, Patrick Elliot could have gotten away with the murder of his wife. Because of the forensic examiner and their responsible, ethical, and just use of digital forensic science, justice was achieved. The successful conviction in this case would not have been possible without the fundamentals of forensic science and the practitioner who put it into practice.

F51 Children of the '70s: Using NCMEC to Identify Unidentified Juvenile Human Remains

Lara Newell, MA, Virginia Office of the Chief Medical Examiner, Richmond, VA*

Learning Objectives: The objective of this presentation is to discuss two long-term unidentified juvenile cases from the early 1970s and the efforts made to identify these children. This presentation will discuss how the National Center for Missing and Exploited Children (NCMEC) assisted with these identifications as well as a brief discussion of how NCMEC can assist with unidentified juvenile remains.

Impact Statement: This presentation will impact the forensic science community by analyzing two unidentified juvenile cases from the 1970s. While any unidentified case from the 1970s case is problematic, juvenile cases are especially so, in part due to the likely lack of fingerprints, high instances of children being classified as "runaways," and records such as dental and hospital medical records that have likely been purged. The NCMEC has numerous resources that medical examiners and law enforcement can use to assist with the identification of these juvenile remains. The benefits of including NCMEC in a long-term unidentified investigation will be discussed.

Abstract Text: In the early 1970s, two sets of juvenile remains were found. One child was found in a creek in 1972 and was determined to be a homicide. The second case was a teenager found in a river.

The child found in 1972 was buried shortly after discovery when he remained unidentified and unclaimed. In 2020, law enforcement attempted to locate his remains for DNA but were unsuccessful. In collaboration with NCMEC, retained evidence was sent for genealogy. With the help of the genealogy team, the possible mother was found, but she was deceased. Using NCMEC funds and a forensic anthropologist from NCMEC, the possible mother was exhumed. A DNA comparison was completed between the mother's remains and the unidentified child which showed a parent-child relationship.

The teenager, found in a river in 1973, was cremated after remaining unidentified and unclaimed. Nearly 50 years later, the case was found by chance and the medical examiner in collaboration with local law enforcement and NCMEC began an investigation. NCMEC alerted the medical examiner to a missing teenager from two weeks prior to the remains being found, but unfortunately, there were no human remains left to use for DNA identification. A film canister was found with negatives dated close to when the teenager was found. NCMEC requested the use of their in-kind partner, the US Secret Service, to print the negatives to see if there were any photos of the teenager's autopsy, face, or clothing. A single morgue photo of the unidentified decedent was found; NCMEC forensic artists sanitized the photo for viewing by the family. Local law enforcement showed the photo to the living siblings who confirmed that the teenager found in 1973 was their brother.

Unidentified juvenile cases can some of the hardest cases to work. Children often don't have fingerprints on file, background checks, or arrests that may include DNA swabs. While children routinely have more dental x-rays than adults, dentists retire and in many cases, records are destroyed.

NCMEC, or the National Center for Missing and Exploited Children, has a forensics unit that can provide assistance to law enforcement, coroners and medical examiners investigating unidentified juvenile cases. Assistance can range from providing financial assistance for exhumations and DNA testing to evidence reviews to media blasts. The assistance that NCMEC can provide is invaluable, as evidenced by the identification of these two children from the early 1970s.

F52 Good Ol'-Fashioned Detective Work in a Case of Dismemberment

Tracy Brisendine, BA, Denver Office of the Medical Examiner, Denver, CO*

Learning Objectives: Attendees will learn the value of foundational investigative work and patience. This case study is an example of old-fashioned police work and a bit of luck coming together to solve the crime and get justice for the victim. An overview of the 2020 murder scene, autopsy findings, police investigation, and, ultimately, the conviction of the suspect will be detailed.

Impact Statement: My presentation will impact the forensic community with a reminder that some cases are solved without theatrics and technology, but are solved with detective work, solid investigation practices, and teamwork. This case study is an example of the attributes of investigations that act as the mainstay of justice in every city, county, and country.

Abstract Text: On December 29, 2020, City of Denver workers plowing snow in a park came across two suitcases.[2] Upon opening and inspecting one of the suitcases what appeared to be a human foot was discovered inside.[2] Evidence on the suitcase led investigators to a possible suspect whose whereabouts were unknown.[2,3] An exam of the body parts located within the suitcases was conducted at the Denver Office of the Medical Examiner on December 30, 2020 and revealed that the "victim's head, left arm, right arm, and lower left leg were not within the bags.[2] The cause of death could not be definitively determined based on the recovered body parts, but the dismemberment likely occurred postmortem.[2] Several days after the suitcases were discovered a double overdose happened on the other side of town.[2] One of the overdose victims had ties to the discovered suitcases.[2,3] A search of the location of the overdoses revealed substantial evidence that a homicide had likely been committed within the same scene.[2] Additional evidence included video surveillance, cell phone records, and tool purchasing.[1,2] The suspect plead guilty and was sentenced to thirty years in prison.[1]

F53 A Cold Case Critical Review: Overcoming Investigation Errors and Omissions to Prove Homicide by Two Distinct Cranial Gunshots Inflicted by .22LR (Long Rifle) Shotshell and Solid Bullet Ammunition Types

Robert J. Sigillito, MD, Independent, Mandeville, LA*

Learning Objectives: The goals of this presentation are to present: (1) a review of perimortem cerebral Computed Axial Tomography (CAT) scan images; (2) the correlation with postmortem autopsy wound photographs; (3) the correlation with post-exhumation autopsy and anthropologic studies; and (4) a presentation of data regarding .22LR shotshell ammunition

Impact Statement: This case study illustrates errors and omissions at multiple steps in a death investigation that led to an incorrect determination of the cause and manner of death. A detailed review of the available evidence raw data, rather than reliance on professional reports, led to the illumination of evidence that "was there all along." Professionals performing postmortem examinations should apply the same methodical scientific approach to review of perimortem clinical information as they apply to postmortem studies. This is the first case report of a human fatality caused by a gunshot using .22LR shotshell ammunition. The evidence of that ammunition type was not recognized during perimortem medical treatment, at autopsy, or during post-exhumation examinations.

Introduction: In 2012, a 14 year-old attending an overnight gathering suffered fatal gunshot wounds of the head. After autopsy, the investigators, private forensic pathologist, and Coroner concluded that the injury was a single accidental self-inflicted gunshot. The decedent's family sought second opinions from several sources over the ensuing 12 years. In 2024, the family requested a review by the author of the available evidence.

Purpose: The goal of this critical evidence analysis is to present the methodical interpretation and correlation of: (1) perimortem cranial CAT Scan images, (2) postmortem photographs of the wound and the recovered bullet, and (3) and post-exhumation photographs from second autopsy and forensic anthropologic examinations. Data regarding the characteristics of .22LR shotshell ammunition will also be presented.

Results: This represents the first reported case of a human gunshot fatality inflicted by .22LR caliber shotshell ammunition. Identification of the culprit ammunition type was accomplished by correlation of clinical perimortem radiographic images with postmortem photographs and investigative studies. This also presents a unique report of the correlation of perimortem cranial CAT Scan images with postmortem photographic evidence to demonstrate ballistic materiel and physical evidence that was not recognized and recovered at autopsy or post-exhumation examinations. The discovery of congruent radiographic and photographic evidence of numerous cranial ballistic shot pellets in the setting of a previously recovered cranial solid bullet proved that the decedent suffered two gunshot wounds, changing the correct manner of death to homicide.

Conclusion: Information essential to the correct determination of the cause and manner of death requires careful consideration of clinical data acquired during perimortem treatment of injuries rather than exclusive reliance on exhaustive postmortem forensic studies.

F54 Inadequate Injury Documentation in the Emergency Setting: Forensic Implications and Evidence From Italian Cases

Annalisa Sofia, MD, University of Pavia, Pavia, Lombardia, Italy; Giulia Brambilla, MD, University of Pavia, Pavia, Lombardia, Italy; Giovanni Cecchetto, MD, PhD, Department of Legal Medicine and Forensic Sciences, University of Pavia, Italy, Pavia, Lombardia, Italy; Alessandra Mammana, MD, University of Pavia, Pavia, Lombardia, Italy; Federica Trevissoi, MD, Department of Cardiac, Thoracic, Vascular Sciences and Public Health, Unit of Legal Medicine and Toxicology, University of Padova, Padua, Veneto, Italy; Alessia Viero, MD, PhD, University of Padua, Padua, Veneto, Italy;*

Learning Objectives: After attending this presentation, attendees will understand how injury documentation in emergency departments can affect the probative value of medical records in subsequent legal proceedings. It will raise the awareness of the crucial role that reliable descriptions, obtained from the first contact between the injured and medical aid, play in the pursuit of justice.

Impact Statement: This presentation will focus on identifying key discrepancies between the description of lesions produced in an emergency setting and their actual forensic significance in order to enhance the forensic community's competence in evaluating emergency injury documentation. Additionally, it will promote collaboration between emergency clinicians and forensic experts to improve documentation practices.

Abstract Text: In forensic practice, the initial medical report produced in the emergency department often represents the first documentation of injuries. In the Italian legal system, however, forensic evaluation frequently can occur weeks or months after the event, when injuries have already healed or consolidated hereby increasing the risk of discrepancies between initial and subsequent assessments.

This retrospective study analyzed medicolegal evaluations performed at the Institutes of Legal Medicine of Padua and Pavia between 2010 and 2025. It focused on individuals who sought emergency care for traumatic injuries in cases involving assault, battery, or attempted murder, and were later assessed by a forensic expert. Inclusion criteria were: (1) an initial clinical examination performed by non-forensic medical personnel, and (2) a subsequent forensic evaluation either in person or based on iconographic material. During the forensic assessment, the specialist reviewed the circumstantial data provided by the victim, assessed the clinical documentation (including radiological investigations and photographs taken by healthcare providers), and reclassified injuries

A total of 100 cases were analyzed, focusing on both the initial clinical evaluation and the subsequent forensic assessment. For the clinical evaluation, the following elements were considered: date of examination, admission diagnosis, injury description (categorized as "accurately described," "inaccurately described," or "not described"), and indication of the mean of production of the injury (classified as either "specified" or "not specified"). As for the forensic assessment, the time interval since the initial medical visit, along with the injury description — distinguishing between currently present injuries and sequelae — and the characterization of the agent determining the injury as either generic or specific. A comparative analysis was conducted to classify cases as either concordant or discrepant, with discrepancies indicating omissions or inaccuracies in the initial documentation relative to the forensic findings.

A significant proportion of emergency department reports were vague, lacked reproducibility, and omitted critical descriptors such as lesion size, shape, orientation, and anatomical location. These deficiencies frequently obstructed the correlation between emergency documentation and forensic findings

These results align with prior international research indicating that clinical reports often fail to meet medicolegal standards when not guided by forensic awareness.[1-4] Furthermore, poor-quality documentation can weaken criminal investigations and compromise the chain of evidence, especially in cases involving assault, domestic violence, or abuse.[5-7]

To bridge this gap, it is crucial to implement forensic training modules for emergency clinicians. These professionals would serve as a bridge between emergency care and forensic medicine, ensuring that documentation is complete, standardized, and legally usable. Our findings underscore the need for a systemic shift toward interdisciplinary communication in the early phases of trauma care, improving legal reliability and stakeholder outcomes.

F55 Lessons Learned From Health Care Serial Killers: The Evolution of the British Medical Examiner Service

Claire Power, MSc, Cameron Forensic Medical Sciences, William Harvey Research Institute, Queen Mary University of London, London, England, United Kingdom; Fiona Wilcox, MD, Cameron Forensic Medical Sciences, William Harvey Research Institute, Queen Mary University of London, London, England, United Kingdom; Sajeel A. Shah, PhD, Cameron Forensic Medical Sciences, William Harvey Research Institute, Queen Mary University of London, London, England, United Kingdom; Nikolas P. Lemos, PhD, Cameron Forensic Medical Sciences, William Harvey Research Institute, Queen Mary University of London, London, England, United Kingdom*

Learning Objectives: After attending this presentation attendees will better understand death investigation protocols in the United Kingdom. They will also gain insight into how past systemic failures, exemplified by health care serial killers, have fundamentally reshaped medicolegal practices.

Impact Statement: This presentation will impact the forensic science community by underscoring the evolving role of the British medical examiner service in enhancing death investigation and preventing future health care tragedies. The importance of continuous systemic reform will also be emphasized.

Abstract Text: The landscape of death investigation in the United Kingdom (UK) has undergone significant transformation, culminating in the recent statutory implementation of a new Medical Examiner framework on September 9, 2024, via the Coroners and Justice Act. This presentation will delve into the historical context driving these changes, particularly the profound influence of prolific high-profile health care serial killers, which exposed critical vulnerabilities and oversights.

Cases involving perpetrators will be examined, exploring how individuals such as Harold Shipman (a family physician responsible for over 200 patient deaths across two decades) and Lucy Letby (a neonatal nurse convicted of murdering 7 infants and attempting to murder 8 others) managed to operate undetected for years, profoundly illustrating the need for a robust and independent death review system. Key takeaways from these tragedies showed that had practitioners felt empowered and safe to discuss anomalous elements independently, and if the families of victims were given adequate time and support to voice their concerns, these events may have been averted earlier. The new framework ensures discussions with treating teams and the bereaved for every death, illustrating the enduring importance of human contact and open communication in an increasingly technology-dominated world.

While the new system is a vital step forward, challenges still faced will be addressed and it will be questioned if the present measures are truly enough. Crucially, the current gap in legally mandated investigation for stillbirths in the UK will be highlighted. The current legislation only applies to those born with signs of life; if there are no such signs recorded, the baby is legally considered to have never lived, and no death certificate is required. This means that factors leading to the stillbirth of a viable pregnancy would not be subjected to the independent scrutiny that a similar situation with even momentary signs of life would be. In the context of health care serial killers, this represents a major loophole, as a perpetrator could cause stillbirths without the events being subject to thorough investigation. Furthermore, the UK's Assisted Dying Bill will be touched upon, which has recently received Parliamentary approval. This legislation introduces new complexities of future cases and highlights the necessity for meticulous scrutiny to prevent potential exploitation.

Comparative analysis of national and international approaches to death investigation and the broader implications for forensic science and public trust will also be discussed. The decentralized legal systems across the 4 nations of the UK (England, Wales, Scotland, and Northern Ireland) have led to the new framework being statutory only in England and Wales. While similar systems are currently in use in Scotland and Northern Ireland, adherence to the new standards are not yet legally enforceable. Consideration will be also given to if similar principles of independent review and discussions might have impacted cases like those of Charles Cullen and Michael Swango, offering insights for international medicolegal reform and public health protection

F56 Fatal and Severe Contrast Media-Related Adverse Effects: A Forensic and Clinical Perspective From Two Cases

Alice Buzzelli, MD, University of Parma, Parma, Emilia-Romagna, Italy; Chiara Carsana, MD*, University of Milan, Milan, Lombardia, Italy; Luca Morini, PhD, University of Pavia, Pavia, Lombardia, Italy; Valentina Bugelli, MD, PhD, University of Parma, Parma, Emilia-Romagna, Italy; Lorenzo Franceschetti, MD, PhD*, University of Milan, Milan, Lombardia, Italy; Gaetano Pietro Bulfamante, MD, University of Milan, Milan, Lombardia, Italy*

Learning Objectives: From this report, attendees will acquire knowledge about two rare adverse effects from contrast media: anaphylactic shock and compartment syndrome. Such cases will impact both the forensic scientific community, bringing attention to a pathological framework that can be bumped into daily activity, and the clinical-surgical scientific community, being a source of update on the topic.

Impact Statement: Contrast Media Extravasation (CMEX) and Gadolinium-Based Contrast Agents (GBCA) adverse reaction are associated with the risk of life-threating conditions. This knowledge provides fundamentals to pathophysiology of a rare event that is useful to improve management of patients with adverse effects from contrast media, which means early identification and treatment with the aim of reducing the worst consequences on patients.

Abstract Text: Radiological examinations constitute routine clinical practice, frequently involving the administration of contrast media, which can lead to various adverse effects, some of which are severe and potentially fatal. We present two cases of rare, yet severe adverse effects associated with the administration of radiological contrast media: fatal anaphylactic shock due to gadolinium-based contrast agents (GBCA) and compartment syndrome resulting from iodinated contrast media extravasation.[1-5] These cases are presented with the aim of highlighting their significance for both the clinical and forensic scientific perspectives.

The first case involves a 70-year-old male patient with no prior history of allergies or hypersensitivity reactions, who required multiple magnetic resonance imaging (MRI) scans utilizing GBCA for follow-up monitoring of orbital squamous cell carcinoma. Despite having tolerated several prior exposures to gadolinium, the patient experienced acute loss of consciousness immediately following administration of gadoterate meglumine, accompanied by severe symptoms including ventricular fibrillation and subsequent cardiac arrest. Advanced cardiac life support efforts initially resulted in a return of spontaneous circulation; the event was not initially associated with contrast medium administration; however, during a subsequent MRI session employing the same contrast agent, he suffered a repeated severe anaphylactic reaction leading to pulseless electrical activity and death. Postmortem analyses, including comprehensive histopathological examinations with specific mast cell staining, demonstrated extensive mast cell infiltration and degranulation within vital organs, confirming the diagnosis of fatal anaphylactic shock secondary to gadolinium exposure.

The second case describes a 58-year-old female patient who developed severe compartment syndrome following extravasation of iodinated contrast medium during intravenous administration for computed tomography (CT) imaging performed as part of endometrial cancer staging. Initially characterized by localized pain, edema, and erythema, clinical recognition of the contrast media extravasation was significantly delayed. The condition rapidly progressed, resulting in extensive forearm and hand involvement with marked neurovascular compromise. This necessitated urgent surgical management, including decompressive fasciotomy followed by subsequent wound curettage and closure. The delay in identifying and addressing the extravasation underscores critical shortcomings in clinical management, emphasizing the importance of immediate diagnosis and rapid intervention to prevent significant morbidity and permanent disability.

These two distinct yet severe cases of contrast media-related adverse events underscore the critical importance of thorough clinical monitoring, prompt recognition of complications, and timely forensic investigations. The findings from these cases provide essential insights into the pathophysiological mechanisms involved and highlight the need for rigorous clinical protocols and forensic assessments to mitigate professional liability and enhance patient safety.

F57 Fatal Entrapment in an Industrial Concrete Mixer: A Forensic Case Report of Polytrauma and Asphyxiation

Benjamin Charroy, MD, Rouen University Hospital, Rouen, Haute-Normandie, France; Camille Launoy, MD, Rouen University Hospital, Rouen, Haute-Normandie, France; Gilles P. Tournel, MD, PhD, CHU de Rouen, Rouen, Haute-Normandie, France; Florence Vincent, MD, Rouen University Hospital, Rouen, Haute-Normandie, France; Benjamin Mokdad, MD, Rouen University Hospital, Rouen, Haute-Normandie, France; Helène Fricker, MD, Rouen University Hospital, Rouen, Haute-Normandie, France*

Learning Objectives: After attending this presentation, attendees will recognize the unique biomechanical and pathological patterns of injuries caused by industrial machinery entrapment, combining compressive, torsional, and shear forces. They will understand the critical role of postmortem imaging (Computed Tomography [CT]) in corroborating autopsy findings for complex polytrauma cases and appreciate the necessity of interdisciplinary collaboration among forensic pathologists, radiologists, and occupational safety experts in investigating workplace fatalities.

Impact Statement: This case will impact the forensic community by demonstrating how advanced imaging can validate autopsy findings in cases of severe mechanical trauma, improving accuracy in cause-of-death determination. It highlights systemic safety failures in industrial settings, urging stricter enforcement of Lockout-Tagout (LOTO) protocols to prevent similar incidents. Additionally, it contributes to the limited literature on fatalities involving concrete mixers, with a focus on injury patterns and medicolegal challenges.

Introduction: Workplace fatalities in the construction sector remain a global concern, accounting for 22.9% of all fatal occupational accidents in the EU.[1] Machinery entrapment incidents frequently involve complex biomechanical forces leading to severe polytrauma and asphyxiation, as documented in other case studies.[2] We present a novel case of fatal entrapment in an industrial concrete mixer, highlighting the interplay of compressive, torsional, and shear forces in injury causation.

Case Report: A worker was fatally entrapped in a 24/7 self-service concrete mixer after failing to reactivate safety protocols following client assistance. Witnesses reported mixer activation by subsequent customers, initiating a 3-minute cycle that resulted in full-body entrapment. Postmortem CT revealed thoracic trauma with bilateral rib fractures (anterior/posterior arcs), lung lacerations, hemopneumothorax, left mainstem bronchus fracture, abdominal injury including liver fracture and hemoperitoneum, extremity trauma featuring complete right foot amputation, comminuted tibia/fibula fractures, degloving injuries with parallel abrasions indicating torsional mechanics and asphyxiation evidenced by cement slurry inhalation (tracheal spumous blood, sinus concretions) compounded by thoracic compression. Autopsy confirmed these findings despite extensive cement coating obscuring external injuries.

Discussion: The injury pattern mirrors the "twisting" mechanism described in industrial entrapment fatalities, with three distinct force vectors: compressive thoracic trauma causing bronchial rupture, torsional extremity injuries producing parallel abrasions and degloving, and shear forces inducing visceral fractures.[2] This case exemplifies systemic safety failures in high-risk industries, particularly absent lockout-tagout (LOTO) compliance—a critical factor in construction fatalities where machinery has highly lethal potential. Postmortem CT provided complementary information, validating its forensic utility in complex polytrauma.

Conclusion: This fatality underscores the lethal synergy of biomechanical forces in industrial entrapment and reinforces the need for mandatory LOTO protocols, multimodal forensic analysis combining imaging and autopsy, and enhanced safety training to prevent similar incidents.

F58 From Scanner to Courtroom: Best Practice Standards for Postmortem Computed Tomography

Jamie M. Elifritz, MD, Forensic Radiology Group, Destin, FL; Summer Decker, PhD*, Keck School of Medicine, University of Southern California, Los Angeles, CA; Natalie L. Adolphi, PhD*, University of New Mexico, Albuquerque, NM*

Learning Objectives: By the end of this session, participants will be able to: (1) identify the essential technical and operational requirements for implementing a high-quality Postmortem Computed Tomography (PMCT) program in medicolegal settings; (2) describe the validated forensic applications of PMCT, along with its known diagnostic limitations and the importance of trained interpreters; and (3) explain how the history of forensic imaging was based in the courtroom and how PMCT findings are integrated into legal systems across the globe.

Impact Statement: This session provides essential guidance on implementing and interpreting PMCT in alignment with global standards. Attendees will gain practical tools to improve forensic imaging quality, ensure responsible use, and support legal admissibility across diverse medicolegal settings.

Abstract Text: Postmortem computed tomography (PMCT) has become an essential tool in modern medicolegal death investigation, offering noninvasive insight into both natural and unnatural deaths. As PMCT becomes increasingly integrated into forensic workflows worldwide, it is critical to be aware of national and international standards that ensure its quality, consistency, and admissibility in legal contexts. This presentation will provide a practical overview of three pillars of PMCT best practice, drawing from published guidelines:

- **Technical Infrastructure and Operational Foundations**
  Successful implementation of PMCT requires more than access to a computed tomography (CT) scanner. Best practice standards define requirements for CT scanners capable of whole-body, high-resolution imaging; appropriate room setup with shielding and reliable power; and sufficient computing infrastructure for image reconstruction and secure storage.

  Imaging protocols (covering positioning, acquisition parameters, and reconstruction techniques) must be tailored to postmortem use. Equally important is the training of technologists in body handling, scanner operation, and quality and safety assurance.

- **Validated PMCT Applications and Known Limitations**
  PMCT has proven to be a reliable and versatile tool across a wide range of forensic case types. In many countries, PMCT is an established part of medicolegal investigations (and has been for decades), supported by practical, experience-driven guidelines. International societies, along with national protocols from Europe, Asia, and Africa, have published detailed best practice guidelines.

  Equally important is recognizing the known pitfalls of PMCT. Certain findings (like vascular or soft tissue pathology) may be missed or misinterpreted. Moreover, interpretation of postmortem imaging requires a unique skill set and accurate interpretation is of paramount importance.

- **PMCT in Legal Contexts: History, Practice, and Global Adoption**
  Forensic imaging has a long history of use in death investigation and has increasingly played a role in courtroom proceedings. From early use of radiographs to identify gunshot wounds or foreign bodies, to modern full-body CT scans for complex forensic cases, imaging has become a powerful supplement—and in some instances, an alternative—to traditional autopsy.

Countries like Switzerland, Japan, and Germany have formally integrated PMCT into national forensic workflows. PMCT is complementary to autopsy and in some contexts, can be used and in lieu of autopsy when cultural or public health considerations apply. These international models highlight that reliable, protocol-driven PMCT meets legal standards and provides credible evidence in medicolegal cases.

Postmortem CT (PMCT) is an increasingly essential tool in medicolegal death investigation, offering noninvasive insight into both natural and unnatural deaths. This presentation outlines best practices for PMCT, drawn from international and national standards, focusing on Technical Infrastructure, Validated Applications and Limitations, and Legal Relevance and Global Adoption.

F59 The Examination of Blunt, Sharp, and High-Velocity Trauma on Burned Human Remains

Darren A. Solomon, MS, Bureau of Alcohol, Tobacco, Firearms and Explosives, Charlotte, NC; Rebecca L. George, PhD, Western Carolina University, Cullowhee, NC; Kaleigh C. Best, PhD, Western Carolina University, Cullowhee, NC*

Learning Objectives: This research examines various forms of trauma applied to a consenting human donor who was then placed inside a compartment that was set ablaze. A comparative view demonstrates the injuries from a pre-burn, post-burn, and autopsy perspective to illustrate the changes and potential for recognition.

Impact Statement: Thermal attack on the human body during a fire event can substantially alter evidence of traumatic injury, creating a substantial challenge for investigators. The ability to compare the same injuries from various investigative stages elevates investigator skills by building foundational knowledge that can be applied to real scenes. This presentation will show the challenges investigators face and the potential for successful recognition in the search for answers.

Abstract Text: This presentation will illustrate the challenges faced by those who investigate fatal fire scenes and the importance of a comprehensive investigative approach to detecting trauma on victims. Fatal fire scenes differ greatly from traditional death scenes because of the destructive effects of thermal assault on the body which can mask evidence of traumatic injury distinctly apparent on victims in non-fire death scenes. Additionally, fire investigators receive minimal training on injury recognition which increases the opportunity for investigative missteps.

To address this issue, research conducted in May 2025 between Western Carolina University's (WCU) Forensic Anthropology Program and the Fire Programs and Training Branch of the Bureau of Alcohol, Tobacco, Firearms, and Explosives (ATF) sought to examine trauma recognition abilities at different investigative stages. Various forms of high-velocity, sharp force and blunt force trauma were applied to a consenting human donor. Specific injuries introduced to the donor included gunshot wounds to the head and torso using various ballistic calibers, stabs to the torso, a broken right femur caused by a blunt force strike and sharp force cuts to the right forearm. The donor was then placed prone inside a three-walled, wood-framed burn cell furnished as a typical living room. After thorough documentation of all injuries and final placement within the burn cell, an unaccelerated fire was ignited and evolved until the compartment was fully ablaze. Burning continued at this intensity for several minutes until suppressed by firefighters.

Post-burn analysis revealed a wide spectrum of wound recognition. Entry and exit wound detection depended heavily on the location of each and the amount of thermal damage to the body or level of protection adjacent to the wound. Stab wounds to the anterior chest region were visible but in a different appearance as skin contracted and their location on the periphery of a protected area. Thermal damage to the forearm hindered recognition of the slashing injury. In great contrast, obvious trauma was noted on the right leg with a broken femur based on its final orientation.

Finally, the donor was transported to a local hospital's autopsy suite where a board-certified pathologist and assistant conducted a full autopsy of the remains with an emphasis on locating and evaluating trauma. Wound artifacts were compared from both external and internal cavity perspectives. This highlighted a vast difference between the external wounds masked by char and anatomical mass loss versus the clear evidence noted internally. The autopsy yielded a greater opportunity for trauma discovery, thus providing critical evidence early in the investigation.

This presentation shares the importance of a holistic approach to fatal fire scene investigations to capture traumatic injuries amid thermal damage. Beginning with an injury recognition baseline, attendees will see alterations of the body and how thermal attack influences injury recognition throughout the investigative process. Although challenging, best practices to help improve wound discovery on burned remains will be discussed. Additionally, this presentation will show the importance of involving other experts beyond the initial scene investigators.

Fire Investigation; Death Investigation; Trauma

F60 Homicide or Suicide? An Interdisciplinary Approach to Reconstruction of a Crime Scene

Jennifer McCampbell, MCS, Dallas Police Department / Veritas Forensics Consulting, Dallas, TX*

Learning Objectives: After attending this presentation, attendees will: (1) understand the interdisciplinary approach to processing a crime scene involving a fatal shooting and how multiple forensic disciplines were required for a successful reconstruction; (2) identify how bloodstain pattern analysis, crime scene processing, and evidence collection were used for the reconstruction and identify the analyses necessary for processing this death scene; (3) identify discrepancies between the physical evidence and the resulting decision on manner of death; (4) be able to identify how bias was problematic in this case; (5) be presented with the final crime scene reconstruction based on physical evidence and reports issued by law enforcement; and (6) understand the limitations based on the lack of communication and refusal of document release.

Impact Statement: Currently, very little attention is given to the myriad of different disciplines involved with a crime scene investigation. Laboratory analysts often don't see and understand the factors in play during a crime scene investigation and, therefore, make assumptions and are sometimes critical about the evidence submitted. It is important for judges, juries, detectives, crime scene investigators, and laboratory analysts to gain an understanding of the dynamic and sometimes chaotic situations present at a crime scene. The crime scene investigator is often overlooked in laboratory analysis and in the justice system. My presentation will highlight the importance of a crime scene investigator and what they have to offer. Attendees will understand factors such as bias, scene contamination, scene documentation, and crime scene protocol. The real case presented will demonstrate these factors and show how mistakes can cause a highly negative, improper investigation of a crime scene, limiting all involved entities with what types of analysis can be conducted and how a detective can be misguided due to improper case investigation. Crime scene investigators get one chance, one opportunity to process a crime scene. There is no going back once the investigation is complete. Every effort must be made to conduct all necessary processing of the scene the first time, because there is no second.

Abstract Text: Upon completion of this presentation, attendees will become familiar with the interdisciplinary nature of reconstructing a crime scene. Attendees will understand the role of the detective as well as the role of the crime scene investigator in complex cases. Attendees will be presented with a complex death investigation case and be able to use critical thinking to reconstruct the events using the skills learned about crime scene reconstruction.[1] Attendees will be able to identify the obstacles one may face at a crime scene and will learn how to mitigate these issues. The proper methods for evidence processing and collection of evidence will be addressed and how scene elements affect those methods. Attendees will recognize how each discipline factors into the investigation of a crime scene. The crime scene investigator must consider the type subsequent analysis performed by a laboratory. Bloodstain pattern analysis, DNA, latent prints, shooting reconstruction, and trace evidence collection will be discussed as they pertain to a death investigation case in general; specifically, attendees will address a current, real death scene and how reconstruction disproved a witness' statements.[1-3] This case presented involves these factors and subsequently describe what was overlooked, mishandled, and how bias was a factor in this investigation.[1,4] A brief discussion on bias will be discussed.[1,2,5,6]

F62 A Novel Method of Preserving Fly-Related Samples at Crime Scenes and in Labs for a Better Demonstration at Trial

John Z. Wang, PhD, California State University-Long Beach, Artesia, CA*

Learning Objectives: After attending this presentation, attendees will learn a new material and method to preserve entomological evidence, namely, fly eggs, maggots/larvae (I, II, III), pupa, and baby/adult flies at crime scenes and in labs.

Impact Statement: Several technical challenges still remain unsolved for the field of forensic entomology: (1) how to preserve original fly eggs, larvae (I, II, and III), pupa, and baby/adult flies collected at scenes for a later lab examination; (2) how to preserve control/reference samples fed in labs for the comparison; and (3) how to present at trial all of the unknown and known samples in their different stages at crime scenes and in labs as their original state. This presentation will impact the forensic community in general and the fields of forensic entomology in particular to better secure a genuine demonstrative evidence for better chain of custody and integrity at trial.

Abstract Text: When a dead body is found, flies will land on corpse with a couple of hours. They lay eggs, which grow into larvae (I, II, III stages). The larvae III instar then change into pupas, which go into underneath the soil surface. Finally, they become baby and then adult flies. Crime scene technicians and/or forensic entomologists collect these samples and take them to labs for examination and evaluation. Meanwhile, as control/reference samples for a comparison and later presentation at trial, forensic entomologists also have to create a similar setting (temperature, and moisture under soil or wood-chipped environment) to grow similar stages of eggs, larvae (I, II, III), pupa, and baby/adult flies. The total growth by flies follows a fixed life cycle in time intervals by which forensic entomologists use to estimate the time since death or called postmortem interval (PMI).

In reality the trial is often delayed months or even years, which is a common situation at present, both the original samples and the control/reference samples would die and decompose before the trial due to their life span limits. While the traditional method is to use formalin to preserve dead samples, the chemical liquid renders both types of samples to be bloated and losing details of their physiological characteristics for identification of species, larvae growth/ages, pupal stages, and differentiation of generations. Therefore, forensic entomologists have to use either dead samples or similar live replica as demonstrative exhibits. As a result, the defense can challenge the following questions at trial to reduce the probative values of the fly evidence: (1) Are the presented samples the original insect creatures in their original stage discovered and collected at the scene? (2) Are the control/reference samples the original creatures in their original stage grown and collected in the lab? (3) If both are NOT, how can you guarantee the accuracy and reliability of your PMI based on the fly life cycle principle?

This presentation will introduce a novel material and method to preserve entomological samples based on a quasi-experimental design. Each preservation step will be shown with details on collection, preparation, framing, sample placing, and final setting-up. The real preserved samples will be displayed and magnified using a digital scope to simulate a presentation and comparison at cross examination.

In sum, as the number of death investigations involving fly activities and samples continues to rise, a better material and method of preserving insect samples become much needed. This new material and related method from the quasi-experimental test have shown the following ten advantages: (1) inexpensive and available by the public, (2) easy to learn, (3) little preparation, (4) crystal clear transparent products, (5) preservation of original eggs, larvae (I, II, III), pupa, and baby/adult flies in their original stages, (6) details of original larvae and pupa bodies for differential stages for better comparison and estimation, (7) better demonstration for accuracy and reliability at trial, (8) better stereo-microscopic examination (20~80 x), (9) bio-hazard free, and (10) decay free for life-time preservation.

F63 Optimizing a Multi-Biochemical Method for the Taxonomic Identification of Single Pollen Grains: A Forensic Application

Jack Trimble, MS, National Center for Forensic Science, Orlando, FL; Madison Adolfs, BS, National Center for Forensic Science, Orlando, FL; Matthieu Baudelet, PhD, University of Central Florida, Orlando, FL; Camron Melendez, BS, University of Central Florida, National Center for Forensic Science, Tampa, FL*

Learning Objectives: Attendees will learn about forensic palynology and how pollen is an often underutilized trace evidence. This presentation will discuss the current capabilities and limitations of forensic pollen analysis and offer an alternative method for pollen identification that aims to alleviate these issues. The use of lipid profiling and DNA barcoding strategies in a combined orthogonal approach will be demonstrated. Attendees will see the success of this method on analyzing bulk samples and how it is being optimized for the identification of single pollen grains.

Impact Statement: This study aims to improve forensic palynology within the modern crime lab. Notably, the method should increase the accessibility of forensic pollen analysis by utilizing methods and instrumentation commonly found in crime labs. Along with facile integration, the method can be optimized for high-throughput analysis to improve sample turnover.

Abstract Text: Pollen is a ubiquitous component of our natural environment and plays an integral role in many disciplines. Forensic palynology, defined as the study of pollen to help investigators solve legal cases, is one example of pollen's importance in modern research. As a forensic tool, pollen is used as a proxy to link individuals or objects to a crime. Traditionally, taxonomic resolution is achieved using microscopy to characterize morphological features of the grain which vary between plant species. While identification to the species level is desired, visual classification is often limited only to the genus or family level. Furthermore, this specialized task is labor-intensive and subject to human bias as it relies on reference image comparison. Thus, a more objective, accessible, and quantitative pollen identification method is necessary to integrate forensic palynology into the modern crime lab.

Previous work from our group aimed to address these concerns using lipid profiling and DNA barcoding in a combined biochemical analysis. A one-pot non-destructive extraction is performed to isolate pollen coat lipids and genomic DNA contained within the grains. Lipid profiles are determined using traditional tandem mass spectrometry methods and compared with reference spectral libraries. Both time-of-flight (TOF) and triple quadrupole (QQQ) detectors were explored due to their prevalence in most laboratories. Separately, three genetic biomarkers (*rbcL*, *matK*, and *ITS2*) are targeted with species-specific primers and amplified using quantitative polymerase chain reaction (qPCR). Both the primers and markers are evaluated for species unicity, and proper amplification is confirmed via Sanger sequencing. While this method has been thus far validated using bulk pollen samples, the identification of single grains is of utmost importance within a forensic context (where pollen counts may be low). This poses new challenges, mainly due to the extremely low concentration of lipids and DNA present within a single pollen grain.

Here we discuss our recent study aimed to optimize the analysis of single pollen grains using the novel biochemical approach. Total ion mobility spectrometry (TIMS) was explored as a possible alternative to traditional TOF and QQQ spectrometry due to its increased sensitivity. Lipid extracts were quantified using a sulfo-phospho-vanillin assay calibration prior to TIMS analysis – known lipids were targeted from the bulk pollen profiles to determine what, if any, lipids were not observed from the single grain extractions. Separately, DNA from single grains was quantified using a cycle threshold (C_T) calibration method. Successful quantification varied by species and biomarker – while most C_T were observed within the calibration range, some consistently measured above the linear dynamic range due to low amounts of starting DNA template. Efforts to improve initial DNA concentrations, such as whole genome amplification, were also explored. While research is ongoing, preliminary results indicate our approach can be modified for the analysis of single pollen grains. This greatly improves its viability as a forensic tool, especially in cases involving low pollen counts.

F64 Termites Turning Point in Crime Detection

S. Venkata Raghava, MD, Bangalore Medical College and Research Institute, Bangalore, Karnataka, India; Charishma Reddy, MBBS, Bangalore Medical College and Research Institute, Tumkur, Karnataka, India*

Learning Objectives: By attending this presentation, participants will be able to: (1) recognize the forensic significance of environmental entomology—particularly termite activity—in the context of crime scene analysis and death investigations; (2) differentiate between genuine accidental injuries and staged crime scenes by evaluating ecological disturbances such as altered insect behavior or concealment materials (e.g., cow dung); (3) interpret how overlooked biological indicators (e.g., termite colonization patterns) can serve as crucial evidence in revealing inconsistencies between reported and actual causes of death; and (4) apply interdisciplinary forensic methods involving pathology, scene reconstruction, and entomological evidence to enhance the accuracy and depth of criminal investigations.

Impact Statement: This presentation will broaden the scope of forensic investigation by introducing termite activity as a novel and underutilized indicator in crime scene analysis. It highlights the value of integrating environmental and entomological evidence—specifically the ecological behavior of termites—in detecting staged deaths and reconstructing complex homicide scenarios. By showcasing how seemingly inconsequential biological interactions can expose tampered evidence, this case study will encourage forensic professionals to adopt a more holistic and interdisciplinary approach, ultimately enhancing the precision and integrity of criminal investigations.

Abstract Text: After attending this presentation, attendees will understand the significance of environmental and entomological evidence—particularly termite activity—in aiding the resolution of criminal cases that may otherwise be misclassified or staged.

This presentation impacts the forensic science community by emphasizing the critical role of overlooked ecological indicators, such as termite activity, in exposing fabricated crime scenes and guiding accurate death investigations.

This case study involves an adult female whose body was exhumed eight days after her reported accidental fall. Initial documentation and witness statements suggested a fatal fall. However, the autopsy revealed a comminuted fracture on the left side of the skull (19 cm × 11 cm), with diastatic fractures involving the sagittal and right temporal sutures, as well as multiple fractures at the skull base. Internal findings included partially liquefied brain tissue, blood discharge from the ear, and antemortem scalp injuries—all inconsistent with the alleged mechanism of injury.

Scene investigation revealed brownish floor tiles, stained with blood and deliberately concealed using freshly spread cow dung. The motive behind this concealment was evidently to obscure bloodstains and mislead investigators. However, this act inadvertently attracted termites—primarily *Odontotermes obesus* and *Heterotermes indicola*—whose cellulose-digesting behavior unearthed concealed reddish stains beneath the cow dung layer. The pattern and depth of termite activity pointed to a biological disturbance localized around the bloodstained area.[1]

Forensic interrogation, guided by these findings, led to a confession from the deceased's cohabiting partner—her husband's first wife—who admitted to the murder and staging of the crime scene to simulate a fall. The pivotal forensic clue in solving the case was the termite activity triggered by the attempt to alter the crime scene environment.[2]

This case underscores the evolving utility of forensic entomology in crime scene reconstruction. It demonstrates that even minor ecological behaviors, such as termite foraging in cow dung, can provide critical leads in criminal investigations. Forensic practitioners are encouraged to adopt a more ecologically aware lens during scene evaluation, ensuring that subtle biological interactions are not dismissed but rather analyzed for their evidentiary potential.[3]

F65 The Fur Project: Species Identification in Forensic Casework Using Phylogenetic Proteomics

Glendon J. Parker, PhD, University of California, Davis, Davis, CA; Nicole McLoughlin, MSc, California Department of Fish and Wildlife, Vacaville, CA; Kyle Burk, MS, UC Davis, Parker Lab, Davis, CA; Ashley Spicer, MScFS, CA Dept. Fish & Wildlife, Sacramento, CA; Barry W. Baker, MA, U.S. Fish & Wildlife Service, Office of Law Enforcement, Ashland, OR*

Learning Objectives: During this presentation, attendees will learn about the application of proteomic methods for species identification. Attendees will know when to apply these methods and the respective potential and limitations of phylogenetic proteomics, existing DNA-based methods such as bar-coding and morphology.

Impact Statement: This presentation will impact the forensic science community by introducing a robust and powerful method to identify the species of origin of casework material. This dramatically expands the capability to extract confirmatory forensic information in previously intractable classes of trace evidence, manufactured fur, and other biological products.

Abstract Text: We report the discovery of taxonomic-biomarker peptides from fur hair that can be used to resolve the taxonomic origin of illegal materials. Confiscated animal items, such as pelts and furs, are often highly processed and rarely contain detectable DNA. Hair morphology is also limited when resolving at the species level. This leaves a major gap in the ability to detect and monitor the illegal fur trade, meet treaty obligations, and enforce the law. This project was divided into two parts: to identify (1) the species of origin from traded fur hair (California Fur-Ban, FGC Code 2023), and (2) illicitly traded Felidae family fur. The California Fur-Ban also contains exempt species (domestic cat and dog, sheep, goats, cattle and deer species), therefore phylogenetic proteomics must also resolve taxonomy to the extent that it can formally exclude these species.

The project fully processed fur hairs from a total of 45 species: 11 exempt species, 17 species from the commercial fur-trade, and 17 additional *Felidae* species. Single hair shafts (20 mm) from 3 individuals were processed in 3 biological replicates (n = 9) from each species (n = 45), submitted to shotgun mass spectrometry (n = 42), and searched bioinformatically using reference proteomes from each species (n = 39). Of these, the resulting peptides, that were in the many 100,000's, were searched to discover peptide sequences that were only present in the target species. The workflow consists of applying a python script that automates peptide submission to the NCBI database (www.ncbi.gov) and then tabulated the species that the amino acid sequences occurred in. These sequences were then screened for properties that make them suitable mass spectrometry peptide biomarkers: sensitivity, signal, short length, lack of chemical modifications, chromatographic resolution, and affordability. Multiple peptides ($n \geq 3$) were identified, if possible, to ensure better sensitivity and protection against other species, such as newly created proteomes from sister species submitted to the NCBI databases, that have the same amino acid sequence. A total of 333 peptides from 32 species resolved to single species in the NCBI databases as they are currently configured. Of these, 3 candidate species-resolving peptides were discovered in 27 species. There were an additional 102 peptides from 6 species, to date, that could reach species-level resolution when detected in combination. The discovery process will continue to obtain peptides that have both suitable chemical and mass spectrometry properties and phylogenetic properties that are taxonomically highly restricted, either in isolation or in combination, down to species-level resolution.

The workflow developed for this project has the potential to provide confirmatory, scalable, and objective mass spectrometry data that can pass the *Daubert*, *Frye*, and *Kelly* standards. The workflow can provide biomolecular tools to forensic investigators who need the species origin of hair and other keratinous evidence, such as feathers, leathers, horns and shells, to investigate and prosecute both human and wildlife crime.

F66 The Killing of Sons and Daughters: An Analysis Beyond the Outcome of Death—Circumstances and Differences Among These Murders and the Necessity of a Filicide's Classification

María Cuadros, MCrim, University of Granada, Granada, Andalucia, Spain; Miguel Lorente, PhD, University of Granada, Granada, Andalucia, Spain; Jose Antonio Lorente, PhD, University of Granada, Granada, Andalucia, Spain*

Learning Objectives: Attendees will gain a comprehensive understanding of how filicide is defined and classified across international studies and the limitations of such classification. In addition, they will be able to identify common profiles of filicides, cultural patterns, and psychological and sociological factors that contribute to filicide.

Impact Statement: This presentation highlights the need for a more comprehensive approach to investigating filicide. This approach would allow for a deeper understanding of the diverse circumstances, motivations, and objectives involved in filicide, ultimately enabling the development of a classification system that accurately reflects the different characteristics of these crimes.

Abstract Text: Filicide is defined as the killing of one's child by a parent or parental figure.[1] While this definition is generally intended to apply across all age groups, it is often inconsistently applied in the literature, and there is no universally accepted consensus regarding the characterization and incidence of filicide.[2] The existing body of research reveals a notable gender bias, with greater emphasis on filicides committed by women, and limited analysis of cases where the perpetrators are men. Mothers who commit filicide tend to be younger and are often driven by factors such as unwanted pregnancies, mental health issues, histories of abuse, or lack of social support. Fathers, by contrast, are more likely to act due to jealousy, revenge, or interpersonal conflict. Despite the severity of filicide, forensic research in Spain remains significantly underdeveloped, particularly in cases involving children under the age of ten. In light of this, the present study analyzes the majority of judicial rulings on filicide cases in Spain between 2007 and 2020, focusing on the characteristics of the perpetrators, the victims, and the criminal context in order to identify underlying motivations and objectives and to propose distinct categories based on shared characteristics.

Specifically, the research examines 48 judicial rulings and aims to identify behavioral patterns, contributing factors, and institutional and forensic areas for improvement.

Key findings include:

Perpetrator identity:

- Mother: 55.5%
- Father/Stepfather: 32.6%
- Both parents (Mother/Father): 14.5%

Age of the victim:

- Less than 24 hours old: 28.3%
- 24 hours to 1 year: 32.6%
- 1–4 years: 23.9%
- 5–9 years: 8.7%
- 10–14 years: 6.5%

These diverse elements, characteristics, and surrounding circumstances demonstrate the need for a forensic classification system based on the motivations and objectives behind these crimes.

F68 Back to Basics: Stratigraphy in Forensic Archaeology: Principles, Pitfalls, and the Path Forward

Ian D. Hanson, PhD, Bournemouth University, Lyndhurst, England, United Kingdom; Laura Evis, PhD, Exeter University, Exeter, England, United Kingdom*

Learning Objectives: Attendees will learn how stratigraphy provides a universal basis for undertaking forensic archaeological investigation, understand the impacts upon method and recording applications, the implications for evidence, and learn of developments in analysis, recording methods, and principles

Impact Statement: The forensic community will be impacted by understanding the basis and importance of stratigraphy to forensic archaeological practice, developing an awareness of impacts on evidence and the potential for development in the discipline and applications

Abstract Text: In archaeological terms stratigraphy is the study and analysis of the order and position of layers (strata) that accumulate over time, the result of human and natural actions. Always influenced by the effects of gravity, the second law of thermodynamics, and time, strata adhere to universal principles or "laws." The recognition and recording of strata through excavation allows analysis to accurately reconstruction of the sequence of events that occurred at the site irrelevant of its age, size or complexity, and is the foundation upon which all interpretations are made.

The adaptation of archaeological methods to forensic settings has resulted in successful use of stratigraphy to define complex series of events, especially on burial murder scenes. Excavation is a destructive undertaking, and should be performed as a controlled archaeological process. Procedures for forensic applications are published and legal requirements in forensic practice demand adherence to defined standards. As a minimum, most jurisdictions have criminal codes which prohibit the loss and destruction of evidence, and stratigraphy provides the potential to maximize the forensic evidence revealed within buried crime scenes.

Archaeological methods and processes based on the principles of stratigraphy and utilization of principles themselves, vary globally, and there are no universal standards. The study of stratigraphy is a complex and highly contested field. Internationally, numerous excavation and recording systems are used, with forensic practitioners often applying those with which they are most familiar and experienced, rather than selecting techniques based on evidentiary need or the nature of the site. The potential to lose evidence, based on method and recording selection has been demonstrated experimentally, and in practice.

Given the ever-increasing involvement of forensic archaeologists in casework in both domestic and international investigations, it is necessary, and ethically imperative, that such inconsistencies are addressed to ensure the field develops to meet thresholds for legal admissibility. This paper will review:

- Definitions of the principles and laws of stratigraphy and their fundamental use for forensic applications
- Requirements for forensic science, in the defining of methods, repeatability, validity, and the demonstration of evidential integrity
- Evidential uses in achieving evidence class retrieval, and contextual association
- Recognizing impacts on evidence, from non-recognition of strata, method variation and evidence destruction
- Management, admissibility, and use of evidence from stratigraphic analysis and interpretation
- Developments in stratigraphic analysis, including diagnostic approaches, recording methods, and additional laws

Through reviewing the applications of stratigraphy in forensic archaeological practice we can continue to meet our ethical obligations as practitioners, increase the range and rate of evidence recovered from crime scenes, and gain the ability to assess the rate and impact of evidence loss.

F71 Keeping It Real: Ensuring Students and Trainees Get Realistic Experiences to Prepare Them for Working in Real Laboratories

Stewart Walker, PhD, Flinders University, Adelaide, South Australia, Australia*

Learning Objectives: The learning objectives are that attendees will consider the authenticity of training presented and reflect on their experiences and reconsider training options at their own institute.

Impact Statement: Attendees will be encouraged to reflect on their experiences and reconsider training options at their own institute. This presentation has the potential to lead to discussions, sharing of experiences, and collaboration.

Abstract Text: As an academic institute that offers courses in forensic science we team with practitioners from Forensic Science South Australia and other real laboratories to ensure that our topics are realistic and prepare students for working, not only in forensic laboratories, but other laboratories where the skills of sample preparation, extraction, analysis and interpretation are required. To achieve this, we regularly reassessed our material, presentation and assessment to ensure that it is fit for purpose and we are "keeping it real."

Three examples will be presented:

- Introduction of proficiencies where the students are given known samples and follow a standard operating procedure to report results. These are modelled on round-robins and proficiency tests that are common components of laboratory accreditation and quality assurance and quality control procedures.

- Although we have a Permit from the South Australian Government for research students to access illicit drugs for the purposes of education, training and research we cannot use real illicit drugs for undergraduate training. We, therefore, use other Over-The-Counter drugs that provide the same or similar experiences for extraction and quantification.

- Reporting of the proficiencies also is modelled on how reports are prepared in forensic laboratories. By the time students reach third-year topics, they have been indoctrinated into thinking that university practicals must be written up with an introduction, material, methods, results, discussion, conclusion and references sections. Instead of this the students are submit the results of the proficiencies on a one-page statement. Initially, we provided the students with an envelope onto which the required details were printing with spaces for filling in details of which method they used, which instrument and, most importantly, what their results were. Printouts from instruments and calculations were placed inside the envelope and sealed and it was signed by the student and the academic or demonstrator. We have now moved to an electronic submission of results and calculations as in LIMS (Laboratory Information Management Systems) systems PLUS a hardcopy one/two-page report that is signed in pen (as is the legal requirement for reports in South Australia).

For the final third-year forensic chemistry topic (FORS3004/8008 Undergraduate and Masters) students undertake proficiencies where they; (1) extract alcohol from blood serum, (2) paracetamol/acetaminophen from a selection of tablets, (3) quinine from tonic water, (4) caffeine from a range of sources and (5) zinc and/or iron from health supplement tablets. The paracetamol proficiency is based on the QA/QC undertaken in a pharmaceutical manufacturing facility. Each student takes 3 x 30 mg aliquots from 20 crushed up tablets—the "homogeneous average" that should be close to the stated concentration of 500 mg per tablet, and crush up one tablet and take 3 x 30 mg samples to identify the concentration in that specific tablet, and also take one tablet and dissolve it and take 3 x the equivalent volume to give 30 mg. Result from the class are used to illustrate accuracy and precision and reproducibility. We are keeping it real.

F72 The Use of Mindfulness Practices to Enhance Thinking, Observation, and Problem-Solving Skills for Forensic Science Students and Forensic Practitioners

Douglas A. Ridolfi, MS, Buffalo State University, Amherst, NY*

Learning Objectives: After attending this presentation, attendees will have gained an appreciation for the use of mindfulness practices beyond simple meditation to enhance observation and problem-solving and prepare the mind to receive new information. Mindfulness can assist the practitioner beyond traditional use as a form of relaxation, stress relief, and building resilience by conditioning to make the mind more receptive for new information.

Impact Statement: This presentation will provide a comprehensive overview of contemplative practices with applications to forensic science practices where concentration, attention to detail, accurate recording of detail, and thinking required to resolve difficult problems need to be performed under optimum efficiency. Meditation produces a quieting of emotions and a grounding to a steady and calm emotional state. Use of contemplative practices such as Zen Koan to help initiate problem solving, Mezirow's reflective methods, journaling, integration of deep study concepts such as Lectio Divina with close reading to enhance understanding of texts and other techniques will be examined.

Abstract Text: The concepts of meditative practices and their benefits and applications to forensic science are taught as part of a class in introductory criminalistics to undergraduate students through a series of written exercises, a semester long project, and through a series of ten PowerPoint presentations that cover a range of contemplative practices:

1. Introduction to Mindfulness Practices.
2. Foundations of Meditative Practices.
3. Visualization Methods.
4. Reflective Journaling.
5. Developing Intuition and Insight.
6. Use of Labyrinth to aid Problem Solving.
7. Mindful Studying Methods and Building a Mindful Environment.
8. Mindfulness Practices to Promote Active Listening, Writing and Effective Questioning.
9. Using Mindfulness Methods to Reduce Stress, Building Resiliency, Reflection and Listening.
10. Contemplative Practices in the Classroom; Building Mindful and Healthy Lifestyle.

What are the results of applying the meditative practices and curriculum? This material is an optional, supplemental aspect of a course in a traditional introductory course in *Criminalistics and Chemistry* and provides an alternative series of lectures, assignments and long-term projects for students who might want to explore these topics emphasizing that practitioners/scientists are the most important foundation of forensic science and it is important that they perform optimally. Students are provided with practice and tools in using meditative methods to enhance reading and observational skills through focused lectures and exercises where these meditative approaches can be applied to forensic problems.

Is it designed to be used by students or practitioners? The lectures and meditative exercises are part of an academic forensic science class, but it is hoped that students will find these practices of value and continue to use them throughout their careers. Students have found a variety of forensic applications in their projects such as forensic-theme coloring mandalas, nature walk observations, use of labyrinths for contemplation and problem solving, use of the DaVinci Device to enhance observational skills, and abstraction laddering.

Can you prove that this helps in a forensic context? I believe that any method that can heighten our concentration and awareness can be of value in a forensic or other context if it expands our approaches to solving problems. Abstraction laddering has applications in field investigations, and I have used it in my previous crime scene experience. Principles of good journaling will also enhance good note taking whether at a scene or in evidence examination within the laboratory. Other meditative practices of direct application to the practitioner will be highlighted in the presentation.[1,2]

F73 Think Like a Scientist, Search Like a Librarian: Information Literacy for Forensic Scientists

Jeff Teitelbaum, MLIS, Florida International University, Largo, FL*

Learning Objectives: After attending this presentation, attendees will understand how information literacy applies to a forensic scientist and will learn how to put into practice some of the core elements, including how to locate credible, relevant forensic science information, how to apply advanced search strategies, and how to navigate around misleading journal articles and paywalled content.

Impact Statement: This presentation will empower forensic science professionals with the core components of information literacy and search skills that will directly enhance the quality, credibility, and reliability of their work. By equipping practitioners with tools to find and critically assess scientific research, the session strengthens the foundation for sound forensic conclusions, informed expert testimony, and ongoing professional development.

Abstract Text: In forensic science, the strength of an analysis or expert opinion is only as sound as the information it's based on. Yet in a field overwhelmed by an unrelenting flood of publications, many practitioners lack the time or training to navigate the complex landscape of scientific and legal information effectively. This presentation introduces forensic scientists to search techniques and information literacy skills modeled on the best practices of librarianship.[1]

Attendees will learn how to conduct focused, efficient searches across key forensic science databases and open-access platforms, using advanced strategies such as citation chaining, site search operators, and subject-specific vocabularies.[2] The session will also address how to critically evaluate sources for credibility, bias, methodology, and relevance—skills essential in distinguishing solid evidence from weak or misleading studies.[3,4]

By combining the analytical mindset of the scientist with the search acumen of the librarian, forensic professionals can improve the quality of their research, strengthen the basis for expert testimony, and contribute to a more transparent and scientifically grounded practice. Real-world examples will highlight how these skills apply to casework and enable practitioners to stay current with emerging technologies and research.

This presentation equips attendees with actionable strategies to find better information faster, and to use that information more wisely, ultimately reinforcing the integrity of forensic science as both a scientific and legal discipline.

F74 AI-Powered Expert Witness Report Review System: Enhancing Pre-Admissibility Quality Control to Prevent Wrongful Convictions

Melda Yazıcıoğlu, PhD, Üsküdar University Graduate School of Addiction and Forensic Sciences and MEF University , Istanbul, Istanbul, Turkey*

Learning Objectives: This presentation will inform attendees about the role of flawed expert witness reports in contributing to wrongful convictions and introduce how Artificial Intelligence (AI), specifically Natural Language Processing (NLP) can be used to evaluate the credibility of such reports. Participants will gain a conceptual and practical understanding of how AI-based tools can assist in pre-admissibility quality control within forensic science, improving the integrity of expert evidence before it reaches the courtroom.

Impact Statement: This presentation will enhance the forensic community's competence in critically evaluating expert witness reports by introducing an evidence-based, AI-supported review framework. It promotes improved decision-making performance in pretrial stages and supports more scientifically grounded outcomes in both conviction review and courtroom practice.

Abstract Text: Wrongful convictions remain a critical concern in modern criminal justice systems, often resulting from overstated or unverified expert witness testimony. This risk is particularly acute in forensic domains with limited scientific consensus, such as bite mark analysis, ear print comparison, and facial recognition, where courts have admitted testimony lacking methodological rigor or empirical support.[1,2] Despite the substantial weight that forensic experts carry in shaping legal outcomes, systematic mechanisms to evaluate the scientific validity of expert reports before trial are infrequently institutionalized across jurisdictions such as the United States and Canada.[3,4]

This abstract proposes a literature-based artificial intelligence (AI) framework designed to conduct pre-admissibility quality evaluations of forensic expert witness reports. Utilizing recent advancements in Natural Language Processing (NLP), the system is programmed to analyze textual features and detect linguistic and methodological red flags that may undermine scientific credibility. Specifically, the model is capable of flagging linguistic overgeneralizations (e.g., "always/never" claims), expressions of unwarranted subjective certainty, outdated or missing citations, and inconsistencies between the described methodology and reported conclusions.[5,6] These features, grounded in linguistic and forensic research, serve as proxies for evaluating the robustness and credibility of expert testimony prior to courtroom use.

The system can generate an AI-derived "risk score" indicating the probability that a given report contains biased reasoning, unsupported conclusions, or insufficient scientific grounding. By offering an early-stage, automated quality control mechanism, this tool can assist Conviction Review Units (CRUs), legal counsel, and judges in identifying flawed expert evidence before they influence judicial decisions.[4,7] Unlike theoretical frameworks, this proposal builds on a systematic review of existing literature, real-world exoneration cases, and cognitive science studies related to forensic decision-making and confirmation bias.[2,3]

This interdisciplinary synthesis of forensic science, legal safeguards, and AI technology offers a pragmatic and scalable pathway for advancing scientific accountability in expert witness practices. As the influence of forensic evidence continues to grow in courtrooms worldwide, establishing objective, evidence-informed mechanisms for evaluating the quality of such reports is imperative for ensuring due process and minimizing the risk of irreversible miscarriages of justice.

F75 Introducing the Responsible Artificial Intelligence Framework for Forensic Science: Developed and Applied in a New Zealand Forensic Laboratory

Janet K. Stacey, MSc, The New Zealand Institute of Public Health and Forensic Science (PHF Science), Auckland, Auckland, New Zealand; Rachel Fleming, PhD, New Zealand Institute for Public Health and Forensic Science, Auckland, Auckland, New Zealand; Niki Osborne, PhD, Institute for Public Health and Forensic Science (PHF Science), Auckland, Auckland, New Zealand*

Learning Objectives: By the end of this session, participants will be able to: (1) describe the key components of the Responsible Artificial Intelligence Framework for Forensic Science; (2) identify domain-specific risks and requirements that distinguish forensic science from other AI-adopting fields; (3) apply the framework's principles to real or hypothetical forensic AI use cases to evaluate alignment with scientific and ethical standards; and (4) compare the forensic-specific framework to broader AI governance frameworks to understand alignment and distinctions.

Impact Statement: As AI-enabled systems begin to play a larger role throughout the forensic lifecycle, the need for responsible governance becomes critical. This presentation will help forensic scientists, quality managers, and legal stakeholders understand and apply a fit-for-purpose framework that supports innovation while ensuring accountability, transparency, and fairness. By adopting a structured approach to AI governance, the forensic science community can build trust with courts, users, and the public and ensure that AI-enabled tools are both scientifically defensible and socially responsible.

Abstract Text: The integration of Artificial Intelligence (AI) into forensic science has the potential to improve efficiency, consistency, and analytical capacity. However, the forensic science community faces unique challenges, including legal admissibility, public accountability, and high-stakes decision-making, that demand a tailored approach to development and deployment. This presentation introduces the *Responsible Artificial Intelligence Framework (RAIF) for Forensic Science*, developed in a New Zealand forensic laboratory at the Institute for Public Health and Forensic (PHF) Science through a collaboration between forensic practitioners, researchers, law enforcement, and AI developers.[1]

This framework has three core components: a questionnaire, a guidelines document, and a project register. Together, these support the ethical and operationally sound implementation of AI across diverse forensic contexts, emphasizing explainability, trust, safety, fairness, and ethical integrity. Drawing on lessons from global AI guidance and standards, the framework is specifically designed to accommodate the realities of forensic workflows.

Attendees will gain practical insight into how the framework can guide development, procurement, evaluation, deployment, and monitoring of AI-enabled systems in forensic science. Discussion of the implementation of an AI-powered drug analysis tool called Lumi Drug Scan, developed in-house at PHF Science will illustrate how the RAIF can be applied throughout the AI lifecycle. By bridging a gap between high-level principles and operational practice, the RAIF offers a pathway toward AI adoption that meets the needs of end users and is scientifically sound and defensible. This presentation invites dialogue around how forensic science service providers, AI developers, and criminal justice partners can collaboratively shape a trustworthy future for AI in forensic decision-making.

F76 The Metaverse and the Basics of Forensic Science: A Framework for Application

Paolo Visci, MD, University of Bari "Aldo Moro", Bari, Puglia, Italy; Annachiara Vinci, MD, University of Bari "Aldo Moro", Bari, Puglia, Italy; Biagio Solarino, MD, PhD, Università degli Studi di Bari Aldo Moro, Bari, Puglia, Italy; Davide Ferorelli, MD, University of Bari "Aldo Moro", Bari, Puglia, Italy; Alessandro Dell'Erba, MD, PhD, University of Bari "Aldo Moro", Bari, Puglia, Italy; Gianmarco Sirago, MD, Università degli Studi di Bari "A.Moro", Bari, Puglia, Italy*

Learning Objectives: Following this presentation, attendees will be able to: (1) identify the current gap in Metaverse research and application between mainstream medical fields and the forensic sciences; (2) propose novel training models using the Metaverse for core forensic tasks, illustrating how virtual environments can enhance practical skills; and (3) evaluate how the integration of immersive virtual tools can enhance core competencies and improve practitioner performance, directly supporting a "Back to Basics" educational approach.

Impact Statement: This presentation will impact the forensic science community by initiating a crucial dialog on how emerging technologies like the Metaverse can be strategically integrated to reinforce, rather than replace, foundational principles. It will challenge the community to address the current innovation gap between forensic science and other medical disciplines, thereby encouraging a proactive approach to technological adoption. By showcasing concrete, evidence-based models for virtual training in autopsy, crime scene analysis, and complex case reconstruction, this presentation will provide a tangible roadmap for implementation, moving the conversation from theoretical potential to actionable strategy. This will directly impact practitioner competence by providing a risk-free, infinitely repeatable environment for skill mastery. Consequently, it will enhance on-the-job performance by improving decision-making, reducing procedural errors, and building confidence in high-stakes situations. Ultimately, this improved reliability translates into more robust and defensible forensic findings, directly strengthening stakeholder outcomes by contributing to a more just and accurate legal process. This work is intended not merely to inform, but to inspire a paradigm shift in forensic education and continuous professional development for the next generation.

Abstract Text: A significant disparity exists between how quickly the Metaverse is being adopted in the broader healthcare sector and its limited presence in forensic and legal medicine. This presentation outlines a detailed framework for using the Metaverse to enhance core forensic methods and principles. The suggested framework views this technology not as a replacement but as a sophisticated addition to traditional training and analysis.

The potential applications are multidisciplinary. In forensic anthropology, virtual labs can be created to provide access to extensive digital collections of skeletal remains, aiding training in identification and trauma analysis beyond the limitations of physical collections. Likewise, accident reconstruction can shift from static diagrams to interactive 4D simulations, establishing a standardized environment for the objective assessment of personal injury. This environment allows practitioners to apply medico-legal standards, such as the AMA Guides to the Evaluation of Permanent Impairment, to virtual subjects with high accuracy, but also to evaluate virtual damage in the future.

The usefulness of this framework extends to fields that depend on trace evidence. For genetics, the Metaverse offers a platform to train investigators in evidence collection protocols under diverse and complex conditions, strengthening techniques to reduce contamination risks. Additionally, for large-scale incidents, virtual simulations of mass disaster events can be used to train multidisciplinary teams in triage and identification protocols in a controlled, repeatable way.

Beyond current training paradigms, the Metaverse requires a forward-thinking approach to legal medicine. This includes developing critical medico-legal frameworks to evaluate new types of psychological and biological harm that may result from interactions within virtual environments.

In conclusion, incorporating the Metaverse into forensic practice signifies a crucial evolution. Its use allows forensic practitioners to improve their skills and achieve greater consistency in their core competencies. This technological shift aims to prepare a new generation of experts for both current and future forensic challenges.

F77 Walking into Uncharted Territory: Understanding the Rise of Asian Youth Gangs

Cliff Akiyama, MPH, MA, Akiyama and Associates, LLC, Philadelphia, PA*

Learning Objectives: Attendees of this presentation will be able to learn about novel Asian youth street gang activities confronting law enforcement and death investigators and to identify ten distinct manifestations of Asian gang violence and eight ethnic differences and similarities among Asian gangs (i.e., definite cultural differences between Asian gangs and various other ethnic gangs; drugs; weaponry; killing over turf/territory; extortion; defacing property/graffiti; women in gangs).

Impact Statement: The impact that this presentation will have on the forensic science community is that it will demonstrate what an impact Asian youth gangs still have on the community as law enforcement, death investors, coroners, and medical examiners continue to risk their lives in investigating the deaths of these youth gangs and how to keep themselves safe while doing so.

Abstract Text: Across the United States every single day we often hear of someone who has fallen victim to gang violence. Youth gangs throughout the United States continue to terrorize the neighborhoods that they claim as their own, causing the citizens in these gang infested neighborhoods to live in constant fear of their lives every single day. As a result of the recent influx of gang violence and gang-related homicides in all communities, the safety of those first responders and investigators at the scene are put in jeopardy, leaving the medical examiners/coroners, death investigators, and detectives as possible targets of intramural shootings just because they are at the scene. In fact, these shootings have increased nearly 67% in the past year.

Throughout the United States gang violence has risen over 89% over the last year. Sadly, every single state has gangs and the problem is getting much worse in areas that would never have thought about gangs a year ago. Gangs are not just an urban problem, but a suburban and rural problem too. With the population of Asian and Pacific Islander Americans (API) continuing to rise in the United States, so do their needs. Unfortunately, not all Asian Americans are as uniformly educated, acculturated, and financially stable as the myth of the "model minority" would have us suggest.

Although adults from many nationality groups between Asian and Pacific Islanders have adapted well to life in the United States, serious problems have emerged among Asian American youth. In particular, youth gang violence in the Asian and Pacific Islander community has dramatically increased in the past few years by nearly 93% nationwide according the U.S. Department of Justice, Office of Juvenile Justice and Delinquency Prevention.[1,2] In Los Angeles County, CA, alone, there are currently 320 Asian youth gangs, with a total gang membership of over 13,000. In neighboring Orange County, CA, gang involvement has reached an all-time high with over 126 documented gangs and a membership of over 6,000. Demographics show gang member (male and female) age average of 15 with a range of 8-22 years. Even more disturbing is the increase of Asian females involved in gang activity. In Orange County, where the Asian gang population makes up 18%, there are 225 Asian female gang members, up 78% from last year. Other surrounding counties in California and the cities of Philadelphia Pennsylvania, Fairfax County Virginia, Philadelphia Pennsylvania and Portland Oregon have seen similar trends in the rise of Asian youth gangs.

The author interviewed over 500 gang members out in the streets, jails, and juvenile halls in California, Virginia, and Pennsylvania. This study identified 10 distinct manifestations of Asian gang violence and 8 ethnic differences and similarities among Asian gangs (i.e., definite cultural differences between Asian gangs and various other ethnic gangs; drugs; weaponry; killing over turf/territory; extortion; defacing property/graffiti; women in gangs).

F78 Elevated Insights: The Acquisition and Implementation of Unmanned Aircraft Systems (UAS) in a State Medical Examiner's Office

Micaela A. Ascolese, MS, RTI International, Durham, NC; Kaylan Peterson, MS, Office of the Chief Medical Examiner, Tulsa, OK; Philip Miller, BS*, Oklahoma Office of the Chief Medical Examiner, Tulsa, OK*

Learning Objectives: Attendees will gain an understanding of how UAS were acquired by the Oklahoma Office of the Chief Medical Examiner (OK OCME) and how they are being integrated into Medicolegal Death Investigation (MDI) workflows. This session will provide historical context on UAS usage (specifically in forensic science), outline the procurement process undertaken by the OK OCME, detail the current functions of UAS technology within the OK OCME, and offer recommendations for future research and for other agencies considering employing UAS in their operations.

Impact Statement: This presentation underscores the potential value of UAS in forensic science and in MDI. Medical examiner and coroner offices, those involved in death scene investigations, and others in the forensic science community could benefit from the insights provided.

Abstract Text: Thanks to advancements in UAS technology, product affordability, and its versatility across a variety of applications, UAS usage is predicted to grow by over 1 million aircrafts by 2028.[1] Despite this rapid growth and UAS' merit in the criminal justice, forensic science, and public health fields, its role in medicolegal death investigation (MDI) remains relatively unexplored.[2-4]

This research takes a closer look at the OK OCME's journey with UAS technology, from when they began using it in 2021 to present day, while highlighting the acquisition process and practical uses. Throughout years of implementation, OK OCME have found their UAS to be extremely helpful. Advantages include, but are not limited to: search and recovery of remains, conducting safety assessment for hazardous scenes, and virtual scene documentation. Although this study discusses several impacts, it only begins to address UAS use in MDI work. Acknowledging any limitations, further research and statistical analyses should be conducted on the outcomes of UAS technology within MDI.

This research offers a foundational look at the procurement process and integration of UAS technology in a state medical examiner's office and can help others who may also be looking to obtain UAS equipment. Ultimately, UAS can serve as a valuable supplemental tool for investigations, building on the basics and fundamentals of investigative processes.

F79 `VR Forensic: Immersive Virtual Reality Training for Forensic Medical Practitioners—From Scene to Courtroom

Benjamin Mokdad, MDr, IML Rouen, Rouen, Haute-Normandie, France; Benjamin Charroy, MD*, Rouen University Hospital, Rouen, Haute-Normandie, France; Giles Tournel, MD, PhD, IML Rouen, Rouen, Haute-Normandie, France*

Learning Objectives: Attendees will explore how immersive Virtual Reality (VR) technologies can enhance the training of forensic medical professionals at three key stages: crime scene investigation, clinical examination of sexual assault victims, and courtroom testimony. Attendees will engage in interactive demonstrations and collaborative discussion on implementation strategies, pedagogical outcomes, and ethical considerations.

Impact Statement: This session will promote a deeper understanding of how VR tools can improve practitioner competence, confidence, and consistency across medicolegal workflows. It will support the development of ethical and scientifically grounded practices by reinforcing core forensic principles through simulation.

Abstract Text: In an era of increasing scrutiny on forensic practices and practitioner performance, immersive training technologies offer a powerful tool to reinforce fundamentals while embracing innovation. The VR Forensic project was developed to address critical gaps in experiential training by offering three virtual reality-based modules: (1) a death scene investigation simulator, (2) a sexual assault consultation simulator, and (3) a courtroom testimony simulator.

The session will begin with an interactive demonstration of the three VR modules:

- **Module 1: Virtual Crime Scene—Body Recovery**
  Participants will observe how VR is used to recreate complex death scenes using photogrammetry and 3D mapping. They will explore how virtual interactions help teach key procedures such as body documentation, environmental assessment, and early forensic interpretation under pressure.

- **Module 2: Virtual Forensic Medical Consultation for Sexual Assault**
  This segment will showcase a clinical consultation with a virtual standardized patient. The simulation integrates medical history-taking, trauma-informed care, anogenital examination protocols, and medicolegal documentation. Attendees will be invited to discuss the ethical stakes, training challenges, and user feedback from healthcare professionals.

- **Module 3: Virtual Courtroom—Expert Testimony in a Criminal Trial**
  The final phase focuses on expert oral testimony in a realistic courtroom setting. Participants will watch how avatars, legal dialogues, and adaptive cross-examination help professionals prepare for high-stakes legal environments. Emphasis will be placed on neutrality, clarity, and fidelity to scientific facts.

Following the demonstrations, the session will transition into a collaborative discussion facilitated by the presenter(s), focusing on:

- Pedagogical design choices and instructional strategies;
- Practical challenges of integrating VR into forensic curricula;
- Assessment metrics and early evaluation data from training cohorts;
- Cross-disciplinary collaboration (medicine, law, engineering, education).

This deep-dive format aligns with the AAFS 2026 theme *"Back to Basics"* by emphasizing that technological innovation must remain in service of core forensic principles: neutrality, thoroughness, evidence-based reasoning, and ethics. Rather than replacing human judgment, VR Forensic strengthens it through immersive repetition, controlled risk, and reflexive learning.[1-3]

F80 UAS Crime Scene Videography

Gerald P. Baum, Jr., BA, Dallas Police Department, Dallas, TX*

Learning Objectives: This presentation will describe: (1) video and its importance as a way to communicate with a jury; (2) the Unmanned Aerial System's (UAS's), or drones', ability to capture video of a crime scene; (3) different applications of UAS for demonstrative evidence; and (4) the program's success in the courtroom.

Impact Statement: UAS Crime Scene Videography offers an innovative approach to documenting crime scenes through aerial video technology. Developed by Detective Baum of the Dallas Police Department, this method has been refined through its application in over 300 fatal vehicle crash investigations.[1] Its straightforward, cost-effective implementation provides investigators with critical visual evidence, enhancing both investigative accuracy and courtroom presentations.

Enhancing Crime Scene Documentation: Drones provide high-resolution aerial imagery, offering comprehensive views of crime scenes that are difficult to achieve with traditional ground-based methods. This aerial perspective allows investigators to capture wide and detailed footage, documenting evidence from multiple angles while minimizing the risk of contaminating the scene. Given that a crime scene cannot be revisited in its original state once cleared, capturing as much detail as possible at the outset is crucial.

Complimenting Photogrammetry: Investigators are increasingly employing drones to photograph crime scenes and using photogrammetry software to create accurate three-dimensional (3D) models. Originally developed for construction and surveying, this technology has proven valuable in policing by enabling virtual revisits to scenes, allowing for observation from various perspectives and precise measurements. Compared to traditional ground-based laser scanners, drones can reduce the time required to measure a location. However, while 3D models are beneficial for analysis, they may be challenging to present effectively in court due to their complexity.

The Importance of Video in Courtroom Presentations: Recognizing that many jurors are more receptive to video content, investigators are turning to drone videography to create compelling courtroom presentations. Drones can capture footage that illustrates distances, road curvatures, and environmental factors influencing a crash. Low-altitude flights can simulate a driver's or pedestrian's perspective, providing valuable insights into potential contributing factors. In cases where actual footage is unavailable, reenactments filmed by drones can reconstruct the sequence of events, illustrating critical details such as distances, paths of travel, and speed. This visual storytelling approach can convey complex information more intuitively to jurors.

Conclusion: The integration of UAS technology into crime scene investigations offers significant benefits, including enhanced documentation, efficient data collection, and improved courtroom presentations. As drone capabilities continue to evolve, their role in building stronger cases and supporting the pursuit of justice is expected to grow, underscoring the importance of embracing this technology in modern policing.

F82 The Phenomenon of Suicide Contagion: Examining Trends in Suicide in Harris County, Texas

Amelia Juneau, MS, Harris County Institute of Forensic Sciences, Houston, TX*

Learning Objectives: Attendance of this presentation will allow for better understanding of potential trends in suicide on a local scale, within Harris County, TX, and their correlation with significant events in popular culture.

Impact Statement: This presentation will impact the forensic science community by delving into the phenomenon of suicide contagion and how a better understanding of suicide contagion may benefit both the public health and forensic investigations spheres.

Abstract Text: Anecdotal evidence suggests that trends in suicide fluctuate in time with small- and large-scale popular culture events, a phenomenon referred to as suicide contagion.[1,2,4,5,8,11] Relatively little research examining this quantitatively has been completed. Those studies that have tend to examine trends in suicide rates and modality following events such as high-profile suicides; media centering around suicide; and the publication, or republication, of materials relating to "self-deliverance" and assisted suicide.[3,6,7,9] These studies show that there may be a correlation between increased suicide rates and popular culture events.[3,6,7] Further, these studies show that trends in suicide modality fluctuate with the same popular culture events.[10] Many studies are focused on singular events at a national scale, but recommendations for more locally scaled research exist.[8]

This study aims to better understand whether these trends are mirrored in Harris County, Texas, by examining the completed caseload of the Harris County Institute of Forensic Sciences (HCIFS) from 2014 to 2024, considering the timing of popular culture events like high-profile suicides, publication and adaptation of books and other media supporting suicide, and the emergence of social media platforms while remaining receptive to correlation not previously considered. Preliminary data analysis shows a steady increase in the number of suicide-related deaths investigated annually by the Harris County Institute of Forensic Sciences. Evidence shows that Harris County, Texas, may indeed experience fluctuations in suicide trends surrounding events of popular culture consequence. The consistency and predictability of these fluctuations, however, may not be reliable. Considering a few well-known popular culture events, the deaths of Robin Williams, Kate Spade, and Anthony Bourdain—suicide rates in 2014 peaked at five per day on two days in quick succession following the death of Robin Williams in August 2014, whose manner of death was ruled as suicide and cause of death as asphyxiation by hanging. The daily average of suicide-related deaths in 2014 was 1.23. The deaths of Kate Spade and Anthony Bourdain, which occurred days apart in June 2018, were both ruled as suicides with cause of death as hanging. Following these deaths, a small increase in suicide-related deaths was noted with two days recording four suicides within the subsequent days to week while the daily average of suicide-related deaths in 2018 was 1.41 and the peak daily rate of suicides in 2018 was six.

While correlation can be found with enough searching, and does not always constitute causation, the results of this study may aid in creating and implementing public health resources in times when increased mental health crises and suicide may be anticipated, with the intent to minimize the occurrence of suicide. These results may also aid in preparing responders, first and last, to anticipate potential influxes not only in overall caseload but also in certain types of cases. The ability to anticipate these trends could aid in allocating resources to better equip responders and potentially slow the onset of burnout so that those responders are, in turn, better equipped to serve their communities.

F83 The Role of the Forensic Anthropologist in "No Body Homicide" Cases: Exploring Case Entry in Two Current Databases

Amy Michael, PhD, University of New Hampshire, Rochester, NH; Robert Eckstein, PsyD, University of New Hampshire, Rochester, NH; Jennifer Bengtson, PhD, Southeast Missouri State University, Cape Girardeau, MO; Cruz Dellasanta, BA, Idaho State University, Durham, NH; Kylee Jedraszek, BA, Lowell Police Department, Lowell, MA*

Learning Objectives: Attendees will learn why the entry of all missing persons cases (regardless of date of last contact) into databases is essential for the resolution of some "No Body Homicide" (NBH) cases. Strategies for better communication about NBH cases between medicolegal practitioners and forensic anthropologists will be presented. Attendees will also learn how to document NBH cases more effectively in databases.

Impact Statement: This research impacts the forensic science community by providing data about the lack of representation of NBH cases in two frequently used databases. These data illustrate that adjudicated cases involving a homicide conviction with no body are not always entered into databases (despite the victim still being a missing person). This presentation will demonstrate how forensic anthropologists can use their skillset to improve case outcomes by working collaboratively with medicolegal professionals to ensure that unidentified remains are/are not victims from NBH trials.

Abstract Text: Forensic anthropologists are tasked with the analysis of unidentified decedents; in cases where identification is not achieved quickly, decedents may remain unidentified for an extended time. While forensic anthropologists are often advocates for entry of unidentified decedents into the National Missing and Unidentified Persons System (NamUs), we argue here that they should also be aware of the need to advocate for entry of a specific subset of missing persons cases, victims of "no body homicides" (NBH), into databases. NBH cases involve decedents whose bodies have never been recovered but whose killers have gone to trial. Ideally, all missing persons from NBH cases would be entered into databases in case their remains are ever found, thus facilitating comparison and identification. However, analyses of two current and reasonably comprehensive databases, NamUs and The Charley Project (TCP), revealed that many NBH cases are not in these databases. An initial sample of 649 NBH cases was generated using a trial lawyer's compiled NBH documents.[1] After removing cases from the sample if information was largely incomplete and/or inaccurate, if the victim was unborn or newborn without a documented name (since they would not be in TCP database), or if the victim's body was later found after the trial concluded, the final sample was 588 cases (364 female, 224 male victims). Data was collected on victims' sex, age at disappearance, urban vs. rural location of disappearance, date of murder/last known contact date, the time elapsed between the murder/disappearance and the date of the perpetrator's trial.

Results demonstrated that NBH victims were more likely to be entered into the civilian-run TCP database than the professional NamUs database. Age of the victim was not a predictor of entry into either database, while female victims were significantly more likely to be entered into databases. NBH cases with an extended disappearance-to-trial time lapse (longer than two years) were significantly more likely to be entered into databases. Victims from urban contexts with greater population sizes were more likely to be entered into databases. Overall, TCP database is used more frequently to document NBH cases than Namus. This finding is concerning considering that forensic professionals are responsible for populating NamUs entries and they rely on NamUs to be accurate and comprehensive. Further, cases that are adjudicated quickly (within two years) are far less likely to be entered into databases. This is problematic since there should still be a concern for finding a victim's body even if a perpetrator is sentenced for their homicide. Case study examples will be presented that illustrate why it is necessary for all missing persons to be entered into available databases (even if the cases are decades old and/or have been fully adjudicated) because if the unidentified remains of NBH victims are eventually recovered, a forensic anthropologist may be tasked with analysis and/or curation in their labs. Therefore, forensic anthropologists should advocate for comprehensive documentation of NBH cases in databases.

F84 The Sound of Gunfire

Andrew J. Winter, PhD, Middlesex County Prosecutor's Office, New Brunswick, NJ; Peter J. Diaczuk, PhD*, John Jay College or Criminal Justice, New York, NY; Ashley Buchman, BS*, Cedar Crest College, Andover, NJ; Frank LoSacco, MA, East Brunswick Police Department, East Brunswick, NJ*

Learning Objectives: This presentation will offer the audience a better understanding of the similarities and differences between the sounds of gunfire and non-gunfire as recorded and documented in this research project. This research project takes into account the sound initiated by the device as well as distance and weather conditions as snapshot in time in a residential environment. This presentation may offer a better understanding of the sounds produced by various types of gunfire, fireworks, and blank imitation firearms.

Impact Statement: This presentation will benefit the local law enforcement community (uniform and crime scene personnel) by providing a better understanding of the sounds documented from various types of firearms and non-firearms (fireworks and imitation blank "Hollywood" firearms) in an effort to determine if it is possible to delineate one sound from another.

Abstract Text: Often the sound of gunfire is confused with other sounds like fireworks, machinery, etc. This confusion impacts the false reporting of alleged gunfire incidents to law enforcement. This can have a significant impact on manpower and time resources of law enforcement agencies leading to misuse of law enforcement resources. This research offers a better understanding of sound as documented on a recording device to compare and contrast common sounds from fireworks and blank guns to that of authentic firearms. This initial research may benefit responding officers and crime scene investigators as response to these types of calls for service can be confusing both in what the human ear is hearing and in statements provided by witnesses and potential suspects.

The purpose of this research is to document the sound of gunfire utilizing a sound meter and comparing it to that of non-firearms. The data collected will be documented and analyzed as part of this research. This research project takes into consideration several variables from the firearm and non-firearm making the sound to the distance from the recording device and ambient temperature. This research was conducted in a residential area to mimic the common conditions as noted in real-world scenarios as experienced by active law enforcement (uniform and crime scene personnel) and community stakeholders.

F85 A Comparative Analysis of Forensic Audit and Traditional Audit Practices: Implications for Fraud Detection

Tracey Heywood, MBA, Texas Southern University, Houston, TX; Jasmine Drake, PhD, Texas Southern University, Houston, TX; Ashraf Mozayani, PharmD, Texas Southern University, Houston, TX*

Learning Objectives: Attendees will understand the key differences between forensic and traditional auditing procedures in the context of financial fraud detection. This presentation will provide the attendees with a measurable grasp of the actual applications, benefits, and limitations of each audit type. Participants will be able to evaluate how incorporating forensic tools into traditional audits may improve fraud detection capabilities and create stronger corporate governance systems.

Impact Statement: This presentation will improve the forensic science community's expertise by identifying the best audit procedures for fraud detection. It will also increase performance by assisting auditors and stakeholders in selecting and implementing audit methodologies that are appropriate for various fraud risk scenarios. Furthermore, it will influence policy decisions affecting legal, regulatory, and commercial supervision frameworks.

Abstract Text: The integrity of the auditing system is crucial to the global financial ecosystem. However, there are serious concerns about the limitations of traditional audits in identifying fraudulent activities. This study compares forensic and standard auditing techniques for detecting and preventing financial crime. Traditional auditing focuses on regulatory compliance and transparency, but forensic auditing uses specialist procedures to detect intricate fraud schemes. This study employs a qualitative approach and a literature assessment of 25 papers, with 16 chosen for in-depth examination. The findings indicate that forensic audits provide better depth, proactive detection, and actionable insights, but they can be more expensive and disrupt business operations. The report underlines the need to integrate both types of audits, as well as the expanding influence of innovative technology in fraud detection. It advocates the need for more forensic audit training, smart resource allocation, technological investment, and institutional support and collaboration.

In summary, forensic audits remain crucial in the fight against high-stake financial fraud, while traditional audits continue to be necessary for financial governance. Combining a hybrid auditing approach, which includes regulatory compliance with in-depth investigation, provides a comprehensive solution for improving public trust, accountability, and organizational transparency, thereby also enhancing the internal control system and strengthening the auditor's proficiency.[1-7]

F86 Understanding Time-to-Recovery: A Demographic and Spatial Analysis of Decedents in Las Vegas, Nevada

Elise J. Adams, MA, University of Nevada, Las Vegas, Henderson, NV; Derek A. Boyd, PhD, University of Nevada, Las Vegas, Las Vegas, NV*

Learning Objectives: After attending this presentation, attendees will better understand the factors that influence time-to-recovery of decedents in a metropolitan context. Through this, attendees will develop a better understanding of patterns of structural vulnerability that can impact time-to-recovery and how forensic practitioners can proactively address this issue.

Impact Statement: This presentation will impact the forensic science community by showcasing how structural vulnerability can impact time-to-recovery and thus the identification of decedents within the medicolegal system. It will also provide an argument for why practitioners should replicate this kind of study in their local jurisdiction.

Abstract Text: Positive identification of decedents is a critical component of medicolegal death investigations but can be challenging when postmortem intervals (PMI) are long. This has implications for structurally vulnerable decedents from diverse metropolitan areas who may have gone missing long before their bodies were found.[1] This preliminary study examines the demographic and spatial factors influencing "time-to-recovery" in the Las Vegas Metropolitan Area.

We collected demographic and spatial data from 552 forensic cases investigated by the Clark County Office of the Coroner/Medical Examiner in Las Vegas, Nevada in 2024. Time-to-recovery was estimated for each decedent by subtracting the date Last Known Alive (LKA) or Last Seen Alive (LSA) from the date pronounced dead. Demographic data collected from the case report documents included age (in years), sex (male or female), and race (White, Black/African American, Latinx, Asian). Spatial factors were based on nine zip-code clusters tied to the city's administrative regions.

Over half of the decedents were recovered within one day (298 or 53.99%). Four of the remaining 254 cases were outliers with extended PMIs (83-90 days). To minimize the risk of zero inflation or overfitting, only the remaining 250 cases were considered for analysis. A log-linear model was fitted to the data to estimate the independent effects of age, sex, race, and region on log-transformed time-to-recovery estimates. After model coefficients were interpreted following back transformation, age was identified as the only statistically meaningful predictor of time-to-recovery ($p < 0.001$), with every year of advancing age being associated with an increase in recovery time of 1.2% per year. However, the adjusted R^2 was 0.046, indicating that age only explained 4.6% of the variation in time-to-recovery.

The findings suggest that, although the effect was weak, older individuals face longer PMIs in the Greater Las Vegas area, which makes sense within the context of the United States census. The US census reports that 24% of adults over 65 live alone in Clark County, NV.[2] Of these, 10.6% live below the poverty line, meaning they may be less likely to afford basic necessities, including health insurance.[2] Increased vulnerability to untreated or poorly treated chronic disease alongside a lack of adequate support systems, increased frequencies of social isolation, and ageism may have increased the likelihood that an older individual died without notice and was recovered long after death.[3] If so, these findings suggest that older adults may represent a structurally vulnerable population in the Greater Las Vegas area and that additional public health measures, such as wellness check programs or interagency response teams assigned to neighborhoods with a higher frequency of older individuals, could be implemented to reduce mortality risk, the time-to-recovery of decedents, and the consequent burden on the medicolegal system. Additional research is needed to increase sample size, to refine model parameters, and to clarify the magnitude of the impact of PMI length on forensic identification in Clark County.

F89 A Forensic Inquiry Into Jean-Michel Basquiat's Lost Subway Portfolio

Nicholas Petaco, MS, John Jay College, Massapequa Park, NY*

Learning Objectives: Attendees will learn about: (1) George Stout's Three-legged Stool Method for Fine Art Authentication; (2) adding another leg to the Stout Method for Fine Art Authentication, in the form of AI search engine inquiry; (3) the Art World Coterie; and (4) the difficulties in getting genuine works of art authenticated.

Impact Statement: This presentation will highlight the importance of using established, standardized, unbiased forensic sciences' best practice scientific methods and procedures in the investigation of art fraud and fine art authentication.

Abstract Text: This article presents the findings of a scientific forensic inquiry into the origins of Tracey Finch's collection of postcards, drawings, and sketches she obtained from Kevin Doyle, an acquaintance of Basquiat in the 1980s who claims he retrieved Basquiat's portfolio, which Jean-Michel forgot while exiting a subway car at Wall Street Station. The previously unknown details, obtained from the recently available Basquiat Estate publications, regarding Jean-Michel Basquiat's life, his early work, the music and movies he enjoyed, were compared to various questioned works in Finch's collection to help establish the true origin of her collection. In this investigation, the essential question is whether Kevin Doyle is a forger of Basquiat's works. Two hypotheses were formed and studied. The first is that Kevin Doyle may be a forger of Basquiat's artwork. The second is that Doyle is telling the truth. The empirical data collected in this inquiry is unmistakable; examples that support Basquiat made and kept images and sketches of his designs and ideas are evident. Many of the same images appear in the apartment he lived in on 12th Street in the Lower East Side, on the neighborhood's concrete walls, in the images he created in his early life at home, published in "King Pleasure," and in his Notebooks. Therefore, the author rejects the first hypothesis that Kevin Doyle is a forger of Basquiat's early works. The evidence presented in this paper proves, within a reasonable degree of scientific certainty, that Kevin Doyle is not a forger of Basquiat's work and that the images purchased by Tracey Finch from Doyle, which were thoroughly examined and chemically analyzed, are early works by Jean-Michel Basquiat before he became BASQUIAT. Therefore, hypothesis number 2, that Doyle is telling the truth, is actual.[1-12]

F90 Falls From Height: Peculiarities of Injuries and Differential Diagnosis Between Accident and Assault

Saverio Gualtieri, MD, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Matteo Antonio Sacco, MD*, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Fortunato Vincenzo Nucera, MD, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Chiara Caruso, MD, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Roberto Raffaele, MSc, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Giuseppe Chiaravalloti, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Pietro Tarzia, MD, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Marta Chieruzzi, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Pietrantonio Ricci, MD, PhD, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Isabella Aquila, MD, PhD*, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy*

Learning Objectives: After attending this presentation, attendees will understand the fundamental injury, dynamic, and toxicological criteria to distinguish accidental falls from human-induced ones in the forensic context.

Impact Statement: This presentation will impact the forensic sciences community by demonstrating the importance of an integrated analysis of autopsy, environmental reconstruction, and toxicology for the correct classification of deaths by fall.

Introduction: Falls from height, particularly from ladders, are a common cause of traumatic death and serious injury. Differentiating between accidental events, suicides, or assaults requires accurate forensic investigation, especially in the absence of witnesses. This work aims to highlight the characteristic signs of each dynamic, offering objective criteria for differential diagnosis. The analysis includes injury patterns, toxicological data, crime scene findings, and the psychological profile of the victim. Emerging literature is reviewed, emphasizing the importance of a multidisciplinary approach integrating autopsy, toxicology, and investigative data for proper case classification.

Materials and Methods: Four cases examined at the Institute of Legal Medicine of the University "Magna Graecia" of Catanzaro were analyzed. Each underwent autopsy, crime scene inspection, and toxicological analysis. A literature review was conducted via PubMed using the keywords: forensic sciences, falls from height, head trauma, blunt trauma. Only full-text peer-reviewed articles were selected.

Case Series: The first case involved a 38-year-old man who died after falling approximately seven meters at work, with polytrauma involving the craniofacial region and spine. Toxicology revealed THC metabolites without clinical relevance. The findings supported an accidental fall. The second case concerned a 47-year-old man found dead near a ladder with multipolar cranial injuries. Toxicology was negative, but the trauma pattern was incompatible with a simple fall, raising suspicion of a violent event. The third case was a woman who fell from a spiral staircase, with injuries to the left fronto-parietal region consistent with head impact on metal steps. Toxicology was negative, and the context indicated an accidental fall. The fourth case involved a man who died after using public transport. Autopsy revealed cranial hematomas and facial-body contusions inconsistent with the reported scenario. Injury distribution suggested an assault, prompting forensic suspicion. Of the four cases, one involved a ladder fall, one a staircase, one an occupational fall, and one was initially reported as a fall from public transport.

Results: In the accidental cases (first and third), directional injuries matched the environment, supporting an autonomous dynamic. In contrast, cases two and four had multipolar cranial fractures with no environmental coherence. The absence of trauma-explaining context led to hypotheses of hetero-induced events. Literature by Galtés et al. and Pollak et al. confirms the usefulness of integrated evaluation based on injury distribution, environmental coherence, and lack of defense signs.[1-3] These criteria enhance accuracy in distinguishing accidental from inflicted trauma.

Discussion: Differentiating accidental falls from violent trauma relies on trauma patterns, injury distribution, and environmental compatibility. Directional injuries matching known surfaces suggest accidents; in contrast, multipolar fractures unrelated to surroundings and lacking defense wounds point to aggression. Even first-level toxicology helped clarify interpretative doubts. Literature confirms the validity of these criteria and underscores the importance of integrating findings.

Conclusion: The combined analysis of autopsy, toxicology, and scene inspection is essential in distinguishing accidental falls from assaults staged as accidents. These cases demonstrate how trauma distribution and environmental comparison can guide forensic diagnosis. In settings without advanced tools, critical interpretation of morphological and contextual data remains the most reliable resource.

F91 Humanizing Forensic Science: Practitioner-Centered STEM Education in Title I Florida High Schools

Jalika R. Waugh, PhD, Pinellas County Schools, Largo, FL*

Learning Objectives: Attendees who select this presentation will gain access to information on utilizing Practitioner Centered STEM education to support a forensic science curriculum at the secondary education level. Specifically, attendees will be exposed to one particular secondary education program whose focus on STEM in the forensic science and crime scene investigation fields are delivered using hands-on labs and field day exercises with current practitioners.

Impact Statement: In Title I public high schools across Florida, implementing forensic science programs empowers students to see themselves as future contributors to justice and scientific integrity. By introducing students to this reality, we can cultivate resilience, purpose, and a deeper respect for the professionals behind the science. This initiative would not only enhance Science, Technology, Engineering, and Math (STEM) engagement but would also foster equity by opening pathways to careers in forensic science for students in underserved communities.

Abstract Text: This presentation highlights the need for additional support of forensic science education initiatives designed for Title I public high schools in Florida, with the goal of fostering equity, engagement, and career readiness among underserved student populations. Ideally, support for these programs would center on a critical yet often underrepresented concept in forensic education: the role of practitioners as individuals. These practitioners and scientists are one of the most important foundations of forensic science. As we know, science does not work on its own; it is the *practitioners* who put it into everyday practice. They are the bedrock of our disciplines and the ultimate pursuit of justice. In the field of forensic science and crime scene investigation, it is well known the workload is constant, the demands are unreasonable, and the expectations can sometimes be consuming. By integrating a human-centered perspective into high school (and potentially middle school) forensic science curricula, students can be introduced not only to technical skills and scientific principles but also to the ethical, emotional, and societal dimensions of forensic work.

Currently, there are several programs in Florida where the curriculum includes hands-on labs, mock crime scenes, and case-based learning that encourages critical thinking, collaboration, and real-world problem-solving. Students engage with forensic professionals through guest lectures and field day programs, gaining insight into the personal responsibility and resilience required in the field. This presentation will share curriculum design strategies, student engagement metrics, and community partnership events that have contributed to one particular program's success. For example, at Pinellas Park High School, their Criminal Justice Academy has marked success with many of their alum working in the fields of law enforcement, the legal field, and forensic investigations. Additionally, their yearly "Law Day" event bridges the gap between community partners and potential employers by inviting over thirty agencies in these fields to highlight the demand and provide access to career pathways for students with STEM education backgrounds. The current curriculum at Pinellas Park has a focus on offering dual enrollment coursework in crime scene investigation and forensic science as well as incorporation of project-based learning modalities to include mock crime scene investigations and lab analysis of collected evidence.

These particular programs aim to demystify forensic science and make it accessible to students who may not otherwise envision themselves in STEM or justice-related careers. They also attempt to address systemic disparities by providing high-quality, practitioner-informed STEM education in schools with limited resources. Ultimately, continued support of these programs would empower students to see themselves as future contributors to a field where integrity, perseverance, and purpose are essential.

Attendees will gain practical tools for implementing similar initiatives and learn how emphasizing the human element of forensic science can inspire a new generation of practitioners committed to both scientific excellence and the pursuit of justice.

F92 Injury as a Silent Witness: Forensic Medicine's Role in Charge Determination in an Explosive Case

Francesco Calabrò, MD, University of Parma, Parma, Emilia-Romagna, Italy; Francesco Saverio Romolo, PhD, University of Bergamo, Begramo, Lombardia, Italy; Marcello Seligardi, MD*, University of Parma, Parma, Emilia-Romagna, Italy; Valentina Bugelli, MD, PhD, University of Parma, Parma, Emilia-Romagna, Italy; Beatrice Defraia, MD, Azienza Ospedaliera-Universitaria Careggi, Firenze, Firenze, Toscana, Italy*

Learning Objectives: After attending this presentation, attendees will gain a better understanding of how detailed injury pattern analysis and interdisciplinary forensic collaboration can critically redefine the reconstruction of criminal dynamics and influence legal charge determination, particularly in cases involving explosive devices.

Impact Statement: This case underscores the pivotal role of forensic pathology in legal proceedings, demonstrating how scientific analysis of injury morphology and distribution can challenge initial investigative assumptions, leading to a reassessment of the explosive's nature and a substantial modification of criminal charges.

Abstract Text: In forensic practice, the reconstruction of criminal behavior and charge determination are often entrusted solely to law enforcement, with forensic medicine playing a marginal, confirmatory role. This approach undermines the scientific contribution of forensic pathology, frequently limiting access to instrumental investigations or excluding expert involvement altogether. Nonetheless, accurate injury analysis remains fundamental and, in specific contexts, may be decisive.

On the shutter of a bookstore a ticking object wrapped in white cloth was discovered. A bomb disposal technician intervened to neutralize the device. During the operation, the device exploded, causing the amputation of the left hand, loss of the right eye, and bilateral thigh lacerations with retained foreign bodies.

The technician claimed the explosion occurred spontaneously while the device was on the ground. Based on this account, charges initially included terrorism accusations and attempted mass murder, considering the alleged explosive power. No terrorism charges were filed. A detailed injury analysis and technical assessment of the device were carried out and particular attention was paid to the morphological and topographical analysis of the injuries.

In disagreement with the reported dynamic, the distribution was highly suggestive of a specific posture at the time of the explosion: a kneeling position with the right knee on the ground, the left leg elevated, and the device held in the left hand, positioned near the right side of the face. The pattern of trauma — characterized by blast injuries and penetrative wounds consistent with ballistic effects from device fragments — demonstrated a highly localized destructive force, reflective of low-order explosive characteristics and insufficient to support the scenario of a high-yield, spontaneous detonation. As a result, the forensic evidence contradicted the initial narrative and led to a substantial re-evaluation of the device's actual explosive power, ultimately contributing to a reclassification of the legal charges as grievous bodily harm, with the exclusion of the most serious indictments. including terrorism charges.

This case highlights the importance of integrated forensic approach, where crime scene investigation, trauma analysis, imaging and technical expertise contribute to clarifying the reconstruction of past events, seeking the material truth behind complex events. A detailed evaluation of injury patterns, combined with ballistic assessment and device analysis, enabled a critical review of the declared version of events and supported the correct charge determination of the event. In this context, injuries served as a "silent witness", providing objective evidence capable of challenging initial criminal charges in court.[1-12]

F93 Judicial Gatekeeping: The Use of Scientific Standards and Forensic Expert Qualification in Oklahoma

Brittlyn E. Eckerd, BS, Forensic Science Institute, University of Central Oklahoma, Oklahoma City, OK; John P. Mabry, JD, University of Central Oklahoma, Forensic Science Institute, Edmond, OK*

Learning Objectives: After attending this presentation, attendees will understand the level of judicial knowledge on forensic science and the judicial use of scientific standards within the state of Oklahoma. Attendees will learn the extent that Oklahoma judges consider scientific standards while qualifying a forensic scientist to testify as an expert.

Impact Statement: This presentation will provide increased awareness regarding the role scientific standards have within the criminal legal system and how scientific standards are applied by Oklahoma judges under the *Daubert* legal standard.

Abstract Text: With the continued issue of wrongful conviction due to the misapplication of forensic science, it is imperative that the judicial gatekeeper role is analyzed for effectiveness. Improvements in forensic science have been made through the development and implementation of scientific standards by the National Institute of Standards and Technology (NIST).[1] The Daubert legal standard for admissibility of expert testimony suggests that judges consider application of standards and controls to gauge reliability of the scientific expert.[2] However, no previous research has directly examined whether or not judges consider scientific standards adherence during forensic expert qualification. Moreover, it is currently unknown whether judges are provided the necessary training and resources that would allow them to do so successfully. Based on previous research, it is hypothesized that judges in Oklahoma will report having varied forensic education levels and limited available forensic resources.[3]

This research surveyed Oklahoma district court judges that see a criminal court docket. The judges were asked questions regarding their training in forensic science, their access to forensic resources, their familiarity with forensic scientific standards, their use of scientific standards while qualifying a forensic expert, and their perceived importance of using standards during expert qualification. Preliminary data from this research suggests that most judges in Oklahoma believe it is necessary to obtain more education and training in forensic science to perform their judicial duties. Additionally, half of the participating judges stated they are not familiar with scientific standards and do not consider the standards factor of the Daubert standard when qualifying a forensic expert to testify. Further, a majority of the participating judges stated they probably do not have sufficient access to information about scientific standards. Statistical results of the data from this research will be calculated and included on the poster.

With the results from this research, efforts can be made to develop and improve the forensic science education and training available for legal professionals in Oklahoma. Creating more accessible resources to strengthen the communication between the forensic practitioner and the legal community could potentially benefit the legal system by lessening the instance of wrongful conviction due to forensic science.

F94 The Sum of All Abbreviated Injury Scale Scores and Total Number of Injuries in Combination: A Tool for Assessing Both Overall Injury Severity and Excessive Injury

Anton F. Mittendorf, MD, Swedish National Board of Forensic Medicine, Gothenburg, Vastra Gotaland, Sweden*

Learning Objectives: Attendees will learn how to reduce the reliance on the individual forensic pathologists' subjective opinion in an ongoing discussion within the discipline. One area of interest is how to evaluate the overall severity of injuries on a person. Most attempts to quantify injury severity are based on the Abbreviated Injury Scale (AIS), which has been repeatedly shown to be reliable for coding injuries. The scales used by traumatologists, such as the Injury Severity Scale (ISS) or the New Injury Severity Scale (NISS) are frequently used in order to communicate injury severity of cases between physicians or researchers. From a forensic perspective, however, these are not ideal as they do not catch minor injuries. Other scales have been proposed for use in forensic medicine, alas Sum of AIS (SAIS) cannot distinguish between many smaller injuries and a few large injuries whereas the Homicide Injury Scale (HIS) relies on subjective opinions about "overkill." Combining two methods, SAIS and Total Number of Injuries (TNI), could help in assessing both cases with many smaller wounds and cases with several severe wounds in a more objective manner. Therefore, this presentation will help attendees understand how assessing injury severity with a systematic approach can be facilitated by using two systems in tandem, especially when working with larger forensic data sets such as the database of the Swedish National Board of Forensic Medicine.

Impact Statement: The main impact will be the benefit of using dual systems, allowing new conclusions about injury severity to be drawn and what research this can be used for on a demographic scale. For the everyday work, the ability to perform a calculation of the overall picture facilitates comparisons between cases and the communication with both professionals and non-professionals in a similar manner to the traumatology scales (ISS and NISS). The method could also help to reduce the reliance on subjective opinions of individual forensic pathologists, which, especially for junior colleagues, could facilitate court appearances insofar as that the physician's opinion of excessive violence can be supported by a mathematical model.

Abstract Text: This poster will help its readers and attendees to understand the systematic research into forensic demographic data that the database of the Swedish National Board of Forensic Medicine allows and how this enables researchers to extract information concerning very case fitting certain criteria.

There are many suggested systems to evaluate injury severity, many of them based on the Abbreviated Injury Scale (AIS) developed by the Association for the Advancement of Automotive Medicine (AAAM).[1] In traumatology, the Injury Severity Scale (ISS) and New Injury Severity Scale (NISS[3] are used to efficiently communicate injury severity between physicians or researchers.[2,3] While these scales have been used in forensic medicine, they are not ideal as the calculations are based on only the most severe injuries.[4] Scales suggested for use in forensic medicine include Sum of AIS (SAIS), which has been shown to be adaptable to individual body regions but cannot distinguish between a large number of minor wounds and fewer, but more severe injuries, as well as the Homicide Injury Scale (HIS), which, while easy to use, is dependent on the opinion of the forensic pathologist.[5-7]

While many of the injuries found in autopsies, such as hesitation marks and defense wounds, are minor when calculated according to AIS, they are of great interest to the forensic pathologist; the number and severity of wounds are essential components when objectively assessing excessive violence. Both the numbers of minor and major injuries and the distribution between the two are therefore of use when discussing hate crimes, crimes of passion or whether several suspects separately have inflicted potentially lethal damage on the deceased.

Unfortunately, existing scoring systems fail to capture cases with a multitude of both minor and major wounds. There may be a solution, however, through using the discrepancies between the SAIS score and the Total Number of Injuries (TNI). Using both values and calculating the difference enables the researcher to communicate whether a certain case, or population of cases, has many small wounds, a few severe injuries or a combination of the two.

As an example, the poster presents data from an ongoing study of lethal sharp force, using SAIS and TNI to show that sharp force injuries to the extremities are more severe on average among the elderly than in the younger population, even when correcting for the differences in manner of death.

F95 The Impact of Finance on the Handling of Forensic Cases: The Case of the Kosovo Agency on Forensics

Herolind Krasniqi, MASc, Kosovo Agency on Forensic, Lipjan, Tirane, Albania; Blerim Olluri, PhD*, AAB College, Pristina, Tirane, Albania; Sokol Dedaj, MASc, Kosovo Agency on Forensic, Pejë, Tirane, Albania*

Learning Objectives: The goals of this presentation are to: (1) understand the role of forensics in justice, (2) assess the impact of funding, (3) analyze case processing delays, (4) compare with neighboring countries, (5) suggest improvement measures, and (6) emphasize the need for investment.

Impact Statement: This presentation aims to raise awareness about the impact of funding levels on the quality and efficiency of forensic services within institutional contexts. Through an in-depth analysis of the Kosovo Agency on Forensics and comparative regional practices, the presentation highlights challenges arising from insufficient financial resources, including case processing delays and shortages of specialized personnel. This approach seeks to provide a clear and well-supported overview that can serve as a foundation for discussions and policy reforms related to forensic science and the criminal justice system.

Abstract Text: Forensic science plays a key role in ensuring justice through the accurate and timely provision of scientific expertise. The Kosovo Agency on Forensics (KAF) serves as the central national institution responsible for these services. However, the agency's limited financial resources have significantly constrained its operational capacity, leading to case backlogs, delays, and limitations in the scope of expertise provided.

This study analyzes the impact of financial resources on KAF's performance during the period 2018–2024, based on budgetary data, institutional statistics, and interviews with officials from KAF and the State Prosecution. The findings show that KAF currently operates with an annual budget of €2,069,639.81, of which €763,000 is allocated to the salaries of 58 staff members, €779,604 to goods and services, and €483,602 to capital investments. Over the past year, KAF handled 5,418 forensic cases and processed 143,067 evidentiary items, demonstrating a workload that exceeds its current financial and human resources. This has resulted in average delays of 30% in critical areas such as DNA, narcotics, and ballistics.

In comparison with forensic agencies in North Macedonia and Albania, KAF faces a relatively higher financial burden due to the volume of evidence and broader scope of cases. Furthermore, North Macedonia and Albania operate with a higher number of scientific staff compared to Kosovo, which enables them to process cases more quickly. For Kosovo to complete cases in a timely manner and ensure the delivery of forensic services, additional budgetary support is required to increase the number of scientific staff – forensic experts.

To address these challenges, KAF has formally requested a budget increase from the Government of Kosovo, including €111,100 for nine additional forensic experts (introducing new fields such as financial forensics and missing persons), €518,500 for laboratory consumables, equipment maintenance, and advanced forensic software, and €300,000 in capital investments to establish new units for DNA, digital forensics, and financial forensics. These targeted increases are essential to enhance the efficiency and professional capacity of KAF.

To place these findings in a broader context, the study also compares KAF's financial situation with that of the Netherlands, a country with strong forensic funding and advanced infrastructure. While the Netherlands allocates significantly more resources per capita and per case resulting in greater efficiency and specialization Kosovo's current underfunding highlights the structural disparities faced by smaller states with increasing demands for forensic services.

The results highlight that this issue is not merely about "needing more funds," but about addressing a structural funding gap that directly impacts the timeliness of justice in Kosovo. Based on statistical analysis and interview data, the study concludes with recommendations to increase the forensic budget, optimize resource allocation, and strengthen inter-institutional coordination. A sustainable financial investment in KAF is essential to improve forensic efficiency and ensure timely justice.[1-5]

F96 Latent Print Evidence and Analysis

Jennifer McCampbell, MCS, Dallas Police Department / Veritas Forensics Consulting, Dallas, TX*

Learning Objectives: After attending this presentation, attendees will: (1) learn about latent prints as physical evidence; (2) be able to provide a brief summary of the history of fingerprints and their formation; (3) be able to discuss the Analysis, Comparison, Evaluation-Verification (ACE-V) method for the comparison of fingerprints; and (4) understand how biometric databases operate.

Impact Statement: Latent prints as physical evidence remain one of the most important types of physical evidence in forensic science. Latent print examiners are able to identify latent prints to known sources and, therefore, link an offender to an item or surface in a crime scene. Oftentimes, latent print evidence may be the only type of physical evidence in a case. It is of upmost importance that understanding how fingerprint evidence can provide vital information about an individual to detectives and investigators for the purpose of solving a case. Latent print examiners provide expert testimony in court to their findings.

Abstract Text: Attendees will understand the role of a latent print examiner within forensic science and its applications. Attendees will receive a brief history and anatomical / physiological information regarding fingerprints and their development (Sourcebook Chapter 2). Attendees will understand the nature of latent prints as physical evidence. Attendees will learn about the types of latent prints found at crime scenes and how the differences of substrate can affect the recovery of identifiable prints. Processing for and the collection of latent print evidence will be discussed.

Attendees will learn how a latent print examiner conducts examinations of latent prints and will understand how comparison and analysis is performed using the ACE-V methodology (Sourcebook Chapter 9).[4] Attendees will learn about the certification process of a latent print examiner through the International Association for Identification.[5] As of June 2025, there are 947 certified latent print examiners in the world (IAI). Attendees will gain an understanding of how latent print examiners are involved within the Criminal Justice System. Latent print analysis is considered expert opinion evidence. Latent print examiners are considered subject matter experts and are therefore permitted to testify in court to their findings (Sourcebook Chapter 13).[4] Attendees will be introduced to the use of electronic search systems for the purpose of identifying fingerprints. They will gain an understanding of how these systems work and realize the benefits of having the ability to search databases worldwide (Sourcebook Chapter 6).[4] Attendees will learn about the proprietary nature of AFIS searching programs and the lack of interoperability among them, which was one of the recommendations of the 2009 NAS Report. The astronomical increase in the use of biometric systems in the private sector will be discussed. There are approximately 77 million records in the FBI repository, which includes civilian records (FBI).[3] There are approximately 28.3 million records in the United Kingdom database (Borak).[1] The Department of Homeland Security currently houses approximately 320 million biometric records in its database (DHS).[2] The total approximate number of records for just these three databases is 425 million. Latent print examination is still considered the strongest physical means of association between evidence of unknown origin and a known source. Due to the random physiological aspects of fingerprint development during gestation and the fact that no two people have been found to share the same fingerprints, regardless of the hundreds of millions of records maintained in electronic databases around the world. Identical twins possess the same DNA yet have different fingerprints. Numerous black box studies have resulted in very low error rates. Statistical models have yet to be developed for latent print examination. Attendees will be presented with a case of the mutation of DNA between a set of identical twins.

F97 Hidden in the Canvas: Isabella of Aragon and the Mona Lisa From a Forensic Perspective

Enrica Macorano, MD, University of Bari, Bari, Puglia, Italy; Angela Colucci, MD, University of Bari, Bari, Puglia, Italy; Francesco Introna, MD, University of Bari, Bari, Puglia, Italy*

Learning Objectives: Participants will explore a multidisciplinary medicolegal approach to historical identification cases, focusing on the investigation of the remains attributed to Isabella of Aragon and the forensic implications for the Mona Lisa hypothesis. They will learn how anthropological, odontological, and imaging-based analyses can be combined to address complex historical questions while maintaining rigorous forensic methodology.

Impact Statement: This study demonstrates the application of core forensic science principles to historical cases of cultural significance. By merging anthropology, odontology, and medicolegal protocols, the research highlights the enduring value of forensic fundamentals in both modern and historical identification scenarios, bridging cultural heritage and scientific inquiry.

Background: Historical identification cases pose unique challenges, requiring forensic methodology to be adapted to centuries-old remains while ensuring scientific rigor. The remains attributed to Isabella of Aragon, Duchess of Bari, have been central to hypotheses linking her to Leonardo da Vinci's Mona Lisa. This study applies a comprehensive medicolegal framework to evaluate the biological profile of the remains and assess their potential connection to the iconic portrait.

Methods: A multidisciplinary protocol was implemented, integrating anthropological examination, odontological assessment, imaging documentation, and facial comparative analysis. Skeletal analysis addressed age-at-death estimation, sex determination, and pathological markers. Odontological evaluation focused on dental morphology, wear, and health status in relation to historical descriptions. High-resolution computed tomography was employed to generate 3D reconstructions, enabling craniofacial assessment and the creation of a permanent digital record. Finally, a facial comparison study was conducted using specialized software to analyze congruences between portraits attributed to Isabella of Aragon and Leonardo's Mona Lisa.

Results: The anthropological profile indicated a female individual consistent with Isabella's historical age-at-death. Odontological analysis revealed dental patterns coherent with contemporary accounts of diet and health, supporting attribution to a high-status individual. Although genetic analysis was limited by diagenetic alteration, preliminary results supported the biological integrity of the remains and their attribution to a high-status female from the period.[1-4] CT imaging confirmed pathological findings, provided evidence of craniofacial traits relevant for historical comparison, and preserved high-quality virtual models for future research. The facial comparison demonstrated a strong morphological overlap between the portraits of Isabella of Aragon and the Mona Lisa, supporting the hypothesis of a shared identity.

Conclusion: The integration of anthropology, odontology, imaging, and facial comparative analysis demonstrates the strength of a multidisciplinary forensic approach in historical identification. While definitive confirmation requires further investigation, the combined medico-legal and iconographic evidence establishes a robust basis for the remains' identification as Isabella of Aragon and strengthens the hypothesis linking her to Leonardo's Mona Lisa. This case emphasizes the universality of the foundations of forensic science, highlighting their applicability both in modern contexts of mass disasters and in historical-cultural investigations and integrating them with modern digital techniques to obtain a comprehensive approach in cases of personal identification.

F98 A Complete Unknown: A Multimodal Approach to the Forensic Identification of Unclaimed Human Remains in the Absence of Missing Persons Reports

Matilde Ruju, MD, Università degli studi di Modena e Reggio Emilia, Sassari, Sardegna, Italy; Irene Pradelle, MD*, Università degli Studi di Modena e Reggio Emilia, Ferrara, Emilia-Romagna, Italy; Luca Diani, MD, Università di Modena e Reggio Emilia, Ferrara, Emilia-Romagna, Italy; Giada Rovito, MD, University of Modena and Reggio Emilia, Ferrara, Emilia-Romagna, Italy; Margherita Neri, PhD, University of Ferrara, Ferrara, Emilia-Romagna, Italy; Angelo Montana, PhD, Marche Polytechnic University, 60121 Ancona, Italy, Ancona, Marche, Italy*

Learning Objectives: After attending this presentation, attendees will learn how a multimodal forensic approach—combining autopsy, anthropological profiling, odontological records, and radiological comparison—can lead to positive identification even when traditional DNA comparison is not immediately available. This presentation will review a series of 13 cases of unidentified deceased individuals discovered without any associated missing persons reports.

Impact Statement: This presentation will impact the forensic science community by underscoring the critical role of interdisciplinary forensic strategies in resolving cold cases and illustrating the challenges when no presumptive identity exists. The findings highlight how proactive, scientifically integrated methods can enhance the identification of marginalized or socially isolated decedents, thereby contributing directly to accurate justice and public health records.

Abstract Text: The identification of unknown decedents is one of the most complex tasks in forensic practice, especially when no missing persons reports exist to guide comparative analysis. This presentation examines 13 cases of unidentified bodies recovered between 2003 and 2025 in the Italian provinces of Ferrara, Foggia, and Campobasso. Some of these individuals were ultimately identified through a comprehensive, stepwise forensic approach despite the initial absence of presumptive leads.

Fingerprint and DNA databases in Italy are still being populated. In the absence of cross-referenced data, the forensic pathologist plays a crucial role in directing the investigation. Over the past two decades, this critical issue has remained essentially unchanged, highlighting ongoing limitations in national databases. However, by employing multiple investigative methods, it is still possible to guide the identification process. The genetic match remains irreplaceable, and DNA was extracted in all 13 cases, although comparative analysis was often not possible due to the lack of reference samples.

The identification process typically unfolds in two phases. The first, generic identification, focuses on reconstructing the biological profile of the body—assessing species, ancestry, sex, age, stature, and possible occupational markers—to narrow down potential matches. The second phase, specific or individual identification, confirms a presumptive identity by comparing postmortem findings with genetic profiles from biological relatives or with the analysis of dental records, radiographs, and medical documentation.

In all cases, a multidisciplinary and cumulative methodology was applied. Each case began with the evaluation of radiological and surgical features, such as orthopedic implants, compared to hospital records. This was followed by anthropological and odontological analyses to estimate age, sex, stature, and ancestry. External features—including scars, tattoos, and clothing (brand, size, color)—were meticulously documented. Fingerprint analysis was attempted when body conditions allowed.

Four of the 13 cases resulted in an identification. In one of these, the victim's sister recognized specific clothing items, prompting a presumptive ID later confirmed by fingerprints matched to a law enforcement record system. In another one, dermal gloves allowed direct match of fingerprints. A third case was resolved by cross-referencing local missing persons reports and confirming identity through dental comparison. In the most recent case, a CT scan revealed an orthopedic plate in the fibula. The implant was removed during autopsy, and its serial number was matched to hospital records, enabling identification without the aid of national databases. This case demonstrates that, in certain circumstances, the forensic pathologist plays a central role in solving cases through targeted investigation and alternative strategies.

Once a presumptive identity had been established in each of the four cases, DNA analysis—the gold standard in forensic identification—was used as the final confirmatory step.

These findings highlight how systematic, multidisciplinary forensic approaches can yield positive outcomes even in the absence of initial leads. They also underscore the need to standardize step-by-step protocols and emphasize the importance database access, and inter-institutional collaboration, particularly in cases involving socially invisible deaths, where no one is actively searching.

F99 Still Nameless Years Later: The Ongoing Challenge of Investigating Unidentified Remains in the Medical Examiner's Office.

Jessica Godoy, BS, D-ABMDI, Delaware County Medical Examiner, Media, PA; Nicolette Sambucci, BS, Delaware County Medical Examiner, Media, PA; Natalia Sanabria, BS, Delaware County Medical Examiner, Media, PA*

Learning Objectives: By the end of this presentation, attendees will be able to identify the common challenges and barriers—social, forensic, and administrative—that contribute to prolonged unidentified human remains cases. This presentation will describe key investigative techniques used in long-term cases, including forensic anthropology, genetic genealogy, radiographic comparisons, fingerprints, dental analysis, and DNA profiling, as well as explain the role of national databases like the National Missing and Unidentified Persons System (NamUs) and the Combined DNA Index System (CODIS) in facilitating identification efforts. Attendees will analyze the impact of missed or improper initial investigations on case outcomes and discuss corrective strategies through case studies. Finally, they will evaluate emerging technologies and interagency collaboration methods that improve the efficiency and success of identifying decedents who have remained nameless for years.

Impact Statement: Unidentified decedents represent enduring challenges that extend beyond forensic science into social, financial, and emotional realms. This presentation underscores how missed initial steps and systemic barriers prolong anonymity, delaying closure for families and straining resources. By spotlighting multidisciplinary approaches, emerging technologies, and collaboration, it advocates for renewed investigative rigor and unity—because every decedent deserves to be named, no matter how much time has passed.

Abstract Text: Despite advancements in forensic science, some decedents remain unidentified for years—even decades—after discovery. This presentation examines the ongoing efforts by the Delaware County Office of the Medical Examiner to identify these decedents, often when first steps were missed or handled incorrectly.[1] This presentation explores the primary and long-term methods used to develop investigative leads, including forensic anthropology, genetic genealogy, radiographic comparisons, fingerprints, dental analysis, DNA profiling, and use of national databases such as NamUs and CODIS. The presentation highlights the administrative, financial, and technological tolls of unresolved cases and discusses how social marginalization, decomposition, trauma, documentation gaps, and lack of antemortem records have hindered positive identifications and delayed the release of remains to their families.

Through select case studies, we demonstrate the consequences of lost or improperly collected evidence and show how subsequent corrective measures can shape the direction of current investigations. Emerging technologies, public awareness, and interagency collaboration have the potential to prevent prolonged or permanent anonymity for the decedent. Fostering communication and exchanging perspectives can untangle the complex web of these investigations and make identification possible. All investigative work and efforts lead back to one singular idea: that every decedent deserves a name, no matter how much time has passed.

F100 Cold Case Homicide: When All the Information Is Known But the Victim Identity—Solved 50 Years Later Using Forensic Investigative Genetic Genealogy

Michelle S. Clark, MS, Connecticut Office of the Chief Medical Examiner, Farmington, CT; James R. Gill, MD, Connecticut Office of the Chief Medical Examiner, Farmington, CT*

Learning Objectives: The goal of this presentation is to highlight the methods used in cold case investigations in which the suspects were arrested and convicted through witness testimony; however, the victim was never identified until 50 years later.

Impact Statement: This presentation will impact the forensic science community by demonstrating that attempts to identify a homicide victim should not stop even after there is a criminal conviction. The medicolegal search to determine the victim's identity should continue and forensic investigative genetic genealogy has provided one more tool to accomplish this.

Abstract Text: In 1974, Connecticut State Police were informed of two homicide victims that were buried in shallow graves in a field. The bodies were exhumed and found to be an adult man and woman. At the time, the man was identified due to his involvement in criminal activity. The woman had used an alias, therefore, the only one who knew her identity was the man that was buried next to her. Witnesses with personal knowledge of the incident came forward and gave detailed statements to the Connecticut State Police. Suspects were arrested and charged with shooting both the man and woman when they unknowingly came to the home of the suspects on New Year's Eve in 1970. Both were shot and killed upon entering the residence. They were wrapped in blankets and brought to the field where they were buried. Connecticut State Police identified the suspects, uncovered why the victims were killed, how the victims were killed, and when the victims were killed. However, the female remained unidentified.

Since 2010, the Connecticut OCME has been working with the state police to identify the female victim. Suspects and witnesses were reinterviewed. DNA was sent to the state lab and uploaded into CODIS and NDIS, and a NamUs case was generated. The female victim's belongings were taken by a witness who turned them over to police. A school ring was among the items which were photographed and made public through the media. Different school ring companies were searched for the school with no success. A phone bill from the days leading up to the homicides was obtained and investigated with no success.

As there were no hits in CODIS no further leads from police, a bone sample was sent for SNP extraction and upload into GEDMatch Pro. Once uploaded, the genealogy was worked on by a Lead Medicolegal Death Investigator at the Connecticut OCME to identify the victim through FIGG.

After 13 months, the identity of the victim was made. Several family members including a sister and a daughter were located and family testing confirmed the identity. The family had been waiting over 50 years to find out what happened to their loved one. The victim now has a name and has been buried on the farm where she grew up.

F101 FIGG or Fingerprints? A Case Study From 1990

Lara Newell, MA, Virginia Office of the Chief Medical Examiner, Richmond, VA*

Learning Objectives: The objective of this presentation is to discuss the dichotomy of using new technology, Forensic Investigative Genetic Genealogy (FIGG), and old technology, fingerprints, to identify long-term unidentified cases. The presentation will discuss the benefits as well as the limitations of each of these technologies, and how, in many cases, using basic methods of identification are often more successful.

Impact Statement: This presentation will impact the forensic science community by discussing a case where all avenues of identification were exhausted in 1990. In 1990, DNA was in its infancy and the Combined DNA Index System (CODIS) was not yet the database that we know it to be today. Unidentified human remains cases without presumed identities were difficult to work and leads often evaporated quickly. FIGG allowed these cold cases to be reignited, but for many cases that undergo this testing, finding fingerprints and dental records can be easy once leads from genealogy are obtained. This presentation will show attendees that many times the flashy, new technology can only go so far, but it can provide information that can allow identification from the most basic information: fingerprints.

Abstract Text: Since the identification of the Golden State Killer in 2018, the use of forensic investigative genetic genealogy (FIGG) has increased exponentially across the country. Countless private labs creating SNP profiles and employing genealogists assist law enforcement and medical examiner's offices on unsolved homicides and sexual assaults, as well as unidentified human remains. Genetic genealogy is new and exciting, and it does provide answers for cold case investigators.

However, fingerprints, which have been used since the 19th century as part of criminal investigations, are still the most basic and easiest way to identify individuals.[1] Many adults are fingerprinted for background checks related to employment; military branches and corrections offices keep fingerprints on file for an extended amount of time. The Federal Bureau of Investigation (FBI) houses a large collection of military, immigration and criminal fingerprints, and often state bureaus send fingerprint cards to the FBI for storage and comparison.

In 1990, the unidentified remains of an adult white male were found in a wooded area. He was fingerprinted at the time of discovery and had dental charting completed, but without a presumed identity antemortem dental records couldn't be obtained. Only the right hand was printed at the time of death and these prints were searched with no identity established. Over 40 years later, with the innovation of FIGG, a new avenue to help identify this individual was pursued. Ultimately, FIGG would only serve as a pathway to identification, fingerprints would finally confirm this individual's identification. Why was he not identified by fingerprints in 1990? Or much later when fingerprints were submitted to NamUs? What role did FIGG play in the identification of this individual, if he had prints on file? What are the limitations of using FIGG for identification? And what are the limitations for fingerprints? In the case of this unidentified male, fingerprints were not an avenue of identification until the advent and use of FIGG. It is important for investigators to remember that our basic method of identification, fingerprints, can still be used to identify individuals, even if FIGG is required to build a family tree and locate "holes" in the tree that provide possible leads.

F102 A Qualitative Study of Crime Scene Investigators and Resiliency

Andrew J. Winter, PhD, Middlesex County Prosecutor's Office, New Brunswick, NJ*

Learning Objectives: This qualitative doctoral research aimed to conduct in-depth, semi-structured interviews to identify crime scene investigators' perception of leadership and support needs to mitigate the impact of exposure to occupational stressors. These professionals are tasked with working in horrific environments, conducting investigations into some of the most heinous crimes. The impact to the crime scene investigator is both physically and mentally taxing. These exposures can lead to occupational stress, burnout, and even suicide. As a law enforcement community, we need to do better to mitigate work-related occupational stressors and strive to provide a wider range of resiliency options for those who serve and protect us. This presentation will attempt to shed light into the occupational stressors impacting crime scene investigators, the influence of organizational leadership on subordinates, and the resiliency needs of these dedicated professionals.

Impact Statement: The purpose of this study was to investigate current occupational stressors, coping mechanisms, and leadership styles. A better understanding of these shed light on effective leadership, resiliency modeling, and the overall mental health of crime scene professionals. The intent is for this research to improve the workplace environment for crime scene professionals, assist organizational leadership in better understanding the needs of these dedicated professionals, and better understand how best resiliency can be modeled to improve the lives of these essential public servants.

Abstract Text: The purpose of this qualitative phenomenological research study was to explore crime scene investigators' perception of leadership and support needs through resiliency to mitigate the impact of crime scene investigation work and occupational stressors.[1] The study expands the existing literature on resiliency, specific to crime scene investigators in the state of New Jersey. Crime scene investigators are tasked with working in less-than-ideal environments conducting scene investigations into some of the most serious crimes. The impact on crime scene investigators is both potentially physically and mentally taxing. This research explored coping strategies used by crime scene personnel as a means of dealing with those horrific crime scenes, organizational occupational stressors, and leadership roles in the support of those specialized team members. Data was collected through semi-structured, in-person interviews. The study explored the lived experiences of crime scene investigators, and the research findings provided both observed and constructive guidance for future research as it pertains to these specialized law enforcement professionals. Study outcomes provide insight into the occupational stressors, coping mechanisms, and leadership styles that impact crime scene personnel. Specifically, the study revealed how crime scene professionals perceive the current state-mandated resiliency program required for all active law enforcement personnel in the state of New Jersey.

F103 A Study on Best Practices in Evidence Management: A Preview of the NIST/NIJ Evidence Management Report

Vincent J. Desiderio, MS, National Institute of Standards and Technology, Gaithersburg, MD; Katherine E. Sharpless, PhD, National Institute of Standards and Technology, Gaithersburg, MD; Melissa Taylor, BA, National Institute of Standards and Technology, Gaithersburg, MD*

Learning Objectives: Attendees will gain insight into the variety of evidence management procedures that exist across the United States. To illustrate points and demonstrate areas of convergence and divergence within the evidence management discipline, visuals of the data collected will be shown to the audience and outcomes and recommendations for improvements to current evidence management practices will be provided.

Impact Statement: This presentation will benefit the forensic science community by sharing data and information related to best practices in the evidence management discipline. Attendees will understand the wide-ranging practices in the field at large, including treatment of evidence collection, handling, and storage, and what improvements should be considered to protect this critical source of information in the criminal justice system.

Abstract Text: In 2016, the U.S. Congress passed the *Justice for All Reauthorization Act,* which called upon the Director of the National Institute of Justice (NIJ) to establish best practices for evidence retention in consultation with federal, state, and local law enforcement agencies and federal laboratories.

Through a memorandum of understanding (MOU) that was signed in 2017, the NIJ commissioned the National Institute of Standards and Technology (NIST) to initiate a project entitled Improving Evidence Management: Best Practices for Handling, Preservation, Retention, and Tracking. The goals of this effort included (1) developing recommendations for the retention, preservation, integrity, and disposition of evidence and property, and (2) encouraging the adoption of practice improvements, through education and engagement, by the broad community of U.S. justice system stakeholders involved in evidence management.

To achieve these goals, the NIST/NIJ Evidence Management Steering Committee (EMSC), consisting of 22 practitioners, executive management personnel, legal professionals, researchers, and educators from local, state, and federal agencies and private organizations responsible for managing physical evidence, was assembled in 2018.

The committee was tasked with developing and executing a national survey of evidence handlers, performing a comprehensive literature review to help identify gaps in evidence handling and storage practices, organizing and delivering a stakeholder workshop, and disseminating their findings via a comprehensive report.

Although the stakeholder event and survey were completed in 2019 and 2021 respectively, the collated results of the project remained unreleased for various reasons outside of the group's control. In the spring of 2025, realizing the quality of the information collected and its potential impact, the project was reinitiated as a priority, and the report is now nearing completion.

This presentation will highlight the activities of the 22 volunteers who graciously dedicated their time to this initiative and provide a preview of the information contained within the report. Emphasis will be placed on the survey results that were analyzed for trends and used to prepare a list of recommendations for potential areas of improvement within the evidence management discipline.

F104 An Evaluation of Temperature Measurement Errors Due to Conduction of Heat Along Thermocouple Probe Sheaths and Partial Probe-Tissue Contact During Forensic Fire-Death Scenarios

David Silveira, MS, California State University, Chico, Chico, CA*

Learning Objectives: After attending this presentation, attendees will have learned about potential errors in temperature data due to heat conduction along thermocouple probe sheaths when measuring internal temperatures of donated human cadavers during forensic fire-death scenarios. The effect of partial contact between thermocouple probe tips and tissues is also quantified.

Impact Statement: This presentation will impact the forensic science community by raising awareness of a source of data errors that can occur when measuring internal temperatures of human donors exposed to fire. Ongoing tissue destruction reduces thermocouple probe immersion depths and increases fire exposure to probe sheaths. Probes with insufficient immersion depths are more likely to produce inaccurate data due to conduction of heat toward the probe tip from probe sections exposed to fire, and this issue is exacerbated by incomplete contact between the probe tip and surrounding tissues.

Abstract Text: Forensic fire-death scenarios involve the live burning of human cadavers, with thermocouples measuring internal temperatures for correlation with the effects of fire exposure on tissues.[1,2] Use of thermocouple wire with exposed fabric insulation greatly increases the likelihood of erroneous data due to insulation failure.[3,4] The use of mineral-insulated metal-sheathed probes mitigates these issues.[5] However, these probes have a higher thermal conductivity due to the stainless-steel sheath that is filled with magnesium oxide insulation, which can cause stem conduction errors due to heat transfer along probe sheaths.

To minimize these errors, the probe's immersion depth into the material being measured should be at least 5-10 times the diameter of the probe sheath.[6,7] However, these values are approximate and do not fully account for variations in heat transfer efficiency between the probe tip and its surroundings. Tissue destruction progressively exposes probe sheaths to fire and reduces immersion depths. Since the fire environment is much hotter than internal tissue temperatures, thermal energy will be conducted toward the probe tip and cause heating of surrounding tissue. Error magnitudes also depend on the amount of contact between probe and tissue. Human muscle tissue and air at 100 ˚C have specific heat capacities of 3421 J/Kg/˚C and 1009 J/Kg/˚C, respectively; and thermal conductivities of 0.49 W/m/˚C and 0.031 W/m/˚C, respectively.[8] When a probe tip has only partial contact with tissue, a reduction in efficiency of heat transfer from probe to surroundings will cause increased error magnitudes.

To quantify the effects of both variations in immersion depth and amount of probe-to-tissue contact, a Wagner Furno 700 heat gun was mounted to a rigid apparatus along with two SCAXL-125U-120 probes (diameter = 0.3175 cm) from Omega Engineering. One probe was used to measure the heat gun output, while the other probe was inserted into a raw pork shoulder at depths of 0.5 cm, 1 cm, 1.5 cm, 2.5 cm, and 3.5 cm. Heat was applied to the probe sheath adjacent to the insertion point. A second series of measurements used the same depths, but with the probe on the tissue surface and approximately 30-40% of the stated probe depth in contact with tissue. Probes were mounted perpendicular to the direction of airflow from the heat gun, with the airflow parallel to the tissue surface. Aluminum foil was used as a shield to minimize tissue heating from the heat gun output. Tests at each depth were run for five minutes each at the maximum setting of 704.4 ˚C.

Experimental results showed strong correlations between temperature error, immersion depth, and amount of probe to tissue contact. When the probe was inserted into tissue, errors ranged from 2.83 ˚C at 3.5 cm to 83.5 ˚C at 0.5 cm. When the probe was laid on the tissue surface, errors ranged from 5.77 ˚C at 3.5 cm to 90.16 ˚C at 0.5 cm. These results indicate that progressive exposure of probe sheaths to fire has the potential to cause increasing error magnitudes, with incomplete contact between probe and tissue exacerbating this effect.

F105 Biomechanical Analysis of an Unusual Cervical Spine Dislocation From a Swinging Metal Cable: Daruma Otoshi?

Stefano Palumbi, MD, Legal Medicine and Toxicology, Department of Cardiac, Thoracic, Vascular Sciences and Public Health, University of Padova, Padova, Veneto, Italy; Yuko Ishida, PhD, Department of Forensic Medicine, Wakayama Medical University, Wakayama, Wakayama, Japan; Toshikazu Kondo, MD, PhD, Department of Forensic Medicine, Wakayama Medical University, Wakayama, Wakayama, Japan; Akiko Ishigami, MD, Department of Forensic Medicine, Wakayama Medical University, Wakayama, Wakayama, Japan; Mizuho Nosaka, PhD, Department of Forensic Medicine, Wakayama Medical University, Wakayama, Wakayama, Japan; Yumi Kuninaka, MS, Department of Forensic Medicine, Wakayama Medical University, Wakayama, Wakayama, Japan*

Learning Objectives: Through the analysis of this case, attendees will learn how to apply biomechanical principles to cervical blunt trauma cases and improve their ability to recognize non-obvious trauma dynamics. Different insights are offered into interpreting complex injury patterns through an interdisciplinary approach involving pathology, imaging, and accident reconstruction.

Impact Statement: This case highlights how pathology, imaging, and accident reconstruction, when combined in a structured way, can enhance the interpretation of complex trauma mechanisms. In the end, the aim is to support stronger medicolegal conclusions through a more accurate reconstruction of the dynamics.

Abstract Text: This case report describes a cervical spine injury caused by a metal cable whip during forestry work. The point of impact was the lateral right region of the neck and the accident resulted in the complete dislocation of the third over fourth cervical vertebra, severe damage to surrounding soft tissues, left common carotid and brain subarachnoid hemorrhage. The radiological and autopsy findings revealed a peculiar injury pattern, interpreted as a shear stress induced vertebral displacement.

The general mechanism shares some characteristics with the better known whiplash combined with blunt trauma. The findings highlight the role of biomechanical analysis in understanding these injuries, how they interact in complex ways and can propagate further from the point of impact.

Thus, this case supports the hypothesis that certain vertebral displacements, although rare, can be generated by tangential high-energy loads applied to the cervical region. The radiological imaging, the macroscopic and microscopic examination, and the reconstruction of the accident scene were analyzed to finally describe in detail the mechanism of injury, revealing an injury dynamic not apparent through traditional methods alone.

To the best of our knowledge, this is the first case report describing a cervical dislocation due to such a mechanism, offering new details about forensic trauma reconstruction and interpretation.

F106 Child Fatality Review as a Quality Improvement Tool: Insights From a Five-Year County Analysis in Context With State and National Trends

Max Veltman, PhD, Boise State University, Boise, ID; Dylan Evans, MS, Canyon County Coroners Office, Caldwell, ID; Tristen Tate, Boise State University, Boise, ID*

Learning Objectives: This presentation will: (1) explain the purpose and structure of Child Fatality Review (CFR) systems and their role in improving investigative quality and prevention strategies; (2) compare county-level data with state and national trends to identify patterns and modifiable factors in child deaths; and (3) apply foundational forensic principles to strengthen CFR processes and advocate for multidisciplinary collaboration to prevent child fatalities.

Impact Statement: This session supports the AAFS 2026 theme—Back to Basics—by highlighting the critical role of systematic death review in improving investigative integrity and prevention. Attendees will gain practical strategies to strengthen review processes and advance forensic nursing practice.

Abstract Text: Child Fatality Review (CFR) teams are essential for understanding the circumstances of child deaths, identifying preventable factors, and shaping public health interventions. However, variability in review processes and documentation practices can hinder data quality and limit opportunities for systemic improvement. This study examined five years of CFR data from Canyon County, Idaho, and compared key findings with statewide and national trends to emphasize the foundational role of standardized review in forensic science.[1-3]

A retrospective descriptive review was conducted using Canyon County CFR cases from 2018–2022 (n = 52). Case-level data included cause and manner of death, preventability, and risk factors, such as unsafe sleep practices and caregiver impairment, demographic and situational events prior to fatality. These findings were contextualized using Idaho CFR reports and national mortality data (CDC WONDER).

Local analysis revealed that a significant proportion of deaths involved potentially preventable circumstances, with unsafe sleep environments emerging as a frequent factor in infant cases, paralleling statewide trends. Injury-related fatalities—such as motor vehicle crashes and suicides—also accounted for a substantial share of cases, aligning with national patterns. Qualitative observations highlighted gaps in documentation consistency and interagency information-sharing practices, underscoring challenges in translating review findings into actionable prevention strategies.

This review reinforces the need to return to fundamental forensic practices—thorough documentation, standardized data coding, and multidisciplinary engagement—to strengthen fatality review outcomes. Forensic nurses, as integral members of CFR teams, are uniquely positioned to champion these best practices, advocate for process improvements, and ensure that lessons learned from case reviews are implemented to reduce preventable child deaths.

F107 From Skid to Signal: The Collection, Isolation, and Analysis of Rubber Particles From Tire Skid Marks

James McAleer, BS, National Center for Forensic Science, Orlando, FL; John G. Lucchi, PhD, National Center for Forensic Science, Orlando, FL; Matthieu Baudelet, PhD, University of Central Florida, Orlando, FL*

Learning Objectives: This study provides an in-depth understanding of how tire particles generated during hit-and-run accidents can be analyzed to support traffic homicide investigations. It incorporates electrostatic lifting as the collection method, coupled to density separation techniques using sodium polytungstate to isolate tire wear particles. Digital microscopy, Fourier Transform Infrared (FTIR), and Inductively Coupled Plasma/Mass Spectrometry (ICP/MS) are employed for detailed characterization and profiling of the tire particles.

Impact Statement: The development of refined tire particle collection and analysis protocols offer a valuable quantitative tool for traffic homicide specialists by supporting the accuracy of crime scene reconstructions and aiding suspect identification. This method strengthens forensic evidence by expanding evidentiary possibilities in hit-and-run fatality investigation.

Abstract Text: In the USA alone, hit-and-run accidents averaged over 1,800 fatalities annually from 2004 to 2022.[1] Typically, crime scene reconstruction involves inferring the sequence of events during the crash. Changes in speed during the incident can produce tire particles. Whether due to sudden acceleration or deceleration, the loss of traction results in the deposition of tire rubber onto the road surface, often leading to the formation of skid marks. Analyzing any evidence left behind by the suspect's vehicle assists traffic homicide specialists by providing a quantitative tool alongside reconstruction of the crime scene. Careful consideration of each step is essential in the development of a procedure to complement highly sensitive analytical techniques.

Efficient collection of road particles produced from skid marks enhances the employment of limited physical evidence. Tapes and gels previously explored for direct road collection may contaminate particles with adhesives or gel residues.[2] Electrostatic lifting using preexisting forensic dust print lifting equipment countered tape and gel shortcomings. Lifted road particles were characterized by digital microscopy and then subjected to further separation.

Density-based separations were carried out using sodium polytungstate (SPT). SPT was used to create solutions of higher densities than conventional salts like sodium chloride, enabling separation of tire particles from asphalt road particles based on density.[3] For increased visibility through the separation process, cryogenically milled tire particles were introduced into some samples. After characterizing and comparing samples using digital microscopy, the SPT solution can be recovered and reused.

Following separation, the consolidated tire particles can be analyzed with greater confidence. Fourier-transform infrared spectroscopy (FTIR) microscopy and inductively coupled plasma mass spectrometry (ICP-MS) were explored to aid in suspect identification with elemental and molecular profiles. Comparing previous tire profiles or existing profiles to suspect tire profiles establishes a new method for traffic homicide specialists.

F108 Enhancing Gunshot Back Spatter With Latent Blood Reagents on Distant Horizontal Surfaces

Nicole Millis, MFS, University of New Haven, West Haven, CT; Peter Valentin, PhD, University of New Haven, West Haven, CT*

Learning Objectives: This presentation explores whether characteristic sub-millimeter bloodstains from gunshot back spatter can be visualized on distant horizontal surfaces using latent blood detection reagents. Through experiments involving atomized blood from a sprayer as well as live-fire trials, the research evaluated the effectiveness of Leuco Crystal Violet (LCV) and Tetramethylbenzidine (TMB) in enhancing and preserving stain morphology necessary for pattern identification. Results demonstrated that LCV was most effective in visualizing latent blood patterns characteristic of back spatter created at a height and from a distance where such stains would not be expected to be found. These findings have the potential to expand crime scene investigation techniques to include the visualization of these gunshot backspatter patterns as well as improve reconstruction possibilities by more precisely locating shooting incidents within a scene from areas previously considered unlikely to yield probative stains.

Impact Statement: This presentation will provide forensic science practitioners with a potential new approach for visualizing gunshot backspatter on surfaces traditionally thought to be beyond the range of deposition. By demonstrating that LCV can reveal and preserve submillimeter bloodstains on distant horizontal surfaces, the study enhances the ability of crime scene investigators to locate and interpret probative patterns that may otherwise go undetected. These findings may lead to improvements in training, evidence collection practices, and crime scene reconstruction protocols, ultimately increasing the accuracy and reliability of shooting incident analyses.

Abstract Text: Bloodstain pattern analysis (BPA) is a discipline within forensic science that provides information to reconstruct events at scenes involving bloodshed. Among the most probative patterns encountered are gunshot-related backspatter stains, which are characterized by their sub-millimeter size and originate from the entrance wound of a shooting victim.[1-3] Traditionally, back spatter is detected only on surfaces close to the gunshot site, as the small droplets only travel short distances and may be difficult to visualize. This research investigates whether back spatter can be detected on more distant horizontal surfaces using latent blood detection reagents and whether those stains can be visualized in a way that preserves the morphology needed for pattern classification.

To test this hypothesis, a method was developed using centrifuged sheep's blood sprayed from increasing heights to simulate sub-millimeter blood deposition. Various latent blood reagents, including Leucomalachite Green (LMG), Tetramethylbenzidine (TMB), and Leuco Crystal Violet (LCV), were assessed for their ability to enhance these patterns, without distorting their morphology.[4] LCV was ultimately found to be the most effective, as it preserves stain size and shape while providing high visibility on non-porous surfaces. Live-fire experiments were then conducted using blood-soaked sponges as tissue simulants, with bullets fired at close range to replicate gunshot back spatter.[5] Laminate flooring tiles placed at measured distances captured potential bloodstains, which were then developed with LCV or TMB.

Tests indicated that sub-millimeter droplets characteristic of back spatter were present on horizontal surfaces up to 25 inches behind and 5'8" below the gunshot blood source and could be effectively visualized using LCV. TMB was less effective, as it failed to preserve morphology and required frequent reagent preparation due to oxidation. Analysis of the images confirmed that multiple samples contained patterns with the key features of back spatter, including small droplet size, absence of large stains, and a mist-like distribution, especially when LCV was used.

This research demonstrates that back spatter can be detected beyond traditionally expected distances when latent blood reagents are used effectively. These findings challenge conventional assumptions in BPA and provide the forensic science community with a new method for locating and interpreting critical bloodstain evidence in shooting scenes. Integrating this approach into scene investigation protocols may improve reconstruction outcomes and enhance the probative value of blood evidence in casework.

F109 A Fundamental Evaluation of Airgun Muzzle Energy Using Chronography: A Forensic Ballistics Approach to Determining Lethality and Legal Classification in the United Kingdom

Tolulope Bayode Abejide, MSc. FS, University of Derby, Derby, England, United Kingdom; Martin Corcoran, BSc, University of Derby, Derby, England, United Kingdom; Kayleigh O'Brien, MSc, University of Derby, Derby, England, United Kingdom; Omowole Sunday Adeniyi, N/A, MFS, Nigeria Police Force, Ibadan, Oyo, Nigeria*

Learning Objectives: The goals of this presentation are to: (1) reinforce fundamental ballistics principles Participants will review the core principles of forensic ballistics, including the calculation and interpretation of muzzle energy in the context of non-powder firearms; (2) understand legal definitions and thresholds of lethality Attendees will learn to apply United Kingdom firearms legislation—including the Firearms Act 1968 and Dangerous Air Weapons Rules 1969—to classify airguns based on measured muzzle energy and legal thresholds; (3) apply chronograph technology in forensic contexts Participants will be able to accurately use chronographs to capture projectile velocity, analyze ballistic performance, and determine whether an airgun crosses into the category of a prohibited weapon; (4) distinguish between airgun types and their forensic implications Learners will identify differences in ballistic behavior between spring-piston and Pre-Charged Pneumatic (PCP) airguns and evaluate their consistency, reliability, and forensic relevance; and (5) develop standardized protocols for airgun examination The session will provide a practical framework for implementing repeatable, court-admissible testing protocols that support forensic investigations involving air weapons.

Impact Statement: This presentation will significantly enhance the forensic science community's understanding of airgun classification by bridging the gap between legal definitions and scientific measurement. By presenting a standardized chronograph-based methodology for evaluating muzzle energy, this research reinforces the importance of objective, quantifiable evidence in determining the lethality and legal status of air weapons. The findings directly inform crime scene analysis, weapon identification, and courtroom testimony involving airguns—an often overlooked yet increasingly relevant area of forensic ballistics. By returning to the foundational principles of kinetic energy assessment and firearm legislation, this work will empower forensic practitioners, legal professionals, and law enforcement agencies to make accurate, defensible decisions in investigations involving non-powder firearms. In line with the AAFS 2026 theme "Back to Basics," the presentation promotes a scientifically rigorous and ethically sound approach to firearm forensics, contributing to improved public safety, informed legislation, and international best practices.

Abstract Text: In forensic ballistics, accurate classification of air weapons is fundamental to determining legal status and criminal liability. The Firearms (Dangerous Air Weapons) Rules 1969 and Firearms Act 1968 provide kinetic energy thresholds that define when air rifles or pistols are deemed "especially dangerous" and require licensing under UK law. This research applied a chronographic method to systematically measure the muzzle energy of various airgun models, with the aim of establishing a reliable forensic approach to assess legality and lethality.

Two airgun types, which are spring-piston and pre-charged pneumatic (PCP), were investigated using .177 and .22 calibre pellets under standardized conditions. For each configuration, ten shots were chronographically determined, and velocity data were used to calculate muzzle energy using the kinetic energy equation. Results revealed that spring-piston models produced average muzzle energies around 11.5 joules, while PCP models approached or exceeded 19 joules, surpassing the legal 12 ft-lb (16.4 J) limit for air rifles.

These findings have significant forensic implications. They demonstrate how commercially available airguns may unknowingly cross legal boundaries and become classified as prohibited firearms. Furthermore, the study emphasizes the role of chronographs as indispensable tools in forensic investigations, providing objective, quantifiable evidence for courtroom interpretation. This work contributes to the foundational practice of forensic ballistics by reinforcing the need for standard testing protocols and legal awareness in airgun investigations. In line with the AAFS 2026 theme, *Back to Basics*, it exemplifies how the ethical and scientific application of core measurement techniques enhance public safety, legal clarity, and investigative accuracy.[1-15]

F110 Quantifying and Testing the Similarity of Breach Face Impressions

Hana Lee, PhD, Iowa State University, Ames, IA; Alicia L. Carriquiry, PhD, Iowa State University, Ames, IA*

Learning Objectives: We describe a novel statistical framework for comparing 3D topology of two breach face impressions to assess whether they may originate from a common source. The audience will learn about our automated alignment process, similarity statistics derived from the aligned impressions, and the potential for developing a statistical testing procedure to support source attribution. The testing concept is motivated by statistical inference techniques previously developed for bullet comparisons and the Congruent Matching Cells (CMC) method for cartridge cases. Participants will also gain insight into objective and reproducible approaches to breach face impression analysis and how statistical methods may inform source identification.

Impact Statement: Our goal is to strengthen forensic cartridge case comparison by advancing a scientifically grounded pipeline that promotes objectivity, ensures reproducibility, and enhances computational efficiency. By offering a systematic approach to cartridge case analysis, our work contributes to broader efforts to enhance the scientific rigor of forensic firearm examination and to support data-driven decision-making within the justice system.

Abstract Text: Cartridge case comparison is a key task in firearm and tool mark examination. The goal is to determine whether two cartridge cases may have been fired from the same firearm. Due to the limitations of traditional visual comparisons, such as subjectivity and limited reproducibility, recent efforts have focused on statistical and algorithmic methods using 3D digital images of fired cartridge cases. Among these, the Congruent Matching Cells (CMC) method, developed by NIST, has emerged as a widely used reference for cartridge case comparison. [1]It divides two impressions into small cells, identifies structurally similar regions using cross-correlation, and predicts common source status based on the number and distribution of matched cells. The method has recently been implemented in the open-source R package cmcR, improving accessibility and reproducibility.[2]

Motivated by a recent statistical testing framework for bullet comparison, we explore a permutation-based statistical test tailored for cartridge case impressions.[3] The bullet test arranges six land impressions from two bullets, finds the optimal pairing configuration with the highest overall similarity, and tests whether the similarity of that configuration is significantly higher than all others. Since comparing a selected maximum to a set of lower similarities introduces bias, the authors addressed the resulting Type I error inflation using an order-statistics-based correction.

We adapt the permutation-based testing framework to the cell-to-cell comparison used in the CMC method, following an automated alignment procedure. Unlike the original CMC approach, which independently aligns each cell in one impression to the most similar region in the other, we seek a global alignment of the entire image pair, using only cell pairs that retain identical relative positions across the two impressions. Specifically, we align the breach face impressions by optimizing the rotation angle and spatial shift that maximize the aggregated cross-correlation across appropriate cell pairs. The maximum cross-correlation at each angle is a summary of cell-level similarity. The weight of evidence is assessed by comparing the distribution of similarities at the optimal rotation angle to those at all other angles, mirroring the statistical logic of the bullet land-to-land comparison test.

This rotation-based testing framework offers a promising direction for evaluating the significance of a similarity value between cartridge cases. We will share findings from a pilot study that explores the statistical properties required to validate the test. As a by-product, the alignment procedure we propose is fully automatable and can be integrated into forensic workflows. Automating the alignment process enhances the efficiency, objectivity, and reproducibility of breach face comparisons, whether or not a formal statistical test is applied. By combining reproducible alignment, interpretable similarity metrics, and principled statistical inference, this work contributes to the broader effort to bring greater scientific rigor and transparency to forensic firearm examinations.

F111 A Comparison Study of Clothing Severance Damage Resulting From Kitchen Knife Sharp Force Trauma in Stabbing Offence Investigations

Leisa J. Nichols-Drew, N/A, MSc, De Montfort University, Leicester, England, United Kingdom*

Learning Objectives: This presentation will provide attendees with: (1) an introduction to the knife crime statistics from the United Kingdom and around the world, (2) an awareness of the examination process undertaken in the forensic laboratory for severance sharp force trauma (stabbing) clothing damage, (3) a robust understanding into a research study undertaken involving multiple kitchen knives on clothing garments, and (4) recommendations to aid investigators in preventing injuries and fatalities from kitchen knives.

Impact Statement: This presentation will impact the forensic science community by increasing knowledge of the challenges of sharp implements encountered in knife crime offenses around the world. It will additionally provide investigators with the visible differences in clothing damage created by different kitchen knives. Ultimately, this presentation aims to inform practitioners as to mechanisms to undertake knife comparisons within the forensic laboratory to ultimately reduce injuries. The research outcomes will assist criminal justice systems around the world involving knives recovered from the crime scene.

Abstract Text: Since 2010, there has been a substantial increase in offences involving sharp or bladed implements reported in the United Kingdom; in the year ending March 2025, the Office of National Statistics recorded 53,047 knife-enabled crimes.[1] According to the 2024 Home Office Homicide Index, kitchen knives contribute to the majority of street based and residential stabbing related incidents.

Here we present a preliminary study involving penetration of a range of upper and lower clothing garments (jumper, t-shirt, skirt, jeans) with novel and conventional knives. Sharp force trauma on the target surfaces was analyzed for 300 downward stabbing motions using 5 types of blade. There is a clear correlation between knife tip shape and fabric severance damage.[2] Qualitatively, rounded tipped (less-lethal) knives failed to penetrate clothing, whereas conventional knives with pointed tips produced the greatest damage. Interestingly, a sheepsfoot knife caused trauma similar to that observed from screwdriver penetration. Scanning Electron Microscopy (SEM) images reveal quantitative insights.

In a subsequent study designed more closely to mimic a stabbing, fabric substrates were placed over tissue simulants prior to the knife impacts. Further work has compared the observed knife damage with that from other penetrating tools encountered at crime scenes, including scissors, chisels and screwdrivers.

The immediate significance of the outcomes in terms of criminal investigations involving textile damage evidence will be discussed. Future benefits in terms of crime reduction and injury prevention in bladed weapon crimes will be considered, based on smarter design of functional knives with diminished utility as weapons.

These findings and recommendations will be of interest to international governments, law enforcement agencies, healthcare professionals, investigators, crime-reduction units, charities, NGOs, knife manufacturers and practitioners, to share one mutual goal in advocating a safer alternative to conventional pointed tip knife blade designs. Additionally, offering an opportunity for crime reduction – a knife of culinary utility without the possibility of accidental injury, and with little or no value in violent crime.

Ultimately, this research has been disseminated around the world as a United Nations policy brief and will inform international criminal justice systems.[3]

F112 The Evolution of VOC Profiles During Early Animal Decomposition

Fantasia Whaley, MSFS, Florida International University, Miami, FL; Sandy L. Dominguez, Florida International University, Miami, FL; Lauryn DeGreeff, PhD, Florida International University, Miami, FL; Joel L. Fuentes Carrasco, BS, Florida International University, Hialeah, FL; Emily Millan, BS, FIU lab assistant, Miami, FL*

Learning Objectives: This presentation will examine and advise attendees on the changes in odor profiles during early decomposition using varying analogs for human remains—pig skin, pig limbs, and mouse carcasses. The transition from the odor profile of fresh remains to decomposed will be demonstrated both chemically, by examining the Volatile Organic Compounds (VOCs) to display how this shift in VOCs may impact canine detection of human remains.

Impact Statement: The results in the presentation will differentiate distinct odor profiles of the various analogs, with a focus on the first 48 hours after death/collection, utilizing laboratory and chemometric analysis. This has applications to Search And Rescue (SAR) and Human Remains Detection (HRD) canines and their abilities to discover crucial evidence in fresh crime scenes or disaster scenarios.

Abstract Text: Human remains detection (HRD) canines provide a crucial role in locating missing persons, particularly in search and rescue (SAR) cases. Previous research has demonstrated that the odor profiles of remains, whether human or animal, change significantly over time. This evolution of VOC profiles can affect canine detection accuracy, requiring that handlers train their dogs on a variety of materials of different ages. While many studies have addressed how decomposition goes through shifts in VOC profiles, they often do so over the course of days, weeks, or months, rather than hours.[1-4] This study aims to address this gap in research and understanding of decomposition VOCs within the first 48 hours after death – a critical timeframe in SAR operations. Anecdotal findings from HRD canine handlers suggest a perceptible change in odor to canines about two to four hours after death, highlighting a need for frequently sampling in the first 24 hours. Due to difficulties in obtaining human remains immediately post-mortem, this work aims to assess full animal carcasses as substitutes: pig skin samples, pig limbs, and mouse carcasses.

Odor analyses of skin, limbs, and carcasses were conducted using headspace solid phase microextraction (HS-SPME) for sample collection and gas chromatography-mass spectrometry (GC/MS) for VOC separation and detection. This allowed for detection of the compounds in the odor profiles and tracked their changes over time. Chemometrics techniques included principal component analysis (PCA), hierarchical cluster analysis, and multivariate curve resolution using constrained alternating least squares algorithm (MCR-ALS), which were applied to reveal statistically significant changes in the odor profiles. Results indicated an early change in the VOC profiles of all samples within the first 24 hours. In this timeframe, there was an early stage (fresh) odor profile with a unique set of VOCs in specific ratios to each other, which then evolved into a later stage (aged) as decomposition progressed. These results implied that early changes in odor profiles of numerous remains samples may impact canine detection of human remains within the first 24, providing valuable insights to the training of HRD canines.

F113 Operational K9 Deaths: A Look at the Past 24 Years

Cheryl F. Nelson, DVM, Nelson Reproductive Services, Versailles, KY*

Learning Objectives: After attending this presentation, attendees will understand the ever-changing demographics of police and military operational K9 deaths over the past 24 years. They will understand the new improvements in K9 Tactical Emergency Critical Care used to reduce these deaths.

Impact Statement: Operational K9s are world-class athletes and can not be replicated by man or machine. These K9s work in military, police, United States Department of Agriculture (USDA), Customs and Border Protection (CBP), Search and Rescue (SAR), Natural Resources and Corrections, and serve for 5-10 years. The premature deaths of these K9s impact each of us. Veterinary diagnostic labs are essential for accurately determining the cause of death, especially if the K9 is part of a crime scene.

Abstract Text: Man began to domesticate the wolf 160,00 years ago. The wolf is the only large carnivore ever domesticated and over 400 breeds of dogs (K9s) are descended from these wolves. Many different breeds serve as operational K9s for the military, police, fire, CBD, SAR, USDA, and Corrections. The global war on terror has increased the need for operational K9s and we may have a cohort of operational K9s with more genetic predispositions to heat stroke leading to deadly consequences. In a study from 2002-2012, 867 K9s serving in US law enforcement departments died while in service with 318 deaths categorized as traumatic. Of these, 25.8 % died after being hit by a vehicle, 24.8 % from heat stroke and 23% of ballistic trauma.[1] The remaining 26.4% died from stabbing , strangulation, drowning, smoke inhalation, being ejected from a vehicle, and falls from a height of 20'. As we look at military working dogs (MWD) from 2001-2013, 77% died of traumatic injuries of which 31.5% died of ballistic trauma, 26.1% from explosive blast injury and 9.8% from heat stroke. In addition, at least 23% died of gastric dilatation and volvulus (GDV).[2] Training these K9s takes at least one year with service of 5 to 9 years. Their work is so important that bounties have been placed on them by cartels and foreign governments. Necropsies must be performed in many cases to correctly determine cause of death especially if toxins and illegal drugs are involved.

The last 10 years have shown a dramatic change in the causes of operational K9s deaths. Many different professionals in human and veterinary medicine are involved in determination of death. Since 2015, 40% of operational K9s died of heat stroke while the percentage dying of ballistic trauma remained steady.[3] There is evidence of a genetic component involved in heat stroke and Gastric Dilatation and Volvulus (GDV) which is twisting of the stomach on its mesenteric axis and Mesenteric Volvulus (MV) a twisting of large intestine on its mesenteric axis. In cases of heat stroke, GDV and MV at least 50% may die and those that survive may be prone to a second episode.[4]

We must train K9 handlers and first responders to recognize the early signs of heat stroke and GDV or MS in order to save these K9s. Other concerns related to K9 deaths are from illegal drugs and toxins present in their environment. These K9s are exposed to fentanyl, carfentanil, synthetic marijuana, nicotine, caffeine, human medications/food, and new designer drugs.[5] Exposure to xylitol, human non steroidal anti-inflammatories (NSAIDS), beta blockers, serotonin re-uptake inhibitors, grapes and raisins or cocaine may be deadly. Work is being done in the United Kingdom to identify the percentage of environmental exposures and deaths related to operational K9s. This involves veterinary and human toxicologists and the creation of new tests and procedures to identify new exposures in the work place. Comprehensive data collection will help provide better prevention and treatment strategies.

F114 Cadaver Dogs in Deep Water: Evolving Forensic Tools for Aquatic Human Remains Detection

Paul Micah Johnson, PhD, FBI, Brighton, MI*

Learning Objectives: This presentation explores the challenges of human remains detection in marine and freshwater aquatic environments and introduces alternatives to conventional cadaver dog use. Attendees—especially crime scene investigators and forensic anthropologists—will examine how evolutionary biology, marine and aquatic ecology, and advanced underwater telemetry can inform novel detection strategies and identify opportunities for interdisciplinary collaboration in the field.

Impact Statement: Reconsidering how we search for human remains in water environments, this presentation advocates for scientifically grounded methods better suited to the medium. It invites collaboration between crime scene investigators, forensic anthropologists, and marine and freshwater biologists to develop strategies that could improve aquatic search operations and lead to more effective victim recovery efforts.

Abstract Text: Locating human remains in aquatic environments presents a persistent and understudied challenge for forensic professionals. While cadaver dogs have been widely used as olfactory sensors for terrestrial searches, their biological constraints as air-breathing terrestrial mammals render them poorly suited for underwater detection.[1,2] The mechanics of scent dispersal in water differ dramatically from air, and dogs are unable to independently search beneath the surface.[3] Despite the widespread use of cadaver dogs on boats and along shorelines, systematic alternatives for submerged remains detection remain underdeveloped.[4]

This presentation explores a biologically grounded alternative: the use of evolutionarily adapted aquatic scavengers tracked using established telemetry techniques. Aquatic organisms that naturally detect and respond to decomposition—such as decapod crustaceans and benthic reptiles—may serve as biological indicators of submerged human remains. Unlike cadaver dogs, these species do not require training, are native to the aquatic environment, and are already evolutionarily equipped to locate carrion.

Evidence from ecological studies demonstrates that aquatic scavengers rapidly and reliably aggregate at submerged mammalian remains (e.g., whale-falls).[5] Foundational research by forensic entomologist Gail Anderson using submerged pig carcasses—the accepted human analog—revealed consistent patterns of colonization by marine invertebrates, underscoring the potential for predictable biological responses to submerged remains.[6] Observational tools, such as baited remote underwater video systems (BRUVS), have been used to further document these behaviors.[7] In addition, acoustic, GPS, and RFID telemetry systems, long established in marine biology, could enable real-time tracking of individual scavengers. Prior applications to species such as snow crabs, alligator snapping turtles, and leopard sharks demonstrate the feasibility of deploying these technologies across both freshwater and marine environments.[8-10]

Although well-established in biological research, these tools remain largely untapped in forensic science. Integrating scavenger movement data with existing forensic practices could reduce the need for diver-based searches, narrow search times and areas, and improve recovery outcomes in aquatic environments.

This presentation serves as a call to action for interdisciplinary collaboration. Forensic anthropologists, freshwater and marine ecologists, and crime scene investigators bring essential and complementary expertise to the problem. Similar to the successful partnerships that gave rise to forensic entomology, expanding human decomposition research to include aquatic ecosystems and collaborating across disciplines may catalyze new methods for locating those gone missing in lakes, rivers, and coastal seas.[11] Establishing aquatic analogs or additions to existing terrestrial human decomposition research facilities or "body farms" would allow for scientifically controlled validation of scavenger behavior using real human remains, ultimately improving recovery operations.

By developing more ecologically appropriate biological tools than cadaver dogs, via the principles and techniques of freshwater and marine biology, forensic professionals may become better equipped to locate human remains in water. This approach seeks not to displace traditional tools but to expand the forensic toolbox by aligning methods with the natural systems in which they are deployed.

F115 A Comparative Study to Determine Training Aids for Human Remains Detection Dogs

Lorna Irish, PhD, Dstl, Salisbury, England, United Kingdom; Sarah Sandle, BSc, DSTL, Northampton, England, United Kingdom; Shari Forbes, PhD, University of Windsor, Windsor, Ontario, Canada; Adee Schoon, PhD, Animal Detection Consultancy, Apeldoorn, Gelderland, Netherlands; Jerushah Mulvany, BSc, DSTL, Salisbury, England, United Kingdom*

Learning Objectives: The audience will learn about the different materials used to train Human Remains Detection (HRD) dogs. They will hear about the outcomes of a collaborative indicative trial, understanding the capabilities of HRD dogs trained on pig tissue versus those trained on human tissue to: (1) detect human tissue, and (2) discriminate animal tissue. The presentation will discuss the different materials available for training HRD dogs around the world. It will also present the implications of the outcomes of the trial on the most appropriate training aids to enable the location of human remains.

Impact Statement: The impact of this research will enhance the understanding of the forensic community on HRD dog capabilities, including their specificity. The outcomes of the trial indicate the importance of benchmarking detection dogs and validating training aids to ensure an effective capability.

Comparative Study to determine training aid for Human Remains Detection dogs: Sometimes, it is not possible to present genuine target material to a detection dog during training due to hazards, legal, and/or ethical reasons. For example, explosives or drugs pose particular hazards to health, while cadaver and/or conservation materials may have legal or ethical restrictions. Chemical analysis can offer insights into the differences and similarities of materials, but it doesn't reveal what detection dogs perceive and cause them to give a trained final response, especially when the target odor is constantly changing over time.

Handlers can provide informal reports on detection dog performance, but true detection rates are often unknown in operational scenarios. Missed targets may remain undetected by dogs and other search techniques, and handlers may give unintentional cues when the target is visible. Environmental factors can also impact detection in operations. Therefore, odor recognition tests can indicate detection rates in a more controlled setting.

For some detection dog disciplines, there is literature on the odor of target and training materials, along with informal reports from practitioners on performance. However, there is a lack of validation on the capabilities and limitations, particularly in human remains detection. It may be possible to combine published chemistry data with detection dog odour recognition tests to understand their capabilities including sensitivity and specificity to target materials.

This presentation showcases data from a collaborative trial between three nations to better understand the detection and discrimination abilities of human remains detection (HRD) dogs trained on different materials. This is the first study of its kind, providing insight into how the results from HRD dogs improve the detection capability.

F116 Prone Restraint Cardiac Arrest: Physiology and Epidemiology

Alon Steinberg, MD, Community Memorial Hospital Systems, Oxnard, CA*

Learning Objectives: Prone restraint death is a controversial subject. We will review the physiology of prone restraint, including the decrease in ventilation and cardiac output that accompanies the position. We will discuss how cardiovascular demand and metabolic acidosis contributes to the mechanism of death in these cases. We will examine risk factors and trends in mortality associated with prone restraint. This presentation will help coroners/medical examiners when encountering a prone restraint death.

Impact Statement: Prone restraint deaths have significant implications for forensic pathologists, medical examiners, and legal investigators. These cases are complex and often controversial and require careful analysis. This presentation will help with understanding of the physiology and mechanism of these deaths.

Abstract Text: Deaths occurring among agitated or violent individuals subjected to physical restraint have been attributed to positional asphyxia. Restraint in the prone position has been shown to alter respiratory and cardiac physiology, although this is thought not to be to the degree that would cause asphyxia in a healthy, adult individual. We will summarize the current scientific literature on prone position and restraint, including experiments that assess physiology on individuals restrained in a prone position. Some of these experimental approaches have attempted to replicate situations in which prone restraint would be used. Overall, most findings revealed that individuals subjected to physical prone restraint experienced a decrease in ventilation and/or cardiac output (CO) in prone restraint. Metabolic acidosis is noted with increased physical activity, in restraint-associated cardiac arrest and simulated encounters. A decrease in ventilation and CO can significantly worsen acidosis and hemodynamics. Given these findings, deaths associated with prone physical restraint are not the direct result of asphyxia but are due to cardiac arrest secondary to metabolic acidosis compounded by inadequate ventilation and reduced CO. As such, the cause of death in these circumstances would be more aptly referred to as "prone restraint cardiac arrest" as opposed to "restraint asphyxia" or "positional asphyxia."

Supporters of prone restraint's safety frequently cite prospective epidemiologic studies that report no fatalities associated with its use. However, these studies typically involve small cohorts and are conducted over limited timeframes, potentially underestimating rare but serious outcomes. In contrast, retrospective analyses, which assess larger populations over extended periods, have identified multiple cases of fatal outcomes linked to prone restraint. We will review a recent epidemiologic study that I performed identifying 229 cases of prone restraint deaths over a decade.

There needs to be more study on this subject including more rigorous, large-scale, and transparent epidemiological studies to better inform public policy, law enforcement practices, and clinical guidelines. The potential lethality of prone restraint must be recognized, and its use re-evaluated in light of both fatal risk and ethical responsibility.[1-3]

F117 Driving Accountability Through Forensic Integration: A Model for Investigative Transformation in Urban Policing

John R. Herzog, III, MS, Baltimore Police Department, Baltimore, MD; Rana A. DellaRocco, MS*, Baltimore Police Department, Baltimore, MD*

Learning Objectives: This presentation will help attendees to:(1) understand the principles and implementation strategies behind Baltimore Police Department's (BPD's) forensic science integration and accountability framework; (2) identify key elements of the implementation process for integrating forensic science into daily investigative practices; (3) analyze the measurable impact of BPD's initiative on crime clearance rates, particularly in burglary cases; (4) recognize the critical role of leadership commitment and collaborative workflows in elevating forensic science's contribution to investigations; and (5) formulate a transferable framework for replicating BPD's approach to enhance police accountability and investigative effectiveness in other urban jurisdictions

Impact Statement: Attendees will learn how to effectively integrate forensic science results from all disciplines into routine investigative processes. They will learn how police accountability in follow-up and action taken on leads provided by forensic science analysis has driven success in a major urban city (Baltimore, MD). Outcomes in case closures have skyrocketed since this integration, notably in property crimes, where outcomes have nearly doubled in just a few years. We believe that if other agencies adopt an accountability-forward approach to the full use of forensic science data in their investigations, outcomes nationwide can be monumental.

Abstract Text: Police accountability and the effective use of forensic science remain persistent challenges for law enforcement agencies across the United States. Too often, critical laboratory results go underutilized, stalling case progression and undermining the value of forensic resources. In January 2024, the Baltimore Police Department (BPD) launched a groundbreaking initiative within its Citywide Investigations Division (CWID) aimed at directly addressing this disconnect. This initiative strategically integrated forensic science into daily investigative practices for non-fatal shootings, robberies, burglaries, aggravated assaults, and vehicle thefts.

At the heart of this transformation was a deliberate partnership between the CWID executive command and the BPD Laboratory Division. Together, they established accountability mechanisms to ensure that detectives reviewed, documented, and acted upon laboratory results in real time. This operational shift, anchored in leadership commitment, collaborative workflows, and data transparency, quickly produced measurable results as every crime category's clearance rate increased. The most notable was BPD's burglary clearance rate which rose from 14.5% in 2019 to 23.6% in 2024, nearly doubling the national average, and reached 27% by July 2025.

This presentation will detail the design, implementation, and impact of BPD's forensic integration strategy, with a focus on how leadership alignment and internal accountability can elevate forensic science from a passive resource to an active driver of investigative success. Attendees will gain a transferable framework to replicate this approach in other urban jurisdictions, advancing both accountability and investigative effectiveness.

F118 The Use of Forensic Methods for Art Authentication: The Picasso Project

Jennifer McCampbell, MCS, Dallas Police Department / Veritas Forensics Consulting, Dallas, TX*

Learning Objectives: After attending this presentation, attendees will: (1) understand the nature of the conventional methods used for art authentication, (2) have the ability to discern the conventional methods from the forensic methods discussed in the presentation, (3) gain historical knowledge of Picasso's cubist period and the collages he produced, (4) be able to describe the use of fingerprint and DNA analyses as they pertain to art authentication in general, and (5) be able to describe the use of fingerprint and DNA analyses specific to the Picasso Case.

Impact Statement: This presentation will introduce new forensic methods for the authentication of artwork, particularly how they can be used to attribute certain works to certain artists. This presentation not only describes historical, subjective methods of art authentication but lends itself to the use of forensic science methods to objectively ascertain a source identification in nontraditional ways. It is important for the forensic science community to consider new uses for forensic science methods in non-forensic situations and, therefore, to be knowledgeable of the possibilities.

Abstract Text: Upon completion of this presentation, attendees will become familiar with the possibilities of using forensic science techniques in a non-criminal matter. The subject matter concerns the use of fingerprint and DNA analyses as a means for the authentication of artwork. The traditional methods of art authentication will be described and the subjectivity of these methods will be discussed. Attendees will learn a brief history of the use of forensic analysis for authentication purposes and how an examiner purporting to have identified artists was subsequently discredited. The case study for this presentation involves the attempted authentication of collages attributed to Pablo Picasso. Attendees will be introduced to the historical nature of Pablo Picasso's work, particularly during his cubist era. Prior to the attempt to use forensic analysis of the collages in question, conventional methods were used to attempt to authenticate the pieces. The results of the use of these methods of authentication of the Picasso pieces will be shared. This case study demonstrates how the use of fingerprint and DNA analyses to authenticate artwork can be achieved. Attendees will be introduced to the use of touch DNA and fingerprint evidence as means for art authentication. The results of the subsequent fingerprint and DNA analyses on the Picasso collages will be discussed. Attendees will be involved in a discussion concerning the forensic methods used and what future ramifications of the analyses could have in non-forensic situations. The limitations of fingerprint (latent print) analysis and DNA analysis as a means to authenticate artwork will be reviewed. Following the presentation, attendees will be given the opportunity to discuss the Picasso case specifically, and art authentication in general.[1-8]

F119 Forensic Science at the National Institute of Justice

Lucas W. Zarwell, MFS, National Institute of Justice, Washington, DC*

Learning Objectives: Audience members will learn about new research opportunities and resources being funded by the National Institute of Justice (NIJ). Participants will also learn: (1) how they can get involved with NIJ initiatives and working groups, (2) how to apply to NIJ notices of funding opportunities, and (3) how the NIJ supports forensic science through federal partnerships.

Impact Statement: Informing the scientific community about forensic science research programs at the NIJ provides opportunities for resources and research to improve the capacity and quality of forensics.

Abstract Text: The National Institute of Justice (NIJ) is the research, development, and evaluation agency of the U.S. Department of Justice, dedicated to improving knowledge and understanding of crime and justice issues through science.[1]As the lead federal agency for forensic science research and development, NIJ, through the Office of Investigative and Forensic Sciences sponsors extramural research projects across the spectrum of forensic science disciplines, coordinates with the stakeholder community to identify needs and develop resources, and facilitates technology transfer and implementation of emerging technologies into forensic practice. This presentation will discuss NIJ program updates, including our opportunities and activities and communicate how conference participants, including practitioners and academics, can get involved in research initiatives to improve forensic science. The goal of NIJ is to inform the forensic enterprise about research trends, technologies, partnership opportunities, and federal efforts in hopes that the knowledge leads to increased forensic laboratory capabilities and collaboration NIJ will discuss DOJ priorities for forensic science, our collaborations with BJA, our statutory responsibilities, upcoming reports, the research library, and status of our working groups such as the Forensic Laboratory Needs Technology Working Group and Medicolegal Death Investigation Working Group.[2] In addition, NIJ will provide brief updates about ongoing projects, such as the Forensic Science Operational Needs Assessment. OIFS will also present on its collaborations with the National Institute of Standards and Technologies, the National Science Foundation, and other federal agencies. The NIJ is committed to providing research and technologies that can make an impact. The mission of NIJ OIFS is to improve the quality and practice of forensic science through innovative solutions that support research and development, testing and evaluation, technology, and information exchange for the criminal justice community. The NIJ invites feedback from the community on ways our agency and partners can further strengthen the current and future practice of the forensic sciences.

F121 Forensic Foundations Revisited: Insights From NIST's Foundation Studies Program

Kelly Sauerwein, PhD, National Institute of Standards and Technology, Gaithersburg, MD; Sandra Koch, PhD*, National Institute of Standards and Technology, Gaithersburg, MD*

Learning Objectives: This presentation will highlight the National Institute of Standards and Technology's (NIST's) Foundation Studies Program and the benefits and applications of scientific foundation reviews that discuss the reliability of forensic methods and practices.

Impact Statement: This presentation will help promote a better appreciation of how the NIST Foundation Studies Program evaluates the capabilities and limitations of forensic methods and practices and how practitioners, researchers, legal experts, and other stakeholders can use these reports.

Abstract Text: Several scientific advisory bodies have expressed the need for scientific foundation reviews of forensic science disciplines.[1-3] A scientific foundation review which was originally termed a "technical merit evaluation" by the National Commission on Forensic Science in 2016, is a study that seeks to identify the scientific foundations that support the forensic methods and practices.[3,4] Since 2018, the National Institute of Standards and Technology (NIST) has been Congressionally funded to conduct these evaluations and has completed reports in DNA mixture interpretation, digital investigation techniques and bitemark analysis with reports on firearm examination, footwear and tire impression evidence, and communicating forensic findings in progress.[5-10] These foundation studies: (1) document and evaluate empirical evidence on the reliability of forensic methods, (2) explore the capabilities and limitations of the methods, and (3) identify potential knowledge gaps or areas for future research.

This presentation will detail how NIST scientific foundation studies are selected and conducted and discuss six completed or in-progress reports. These reports assess publicly available information on forensic methods and practices. While these reports and associated supplemental resources are publicly available, they appear to have not been broadly implemented yet by the forensic community, perhaps in part because of a lack of awareness of their availability or not knowing how to use and cite them. This presentation will provide information about the various reports and their supplemental resources, the approaches used to create them, and how to access and use this information. NIST scientific foundation studies can aid practitioners, researchers, legal experts, and other stakeholders in efforts to strengthen the appropriate use of forensic casework methods and practices, recognize the appropriate limitations of results and interpretations, identify new areas of research, and point toward resources that have independently assessed the scientific foundations of methods and practices.

F122 Standards Synergy: Collaborate to Elevate

Vincent J. Desiderio, MS, National Institute of Standards and Technology, Gaithersburg, MD; Allison Getz, MS*, National Institute of Standards and Technology, Gaithersburg, MD*

Learning Objectives: Attendees will gain insight into the evolving forensic science standards landscape, explore how key stakeholders are joining forces to drive innovation and advance standards development and implementation, and be introduced to the latest ISO 21043 series— a suite of standards designed to enhance the rigor and consistency of forensic science practices worldwide.

Impact Statement: This presentation will benefit the forensic science community by revealing key opportunities and forward-thinking strategies to harmonize and strengthen forensic science standards. It will showcase how collaboration among experts is enhancing scientific rigor and consistency, ultimately raising the overall credibility of forensic practices.

Abstract Text: For over a decade, the forensic science community has actively developed both interdisciplinary and discipline-specific standards. Going "back to basics," a fundamental principle of quality management—the Plan-Do-Check-Act (PDCA) cycle—reminds us to periodically evaluate our progress. As the field advances with new technologies and research, and as the number of published standards continues to grow, there is a need to evaluate the current landscape to determine if the needs of the field are truly being met.

Such an evaluation should ideally involve a comprehensive cataloging of existing standards, analysis to identify redundancies, efforts to harmonize overlapping standards, and prioritization of new standards critical to the field's future.

At first glance, this appears to be a complex challenge. Standards development occurs in various settings, and the standards are further refined and published by several different standards development organizations (SDOs), each with its own policies, procedures, and objectives. Wouldn't it be ideal if these disparate efforts could be aligned on a common path?

Encouragingly, the recently published ISO 21043 series of forensic science standards offers a promising foundation for this alignment. Covering essential areas such as vocabulary; recognition, recording, collecting, transport and storage of items; analysis; interpretation; and reporting—all from an international consensus perspective—these standards can serve as seed documents to foster a more harmonized and robust forensic standards ecosystem.

This presentation will highlight the release of the ISO 21043 series, explore their significance, and outline how the National Institute of Standards and Technology (NIST) is leveraging these standards to promote greater collaboration and harmonization across the forensic standards development landscape.

By enhancing the harmonization of standards throughout the forensic sciences, we aim to establish a more cohesive and interoperable framework that supports both innovation and consistency. Through rigorous review of current standards, we can identify gaps and redundancies to better enable strategic and collaborative solutions. Ultimately, these efforts will strengthen the scientific rigor of forensic standards, thereby fostering greater trust, reliability, and advancement in forensic science.

Standards; Quality Management System; Interdisciplinary

F123 Visualizing Data at NIJ: Adopting Modern Tools to Show the Impact of Grantees in the Forensic Community

Tiffany Layne, PhD, National Institute of Justice, Washington, DC; Jillian Conte, PhD, National Institute of Justice, Washington, DC; Tracey L. Johnson, MSFS, National Institute of Justice, Washington, DC*

Learning Objectives: Attendees will learn of newer data visualization software tools and how these tools can be used to connect information across multiple datasets to evaluate the data and draw conclusions. As an example, interactive dashboards will be shown to demonstrate how the National Institute Of Justice (NIJ) -funded grantees have impacted the forensic community. Attendees will have a greater array of tools for collaborations and to publicly show the impact of their organizations.

Impact Statement: The topic of this presentation will impact the forensic community by demonstrating the utility of data visualization tools using Power BI that can connect multiple data sets, help draw conclusions, and provide interactive dashboards through the use of a forensic research impact example. These data visualizations can be used to demonstrate organizational impact, return on investment, and assist with strategic planning and data-driven decision making.

Abstract Text: Mechanisms to visualize data have been around for centuries, largely starting with cartography and hand drawn maps, then exploding in the late 20th century with advancement of computer technology. With the betterment of technology and the incorporation of AI, there are a myriad of data visualization tools available and able to analyze any type of data. This topic has been explored by various entities within and outside the forensic community. Microsoft® Excel is a standard data visualization tool that has been used with great success, however, newer tools are available such as Power BI, Tableau, and others. NIJ is working to expand their use of newer data visualization tools as a more efficient way to visualize large datasets collected over the lifetime of their programs. These newer data visualization platforms allow for easy manipulation of graphs, linking multiple data files, and collaboration with others. Now, we can synthesize data from research performance progress reports (RPPRs) such as grantee publications and conference presentations that span over 20 years of research. These measures and resulting visualizations can assist with understanding forensic science impact for dissemination to stakeholders and policymakers.

The results of our data visualization efforts include key insights into the Graduate Research Fellowship (GRF), Research and Evaluation in Publicly Funded Forensic Laboratories (PubLabs), Research and Development in Forensic Science for Criminal Justice Purposes (FSCJP) programs and the activities of the Forensic Science Research and Development Technology Working Group. One way to measure research impact is to collect metrics on products produced by grantees. Of the forensic science programs at NIJ, it takes an average 3 years for a grantee to publish a journal article from the award start date and an average 3 publications per award (GRF = 3 years, 2 publications; FSCJP = 3 years, 4 publications; PubLabs = 2 years, 2 publications). The time until grantees have research prepared to present is much shorter, with the average time to first presentation at 1 year and the average award provides 7 presentations. Interestingly, of all presentations made by NIJ grantees, 20% were given at the American Academy of Forensic Science Annual Meeting, the highest of any conference. The short-range timeline for presentations together with the mid-range timeline for a publication makes for effective and frequent dissemination of NIJ-funded research.

Our data visualization efforts have given us a deeper glimpse into the different forensic disciplines we fund that fall under the forensic biology portfolio. Of applications received in forensic biology since 2015, 24% of applications have transitioned into awards with an average award funding amount of $530,000. Looking qualitatively at the funded awards, the majority of the research awards focused on NGS and qPCR technology and the collection and analysis steps of the forensic biology workflow. Additional rich and significant data will be presented from this move toward newer data visualization tools. This presentation will demonstrate data visualization capabilities to create interactive dashboards, analyze data across multiple datasets, draw conclusions while determining the impact in the forensic community from NIJ-funded grantees.[1,2]

F124 Hide and Seek: A Pseudo Operational Study of Fingerprint Development and Enhancement on Leather Surfaces to Assist Practitioners

Leisa J. Nichols-Drew, MSc, De Montfort University, Leicester, England, United Kingdom*

Learning Objectives: This presentation will provide attendees with: (1) an introduction to the challenges of leather surfaces, including porosity, color, texture, species, and surface finish, (2) an awareness of the varieties of novel leather surfaces that may be encountered in the casework setting, including more sustainable and vegan materials using Scanning Electron Microscopy (SEM), (3) a robust understanding into a research study undertaken involving multiple fingerprint donors, surfaces, aging periods, and processes, and (4) recommendations to aid practitioners in successfully developing fingerprints on leather exhibits at the crime scene or in the laboratory.

Impact Statement: This presentation will impact the forensic science community by increasing knowledge of a relatively limited topic at present. It will additionally provide practitioners with viable methods to develop fingerprints on what is a challenging surface. Ultimately, this presentation aims to equip practitioners with techniques to increase fingerprint yield and numbers of identifiable fingerprints. The research outcomes will assist criminal justice systems around the world involving leather exhibits recovered from the crime scene.

Abstract Text: Leather exhibits (clothing, footwear, weapon sheaths, bags, belts, accessories) are frequently encountered in investigations of diverse criminal offences (homicide, sexually motivated, acquisitive) and both civilian and natural mass disasters. Their recovery from the incident scene can be pivotal to identification of persons who have handled them. Currently, the Fingermark Visualisation Manual (FVM) has limited information with regards to development processes targeting genuine or faux leather substrates.[1] This may be hindered by the complexity of surface variations in animal origin, color, permeability, porosity and texture.

One approach to this challenge is guided by the evaluation of two UK police force Freedom of Information requests relating to examination procedures and practitioner expertise regarding fingerprint/mark evidence on leather exhibits.[2] Motivation for pursuing this is heightened by the challenges of increasing environmental concerns over the sustainability of fashion textiles and their production, highlighted by the United Nations 17 Sustainable Development Goals.[3] These have resulted in the implementation of a range of synthetic "leather" materials, based on plant-, fungi- and bacteria-based 'vegan' alternatives, for which there are presently no recommended fingerprint/mark development procedures.

Here we present an investigation of these novel substrates using scanning electron microscopy (SEM) imaging to provide topographic analysis of these materials. The outcomes are diagnostic of the source species / material to guide subsequent fingermark development processes. Latent fingermarks (from multiple donors) aged up to 3 months, and blood fingermarks aged up to 6 months, on these novel and conventional surfaces were successfully visualized using a combination of methodologies.[4,5] Performance statistics will be discussed including: quantitative (fingerprint/mark yield) and qualitative (identifiable details). Evaluation of the limitations and opportunities of these processes will be included in the context of practitioner needs and aspirations for this difficult substrate.

Ultimately, sequential process flowcharts will provide recommendations to aid the operational setting in Criminal Justice Systems around the world.

F125 Assessing the Landscape of Independent Forensic Consultation: A Cross-Disciplinary Survey of Compensation and Practice

Diana Messer, PhD, West Tennessee Regional Forensic Center, Memphis, TN; Stephanie J. Cole, PhD, Des Moines University, West Des Moines, IA; An-Di Yim, PhD, George Mason University, Manassas, VA; Sara M. Getz, PhD, Oklahoma Office of the Chief Medical Examiner, Oklahoma City, OK*

Learning Objectives: This study surveyed American Academy of Forensic Sciences (AAFS) members of all sections and explores both quantitative trends and qualitative perspectives on professional billing practices and compensation differences within and between disciplines. Attendees will gain insight into how compensation practices, fee structures, and the use of pro bono and reduced-rate services vary across forensic disciplines.

Impact Statement: This study will impact the forensic science community by presenting discipline-specific trends in forensic consultation and expert witness compensation, including frequency of paid consultation, prevalence of pro bono and reduced-rate services, and fee structures across employment settings. The study highlights data-driven insights into compensation disparities and the need for discipline-specific guidelines and best practice recommendations.

Abstract Text: Forensic consultation and expert witness services play an important role in the judicial process, yet limited data exist on compensation and practice across disciplines. To address this gap, we conducted a cross-sectional survey of non-student members of the American Academy of Forensic Sciences (AAFS).

A total of 371 members representing all sections participated with most responses from Criminalistics (32%), Pathology/Biology (15%), and General (14%). Most respondents reported working in private practice (25%), crime laboratories (23%), or academic institutions (18%), with approximately 83% having more than 10 years of professional experience. Over 70% of respondents reported providing independent consultation or expert witness testimony, and, of those, approximately 80% reported charging a fee for some or all services.

Common services included case review, expert witness testimony, report writing, and laboratory analysis. Fee structures varied: 71% (146/206) charged hourly (typically between $100–$600/hour), while others billed per case or per service, often adjusting for experience or case complexity. Reported fees ranged from $75/hour to $50,000/ case, reflecting variability within and between disciplines.

Pro bono work was common. Sixty percent (212/353) reported providing pro bono services at some point, and 85% (180/211) had done so within the past 5 years. Anthropology and Odontology reported the highest proportion of pro bono work (37%; 10/27 and 25%; 3/12, respectively). Motivations included ethical or justice-driven considerations (e.g., wrongful convictions), client's inability to pay, specific cases (e.g., sexual assault), or avoiding conflicts of interest with a primary employer. Reduced-rate services were similarly offered, most often due to client's inability to pay or attorney request.

Certification was not associated with pro bono work. More experienced respondents (11+ years) were generally more likely to engage in pro bono work (65%; 191/293); however, Anthropology was an exception, with respondents with < 10 years of experience reporting slightly higher rates of pro bono work than their more experienced counterparts. Most respondents indicated that experts in their field were regularly compensated for independent consultation (67%; 232/346), and that charging for such work was standard practice (74%; 253/344). Notably, more respondents were unsure whether compensation regularly occurred (29%; 99/346) than answered 'No' for this question (3%;12/346). Anthropology and Criminalistics accounted for one-third of the 'No' responses (4/12, respectively) and were the only sections with more than one respondent selecting that option. Eleven percent (37/344), primarily from Toxicology, General, and Anthropology, reported that compensation depends on the specifics of the case or primary employment.

Qualitative responses highlighted the absence of standardized fee guidelines across forensic disciplines. Some supported establishing best practices, while others noted challenges due to variability in case type, complexity, and the expert's experience. Several emphasized balancing public service with fair compensation, framing forensic consultation as both a civic responsibility and a supplement to primary employment.

This study provides a multi-disciplinary overview of forensic consultation compensation patterns across AAFS sections and a foundation for future investigation. Results highlight the need for discipline-specific fee guidelines, best practices, and broader recognition of forensic expertise as a valuable, yet inconsistently compensated, contribution to the judicial system.

F126 From Metrics to Meaning: Assessing Quality Management in a Medical Examiner Office

Cassandra Rock, MFS, Allegheny County Office of the Medical Examiner, Pittsburgh, PA; Theodore Sanford, BA, Allegheny County Office of the Medical Examiner, Pittsburgh, PA; Mandy Tinkey, MFS, Allegheny County Medical Examiner & Division of Labs, Pittsburgh, PA, PA; Lindsay L. Kotchey, MSFS, Allegheny County Office of the Medical Examiner, Pittsburgh, PA*

Learning Objectives: After attending this presentation, attendees will have learned how forensic organizations can use Quality Management System (QMS) data (such as non-conformities and risk assessments) analyzed through negative binomial distribution models to evaluate section-level and organization-wide performance and support continuous improvement initiatives.

Impact Statement: This presentation is impactful to the forensic science community by demonstrating that quantitative QMS data can move forensic science beyond accreditation compliance toward continuous improvement by providing a framework for a thorough evaluation of key quality metrics.

Abstract Text: Quality management systems (QMS) in forensic science has evolved significantly, influenced by industrial trends and the formalization of accreditation processes.[1] Standards like ISO/IEC 17025 and ISO/IEC 17020 have established frameworks to ensure technical competence and consistent organizational practices, which are now widely adopted.[2] While these standards structure the implementation of quality management in forensic science, they do not offer a direct method for evaluating the operational effectiveness of those quality management systems. This research addresses that gap by analyzing internal QMS data from the Allegheny County Office of the Medical Examiner (ACOME), demonstrating how these metrics can offer meaningful insight into laboratory performance, trends, and opportunities for improvement.

Data was collected from a five-year span (2020-2024) for key quality actions: nonconformities, preventative actions, risk assessments, and deviations. Data was accessed from ACOME's QMS tool, Ideagen, which is utilized to document and manage quality-related events. To perform a quantitative evaluation of the key quality metrics, we developed a custom Python (version 3.13) script to perform a negative binomial regression analysis, a statistical approach well-suited to modeling over dispersed count data. This enabled accurate estimation of event rates and detection of meaningful differences across laboratory sections and years.[3] The results indicate that the Forensic Biology section and "multiple sections" category exhibited higher rates of nonconformities. The increased frequency in Forensic Biology is consistent with this section's adherence to both ISO 17025 and FBI QAS requirements. The "multiple sections" category emphasizes ACOME's collaborative approach to corrective actions, ensuring cross-disciplinary engagement when addressing complex issues. No statistically significant trends were observed for preventative actions and risk assessments (p-value > 0.05) across the five-year span. However, a significantly lower number of deviations were reported in 2020 (p-value = 0.028), likely reflecting the early adoption and learning curve associated with a newly implemented deviation reporting workflow in Ideagen.

This study demonstrates that data stored in a digital quality management documentation system can be modeled and analyzed to provide insights into organization performance over time. The ability to model and visualize trends is valuable for future quality management efforts. By utilizing a negative binomial regression model, we have shown a way to quantitatively evaluate a quality management system based on four key quality metrics: nonconformities, preventative actions, risk assessments, and deviations. By establishing a baseline, future trend analyses can help guide organizations in determining the effectiveness of their quality management systems. Negative binomial regression modeling can be a powerful tool for evaluating a forensic laboratory's quality management system, enabling laboratories everywhere to assess performance trends using their own historical data.

F127 Building a Quality Culture at the Laboratory

Rachel Duke, MS, A2LA, Frederick, MD*

Learning Objectives: The goals of this presentation are to: (1) define quality culture; (2) show consequences of a negative quality culture; and (3) present ideas and recommendations on how to build a positive quality environment in the laboratory.

Impact Statement: This presentation will empower participants with ideas to improve the quality culture in their laboratory, thereby increasing work quality, decreasing stress at the workplace, and encouraging collaboration and teamwork.

Abstract Text: A quality culture within the crime laboratory is centered around constructing an environment of trust, active participation, collaboration, accountability, and effective communication, all of which are aimed at supporting quality objectives in all aspects of its operations. Quality is more than simply "checking a box" for compliance with accreditation supplemental requirements, quality assurance standards, international standards, and the laboratory's policies and procedures. To build a strong positive quality culture, crime laboratory management need to step away from the "zero tolerance" for making mistakes which is an unrealistic expectation. It is not a matter of "if", it is a matter of "when" a mistake will be made. It involves fostering a proactive approach to quality assurance and quality management into the day-to-day operations and incorporating a sense of community among the forensic science practitioners including technicians, analysts/examiners, and management within the crime laboratory. This presentation will highlight various strategies and recommendations for cultivating a positive quality culture that will enhance the overall quality environment, promote professional development, and recognize accomplishments. By implementing these ideas, the crime laboratory management can expect to observe improvements in the overall quality of casework, a reduction in stress at the workplace, and a boost in collaboration and teamwork.

F128 From Evidence to Action: Navigating the Complexities of Animal Hoarding Cases

Becky Morrow, DVM, Frankie's Friends Humane/Penn State University, University Park, PA*

Learning Objectives: By attending this session, attendees will: (1) be able determine what precautions have to be taken when responding to animal hoarding cases based on the hazards that may be encountered, (2) examine the specific challenges of animal hoarding cases from the perspective of animal welfare organization, victims of animal cruelty, and the law, and (3) understand what role the forensic veterinarian plays in assisting law enforcement at the crime scene, performing live animal and postmortem forensic exams, and serving as the expert witness in court.

Impact Statement: This presentation will significantly impact the forensic science community by equipping professionals with specialized skills and knowledge to navigate the complex and often hazardous realities of animal hoarding cases. Through practical guidance and real-world case studies, it will enhance the effectiveness of evidence collection, legal collaboration, and expert testimony—ultimately strengthening the intersection of veterinary forensics, law enforcement, and animal welfare.

Abstract Text: Animal hoarding cases represent a particularly complex subset of forensic investigations, requiring forensic professionals to integrate multidisciplinary expertise, scientific rigor, and situational adaptability. These cases frequently involve environments characterized by severe neglect, compromised biosecurity, and high animal density, which complicate both forensic procedures and animal welfare interventions. This presentation will examine the multifactorial challenges inherent to animal hoarding investigations, with a primary focus on systematic evidence documentation where the evidence collected includes living and deceased animals.

Particular attention will be given to the occupational and public health risks associated with hoarding environments, including exposure to zoonotic pathogens, structural hazards, and airborne contaminants. The session will also explore evidence-based strategies for triage, clinical assessment, and documentation of both live animal and postmortem findings, which are essential for establishing legal standards of cruelty, neglect, or abuse. Additionally, considerations related to the legal custody of animals as evidence—including extended care, housing, and the financial burden on sheltering agencies—will be addressed in the context of legislation such as the Cost of Care Act, which seeks to shift responsibility for ongoing animal care to the accused pending case resolution.

Participants will analyze real-world case studies to gain insight into the forensic veterinarian's role within a multidisciplinary response team, including collaboration with law enforcement, animal control, and legal professionals. By the end of the session, attendees will be better equipped to contribute objective, scientifically sound findings in court proceedings and to support long-term outcomes for both animal victims and the communities affected by these complex cases.

F129 The Science on Trial and Forensic Testimony Tune-Up: Testifying With Clarity, Confidence, and Credibility in Adversarial Courtrooms

Kathryn Ambeau, PhD, Mountain Skye Psychology; Castle Rock, CO; Jarrett Ambeau, JD*, Ambeau Law Firm, Baton Rouge, LA*

Learning Objectives: By the end of this session, participants will be able to: (1) identify how adversarial legal dynamics can distort or misrepresent forensic scientific findings, (2) prepare for cross-examination by developing communication strategies grounded in discipline-specific accuracy and plain language, (3) avoid common ethical pitfalls such as scope overreach, speculation, and ambiguous testimony, (4) demonstrate testimony techniques that reinforce credibility and clarity through live expert-attorney role-play, and (5) understand the strategic goals of attorneys during cross-examination and how to stay grounded in scientific objectivity.

Impact Statement: This session directly enhances the quality and credibility of forensic expert testimony across disciplines by equipping scientists with tools to effectively navigate adversarial courtroom settings. Through interdisciplinary collaboration between a forensic psychologist and a criminal defense attorney with a master's in forensic DNA, the presentation offers a unique dual perspective on how scientific evidence is scrutinized, reframed, or undermined in court.

By modeling both strong and weak testimony techniques, the session bridges the gap between scientific precision and legal performance, providing attendees with actionable strategies to protect their findings, maintain ethical boundaries, and communicate clearly to non-scientific audiences. These skills are critical to advancing justice, as the strength of a case often hinges not just on the science itself, but on how well it is explained and defended in court.

This training ultimately supports the integrity of the forensic sciences by helping practitioners uphold their role as neutral, competent, and ethical communicators of evidence.

Scientific accuracy is only half the battle. How you testify about your findings in court can determine whether they are believed, misunderstood, or dismissed entirely. In this engaging and skills-based presentation, forensic psychologist Dr. Kathryn Ambeau and criminal defense attorney Jarrett Ambeau (who holds a master's degree in forensic DNA) bring both sides of the courtroom together to help you protect your science in the adversarial arena. Through live role-play and real-world case examples, the presenters will model how expert testimony can go wrong even when the underlying analysis is technically sound. They will contrast common testimony mistakes—such as using overly technical jargon, straying beyond one's scope, or appearing defensive—with clear, effective strategies grounded in ethical and scientifically accurate communication.

Attendees will learn how to anticipate attorney tactics, understand how legal framing can recontextualize scientific findings, and practice ways to clarify conclusions for non-expert audiences. The session will break down the strategic goals of cross-examination and teach you how to maintain your credibility without sounding combative or uncertain. If your forensic work might ever face legal scrutiny, this presentation will give you the tools to respond with confidence, protect your professional reputation, and uphold the integrity of your field. This session is highly practical, fully interdisciplinary, and applicable across all forensic science specialties.

Interactive, Ethical, Immediately Useful in Real Cases

F130 Characterizing the Human Decomposition Hotspot: Integrating Soil Biogeochemistry and Microbiology

Lois S. Taylor, PhD, University of Tennessee, Knoxville, TN; Jennifer DeBruyn, PhD, University of Tennessee, Knoxville, TN*

Learning Objectives: After attending this presentation, attendees will gain an understanding of the complex interactions between soil biogeochemistry and microbial ecology in decomposition soils. Attendees will also learn about current climate- and geographically-based knowledge gaps, and how efforts to ensure robust data coverage will assist in the development of emerging technologies.

Impact Statement: This work will impact the forensic science community by providing a current understanding of coupled soil biogeochemical and microbial interactions, and existing knowledge gaps will be identified. Emerging soil and modeling technologies will be presented, and the implications of broad data collection for these technologies will be discussed.

Abstract Text: The decomposition of human remains is a dynamic process creating soil "hotspots": regions of elevated biogeochemical cycling and biological activity. Results spanning 10 years of study performed at the University of Tennessee Anthropology Research Facility will be highlighted, focusing on the integration of datasets originating from disparate disciplines. Cumulatively, these studies have incorporated 57 donors across all seasons, and datasets include 17 soil chemical parameters, bacterial and fungal sequencing libraries and quantification, lipidomics, and metabolomics. Additionally, the use of emerging non-invasive soil testing techniques will be discussed with particular attention focused on the use of fully-integrated datasets for model construction and training.

Soft tissues decompose on short timescales (days to weeks), and yet effects upon soil chemistry and microbial communities can persist for months to years. Soil chemical changes include: altered pH, elevated electrical conductivity, temporary soil hypoxia due to increased microbial respiration, elevated ammonium-nitrogen (N), and elevated quantities of a host of other macro- and trace elements.[1,2] Metabolic heating from insect larval activity raises soil temperatures, frequently > 30°C, increasing enzymatically mediated reaction rates. Microbes from the human as well as necrophageous insects are also introduced, mixing with native soil microbes.[3] Soil hypoxia initially structures these coalesced microbial communities. These communities are still structurally and functionally altered following a year of decomposition, and it is not yet known if they eventually recover to previous conditions or whether a new baseline is established.[1]

Human decomposition studies present challenges. Biological replication is impossible due to inter- and intra-individual variation stemming from mass, body and tissue composition, toxicological loadings, and disease states.[4] On local scales, season and climate controls decomposition rates, modulating the magnitude and timing of the decomposition pulse and concomitant biogeochemistry and microbiology. Large-scale climate and geographical variations introduce greater environmental variation, each with differing edaphic chemistries. Existing human decomposition soil and microbial datasets represent a limited range of climate and soil types, primarily sourced from within North America. These findings need validation across a broader representation of climate and soil types in order to account for regional variation and to construct a robust foundation for model construction. Likewise, it is critical that emerging technologies, such as remote sensing, have widely-representative datasets for ground-truthing, training, and testing machine learning models.

F131 Decompositional Impact on Soil Microbiomes: Advancing Postmortem Interval Estimation in Petroleum-Impacted Environments

Meiko Thompson, PhD, Southern University at New Orleans, New Orleans, LA; Brittney Sylvester, Southern University at New Orleans, New Orleans, LA; Latavia Williams, Southern University at New Orleans, New Orleans, LA; Georgia A. Williams, MS, George Mason University, Manassas, VA*

Learning Objectives: Attendees will learn how soil microbial communities change in response to the decomposition of organic remains under varying environmental conditions, with a focus on petroleum-impacted soils. The presentation will explain how these microbial shifts can inform forensic Postmortem Interval (PMI) estimations, especially in challenging recovery scenarios involving burial or advanced decay.

Impact Statement: This presentation supports the forensic science community by offering an innovative approach to estimating time since death through the analysis of soil microbiomes. By incorporating environmental variables such as petroleum contamination, it expands practitioner competence in interpreting decomposition patterns and contributes to more accurate death investigations.

Abstract Text: This study evaluates changes in soil microbial communities during decomposition to assess their potential as postmortem interval (PMI) indicators, particularly in petroleum-impacted environments. We hypothesized that petroleum contamination alters decomposition-driven microbial succession, which may obscure traditional PMI timelines. Juvenile swine carcasses were placed in both buried and surface conditions in Northern Virginia. Soil samples were collected longitudinally from beneath and adjacent to the remains and compared to control soils. Swab samples (mouth, skin, rectum) were also collected.

Microbial analyses were performed using culture-based methods (nutrient, blood, and Bushnell-Haas) to detect organisms with hemolytic activity and hydrocarbon-degrading capacity. Distinct shifts in microbial succession were observed between burial types, with buried environments showing delayed but sustained microbial activity compared to surface conditions. Soil samples near decomposing remains exhibited increased microbial richness over time, while control soils remained relatively static. Notably, *Thalassolituus oleivorans*, a petroleum-metabolizing, hemolytic bacterium, from several soil samples.

These findings suggest petroleum contamination may alter decomposition-driven microbial patterns, potentially complicating PMI estimation. The study supports soil microbial profiling as a valuable forensic tool, particularly in cases with degraded or absent soft tissue, when contextualized with environmental conditions. This research advances forensic microbiology by highlighting soil as an evidentiary matrix and underscores the need to account for site-specific ecological influences (e.g., contaminants) in decomposition studies.[1-3]

F132 Utilizing Honey Bees (*Apis Mellifera*) as a Surveillance and Monitoring Technique for Bacterial Pathogens in Specific Environments

Jordan H. Walter, MS, ARL BioPharma, Edmond, OK; James P. Creecy, PhD, University of Central Oklahoma, Edmond, OK*

Learning Objectives: This presentation will highlight how honey bees (*Apis mellifera*) can serve as valuable tools in the early detection and surveillance of bacterial pathogens that pose risks to human health and safety. Through their natural foraging behavior, honey bees come into contact with a wide range of environmental surfaces, inadvertently collecting microorganisms that reflect the presence and distribution of bacteria in their surroundings. Attendees will learn how analyzing hive debris using metagenomic sequencing and bioinformatics techniques can uncover bacterial community structures relevant to forensic and epidemiological investigations. This research demonstrates the potential of honey bee-based surveillance to identify sources of environmental exposure, trace patterns of pathogen spread, and support early warning efforts for biological threats. The presentation will also address current gaps in pathogen monitoring and explore how this approach can enhance public health surveillance, strengthen biosecurity protocols, and make meaningful contributions to microbial forensic science. By the end, participants will understand how honey bees can help bridge critical gaps in detecting and responding to infectious disease threats affecting human populations.

Impact Statement: This presentation will impact the forensic science community by introducing a novel, science-based approach to environmental pathogen surveillance using honey bees as passive biological collectors. By demonstrating how hive debris analysis through metagenomic sequencing can provide detailed insights into bacterial community structure across environments, this research advances the field of forensic microbiology and supports early detection of infectious agents relevant to public health and biosecurity. The findings offer forensic practitioners a potential tool for identifying sources of bacterial exposure, tracing environmental contamination events, and informing outbreak investigations. This work strengthens the integration of forensic science with epidemiology and environmental monitoring, encouraging the development of non-invasive, scalable, and cost-effective biosurveillance methods that support both human health and forensic inquiry.

Abstract Text: Biological threats, in the form of infectious diseases and pathogens, are attacking and harming environmental populations around the globe. These threats occur through both deliberate acts and naturally occurring outbreaks. Microbiologists, epidemiologists, and forensic scientists have worked to find ways to detect these threats and protect animal, plant, and human populations. Through the implementation of technologies, practices, and infrastructure, these various entities have provided possibilities to aid in detecting pathogen spread. While this has been beneficial, there are still challenges, limitations, and a need for specific practices for the defense aspect of biosecurity and biosafety. One primary practice is surveillance and monitoring, which is used to detect pathogen spread and epidemics. Due to that, finding ways to effectively surveil and monitor infectious diseases and pathogens is of the utmost importance. This research investigated honey bees (*Apis mellifera*) as biomonitors to detect bacterial pathogens across distinct environments. Honey bees actively interact with all aspects of their foraging environments, unintentionally collecting microbes and transporting them back to their hives. It was hypothesized that the foraging behavior of honey bees enables them to interact with their environment and reflect the surrounding bacterial community composition and structure. To test this hypothesis, hive debris was sampled from honeybee colonies placed both within a shared environment and across distinctly different locations throughout Edmond, OK. Metagenomic analysis using Illumina 16S rRNA sequencing and bioinformatics analysis through QIIME2 was performed on these samples to identify and characterize bacterial communities. Results revealed notable variability in bacterial community structures both within the same location and across different environmental settings, highlighting the potential of honeybees to capture distinct microbial signals that may inform pathogen monitoring strategies. Temporal analyses revealed consistent patterns in bacterial presence throughout the sampling period, further supporting honey bees' utility in continuous monitoring. Information gathered from this study demonstrates the potential of honey bees to inform pathogen surveillance efforts and support early detection strategies within an environmental health context.

Microbial forensics is an emerging discipline, particularly important in the prevention and investigation of bioterrorism cases. One of the earliest examples of its use was the 2001 Amerithrax case, where environmental sampling was critical to understanding the spread and tracing the source of *Bacillus anthracis*. Our research using honey bees to monitor the environment offers a wholistic method. Honey bees can act as passive collectors of environmental microbes that support forensic analyses. Microbial evidence is gathered during foraging across wide areas and diverse environments, then deposited in the hive where it can be sampled and analyzed. This method has the potential to strengthen identification, characterization, and attribution by providing microbial evidence that is timely, location-specific, robust, and fully representative of all bacterial species within a sample. This makes honey bees a valuable tool for early detection and warning in cases involving the intentional release of pathogens.[1-3]

F133 Inter-Rater Reliability and Practical Utility of Five Victim Typologies in Homicide Case Analysis

Adriana M. Graybeal, PhD, Oklahoma State University Center for Health Science, Bixby, OK; Jason Beaman, DO*, Oklahoma State University Center for Health Science, Tulsa, OK; Ashley Keener, PhD*, Oklahoma State University Center for Health Science, Tulsa, OK; Reagan Gill, DO, Oklahoma State University Center for Health Science, Tulsa, OK*

Learning Objectives: This presentation will: (1) define and differentiate five foundational victim typologies commonly used in homicide case analysis ; (2) evaluate the inter-rater reliability of each typology by applying them to standardized homicide case summaries; (3) assess the practical utility of each typology in supporting investigative decision-making and behavioral analysis; (4) identify challenges and limitations in applying theoretical victim classifications to real-world homicide cases; (5) interpret patterns of agreement and disagreement among raters to understand how victim typologies function across evaluators with different backgrounds; (6) develop recommendations for improving consistency and usefulness of victim typologies in forensic and law enforcement settings; (7) enhance critical thinking skills in evaluating the role of victim characteristics in the context of offender behavior and situational dynamics; and (8) apply victim typologies as analytical tools within a multidisciplinary forensic framework, integrating psychological, criminological, and sociological perspectives

Impact Statement: The research project addresses a critical gap in forensic victimology by empirically evaluating the consistency and usefulness of victim classification systems in real-world casework. Despite the central role that victims play in understanding the dynamics of homicide, limited empirical attention has been given to the reliability and practical applicability of existing victim typologies developed by early victimologists. This study offers a systematic assessment of five foundational typologies, measuring inter-rater reliability among trained evaluators and exploring their utility in generating investigative insights. The results have the potential to guide forensic professionals in selecting typologies that not only produce consistent classifications across analysts but also enhance case interpretation, behavioral profiling, and investigative direction. By combining methodological rigor with practical relevance, this project contributes to the professionalization of forensic victimology and strengthens its role within multidisciplinary homicide investigations. Ultimately, the findings may inform training protocols, improve analytical frameworks in violent crime analysis, and support the development of standardized victim classification tools—advancing both academic research and applied forensic practice.

Abstract Text: Victimology is a relatively young field emerging formally in the mid-20th century. Research in this area, while sparse, remains crucial as victims are a central yet historically overlooked aspect of criminology. Victimology seeks to try and understand the relationship between the victim and the offender, which can help to provide insight into why crime occurs. In the criminal justice system, victims have been seen as disposable and categorized as such, which is why this research is so crucial. Early victimologists (Benjamin Mendelsohn, Hans von Hentig, Stephan Schafer, Marvin Wolfgang, and Menachem Amir) developed classification systems that helped categorize victims based on biological, social, and psychological factors that play a role in how much or how little involvement or blame may be placed on the victim. After looking into the history of this field, it was found that research on victims has been mainly focused on cases of rap. Which is why when this study was proposed homicide case data was utilized. Data surrounding 241 closed homicide case synopses were copied from original case synopses, subjects rated each synopsis based on the typology instructions presented. Findings indicate that Menachem Amir and Hans von Hentig's victim typologies demonstrated the highest percent agreement in this study. Descriptive statistics confirmed these trends with von Hentig's typology showing the least variability in ratings and Wolfgang's typology exhibiting the highest. The results for Stephan Schafers and Benjamin Mendelsohn's typologies suggest that these two classification systems have fair agreement. These findings highlight the need for further refinement of victim typologies, particularly in homicide research. Future studies should explore additional variables influencing victim-offender dynamics and assess how contemporary victim classification models align with modern criminological perspectives.

F136 Forensic Ethics in Practice: Bridging Global Standards, Skills, and Moral Responsibility

Giuseppina Seppini, MSN, S. Croce e Carle General Hospital/Forum Lex Association, Volvera, Piemonte, Italy; Ippolito Iolanda, MSc, Forum Lex Association, Volla, Campania, Italy*

Learning Objectives: Participants will understand the ethical implications and moral responsibility associated with both forensic science and decision-making and the importance of developing distinctive ethical skills among forensic experts.

Impact Statement: This presentation will contribute to the discussion on ethical implications, the need to develop distinctive skills, integration between different elements, including regulatory and legal ones, and the impact that all these elements can have on the decision-making process.

Abstract Text: In today's legal landscape, forensic science is a fundamental tool for reconstructing and ascertaining the truth. However, this is a complex process that requires an ethical framework, without which it could risk becoming ambiguous. Ethics in the forensic field becomes a substantial element in ensuring that scientific practices are guided by principles of impartiality, transparency, and respect for human rights.[1] The term forensic science refers to the application of scientific knowledge and methodologies to the resolution of legal issues and problems involving individuals and society. It also includes processes such as observation, documentation, collection, analysis, evaluation, and scientific interpretation of evidence during investigations conducted in different areas of law (criminal, civil, etc.). Ethics within forensic science can be defined as a set of moral and professional principles that guide the actions of forensic experts, both from a technical point of view and with regard to social responsibility and respect for human rights.

There are three aspects of ethics (metaethics, normative ethics, and applied ethics) that allow us to define a useful framework for the "adoption of ethics" within forensic science. Ethics in forensic science is an essential requirement, resulting from the awareness that scientific truth and its attainment are closely linked to respect for justice and human dignity. Ethical implications constantly affect the decision-making process of forensic experts, and ethical challenges can arise in the daily lives of these professionals when different interests intersect.[2] Ethical training is an important element in addressing these challenges, but it alone is not sufficient to deal with the complexity of ethical dilemmas. It is essential to adopt a framework that outlines the fundamental ethical principles of forensic science, together with training on ethical problem solving and the structural processes that guide decision-making. Furthermore, forensic ethics should be understood as a true "professional conscience," which guides the professional's modus operandi in accordance with transparency, truth, and rigor.[3]

It is also important to remember that, at present, the power of scientific techniques and innovative technologies must be balanced by a solid ethical and regulatory framework. In this context, ISO standards and ethical principles play an essential role because they ensure the quality and standardization of practices and respect for universally defined moral values.[4,5]

In an age where truth can be manipulated and technology used in a distorted way, it is essential to rediscover fundamental ethical values and adhere to strict standards in order to preserve the integrity of forensic science. Only through this alliance between ethics and standardization can justice be guaranteed to be effective, fair, and humane.

In this process, it is important to recognize the importance of integrating ethics into the training of forensic professionals and developing ethical skills that are considered fundamental to the development of moral responsibility and to avoiding cognitive distortions and institutional pressures that can compromise the integrity of forensic investigations.[6]

F137 My Report Says What?! A Deep Dive Into Documents Fabricated by Individuals Outside of the Laboratory

Taylor A. Shafirovich, MS, Baltimore Police Department Firearms Analysis Unit, Timonium, MD*

Learning Objectives: Attendees will learn of a recent fabricated report case in which the fabrication was created by an individual not working in the laboratory, the means of which the fabrication was recognized by laboratory personnel, and the steps that were taken after reporting the fabrication to the Quality Assurance Office and State's Attorney's Office. Attendees will also be urged to ensure that consistent wording is followed within their respective discipline's laboratories so as to more easily recognize potential fabrications from external sources. Additionally, staff should be aware of external report fabrication as a possibility and be educated in the format of archived reports in the event of lengthy post-conviction proceedings for which analysts no longer remain in the lab.

Impact Statement: This presentation seeks to make the broader forensic community aware of the possibility of reports and documents fabricated by individuals that do not work within the laboratory. The recognition of such discrepancies during pre-trial or in-trial proceedings is required to ensure that the information and evidence being presented to the fact finder is fair and accurate.

Abstract Text: A case study is presented involving a fabricated report related to 2007 Baltimore City police involved homicide.[1] In the original report, it was concluded that, in addition to evidence identified to a departmental weapon, cartridge case evidence and a fatal bullet were identified as having been fired from a civilian suspect weapon. However, in 2025, a document was submitted to the Baltimore Police Department (BPD) Firearms Analysis Unit (FAU). This alleged final firearm examination report was submitted by defense attorneys for review by assistant state's attorneys. Upon review by the FAU, discrepancies from the original report were revealed. Such discrepancies included: (1) report wording which would not be used by firearms examiners, (2) the inconsistency in the conclusions conveyed by the examiners of the case, (3) the exclusion of other firearms related evidence that was submitted to the FAU for analysis, (4) the inclusion of examiners who did not complete any analytical work in reference to the case, and (5) improper formatting of document pages typical to the BPD FAU. These initial discoveries led to the determination that the firearms examination report documents submitted to the State by the defense were fabricated. Further, the understanding of individual examiners' wording and the consistency in the forensic firearm discipline's report wording are discussed. Consideration is also given to the importance of adherence to laboratory procedures, vigilance in the review of documents provided, and the recognition and reporting of when non-conforming processes in forensic laboratory documents are revealed.

F138 Autopsy Findings in 45 Cases of Honor Killings in Jordan: A Retrospective Forensic Analysis

Ibrahim Al-Habash, MD, University of Trieste, Mutah University, Trieste, Friuli-Venezia Giulia, Italy; Asma M. Alshaeb, MD, Faculty of Medicine, Al-Balqa Applied University and Mutah University, Madaba, Madaba, Jordan; Stefano D'Errico, PhD, University of Trieste, Trieste, Friuli-Venezia Giulia, Italy; Davide Radaelli, PhD, university of Trieste, Trieste, Friuli-Venezia Giulia, Italy; Maria Buffon, MBBS, University of Trieste, Trieste, Friuli-Venezia Giulia, Italy*

Learning Objectives: The goals of this presentation are to: (1) define honor killing and understand its socio-cultural context; (2) recognize the common demographic characteristics of honor killing victims, including age, marital status, and relationship to the perpetrator; (3) understand the typical autopsy findings in honor killing cases, including patterns of injuries, anatomical distribution of injuries, methods of homicide, presence of defense wounds, and toxicological results; (4) identify the most frequently reported alleged motives for honor killings, such as suspected illicit relationships and pregnancies outside of marriage; (5) understand the importance of comprehensive medicolegal documentation in cases of gender-based violence and its role in public health and legal justice; and (6) evaluate the broader societal and legal challenges in addressing honor killings and the urgent need for multidisciplinary interventions.

Impact Statement: This presentation will enhance the forensic science community's understanding of honor killings by providing evidence-based insights into their distinctive medicolegal features. It highlights specific injury patterns, methods of homicide, and victim-perpetrator dynamics, offering valuable data for improving autopsy evaluations, case documentation, and identification of gender-based violence. By contextualizing these findings within a socio-cultural framework, the study promotes a more informed and multidisciplinary approach to investigating and preventing such crimes.

Abstract Text: **Background:** Honor killing represents a significant public health and human rights issue in different regions of the world. This study examines the medicolegal autopsy findings of 45 cases of homicide related to honor killing in different areas in Jordan over 35 years (1990-2025).

Methods: A retrospective study was conducted on the medicolegal reports of 45 cases of female victims of homicide in which the manner of death was confirmed to be related to honor killing. Data collection included victim demographics, relationship to perpetrator, homicidal methods, injury patterns, anatomical distribution of injuries, toxicology findings, and alleged motives.

Results: The mean age of victims was 22.7 years (range: 15-40), with 66.7% being under 25 years. Most victims were single (68.9%) and killed by a brother (51.1%) or father (20.0%), in some cases by others, such as the uncle or the son. Pregnancy was identified in 35.6% of cases, and 43.8% of them were in the first trimester. Most of these crimes (75.6%) occurred in the victim's home. Gunshot was the most used method (46.7%), followed by using sharp instruments, particularly for stabbing and cut throat (31.1%). Multiple injuries by using multiple instruments (2-5) were observed in 40.0% of cases, while excessive injuries (>5) were found in 33.3%. The chest was the most common site of fatal injuries (42.2%). Defense wounds were present in 37.8% of victims, suggesting resistance. Toxicology was negative in 86.7% of cases. The most frequent alleged motives were suspected illicit relationships (42.2%) and pregnancy outside marriage (35%).

Conclusions: This forensic analysis revealed a particular pattern of honor killing in Jordan. Young and unmarried women have the highest risk. Brothers and fathers are the most frequent perpetrators. Pregnancy and sexual relationships outside marriage were the main motives for the killing due to their related stigmas within the society. Firearm was the most commonly used method. This study, with related findings, highlights the need for a comprehensive forensic documentation and indeed the urgent need for intervention to deal with this form of gender-based violence.

G1 An Injury Causation Analysis in Low-Impact Collisions: A Case-Based Application of Bradford Hill Principles and the Etherton Legal Standard

Alireza Bagherian, DC, Synapse Health Center, San Francisco, CA*

Learning Objectives: This presentation will equip medical-legal professionals, forensic experts, and clinicians with a reproducible method for inferring injury causation in general and motor vehicle collisions. Attendees will learn how to apply a structured, evidence-based methodology for inferring injury causation. Using a case-based approach, the presentation integrates the Etherton legal framework with three key Bradford Hill criteria, including biological plausibility, temporal proximity, and differential etiology. A visual forensic flowchart will also be introduced to illustrate the analytical process and support reproducibility in clinical and legal settings.

Impact Statement: This presentation advances the forensic science community by introducing a replicable, interdisciplinary model for analyzing injury causation in motor vehicle crashes, an area routinely complicated by unclear medical findings and conflicting expert opinions in litigation. By integrating epidemiological standards from the Bradford Hill criteria with the legal reasoning established in *Etherton v. AutoZone*, the framework bridges scientific methodology and judicial admissibility. The introduction of a visual forensic flowchart enhances consistency in expert evaluations and strengthens the evidentiary foundation for testimony where traditional biomechanical thresholds fall short. This approach equips forensic professionals with a defensible toolset for complex medicolegal assessments, expanding the scope and reliability of causation analysis in contemporary injury litigation.

Abstract Text: Determining injury causation in low-velocity motor vehicle collisions (MVCs), particularly those with minimal vehicular damage and individuals with preexisting degenerative conditions, poses a persistent challenge in medicolegal analysis. This abstract introduces an integrative and structured framework that merges the judicial reasoning in *Etherton v. AutoZone* with established epidemiological constructs derived from the Bradford Hill criteria. When biomechanical evidence is sparse or ambiguous, this combined framework provides a scientifically grounded and legally supportable means of inferring injury causation. This combined approach facilitates a defensible methodology for inferring causation in the absence of clear biomechanical data, enhancing analytical reliability in cases where traditional mechanical thresholds fail to capture the nuances of human vulnerability and injury potential.

This case involves a 79-year-old female with advanced pre-existing cervical degenerative joint disease who sustained a cervical injury following a low-speed rear-end collision. The incident lacked overt biomechanical force sufficient to explain the reported symptomatology, and diagnostic imaging revealed multilevel degenerative pathology. Despite the presence of confounding variables such as multilevel cervical degeneration and low-impact collision dynamics, this case was analyzed using a structured approach incorporating patient-specific risk factors alongside three central Hill criteria: biological plausibility, temporal proximity, and differential etiology or exclusion of alternative explanations. These three criteria, each rooted in accepted scientific and medicolegal methodology, also form the basis of the judicial reasoning articulated in *Etherton v. AutoZone*. Their combined application of case specific risk analysis and hill criteria provided compelling support that the subject MVC was the primary causal factor in the patient's symptom complex.

To support methodological transparency and practical implementation, a visual causation flowchart has been created and will accompany this submission as part of a detailed poster presentation.[1-4]

G2 Standards for Managing Cases of Missing Persons and Unidentified Human Remains in Conflict: The Effects of Human Rights Jurisprudence on International Humanitarian Law

Maria Nektaria Antoniou, LLM, MSt, University of Oxford, Oxford, England, United Kingdom*

Learning Objectives: Attendees will gain an understanding of how human rights jurisprudence addressing peacetime forensic investigations and capacity-building affects the interpretation of the law that applies to missing persons and unidentified human remains in international armed conflicts. This presentation will thus provide insight into how the legal standard for managing conflict-related fatalities interacts with peacetime forensic standards.

Impact Statement: This presentation clarifies the effects of human rights jurisprudence on the international humanitarian law that deals with missing and deceased persons in conflict. It proposes that the effect of this jurisprudence is the raising of the scientific standards that are expected in conflict with the introduction of expectations of the application of forensic sciences to manage missing persons' and unidentified human remains' cases in conflict.

Abstract Text: Human rights bodies have fleshed out obligations that states party to human rights treaties must comply with as regards the management of cases of missing persons and unidentified human remains, leading to the creation of specific expectations regarding forensic capacity-building in peacetime. This includes detailed obligations applying to the following stages of the forensic cycle: the search for missing persons; the recovery of human remains; the handling of human remains; the investigation of suspicious deaths; and the disposal of human remains.[1-14] It is suggested that peacetime implementation of the standards expected by international human rights bodies alters the standards applicable under international humanitarian law (IHL), the body of law that applies in conflict. This is demonstrated via analysis of the requirements of IHL and of the relationship between each of these requirements and the human rights jurisprudence addressing each of the above stages of the forensic cycle.

With respect to the search for missing persons, parties to a conflict "must take all feasible measures to account" for the missing.[15] In other words, any measures that are feasible are mandatory. What is feasible is determined on the basis of the circumstances the state finds itself in, and account is taken of the technology, equipment, manpower, and expertise available to it. Where states comply with their peacetime obligations under human rights law to search for persons who disappear under suspicious circumstances and to continue the search until their whereabouts have been verified, they will already have the infrastructure necessary to search for the missing in conflict. Similarly, IHL requires that states "take all possible measures" to collect the dead and prevent their despoilment, while they must also "record all available information" from the body of the deceased.[15] If states apply human rights jurisprudence regarding the use of forensic sciences in the investigation of suspicious deaths and treatment of the deceased in peacetime, the information that will be "available" to record from human remains in conflict will be that which forensic scientists can extract. Finally, IHL obligations on respectful disposal of the dead are mirrored in the human rights jurisprudence that concerns religious rites, family involvement, and access to gravesites.[15]

Although the feasibility of specific measures may be modulated by the numbers of fatalities in conflict as compared with peacetime, on the one hand human rights jurisprudence has addressed forensic capacity-building for emergencies, and on the other the parameter most likely to be negatively affected by large numbers of fatalities is the speed that is considered reasonable in the circumstances rather than which measures can be applied. If states comply with their peacetime obligations to build the forensic capacity necessary to manage human remains and missing persons' cases, the measures available to them when they are required to manage such cases in conflict expand, with various strands of the forensic sciences being introduced as available measures. This raises the scientific standards expected under IHL.

G3 The Correlation of State-Level Autopsy Laws and Infant Autopsy Rates: A Quality Assessment of the United States Medicolegal Death Investigation Systems

Alexis Orbeta, Virginia Commonwealth University, Richmond, VA; Tal Simmons, PhD, Virginia Commonwealth University, Jerusalem, Yerushalayim, Israel; Christopher Ehrhardt, PhD, Virginia Commonwealth University, Richmond, VA; Jenise Swall, PhD, Department of Statistical Sciences and Operations Research, Department of Statistical Sciences and Operations Research, Virginia Commonwealth University, Richmond, VA; Renee Robinson, MD, Office of the Chief Medical Examiner, Richmond, VA*

Learning Objectives: In this presentation, attendees will gain further insight into the complexities of the United States medicolegal death investigation system through visual representation of each state's differences. The focus is the difference in state legislature and how it correlates with associated death and autopsy rates of infants, specifically those ruled Sudden Unexpected Infant Death (SUID). The results argue that standardization of infant death investigations and infant autopsies should be required and a principal goal for the forensic science community.

Impact Statement: This presentation will impact the forensic community by highlighting competency of various medicolegal death investigation systems on a state-wide level in determining cause of death in infants as related to the rigor of a state's autopsy laws. One of the leading causes of death in infants, SUID, should only be determined when the cause of death remains unknown even after a thorough death investigation.[1] There is a lack of standardization between state-wide levels of medicolegal death investigation systems, thus allowing the possibility for inaccuracies to occur since procedures, such as an infant autopsy, may not be required.

Abstract Text: The United States medicolegal death investigation system is often described as a "patchwork" due to the lack of standardization. In an attempt at standardization, the National Association of Medical Examiners (NAME) has implemented a set of guidelines titled the *Forensic Autopsy Performance Standards,* which require infant autopsies in all cases where the death was unexpected and unexplained.[2] This, however, is not enforced. Instead, state laws determine which types of cases require an autopsy, and thus may not be adequate for assessing (e.g., abuse and neglect in infant deaths).

This research analyzed how closely each state's laws follow the NAME guidelines through use of a grading system. The grading system is based on four qualities of the state's laws pertaining to autopsy protocols. Information from each state's death investigation reports such as the number of infant deaths certified per year, the number of autopsies performed on infants, and the manner of death ruled for infant deaths was examined to determine the rigor of that state's death investigation system. The grade of each state was then assessed in relation to that state's associated death investigation reports concerning infant deaths. A Geographical Information System (GIS) was used for visualization of the data by directly plotting it onto a map of the United States. This system was also be used to explore patterns within each state relating to the differing death investigation systems and determined causes of infant deaths.

Data were difficult to access and parse due to widespread differences in tracking cases as well as the categorization of deaths across the United States. Preliminary results of this study suggest that states with lower scores indicate lower infant autopsy rates. States with average scores either plateaued or fluctuated, with no readily discernible pattern, and states with the highest scores were seen to exhibit higher autopsy rates. GIS revealed a trend related to socioeconomic status of the state itself, where state wealth also correlates with autopsy rates.

G4 The Role of the Autopsy in Judicial Investigations—A Source of Evidence and an Essential Guide for the Formulation of Appropriate Charges: An Analysis of Three Cases

Federica Genchi, MD, University of Foggia, Foggia, Puglia, Italy;; Luigi Cipolloni, MD, PhD, University of Foggia, Foggia, Puglia, Italy; Andrea Cioffi, MD, University of Foggia, Foggia, Puglia, Italy; Camilla Cecannecchia, MD, University of Foggia, Foggia, Puglia, Italy; Giovanni Pollice, MD, Università di Foggia, Foggia, Puglia, Italy; Donatella Curtotti, PhD, University of Foggia, Foggia, Puglia, Italy*

Learning Objectives: This presentation highlights the essential role of the judicial autopsy in clarifying the cause of death, especially in complex or suspicious cases. The three cases discussed show how autopsy findings can correct initial errors, prevent wrongful accusations, and provide crucial evidence for judicial decision-making.

Impact Statement: The study emphasizes that reliance solely on external examinations can result in serious judicial errors, including wrongful accusations. Autopsy findings were pivotal in all three cases, leading to acquittals or charge reassessments by revealing objective, verifiable causes of death. These cases reaffirm the forensic autopsy as an essential investigative tool that upholds both scientific rigor and legal justice.

Abstract Text: Over the past decade, a notable decline in the number of judicial autopsies has been observed, accompanied by an increasing reliance on external examinations of corpses.[1-3] While external inspections may suffice in certain cases, they often prove inadequate when dealing with suspicious or complex deaths.[4-7] This report emphasizes the irreplaceable role of forensic autopsy in accurately determining the cause of death and guiding judicial investigations, particularly when initial assessments are inconclusive or misleading.

Three illustrative cases are presented to demonstrate the critical value of autopsy findings in legal contexts. In the first case, a man died following a road traffic accident involving a car and a truck. Based on external injuries consistent with the accident dynamics, the truck driver was charged with vehicular homicide. However, nine months later, a judicial autopsy performed after exhumation revealed the absence of vital reactions at the fracture sites, indicating that the injuries were post-mortem. This finding led to the driver's acquittal. In the second case, a woman with a known history of domestic violence was found dead at home with multiple bruises. Initial suspicions fell on her partner, who was charged with homicide. The autopsy, however, revealed a natural death caused by aortic dissection, thereby excluding foul play and resulting in the partner's exoneration. In the third case, a child died in the hospital during treatment for an abscess. Healthcare professionals were initially investigated for medical malpractice. Autopsy findings, however, revealed a sudden cardiac rupture, prompting a reassessment and reformulation of the charges.

These three cases underscore the indispensable role of judicial autopsy in avoiding wrongful accusations and ensuring accurate medico-legal conclusions. The integration of autopsy with laboratory and radiological techniques enhances diagnostic precision and contributes significantly to the administration of justice. Despite recent trends toward minimizing invasive post-mortem examinations, this report reaffirms the necessity of comprehensive autopsy procedures, especially in cases involving legal consequences. Forensic autopsy remains a cornerstone of death investigation, providing objective, verifiable evidence that supports both scientific inquiry and legal truth.

G5 The Rapid Acceptance of Rapid DNA: The Implications on the Field of Forensic Science, the Practitioner, and the Legal Professional

Lisa Montanez, MSFS, Perlmutter Center for Legal Justice at Cardozo Law, New York, NY*

Learning Objectives: Since the recent Federal Bureau of Investigation (FBI) Quality Assurance Standards (QAS) update expands the approved use to forensic samples, Rapid DNA is set to become a common feature in forensic laboratories throughout the country.[1] This presentation serves to provide the community with an understanding of how adopting this technology may affect various aspects of the field, such as policy frameworks, quality management systems, the mitigation of cognitive bias, and the efforts at preserving objectivity in scientific analyses.

Impact Statement: This presentation will help forensic practitioners, and other criminal justice stakeholders, recognize and consider the implications of Rapid DNA, equipping them to anticipate and proactively manage challenges that may emerge from its adoption.

Abstract Text: After attending this presentation, attendees will be able to identify, and consider, the significant implications Rapid DNA could have on the criminal legal system, and the potential impacts on various stakeholders (e.g., prosecutors, defense, forensic scientists, law enforcement, wrongful conviction/innocence advocates). This presentation will serve as a resource for stakeholders to better understand and prepare themselves for issues they may encounter given the recent July 2025 QAS update.[1]

Rapid DNA is described as a fully automated system that performs STR analysis in less than 2 hours.[2] The use of this instrument in law enforcement applications has been documented as far back as 2011; since the passage of the Rapid DNA Act in 2017, stakeholders investing in the technology believe it can address some of the persistent issues in forensic science, such as mitigating the backlog faced by crime laboratories throughout the country.[3] Although Rapid DNA is represented as a fully automated system, currently, raw data from mixed samples must still be processed and interpreted manually by a DNA analyst in short-staffed laboratories. The introduction of new technology into a crime lab routinely involves a significant volume of work to develop and integrate the system into the workflow. However, Rapid DNA is also accompanied by new responsibilities, questions, and concerns that directly impact scientists, attorneys, and law enforcement.

The implications are multi-layered: training of law enforcement officers as operators of scientific instruments, software validations for fully automated processing, compatibility with PG software, instrument validations, report writing and the transparency of use in discovery, evidence consumption and sample preservation, and the practicality of mobile applications, to name a few. An added layer of complexity involves the uploading of Rapid DNA data to local databases, which will alarm privacy advocates.

Recently, policies have shifted to enhance forensic laboratory operations independent of government agencies in order to support unbiased, scientific evidence evaluation.[4] This is in an effort to mitigate cognitive biases, with a focus on safeguarding the objectivity of scientific analyses from law enforcement influence. While new technologies like Rapid DNA excite the community, we must approach the advancements with caution, to ensure we are innovating in a way that supports the end goal of unbiased evaluation. There are far reaching consequences that can impact the integrity of the forensics discipline, and most importantly, an individual's life and liberty.

G6 One State's Approach to Expanded Use of Rapid DNA Technology for CODIS Search of Crime Scene Samples

Jarrah R. Kennedy, MSFS, Texas Forensic Science Commission, Kansas City, MO; Leigh M. Tomlin, JD, Texas Forensic Science Commission, Austin, TX; Lynn Garcia, JD, Texas Forensic Science Commission, Austin, TX; Gary Molina, BA, Texas Department of Public Safety, Austin, TX; Brady Mills, MS, Texas Department of Public Safety, Austin, TX; Brandon Letts, PhD, Texas Department of Public Safety, Austin, TX*

Learning Objectives: After attending this presentation, attendees will learn about Texas' collaborative approach to expanding its use of Rapid DNA technology, following the Federal Bureau of Investigation's (FBI) July 1, 2025, rule change permitting crime scene samples to be run through Rapid DNA instruments and uploaded and searchable in the Combined DNA Index System (CODIS).

Impact Statement: The FBI's rule change expanding the use of Rapid DNA technology included a recommendation that every state develop its own working group to determine the best oversight approach for use of the technology.[1] In April 2025, the Texas Forensic Science Commission (FSC), the forensic analysis oversight body for the State, established a Rapid DNA Working Group of key stakeholders, including representatives from the Sheriff's Association of Texas, Texas Police Chiefs Association, Texas Rangers, Texas Criminal Defense Lawyers Association, Texas District and County Attorneys Association, Texas Association of Crime Laboratory Directors, Texas Association of Forensic Quality Assurance Managers, ANSI National Accrediting Body (ANAB), American Association of Laboratory Accreditation (A2LA), and a representative from the Commission's Licensing Advisory Committee. The working group plans to develop guidelines, recommendations, and a Rapid DNA Operator licensing program aimed at making the best use of Rapid DNA technology for crime scene samples while preserving the integrity of the forensic analysis process.

Abstract Text: Rapid DNA is the fully automated (hands-free) process of developing a CODIS-acceptable short tandem repeat (STR) profile from a casework reference or forensic sample.[2] The "swab in profile out" process consists of automated extraction, amplification, separation, detection and allele calling without human intervention and can deliver results in as little as 90 minutes, significantly faster than traditional DNA testing methods. With the FBI's approved expansion of the use of Rapid DNA technology for crime scene samples, Texas criminal justice stakeholders anticipate law enforcement agencies' use of the technology for comparisons in CODIS that can significantly improve the speed of response to disasters, crime scene investigations and the identification individuals in custody (potentially linking them to unsolved crimes).

The FSC's Rapid DNA Working Group met for the first time on April 17, 2025, and addressed the implications of the FBI's rule change and problems that may arise for law enforcement and crime laboratories using the technology. At its second meeting, June 27, 2025, the group established a three-pronged scope of work to include the development of: (1) a statement regarding the types of samples that are best suited for Rapid DNA based on existing technology and research; (2) an accreditation umbrella memorandum of understanding (MOU) for adoption by laboratories accredited by ANAB or A2LA in partnership with law enforcement agencies, based on a model MOU by the FBI; and (3) a Rapid DNA Operator licensing program.

In June 2025, the Texas Legislature funded a pilot program for the use of Rapid DNA technology in booking stations and provided the necessary funding. Texas' Rapid DNA Working Group is one example of a proactive and balanced approach to integrating Rapid DNA technology into a state criminal justice system. By combining robust oversight, stakeholder collaboration, and legislative support, the State aims to ensure that the use of Rapid DNA technology enhances public safety without compromising the scientific integrity or legal reliability of the forensic evidence. As Rapid DNA becomes a more integral part of investigations, Texas hopes to position itself as a national leader in responsible, effective implementation.

G7 The Successful Development of a DNA Profile From the Quantisal Oral Fluid Collection Device

Jennifer F. Limoges, MS, NYS Police Forensic Investigation Center, Albany, NY; Lola Murray, MS, NYS Police Forensic Investigation Center, Albany, NY; Kaitlin Fidd, BS, NYS Police Forensic Investigation Center, Albany, NY; Rebecca Love, MS, New York State Police Forensic Investigation Center, Albany, NY; Margaret Raydo, BS, NYS Police Forensic Investigation Center, Albany, NY; Carrie A. McGinnis, MPA, CFM-II, NYS Police Forensic Investigation Center, Albany, NY*

Learning Objectives: Attendees will learn how a suitable DNA profile was successfully developed from a toxicology evidential oral fluid collection device. A DNA profile was obtained from three different parts of the collection device.

Impact Statement: This presentation will impact the forensic science community by informing attorneys, forensic scientists, and other traffic safety partners of the possibility of using a drug testing oral fluid collection device for subsequent DNA testing if unique circumstances warranted such a need. The potential need would be analogous to the rare situations in which a toxicology blood kit has been used for DNA testing.

Introduction: Impaired driving investigations typically involve the testing of biological samples for the presence or absence of alcohol and other drugs. On occasion, DNA testing is involved in these investigations in order to establish the biological sample is from the defendant, in particular when a chain of custody issue has been raised. In other circumstances, DNA testing is used to establish occupant location associated with driving (e.g., testing for DNA on the driver's airbag or driver's side door). In these situations, a buccal swab is typically collected as the DNA control sample, but on rare occasion, the toxicology blood sample has been used.

As oral fluid is a relatively new specimen for drugged driving investigations in the United States, our laboratory wanted to investigate if it were possible to develop a DNA profile from the Quantisal™ collection kit used for our evidential oral fluid toxicology testing program.

Methods: Authentic human oral fluid was collected from eight volunteers using the Quantisal™ device, following manufacturer's instructions.[1] Participants were all forensic scientists in the Biological Sciences section of the laboratory who provided informed consent. The samples were processed by the Toxicology section following routine procedures for combining the oral fluid from the pad with the buffer.[2] No toxicology drug testing was performed. The samples were forwarded to the Biological Sciences section for further analysis.

Three DNA sample types were created from each oral fluid collection: a cutting of approximately one quarter to one third of the extracted oral fluid pad, 75 µL of liquid (combined oral fluid and buffer), and a swabbing of the collection stick from the end that would have been in the subject's mouth. Each sample went through the section's routine DNA extraction, quantification, amplification, and analysis procedures.

Results: There were 16 oral fluid collections from eight volunteers, with three samples from each collection, for a total of 48 samples. A full single-source DNA profile was developed from all samples except one swab which produced a partial profile. The cuttings from the pad resulted in the highest DNA quantitation, and 81% of those required dilution prior to amplification. The liquid samples produced the next highest DNA quantitation, but only 19% of those required dilution for amplification. The swabs produced the lowest DNA quantitation, none required dilution for amplification, and 75% amplified below the target of 1ng/µL.

Discussion: The ability to obtain a DNA sample from the toxicology evidential oral fluid collection device is comparable to the development of a DNA profile from a typical impaired driving blood kit. Whether or not a specimen originally collected for toxicology testing purposes can be used for DNA testing in an investigation would likely be handled on an individual case basis based on state statute, legal precedent, and other ethical and legal considerations. This study simply demonstrated that it is possible using this laboratory's toxicology and DNA protocols.

G8 The Performance and Legal Grounds of DNA Mass Screenings Around the World

Dariusz Wilk, PhD, Jagiellonian University in Kraków, Kraków, Malopolskie, Poland*

Learning Objectives: Attendees will enhance their understanding of the performance and legal basis of DNA mass screenings across different countries, as well as the differences between common law and civil law systems in the collection of DNA samples.

Impact Statement: This presentation will benefit the forensic science community by enhancing knowledge of the performance and legal basis of DNA mass screenings in different countries, and by demonstrating how such screenings can serve as a catalyst for changes in law and practice in participants' own countries.

Abstract Text: Mass collection of control (comparative) biological samples from individuals who exhibit similar features as perpetrator, that is DNA mass screenings, is method for detection of perpetrator.

In this study, the performance of DNA mass screenings was evaluated in several countries. An updated report from the USA revealed that such procedures were unsuccessful in 90% of 21 cases between 1991 and 2004. Higher efficiency was observed in the United Kingdom, where 21% of 292 cases were solved, and in Germany, where perpetrators were identified in 29% of 69 cases. Own analysis of criminal cases in Poland showed that DNA mass screenings led to the detection of perpetrators in 36% of 25 cases between 2000 and 2024.

The collection and processing of DNA samples and profiles in mass screenings primarily concern third parties. Such actions significantly interfere with the right to privacy of many individuals. Therefore, a clear legal basis for these procedures is necessary, or they should be explicitly accepted by the judiciary.

Comparative analyses were conducted for European countries, the USA, Canada, and Australia. The research shows that DNA mass screenings are not regulated in the criminal procedures of common law countries. In contrast, in some European countries (e.g., Germany, the Netherlands, Ireland), such procedures are specified by law and biological material may be collected with the individual's consent. In Switzerland, DNA mass screenings are permitted without consent. In many European countries (e.g., Poland, Italy) biological material can be collected from third parties without consent, as permitted by the legal framework.[1-4]

G9 Forensic Likelihood Ratios From Low-Coverage Whole Genome Sequencing

Dan E. Krane, PhD, Wright State University, Dayton, OH; Feriel Ouerghi, BS, Quantitative and Computarional Biology, Los Angeles, CA; Doc Edge, PhD, Quantitative and Computational Biology, Los Angeles, CA*

Learning Objectives: Attendees will be able to explain the question addressed by standard likelihood ratios and appreciate how that question differs from an approach that only assesses the likelihood that a member of a specific reference panel could be the source of Single Nucleotide Polymorphism (SNP) information generated with low-coverage whole genome sequencing of an evidence sample.

Impact Statement: Low-coverage whole genome sequencing can yield substantial information relevant for identity inference. The issue is attaching a reliable (or conservative) assessment of the strength of the evidence for identity. There are several possible routes to address this issue but a likelihood ratio that does not consider the chance that a "random man cannot be excluded" can overestimate the weight of such evidence by many orders of magnitude.

Abstract Text: Advances in sequencing technology are allowing forensic scientists to access genetic information from increasingly challenging samples. A recently published computational approach, IBDGem, analyzes sequencing reads, including from low-coverage samples, in order to arrive at likelihood ratios for human identification.[1] We show that likelihood ratios produced by IBDGem are best interpreted as testing a null hypothesis different from the traditional one used in a forensic genetics context.[2] In particular, rather than testing the hypothesis that the sample comes from a person unrelated to the person of interest, IBDGem tests the hypothesis that the sample comes from an individual who is included in the reference database used to run the method. This null hypothesis is not generally of forensic interest, because the defense hypothesis is not typically that the evidence comes from an individual included in a reference database. Moreover, the computed likelihood ratios can be much larger than likelihood ratios computed for the standard forensic null hypothesis, often by many orders of magnitude, thus potentially creating an impression of stronger evidence for identity than is warranted. We lay out this result and illustrate it with examples, giving suggestions for directions that might lead to likelihood ratios that test the typical defense hypothesis.

G10 Likelihood Ratios and Belief Updating

Thomas Busey, PhD, Indiana University Bloomington, Bloomington, IN*

Learning Objectives: This presentation will describe the results of four experiments that explore how likelihood ratio evidence is interpreted and combined with other evidence. Concepts such as Steven's Power Law, the ordered probit model, and Bayesian inference will be explored to demonstrate the interpretation and combination of likelihood ratios by laypeople.

Impact Statement: Among the forensic disciplines, there is a shift toward more evaluative reporting such as likelihood ratios. This reporting has a number of advantages in that it does not rely on base rates, can be combined with other likelihood ratios using Bayesian updating, and avoids definitive conclusions that can lead to evidence overinterpretation. I explore how laypeople interpret likelihood ratios using tools from psychophysics. The results are a cautionary tale that suggests that work is still needed before a general introduction of likelihood ratios across all of forensics.

Abstract Text: Many forensic fields use likelihood ratios and other forms of evaluative reporting. From a Bayesian perspective, this form of reporting fits nicely within a framework where the prior odds are multiplied by the likelihood ratio to produce the posterior odds, and this process continues for subsequent forms of evidence presented at trial. However, multiplication is at odds with the "scales of justice", which is an additive model. Despite this, if laypeople perceive likelihood ratios on a log scale, this disconnect might be ok.

In the present work we use psychophysics to measure the relation between a likelihood ratio and its impact on belief change. We presented mock crime cases and asked laypeople to express their beliefs on an 8 point scale ranging from guilty to not guilty. We used an ordered probit model to recover the underlying latent dimension upon which these ratings were based.

The resulting data was well-fit by a power function, which supports an additive combination process. However, when asked to combine likelihood ratios in simulated court cases, laypeople adopted a combination strategy that was very far from ideal. In many cases their combination process was sub-additive, reminiscent of the weak evidence effect. Under no circumstances was the combination process similar to what would be expected from a multiplicative combination process. Using log-likelihood evidence produced near-linear belief change functions, but still sub-multiplicative combination performance.

The results suggest that likelihood ratios still face barriers for adoption if they are to be used widely in forensic testimony. Likelihood ratio evidence may be underestimated by jurors when combining evaluative reporting with other forms of evidence.

G11 A Movement Toward Greater Clarity and Transparency in Firearms Comparison Reporting in Texas: A NIST Collaboration

Lynn Garcia, JD, Texas Forensic Science Commission, Austin, TX; Henry Swofford, PhD*, NIST, Gaithersburg, MD; Robert Smith, JD*, Robert Smith, Austin, TX; Steven Lund, PhD*, National Institute of Standards and Technology, Gaithersburg, MD*

Learning Objectives: After attending this presentation, attendees will learn about steps the Texas Forensic Science Commission has taken to improve the way the reliability of Firearm and Toolmark (FATM) evidence is reported and communicated to legal end-users. Following the publication of a report by the Texas Forensic Science Commission that aims to implement suggestions from a May 2024 article by Swofford et al. titled "Inconclusive Decisions and Error Rates in Forensic Science," the Texas Forensic Science Commission established a FATM working group, including forensic and legal practitioners across the state of Texas as well as researchers from the National Institute of Standards and Technology (NIST).[1] This presentation will provide an update on the approach and progress the working group has made to implement those suggestions in the FATM comparison discipline.

Impact Statement: This presentation will help attorneys identify the type of questions they need to be considering with respect to assessing the reliability of FATM comparisons; it will also offer guidance to forensic science service providers regarding a more transparent and effective method of reporting results.

Abstract Text: In the early 1990's, in the capital murder case of Nanon Williams, a firearms examiner from the now defunct Houston Crime Laboratory mischaracterized a deformed projectile recovered at autopsy as a .25 caliber bullet (consistent with the defendant's firearm). Post-conviction testing established the deformed projectile was in fact a .22 caliber bullet fired from the co-defendant's firearm. The mischaracterization was caused by several factors including the fact the projectile was distorted, the co-defendant's firearm was not originally submitted as evidence, the examiner did not conduct a microscopic examination, and the laboratory's overall lack of quality controls during that timeframe.

Landmark forensic science reports have called for empirical proof of the reliability and validity of FATM examinations and have specifically stressed the need for appropriate black-box studies to provide estimates of reliability. Recently, several black-box studies on the accuracy, reproducibility, and repeatability of FATM examination have been published related to bullet and cartridge case comparisons. One area of protracted disagreement concerns the best way to convey the reliability of FATM comparisons, especially when considering the result when applied to a particular case at hand.

Generalized error rates are often used to convey the reliability of FATM evidence; however, the TFSC agreed with authors of the referenced paper that error rates from black-box studies focusing on false positive and false negative results are neither comprehensive nor necessarily relevant to the context of a particular case.[1] The AFTE Range of Conclusions provides examiners with five options: (Identification, Inconclusive (Types A, B, or C) or Elimination. It can be misleading to use false positive and false negative error rates from black box studies as a metric of performance in a discipline that does not limit an examiner to only two choices (identification or elimination) and when Black Box studies have shown that various case-dependent factors, such as the firearm:ammunition:quality combination, can impact performance.

In the proposed new approach, Texas FATM examiners would present data for consideration that are most relevant to the evidentiary circumstances for the cast at hand and derived from their own validation data. The data would be presented in two tables referred to as a "Discriminability Table" (detailing the extent to which the method can distinguish between same source/different source) and a "Reproducibility Table" (detailing the extent to which outcomes of the method are consistently produced by different examiners). These data provide greater transparency about the method's overall performance. The authors will present an update on the work of a statewide working group with the responsibility for implementation. They will also discuss other related recommendations from the TFSC's report. Finally, they will explore ways this approach may be extended to other forensic disciplines.

G12 "U Can't Touch This!" Examining Activity Level Proposition Evidence Through a Constitutional Lens

Allison Lewis, JD, The Legal Aid Society, New York, NY*

Learning Objectives: After attending this presentation, attendees will understand and appreciate potential Constitutional challenges to activity level propositions testimony and reports in criminal trials, specifically as to Fifth and Sixth Amendment objections to admission.

Impact Statement: This presentation will impact the forensic science and legal community by demonstrating how testimony regarding activity level propositions may violate the Fifth and Sixth Amendment bedrock principles of trial by jury, burden of proof by a reasonable doubt, and the presumption of innocence, and therefore, face significant hurdles to being admitted in evidence in criminal prosecutions.

Abstract Text: Increased sensitivity of DNA testing has detected the presence of the DNA of irrelevant contributors on crime scene evidence, often on incredibly inculpatory items of evidence.[1] The danger of DNA wrongly accusing individuals has increased awareness and exploration of secondary (and tertiary, etc.) transfer in recent years.[2] In the adversarial system, defense attorneys may highlight alternative explanations for the presence of DNA that vary from reasonable to implausible at trial. The jury must assess and weigh the facts presented in evidence and arguments about their relevance to the allegations. In response to an increased appetite for context to accompany and explain the presence (and probability) of seeing DNA in various circumstances, research and interest in activity level propositions have greatly proliferated in recent years.[3]

Setting aside other challenges to the admissibility of this evidence such as evidentiary objections, problematic reporting, and admissibility objections under *Frye/Daubert* this author will propose that activity level proposition evidence violates the Fifth and Sixth Amendment of the U.S. Constitution in three critical ways.[4,5] First, the use of a defense hypothesis violates the presumption of innocence, requiring an explicitly defined defense explanation or theory. While arguments have been made that probabilistic genotyping and the use of likelihood ratios already violate these bedrock principles, activity level propositions go much further.[6] Second, equal treatment of two competing hypotheses (prosecution and defense) violates the burden on the government of establishing proof beyond a reasonable doubt by setting the government's theory on equal footing with the defense hypothesis. The burden of proof and right to remain silent are core Constitutional principles, maintaining the "moral force" and legitimacy of our criminal justice system while attempting to prevent wrongful convictions, and the admission of this evidence runs afoul of those rights.[7] Third, the use of a likelihood ratios to assess competing hypotheses, attempting to provide the jury with an expert opinion about the likelihood of one proposition over the other, invades the province of the jury and violates citizens' right to a trial by jury. Activity level propositions go to the very fact-finding mission of the jury, usurping their role of the factfinders and overwhelming their judgment. This presentation will discuss these objections, provide an evaluation of their strength, and propose that getting 'back to basics' must include consideration of the Constitutionality of activity level proposition evidence.

G13 Activity Level Testimony in United States Courts: The Problem of Proof

Ted R. Hunt, JD, Federal Bureau of Investigation, Quantico, VA*

Learning Objectives: After attending this presentation, attendees will understand why most formal activity level testimony would be inadmissible in United States courts. The legal bases for asserting valid objections to inadequate proof for speculative propositions will be explained.

Impact Statement: This presentation will impact the forensic community by informing legal and scientific practitioners how the scientific literature and guidance on formal activity level reporting fails to account for differences in legal systems that will affect its admissibility in United States courts. Understanding why formal activity level testimony would be largely inadmissible (given a proper objection) in the United States will help the forensic community find more operationally feasible alternatives.

Abstract Text: The frequent occurrence of activity level issues in criminal cases has led to increased calls for U.S. forensic laboratories to implement formal activity level evaluations. Such evaluations, based largely on guidance authored by the international forensic community, require that practitioners: (1) consider the framework of case circumstances; (2) consider two or more competing propositions that represent the parties' positions (the prosecution's proposition, Hp, and the defense proposition, Hd); and (3) consider the probability of the findings given the propositions addressed.

The second requirement presents prosecutors with significant problems of proof in U.S. courts. When the defense fails to disclose Hd in the pretrial phase of the case (which it is not obligated to do and almost never does), activity level documents recommend the expert adopt on behalf of the defense one or more "reasonable" or "relevant" propositions that likely reflect the defendant's position on the activity level issue. Some activity level papers go so far as to propose that Hd be formulated based on speculative and unspecified "social contact" between the complainant and the defendant. Finally, a large-scale European inter-laboratory research project is currently underway to generate experimental data for formal activity level evaluations. The project is using controlled experiments to simulate typical casework scenarios that will be used as proxy defense propositions. These recommendations, workarounds, and experimental efforts may be reasonable *scientific* solutions for an unknown Hd, but they fail to solve the *legal* problem of proof. If the prosecution cannot offer adequate independent evidence of the facts assumed by its expert (Hd in particular), it will fail to satisfy the requirements of conditional relevance under Federal Rule 104(b), "fit" (foundational relevance) under Federal Rule 702(a), and scientific "knowledge" under Federal Rule 702(b). In addition, U.S. law requires that inferences drawn from admitted (but often ambiguous) facts must be reasonable, not speculative in nature. Given a timely objection, the prosecution's failure of proof would lead to the exclusion of: (1) Hd; (2) the probability of the evidence given Hd; and (3) the resulting likelihood ratio. This cascading collapse of the evaluative framework would leave only Hp and the probability of the evidence given Hp intact.

Even if a defendant has disclosed his activity level Hd in the pretrial phase of the case, he is not obligated to maintain that position at trial. Instead, the defense retains the right to revise, reconstruct, or completely reject it during trial effectively turning Hd into a real-time moving target for the prosecution. This creates serious (even insurmountable) legal, practical, and scientific problems for the government's activity level theory (which *must* include its chosen Hd), making it inadmissible in most cases. Given the small number of cases in which formal activity level testimony would be possible, practical, and legally admissible, the best path forward may be to pursue informal activity level approaches that carefully define and follow scientific and legal limitations.

G14 Help vs. Harm: What Should Be the Role of Activity-Level Evaluations in United States Courts?

J.D. Schmid, JD, Minnesota Board of Public Defense, Duluth, MN*

Learning Objectives: After attending this session, participants will better understand the risks of introducing probabilistic evaluations of DNA evidence given activity-level propositions in United States courts. Applying probabilities derived by advocates of activity-level reporting to quasi-ground truth scenarios from real cases and counterintuitive experimental data demonstrates the potential for activity-level reporting to mislead fact finders and contribute to miscarriages of justice.

Impact Statement: This presentation will impact the forensic community by making practitioners aware of the potential pitfalls of using activity-level reporting in United States courts. Knowledge of how DNA evidence can lead to wrongful convictions is essential for determining the best way to help courts answer questions about how and when DNA got to be where it was found.

Abstract Text: Current DNA testing kits are incredibly sensitive. There is now a substantial risk that an innocent person's DNA will be detected in a crime-scene stain. As a result, the relevant question in many cases with DNA evidence is not whether the defendant is the source of DNA in a crime scene stain, but how did the defendant's DNA come to be where it was found.

General practice in most U.S. court cases with DNA evidence includes expert testimony designed to address questions about "who" is the source of DNA, but not "how" or "when" the DNA was deposited. To address this void, some members of the forensic biology community have advocated for expert testimony that evaluates DNA evidence given activity level propositions. Advocates for activity-level reporting urge that the practice will help courts when the disputed issue in a case relates to the activities that caused the DNA to be where it was found.

Advocates of activity-level reporting have not, to my knowledge, empirically assessed whether the probabilistic methods they propose will actually help courts reach the correct outcome. The correct outcome in any criminal trial distinguishes persons who are factually guilty from those who are factually innocent, with one very important caveat. The court system in the United States prioritizes preventing wrongful convictions over holding guilty people accountable. Acquitting someone who is factually guilty may be the correct outcome when the evidence does not prove guilt beyond a reasonable doubt. Convicting someone who is factually innocent is never the correct outcome.

Proving helpfulness therefore requires proponents of activity level reporting to show that their methods will not contribute to wrongful convictions. Evaluating DNA evidence from quasi-ground truth real cases, and counterintuitive experimental data suggests that this will be difficult, if not impossible, task. Such data instead demonstrates the risks associated with activity-level reporting within the U.S. court system and the limits on our current knowledge of the variables that impact how or when DNA got to be where it was found.

The materials in this presentation will encourage practitioners not to assume that probabilistic activity-level evaluations will help prevent miscarriages of justice. The path forward must be forged by research dedicated to understanding how to best educate laypersons about the principles of transfer, persistence, prevalence, and recovery in a way that helps them reach the correct outcome. Such research must account for the limits in our current understanding of variables that can impact the accuracy of an activity-level assessment, quasi-ground truth real cases and counterintuitive experimental data, and the limitations of the United States court system. Absent such research, activity-level reporting in the U.S. courts risks misleading end-users and contributing to, rather than preventing, miscarriages of justice.

G15 The Perilous Use of GenAI in Legal Briefs, Non-Expert Analysis, and Police Reports

Carole E. Chaski, PhD, Institute for Linguistic Evidence, Georgetown, DE; Gil Sapir, JD, Chicago, IL*

Learning Objectives: After attending this presentation, attendees will be aware of four areas in forensic science where the use of generative artificial intelligence is perilous and avoidable.

Impact Statement: The forensic science community will be impacted through gaining awareness and subsequent conscious measures to minimize the unwarranted and troublesome use of generative artificial intelligence.

Abstract Text: This talk presents an overview of artificial intelligence (AI), differentiating three strands using computational linguistics.[1,2] It includes three examples of generative artificial intelligence's (genAI) nascent use within forensic science that are problematic to the legal system. avoidable and rooted in a misunderstanding of genAI. AI is an academic area that traditionally includes cognitive psychology, computational linguistics and computer programming.[3] The original impetus for artificial intelligence is the idea that a machine can be programmed to perform tasks that humans can do well, thereby reducing human effort while also supporting human expertise. The first AI systems were known as expert systems: software that encoded the expert's knowledge and automated the decision-making process of an expert or mimicked the behavior of a human expert. Expert systems require a considerable engineering knowledge of ontologies related to the particular expertise: they are specific, rule-governed and difficult to build. Further, they are usually accurate, reliable and helpful.[4-8]

A second phase of artificial intelligence derives from an extension of statistical analysis called machine learning (ML) and pattern recognition (PR). The impetus for artificial intelligence systems using ML/PR is that humans may not perceive or consciously recognize all of the relevant features and patterns required for performance or classification, whereas machines can be coded and trained to do so. Human limitations include limited experience and lack of awareness or terminology for tacit patterns. Machines can be given huge data sets that are larger than any individual's experience and may be coded to quantify and make visible tacit patterns.[9] Data selection is crucial for machine learning and pattern recognition; when data sets are large but still limited to a particular subset, bias results.[10]

The third strand is generative AI, which is the most popularized form. Unlike the other strands of AI, genAI does not seek to support an expert's specific task or recognize patterns related to a specific task. Instead, genAI simply produces ("generates") text based on a stimulus ("prompt") which provides it with the keywords to be included in the generated text. GenAI creates fluent text by selecting the most likely next word.[11,12] GenAI does not think, reason or comprehend the text that it is producing. Rather, genAI users may believe that GenAL thinks, reasons and comprehends the text and imputes those cognitive behaviors to the generated output. The users misunderstanding of genAI is integral to the peril of deploying genAI within forensic science and the justice system.

Three current examples for each phase of investigation and adjudication are presented. The first example is the use of generative artificial intelligence to compose police reports.[13] The second example is the use of generative artificial intelligence by non-experts to produce what appears to be scientific evidence. The third example is the use of generative artificial intelligence by attorneys to compose briefs and motions for judicial review.[14] These three uses of genAI are discernibly pernicious, violate constitutional rights and disregard legal standards for scientific evidence.

G16 AI in Police Reports: Due Process and Disclosure Obligations

Gil Sapir, JD, Chicago, IL; Jay Zager, Parkland, FL*

Learning Objectives: After attending this presentation, attendees will understand the constitutional rights of due process and confrontation requires disclosure of Artificial Intelligence (AI) use in police reports.

Impact Statement: The forensic science community will be impacted through nondisclosure of AI, thereby violating the constitutional rights of due process and confrontation, evidentiary integrity, and transparency.

Abstract Text: Police reports are integral to criminal investigations and prosecutions and are often the only account of an incident. The standard for police reports are: accuracy; completeness; clarity; conciseness; objectivity; and correctness. Traditionally, police case reports are prepared manually by officers making them prone to human biases, errors, or inconsistencies.

Artificial intelligence involves an increasing role in report preparation by automating narrative generation, analyzing data patterns, and ensuring documentation consistency.[1-3] AI is transforming law enforcement and forensic science. Police departments are using proprietary AI with minimal guidelines or oversight causing significant forensic and legal concerns.[4] AI is used in the operation, review, generation and submission of police reports. Police have a duty to disclose AI involvement. AI's has application and auditing problems. AI disclosure in police reports allows for evidential evaluation through discovery. Marketing AI claims include: quicker report preparation; improved accuracy; better officer utilization; report quality; completeness; consistency; compliance and informed decision making.[3] Data is purportedly subjectively reviewed for validation by the law enforcement agency yet not retained. Use of nondisclosed proprietary AI by police is troublesome.

What assurances exist that police use of AI is trustworthy and not contaminating the evidence? AI integration entails privacy and ethical concerns, reliability, accountability, algorithm bias, discrimination, mistakes, "generative suspicion" and fabricated information or "hallucinations."[5] What information is being relied upon to correct error if the user's information is unknown? What intellectual property rights has the AI vendor reserved concerning conflicts with court rules and statutes? Failure to disclose AI can be considered deceptive or misleading potentially violating legal and ethical standards including civil rights.(4) A 2024 national survey with 203 responding law enforcement agencies shows only 10.8% had an AI policy.[4] Furthermore, AI does not shorten report writing time.[6]

Currently no U.S. federal laws mandate disclosure of AI use in police reports. What the company and police department do with AI information is not reasonably subject to legal privacy protections. National programs of testing and evaluation for AI police disclosure generally do not exist. Case law does not address non-reporting. Viable statutory compliance, use and standards for AI generated police reports does not exist with Utah being the possible exception.[7,8] Peer-review findings addressing AI assistance in police reports is lacking. State and federal false and deceptive practices statutes may be applied to AI use. Federal courts are requiring attorneys' strict disclosure of AI use in litigation.[9]

The prosecution has a duty to disclose evidence favorable to the defendant and is responsible for its agents, irrespective of the good faith or bad faith.[10] The prosecution relies on the police report. Police rely on questionable AI. Arguably, AI can be barred due to denial of confrontation. Attorney use of AI is monitored but not law enforcement's use of AI. At issue is disclosure of AI in police reports and amending discovery rules to account for AI discovery. Courts should require detailed documentation of AI's use and decision making process to preserve transparency, reveal bias, ensure evidentiary integrity and protect the defendant's constitutional rights.

G17 Scientific Support for DNA "Probabilistic Genotyping" Evidence Depends on Testing Lab-Created Mixtures, Although Inadequate

Charles H. Brenner, PhD, DNA-VIEW, Oakland, CA*

Learning Objectives: Nearly all analysis of crime scene DNA via "probabilistic genotyping" doesn't have the option of different numbers of contributors for defense likelihood calculation as for prosecution. New research suggests that the option wouldn't have a large effect though—perhaps 7%.

Impact Statement: The complications and the difficulty of modeling will be discussed. Sometimes "difficulty" means "impossibility."[1] There may be lots of situations that require giving up. Thought is needed.

Abstract Text: Courts require standards agreed by scientists to accept scientific testimony. So far, the scientific support for "probabilistic genotyping" is testing lab-created mixtures. Furthermore, I expect an analyst calculating the strength of DNA evidence against a suspect in a crime to often over-estimate the strength of the evidence. Why? Because the computation software assumes simple models – which are of course imperfect (though sometimes useful as the saying goes).

The simple model computes an LR ("likelihood ratio") based on a prosecution hypothesis Hp and a defense hypothesis Hd, each of which assume the same number of contributors (let's say *three*), but Hp and Hd differ in that only Hp includes the DNA of the suspect. A better model considers and computes also an Hd of only *two* contributors, which sometimes (especially when the suspect is innocent of contributing DNA) results in a smaller LR. That means the "simple model" LR was an over-estimate.

Therefore, nearly all labs use software that sometimes – often in fact – calculates an unfairly large LR against innocent suspects. That seems to mean that no LR result against a suspect can be trusted. However, with research I found a probable work-around. Experimental (in-silica GlobalFiler mock cases) testing patterns that I guessed to be questionable, at worst reduced LR by a factor of about 7.

The simple model also assumes that all genotypes are unrelated. If the DNA mixture includes two brothers at least one of which has unknown genotype, I would be stuck (except with identical twins, whom we can treat as one person).

Additional awkward or impossible situations exist. The modern software – fully continuous (aka "probabilistic genotyping"), even semi-continuous – are complicated.

Conclusion: Long list of totally ignored, possibly important, concepts. Some can be tested with computer modelling. Not all.

Epilogue: While researching this presentation I found a 2014 paper of Taylor that seems similar.

G18 New FRE 707: AI Meets *Daubert*

Donald E. Shelton, PhD, Michigan State University, Saline, MI*

Learning Objectives: After attending this session, attendees will learn about the impact of the new Federal Rule of Evidence 707. Particularly, attendees will understand how the admissibility of artificial intelligence-generated evidence will depend on its ability to meet the requirements set forth in FRE 702 and the case of *Daubert v. Merrill Dow*.

Impact Statement: The forensic science community is being affected by the use of artificial intelligence tools to prepare evidence for use in court. This presentation about the new FRE 707 will equip both scientists and lawyers to be prepared to justify the admissibility of such evidence on the basis of the reliability requirements of FRE 702 and the *Daubert* case.

Abstract Text: Increasingly, artificial intelligence is being used to generate evidence for use in court and there are significant questions about the admissibility of such evidence. In response, the Judicial Conference of the U.S. has recommended adoption of the new Federal Rule of Evidence 707. The new rule states:

Rule 707. Machine-Generated Evidence

When machine-generated evidence is offered without an expert witness and would be subject to Rule 702 if testified to by a witness, the court may admit the evidence only if it satisfies the requirements of Rule 702 (a)-(d). This rule does not apply to the output of basic scientific instruments.

The committee note explains that "This newly adopted rule is designed to address growing concerns around the use of AI-generated evidence, particularly when such evidence functions similarly to expert testimony and raises parallel questions of reliability, bias, error, and interpretability."

The new rule comes on the heels of amendments last year to FRE 702, which made it clear that judges must hold a hearing and require the proponent of forensic science evidence to establish by a preponderance that the offered evidence is both reliable and reliably applied. The Supreme Court effectively told judges to do a better gatekeeping job and to actively apply the requirements established in *Daubert v. Merrill Dow*.

The result of these new and amended rules is that courts must now apply the Daubert criteria to AI generated evidence in the same way as any other expert evidence. The proponent of the AI generated evidence must establish that the AI evidence meets the Daubert requirement of testing, error rates, peer review, standards and general acceptance. This may prove difficult for several reasons. The courts may require, especially in criminal cases, disclosure of the source code used to produce the AI evidence and AI commercial providers may be reluctant to comply. Additionally, while attorneys have embraced AI, many judges are skeptical about the use of AI based on instances where AI has created "deep fakes" including the hallucination of cases and other false sources. The authenticity of AI generated evidence is now subject to challenge under a new amendment to FRE 901 providing that, if challenged, the proponent must then prove to the court that the evidence is more likely than not authentic for it to be admissible.

Evidence; Artificial Intelligence; Admissibility

G19 You Be the Judge: Admitting Expert Testimony When Ethics Conflict With Peer Review

William M. Nuzum, III, JD, Golden & Amos PLLC, Vincent, OH; Stephanie Domitrovich, PhD*, Admin Office of PA Courts, Erie, PA*

Learning Objectives: By attending this session, attendees will learn: (1) the standards and rules used in court for admission of expert testimony; (2) the types of peer review processes used in scientific and technical journals and in the medical field; (3) the *Daubert* standards that include peer review and the limitations courts are finding on the necessity of peer review in admitting expert testimony; and (4) the ethical dilemma of admission of peer reviewed evidence in medical cases.

Impact Statement: This session will enable those who are practicing attorneys and those who may be called upon to testify as and expert witness to understand the rules under which the proffered testimony will be examined by a judge before deeming it admissible. It will examine recent cases that question the peer review process as being necessary for admissibility of evidence and the impact of medical ethics that conflict with admissibility of peer reviewed evidence.

Abstract Text: In this session the presenters will examine the foundation and elements of admissibility of expert testimony in court cases. The presenters will review decisions of the United States Supreme Court and other appellate court decisions related to admissibility of expert testimony and evidence issues, particularly as those are related to peer review as articulated in the *Daubert* Standard and in medical peer reviewed cases. Presenters will review the federal rules of evidence and relevant rules of procedure regarding admissibility of evidence and expert testimony. Additionally, the presenters will examine the elements of peer review as one of the foundational considerations in admissibility expert testimony related to scientific and technical evidence in court cases. Finally, the presenters will provide hypothetical scenarios based on actual court cases, where ethical and procedural considerations of peer the review standards applied in the testimony or evidence should be considered in making a judge's ruling on the proffered expert testimony presented. The audience members will be challenged to place themselves in the position of the judge in making their own decisions on the admissibility of expert testimony in each scenario. After discussion, the presenters will reveal the actual decision of the court in each case and reveal the rationale for the decision expressed by the court.

Ethics; Expert Testimony; Peer Review

G20 Understanding the Use and Challenges of GC/MS in Fentanyl Testing in Drug Cases in New York Criminal Courts (With Discovery, Trial, and Policy Implications)

Molly Kalmus, JD, CUNY Graduate Center/ John Jay College of Criminal Justice, New York, NY; Michelle D. Miranda, PhD, Center for Criminal Justice Studies, Farmingdale, NY; Sarah Chu, PhD, Perlmutter Center for Legal Justice at Cardozo Law, New York, NY*

Learning Objectives: After attending this presentation, attendees will gain insight into challenges concerning discovery and trial practices in drug analysis cases. In addition, attendees will be presented with approaches to understand and critically assess laboratory drug analysis techniques such as Gas Chromatography/Mass Spectrometry (GC/MS), laboratory documentation obtained during discovery, and subsequent testimony by drug chemists.

Impact Statement: The presentation will impact the forensic science community by drawing attention to the challenges faced by attorneys when reviewing and interpreting crime laboratory reports issued by a drug section in an effort to prepare for trial. The presentation will advocate for improved discovery practices and the need for balanced and unbiased expert intervention in order to understand laboratory procedures and analytical methods.

Abstract Text: The use of increasingly complex analytical instruments and methods in the crime laboratory has proliferated over the last 50 years. Since the release of the National Research Council's *Strengthening Forensic Science in the United States: A Path Forward* (2009), the forensic science system has seen a seismic push for standardization and regulation, especially at the laboratory level.[1] One impact can be found in New York City, where two city-run, and city-operated laboratories manage and assess all forensic evidence according to standard operating procedures and quality assurance requirements.[2]

In light of the evolving landscape of drug chemistry and abuse, the analytical methods employed in crime laboratories, and the continuous push for standardization, attorneys must be informed about the latest laboratory policies and procedures, as well as the documentation available at the laboratory regarding such standard practices. Moreover, for evidentiary (discovery) purposes, it is important for members of the legal profession (e.g., prosecutors, defense attorneys, judges) to be familiar with laboratory nomenclature; be able to read and understand the results from GC/MS instruments; and be able to identify when printouts are missing elements or exhibiting discrepancies. It is also important for lab technicians and forensic scientists to be able to articulate the scientific methodology employed in their casework and communicate findings and interpretations to attorneys (whether prosecutors, defense attorneys, or judges) in a manner free from influence and ambiguity. Focusing on discovery, trial, and policy implications, this presentation will discuss the use of, and challenges encountered in, drug analysis cases in New York City labs, with specific emphasis on fentanyl cases employing GC/MS.

G21 Errors in Toxicology Testing and the Need for Full Discovery

Aaron Olson, BS, ARO Consulting LLC, Hugo, MN*

Learning Objectives: Attendees will learn to identify common error patterns in forensic toxicology laboratories, understand the critical importance of comprehensive discovery practices, and recognize institutional vulnerabilities that can persist for decades without detection.

Impact Statement: This presentation will impact the forensic science community by providing evidence-based recommendations for laboratory reform, discovery transparency, and quality assurance improvements that can prevent errors and enhance scientific integrity in toxicology testing.

Abstract Text: Despite toxicology's foundation in analytical chemistry and quantitative measurements, it remains vulnerable to errors that can impact criminal justice outcomes. This presentation reviews notable toxicology errors documented over 48 years of combined field experience, categorizing them by type: traceability errors, calibration failures, discovery violations, maintenance problems, source code defects, fraud, interfering substance issues, reporting errors, laboratory contamination, and chain of custody breaches.

Our analysis reveals critical patterns: many errors persisted for years or decades before detection (including a 14-year breath alcohol miscalibration in Washington, DC), discovery often came from external sources and new employees rather than internal quality controls, and institutional resistance to disclosure frequently impeded corrective action. Notable cases include the Massachusetts Office of Alcohol Testing's systematic withholding of exculpatory evidence affecting 27,000 cases, the Randox Testing Services fraud impacting over 10,000 criminal cases in the UK, and multiple instances of whistleblower retaliation against forensic scientists reporting analytical problems.

The compilation shows that technical competence alone is insufficient. Institutional culture, discovery practices, and oversight mechanisms are equally important. A single-point calibration method error in Maryland persisted through multiple accreditation cycles, while source code defects in breath alcohol analyzers affected thousands of tests across multiple jurisdictions. Cases of deliberate fraud, from falsified calibration records to data manipulation, highlight the need for independent oversight.

Key reform recommendations include: mandatory online discovery portals for transparent access to validation studies and quality assurance records; required retention of digital data and metadata; independent laboratory accreditation with rigorous oversight; legal protections for whistleblowers; and regular third-party audits. The Massachusetts State Police's post-scandal implementation of an online discovery portal provides a model for other jurisdictions.

This systematic review demonstrates that many jurisdictions likely harbor similar vulnerabilities. By examining past errors, the forensic science community can develop evidence-based policies to prevent future mistakes and enhance both scientific integrity and the pursuit of justice.[1-11]

G22 An Autopsy of the UIC-AFTL Crime Lab THC Marijuana Cover-Up

Donald Ramsell, JD, Donald Ramsell & Associates, LLC, Wheaton, IL; Gil Sapir, JD, Chicago, IL*

Learning Objectives: The presentation's attendees will understand the University of Illinois Chicago-Analytical Forensic Testing Laboratory (UIC-AFTL) analytical laboratory's discrepancies of testing human blood/urine samples in Driving Under the Influence/Driving Under the Influence of Drugs (DUI/DUID) cases to identify psychoactive delta-9-tetrahydrocannabinol (Delta-9 THC).[1]

Impact Statement: The forensic community will be impacted through non-compliance with clinical laboratory International Organization for Standardization (ISO) - 17025 and American National Standards Institute/ANSI National Accreditation Board (ANSI/ANAB) Standard 036 Method Validation Guidelines that violates a person's constitutional rights.

Abstract Text: The UIC-AFTL laboratory's testing of human blood and urine due to its inability to separate and detect Delta-8-tetrahydrocannabinol THC (Delta-8 THC) from Delta-9 THC causing its controversial closing will be presented.[2]

The Illinois State Police notified UIC-AFTL in March 2021 to check its methodologies as it appeared delta-8 THC isomers and metabolites were being reported quantitatively together with Delta-9 THC for DUID convictions.[3] Subsequent UIC-AFTL internal validation established that Delta-8 THC was included as Delta-9 THC. UIC-AFTL apparently did not notify anyone of the discrepancy until May 16, 2024, nor did it ever correct its analytical methodology.[4]

Significant events: Oct. 24, 2023 a complaint was filed with ANAB against UIC-AFTL for untruthful, inaccurate and unqualified testimony being provided by its toxicology analyst; Feb. 2024 UIC-ATFL was audited by ANAB; Feb. 6, 2024 UIC-AFTL ended human testing; March 5, 2024 ANAB investigation was reported; UIC-ATFL toxicology testimony is discredited due to being "inaccurate and unqualified;" March 15, 2024 private attorney inquiry was made seeking separation validation data of Delta-8 and Delta-9 THC; UIC-AFTL could not locate the separation validation data; March 25, 2024 UIC-AFTL is unable to distinguish between Delta-8 and Delta-9 THC since May 2018 including root cause analysis questioned; May 16, 2024 UIC-AFTL letter to DuPage County States Attorney stating ineffective methodologies may reflect a combined amount of Delta-8 and Delta-9 THC if both are present; May 18, 2024 being unclear why standards were not routinely run to verify isomers; UIC-AFTL failed to performed a complete method validation for this in-house testing method based on ISO-17025, ANSI/ANAB Standard 036 Method Validation Guidelines, and its own internal guideline SOP GE-005.[5-10]

Court testimony and related complaints against UIC-AFTL preceded resignation of its senior analytical toxicologist and UIC-AFTL's eventual closing. Multiple missteps, misleading information and misidentification of Delta-8 THC were possible UIC-AFTL's cessation factors. UIC-AFTL's closing effected hundreds, if not thousands, of DUID cases.[11]

On May 28, 2025, the law firm hired by the University of Illinois-Chicago published its disputable report, concerning testing inaccuracies and measuring THC. The report in part stated methods should have "been modified" to distinguish between two related forms of THC. Nevertheless, the reliability of those test results may be confirmed on a case-by-case basis.[12]

UIC-AFTL has been closed for over a year. Therefore, samples are incapable of being retested. It appears the law firm's primary objective regarding the University was: to protect it; minimize its risk; and discourage filing of potential 42 U.S.C. §1983 civil rights and class action lawsuits against it.[13]

Constitutional, legal and ethical issues exist due to possible fabrication of formative toxicological evidence. The integrity of forensic science must be maintained and beyond reproach.

Acknowledgments: Kevin McMahon; Paul Moreschi; Dr. Kevin Schug; Dr. James O'Donnell for case work, research and consultation.

G23 An Off-Duty Officer Fatal Traffic Collision Leads to Misdemeanor Negligent Manslaughter Charges

Kurt D. Weiss, MSME, Case Study Collision Science LLC, Santa Barbara, CA*

Learning Objectives: This presentation will demonstrate with a detailed case study how the prosecutor's efforts to charge and convict the driver accused of their officer's death resulted in a series of missteps, leading to acquittal.

Impact Statement: This presentation will assist the forensic community by demonstrating generally accepted traffic collision reconstruction techniques, including drone photography, event data recorder pre-impact data analysis, and forensic video analysis.

Abstract Text: Shortly after departing his apartment, an off-duty police officer mounted his personal motorcycle and headed east on a long boulevard of a coastal community. At the first intersection ahead, the rider advanced on a green light well before the awaiting cars moved forward. Three blocks ahead at a T-intersection, a northbound SUV turned left across the boulevard. The motorcycle slammed into the SUV. The rider suffered significant head injuries. The county district attorney's office declined to press charges. However, despite an apparent conflict of interest, the city prosecutor filed misdemeanor negligent manslaughter charges for the death of their officer. What ensued was a three-year effort to exonerate the SUV driver.

Examples of the prosecution's incompetent investigation arose. Blood samples taken from the rider were positive for cannabis, but the B sample was lost. Therefore, this evidence was excluded. Likewise, video recordings captured by a municipal bus's multi-camera system, was saved into evidence, but did not contain the one video whose camera position was sufficient to capture the collision. The transit company suggested this camera was inoperable at the time. All videos on that date were deleted after the one-year retention policy had lapsed. Furthermore, mishandling of the SUV's event data recorder (EDR) by detectives resulted in an inadvertent event record. These examples, and others, demonstrate the necessity for an independent agency's thorough investigation, including proper evidence handling.

Inspection of the incident intersection revealed the stop line setback distance, landscaping, and parked vehicles reduced the corner sight distance of northbound traffic by 50-percent. To overcome this disadvantage, drivers pulled forward of the stop line to observe the approaching eastbound traffic. Traffic survey data for the boulevard with a regulatory posted speed limit of 30 mph demonstrated an 85-percentile speed of 34 mph. Therefore, drivers intending to turn left had ample time, and distance necessary to safely cross the boulevard.

The EDR's pre-crash data was used to determine the SUV's time-position, and to evaluate the driver's response to the quickly approaching motorcycle. A surveillance camera outside a nearby apartment building captured the collision event, but the motorcycle's approach speed could not be accurately determined because it was visible in very few video frames. However, a passing Tesla captured essential video evidence that allowed for a substantive analysis of the incident.

Analyzing the Tesla's forward camera video revealed the motorcycle entered the intersection three blocks from impact at approximately 37 mph. A combined analysis using the surveillance and the onboard videos determined the motorcycle's time to impact was approximately 5.1 seconds. The distance from the green light intersection to impact was approximately 436 feet. Therefore, the motorcycle's impact speed of approximately 79 mph was more than twice the 85th-percentile speed.

The SUV driver testified they observed the signal light turn green, and estimated there was sufficient time to safely cross. However, the motorcycle approaching high speed was not anticipated, and efforts to avoid the impact were unsuccessful. After a trial lasting approximately six weeks, the SUV driver was acquitted of all charges.

G24 An Argentine Prosecutor's Death: Ten Years of Impunity—The Prosecutor's Report 2025.

Maria S. Ciruzzi, PhD, St Jude Children's Research Hospital, Memphis, TN*

Learning Objectives: After this presentation, attendees will: (1) have a glimpse of the Argentine legal system and be able to appreciate the difficulties that the interaction between incompetence, disdain, and willful ignorance play in criminal proceedings with high political impact, especially in Latin America; (2) assess the importance of ethics and professionalism in forensics; and (3) approach the need for independence and expertise in the judiciary.

Impact Statement: This presentation will impact the forensic and social community by showing key aspects of the prosecution office to straighten out and get back on track a judicial process plagued by irregularities, with the goal of delivering justice, even after ten years, and disproving the very Argentine saying: "When time goes by, truth flees, and justice is lost."

Abstract Text: On January 18, 2015, late at night, Dr. Alberto Nisman, federal prosecutor in charge of the Unit for the Investigation of Terrorist Attack at the AMIA Institution, was found dead at his luxury home, in Buenos Aires City, with a gunshot wound to the head. Four days before, he had filled a complaint against Argentine President, her Minister of Foreign Affairs, two other minor political partners of the ruling party and an ex-spy from the National Intelligence Agency, accusing them of conspiring to cover up the AMIA terrorist attack. The next day, Monday 19, he was expected to appear before Parliament to reveal the evidence regarding his accusation.

The AMIA bombing was a terrorist attack against one of the main Jewish institutions in Argentina, on July 18, 1994; 85 people were dead and more than 300 injured. It was one of the most major attacks against Jews from Second World War.

The Argentine Jewish Community is the biggest in Latin America and fifth in the world.

Dr. Nisman was the federal prosecutor in charge of the AMIA terrorist attack investigation. On October 25, 2006, Argentine's Court, on behalf of Dr. Nisman's prosecution, accused Iranian government of being the mastermind behind the attack and Hezbollah of being the perpetrator.

Just days before the tenth anniversary of federal prosecutor Natalio Alberto Nisman being found shot in the head in the bathroom of his rented apartment in the Buenos Aires neighborhood of Puerto Madero, the Third Federal Criminal and Correctional Prosecutor's Office released a detailed report on the investigation, confirming that the representative of the Public Prosecutor's Office was murdered for his work at the UFI-AMIA and, in particular, for his investigation and complaints regarding the Memorandum of Understanding with the Islamic Republic of Iran, signed by the then President of Argentina, Cristina Fernandez de Kirchner.

The "Report Investigation Case No. 3559: homicide of federal prosecutor Natalio Alberto Nisman," consists of 52 pages in which the prosecutor's office led by federal prosecutor Eduardo Taiano, with the intervention of assistant prosecutor Hernán Kleiman, makes a detailed review of the decade that the investigation has been going on, the measures adopted since its beginning in the national criminal and correctional jurisdiction and those that have been carried out since the case was filed in the federal jurisdiction in 2016, with the investigation delegated to his prosecutor's office.[1]

The crime scene was contaminated and badly preserved: people walked barefooted; hands touching all around without gloves; the gun was cleaned at the scene with toilet paper; the Secretary for Security –head of the police officers acting as Nisman`s bodyguards- had been at the scene long before the judge and the prosecutor on duty arrived at the scene, among other irregularities mentioned in this report.

We will discuss at the presentation the findings from the prosecution and how justice could be served after 10 years.

G25 Eyewitness Identification in Civil and Common Law Countries in the Perspective of Standardization and Internationalization of Criminal Proceedings

Dariusz Wilk, PhD, Jagiellonian University in Kraków, Kraków, Malopolskie, Poland*

Learning Objectives: After attending this presentation, attendees will understand the differences in legal basis of eyewitness identification rules in civil and common law countries, the importance of standardization of evidencing rules, and the main rules of eyewitness identification.

Impact Statement: This presentation will impact the forensic science community by informing attendees regarding the internationalization of forensic science evidence rules, the rules of remote eyewitness identification and cooperation of police authorities, and the minimum requirements for assessment of eyewitness evidence by judges or prosecutors.

Abstract Text: Eyewitness identification within physical, photo or video lineups is one of the important and frequently used ways to detect perpetrators. According to earlier studies this method of identification is assessed by Police officers and prosecutors as reliable, despite the low assessment of the scientific nature of the method. Eyewitness identification is also one of the main sources of errors in criminal justice.

The aim of research was to check the level of requirements for eyewitness identification in criminal procedure regulations in various countries around the world. Comparative legal analyses were conducted for several selected EU countries, as well as for UK, USA, Canada and Australia.

Research shows different approaches in Police lineups. The status of the activity also varies (as interview of witness, confrontation or as separate procedural activity). In common law countries standards have been developed through case law and they are specified in detailed guidelines (e.g., PACE D in the UK, guidelines of the National Institute of Justice in the USA). To minimize false indications a large minimum number of persons in identify parade is required and Police officers are obliged to give witnesses an appropriate instructions and cautions.

Only in selected civil law countries specific requirements for eyewitness identification have been given in criminal procedure codes (e.g., in Central and Eastern European countries, such as Poland, the Czech Republic and Croatia). In many countries Police lineups are not specified at all in criminal procedure codes (e.g., Germany, Netherlands, France, Belgium). The suspect's obligations to participate in identification procedures, in light of the principle of nemo se ipsum accusare tenetur, are also defined differently in European countries.

In the context of tightening EU legal systems and needs of ensuring an appropriate level of credibility and reliability of evidence, such situation is not an optimal. Therefore, standardization of the evidence rules and implementation of minimum requirements for eyewitness identification in criminal procedure codes have been proposed for EU countries. The ability to conduct the eyewitness identification fully remotely may also important for international cases. Nevertheless, such an approach requires some technical resources and cooperation between law enforcement agencies.

G26 Practical Recommendations for Investigating Shifting Science in Post-Conviction Relief Cases

Terry-Dawn Hewitt, LLM, McKenna Hewitt, Denver, CO*

Learning Objectives: After attending this presentation, attendees will understand some of the inquiries that attorneys or their experts should consider when evaluating a case of "shifting science," (in which forensic evidence once thought to be credible has been brought into disrepute). This includes the factors that may assist in determining if or when a scientific consensus has been reached concerning the disputed forensic evidence.

Impact Statement: This presentation will impact the forensic science community by delivering practical recommendations for avenues of research that may shed light on when certain forensic evidence came into question and the extent to which the issue has been resolved by the relevant forensic discipline. It will also explain the role of voluntary consensus standards as evidence of shifting science and the relevance of standards in determining the extent to which the scientific community has achieved a general consensus on the issue. The information is presented in the context of post-conviction relief, but may also be relevant in challenging the admissibility of expert testimony (under FRE Rule 702, *Daubert*, or *Frye*).

Abstract Text: In 2024, the Supreme Court denied judicial review of a lower court's decision for Charles McCrory. McCrory sought relief from his 40-year old conviction for killing his wife. His conviction was based on forensic bite-mark testimony that has been totally discredited. In her statement respecting the Court's decision, Justice Sotomayor noted:

One in four people exonerated since 1989 were wrongfully convicted based on false or misleading forensic evidence introduced at their trials. Hundreds if not thousands of innocent people may currently be incarcerated despite a modern consensus that the central piece of evidence at their trials lacked any scientific basis.[1]

The McCrory case dealt with an Alabama statute that allows relief based on newly discovered material facts. Justice Sotomayor summarized problems that can arise when such a provision is applied to discredited forensic evidence, saying, "Unlike a murder weapon left in an abandoned warehouse, forensic science does not lie around waiting for sudden discovery."[2] She made the point that science can develop slowly and it can be difficult to determine when the defendant or their counsel should have discovered that faulty forensic evidence was presented by the prosecution at trial. A related issue not mentioned in this decision is that it can also be difficult to determine the point at which the relevant scientific community achieved a consensus that the forensic evidence at issue is unreliable.

McCrory and a growing body of legal publications deal with the legal issues in post-conviction litigation concerning "shifted science"—scientific evidence that was considered credible at the time of trial but is later determined to be unreliable.[3] Rather than addressing these legal issues, this presentation focuses how defense attorneys or their experts can investigate the details of when the relevant science changed and when the forensic practitioners in that discipline should or could have become aware of the changes.

This presentation will suggest inquiries to consider when faced with a case of shifted (or shifting) science. For example:

- The role of voluntary consensus standards developed by ANSI-accredited standards development organizations as evidence of shifted science and the relevance of such standards in evaluating the reliability of forensic evidence;
- The relationship between standards and general acceptance;
- Other factors that may provide evidence of whether a scientific consensus has been reached, including a literature review, positions taken by relevant forensic science associations, and trainings offered on the topic by leaders in the discipline.

Finally, we will suggest some strategies for analyzing and presenting the evidence of the shifted science including the creation of a detailed timeline. We will draw our examples from the fire investigation field, but attendees concerned with other forensic disciplines can apply similar techniques. Although this presentation is set in the context of post-conviction relief, this information may be beneficial at the trial stage in challenging the admissibility of testimony by prosecution experts.

G27 Forensic Testimony Errors in a Death Penalty Case: Lessons for Science, Law, and Justice

Tiffany A. Roy, JD, MSFS, ForensicAid, LLC, Singer Island, FL*

Learning Objectives: The goals of this presentation are to:

- Recognize the heightened legal and ethical standards in death penalty cases
- Appreciate the irreversible consequences of errors when the ultimate penalty is at stake
- Distinguish between overstated, misstated, and unsupported forensic opinions
- Understand how flawed scientific reasoning, methodological weaknesses, or miscommunication can lead to inaccurate testimony
- Examine the specific forensic testimony errors that occurred in the case
- Understand how these errors influenced the prosecution's theory, defense strategy, and trial outcome
- Review how errors were identified, challenged, and addressed in court
- Understand the role of appellate review, post-conviction relief, and innocence investigations in death penalty cases
- Understand the duty to provide objective, scientifically valid testimony regardless of which side calls you
- Recognize the responsibility to correct or clarify erroneous testimony if discovered after trial
- Apply quality assurance, peer review, and pre-trial preparation to reduce the risk of misstatements
- Use clear, precise, and legally appropriate language to ensure accurate communication of findings
- Understand how forensic errors can contribute to wrongful convictions in capital cases
- Discuss the role of collaboration between forensic scientists, attorneys, and courts in safeguarding due process

Impact Statement: This presentation addresses one of the most critical intersections of science and law—the use of forensic testimony in death penalty cases. By examining a real-world example where flawed forensic opinions were identified by the laboratory themselves, this session underscores the life-or-death consequences of scientific error in the courtroom. Attendees will gain practical strategies to avoid overstatement, strengthen the accuracy of their testimony, and fulfill their ethical obligations when operating under the highest stakes in the justice system. The lessons from this case extend beyond capital litigation, offering guidance for all forensic practitioners on safeguarding the integrity of their work, maintaining public trust in forensic science, and preventing miscarriages of justice. Ultimately, the insights shared in this presentation will equip participants to be more vigilant, more precise, and more collaborative in protecting the fairness and accuracy of the legal process.

Abstract Text: Gerald Delane Murray has been on Florida's Death Row for 30 years. He has been tried a total of four times and in his final trial, the single piece of physical evidence presented to the jury was overstated microscopic hair testimony that has since been identified by the Microscopic Hair Analysis Review team as "exceeding the limits of science and are therefore invalid." This presentation examines Murray's case—including the opinions provided— and explores how these errors were ultimately identified and addressed by the laboratory, case analyst and Florida state court system.

By reviewing the statements made in Murray's case, investigation documents and court rulings, participants will learn how the forensic science quality structure and the criminal justice system deal with error once it has been identified. The presentation will also address the heightened ethical obligations of forensic scientists in death penalty cases, the critical role of peer review and quality control, and strategies for providing precise, scientifically valid opinions under adversarial questioning.

By the end of the session, participants will:

- Understand how forensic testimony errors can arise and affect death penalty trials
- Recognize the legal and ethical responsibilities of forensic scientists and justice partners in capital cases
- Apply best practices to ensure accurate, reliable, and admissible testimony in high-stakes proceedings

This session is designed for forensic scientists, attorneys, and justice system stakeholders seeking to strengthen the reliability of forensic evidence in the most consequential cases.

G28 The Future Involves Going Back to the Basics: Post-Conviction Cases That Recognize Wrongful Convictions Arise From Subsequently Discredited Science Also Suggest a Need to Examine Fundamentals

Jane Eggers, JD, MSSW, The Forensic Project Austin, TX; Christen Chipman, MSc*, The Forensic Project, Austin, TX*

Learning Objectives: Participants will learn how wrongful convictions may arise from the use of discredited methods and may also arise from fundamental issues within a lab or with the evidence before it is tested. These fundamental issues include, for example, problems with the relevancy and the scientific integrity of the evidence, insufficient documentation of the handling and testing of the evidence, and the State's failure to disclose material records. The speakers will also discuss positive legal and policy changes implemented in Texas and other states to address forensic science issues.

Impact Statement: Participants will share and learn about ways in which professionals in law and science can collaboratively work to prevent erroneous forensic science evidence from continuing to be a basis of wrongful convictions.

Abstract Text: Texas Code of Criminal Procedure Article 11.073—the first changed-science, post-conviction statute in the nation—is a forward-looking law that critically recognizes what scientists have long known to be true: our understanding of what constitutes reliable science has changed and will change. Speakers Jane Eggers and Christen Chipman have participated in the review of hundreds of Texas cases involving DNA mixture evidence that were analyzed by a now-shuttered DNA lab.[1] They have also been the lead attorney and forensic investigator in cases where their wrongfully convicted clients received Article 11.073 relief. Through this work, they have learned that wrongful convictions may arise from the use of outdated scientific methods but may also arise from fundamental issues with lab processes and the evidence before it is tested.[2]

Attending this session will give participants a sense of these fundamental issues, such as problems with the relevancy and the scientific integrity of the evidence, insufficient documentation of the handling and testing of the evidence, and the State's failure to disclose material records.[3-5] The speakers will discuss positive legal and policy changes implemented in Texas and other states to address fundamental forensic science issues. The speakers will conclude with a discussion on ways in which professionals in law and science can collaboratively work to prevent erroneous forensic science evidence from continuing to be a basis of wrongful convictions.[6]

G29 The "Past" Under Investigation: New Investigative Methodologies at Crime Scenes and Their Impact on "Definitive" Criminal Trials in Italy

Wanda Nocerino, PhD, Department of Social Sciences, University of Foggia, Foggia, Italy; Angela Procaccino, PhD, Associate Professor, University of Foggia, Fogia, Italy; Guido Colaiacovo, PhD, University of Foggia, Foggia, Italy; Stefania De Simone, PhD, University of Foggia, Foggia, Italy; Alessandro Valenti, PhD, University of Foggia, Foggia, Italy; Christian Pallante, University of Foggia, Foggia, Italy*

Learning Objectives: By engaging with this content, participants will be able to: (1) understand the role of forensic science in the justice system. Gain insight into how forensic science contributes to criminal investigations and legal proceedings, especially in high-profile cases that attract media and public attention; (2) explore the impact of technological innovation on criminal evidence. Learn how recent scientific and technological advancements have made it possible to reexamine physical evidence from past cases—sometimes decades later—leading to new investigative leads or even the reopening of trials once considered closed; (3) reflect on the relationship between law and science. Discuss how legal systems can and should evolve in response to new scientific tools and methods while safeguarding fundamental legal principles such as due process and legal certainty; (4) analyze key case studies: Garlasco and Erba. Examine two emblematic Italian cold cases to understand how modern forensic techniques—such as advanced fingerprint and DNA analysis—have challenged or complemented earlier conclusions, revealing both the strengths and limitations of these methods; (5) deepen understanding of "truth" in legal contexts. Reflect on the concepts of historical truth versus procedural truth and how forensic science can help bridge the gap between what actually happened and what is proven in court; and (6) become familiar with current academic developments in investigative sciences in Italy. Learn about the University of Foggia's pioneering role as the only institution in Italy currently offering a specialized degree in Investigative Sciences, highlighting the growing academic focus on the intersection of law, science, and criminal investigation.

Impact Statement: This presentation aims to make a meaningful contribution to the forensic science community by fostering an interdisciplinary dialog among forensic scientists, legal professionals, and scholars of criminal procedure. Through the in-depth examination of real-world cases—such as the Garlasco murder and the Erba massacre—it will demonstrate how advances in forensic methodologies can radically reshape the interpretation of evidence, opening investigative and legal avenues that were previously considered closed.

The presentation highlights the growing need for continuous technical and legal training, emphasizing the importance of specialized education and a multidisciplinary approach to forensic practice. It will encourage professionals to critically reflect on the challenges and responsibilities that come with integrating scientific innovation into judicial processes. Moreover, the presentation seeks to raise awareness within the forensic science community about the urgent need to develop legal and procedural frameworks that can keep pace with scientific progress—without compromising the core principles of fairness, due process, and legal certainty. Ultimately, this work aspires to strengthen the understanding of how forensic science not only plays a key role in reopening cold cases, but also contributes to the credibility, transparency, and evolution of the justice system as a whole. In doing so, it hopes to inspire more rigorous practices, deeper critical thinking, and forward-looking policy in both national and international forensic contexts.

Abstract Text: Forensic science plays an increasingly critical role in modern justice systems, particularly in high-profile criminal cases that attract public and media attention. In recent years, technological progress has introduced new investigative tools that allow for the reexamination of physical evidence and traces, even in cases previously deemed closed.[1,2] This shift challenges both forensic experts and legal professionals to reconsider how scientific innovation can and should be integrated into judicial processes without undermining legal certainty or procedural fairness.[3-6]

This presentation explores the intersection between evolving forensic technologies and the legal frameworks that govern their application. It raises a central question: how can the law adapt to accommodate new scientific discoveries while upholding the foundational principles of due process and finality of judgments?

Two emblematic Italian cases—the Garlasco murder (2007) and the Erba massacre (2006)—serve as key case studies.

In the "Garlasco case" (2007), the advent of new methods for identifying comparison points in papillary fingerprints found (already at the time of the crime) on the crime scene has allowed, nearly twenty years later, new investigations to be conducted. The analysis of certain fingerprints and palm prints, previously unidentifiable with the methods available at the time, led to the identification of a new possible suspect thanks to a detailed comparison of specific characteristics.[7]

Similarly, in the "Erba massacre" (2006), the use of advanced forensic technologies has allowed the reexamination of some evidence collected at the crime scene that, with the tools available at the time, could not be analyzed with sufficient precision or were partially interpreted. Although, to date, there has been no official reopening of the investigation, the application of more sophisticated techniques has made it possible to identify new biological elements or confirm the presence of already known traces with greater certainty; perform more accurate comparisons of DNA samples, improving the reliability of the results; and verify the authenticity and chain of custody.[8]

The "Garlasco case" and the "Erba massacre" thus serve as paradigms of the challenge that Italian—and more broadly international—justice must face: integrating the advances of forensic science with a legal system capable of evolving to ensure trials that increasingly reflect the factual reality, even many years after the fact. The Italian (and international) legal system is called upon to recognize the validity of emerging new evidence and to define rules and procedures that allow the reopening of closed trials when significant scientific proof is presented, without compromising fundamental principles of fairness and due process.[9-11] Based on research conducted by the University of Foggia - currently the only academic institution in Italy offering a specialized degree in Investigative Sciences - this abstract underlines the urgent need to build flexible and robust normative and procedural instruments capable of reconciling scientific innovation with the principles of a "fair trial" (above all, legal certainty), in order to ensure the achievement of a truth that is a just synthesis between historical truth and procedural truth.

G30 Borrowing From Bioethics: Lessons for Forensic Science on Disclosure, Correction, and Privacy

Sarah Chu, PhD, Perlmutter Center for Legal Justice at Cardozo Law, New York, NY*

Learning Objectives: Attendees will learn how core bioethics principles—autonomy, beneficence, non-maleficence, and justice—can guide forensic science practices related to the disclosure of errors, privacy, and transparency. The presentation will offer a framework for adapting medical ethics norms to forensic science to improve public trust, provide safety for practitioner accountability, and ethical governance.

Impact Statement: This presentation will enhance the forensic science ecosystem's ability to develop ethically sound policies for disclosure and notification when errors or changes in science occur and understand privacy considerations for data-based applications. By applying bioethics-informed approaches, forensic professionals can enhance public safety through improving institutional performance and strengthening the integrity of the forensic process.

Abstract Text: As forensic science increasingly contends with issues of transparency, accountability, and public trust, it must confront urgent ethical questions about how to manage sensitive information and implement both current and emerging technologies in a just and equitable manner. Existing legal and regulatory frameworks often fall short in providing comprehensive ethical guidance. This presentation proposes that the forensic science ecosystem draws from the field of bioethics to cultivate and sustain the trust essential to its scientific and societal legitimacy.

Bioethics has long guided practices in medicine and public health related to error disclosure, patient notification, and informed consent. These principles provide a roadmap for developing similar practices in the application of forensic science in the criminal legal system. For example, the medical ethic of respecting individual autonomy can inform the obligation to inform justice-involved individuals when flawed or unreliable evidence may have contributed to a conviction. Similarly, the balance between beneficence and privacy in medicine can inform policies regarding data sharing and the use of genetic or other biometric information in forensic investigations.

By translating medical ethics norms into forensic contexts, this presentation offers values-based guidance for practitioners, laboratory directors, legal stakeholders, and policymakers. It argues that adopting a bioethics-informed framework can enhance transparency, minimize harm, and reinforce the legitimacy of forensic science.

As the field of forensic science continues to grow and as courts confront the ethical implications of evolving forensic technologies, grounding forensic practice in ethical fundamentals is essential. Drawing on bioethics can help build a more accountable, trustworthy, and person-centered forensic science system.[1-5]

G31 The Anatomy of a Forensic Trace Evidence Case Review

Christopher S. Palenik, PhD, Microtrace LLC, Elgin, IL*

Learning Objectives: This presentation is intended for forensic stakeholders, including attorneys on both sides of the court, judges, and forensic scientists. Through examples from several decades of case reviews, spanning a variety of trace evidence, this presentation will discuss the way in which each aspect of a forensic analysis, from sample collection through testimony, can impact the presented message. This presentation will also illustrate the importance of a complete discovery packet and the way in which seemingly minute details can have a significant impact on the message conveyed to our stakeholders.

Impact Statement: It is anticipated that this analysis will help to bridge trace evidence and the legal system it supports by providing information about the ways in which each aspect of a forensic analysis, including seemingly minor details, can impact the conveyed message.

Abstract Text: Details are the currency of a forensic scientist. Each stage of the forensic process, from evidence collection and preparation to analysis, interpretation, and testimony, is based upon detail and expert judgement. These decisions and results at each stage of the process are synthesized to address a hypothesis and then conveyed to audiences with varying perspectives and levels of knowledge (e.g., attorneys, judges, juries, and other experts).

At the heart of this process, a typical crime laboratory report reduces a wealth of details into one or two sentences selected from a preapproved list of boilerplate statements. While designed to provide a conservative, consistent result, this form of reduction seen in many forensic reports has the potential to: (1) *reduce transparency* through its lack of detail (e.g., the strengths and limitations of a particular method of analysis or comparison are lost), (2) *limit relevance* of a scientific result by remaining agnostic to the context of a case (e.g., the context of a collected soil sample may render it entirely unsuitable for the requested analysis, but without explanation, the attorneys have no way to interpret the (in)significance of the results), and (3) *encourage speculation* when case-specific significance is considered in court (e.g., discussions of transfer and persistence, which may be scientifically accessible questions that were never formally considered during the analysis, reporting, and internal review process).

Many reviews are triggered post-conviction as a result of flagged or concerning testimony statements. However, when delving deeper into such reviews, the details of each step in the forensic process: (1) sample selection and preparation, (2) method selection and data collection parameters, (3) data, (4) interpretation, (5) reporting, and (6) testimony have the potential to significantly impact the final message conveyed to a jury. Many, if not most, of these details are not reviewable without more detailed discovery information. As such, a forensic case review, should ideally review each step of this process, both individually and within the context of the overall case. Of course, this can depend on the extent of discovery material produced.

This presentation will address: (1) the types of information and extent of data that may be relevant to a review and could be requested through discovery, (2) examples of observations at each of these steps that have the potential to impact the proffered conclusions, and (3) ways in which reanalysis or further analyses could address some of the issues that a document review may bring to light. Illustrative examples stemming from numerous case studies will be drawn from decades of experience spanning diverse evidence types (e.g., fibers, gunshot residue, soil, paint, explosives, tape, hair), offenses, and jurisdictions.

Case Review; Expert Testimony; Trace Evidence

G32 Beyond the Lab Coat: Understanding ISO 21043's Reach

Dana Delger, JD, Self Employed, Sundbyberg, Stockholms Lan, Sweden; John Paul Jones, II, MBA*, National Institute of Standards and Technology, Gaithersburg, MD*

Learning Objectives: Attendees at this session will learn about the International Organization for Standardization (ISO) 21043, a critical new forensic science standard series published by ISO in June 2025.[1] Both practitioners and non-practitioner stakeholders, particularly lawyers, will gain an understanding of these new standards; how they can affect and improve practice in the lab; and how they might be interpreted and applied by courts.

Impact Statement: This presentation will impact the forensic science community by introducing it to important new ISO standards that are likely to shape forensic practice significantly over the coming years. Both forensic science practitioners and legal stakeholders will learn what these standards are and how they can be used to improve forensic practice.

Abstract Text: Most forensic science practitioners and other stakeholders are very familiar with International Organization for Standardization (ISO)/International Electrotechnical Commission (IEC) 17025:2017 *General requirements for the competence of testing and calibration laboratories* and ISO/IEC 17020:2012 *Conformity assessment Requirements for the operation of various types of bodies performing inspection*, the two major voluntary accreditation standards used by crime laboratories across the United States. But a new ISO standard, ISO 21043 Forensic Sciences (Parts 1-5), for forensics has been published, and understanding what it is and how to use it will be critical for practitioners and non-practitioners alike in continuing the quest to improve forensic science.

This presentation will introduce ISO 21043 and its component parts. It will highlight particular areas of interest, especially the standard's discussions of observations, interpretations, and opinions. This presentation will emphasize where these considerations diverge from the current American practice. To that end, the presentation will also discuss how ISO 21043 may fit into the broader voluntary accreditation and standards implementation scheme already widely in use in the United States.

The presentation will also seek to offer some insight into how legal stakeholders and courts are likely to understand ISO 21043 as it comes into implementation. Through consideration of how other voluntary standards have been applied by courts, both historically and over the last year, this presentation will seek to forecast how ISO 21043 and its component parts may come to be applied, considered, or litigated in American courts.

ISO 21043 is a critical new forensic science standards series with the potential to improve the quality of forensic practice both internationally and in the United States. Attendance at this program will help prepare practitioners and stakeholders to use and understand this important content.

G33 Back to Basics: *Daubert*, Abusive Head Trauma, and Pediatric Short Falls

Kathleen Pakes, APM, Wisconsin State Public Defender, Madison, WI*

Learning Objectives: Using the context of a pediatric short fall case, attendees will gain an understanding of how to analyze and challenge a forensic medicine opinion using a *Daubert* (or *Frye*) analysis. This presentation will review basic *Daubert/Frye* topics such as peer review, relevant scientific community, how to read scientific literature, and the role of training and experience as a basis for reliability. Within the context of abuse vs. accident, attendees will learn how to dissect clinical methodology (differential diagnosis) and assess reliability of forensic opinion with an eye toward subjectivity, bias, and error. This session will also review case law related to the admissibility of biomechanical expert opinion when the theory of injury (general causation) is biomechanical exposure. Attendees will also gain knowledge of the pediatric short fall literature.

Impact Statement: This presentation will provide lawyers (defense or prosecution) who handle forensic medicine cases (abuse or homicide) with the tools needed to evaluate medical-based diagnoses within the legal context and develop expert testimony and reliability challenges.

Abstract Text: Using the context of a pediatric short fall case, attendees will gain an understanding of how to analyze and/or challenge a forensic medicine opinion using a *Daubert* (or *Frye*) analysis. This presentation is from a jurisprudence perspective, and will address topics such as the meaning of peer review for *Daubert* analysis, the relevant scientific communities for a short fall case, how to read scientific literature for lawyers, and assessing an expert's training and experience as a basis for reliability.

Within the context of abuse v. accident, attendees will learn how to dissect clinical methodology (the differential diagnosis) and identify theories of general causation. This presentation will discuss caselaw related to clinical decision making, and how the analytical gap between general causation theory and specific causation in an individual case must be reliability bridged for admissibility purposes.

Attendees will learn to assess forensic opinion with an eye towards those places in the methodology where subjectivity, bias, and error can affect the reliability, and admissibility, of the ultimate opinion.

This session will also review the basics of biomechanical analysis, and review caselaw related to the admissibility of biomechanical expert opinion when the theory of injury (general causation) is biomechanical exposure.

Attendees will also gain basic knowledge of the pediatric short fall medical literature, including witnessed and recorded cases of short falls leading to serious injury and/or death, and end with discussion of the limitations of expert testimony when a short fall cannot be ruled out.

H1 3D Palatal Rugae Superimposition for Human Identification

Andrea Pase, DDS, Private Dental Clinic, Farra di Soligo, Veneto, Italy; Zecca Piero Antonio, DDS, University of Insubria, Varese, Lombardia, Italy; Emanuele Paoletto, Laboratory Orthodmodul, Sandrigo, Veneto, Italy; Mario Torreggianti, MSc, University of Turin, Teramo, Abruzzi, Italy; Marco Brady Bucci, DDS, Italian Academy of Forensic and Legal Dentistry, La Spezia, Liguria, Italy; Emilio Nuzzolese, PhD, University of Turin, Turin, Piemonte, Italy*

Learning Objectives: Attendees will gain an understanding of the methodology and significance behind using 3D scanning technology to analyze palatal rugae patterns and a novel superimposition method for individual identification.

Impact Statement: The presentation aims to significantly impact the forensic science community by introducing a cutting-edge approach utilizing 3D scanning technology and innovative superimposition methods for individual identification based on palatal rugae analysis. By sharing these insights, the presentation seeks to contribute to the continuous evolution and advancement of forensic odontology practices.

Background: Dentition and palatal rugae have been established as reliable and stable identifiers for individual identification in forensic odontology. This study aimed to introduce an innovative superimposition method for human identification based on palatal rugae using overlapping 3D scans of the palate.[1] In contrast to conventional methods utilizing dental casts, this research employed intraoral scanning technology for optical impressions with photogrammetry technology.[2,3]

Methods: The workflow was executed on a high-performance workstation featuring an Intel® Core™ i9-12900K processor, 64 GB of RAM, and an NVIDIA GeForce RTX 4080 graphics card. The digital dental models, available in stereolithography (.stl) file format for each patient at T1 and T2, were imported into the reverse-engineering software Geomagic® Wrap™ 2021. A preliminary registration was performed to establish a common coordinate system and achieve a coarse alignment between the T1 (reference) and T2 (test) models. A specific Region of Interest (ROI) was isolated from the full digital models to standardize the analysis and reduce confounding variables. A multi-step cropping procedure delineated anatomically precise palatal segments for each patient. The isolated T1 and T2 ROI segments underwent a high-precision, automated registration within Geomagic® Wrap™ 2021 using an Iterative Closest Point (ICP) algorithm.[4] The aligned models were then exported for quantitative analysis in CloudCompare. In CloudCompare, a final registration was conducted using the built-in ICP algorithm with a convergence criterion set for a root mean square (RMS) error. The point-to-point distance between the T1 reference surface and the T2 test surface was calculated, generating a dataset of 3D displacements.

Results: The method enabled accurate superimposition of palatal rugae with RMS errors consistently below 0.27 mm.

Conclusion: The study effectively demonstrated the method's accuracy in individual identification through the superimposition of 3D palatal rugae scans and the utilization of intraoral scanners in dental autopsies.[4-6] This research highlights the potential of employing 3D palatal rugae scans as a significant supplementary method for human identification in preserved human remains, reaffirming the strong connection between patients' dental digital records and human identification requirements, as well as the possibilities of a digital dental database of intraoral dental scans.

H2 The Cayor Atlas: A Black Senegalese Dental Atlas for Permanent Tooth Formation

Sankoung Soumboundou, MD, PhD, Cheikh Anta Diop University, Dakar, Dakar, Senegal; Christophe Bou, PhD, University of Bordeaux, Bordeaux, Aquitaine, France; Mamadou Lamine Ndiaye, PhD, University Cheikh Anta Diop, Dakar, Dakar, Senegal; Papa Abdou Lecor, PhD, University Cheikh Anta Diop, Dakar, Dakar, Senegal; Babacar Toure, PhD, University Cheikh Anta Diop, Dakar, Dakar, Senegal*

Learning Objectives: In this study, we highlight the influence of this factor on tooth formation. The results of the study show a significant difference in tooth maturation sequences. These results are important to consider in light of migratory phenomena. West African melanoderm subjects have a different maturation pattern than South African and Asian subjects.

Impact Statement: For the scientific community, this work brings something new to age estimation methods. By applying this atlas to other populations, it will be possible to highlight the role of many factors that have been found to influence tooth formation.

Abstract Text: **Introduction:** Many aspects of tooth development have been documented, particularly in Caucasian populations. However, dental development has not been extensively studied in West Africa.

Objective: The present study was designed to provide information on the sequences of tooth calcification in West African Black Senegalese children and to compare the results with those of other populations, notably the London Atlas.

Methods: A total of 556 orthopantomograms (OPGs) from 289 males and 266 females with a mean age of 11.34±3.84 years were analyzed. Demirjian A-H staging was applied to record the stages of tooth development. Tables of tooth development stages for each tooth were generated separately for age cohorts and by sex. The most common stage of tooth formation (modal) was the characteristic age stage of development. Differences between boys and girls and between maxillary and mandibular teeth were also analyzed using chi-squares. Accuracy was assessed by comparing the age estimated by the Dental Development Atlas for this population (Cayor Atlas) and the London Atlas tooth with chronological age using the Bland–Altman test.[1]

Results: There was no significant difference in tooth development between girls and boys, $p>0.05$. Maxillary teeth had similar dental development to mandibular teeth, $p>0.05$. The Pearson correlation test showed a strong correlation between chronological age and the age estimated by the Cayor atlas, $p< 0.001$. The Bland–Altman test also showed greater accuracy than the London Atlas.

Conclusion: These results show dental calcification sequences different from those of the London Atlas Tooth and the Witts Atlas (Atlas of Black South African Subjects).

H3 The Effects of Orthodontic Treatments on Palatoscopy

Mehmet Ali Kılıçarslan, PhD, Ankara University, Ankara, Ankara, Turkey; Ersungül Er, PhD, Ankara University, Ankara, Ankara, Turkey; Merve Berika Kadıoğlu, PhD, Ankara University, Ankara, Ankara, Turkey; Kaan Orhan, PhD, Ankara University, Ankara, Ankara, Turkey*

Learning Objectives: This study provides a brief description of the interaction between orthodontic treatments and rugae changes. Learning objectives include the effect of jaw expansion. The learning objectives help attendees understand forensic dentistry.

Impact Statement: Forensic dentistry and its field, palatoscopy, play a crucial role in forensic science. This study presents the impact of routine dental treatments on criminalistics. For this purpose, the effect of orthodontic treatments on rugae is presented.

Abstract Text: This study aimed to determine in three dimensions the changes in the palatal rugae morphology of patients who underwent maxillary expansion treatment. Between the ages of eight and 28 individuals were included in the study who have not received orthodontic treatment before, had a posterior crossbite, do not have habits such as tongue thrusting or thumb sucking, do not have any pathology in the palatal rugae area and whose pre- and post-treatment plaster models are of good quality, who receive treatment with and/or without extraction. Three groups were formed from the patients who met the inclusion conditions in the study: those who received rapid maxillary expansion treatment (group 1), slow maxillary expansion treatment (2nd group), and fixed orthodontic treatment (3rd group). Fast and slow orthodontic expansion treatment represents the experimental group, and fixed orthodontic treatment represents the control group. 24 patients who had RPE treatment, 22 patients who had SME treatment, and 18 patients who had fixed orthodontic treatment were included in the study. Plaster models of patients who underwent rapid and slow maxillary expansion treatment and fixed orthodontic treatment were scanned with an extraoral model scanner (Sirona inEos X5, Dentsply Sirona, Bensheim, Germany), and a digital model was created and STL saved in format. The produced STL files were transferred to Mimics (Materialize Mimics Innovation Suite 23, 3-matic Version Medical 17, Materialize) software. Rugae were classified according to Lysell's palatal rugae classification method; It was named as the first ruga at the front, the second ruga, and the third rugae at the back. Upper jaw palatal rugae anteroposterior points, transverse points, angular angle measurement points, palatal area, and volume points were marked. The plaster models taken at the beginning of the treatment (pre-expansion) were recorded as T1, and the plaster models taken at the end of the treatment (post-expansion) were recorded as T2. In patients who undergo expansion treatments, the anterior and mesial rugae are not stable in the anteroposterior direction. In patients who receive fixed orthodontic treatment, the 2nd-3rd. Rugae region and distal endpoints in general are not safe in terms of stability. In the RPE and SME groups, the largest change in transverse-1 and transverse-2 measurements was measured in the 1st Ruga. The stability of the mesial endpoints in the anteroposterior-1, anteroposterior-2, and transverse-1 directions of the control group receiving fixed orthodontic treatment is safer. In the control group, the greatest change in transverse-1 and transverse-2 measurements was measured in the 3rd ruga. According to the results we obtained in the study at the control group the 1st Ruga was found to be more stable in the anteroposterior and transverse planes.

It was concluded that the findings we obtained as a result of this thesis study will be guiding for the changes that can be seen in the palatal rugae region with palatal treatments performed in our society. Accordingly, it is thought that maxillary expansion treatments and fixed orthodontic treatment will cause changes in the palatal rugae area and will not be reliable.

H4 The Tooth, the Whole Tooth, and Nothing But the Tooth: Forensic Odontology in Car Fire Victim Identification

Howard I. Cooper, DDS, DMORT, Antioch, IL*

Learning Objectives: Bodies exposed to extreme thermal exposure, such as fire, can be difficult to identify. This is due to the thermal damage of the organic material and the alteration, by incineration, of the physical structures. Dental evidence, although altered, can generally be discovered, even in high heat environments. After attending this poster presentation, attendees will understand the painstaking process of locating teeth and associated dental restorations from an incinerated car and how they are used by a forensic odontologist to identify the victim found in the car.

Impact Statement: This presentation will impact the forensic science community by describing and teaching the key aspects of victim identification after a car fire using teeth and associated oral and maxillofacial structures. This presentation will also show the importance of collaboration with first responders, especially in evidence collection, which will promote accurate and efficient victim identification.

Abstract Text: Teeth, and associated oral and maxillofacial structures, have long been used to identify victims, as a validated scientific method, in conjunction with other established identification modalities. The evidence used in other scientific modalities may be destroyed, or rendered unusable, by thermal damage. Teeth, along with supporting structures and restorative materials, can retain their identifiable characteristics, despite advanced thermal trauma. After a body has been incinerated, teeth may be the fastest, and most efficient, means of victim identification.

Once the body has been transported to the Coroner's office, the car is brought to a secure, controlled location and the thorough and important process of teeth, supporting structures, and restorative material collection begins. Investigators from the Coroner's office collaborate with the forensic odontologist to confirm the items collected are indeed dental related. Without teeth, supporting structures, and/or the associated restorative materials, dental based victim identification may not be completed.

After a car fire, teeth, supporting structures, and the associated restorative materials may be difficult to locate, but once recovered, a postmortem profile of the victim can be established. Dental records of the presumed victim can be obtained and used, along with the postmortem dental evidence, for comparative dental analysis by the forensic odontologist. The forensic odontologist may then be able to accurately, and efficiently, identify the victim and bring closure to family members, in a relatively short amount of time.

H5 The Maura Murray Cold Case: Revisiting Dental Charting for New Leads

Grace Chung, DDS, Clark County Office of the Coroner Medical Examiner, Henderson, NV*

Learning Objectives: Using the cold case of Maura Murray, this presentation will explore how evolving practices in forensic dental charting can influence the scope of potential matches in missing persons investigations. The initial charting was completed in the early 2000s, and since then, we've come to understand that how we think—and how we chart—can significantly impact case outcomes. The current best practice emphasizes charting conservatively for missing persons and more aggressively for unidentified remains. This session will also review basic dental charting principles to help attendees apply these strategies effectively.

Impact Statement: This presentation highlights the critical role that dental charting practices play in the identification of missing persons, using the cold case of Maura Murray as a focal point. By revisiting older cases with modern forensic insight, we demonstrate how subtle shifts in documentation—such as adopting conservative charting for missing persons and aggressive charting for unidentified remains—can significantly expand the pool of potential matches. This approach not only improves the accuracy of national databases like the National Crime Information Center (NCIC) and National Missing and Unidentified Persons System (NamUs) but also reinforces the value of ongoing re-evaluation in long-term unresolved cases. The session aims to empower forensic professionals with practical strategies that may ultimately lead to long-awaited identifications and closure for families.

Abstract Text: In 2004, Maura Murray went missing after a single-vehicle crash on a rural road in Haverhill, NH. Despite national attention and ongoing efforts by law enforcement and her family, Maura remains missing more than two decades later. As part of a recent review of her case, I examined the dental charting submitted to NCIC and NamUs. While the original charting is appropriate and within acceptable forensic standards at the time, advances in our understanding of dental identification strategies have since emerged.

Specifically, today's best practices suggest charting missing persons cases conservatively—for example, marking missing teeth as "V" rather than definitive extractions—and using more aggressive charting approaches for unidentified remains. This strategy helps maximize the possibility of generating potential matches, particularly in cold cases where older charting may inadvertently limit database search outcomes.

Recharting a case like Maura's, however, is not straightforward. Determining how to revise existing records in federal systems has been challenging, especially when original submissions were done by other professionals. This presentation will walk through the case, outline the charting concerns, and discuss the procedural hurdles encountered. By February, I hope to share practical guidance for navigating similar updates. Ultimately, this session encourages forensic odontologists to critically review their dental charting methods to help bring resolution to long-term missing persons cases.

H6 The 2007 Murder Case of Riley Ann Sawyers: A Forensic Triumph in Identification

Jeanne C. Geer, DDS, Fort Bend County Medical Examiner's Office, Richmond, TX*

Learning Objectives: Attendees will learn the importance of collaboration between our forensic disciplines. All of our disciplines, using scientific methods, must work together along with law enforcement to resolve cases.

Impact Statement: Collaboration between our forensic disciplines will lead to resolved criminal cases, providing both justice for the victim and closure for the surviving family members. Equally important is for our prosecutors to charge the guilty and punish them appropriately.

Abstract Text: The 2007 murder investigation of Riley Ann Sawyers, a 2-year-old child initially known only as "Baby Grace" after her severely decomposed remains were discovered by a fisherman in Galveston Bay, TX, highlights the indispensable role of interdisciplinary forensic science in resolving complex criminal cases. This presentation examines the collaborative scientific methods employed to establish the victim's identity and support the criminal investigation. Key forensic disciplines involved included DNA analysis by the FBI Laboratory, which confirmed identity through comparison with a familial reference sample; forensic anthropology by the Galveston County Medical Examiner's Office, providing critical estimates of age and sex; and a composite facial reconstruction by forensic artist Lois Gibson, whose sketch generated a vital tip from the victim's grandmother. Autopsy findings by Dr. Stephen Pustilnik revealed fatal blunt force trauma, while forensic odontologist, Dr. Peter Marsh, using dental radiographs, narrowed the estimated age of the victim, aiding in exclusion of unrelated missing persons cases.

Together, these coordinated efforts enabled law enforcement to identify Riley, secure convictions for her mother and stepfather in 2009, and deliver justice. This case exemplifies the profound impact of integrated forensic sciences in the identification of unknown remains and the pursuit of justice in homicide investigations.

Age Estimation; DNA; Murder

H7 Bitemarks—Vital Reaction, Permanent Injury, and Position of Biter

Richard R. Souviron, DDS, Miami Dade Medical Examiner Office, Coral Gables, FL*

Learning Objectives: The learning objective for the attendees is to realize the importance of bitemark evidence separate from attempts at matching or identifications. Vital reaction is present in a living victim but not in inanimate object (food such as cheese) or in cadavers.

Impact Statement: Medical examiners, the forensic odontologist, or the crime scene personnel needs to appreciate the importance of bitemarks in relation to the position of the biter vis-a-vis the victim. Examining the injury pattern, determining if it is a human bitemark, the position of the biter, and the effects of the vital reaction are important without any attempt at matching or comparison.

Abstract Text: This presentation will emphasize areas of bitemark analysis that deals with vital reaction, permanent injury and the biters position vis-a-vis the victim. Actual case presentation dealing with the importance of the vital reaction of the bitemark, and with no attempt at comparison to the biter. In addition to the bitemark inflicting pain, which is subjective, it is possible to produce a permanent injury. The formation of a scar or the loss of sensation due to nerve compression, may occur with a bite mark and can be considered a permanent injury. The position of the teeth (class characteristics) can be and often times are critical in determining the validity of statements by the victim (number one) that her bite was inflicted in self-defense while in a chokehold versus the statement by victim (number two) that the biter was the aggressor. Vital reaction occurs when an individual is alive and can be important in determining whether a bite was inflicted while the victim was alive or near the time of death. In cases where the bitemark is witnessed and can be documented as such, may lend validity to statements by the victim as to what occurred during the incident. It has proven to be an important piece of evidence, especially in cases where police were involved in the homicide. Laboratory-produced bitemarks on cadavers or inanimate objects such as cheese lacked the effects of vital reaction and are basically academic. However, bitemarks inflicted on living individuals (volunteers) demonstrate the effects of vital reaction and can be documented photographically and recorded over time. Even these experimental cases on living individuals with dental casts in a vice grip do not equate with the results of natural teeth inflicting the wound on a living individual.

This presentation will demonstrate experimental bites produced on living individuals (volunteers) and document the vital reaction both photographically and by the effect of time. The presentation will contrast the effects of the vital reaction and the volunteers versus actual cases with emphasis on the analysis of the injury and not attempting to match or compare to the biter. By determining the position of the teeth (class characteristics) to the wound, the odontologist may be able to opine as to the validity of the statement of the two individuals involved (the receiver and the deliverer of the bite).[1-4]

H8 Shaping the Future of Forensic Odontology Through Standardization

Kenneth Aschheim, DDS, Office of Chief Medical Examiner of the City of New York, New York, NY; Cristiana Palmela Pereira, PhD*, University of Lisbon, Lisboa, Lisboa, Portugal; Kathleen Ann Kasper, DDS*, Kathleen A Kasper DDS, Carrolltonj, TX; Lindsay Spears, DDS*, E37 Forensic Dental Consulting, Statesville, NC; Raymond G. Miller, DDS*, SUNY at Buffalo School of Dental Medicine, Tonawanda, NY; Phyllis Ho, DDS*, Office of the Suffolk County Medical Examiner, New York, NY; Richard Fixott, DDS*, Redmond, OR*

Learning Objectives: By the end of this presentation, attendees will have a clear understanding of both current and developing standards specific to the field of forensic odontology, along with the processes involved in creating, implementing, and approving these standards. They will gain a complete understanding of how, historically, the Organization of Scientific Area Committees (OSAC) for Forensic Science has collaborated with Standards Developing Organizations (SDOs). These include the American Dental Association Standards Committee on Dental Informatics (ADASB), the Academy Standards Board (ASB), and international partners such as the International Standards Organization (ISO). Due to funding changes, this collaboration will shift in structure; however, moving forward, these SDOs will continue to work together to update existing standards, develop new guidelines, and promote global alignment to ensure the field remains current, scientifically sound, and responsive to emerging challenges. This session will take a more in-depth look at published standards, proposed documents, and in-development work products relevant to forensic odontology, including those addressing terminology, photographic documentation, education and training, human identification, and suspected abuse reporting. By taking part in this presentation, forensic professionals will be better equipped to implement, assess, and actively contribute to the advancement of standards in forensic odontology.

Impact Statement: This presentation will have a meaningful impact on the forensic odontology community by increasing awareness and encouraging adoption of existing and emerging forensic odontology standards. It will help practitioners stay informed about both current and proposed standards, understand the contributions of key organizations like OSAC, ASB, ADA, and ISO, and engage more fully in conversations about best practices. The content will encourage the use of consistent, evidence-based approaches, promote standardized education, and aid in compliance across various institutions. In the long term, this session will help enhance the reliability and scientific foundation of forensic odontology, reinforcing its credibility.

Abstract Text: Forensic odontology practices are rapidly advancing through joint efforts to establish standardized procedures both in the United States and internationally. These standards are critical for ensuring consistency, accuracy, and reliability in forensic dental examinations. This presentation will provide an overview of the current state of the standardization efforts and highlight their relevance to the profession.

Historically, the Organization of Scientific Area Committees (OSAC) for Forensic Science has played a key role in advancing forensic standards. The OSAC Forensic Odontology Subcommittee has been responsible for drafting specialized documents, which are then forwarded to recognized Standards Developing Organizations (SDOs), such as the Academy Standards Board (ASB) and the American Dental Association (ADA). After passing scientific and technical review, these documents are added to the OSAC Registry, a centralized repository of consensus-based forensic standards.

Looking ahead, and due to recent structural changes within OSAC, SDOs will now take the lead in shaping the future of forensic odontology. The SDOs will continue to produce, update, and refine current standards, technical reports, and best practices guidelines to meet the needs in the field. This work will ensure forensic odontology remains aligned with scientific advancements, legal frameworks, and global best practices.

This session will highlight several foundational documents that are currently influencing the discipline. These include ISO CD 20888, now incorporated into ANSI ADA 1058, which defines standardized orodental terminology, and proposed updates to ANSI ADA 1088, which addresses human identification through dental comparison. Additional documents to be discussed include ADA TR 1077 on human age assessment, ASB Technical Report 194 on terminology for suspected dental patterns, and ISO 21611, which focuses on vocabulary for dental source conclusions. The session will also cover ISO 5365 on tooth development stages, OSAC 2022-N-0028 on suspected abuse reporting, OSAC 2023-N-0025 on education and training standards, and OSAC 2024-S-0013 on photographic documentation of dental evidence.

On the international front, ISO Technical Committee 106 is leading efforts to align terminology and to establish best practices for forensic data interpretation and reporting. These initiatives influence domestic standards while promoting international consistency and collaboration. Suggestions for supporting the adoption and application of these standards, along with an overview of the related documents, will strengthen the ability to implement current guidelines, support ongoing development, and advance best practices in forensic odontology.[1-5]

H9 Revisiting the Demirjian Legacy: A Comparative Analysis of Original and ISO Tooth Development Staging Using the Historic Demirjian Radiographic Collection

Wei Wu, DMD, Université de Montréal, Montreal, Quebec, Canada; Corinne D'Anjou, DMD*, LSJML, Saint-Lambert, Quebec, Canada; Derek Draft, DDS*, Incisal Dental, PLLC, St Lambert, Quebec, Canada; Normand Bach, MSc, Faculté de médecine dentaire Université de Montreal, Montréal, Quebec, Canada; Pierre Rompré, MSc, Université de Montréal, Montréal, Quebec, Canada; Katrina L. Kontaxis, DMD, Université de Montréal, Montreal, Quebec, Canada*

Learning Objectives: This presentation will introduce attendees to the new International Organization for Standardization (ISO) tooth development staging and evaluate its intra- and inter-observer reliability compared to the Demirjian's system. It will also provide an opportunity to critically examine Demirjian's approach to dental age assessment within the broader context of age estimation.

Impact Statement: The study's findings will enhance the forensic team's confidence in age estimation through transparent statistical analysis and clearly defined confidence intervals. Moreover, they will support the potential broader adoption of the ISO tooth development staging system.

Abstract Text: The widely adopted Demirjian method for dental age estimation, first published in 1973, has remained foundational despite ongoing debate surrounding its statistical formulation, particularly the opaque derivation of the maturity scores used for age estimation.[1,2] In this study, we re-examine this foundational method using the original digitized panoramic radiographs from the Demirjian collection, recently archived by the University of Montreal.

A number of radiographs have been selected with a uniform age distribution and an equal male-to-female ratio. Each of them has been staged by calibrated observers using both the original Demirjian staging system and the current ISO standard for dental age estimation.[3] We present a comparative analysis of the two systems, focusing on interobserver reliability, methodological limitations, and predictive accuracy. Preliminary findings suggest measurable differences in staging granularity and alignment with chronological age.

In addition to assessing the relative strengths and weaknesses of each method, this research explores the feasibility of modernizing the original Demirjian approach by deriving a new estimation formula from the historical dataset, offering a statistically transparent and potentially more precise model for dental age estimation in contemporary forensic and anthropological contexts.[4]

This study aims to advance the field's understanding of dental development staging and to foster a more scientifically rigorous approach to age estimation using historical datasets.

H10 Statistical Basis for Forensic Dental Identification Using Independent Feature Probability

James P. Fancher, DDS, MA, PhD, Texas State University, San Marcos, TX*

Learning Objectives: Attendees will learn a proposed method to complete a probability calculation of correct dental identifications based on comparison data that is usually available in the identification report.

Impact Statement: This proposed statistic may be used to support testimony to the triers of fact, and it also can be used for additional statistical analyses. Calculations are easy and accessible to all abilities.

Abstract Text: A statistical expression of probability of a correct odontology identification conclusion can be useful to support testimony to the triers of fact in any given case, although finding a statistical basis for such identifications has been elusive. This presentation will show a method and data to support using the concept of equal probability for comparing each individual dental trait (i.e., teeth, restorations, and anatomical or pathological conditions) between the antemortem and postmortem dental records to calculate a-priori probability statistics. While a pattern comparison can derive a statistic for a particular set of identification traits in a generic or partially detailed manner, this result does not speak to the specific identifiers required for definitive identification such as radiographic, photographic, or stone cast comparisons of individual dental features and anatomy.[1-7] The assumptions are that each comparable unit of data or feature is independent, is observable in existing records, and each feature can be compared one to one in both antemortem and postmortem dental records. Although many of the features may be generic or non-specific, a positive dental identification requires at least one distinctive or unique feature that can be reasonably assumed to represent one individual at the exclusion of all other individuals that are under consideration. In this proposed model each dental feature is assigned an equal probability of matching in the antemortem and postmortem state, a probability of 0.5 (the same probability of flipping a fair coin) because population at large databases for distinctive dental traits do not exist. In identification cases all features must match or be explainable, which is the same probability of getting the same result every time as in coin flips, heads or tails. This is expressed as Probability = $P = 1/2^N$, where the number 2 represents the two options (match or not for each feature) and N represents the number of features that are noted or measured (i.e., individual teeth, restorations, anatomy, pathology, and distinctive traits). The results of this method are illustrated using data from thirteen odontology identification cases from an incident that is now in the public domain. This a-priori data can be used to calculate Likelihood Ratios and other statistical tests.

H11 Integrated Forensic Age Estimation in Subadults Through a Machine Learning Combination of Dental and Skeletal Data

Ilenia Bianchi, PhD, Laboratory of Personal Identification and Forensic Morphology, Department of Health Sciences, University of Florence, Florence, Italy, Pieve A Nievole, Toscana, Italy; Giorgio Oliva, DMD, Department of Neuroscience, Reproductive Sciences and Oral Sciences, Section of Orthodontics, University of Naples Federico II, Naples, Italy, Firenze, Toscana, Italy; Giulia Vitale, DMD, Laboratory of Personal Identification and Forensic Morphology, Department of Health Sciences, University of Florence, Florence, Italy, Firenze, Toscana, Italy; Francesco Pradella, DMD, Laboratory of Personal Identification and Forensic Morphology, Department of Health Sciences, University of Florence, Florence, Italy, Firenze, Toscana, Italy; Martina Focardi, MD, Laboratory of Personal Identification and Forensic Morphology, Department of Health Sciences, University of Florence, Florence, Italy, Firenze, Toscana, Italy; Vilma Pinchi, PhD, Laboratory of Personal Identification and Forensic Morphology, Department of Health Sciences, University of Florence, Florence, Italy, Firenze, Toscana, Italy*

Learning Objectives: Following this presentation, participants will have gained insights into the challenges and potential of integrated age estimation radiological approaches in subadults, highlighting how Artificial Intelligence (AI) can enhance the combination of skeletal and dental indicators.

Impact Statement: This presentation will advance the forensic science community by promoting innovative, AI-supported techniques for age estimation in subadults, emphasizing the potential of automated tools to improve the integration of multiple predictive factors in line with international protocols, ultimately contributing to more reliable and legally defensible age assessments.

Abstract Text: The assessment of biological age in living subadults is a current forensic challenge with notable social, legal, and ethical implications. Internationally accredited guidelines and protocols (AGFAD- 2008, EASO-2018) recommend independent estimations of dental and skeletal age with dental age via orthopantomography (OPG), assessing second molars in children and third molars in young adults, and skeletal age via wrist radiographs for individuals up to 17–18 years.[1,2] However, no quantitative methods currently exist to integrate the two estimates and the rarity of paired OPG and wrist radiographs from the same individual further limits comprehensive analysis, thus experts can ultimately offer qualitative considerations on the rate of agreement between teeth and wrist maturation.[3]

A previous study involving several hundred matched OPG and wrist images from Italian subadults applied multiple dental and skeletal age estimation methods and implemented two machine learning models, Random Forest and Boosted, to integrate data from both anatomical districts.[4] Preliminary findings indicated that combining dental and skeletal data using AI significantly improves the age estimation accuracy. The Boosted model achieved a prediction interval of ±1.48 years (95% CI), outperforming Random Forest and traditional single-method approaches.

This study aims to expand upon those findings by evaluating new integration strategies using advanced machine learning models, to enhance the precision and reliability of forensic age estimation in subadults in accordance with international standards. A dataset of 456 individuals (230 males, 226 females), aged 6–20 years (2216–7647 days), with same-day OPG and wrist-hand radiographs, was analyzed. Dental age was estimated using Demirjian 7-teeth (D-7), Demirjian 8-teeth (D-8), and Willems (W) methods; skeletal age via TW3- RUS (TW3) and Greulich & Pyle (GP) methods. Two tabular regression models, LightGBM and TabPFN, were trained and tested on the obtained estimates. LightGBM is a high-performance gradient-boosted decision tree system, while TabPFN (Prior-Data Fitted Network) is a pre-trained Prior-Data Fitted Network specialized in generalizing results from limited sample sizes.[5] Both models were trained on the 70% of the total sample, and tested on the same 30% hold-out set. Performance was evaluated using mean absolute error (MAE) in days, and prediction-error intervals at 80%, 90%, and 95% confidence levels. LightGBM achieved a mean absolute error of 240.78 days on the test set, but TabPFN outperformed LightGBM with a MAE of 203.74 days. For TabPFN, 80% of predictions fell within ±0.89 years (~325 days), 90% within ±1.10 years (~402 days), and 95% within ±1.31 years (~478 days), improving upon both the previous Boosted model and traditional techniques based on single district.

This research, based on a sample of formidable rarity, demonstrates the potential of AI-based multimodal integration for the age assessment based on both dental and skeletal estimation. It provides validated quantitative models that enhance accuracy and support forensic experts with reliable tools aligned with international best practices and protocols.

H12 Dental Age Assessment for Victim Stratification in Closed Population, Multiple-Fatality Incidents

John B. Nase, DDS, Dental Forensic Services of Indian Valley, Harleysville, PA*

Learning Objectives: After attending this presentation, the attendee shall be familiar with the concept of using dental age assessment as a tool in the identification of subadult victims in closed population, multi-fatality incidents.

Impact Statement: This presentation furthers the knowledge base of using dental age assessment as one tool that can be used in cases of closed population, multi-fatality incidents.

Abstract Text: This presentation will update the audience on the process of victim stratification and in some instances positive identification through the use of various dental age assessment methods, including the London Atlas alone and in conjunction with Moorees, Fanning and Hunt (MFH) or Demirjian dental morphologic staging. The use of the Mincer modification and UT-Age will also be introduced to include appropriate analysis of adolescents. Since the type of incidents discussed are closed population events with presumed identities of victims, utilization of ancestral sub-studies is very appropriate and will be discussed. Once dental age assessment is performed and a dental age estimate is reported using a statistical range at the accepted 95% confidence interval, the array of victims can be delineated on an age "floating" bar graph for comparison. Often this comparison between victims' age ranges not only results in stratification but can also be the basis for positive identification.

Several examples of dental age assessment victim stratification will be presented from casework. Tragically, these fatal incidents involved mostly families with multiple siblings engulfed in housefires. This fact limited the facility of personal identification through DNA analysis, since isolated, individual antemortem reference samples were not available as is common in these situations; the persistence of dental evidence prevails.

Age Assessment; Dental Identification; Mass Fatality

H13 Artificial Intelligence Methods for Estimating the Age of Unaccompanied Minors

Javier Venema, MSc, Panacea Cooperative Research S.Coop., Granada, Andalucia, Spain; Stefano De Luca, PhD, Universidad de Oviedo, Oviedo, Castilla y Leon, Spain; Pablo Mesejo, PhD, Universidad de Granada, Granada, Andalucia, Spain; Oscar Ibáñez, PhD, Universidade da Coruña, A Coruña, Galicia, Spain; David Navega, PhD, Panacea Cooperative Research S. Coop, Ponferrada, Castilla y Leon, Spain*

Learning Objectives: After attending this presentation, attendees will understand the application of specific Artificial Intelligence (AI) models for legal age estimation from radiological images. They will learn about the performance and accuracy of these automated methods on teeth, the carpus, and the clavicle. Furthermore, attendees will be able to assess the results of a validation study comparing an AI-driven dental age estimation method against the performance of forensic anthropology experts in a simulated forensic context.

Impact Statement: This presentation will impact the forensic science community by introducing a validated, data-driven tool that can augment traditional age estimation methods, potentially increasing accuracy and objectivity. By providing practitioners with a robust quantitative method, this work directly supports the fundamental goals of forensic science, enhances the scientific basis for legal age assessment, and offers a scalable solution to a pressing social challenge.

Abstract Text: The estimation of legal age in unaccompanied migrant minors is one of the most urgent social challenges in Europe. The European projects UMAFAE and M2IbAE have addressed this problem by integrating Artificial Intelligence (AI) with Forensic Anthropology and Odontology. This presentation details the development and analysis of automated methods for legal age estimation using radiological images of teeth, the carpus (hand), and the clavicle.

Distinct AI methods, based on machine learning and computer vision, were implemented and validated for each anatomical region. The models were trained on three respective datasets: 10,739 orthopantomographs from 12 countries, 2,881 hand radiographs from three countries, and 1,067 CT scans of clavicles from the United States. The age range of the total sample is between 14 and 26 years. To test real-world applicability, the dental age estimation method was further validated in a simulated forensic scenario where 24 forensic anthropologists estimated the age of twenty undocumented migrants—whose true ages were subsequently revealed—both with and without the assistance of the AI tool.

The methods achieved a mean absolute error of 1.12, 0.67, and 1.53 years for teeth, hands, and clavicles, respectively. In the simulated scenario, the AI-driven method for dental age estimation proved to be more accurate on average than the human experts, with mean errors of 0.99 years for the AI versus 1.20 years for the experts. These results demonstrate that the project objectives were successfully met, and work is ongoing to develop trustworthy, multifactorial, and multimodal systems.

H14 Victim Identification of a Mass Fatality Event

Howard I. Cooper, DDS, DMORT, Antioch, IL*

Learning Objectives: This presentation will explore the process of victim identification following a catastrophic factory explosion. After attending this presentation, attendees will gain a comprehensive understanding of the principles of victim search and recovery and victim identification in mass fatality incidents. Attendees will understand how forensic odontologists obtain and use dental records to identify the victims. In addition, they will understand how the coroner's office helped families and the community handle a very difficult situation.

Impact Statement: This presentation will impact the forensic science community by describing and teaching the key aspects of victim identification after a mass fatality event using teeth and associated oral and maxillofacial structures. This presentation will also show the importance of collaboration with first responders, especially in evidence collection, which will promote accurate and efficient victim identification.

Abstract Text: Teeth, and associated oral and maxillofacial structures, have long been used to identify victims as a validated scientific method, in conjunction with other established identification modalities. Teeth, along with supporting structures and restorative materials, can retain their identifiable characteristics, in a variety of environments. After an explosion, or any mass fatality event, teeth may be the fastest and most efficient means of victim identification.

After a mass fatality event, such as this factory explosion, it is necessary to determine how many victims are present and their location. This process can be the most time consuming and requires detailed information from the responders, business owners, and the families, to establish a manifest of potential victims. This presentation will also highlight the collaborative role of the Coroner's office and the Fire Technical Rescue Team in locating and recovering remains from the disaster site. Once recovered, the victim's remains were transported to the Coroner's office for a complete evaluation and identification. Dental records were obtained quickly and, in this case, were a much faster alternative to identification via DNA. Using obtained dental records, the forensic odontologist can examine, compare, and ultimately identify the victims accurately and bring closure to the family members in a relatively short amount of time.

H15 Paul Revere: Silversmith, Spy, Dentist, Coroner

Denise C. Murmann, DDS, Murmann Dental Health, Naperville, IL*

Learning Objectives: The attendees will learn: (1) the history of why Paul Revere went into dentistry, (2) how his dental career and membership in the Sons of Liberty helped him make the first known dental identification completed by a dentist in United States history, and (3) that Paul Revere later went on to serve as a coroner

Impact Statement: It is important for members of any profession to know the history of how that profession came to be. In addition, it is wise to learn from history as we make our path forward in the present.

Abstract Text: Paul Revere is remembered most for his famous "midnight ride," when he rode to warn his fellow minutemen in the Province of Massachusetts Bay that the Regulars were coming out. This came not from the history books, but from the pen of Henry Wasworth Longfellow in 1860.

Paul Revere was not just a minuteman; he was also a member of the Sons of Liberty, which was a secret organization of colonists who wanted to defend their rights. They worked as spies to gather information about the movements of the British Regulars. One of the most important issues they were unhappy about was the Stamp Act of 1765, which inspired the slogan, "No taxation with representation!" Revere was one of the Sons of Liberty who took part in the Boston Tea Party in 1773.

The Stamp Act hurt the economy of the colonists. Revere had three children and a wife to take care of, so he considered what other ways he could earn a living and chose dentistry. The career expansion made sense, as he was a silversmith and goldsmith already. He used those skills to make the wire he used to fasten in false teeth for patients. He learned the skills from an English Surgeon-Dentist, John Baker, who was in the colonies at the time.

One of Paul Revere's most famous patients was Dr Joseph Warren. He was a Harvard trained physician and active member of the Sons of Liberty. It was he who sent Revere on that midnight ride to warn Concord of the approaching British regulars. Dr. Joseph Warren is considered one of the Founding Fathers of the United States and one of the first martyrs, as he died in the Battle of Bunker (Breeds) Hill on June 17, 1775.

When the battle was over, the British had control of the battlefield. They buried the dead in unmarked graves where they had fallen, to the dismay of the colonists, who were not allowed to retrieve them. Ten months later, the colonists had control of the site and families went to the grim task of trying to find and identify their loved ones. Dr. Joseph Warren's brothers, also physicians, went to find him, and Paul Revere went with them. The bodies would have been in advanced decomposition by then. The brothers examined a decedent and felt confident it was Joseph Warren. In addition, Revere was able to identify his friend by the dental work that he had done.

There is no evidence that Paul Revere continued in dentistry after the American Revolutionary War. He did continue as a silversmith, tried being a merchant, then started to cast iron, which was a new technology at the time. In 1795 he was appointed as the Suffolk County Coroner, a role he filled for eight years. In that time, he investigated 47 cases.

H16 Forensic Odontology in Battlefield Archaeology: An Analysis of Revolutionary War Remains From Red Bank Battlefield in New Jersey

Stuart Alexander, DMD, NJ State Police, Cranbury, NJ; Anna W. Delaney, DCrim, New Jersey State Police, Hamilton, NJ*

Learning Objectives: After attending this presentation, attendees will understand the difficulty of recovering and preserving historic remains using present-day dental modalities, including radiography, photography, and impression taking.

Impact Statement: This presentation will impact the forensic science community by highlighting the critical contribution the forensic dentist makes as part of an interdisciplinary team researching unidentified remains from archeological sites.

Abstract Text: In 2022, the unexpected discovery of human skeletal remains at Red Bank Battlefield in New Jersey site of the 1777 clash between American forces and Hessian soldiers working for the British prompted a multidisciplinary investigation involving forensic dentistry, archaeology, and anthropology Given the poor preservation of the bones, the dentition provided the most informative demographic information about the individuals whose remains had been buried in the trench around the American fort the day after the battle.

Recovery and preservation of the teeth from this archaeological site presented unique challenges. This presentation focuses on the field methods, the odontological findings, and their significance in the identification and interpretation of these historical soldiers' remains. Detailed dental examinations were conducted to assess age-at-death, ancestry estimations, and pathological conditions including caries, periodontal disease, enamel hypoplasia, and occlusal wear patterns. Complementing this data, stable isotope and strontium analyses of the dental enamel provided geochemical signatures consistent with regions in central Europe, supporting the identification of the remains as Hessian soldiers who came from what is now central Germany. Additionally, dental evidence provided valuable insights into the health, diet, and life history of 18th-century soldiers fighting in the American Revolutionary War.

This case underscores the indispensable role of forensic odontology in archaeological contexts and highlights its potential to contribute meaningfully to both historical documentation and the advancement of dental science.

H17 An Illinois Missing Person Cold Case—A Resolve After 42 Years: The Case of Karen Schepers

David A. Wold, DDS, Sugar Grove, IL*

Learning Objectives: After attending this presentation, attendees will understand how a 42-year-old Illinois missing persons cold case was resolved. The use of a law enforcement's novel approach aided by contemporary technology and expanded resources led to the recovery of presumptive human remains and, ultimately, the positive identification through back-to-the-basics practical applications of forensic odontology.

Impact Statement: The presentation will impact the forensic science community by presenting a summation of contemporary processes taken by the Elgin Police Department in Illinois, the originating missing persons law enforcement agency, and their investigational paths to locate and recover presumptive human remains missing since 1983. These processes, coupled with the remarkable retention of archived dental records and the use of current applications of forensic odontology, provided a rapid, positive identification from the coroner to the ever-waiting family. The cold case presented, and its outcome should be an incentive for other communities to consider. Case presentations are explicit ways to showcase the impact that forensic sciences have within our society.

Abstract Text: On April 16th,1983, a young, energetic, 23-year-old woman, Ms. Karen Schepers from Elgin, IL, and her car went missing, simply vanished. Upon her reported as missing, her whereabouts were heavily investigated with no avail. The case eventually went cold. Years passed and investigative updates were processed as the case remained active but also remained very cold. However, in May of 2024, there was a formation of new light. The Elgin Police Department established a cold case unit under the direction of Chief Ana Lalley with two lead detectives, Andrew Houghten and Matt Vartanian. The Chief of the Elgin police department had the idea to develop a pod cast to strike new leads in the case from a more open and public forum; hence the *Somebody Knows Something* EPD podcast was developed. This was a podcast with a think tank style that collated episodes to just one case at a time, almost in real time, as the investigation progressed. Of the agency's six missing person cold cases, the disappearance of Karen Schepers was chosen as their first to air. The presentation will outline the developing investigation the use of outside resources, namely Chaos Divers, the recovery of property, the recovery of remains, the identification of those remains, the closure for the family, and the ongoing investigation of what may have led to Karen Schepers untimely death. There were many forensic experts used in this case as well as several local, county, and state agencies of Illinois. The Chaos Divers are a sonar search and recovery dive team from Harrisburg, IL, that assist agencies and families nationwide. Their collaboration with law enforcement, first responders, and other dive teams is provided without cost to those they are helping.

In conclusion, the gratitude expressed by Karen's family was genuine and heartfelt, and a mother, now in her 90s, has her daughter back resting in eternal comfort.

H18 The Unseen Burden: When Evidence Leaves Its Mark on the Forensic Odontologist

Kathryn Seigfried-Spellar, PhD, Michigan State University, East Lansing, MI; John P. Kenney, DDS*, Davidson County TN Medical Examiner's Office, Nashville, TN; Raymond G. Miller, DDS*, SUNY at Buffalo School of Dental Medicine, Tonawanda, NY; Emilio Nuzzolese, PhD*, University of Turin, Turin, Piemonte, Italy*

Learning Objectives: Attendees will learn about the impact of work-related stress, including vicarious trauma, burnout, compassion fatigue, and barriers to helping-seeking, with insight from professional forensic odontologists.

Impact Statement: Our goal is to break down barriers and offer valuable insights and practical recommendations to enhance the well-being and resilience of professionals in the field of forensic odontology.

Abstract Text: Research consistently shows that criminal justice professionals experience high rates of work-related stress as a part of the investigative process.[1] Despite forensic scientists' prominent role in this process, literature on work-related stress has focused primarily on law enforcement officers investigating homicides, crimes against children, and other violent crimes. Vicarious trauma refers to secondary traumatic stress that is the result of indirect exposure to traumatic events or experiences. Forensic odontologists, like other forensic professionals, are routinely exposed to distressing and graphic details of traumatic events. This exposure can be indirect, such as analyzing evidence from violent crimes, or more direct, such as working with human remains in mass casualty incidents or child abuse cases.[2]

Job strain and burnout can lead to behavioral and physical reactions, including loss of productivity, lengthened sick leave, turnover or attrition, frequent headaches, substance abuse, and even heart disease.[3] Forensic science professionals are also at an increased risk for poor psychological well-being, including PTSD, depression, anxiety, and hypervigilance. Finally, these emotional and physical reactions may surface after one difficult case, after decades on the job, or after a life-changing event or stressor such as having a child or losing a loved one.

The managerial and supervising staff, who comprise the forensic environment, also contribute to the occupational stress experienced by forensic science professionals. Although wellness programs, organizational support, and resiliency practices can improve well-being[4], stigma is the greatest barrier to help-seeking behavior. Criminal justice professionals report being afraid that they will be seen as weak; that colleagues will question their work; that seeking mental health support will jeopardize job security or promotion opportunities.[5]

Organizations should develop customized wellness programs for forensic scientists, with a focus on stress management, mental health awareness, and work-life balance. These programs can help individuals effectively cope with job-related stress. In addition, creating a supportive work environment through leadership training, promoting peer support networks, normalizing help-seeking behavior, and providing resilience training can enhance well-being and reduce mental health stigma related to vicarious trauma.[6]

Overall, this presentation will introduce various constructs such as vicarious trauma, burnout, compassion fatigue, and stigma with insight from professional forensic odontologists. Our goal is to break down barriers and offer valuable insights and practical recommendations to enhance the well-being and resilience of professionals in the field

H19 Unveiling Drug Traces in Teeth: A Forensic Study on Methadone, Cocaine, and THC Orally Assumed

Ilenia Bianchi, PhD, Laboratory of Personal Identification and Forensic Morphology, Department of Health Sciences, University of Florence, Florence, Italy, Pieve A. Nievole, Toscana, Italy; Emma Croce, MSc, FT-LAB Forensic Toxicology Laboratory, Department of Health Science, University of Florence, Florence, Italy, Firenze, Toscana, Italy; Alexandra Dimitrova, MSc, Laboratory of Personal Identification and Forensic Morphology, Department of Health Sciences, University of Florence, Florence, Italy, Firenze, Toscana, Italy; Martina Focardi, MD, Laboratory of Personal Identification and Forensic Morphology, Department of Health Sciences, University of Florence, Florence, Italy, Firenze, Toscana, Italy; Fabio Vaiano, PhD, University of Florence, Florence, Toscana, Italy; Vilma Pinchi, PhD, Laboratory of Personal Identification and Forensic Morphology, Department of Health Sciences, University of Florence, Florence, Italy, Firenze, Toscana, Italy*

Learning Objectives: After this presentation, participants will gain a deeper understanding of the pathways and mechanisms of penetration and accumulation within dental structures of orally administered drugs of abuse.

Impact Statement: This presentation aims to contribute to the forensic science field by showcasing a novel *in vitro* study on the deposition of orally administered substances of abuse in dental tissues. A more suitable understanding of the potential oral contamination of dental tissues in drug-dependent individuals provides valuable insight for the use of alternative matrices in postmortem toxicology.

Abstract Text: Teeth represent a resilient and underutilized alternative matrix in post-mortem toxicology, particularly valuable in cases where traditional matrices are unavailable (e.g., burned, skeletonized, or exhumed bodies). The presence of distinct tissue layers—pulp, dentin, and enamel—may allow for the detection and differentiation of acute versus chronic drug exposure. However, the mechanisms by which drugs accumulate in dental structures remain unclear, especially in cases of orally administered substances, for which an external contamination through enamel from the oral cavity should be considered.[1-3]

A previous *in vitro* study demonstrated that methadone and dextromethorphan (DXM), both in syrup formulations with sugar and acidic pH, were able to penetrate enamel and accumulate in deeper dental tissues, including dentin and pulp. The sugar content and acidity were found to significantly influence permeability, supporting the use of dental tissues for evaluating chronic oral drug intake.[4]

This study broadens preliminary findings by testing three substances of abuse with different physico-chemical properties and routes of administration: methadone, cocaine free-base, and Δ^9-tetrahydrocannabinol (THC). Fifteen human teeth extracted for clinical reasons were collected and randomly divided into three groups based on dental health (sound or worn enamel, and periodontal teeth).[5] For Methadone, 9 teeth were immersed for 30 minutes each cycle in syrup such as commercially formulated (including sugar and acid), at three exposure durations: simulating 7, 14, and 30 days of assumption. For Cocaine and THC, 6 teeth were immersed for 10 minutes in sugar-free solutions, at a simulated exposure duration of 30 days, since usually inhaled and not directly ingested. Solutions were refreshed every 48 hours, and samples were stored at physiological temperature. All teeth were immersed only with the crown submerged; roots were excluded to prevent systemic contamination. After treatment, teeth were sectioned and pulverized to separate enamel, dentin, and pulp. Each tissue type underwent liquid-liquid extraction and was analyzed using liquid chromatography tandem mass spectrometry (LC-MS/MS).

This study aims to validate whether longer exposure times to methadone increase accumulation in dentin and pulp, potentially distinguishing chronic from occasional intake, and to explore whether drugs typically not combined with acids or sugars (e.g., cocaine and THC) show reduced or superficial deposition in dental tissues when exposure is shorter (typically inhaled) and molecules are more volatile (e.g. THC).

The ongoing results will be presented during the communication, and they will increase the knowledge about the dynamics of the deposition of orally assumed substances in dental matrices, thus contributing to a valuable insight into the forensic interpretation of drug-related deaths.

H20 DAE QuickSheets—The Next Generation

Derek Draft, DDS, Incisal Dental, PLLC, St Lambert, Quebec, Canada*

Learning Objectives: By the end of this presentation, attendees will be able to utilize the Dental Age Estimation (DAE) QuickSheets App to efficiently select appropriate DAE methods, input case-specific data, and interpret age estimates for use in forensic casework across both iOS and Android platforms.

Impact Statement: The DAE QuickSheets App advances forensic odontology by providing practitioners with a portable, intuitive tool for performing DAEs in real time. By streamlining method selection, data entry, and age calculation, the app enhances accuracy, consistency, and efficiency in forensic casework, supporting both field and laboratory applications.

Background: Dental age estimation is a foundational component of forensic identification, particularly in cases involving undocumented individuals, disaster victim identification, and age verification. As digital tools evolve, forensic practitioners benefit from mobile platforms that streamline complex analyses while preserving scientific rigor. The DAE QuickSheets project began as a collection of Excel-based calculators for age estimation, designed to make validated methods easily accessible at the casework level.

Objective: To present the development of DAE QuickSheets The Next Generation, a cross-platform mobile application (iOS and Android) that advances the original spreadsheet tools into a robust, field-ready digital solution for forensic dental age estimation.

Methods: DAE QuickSheets integrates multiple peer-reviewed dental age estimation methodologies, including those by Demirjian et al., Moorrees-Fanning-Hunt, Cameriere, Kvaal, Maples, and others. Users input case-specific dental data such as tooth development stages, pulp/tooth ratios, and root translucency metrics. The app processes these inputs using method-specific algorithms and built-in lookup tables to output estimated age ranges with corresponding references. A dynamic method selector tool aids in choosing the most appropriate technique based on case type (age group, subject status, and evidence type). The app supports secure PDF report generation for case documentation and integrates offline functionality for fieldwork.

Results: The app has undergone iterative design and field testing. Feedback from forensic practitioners has driven enhancements in usability, visual layout, and method organization. The transition from spreadsheets to mobile platform retains the scientific core while adding portability, flexibility, and improved user experience.

Conclusion: What began as a spreadsheet-based utility has evolved into a fully featured mobile application supporting modern forensic odontology. DAE QuickSheets bridges classic forensic methods with contemporary technology, enabling accurate, efficient, and defensible age assessments in both routine casework and mass disaster settings.

H21 The Identification of German Nurses Captured by the Viet Cong

Richard H. Fixott, DDS, DMORT, Ada CO Coroners, OMFIT, Redmond, OR*

Learning Objectives: This presentation will review two dental identifications in a historical context and provide examples of interagency and inter-discipline cooperation to achieve identification of missing persons. Discussion of the levels of evidence needed to propose an identification will be discussed also.

Impact Statement: Review of case work, especially historical or older case work, is helpful in supporting the foundation of current case work as well as offering perspectives that are still valid in current times.

Abstract Text: In April of 1969, five German volunteers of the Malteser Hilfsdienst Hospital in AnHoa, Vietnam—Bernard Diehl, Monika Schwinn, Marika Kortman, Marie-Louise Kerber and Georg Bartsch—left the hospital area to sightsee and take photographs to send home to relatives. The five were captured by Viet Cong soldiers, who mistook them for Americans. Their ordeal began with a 10-day march through the jungle, during which time all became weak from exhaustion, dehydration, and developed severe foot infections and the onset of malaria. After a day of rest, Bernard, Rika, and Georg moved to another camp they later called the "American Camp." Several days later, Monika followed after the death of Marie Louise. Rika and Georg both died in the American Camp several months later. Bernard and Monika survived captivity and were released in 1973.

In April 1986, remains were repatriated from the Socialist Republic of Vietnam (SRV) to the Central Identification Laboratory, Hawaii (CILHI) with the name association of an American soldier. Initial analysis indicated the remains were female and likely those of Rika Kortman. In January 1989, remains were repatriated from the SRV to CILHI with the name association of Georg Bartsch. Between 1989 and 1990, antemortem information was received from German sources allowing for identification recommendations to be made.

The presentation will cover the captivity of the Germans and the accession and analysis of the antemortem evidence and subsequent identification recommendations.

H22 Canine Injuries: A Forensic Analysis of Bitemarks in a Fatal Dog Attack

James F. Goodrich, FFOMP, NZSFO, Cambridge, Waikato, New Zealand*

Learning Objectives: After attending this presentation, attendees will have an understanding of a case that involved using patterned injuries/bitemarks to give information regarding which of two suspected dogs may have been responsible for the death of a newborn baby.

Impact Statement: This presentation explores some of the practical challenges associated with comparative analysis of non-human bitemarks and explains why the process was useful to the police and to a trier of fact. The outcome of the case will also be explained.

Abstract Text: After attending this presentation attendees will have an understanding of a case which involved using patterned injuries/bitemarks to give information around which of two suspected dogs may have been responsible for the death of a newborn baby.

A baby was taken from its crib and attacked, presumably by one of the two dogs present on the property. The baby did not survive the wounds sustained during the attack. Some effort was undertaken to try and establish which of the dogs may have been responsible.

The difference in size of the two suspected dogs, and the nature of the closed population due to a fully fenced yard, are two significant factors in this being unlike most bitemark cases. Likewise, the type of injuries seen in this case are unlike most human bitemarks, and the level of evidential information held within the patterned injuries is also different to most cases involving a human biter. These differences may allow a level of confidence not possible with human bitemarks, and this presentation will show the process behind the eventual decision to exclude one of the suspect dogs as the cause of at least one of the injuries.

This presentation explores some of the practical challenges associated with comparative analysis of non-human bitemarks and explains why the process was useful to the police and to a trier of fact. The outcome of the case will also be explained.

H23 Dental Autopsy Incision and Resection Techniques: A Review

John B. Nase, DDS, Dental Forensic Services of Indian Valley, Harleysville, PA*

Learning Objectives: After attending this presentation, the attendee will have a working knowledge of the various approaches to soft tissue dissection and osseous resection of the lower face commonly utilized during dental autopsy.

Impact Statement: A working knowledge of oro-facial surgical dental autopsy techniques is important in the proper gathering of odontological postmortem evidence for personal identification and biological profiling.

Abstract Text: Postmortem oral examination of dental structures can be challenging in terms of access and visualization for radiography and photography, due to rigor mortis and the overall state of the remains. Burned victims can be especially challenging in this regard due to contracture and immobility of charred soft tissue, as well as fragility of carbonized osseous and dental evidence. Likewise, mummified remains present a challenge for oral access. Moreover, dental autopsy (after proper medical examiner/coroner consent) should be considered in every postmortem odontological case, because even simple incision can be invaluable for thorough examination and comprehensive imaging for later reference. In cases of a possibly viewable decedent, particular attention should be given to proper consent. However, even in these situations, it is possible to perform dental autopsy in such a way as to afford re-approximation of bone and soft tissue structures of the face to facilitate subsequent funeral viewing.

Both incisive and resective techniques will be outlined using anatomic illustrations and real-world examples. These will include:

- Several versions of the bi-lateral, single, horizontal incision.
- The Silver and Souviron cruciate reflection
- Peel and partial faceoff techniques
- Submandibular degloving approaches
- Stryker saw and "Sawzall" resection
- Shears resection

H24 Advancements in Forensic Odontology: Anatomage Table and Metaverse Innovations

Corrado Cali', PhD, University of Turin, Turin, Piemonte, Italy; Claudia Viteritti, MD, University of Turin, Turin, Piemonte, Italy; Emilio Nuzzolese, PhD*, University of Turin, Turin, Piemonte, Italy*

Learning Objectives: Attendees of this presentation will learn about two tools that can revolutionize the field of forensic odontology: the Anatomage Table and the Metaverse. Through the Anatomage Table, attendees will discover a hands-on approach to anatomical study, enabling precise manipulation and analysis of 3D anatomical structures for virtual dental autopsies. Additionally, attendees will explore the innovative use of the Metaverse, a new technology leveraging virtual reality to enhance odontology education through scanned 3D jaws. By integrating these tools, attendees will gain insights on how technology can improve forensic odontology practices and educational strategies, offering a dynamic and immersive learning experience for future professionals in the field.

Impact Statement: This presentation will impact the forensic science community by introducing the utilization of the Anatomage Table for virtual dental autopsies and the Metaverse for immersive odontology education, which signifies a shift toward more efficient and accurate forensic identification processes. Through the integration of these technologies, we not only enhance the skills and knowledge of current professionals but also pave the way for a new generation of aspiring forensic odontologists to experience dynamic and interactive learning.

Abstract Text: This presentation introduces two cutting-edge tools transforming the landscape of forensic odontology: the Anatomage Table and the Metaverse. The Anatomage Table offers a hands-on approach to anatomical study with its user-friendly interface and interactive features on an 83-inch touchscreen, facilitating precise manipulation and analysis of 3D anatomical structures based on reconstructions from TC scans.[1-3] It is proposed for conducting virtual dental autopsies, enabling the extraction of crucial dental data through *virdentopsy* examinations.[4,5] This process leads to the development of comprehensive biological profiles and portrait images of deceased individuals.

Methods: A relatively new technology, the Metaverse, presents a revolutionary and complimentary method for odontology education, leveraging scanned 3D jaws and virtual reality to enhance the training of odontologists.[6-8] This immersive virtual environment allows users to delve deep into the nuances of dental autopsies within a collaborative digital space. Through the integration of these innovative technologies, we aim to improve and innovate forensic odontology practices and educational strategies.[9]

Results: By combining the Anatomage Table's capabilities for interactive dental autopsy analysis with the Metaverse's remote collaborative odontology training, we propose a holistic approach to leveraging technology in the field.

Conclusion. These tools not only enhance the efficiency and accuracy of forensic identification processes but also revolutionize the way odontology education is delivered, offering a dynamic and immersive learning experience for aspiring professionals in the field.

H25 Artificial Intelligence: Elevating Forensic Odontology Beyond Traditional Boundaries

Kenneth Aschheim, DDS, Office of Chief Medical Examiner of the City of New York, New York, NY; Guy Kaplan, MSc, Bright Forensic Innovations, Tel Aviv, Tel Aviv, Israel; Ben Cohen, BSc, Bright Forensic Innovations, Tel Aviv, Tel Aviv, Israel*

Learning Objectives: Participants will gain an understanding of how Artificial Intelligence (AI) and Augmented Intelligence (AuI) technologies can be integrated into forensic odontology workflows to enhance Dental Victim Identification (DVI), particularly in cases where individuals lack dental restorations. They will understand the limitations of traditional DVI software systems that rely on coding dental restorations, particularly their reduced effectiveness in younger individuals who have been exposed to fluoride from an early age, and explore how AI and AuI-based algorithms can overcome these challenges. Through analysis of recent research and case studies, participants will be able to assess the practical application, scalability, and adaptability of AI in forensic settings and understand its potential to improve accuracy, reduce tied ranks, and streamline identification processes in mass fatality incidents.

Impact Statement: This research will have significant implications for the future use of forensic odontology software in its use in mass fatality victim identification. By demonstrating that AI and AuI-based systems outperform traditional ranking software—especially in populations lacking dental restorations—it highlights the urgent need to modernize existing forensic identification tools. The results show that these AI-driven algorithms can more effectively distinguish individuals with few or no dental restorations. Incorporating AI and AuI into forensic work not only improves efficiency but also delivers more objective, data-driven outcomes. This work supports broader global efforts to integrate intelligent systems into forensic science, enabling more reliable and timely identifications.

Abstract Text: Forensic odontology has long been dependent on the use of conventional dental ranking software to aid in victim identification during mass fatality incidents. These traditional systems depend primarily on the presence of dental restorations—such as fillings, crowns, or bridges—to distinguish between individuals. A recent analysis of a mass fatality incident highlighted a growing concern: traditional dental victim identification (DVI) methods may no longer be sufficient to meet the demands of modern identification challenges. It also emphasized that no two mass fatality populations are the same, reinforcing the need for scalable and flexible technologies in forensic workflows. One of the most significant challenges for traditional algorithms is the widespread use of fluoride, which has resulted in fewer individuals with dental restorations, thereby reducing the effectiveness of restoration-dependent software.

Meanwhile, significant advancements in computer vision and artificial intelligence (AI), particularly in 2D radiographic analysis, have opened up new avenues for forensic science. This study examines the effectiveness of AI to improve Disaster Victim Identification (DVI) outcomes by minimizing dependence on dental restorations and increasing identification accuracy across diverse populations.

This research study was a comparative evaluation of AI and AuI-based algorithms versus traditional forensic odontology software. It focuses on measuring key performance metrics on the restoration-free segment of the dental population. It compares ranking performance on multiple datasets composed of radiographic images from individuals without restorations, including bitewing-only, panoramic-only, and mixed image types, to reflect the range of cases typically seen in real-world DVI scenarios.

Results demonstrated that AI and AuI-based models consistently outperformed conventional systems in cases with minimal or no dental restorations. The AI algorithms were consistently able to differentiate individuals who have tied ranks in non-AI-based software and increased correct match rates, even in datasets lacking the coded markers that traditional systems rely on. This confirms that AI technologies are more effective for varied victim populations and maintain high accuracy without depending solely on restorations.

AI and AuI-based systems represent a significant advancement in forensic odontology. These algorithms are better able to overcome the constraints of traditional methods; these technologies offer a more accurate and scalable solution for dental victim identification in increasingly restoration-free populations. The findings support continued research and investment in AI-enhanced forensic tools to meet the evolving demands of global disaster victim identification efforts.[1-5]

H27 Forensic Odontology Identification: Cases That "Left a Lasting Impression"

Walter F. Zoller, DMD, Forensic Odontologist, Titusville, FL*

Learning Objectives: Upon attending this presentation, attendees will understand the lifelong lasting effects forensic odontologists "receive," following the identification cases they are asked to evaluate. In addition, the forensic teams we are honored to work with will be highlighted, allowing viewers of this presentation to quickly appreciate the many talented colleagues that assist us to analyze and "solve" the forensic puzzles we deal with.

Impact Statement: The impact of this presentation will be very clear to the attendees. That is, no forensic cases are routine. Many cases stick with you for quite some time, if not forever.

Abstract Text: Specific identification cases the author has been involved with will be highlighted. Many times, it is only after reflection that one realizes we've learned more from these encounters than was originally thought or expected; providing long lasting educational and emotional experiences.

Most investigators generally approach each case with a personalized methodology, based on known forensic principals. The first step, communicating with the medical or law enforcement professions presenting the case. This, normally is followed by working with this team via an individualized, yet accepted protocol for evaluation. The procedure from here is many times unique to the individual investigator; with the completion leading to, hopefully, an accurate and thorough form of reporting to the appropriate medical and/or law enforcement team.

From this prospective, four cases will be presented, in a similar manner.

- How the case was initially presented for investigation
- How the case was investigated from an odontologic/dental "angle"
- The conclusion and how it was determined, odontologically
- How the case left a long-lasting impression/memory with *this* forensic odontologist

"The Pilot and his Instructor": A somewhat routine identification case, with excellent ante mortem data, leading to an interesting discovery.

"The Veterinarian and his Dogs": After the initial case introduction, this investigator wondered why his services were required at all. This confusion was quickly clarified. The deceased gentleman/veterinarian was an obvious animal loving individual, spending his final days in isolation; after a long life of service to his community.

"The Face Biter": This was not the normal "bitemark" identification presentation. In fact, as the investigation progressed over the *many* years the case was active, the final resolution revealed that it was not a bitemark identification case at all!

"The Family": Unfortunately, an investigation that revealed four deceased individuals from one family. This case teaches that what may appear as a "routine" identification case can 'stay' with the investigator forever.

Conclusion: Even the most routine odontology/dental forensic identification cases can offer learning opportunities and lingering memories that one "did not see coming."

H28 A Tri-Dimensional Pattern Analysis of Foodstuff Bite impressions A Quantitative Method of Comparison

Enrica Macorano, MD, University of Bari, Bari, Puglia, Italy; Valeria Santoro, MD, PhD, University of Bari, Bari, Puglia, Italy; Mariagrazia Guerra, PhD, Politecnico di Bari, Bari, Puglia, Italy; Luigi Maria Galantucci, Politecnico di Bari, Bari, Puglia, Italy; Francesco Introna, MD, University of Bari, Bari, Puglia, Italy*

Learning Objectives: Participants will learn a novel quantitative approach to bite mark analysis on foodstuff using tri-dimensional scanning and reverse engineering. They will understand the limitations of traditional 2D methods and how 3D modeling can provide objective and reproducible parameters for forensic comparison. The session emphasizes both methodological innovation and experimental validation, bridging odontology and engineering in forensic science.

Impact Statement: This study introduces a standardized 3D protocol for analyzing bite impressions on foodstuff, reducing subjectivity in forensic odontology. By integrating engineering-based reverse modeling with forensic expertise, the research contributes to establishing a more objective and scientifically grounded method for bite mark comparison, with potential application in judicial investigations.

Background: Bitemark analysis has long been a cornerstone of forensic odontology, yet it remains controversial due to its inherent subjectivity and the limitations of 2D methodologies. The National Institute of Standards and Technology has highlighted the lack of sufficient scientific foundation for conventional bitemark analysis, particularly concerning uniqueness and reproducibility.[1] To address these challenges, this study proposes a three-dimensional (3D) quantitative protocol using reverse engineering to analyze bite impressions on foodstuffs.

Methods: Bite impressions were imprinted on standardized Italian cheese (scamorza) by eight adult volunteers (4 males, 4 females). Dental casts of each subject were digitized along with the corresponding food items using a REVOPOINT Blue Light Mini 3D scanner. Digital models were processed with GOM Inspect and analyzed using a three-step protocol: (1) surface superimposition with colorimetric deviation mapping, (2) extraction of 2D profiles from 3D data, and (3) computation of three quantitative indicators: three-point angle, distance-perpendicular ratio, and elliptical ratio. A probabilistic model was applied to evaluate the likelihood of a match between each bite impression and dental arch.[2-4]

Results: The 3D workflow allowed for minimal handling of evidence and preserved the integrity of the bite pattern. Colorimetric maps successfully highlighted deviations within 5 mm and 2 mm tolerance ranges, enabling preliminary screening and refined matching. Quantitative indicators demonstrated good discriminatory power, with correct matches identified for the majority of subjects. Cases with substrate deformation highlighted the importance of integrating surface analysis with profile-based indicators to mitigate geometric distortion. The combined use of 3D scanning and reverse engineering reduced angular distortion and information loss associated with 2D conversion, producing more consistent and reproducible results compared to traditional methods.[5,6]

Conclusion: This research demonstrates the feasibility of a standardized, engineering-based approach to analyzing foodstuff bite impressions. By merging forensic odontology with reverse engineering, the proposed protocol provides objective, quantitative parameters and a reproducible workflow. The experimental validation underscores the potential of 3D methodologies to enhance evidentiary reliability in bitemark comparison and supports the development of more scientifically grounded practices in forensic odontology.

H29 Shark Tales: A Fatal Animal Bite Case Presentation

James F. Goodrich, FFOMP, NZSFO, Cambridge, Waikato, New Zealand*

Learning Objectives: After attending this presentation, attendees will have an understanding of a case that involved analysis of a fatal bite to estimate the species of the biter and the size of the animal that inflicted the injury.

Impact Statement: In this case, it was possible to estimate the species of the biter with confidence and also the size of the animal. This presentation will explain the process behind both of these assessments and discuss some of the challenges involved with the case.

Abstract Text: A woman swimming in the ocean was bitten and did not survive the wound. The office of the coroner wished to have as much information as possible about what may have caused the bite and the animal responsible, to aid in possible improvements to public safety.

In this case ,it was possible to estimate the species of the biter with confidence and also the size of the animal. This presentation will explain the process behind both of these assessments and discuss some of the challenges involved with the case.

To reach these conclusions, the forensic analysis involved comparison of the wound characteristics with known patterns from various marine animals found in the waters of New Zealand, and collaboration with marine biologists aided greatly in the approach to the case. Detailed examination of the wound provided clues as to the dentition and jaw mechanics of the biter, and recent research was employed to estimate the size of the animal based on the characteristics and metric analysis of the wound.

H30 A Scientific Mathematical Model to Define the Class Characteristics of the Human Anterior Maxilla

Kenneth Aschheim, DDS, Office of Chief Medical Examiner of the City of New York, New York, NY; Botond Simon, PhD, Semmelweis University, Budapest, Budapest, Hungary; János Vág, DSc, Semmelweis University, Budapest, Budapest, Hungary*

Learning Objectives: Upon completing this presentation, attendees will understand how quadratic regression modeling can objectively define forensic odontology metrics for the maxillary dental arch, thereby enhancing quantitative analysis methods for class characteristic assessments.

Impact Statement: This research presents a mathematical framework that objectively defines dental arch morphology, addressing long-standing concerns over subjectivity in forensic odontology. By establishing reproducible and quantitative class characteristics, this model enhances the scientific validity of class characteristic recognition and analysis within forensic practice.

Objective: Historically, forensic odontology has been criticized for lacking clear, quantifiable definitions for the class characteristics of human dental arches. In the past, determining a dental arch has relied mainly on qualitative assessment. This is the first of a series of studies aimed at developing a mathematical model using quadratic regression analysis to define the class characteristics of the human maxillary dental arch in scientifically measurable terms. Creating objective mathematical models is essential for advancing the field by standardized measurements rather than relying solely on individual expert judgment.

Materials and Methods: Intraoral digital scans of the maxillary arch were collected from adult patients who met specific criteria, such as a complete anterior maxillary dentition and no significant dental anomalies that would significantly alter the maxillary arch shape. Key metric points on each scan were marked with analytical software to capture anatomical landmarks essential for analyzing arch curvature. These data points were then used to build quadratic models that described the curvature and dimensions of each maxillary dental arch. Two different methods were used to generate a quadratic equation from a 2D-generated image of each individual's scan, allowing for comparisons between different arches and an assessment of how these measurements varied across the population.

Results: The quadratic regression model successfully defined the shape and curvature of the maxillary dental arch for each individual. The equations clearly showed that the dental arch can be defined within a narrow, quantifiable range and that the measurements were consistent throughout the sample group. The analysis produced predictive equations with strong goodness-of-fit indicators, demonstrating that human dental arches conform to a predictable mathematical range. Since there were only minor variations between individuals, this method could be a dependable way to identify the presence of human maxillary arch class characteristics in 2-D images. Also, there were no notable differences in arch shape between men and women, showing that the model is suitable for a wide range of adults.

Conclusion: This study demonstrates that quadratic regression analysis provides an objective and quantifiable method for defining the class characteristics of the human maxillary dental arch. This provides a scientifically reliable method that can add objectivity to analyses of the dental arch that were previously based on more subjective qualitative analysis. These findings establish foundational metrics that can inform future research, contribute to the development of standards, and support efforts to enhance the credibility and admissibility of forensic dental evidence within medicolegal contexts.[1]

H31 Identification in Multiple Comparison Scenarios Guided by Automatic 3D-2D Dental Image Superimposition

Oscar Ibáñez, PhD, Universidade da Coruña, A Coruña, Galicia, Spain; Antonio D. Villegas, MSc, Panacea Cooperative Research, Granada, Andalucia, Spain; Guillermo Ramírez-García, MASc, Panacea Cooperative Research S. Coop., Granada, Andalucia, Spain; Oscar Cordón, PhD, University of Granada, Granada, Andalucia, Spain; Daniel Pérez-Mongiovi, PhD, University Institute of Health Sciences CESPU, Porto, Porto, Portugal; Teresa Pinho, PhD, University Institute of Health Sciences CESPU, Porto, Porto, Portugal*

Learning Objectives: Attendees will be first introduced to the problem of 3D-2D image superimposition and its modeling as a camera calibration problem. Then, two different technical approaches to solve this problem will be presented. Attendees will learn how these approaches can be directly employed in the field of human identification using dental images. A sound experimental design will serve the audience to discover the possibilities and limitations of this novel paradigm.

Impact Statement: This presentation will impact the forensic science community with a valuable, cost-effective, human identification tool, with a high potential of applicability (the only antemortem data required is a facial photo with teeth visible) yet reliable and fast.

Abstract Text: Acquiring 3D intraoral models for *postmortem* records is no longer a technological challenge. These models, together with antemortem photographic records, offer the possibility of a new approach to dental comparison, allowing 3D-2D comparisons of teeth and exploiting the identifying power of these. Two approaches have been implemented and validated. The first consists of superimposing the intraoral scanner with facial photographs using a set of dental landmarks (three different sets were studied) in both images, calculating a similarity score based on the average distances between pairs of landmarks.[1] The second uses the occlusal contours of the upper teeth, both in the photograph and in the 3D model, and calculates the similarity between the two.[2] The performance of both approaches was measured using a sample of 142 subjects, making a total of 20,164 cross-comparisons. The metric used was the average ranking for each photo vs. the 142 3D models (i.e., 142 rankings, providing the average error and error distribution [quartiles]). In the landmark-based approach, the average ranking is 1.6-2.4 depending on the set of landmarks used, while in the contour-based approach, the average ranking is 1.5. The main conclusion is that the methods developed can help to dramatically reduce the number of possible candidates in multiple comparison situations.

H32 Digital Mandibles: The Role of 3D Printing in Personalized Jaw Reconstruction

Shalini Gupta, PhD, King Georges Medical University, Lucknow, Uttar Pradesh, India*

Learning Objectives: This session explores the transformative role of 3D printing in mandibular reconstruction, highlighting how digital workflows are enhancing precision, functionality, and aesthetics in jaw rehabilitation. Attendees will gain insights into the integration of the technology in forensic odontology, understand the implications of digitally guided reconstruction, and examine case-based evidence demonstrating improved outcomes The session also discusses challenges, limitations, and future directions in the use of additive manufacturing for craniofacial reconstruction.

Impact Statement: This presentation bridges the gap between clinical innovation and forensic science by demonstrating how 3D printing in mandibular reconstruction can aid in postmortem facial reconstruction, identification of unknown remains, and interpretation of trauma patterns. By showcasing personalized, anatomically accurate mandibular models derived from digital imaging, the session emphasizes how these technologies can enhance forensic reconstructions, improve courtroom visualizations, and support interdisciplinary collaboration between surgeons, forensic odontologists, and anthropologists. Attendees will gain a deeper appreciation for the role of digital fabrication in preserving anatomical fidelity and reconstructing identity in forensic contexts.

Abstract Text: Mandibular defects resulting from trauma, tumor resection, or congenital anomalies present complex clinical and anatomical challenges. Traditional reconstruction techniques, though effective, often fall short in replicating the precise anatomical contours and function of the mandible. The advent of three-dimensional (3D) printing has revolutionized mandibular reconstruction by offering patient-specific, anatomically precise, and functionally superior outcomes.[1,2]].

Beyond clinical utility, this technology has significant implications for forensic science. 3D-printed mandibular models can serve as valuable tools in forensic reconstruction, aiding in the identification of unknown remains by restoring anatomical structure based on digital imaging and comparative analysis.[3] Personalized digital archives can also assist in postmortem analyses, bite mark comparisons, and reconstruction of trauma scenarios. Furthermore, 3D modelling provides powerful visual aids for courtroom presentations and forensic documentation, improving communication of complex anatomical evidence to non-expert audiences.

Through case-based examples which will be presented in the conference through the use of Haptic device and Geomagic freeform software already present in the Department 3-D printing Lab, this presentation will demonstrate how 3D printing enhances accuracy in mandibular reconstruction and supports interdisciplinary applications across maxillofacial surgery, forensic odontology, and anthropological investigations. The paper will also address current limitations, including cost, regulatory considerations, and the need for standardized digital protocols, while projecting future directions in integrating AI and bio-printing in forensic workflows. The incorporation of the present technology requires multidisciplinary approach for successful implementation. (No commercial product or service is used for 3-D mandibular reconstruction and virtual surgical planning.)

H33 The Identification of Bodies Using the Automated Search Notice in Forensic Odontology in France

Gwenola Drogou Saout, DDS, President AFIO French Association of Forensic Odontology, Ploemeur, Bretagne, France*

Learning Objectives: After attending this presentation, attendees will understand the protocol for identifying unidentified bodies or human remains using a dental data search engine: the Automated Search Notice in Odontology in France. This system can be used in single identification cases, cold cases, or after mass disasters.

Impact Statement: This presentation will impact the forensic community by demonstrating the potential and effectiveness of the Automated Search Notice in Odontology (AROA in French). The system enables the automated and digital distribution of postmortem odontograms to dental practices for comparison with patient records, hopefully leading to the identification of unknown bodies. This is an anonymized query of a virtual dental mega database and represents an innovative and underutilized tool for forensic identification in France. The entire protocol and the role of the forensic dental expert will be presented during the session.

Abstract Text: The identification of deceased individuals is a critical step in both forensic and humanitarian contexts. According to Interpol, three primary methods are recognized for human identification fingerprints, DNA, and dental data.[1] While fingerprint and DNA databases are nationally established in France, no centralized dental database currently exists.

Yet, dental records remain a valuable and often underused source for forensic identification, particularly in cases where fingerprints or DNA are unavailable or inconclusive. In France, dental data is dispersed across thousands of dental practices, each retaining patient records individually. To bridge this gap, the *Automated Search Notice in Odontology* (AROA) was developed.

This system was proposed by Dr. Pierre Fronty and the French Association of Forensic Odontology (AFIO), in collaboration with the National Dental Council, in the early 2000s.[2] The widespread digitalization of dental practices makes the use of this system possible.

The development of this system faced several challenges:

- The protection of health data, which is strictly regulated under French law. In November 2013, the CNIL (National Commission on Informatics and Liberty) approved its use under a well-defined data anonymization protocol
- A lack of awareness among judicial and investigative authorities regarding the value and potential of this system
- Limited involvement from some dental software providers (only 1 out of 3 participated actively)
- The necessity for practitioners to maintain well-documented and accurate dental records (including odontograms)

Despite these obstacles, the AROA system has continued to evolve. Tests using anonymized dental records were conducted with volunteer practitioners using compatible software. Regular consultation meetings have been held with the National Dental Council, The French Association of Forensic Odontology (AFIO), judicial and police authorities, the developers of dental practice management software, the Ministry of Justice, as well as associations of families of missing persons, in order to promote, standardize, and improve the system.

In 2025, the AROA system received official validation from judicial and law enforcement authorities, and the first identification searches were initiated.

H34 When Time Is of the Essence: Establishing DVI Facilities During Warfare

Esi Sharon, DMD, Israel Police, Jerusalem, Yerushalayim, Israel; Tzipi Kahana, PhD, Israel Police, Jerusalem, Yerushalayim, Israel*

Learning Objectives: After attending this presentation, attendees will better understand the need for adapting Disaster Victim Identification (DVI) protocols to religious constrains as well as to intelligence needs and security requirements. The crucial role of forensic odontologists within the DVI framework, under extreme conditions, will be explained.

Impact Statement: This case study showcases the critical value of cross-agency collaboration in developing tailored strategies to address the complex challenges of wartime victim identification while upholding the highest standards of forensic practice.

Abstract Text: This presentation explores the challenges and strategies involved in establishing ad-hoc Disaster Victim Identification (DVI) facilities under urgent and extreme conditions. Between 2023 and 2025, Israel faced multiple DVI scenarios, including the October 7, 2023, massacre of over 1,200 civilians, police, and military personnel; the recovery of abducted bodies from Gaza; and ongoing missile attacks from Iran and Yemen. These events required rapid identification of victims under complex and dynamic circumstances.

Timely identification was critical—not only to determine the number and identity of hostages following the Hamas attack in southern Israel, but also to distinguish victims from perpetrators during active conflict, and to uphold Jewish burial laws. The presentation will demonstrate how existing mortuary facilities were adapted to manage mass fatalities, how temporary morgues were established in non-dedicated structures, and how DVI teams operated effectively in field conditions.

The role of forensic odontologists will be discussed within the broader DVI framework, emphasizing their contribution and achievements under extreme conditions. This case study underscores the adaptability of both civilian and military DVI teams and the importance of cross-agency collaboration. Through this integrative approach, customized strategies were developed to meet the unique demands of wartime victim identification—while maintaining the highest forensic standards

H35 How a CT Screen Capture Assisted in the Identification of an Individual

Mark D. Porco, DDS, Mark D. Porco, DDS, Lincoln, CA*

Learning Objectives: Medical records may include dental structures for identification. Learning outcomes for this presentation are: (1) attendees will understand other potential available records for use in identification, and (2) attendees will evaluate the utility of using an existing medical Computed Tomography (CT) imaging scan in postmortem identification.

Impact Statement: After this presentation, attendees will understand an unusual source of antemortem records and how this information can be used to assist in an identification. Use of an existing medical CT scan to assist in the identification of an individual when typical dental records are unavailable reduces the incidence of unidentifiable victims.

Abstract Text: This presentation will discuss and explain a recent case of a victim identification confirmation where the records traditionally utilized were not available. Dental x-rays and written treatment records are commonly used in the comparison of ante-mortem with post-mortem records for confirmation of identification. In this case, there was presumption of identification without any ante-mortem dental records. This victim was found extremely decomposed after an extended period of time in a local river. As a result, the use of traditional fingerprinting techniques routinely used to identify, proved to be unsuccessful. The coroner's office chose not to use DNA testing for various reasons. Deprived of the ability to use fingerprints or DNA analysis, and without the traditionally utilized resources available, it is possible that this victim would remain a John Doe, an outcome that lands in the less-preferred category. By the grace of a colleague in the Coroner's Office a medical CT scan was provided for evaluation for use as a potential record for comparison. While less common, this scan did contain oral structures which allowed for the confirmation of identity. The history of the case as well as the steps necessary to complete the identification using novel records will be illustrated.

H37 Unlocking Identity Through Proteomics: A Review of Protein Biomarkers in Forensic Science

Shria Sharma, MSc, Panjab University, Punjab, Punjab, India; Shubham Thakur, MSc, Panjab University, Chandigarh, Chandigarh, India; Sanya Gaur, PhD, Panjab University, Chandigarh, Chandigarh, India*

Learning Objectives: After attending this presentation, the attendees will understand the role of protein biomarkers as a promising alternative tool to molecular analysis, particularly for the identification of heavily degraded samples.

Impact Statement: This presentation will impact the forensic science community by highlighting the significance and potential of the alternate analytical technique of proteomics for forensic anthropological identification purposes.

Abstract Text: Human identification plays a major role in forensic science, especially in the conditions of criminal investigation and mass fatality incident.[1] Commonly, this process has been largely dependent on DNA based methodologies, which have served as the best practice for identifying human remains. When DNA is either too degraded or entirely absent, it becomes crucial to rely on other bio-molecular methods. According to Parker et al. human identification from biological material is largely dependent on the ability to characterize genetic polymorphisms in DNA.[2] Unfortunately, while DNA is exposed to environmental deterioration and may fall below the level for PCR amplification, proteins exhibit greater chemical stability and can remain preserved in biological materials for long durations. Proteomics relies on identifying proteins to understand function and interaction, supporting its wide-ranging applications in both medical and biological sciences.[3] With the help of proteomics extensive protein analysis can be done and it can provide valuable insights to genomics methods in forensic science for degraded samples like hair or bone helping in the recognition of body fluids, individual characteristics and post-mortem intervals.[4] Proteomic analysis of human teeth is an emerging area that offers an important understanding of the distinct protein compositions of dental tissues and their possible applications in identification. Teeth are composed of enamel, dentine, cementum and occasionally preserved tissue, each possessing a unique proteome associated with its specific formation and function.[5] Tooth enamel structural proteins are important for enamel formation, but most are cleared during mineralization. However, some protein fragments persist in erupted enamel and have been identified using proteomics.[6] Research into the proteome of human teeth is gaining momentum across biological, medical and analytical disciplines. Biological markers are measurable indices of biological states or processes. As proteins have distinct properties, they serve as valuable biomarkers, making proteomics a very promising way for their identification and analysis.[7] In forensic science, proteomic analysis utilizes advanced technologies- including liquid chromatography tandem mass spectrometry, MALDI-TOF/MS, and targeted approaches like multiple reaction monitoring (MRM) to identify and characterize protein biomarkers. Proteomic techniques present distinct benefits, yet their use in forensic science is limited due to various challenges like minimal quantity, protein breakdown, restricted databases and the absence of standardized protocols.[4] With the help of proteomics, various diseases can also be diagnosed. Proteomics plays a great role and is a key research tool in TB studies, which is a major health issue in India. Institutes like the National JALMA Institute (Agra) and NIRT (Chennai) lead advancements in this field.[8] These proteomic advances hold the potential to redefine future directions in both fundamental and biomedical research.

I1 A Forensic Insight Into a Peculiar Case of Autoerotic Asphyxiation

Saverio Gualtieri, MD, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Matteo Antonio Sacco, MD*, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Maria Cristina Verrina, MD*, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Maria Daniela Monterossi, MD, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Gioele Grimaldi, MD, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Mattia Solano, MD*, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Isabella Aquila, MD, PhD*, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Giuseppe Chiaravalloti, Arms of Carabinieri, Catanzaro, Calabria, Italy; Marco Cisa, Arms of Carabinieri, Catanzaro, Calabria, Italy; Santo Gratteri, MD, PhD, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Isabella Aquila, MD, PhD*, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy*

Learning Objectives: After attending this presentation, attendees will understand the critical role of a multidisciplinary forensic approach in identifying, classifying, and interpreting complex autoerotic death cases for judicial purposes.

Impact Statement: This presentation will impact the forensic science community by demonstrating how autopsy plays a fundamental role in the multidisciplinary evaluation of these peculiar forensic cases.

Introduction: Autoerotic deaths, defined as accidental fatalities occurring during solitary sexual activities, pose complex forensic challenges due to their diverse mechanisms and atypical death scene presentations. The scene is often bizarre, and the death unexpected, which frequently necessitates a forensic autopsy. Autoerotic death is considered accidental when caused by devices or props used to enhance sexual stimulation during solitary sexual activity. These incidents are classified into "typical" cases (asphyxia by hanging/suffocation, inhalation of chemicals/gases) and "atypical" cases (electric accidents, body binding, chest compression). The present study analyzes a peculiar case in which a traumatic event arising from an extreme autoerotic practice led to mechanical asphyxiation by hanging.

Materials and Methods: A judicial scene inspection was performed, with systematic collection of all materials present, including women's clothing, sexually connoted objects, and items likely used for autoerotic purposes. A full autopsy was conducted with particular attention to the anogenital region and the search for traumatic signs suggestive of penetrative practices. A literature review was also carried out using the PubMed database with the following keywords: "forensic sciences; "autoerotic asphyxiation;" "autoerotic deaths;" "erotic accessories;" "forensic pathology;" and "on-site investigations."

Case Report: A male corpse, approximately 60 years old, was discovered during a judicial inspection in an abandoned rural ruin. The body was suspended by a rope attached to a wooden ceiling beam, in a configuration consistent with incomplete hanging, as the body was partially resting on the ground. The decedent was cross-dressed, wearing a female wig, tight leggings with large tears near the anal region, and high-heeled shoes. The surroundings contained female garments, cross-dressing accessories, and erotically connoted items. Near the body, a cylindrical wooden object—later identified as a pole—was found on the ground and seized.

Results: Autopsy revealed a typical ligature mark from incomplete hanging. External examination of the anogenital area showed millimetric perianal lacerations, anatomically consistent with tears observed in the leggings, which were extensively torn near the anal area. The seized cylindrical object was compared with anatomical and clothing findings, showing functional compatibility. The integration of scene inspection and autopsy findings, in the absence of evidence suggesting third-party involvement, supported the diagnosis of accidental death due to mechanical asphyxiation in the context of autoerotic activity, with penetrative and ritualistic components.

Discussion: Autoerotic deaths are a complex area within forensic pathology, often characterized by atypical scenarios, ritualistic elements, and the need for thorough integration of death scene data and postmortem findings.[1,2] The present case highlights the critical importance of meticulous scene investigation and complete autopsy, particularly in the presence of extreme sexual practices and cross-dressing. The lack of evidence for third-party involvement and the concordance between environmental, anatomical, and clothing findings support the hypothesis of an accidental autoerotic death. Timely recognition of such dynamics is crucial to avoid misinterpretation as suicide or homicide and to ensure accurate medicolegal reconstruction.

I3 Drowning in Big Data: An Evidence-Based Forensic Assessment of Lung Weights in Drowning Cases, Modeled on a Database of Over 22,500 Autopsies

Johannes Busch, PhD, Section of Forensic Pathology, Department of Forensic Medicine, University of Copenhagen, Copenhagen, Hovedstaden, Denmark; Carl Johan Wingren, PhD*, University of Copenhagen, København ø, Hovedstaden, Denmark*

Learning Objectives: After attending this presentation, attendees will gain an understanding of how an evidence-based diagnostic process is essential in forensic medicine. The presentation will specifically cover the concepts of confounding, circularity bias, and use of statistical methods in the diagnostic process. To illustrate these objectives, we employ the evaluation of lung weights in drowning cases as an example and base our models on a large forensic autopsy data set. In addition, attendees will gain an appreciation of how to establish big data sets relatively simply using modern technology and how such databases are a vital tool for promoting evidence-based diagnostics in forensic pathology.

Impact Statement: This presentation will impact the forensic science community by increasing knowledge about evidence-based forensic medicine, strengths and limitations of findings inherent in postmortem diagnoses, and how single data points, such as increased lung weight, cannot stand by themselves in the diagnostic process.

Background: Death by drowning is a challenging diagnosis for the forensic pathologist. Scene investigations, witness accounts, postmortem radiology, and specific autopsy findings may each provide a piece of the puzzle. An increase in pulmonary weight is generally considered supportive for the diagnosis, but the finding is not specific and the published recommended cut-off values do not consider other potential confounders of increased lung weight such as male sex, large body size, chronic and acute cardiac disease, passive influx of water in bodies submerged in water, or variances in autopsy methodology among pathologists.

Methods and Material: In this study, we utilize a database on 22,816 forensic autopsies. We extracted the data from digitized history autopsy records using a custom Python-script. The algorithm extracts data on organ weights, body height and weight, age, sex, and putrefaction stage. Additionally, the algorithm extracts and classifies information on causes of death such as drownings and acute heart failure. Using this data, we explore the diagnostic accuracy of thresholds for "heavy lungs" in classifying the cause of death as drowning, acute heart failure, or neither of these. We then evaluate whether the diagnostic accuracy can be increased by including biometry and other autopsy findings.

Results: After excluding pediatric cases and cases with a moderate or pronounced degree of putrefaction and outlier values, 17,447 cases remained for analysis. We identified 384 cases of drowning, 1,324 cases of Acute Heart Failure (AHF) and 15,739 cases with neither of these causes of death recorded immediately at autopsy; the latter group was used as controls. Mean total lung weights were 1,387 g in drownings, 1,264 g in AHF, and 1,154 g in controls. In univariate regression models, body height showed a weak, but significant association with total body weight ($R^2 = 17\%$). Additionally, the mean amount of pleural fluid was significantly increased in drowning cases. When controlling for body weight, body height, and age, the mean weight of lungs and pleural fluid were 1,828 g in drownings, 1,581 g in AHF, and 1,546 g in controls.

Conclusion: Increased lung weight is associated with drowning, but not specific to this condition. The effect of body height and the diagnostic value of increased weight of the lungs should be considered when assessing lung weight at autopsy for the diagnosis of drowning.

I4 Incidental Central Pontine Myelinolysis in Chronic Ethanolism: A Case Report

Shera Wanner, MD, University of California, San Francisco, San Francisco, CA; Christopher Liverman, MD, PhD, San Francisco Office of Chief Medical Examiner, San Francisco, CA; Jordan Taylor, MD, San Francisco Office of the Chief Medical Examiner, San Francisco, CA; Marcus Conley, BS*, San Francisco Office of the Chief Medical Examiner, San Francisco, CA*

Learning Objectives: The goal of this presentation is to present a case of Central Pontine Myelinolysis (CPM) in chronic ethanolism outside of the typical hospital setting and detail its diagnostic criteria.

Impact Statement: This presentation will impact the forensic science community by detailing the rare finding of CPM in the setting of chronic ethanolism occurring outside the hospital setting.

Abstract Text: CPM is a demyelinating disorder affecting the center of the basis pontis, which is often caused by the rapid correction of hyponatremia. This presents clinically with a spectrum of muscle weakness, paralysis, difficulty speaking and/or swallowing, and confusion. Its most severe presentation is complete paralysis of voluntary muscles, excluding eye movement, known as "locked-in syndrome."[1] Other precipitants of CPM include severe liver disease and alcohol withdrawal without specific electrolyte abnormalities and subsequent correction. It is thought that those with a history of chronic ethanolism are unable to mitigate cerebral osmotic stressors, even when normonatremic, particularly in the setting of alcohol withdrawal. Correction of electrolyte abnormalities other than hyponatremia can also precipitate CPM. This includes hypophosphatemia, which is associated with refeeding syndrome in those who are malnourished, a common scenario in those with an alcohol use disorder.[2]

CPM is a critical differential diagnosis in the acute clinical setting as the symptoms of alcohol withdrawal and cerebrovascular ischemia (stroke) greatly overlap with CPM. The importance of this distinction lies in both the detection and management of CPM, which may not be identified on non-contrast Computed Tomography (CT) of the brain, which is the gold standard for ischemic stroke recognition. Magnetic Resonance Imaging (MRI) is more likely to show the pontine perfusion aberrations characteristic of CPM. A diagnosis of CPM requires careful electrolyte management in addition to supportive care to prevent permanent neurological damage.[3,4]

Here we present a 42-year-old man with a history of mild hyponatremia and chronic ethanolism who was found in his bedroom, which showed evidence of tobacco and heavy alcohol use. External examination showed severe jaundice and scleral icterus. Autopsy examination revealed a 3,030 gram firm, yellow-brown, cirrhotic liver; xanthochromia; and dilated cardiomyopathy. Neuropathologic examination revealed a soft, triangular to T-shaped, yellow-orange lesion in the basis pontis. Histological examination, including immunohistochemical staining with Luxol Fast Blue (LFB) and neurofilament, confirmed myelin loss with axonal preservation, consistent with the diagnosis of CPM. Toxicologic analysis showed a very low blood ethanol level, consistent with early post-mortem decomposition.

This case demonstrates the rare finding of CPM in an atypical setting. In all decedents with chronic ethanolism, this diagnosis should be considered and appropriate testing should be ordered when in the differential diagnosis.

I5 Unexpected Fatal Hemoperitoneum: A Case of Spontaneous Non-Traumatic Omental Hemorrhage

Kaylee D. Fox, DO, Atrium Health Wake Forest Baptist Medical Center Department of Pathology, Winston Salem, NC; Patrick E. Lantz, MD, Atrium Health Wake Forest Baptist Medical Center, Winston Salem, NC*

Learning Objectives: This presentation will: (1) identify key autopsy findings in a case of spontaneous non-traumatic omental hemorrhage, including gross and histologic features ; (2) create a differential diagnosis for spontaneous non-traumatic intraperitoneal hemorrhage and identify the major categories of underlying causes ; (3) describe one pathologic mechanism—necrotizing vasculitis—that can lead to spontaneous omental bleeding and how it may appear histologically; (4) discuss the implications for clinical and forensic practice, including the need for ongoing education in abdominal vascular anatomy and timely surgical recognition of rare but potentially preventable fatal conditions; and (5) demonstrate the importance of full medicolegal autopsy in uncovering unexpected causes of death that might be misattributed based on toxicology or external findings alone.

Impact Statement: This presentation highlights a rare case of spontaneous non-traumatic omental hemorrhage, underscoring the critical role of thorough forensic autopsy in identifying uncommon and potentially misclassified causes of sudden death, especially when positive toxicology is involved. This case report expands on the differential diagnosis for hemoperitoneum and reinforces the need for continued education in abdominal vascular pathology. The findings have important implications for death certification accuracy, medicolegal investigation, and public health surveillance, offering valuable insights that will enhance diagnostic vigilance and interdisciplinary collaboration within the forensic science community.

Abstract Text: Spontaneous non-traumatic rupture of omental blood vessels rarely occurs but can cause fatal intra-abdominal hemorrhage. A 34-year-old, recently incarcerated woman became acutely agitated and collapsed while in custody. Resuscitative efforts were unsuccessful. Her medical and social history was notable for intravenous substance use and hepatitis C. A medicolegal autopsy revealed “violin string” fibrous adhesions between the hepatic capsule and diaphragm, characteristic of Fitz-Hugh-Curtis disease, a postmortem femoral blood fentanyl concentration of 7.2 ng/mL, and a 950 mL hemoperitoneum. A thorough dissection revealed an arterial rupture within the greater omentum as the source of bleeding. Histologic examination showed focal, necrotizing vasculitis with transmural inflammation, vessel wall perforation, and intraluminal thrombus formation.

Spontaneous non-traumatic intraperitoneal hemorrhage is rare and fatal if not recognized and treated promptly.[1-4] The differential diagnosis for spontaneous non-traumatic omental hemorrhage includes vascular pathologies (arteriosclerosis, variceal rupture, arteriovenous malformations, segmental arterial mediolysis, aneurysmal rupture, systemic coagulopathies); neoplastic processes (primary omental tumors, metastatic disease); inflammatory and infectious conditions; and iatrogenic or medication-related factors. The literature on spontaneous non-traumatic intraperitoneal hemorrhage (abdominal apoplexy) is limited and mostly reported when the proximate cause of bleeding was not clinically identified.[5-7]

This case highlights several key considerations. First, omental hemorrhage, though rare, should be included in the differential diagnosis of acute abdomen, especially in patients with known risk factors, including vasculitis, intra-abdominal fibrous adhesions, or substance use disorder. Second, ongoing education in abdominal vascular anatomy is essential for clinicians and pathologists alike.[3] Third, this case underscores the potential preventability of such deaths through timely diagnosis and surgical or interventional management. Finally, without a full autopsy, this case may have been misclassified as an accidental drug toxicity, given the external examination and toxicology findings alone.[8]

Because spontaneous non-traumatic omental bleeding occurs infrequently, this report adds to the limited literature and emphasizes the critical role of a thorough autopsy in identifying elusive and unexpected causes of sudden death.

I6 Living With the Dead: Harris County's Investigations Into Life Alongside the Deceased

Bethany Bless, MSc, Harris County Institute of Forensic Sciences, Houston, TX; Hannah C. Jarvis, MRCS, Harris County Institute of Forensic Sciences, Rosharon, TX*

Learning Objectives: The goals of this presentation are to examine how integrating expertise from forensic investigations, forensic pathology, law enforcement, and behavioral science improves the investigative process in cases involving delayed discovery of remains within a shared living space and to identify scene-based indicators that may point to prolonged cohabitation with the deceased.

Impact Statement: Applying a forensic lens to cases of postmortem cohabitation reveals critical patterns in behavior, environment, and death scene dynamics that may otherwise go unrecognized. A multidisciplinary investigative framework not only strengthens evidentiary findings but also ensures that atypical scenes are interpreted with the nuance required for accurate medicolegal conclusions.

Abstract Text: Forensic professionals are encountering a growing number of cases involving individuals who continue to reside with the decomposing remains of a relative.[1] These cases present highly atypical death scenes, characterized by social isolation, psychological impairment, and the physical and chemical changes in the environment that occur because of decomposition, neglect, and delayed body discovery. This poses health and safety risks, affects the interpretation of forensic evidence, and arouses suspicion.[2] A multidisciplinary approach is necessary, integrating forensic pathology, entomology, scene investigation, law enforcement, and mental health expertise, to ensure accurate death certification, a holistic understanding of the surrounding context, assess the well-being of the surviving resident, and ensure a comprehensive evaluation of the scene.[3,4] A review was performed for Harris County, TX, to identify case examples.

Several cases involved psychiatric illness or cognitive impairment. In one case, a mentally ill man living with a woman believed her to be sleeping, but she was decomposing on the floor. In another case, a son living with his mother appeared to misunderstand or deny her death and had attempted to feed her the day before her decomposed body was found. Another example was a woman with agoraphobia and dementia discovered hiding under bedcovers with her mummified husband.

Perceived barriers also lead to delayed responses. A spouse cited financial hardship as the reason for not seeking help. He was found incapacitated on the floor with injuries from a fall. The scene showed signs the spouse was attempting to clean the floor around the decomposing remains of his wife.

Several cases revealed disparate decomposition changes suggesting one individual had lived with the deceased for some time prior to their own demise, providing additional challenges as witness accounts and psychological evaluations are not available. The manners of death varied between natural, accident (unintentional neglect), and undetermined due to the extent of decomposition and lack of investigative information.

It is important not to make immediate assumptions based on the condition of remains or unusual behavior of survivors. An 85-year-old woman was discovered in advanced decomposition, wrapped in a blanket and carpet inside a closet for one year. Her schizophrenic son admitted to hiding the body and cashing her social security checks. Following an extensive investigation, the death was certified as natural (hypertensive and atherosclerotic cardiovascular disease) after excluding trauma and intentional harm.

There is scarce literature and research on the "Living with the Dead" phenomenon. In all cases, the inability of the individual to report the death or seek help requires careful scene evaluation and multidisciplinary efforts to determine cause and manner of death and exclude neglect or homicide. They present unique and complex challenges that extend beyond traditional death investigation protocols and often involve overlapping issues related to mental health, social isolation, cognitive impairment, and environmental hazards. Such coordinated efforts not only support accurate death certification but also help identify systemic gaps in care and intervention opportunities for vulnerable individuals.

I7 Maternal Deaths Associated With Hyperemesis Gravidarum

Titash Biswas, BS, St. Louis University School of Medicine, Saint Louis, MO; Tatiana Bihun, MD, Saint Louis City Medical Examiner's Office, St. Louis, MO; Joseph A. Prahlow, MD, Medical Examiners Office, City of St. Louis, St. Louis, MO*

Learning Objectives: The goal of this presentation is to present two deaths related to hyperemesis gravidarum, focusing on risk factors and the forensic pathology work-up of such cases.

Impact Statement: The presentation will impact the forensic community by presenting two cases of maternal death in pregnancy related to hyperemesis gravidarum in combination with additional comorbidities. The appropriate forensic pathology evaluation of such cases will be emphasized.

Abstract Text: Hyperemesis gravidarum is a severe complication of pregnancy characterized by persistent nausea, vomiting, and dehydration.[1,2] Treatment for this condition involves IV fluids, dietary changes, and medications, including antiemetics and vitamin B6, to prevent metabolic disturbances and malnutrition.[3-5] Although rarely fatal, hyperemesis gravidarum without appropriate management can be life-threatening in combination with other medical conditions. We report two cases of maternal mortality due to compounding effects of dehydration associated with hyperemesis gravidarum and concurrent conditions of underlying respiratory illness and maternal sepsis.

Case 1: A 32-year-old gravida 2 para 1 woman at approximately 28 weeks gestation was found deceased in her home. In the three days prior to death, the woman reported cramping, generalized weakness, and regurgitation of brown fluid. Medical history included complications of pregnancy, including recurrent episodes of severe vomiting and dehydration, requiring hospitalization three months prior to death. Her first pregnancy was characterized by similar symptoms at reduced severity. Autopsy revealed that her eyes had a "sunken-in" appearance and upper respiratory tract contained brown-tinged fluid. Microscopic examination of the lungs yielded findings of bronchiolitis, bronchitis, and patchy bronchopneumonia. Postmortem lung bacterial cultures grew *Streptococcus pneumoniae*. Lung viral culture did not isolate any viruses. Vitreous chemistry testing revealed the following: Sodium – 130 mEq/L, Potassium – 4.4 mEq/L, Chloride – 90 mEq/L, Urea nitrogen – 82 mg/dL, Creatinine – 1.9 mg/dL, Glucose – 40 mg/dL. Toxicology testing was positive for pseudoephedrine at therapeutic levels. The cause of death was acute and chronic bronchiolitis and bronchitis, with associated bronchopneumonia, with a contributing cause of dehydration related to hyperemesis gravidarum as a complication of pregnancy. The manner of death was natural.

Case 2: A 24-year-old gravida 4 para 3 woman at 17 weeks gestation was found deceased in a supine position. Medical history included several pregnancies with complications, including anemia during third trimester, trichomonal vaginitis, and hyperemesis gravidarum. The latest pregnancy experienced the strongest severity of recurrent vomiting, dehydration, and abdominal and back pain. Autopsy revealed generalized cachexia with temporal wasting and prominent bones, including ribs, clavicle, and iliac crest, associated with hyperemesis gravidarum. Microscopic examination of the placenta highlighted extensive decidual necrosis with florid acute inflammation, compatible with fetal death prior to maternal death caused by maternal sepsis. Vitreous chemistry testing revealed the following: Sodium – 133.2 mEq/L, Potassium – 18.92 mEq/L, Chloride – 122.6 mEq/L, Urea nitrogen – 72 mg/dL, Creatinine – unsuitable, Glucose – 25 mg/dL. Toxicology testing was positive for cannabinoids. The cause of death was maternal sepsis due to necrotizing deciduitis, and hyperemesis gravidarum was considered a contributory cause. The manner of death was natural.

These cases highlight the potential for fatal complications as a result of unmanaged hyperemesis gravidarum, especially dehydration and metabolic disturbances, which can exacerbate comorbid conditions. Continuous medical evaluation and treatment throughout high-risk pregnancies is necessary to avoid lethal complications. Forensic evaluation of these cases requires detailed social and medical history, vitreous electrolyte evaluation, histology, and additional studies pertinent to the specific pregnancy such as placenta examination and microbiological studies.

I8 Nothing Is as It Seems: A Differential Diagnosis Between Postmortem Animal Predation and Caustic Ingestion in a Case of Complex Suicide

Cristina Elia, MD, University of Salerno / University of Foggia, Salerno, Campania, Italy; Elena de Laurentiis, MD*, University of Salerno/ University of Foggia, Sassano, Campania, Italy; Tommaso Livieri, MD, University of Trieste, Trieste, Friuli-Venezia Giulia, Italy; Calogero Cuttaia, MD, University of Trieste, Trieste, Friuli-Venezia Giulia, Italy; Francesco Orsini, MD, University of Foggia, Foggia, Puglia, Italy; Raffaele Cirillo, MD*, University of Salerno, Agropoli, Campania, Italy; Alessandro Santurro, MD, PhD*, University of Salerno, Salerno, Campania, Italy; Roberta Bibbò, MD, Università degli Studi di Foggia, Foggia, Puglia, Italy; Chiara Fabrello, MD, Università degli Studi di Foggia, Foggia, Puglia, Italy*

Learning Objectives: After attending this presentation, participants will be able to critically assess the impact of postmortem artifacts from animal activity on the forensic determination of cause and manner of death and differentiate between antemortem traumatic injuries and postmortem alterations, especially in delayed autopsy contexts, through the integration of environmental, scene, and autopsy data in the interpretation of cadaveric changes in complex forensic cases.

Impact Statement: This case highlights the need to consider animal predation as a potential confounding factor in the assessment of cadaveric injuries, especially when injuries involve exposed body areas and occur in outdoor environments where postmortem artifacts may mimic antemortem trauma or obscure key forensic findings.

Abstract Text: Cadaveric changes related to animal predation involve many issues related to identification, injury assessment, and sometimes the definition of the causes of death. Indeed, many animal species can be responsible of cadaveric depredation, with considerable variability related to geographic area, season, and environment (indoor/outdoor).

The reported case concerns the death of a 61-year-old man found lying on the ground in the garden of his country house, partially suspended by a rope, tightened on the neck, and fixed on the upper pergola. Close to him, a package of caustic household products was found, creating the first hypothesis of a complex suicide, committed by vein cutting, caustic ingestion and hanging. Autopsy was carried out after some days by operators who were not on the crime scene and had never seen the corpse before. The examination of clothes showed were diffusely soiled with filiform grayish-white material. The external examination revealed, beyond the cervical furrow, the presence of extensive facial skeletonization and cervical tissue loss exposing the underlying tissues. Also, both wrists showed multiple linear, variably deep, infiltrated incised wounds. The autopsy showed partial laceration of the tongue, infrahyoid muscles, the thyroid shield, and the loss of the left lobe of thyroid.

Autopsy and scene findings supported violent mechanical asphyxia due to hanging, following an unsuccessful attempt at exsanguination. Caustic ingestion was ruled out due to intact oral and esophageal mucosa, while facial and neck injuries were attributed to macrofauna action, where the presence of non-infiltrated margins, with kerning or “double-track” appearance and the exclusive involvement of the undressed areas, allowed the hypothesis of a rodent’s postmortem aggression, confirmed by analysis of the material found on the clothing, attributed to animal hair.

This case highlights how a careful assessment of cadaveric injuries must consider environmental factors interfering with the cadaver, with particular attention to artifacts attributable to animal predation, capable of diverting the logical process underlying a correct postmortem diagnosis.

I9 Opioid-Induced Constipation With Massive Colonic Dilation and Stercoral Colitis: A Rare Autopsy Finding in Fentanyl Overdose

John X. Hu, MD, PhD, Pinal County Medical Examiner's Office, Florence, AZ; Afifa Bhutta, MD, Pinal Country Medical Examiner's Office, Florence, AZ; Andrea W. Oeinck, DO, Pinal County Medical Examiner's Office, Florence, AZ*

Learning Objectives: Attendees will gain essential insights into recognizing the magnitude of Opioid-Induced Constipation (OIC) as a serious complication of chronic opioid use. They will become familiar with the gross and microscopic autopsy findings—such as massive colonic dilation and stercoral colitis—that underscore the severity of this condition. Furthermore, participants will learn the vital role of comprehensive gastrointestinal examinations in overdose cases, which are crucial for improving diagnostic accuracy and raising public health awareness.

Impact Statement: This presentation highlights a serious but often overlooked complication of chronic opioid use: fecal impaction with severe colonic pathology. By illuminating the gastrointestinal consequences of opioid use, it advocates for more thorough postmortem evaluations. This approach not only improves the accuracy of cause-of-death determinations but also informs public health strategies within the forensic community—ultimately supporting better health outcomes and potentially saving lives.

Abstract Text: Fentanyl, a synthetic opioid with potent central nervous system effects, is a significant contributor to the opioid epidemic and overdose-related deaths in the United States. While its role in respiratory depression is well recognized, its gastrointestinal sequelae, particularly OIC, are underappreciated. OIC results from μ-opioid receptor activation in the gut, leading to decreased peristalsis, prolonged transit time, and ultimately fecal retention. In extreme cases, these changes can culminate in massive colonic dilation, stercoral colitis, ischemia, and perforation.

We present the autopsy findings of a 27-year-old woman with a history of chronic polysubstance use, including fentanyl, methadone, and methamphetamine. She was found unresponsive with drug paraphernalia nearby. Postmortem toxicology confirmed lethal levels of fentanyl and methamphetamine. On internal examination, the colon was markedly dilated, measuring up to 9 cm in diameter in the sigmoid region (N < 5cm) , and filled with hardened fecal matter. The colonic mucosa exhibited progressive discoloration from the ascending to the sigmoid colon. Microscopic analysis revealed mucosal ulceration, inflammation, and signs of chronic ischemic injury, consistent with stercoral colitis. No colonic perforation was identified. The cause of death was determined to be mixed drug intoxication with contributory findings of severe colonic dilation and stercoral colitis.

This case highlights an underrecognized but serious consequence of chronic opioid use, particularly in younger populations. Massive fecal impaction and colonic dilation are rare findings on autopsy, especially in individuals without underlying gastrointestinal disorders. Our findings reinforce the need for increased clinical and forensic awareness of the full systemic impact of opioids, beyond respiratory suppression. For forensic pathologists, this case emphasizes the value of thorough gastrointestinal examination in overdose deaths. From a public health perspective, it raises awareness of gastrointestinal morbidity in chronic opioid users, potentially prompting earlier intervention strategies. By sharing this case, we aim to illuminate and advocate for integrative public health responses to the opioid crisis.

I10 Tracing the Ear to the Heart: Frank's Sign as a Forensic Marker in 14 Years of Autopsy-Based Cardiac Deaths

Enrica Macorano, MD, University of Bari, Bari, Puglia, Italy; Francesco Introna, MD, University of Bari, Bari, Puglia, Italy*

Learning Objectives: Participants will understand the forensic value of Frank's sign (Diagonal Earlobe Crease [DELC]) in the context of cardiac-related deaths. They will learn how to evaluate DELC during autopsy, correlate it with cardiovascular risk factors, and integrate it into medicolegal diagnostic protocols. The session highlights the combination of morphological indicators and classic forensic methodology for improving postmortem cardiovascular assessment.

Impact Statement: This study emphasizes the importance of simple morphological signs as forensic markers of cardiovascular risk. By analyzing three decades of autopsy data, the research bridges clinical cardiology and forensic pathology, underscoring the potential of Frank's sign as a rapid, non-invasive indicator to guide postmortem investigations and enhance the determination of natural cardiac deaths.

Background: Frank's sign, a DELC, has been repeatedly associated with Coronary Artery Disease (CAD) and cardiovascular mortality, yet forensic autopsy-based evidence remains limited.[1,2] This study investigates the prevalence and prognostic value of DELC in cardiac-related deaths over a 14-year period, aiming to evaluate its correlation with heart weight, preexisting cardiovascular disease, and atherosclerotic burden.

Methods: A retrospective review of autopsies performed at the Institute of Legal Medicine, University of Bari (2010-2024) was conducted. Inclusion criteria comprised confirmed cardiac-related causes of death and availability of intact earlobes photos. DELC presence and grade (0-3) were recorded according to standardized criteria.[3] Cardiac weight, macroscopic coronary artery disease (CAD) severity, and preexisting cardiovascular conditions were documented. Statistical analyses assessed correlations between DELC grade and cardiovascular parameters, including Spearman's rank correlation and logistic regression models.[4,5]

Results: Preliminary findings indicate a significant association between high-grade DELC (2b) and severe CAD, increased heart weight, and generalized atherosclerosis. A positive correlation was observed between DELC grade and the presence of preexisting cardiovascular pathology. In cases of sudden cardiac death, high-grade DELC was present in the majority of individuals, particularly in those under 60 years, highlighting its potential as an early forensic marker. Age-adjusted analyses confirmed DELC as an independent predictor of cardiac-related mortality, though age remained a strong confounding factor consistent with previous studies.[6,7]

Conclusion: The study supports Frank's sign as a valuable adjunct in forensic evaluation of cardiac deaths. The presence of a high-grade DELC should prompt careful examination of the cardiovascular system and can provide a rapid, non-invasive morphological clue during autopsy. Integrating DELC assessment into standard medicolegal protocols reinforces the role of simple anatomical indicators in bridging clinical and forensic diagnostics and underscores the enduring relevance of morphological examination in the era of advanced imaging and molecular testing.

I11 CDT and Alcohol Abuse: A Metabolomic Perspective

Alberto Chighine, MD, PhD, University of Cagliari, Cagliari, Sardegna, Italy; Emanuela Locci, PhD, University of Cagliari, Cagliari, Sardegna, Italy; Giacomo Musile, PhD, University of Verona, Verona, Veneto, Italy; Franco Tagliaro, MD, PhD, University of Verona, Verona, Veneto, Italy; Ernesto d'Aloja, MD, PhD, University of Cagliari, Cagliari, Sardegna, Italy; Nadia Porpiglia, PhD, University of Verona, Verona, Veneto, Italy*

Learning Objectives: Attendees will learn how metabolomics complements Carbohydrate-Deficient Transferrin (CDT) in detecting chronic ethanol abuse, identifying key metabolites, and understanding their correlation with CDT levels. They will explore metabolomic profiling techniques, discriminatory metabolites, and their potential to extend detection windows and improve diagnostic specificity in forensic toxicology.

Impact Statement: This presentation will advance forensic pathology and toxicology by introducing metabolomics as a complementary tool to CDT, enhancing the detection of chronic ethanol abuse. It offers insights into metabolic biomarkers, potentially improving diagnostic accuracy and specificity, thus impacting forensic assessments in legal and medicolegal contexts.

Abstract Text: Chronic ethanol abuse represents a significant public health and medicolegal issue, contributing to a wide range of chronic degenerative diseases and socially dangerous behaviors, including road and workplace accidents, domestic and sexual violence, and substance-related crimes. CDT is currently one of the most widely used biomarkers for assessing chronic ethanol consumption (>60 g/day), offering a detection window of approximately 10–14 days. However, CDT's temporal sensitivity and susceptibility to confounding factors, such as physiological or pathological conditions, necessitate longitudinal assessments or complementary tools.[1] Metabolomics, which comprehensively analyzes low-molecular-weight metabolites, offers a promising approach to identify characteristic metabolic profiles associated with chronic ethanol abuse, potentially addressing CDT's limitations.[2]

This study, conducted as a collaborative effort between Legal Medicine Institutes of the Universities of Cagliari and Verona, aimed to perform a comparative metabolomic analysis of serum samples from individuals with CDT levels indicative of chronic ethanol abuse (>2%) versus a control group. A total of 45 serum samples were analyzed, comprising 15 samples from individuals with CDT ranging from 2.2% to 10.1% and 30 control samples with CDT between 0.7% and 1.8%. Samples were collected from subjects of both sexes (predominantly male, M/F ratio >3) aged 18–72 years, during fitness-to-drive evaluations under Article 119 of the Italian Driving Code.

Serum metabolites were extracted using solid-phase extraction and analyzed via Ultra High-Performance Liquid Chromatography Coupled with quadrupole Time-Of-Flight Mass Spectrometry (UHPLC-qTOF/MS) in both positive and negative ion modes (ESI+ and ESI-). Data were processed using multivariate statistical techniques, including supervised (Principle Component Analysis [PCA]) and unsupervised techniques (Orthogonal Partial Least Squares [OPLS], Orthogonal Partial Least Squares Discriminant Analysis [OPLS-DA]), to identify discriminatory metabolites and correlations with CDT levels. Pathway analysis was employed to identify the most important metabolic pathways involved.

PCA analysis revealed a clear separation between the CDT-positive and control groups, indicating distinct metabolomic profiles associated with chronic ethanol abuse. The OPLS-DA model further confirmed robust class discrimination, identifying key metabolites such as arginine, squalene, 2-ketobutyrate, and malonate as characteristic of the CDT-positive group, while hypoxanthine, nicotinamide, taurine, and thiamine were more prevalent in controls, suggesting their reduction in chronic ethanol abusers. OPLS regression demonstrated a strong linear correlation between CDT levels and metabolomic profiles, particularly in the CDT-positive group. These findings highlight the sensitivity of metabolomics in detecting ethanol-related metabolic alterations.

This proof-of-concept study confirms the feasibility of metabolomic profiling to distinguish chronic ethanol abusers from moderate drinkers and supports a correlation between serum metabolome and CDT levels. Notably, the observed reduction in thiamine and nicotinamide aligns with clinical evidence of their deficiency in chronic alcoholism, linked to neurological and metabolic complications. Despite limitations, including a small sample size and lack of metadata (e.g., comorbidities), these preliminary results lay the groundwork for larger longitudinal studies to validate the metabolomic approach, potentially extending the detection window beyond CDT's current perspective and improving specificity by distinguishing ethanol-related CDT elevations from physiological or pathological confounders. The discovery of alcohol-induced modifications in the metabolome also support the translation in the postmortem setting for the identification of causes of death related to chronic alcohol abuse.

I12 On Thin Ice: The Frozen Facts

Jacob Teigen, BA, University of North Dakota School of Medicine and Health Sciences, West Fargo, ND; Grace L. Blair, BS, University of North Dakota School of Medicine and Health Sciences, Grand Forks, ND; Susan Roe, MD, University of North Dakota School of Medicine and Health Sciences, Grand Forks, ND; Selly Strauch, MD, University of North Dakota School of Medicine and Health Sciences, Grand Forks, ND; Wai Szeto, MD, University of North Dakota School of Medicine and Health Sciences, Grand Forks, ND*

Learning Objectives: The first learning objective of this presentation is to identify key forensic findings in cold-water drowning deaths associated with vehicle submersion. Attendees will learn how autopsy findings, such as water in the lungs and gastrointestinal tract and cerebral and pulmonary edema can support the diagnosis of drowning and hypothermia. They will also explore how trauma may contribute or relate to cause of death in such incidents. The second objective is to understand the impact of climate change on seasonal drowning risks. Participants will examine how climate-driven changes in ice formation and break-up patterns may increase the incidence of winter drownings, particularly those involving heavy vehicles on frozen lakes. This knowledge will inform public safety and policy efforts aimed at mitigating future risk. The third objective is a discussion of the demographic and behavioral risk factors contributing to ice-related drownings. Attendees will analyze common risk behaviors (e.g., late-season ice activities like ice house removal), the role of age and pre-existing health conditions, and environmental context in cold-weather drowning fatalities to better target prevention strategies.

Impact Statement: This presentation discusses drownings resulting from vehicle submersion through ice, which is a preventable public health concern with a projected increase in risk with ongoing climate change. By detailing the forensic findings of two cold-water drowning fatalities, this presentation enhances the forensic science community's understanding of postmortem indicators specific to hypothermic drowning in icy conditions. Additionally, it highlights the importance of integrating environmental awareness into death investigations and public safety policy. As ice stability becomes less predictable, forensic pathologists and death investigators will play a pivotal role in identifying, documenting, and contextualizing these deaths, contributing essential data to support prevention efforts and adapt investigative protocols in response to evolving environmental hazards.

Abstract Text: Globally, drowning is the third leading cause of unintentional injury deaths, with 20% occurring in winter months.[1] Many of these winter deaths involve heavy vehicles breaking through frozen bodies of water. We present two cases of drowning that occurred due to vehicles falling through frozen lakes. Decedent #1 was a 62-year-old male with a past medical History (PMH) of type two diabetes mellitus who was witnessed attempting to remove an ice fishing house using a large truck. The truck fell through the ice and remained submerged for 45 minutes. The decedent was removed from the submerged vehicle and cardiopulmonary resuscitation was initiated. The decedent was flown via helicopter to the nearest trauma center and was pronounced dead on arrival. Decedent #2 was a 70-year-old male with a PMH of atrial fibrillation and chronic obstructive pulmonary disease who was reported missing after failing to meet friends to go fishing. He also was attempting to retrieve an ice fishing house on a frozen lake. He was discovered face down floating in the water above a break in the ice with his vehicle and ice fishing house submerged beneath him. It was unclear if he was in the vehicle at the time of the ice breaking. The decedent was declared dead on site and no resuscitative measures were initiated.

Autopsy findings for Decedent #1 included a left periorbital ecchymosis and a subgaleal contusion with no associated intracranial injury. Traumatic injuries also included a left renal laceration, a splenic laceration, and bilateral serial rib fractures. Water was present in the respiratory and gastrointestinal tracts. There were cerebral and pulmonary edema. Fluid was aspirated (2.5 mL) from the sphenoid sinus. The cause of death was determined to be drowning with an associated condition of hypothermia. The sustained trauma was deemed to not be the cause of the decedent's death due to minimal associated internal hemorrhage and no evidence of lethal internal injuries on autopsy. The injuries likely contributed to the decedent's susceptibility to drowning, but were deemed unlikely to be the cause of death.

Autopsy findings for Decedent #2 included water in the respiratory and gastrointestinal tracts. There were cerebral and pulmonary edema and 1 mL of fluid aspirated from the sphenoid sinus. There was pulmonary marginal and subpleural emphysema. The cause of death was listed as drowning with associated hypothermia. Drowning was determined by the presence of fluid in lungs, GI tract, and sinus aspiration, indicating submersion and a compromised airway. Hypothermia was concluded from environmental exposure and consistent circumstances of both decedents being submerged in water with temperatures below 40°F. Together, autopsy findings and scene investigation confirmed drowning and hypothermia as the causes of death.

Postmortem toxicological analyses was non-contributory in each case.

Due to changing climates, an estimated 100 million people are likely to experience earlier ice break-up, later ice formation, and shorter seasons of ice cover.[2] This causes concern for increased drowning events in winter months. These two cases highlight issues of ice-related drownings, providing insight with important future implications.

I13 Estimating the Minimum Postmortem Interval: The Role of Forensic Entomology in Outdoor Cases in Central Italy

Luca Manelli, PhD, Bournemouth University, Bournemouth, England, United Kingdom; Marcello Seligardi, MD, University of Parma, Parma, Emilia-Romagna, Italy; Valentina Bugelli, MD, PhD, University of Parma, Parma, Emilia-Romagna, Italy; Sara Bortolini, PhD, Research Center Laimburg, Vadena (BZ), Italy, Bolzano, Trentino-Alto Adige, Italy*

Learning Objectives: After attending this presentation, attendees will learn how forensic entomology can be used to narrow the estimated postmortem interval in bodies found outdoors in advanced stages of decay.

Impact Statement: This presentation will impact the forensic science community by helping understand the role of forensic entomology in real casework in the estimation of the time of death. This study also identifies the most common insect species found on human remains in outdoor locations in central Italy, providing important data for further regional forensic investigations.

Abstract Text: The authors present a series of ten case studies in which human bodies were discovered in the advanced stages of decomposition or full skeletonization in outside locations in Central Italy. The cases occurred between 2019 and 2022, encompassing all seasons. The bodies were found in a wide variety of outdoor environments, such as woodlands, gardens, or roadside spaces. Entomological evidence was collected during on-scene investigations and postmortem examinations, while temperature data was retrieved from the nearest meteorological station or sampled at the location where the bodies were found by placing a data logger on-site. The minimum Postmortem Interval (minPMI) estimated using entomological evidence in the presented cases ranged between four days and six months, highlighting the application of this discipline across a broad range of timeframes.

Blow fly (Diptera: Calliphoridae) species were found in eight cases, with the most common being *Calliphora vomitoria* and *Lucilia illustris. Chrysomya albiceps* was found in six cases, while *Phormia regina, Lucilia ampullacea, Calliphora vicina,* and *Lucilia caesar/illustris* were also discovered in some instances. Other insect taxa were also identified, including Muscidae *(Hydrotaea sp.),* Sarcophagidae *(Sarcophaga sp.),* Dermestidae *(Dermestes sp.),* Silphidae *(Necrodes littoralis),* and Staphylinidae *(Creophilus maxillosus).*

In this study, entomologic evidence was able to refine the estimated minPMI in 90% of cases when compared to other forensic techniques. Furthermore, this research identifies the most prevalent insect species associated with outdoor human remains in Central Italy, providing critical taxonomic data for regional forensic investigations.

I14 Identifying the Transition From Antemortem to Postmortem Odor in Cadavers in an Outdoor Environment

Darshil Patel, PhD, University of North Dakota, Grand Forks, ND; Wesley Burr, PhD, Trent University, Peterborough, Ontario, Canada; Shari Forbes, PhD, University of Windsor, Windsor, Ontario, Canada; Benoit Daoust, PhD, Université du Quebec a Trois-Rivieres, Trois-Rivieres, Quebec, Canada*

Learning Objectives: Upon completion of this session, attendees will be able to understand how antemortem Volatile Organic Compound (VOC) profiles evolve into postmortem odor during the first days of outdoor decomposition. They will recognize the persistence of antemortem odor in the early postmortem period and identify key chemical markers that signify the transition. Attendees will also be able to apply this understanding to optimize the timing and deployment of search and rescue and human remains detection dogs.

Impact Statement: This study delivers the first detailed account of early postmortem odor in outdoor human remains, documenting how antemortem volatiles persist and transform over the initial 0–96 hours after death. By pinpointing chemical markers that mark this earliest transition, it builds practitioner competence in interpreting VOC profiles and supplies evidence-based guidance for optimizing the timing of search and rescue and human remains detection dog deployments.

Abstract Text: This study investigates the transition from antemortem to postmortem odor in human remains during the early postmortem period in an outdoor environment. Three cadavers (donors) were placed at an outdoor human decomposition facility, and VOCs were collected and analyzed using Thermal Desorption coupled with comprehensive Two-Dimensional Gas Chromatography-Time-Of-Flight/Mass Spectrometry (TD-GC×GC-TOF/MS). The key findings revealed that nitrogen-containing compounds were predominant in early postmortem VOC profiles, driven by enzymatic and bacterial activity. Esters, alcohols, and halogenated compounds were also identified, with esters linked to microbial transformation and alcohols possibly formed by lipid peroxidation. Antemortem VOCs were persistent across samples, influenced by skin microbiota and environmental factors like Ultraviolet (UV) radiation, complicating the detection of decomposition odor. Postmortem VOCs became more prominent after Accumulated Degree Days (ADD) of 73.4 (experimental day 3), signaling the transition to the bloat stage of decomposition. Variations in sample collection methods and external factors such as temperature were found to affect VOC abundances.

This study provides critical insights into odor transition and has implications for the use of Search And Rescue (SAR) and human remains Detection (HRD) dogs. Further research is needed to standardize methods and assess odor transitions across diverse environments and seasons.

I15 The Diagnostic Value of Tissue Detection of Aquatic Bacteria (*Aeromonas* and *Vibrio*) in Death by Drowning by PCR and the Metagenomic Approach

Claire Villard, MD, CHU Montpellier, Montpellier, Languedoc-Roussillon, France; Mylène Toubiana, PhD, HydroScienceMontpellier, Montpellier, Languedoc-Roussillon, France; Estelle Jumas-Bilak, MD, PhD, HydroScienceMontpellier, Montpellier, Languedoc-Roussillon, France; Pierre-Antoine Peyron, MD, PhD, CHU La Réunion, Saint-Denis, French Southern Territories, French Southern and Antarctic Lands*

Learning Objectives: Attendees will: (1) review the challenges in diagnosis drowning; (2) learn about the composition of the microbial communities of cadavers (thanatomicrobiome) after drowning in fresh and salt water; and (3) discover a new diagnosis test based on the detection of aquatic bacteria by Polymerase Chain Reaction (PCR).

Impact Statement: This work will present the diagnostic performance of tissue bacterial detection by PCR in drowning deaths in comparison to taxonomy identification obtained by Next Generation Sequencing (NGS). This dual approach is the first to have been implemented on such a large cohort of cadavers. Sharing this PCR method with other forensic institutes could provide a new tool to better diagnose drowning.

Background: Death by drowning is a difficult diagnosis, due to non-specific autopsy signs and ancillary tests of questionable reliability, that are often under-used.[1,2] Postmortem detection of aquatic bacteria in blood and organs represents an innovative approach that could support this diagnosis.[3-7] However, little is known about the composition of the cadaver microbiome (thanatomicrobiome), particularly in drowned cadavers. Our objectives were: (1) to study the microbial composition of drowned cadavers; (2) to identify marker bacteria of fresh and salt water drownings; and (3) to develop a detection method that can be used in routine forensic practice.

Methods: Thirty-five bodies found in or near an aquatic environment and autopsied at the Forensic Institute of Montpellier in France were categorized according to cause of death and type of immersion water. Organ samples (liver, kidney, lungs) and blood samples (right and left cardiac blood, femoral blood) were taken. After DNA extraction, the total bacterial community composition of samples from 17 drowned cadavers and 2 control cadavers were studied using a metagenomic approach targeting the V3-V4 portion of the gene encoding 16S rRNA (sequenced by Illumina). Specific PCRs targeting the aquatic genera *Aeromonas (zipA)* and *Vibrio (pyrH)* were then performed on all cohort samples.

Results: Metagenomic analyses revealed that the drowning corpses' thanatomicrobiome is composed of human microbiome bacteria as well as aquatic bacteria (*Aeromonadaceae* and *Vibrionaceae*). The latter were absent from control patients. The *zipA* PCR had an excellent Positive Predictive Value (PPV) of 97% and a Negative Predictive Value (NPV) of 77% for the detection of *Aeromonas* spp. while the *pyrH* PCR had a PPV of 28% but an excellent NPV (99%) for the detection of *Vibrio* spp. Overall, the specific PCRs enabled the detection or the absence of *Aeromonas* or *Vibrio* with a reliability of over 80%.

Conclusion: These results confirm the relevance of PCR as a simple and inexpensive test for the detection of aquatic bacteria for diagnostic purposes in cases of suspected drowning. Further studies, including more non-drowned immersed controls, are required to prove the absence of aquatic bacteria in the thanatomicrobiome after postmortem immersion.

I16 The Impact of Substance Use Disorders on Postmortem Microbiome Signatures

Christina Harris, BS, Alabama State University, Montgomery, AL; Olivia Willoughby, BS, Alabama State University, Deatsville, AL; Gulnaz T. Javan, PhD, Alabama State University, Montgomery, AL; Silvia D. Visonà, MD, PhD, Department of Legal Medicine and Forensic Sciences, University of Pavia, Italy, Pavia, Lombardia, Italy*

Learning Objectives: After attending this presentation, attendees will understand how to use high-throughput next-generation 16S rRNA amplicon sequencing analyses to characterize the postmortem microbiome of internal organs from actual cadavers in criminal cases (e.g., homicide, suicide, and overdose) from Italy.

Impact Statement: This presentation will impact the forensic science community by providing results to support the Human Postmortem Microbiome Project (HPMP) catalog. By analyzing the relative abundances of specific microbes present in the postmortem samples, a comparative approach was used to identify a possible link between commonly abused drugs and microbes associated with the decomposition process.

Abstract Text: Human postmortem microbiome studies have demonstrated that microorganisms inhabit and proliferate externally and internally throughout the body and are the primary mediators of putrefaction after death. Studies have shown that disruptions in the gut microbiota have been associated with substance use disorders.[1] The interplay of gut microbiota in substance abuse disorders has not been elucidated; however, postmortem microbiome profiles may produce promising avenues for future forensic investigations.

The goal of this study was to determine gut microbiome composition in substance abuse disorder cases using postmortem tissues of 20 overdose criminal cases versus 20 non-overdose-related cases from Italy. We hypothesized that postmortem samples of the same cause of death will reveal similar microbial taxonomic relationships. We compared microbial diversity profiles using amplicon-based sequencing of the 16S rRNA gene V4 region versus the V1-V3 hypervariable regions.

In this study, we investigated the microorganisms obtained from the internal organs of corpses from Italy. Alpha diversity was determined through the number of observed genera, Shannon diversity and Inverse Simpson Index, and visualized through boxplots. Statistical significance was determined through Pairwise Wilcoxon analysis with False Discovery Rate correction. Beta diversity was determined using Bray-Curtis distances and visualized through boxplots. Statistical significance was determined using Mann-Whitney analysis. Differentially abundant taxa were determined using the R package MaAsLin2, and coefficients were visualized using bar plots. While results showed no significant differences in alpha diversity in drug overdose vs. non-drug overdose deaths, the Postmortem Interval (PMI) was negatively correlated with alpha diversity in drug overdose deaths, regardless of the variable region. In addition, alpha diversity was positively correlated with weight and height in non-drug overdose deaths, regardless of the variable region. *Enterococcus*, *Citrobacter*, and *Pseudomonas* were among the most abundant taxa across the sampled organs in drug overdose and non-drug overdose deaths, regardless of variable region. *Pseudomonas* was positively correlated with PMI in drug overdose deaths (V4 region) and negatively correlated with height in non-drug overdose deaths (V1V3 region).

In conclusion, we investigated the influence of 16S rRNA gene primer choice in determining the different community profiles to provide empirical data to support the HPMP for studying the thanatomicrobiome.

I17 Tissue-Specific Protein Degradation in Human Autopsy Cases: A Comparative Study for Postmortem Interval Estimation

Laura Flachberger, MSc, Dept. of Legal Medicine, Paris-Lodron University of Salzburg, Salzburg, Salzburg, Austria; Stefan Pittner, PhD, Dept. of Legal Medicine, Paris-Lodron University of Salzburg, Salzburg, Salzburg, Austria; Fabio Monticelli, PhD, Dept. of Legal Medicine, Paris-Lodron University of Salzburg, Salzburg, Salzburg, Austria; Peter Steinbacher, PhD, Dept. of Environment and Biodiversity, Paris-Lodron University of Salzburg, Salzburg, Salzburg, Austria*

Learning Objectives: Attendees will learn how tissue type influences postmortem protein degradation and how this variability can inform Postmortem Interval (PMI) estimation. The presentation will explain the methodology for detecting protein stability in human autopsy tissues, highlight key findings, and identify the challenges and future directions in developing reliable molecular markers for forensic time of death estimation.

Impact Statement: This presentation contributes to forensic science by expanding understanding of tissue-dependent protein degradation patterns in human cadavers. The results support the development of more accurate and adaptable molecular tools for PMI estimation and encourage further research into tissue-specific biomarkers, ultimately improving forensic case evaluations and time of death determinations.

Abstract Text: Estimating the PMI remains a fundamental yet complex task in forensic science, with critical relevance for legal investigations and death scene reconstruction. Conventional techniques often face limitations due to environmental variability and narrow time frames of applicability, underscoring the need for molecular approaches with greater reliability and broader temporal reach.

This study examined the degradation dynamics of five structural and metabolic proteins—Vinculin, GAPDH, Actin, α-Tubulin, and Desmin—across six human tissues: liver, lung, muscle, skin, cartilage, and bone. Using Sodium Dodecyl Sulfate-Polyacrylamide Gel Electrophoresis (SDS-PAGE) and Western blotting, protein stability was assessed in samples from nine forensic autopsy cases. The extent of decomposition was quantified via the Total Body Score (TBS), enabling comparative analysis of protein degradation across tissue types.

Findings revealed pronounced tissue-specific degradation patterns. Rapid protein breakdown was observed in the liver and lungs, while muscle and skin degraded more gradually. Cartilage and bone exhibited the greatest resistance to postmortem change, with detectable protein signals persisting even in advanced decomposition stages. Not all proteins were consistently detectable across all tissues, and variability in band intensity was noted—potentially due to technical challenges or individual case-related factors influencing proteolytic activity and tissue preservation.

These results emphasize the importance of intrinsic tissue properties—such as architecture, enzymatic milieu, and metabolic rate—in shaping postmortem protein degradation. The data support the potential use of tissue-specific protein markers for PMI estimation and lay the groundwork for further validation. Future studies should aim to increase sample size, identify additional robust markers, and include cases with well-documented PMIs to enhance model accuracy.

I18 A Novel Approach to Estimate the Postmortem Submersion Interval Using Barnacles and Drift Trajectories: A Mediterranean Study

Beatrice Spadaro, MD, Unime, Messina, Sicilia, Italy; Anna Messina, MD, Messina University, Messina, Sicilia, Italy; Daniela Sapienza, PhD, Unime, Messina, Sicilia, Italy; Elvira Ventura Spagnolo, MD, Messina University, Biomorf Department, Medicolegal Section, Messina, Sicilia, Italy; Roberta Somma, PhD, Unime, Messina, Sicilia, Italy; Salvatore Giacobbe, PhD, Unime, Messina, Sicilia, Italy*

Learning Objectives: The importance of evaluating both marine biological data, such as the identification of different crustacean species, their size, and growth for minimum Postmortem Submersion Interval (mPMSI) estimation, and oceanographic modeling to reconstruct drift trajectories for shipwreck site localization has been highlighted.

Impact Statement: This case study illustrates the importance of a multidisciplinary approach in forensic science. It enabled a more accurate estimation of the mPMSI and contributed to the reconstruction of complex postmortem scenarios following shipwrecks, providing essential support to the judicial authorities.

Abstract Text: The Mediterranean Sea is unfortunately known as a site of numerous shipwrecks associated with migratory flows originating from North Africa. In recent years, several bodies have been discovered close to its shores, often lacking identity or other features that could aid in their identification.

Estimating the PMI of bodies recovered from marine environments remains a significant challenge, as commonly used methods, such as the Henssge nomogram, become unreliable under such conditions. Marine environmental factors, including temperature, salinity, currents, and fauna, interact with individual characteristics (e.g., clothing, causes and mechanisms of death) in complex and often unpredictable ways, making postmortem assessments particularly difficult.

A key parameter in these investigations is the mPMSI, which represents the minimum time between a body's immersion and its recovery. In this study, a combined approach involving marine crustacean colonization and ocean current modeling was employed to assess the drift trajectories of bodies following shipwrecks. This approach aimed both to estimate the mPMSI and to identify the likely site of the shipwreck.

Four decomposed bodies were examined after being recovered along the northeastern shoreline of Sicily and its surrounding waters between spring and summer 2024. Crustaceans such as barnacles were observed on the corpses and collected for forensic analysis. Oceanographic simulations were conducted using the OpenDrift modeling framework (Norwegian Meteorological Institute), along with environmental datasets from the Copernicus Marine Data Store, to reconstruct the plausible drift paths of the bodies over the relevant time frame.

The identification, size, and growth rate of different crustacean species allowed the estimation of the mPMSI. Meanwhile, the oceanographic modeling enabled the authors to hypothesize the likely site of the shipwreck. These forensic findings were later confirmed by investigations conducted by the Judicial Authority, which verified that the victims were involved in the same maritime accident that occurred a few months prior to the recoveries between Tunisian coast and Sardinia.

I19 Body Fluid Proteomics of DNA Extraction Waste Products

Daniella Corene C. Luistro, MSFS, University of California, Davis, Vallejo, CA; Glendon J. Parker, PhD, University of California, Davis, Davis, CA; Kyle Burk, MS, University of California Davis, Parker Lab, Davis, CA*

Learning Objectives: During this presentation, the attendees will learn of a possible alternative method to obtaining body fluid identification using waste products generated from Promega's DNA IQ Extraction Kit and mass spectrometry-based proteomics. This process prioritizes crime scene samples for DNA profiling while still obtaining the necessary information for sourcing evidence.

Impact Statement: This presentation will impact the forensic science community by providing forensic scientists a supplemental method of obtaining confirmatory body fluid identification without the need of performing additional presumptive/confirmatory body fluid tests, thus obtaining information without further consumption of the sample.

Abstract Text: DNA extraction methods are prevalent within the forensic science field, with DNA playing a major and crucial role in forensic case work. Yet often, it is found that DNA is highly degradable due to factors such as temperature, humidity, and ultraviolet radiation, making it difficult to test DNA in cases where it is necessary.[1] When this is the case, investigators need to consume the evidentiary sample to obtain identifying information. This sacrifices the potential of obtaining valuable body fluid identification information, an important element in developing the context of a case and reconstructing the crime scene.[2]

Proteomics has been emerging as a promising field of study, with samples such as blood, saliva, semen, and vaginal fluid being tested to have shown vital information.[3] Yet the use of proteomics can be hampered by the need to conserve the sample or to fully consume it for DNA-typing. Several DNA extraction kits are adopted throughout the nation's forensic laboratories for an easy assist to isolate DNA. The main extraction kit that will be discussed in this research is the DNA IQ Extraction Kit from Promega, though there are other popular extraction kits from companies such as ThermoFisher and Qiagen. The common theme in these extraction kits is that there are lysis, wash, and extraction steps. Within the lysis step, the DNA is released into the solution and the cellular debris remains in the supernatant.[4] In DNA IQ, Proteinase K, a protease, is not added to the lysate solution.[5] The purpose of this research is to determine if there is viable proteomic data within the usually discarded buffer steps in different biological fluids. If this is the case, then proteomics will be fully compatible with DNA processing.

In this project, biological fluids, including blood, saliva, semen, and vaginal fluid, were run on DNA IQ, and the typically discarded lysis, wash, and extraction samples will be saved for proteomic analysis on Sodium Dodecyl Sulfate-Polyacrylamide Gel Electrophoresis (SDS-PAGE) gels and mass spectrometry. The protein density before and after the addition of the magnetic beads was collected, and the proportion of protein in the initial wash was 78.8 ± 25.5% for blood, 98.5% ± 2.6% for saliva, 91.5 ± 5.6% for semen, and 92.4 ± 6.3% for a semen/vaginal fluid mix (1:1). There was no change in the amount and quality of proteins in the pre-bead and post-bead samples. The same ratios were found when comparing trypsin-treated body fluids to major biomarker protein profiles, allowing easy comparison with known body fluids.

I20 Forensic Botany in Postmortem Interval Estimation: The Current State and Future Perspectives

Alessandro Pasquale Tarallo, MD, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Matteo Antonio Sacco, MD*, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Maria Cristina Verrina, MD*, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Luca Calanna, MD, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Jasmine Calafiore, MD, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Chiara Caruso, MD, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Aida Iaconetta, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Isabella Aquila, MD, PhD*, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy*

Learning Objectives: After attending this presentation, attendees will understand how forensic botany can contribute to Postmortem Interval (PMI) estimation through the analysis of vegetation changes and soil chemistry within Cadaver Decomposition Islands (CDIs).**Impact Statement**: This presentation will impact the forensic sciences community by demonstrating how the integration of botanical data and changes in soil biocenosis can improve the accuracy of PMI estimation, particularly when classical thanatochronological methods are unavailable or unreliable, offering innovative tools for PMI identification.

Introduction: Accurate estimation of the PMI is a central challenge in forensic investigations. The decomposition process is affected by environmental conditions and the time elapsed between death and discovery, often rendering traditional taphonomic or entomological approaches insufficient. Forensic botany has recently gained relevance as a discipline capable of analyzing plant communities, root systems, and soil characteristics within CDIs—areas of ecological disruption that are visually and chemically identifiable. Recent studies have shown that volatile organic compounds released during decomposition, soil alterations, and plant physiological responses near CDIs can serve as reliable indicators for PMI estimation.

Materials and Methods: A systematic review of the literature was conducted using scientific databases such as PubMed and ResearchGate. Keywords included: "cadaver decomposition island," "plant succession," "forensic botany," "PMI estimation," and "root growth analysis." Inclusion criteria were peer-reviewed articles in English or Italian focusing on terrestrial decomposition with relevant data on vegetation, soil chemistry, or microbiology. Studies involving forensic applications, root histology, dendrochronology for root-bone interactions, and remote sensing were also included. Exclusion criteria encompassed aquatic environments, non-human models without forensic application, articles lacking experimental data, or publications with limited scientific validity or accessibility.

Results: The literature reports significant increases in ammonium nitrogen and phosphate levels in soil within 30–90 days postmortem. Dissolved organic carbon and altered pH have been detected up to 1,752 days after death. Pioneer plant roots often colonize CDIs with altered growth patterns, and in some cases, they penetrate bone cavities—enabling PMI estimation through annual ring counts. Changes in microbial flora and bacterial communities in the soil persist for up to two years. Spectroscopic changes in leaves of herbaceous and shrub species, caused by nutrient and heavy metal release from the cadaver, are detectable using remote sensing technologies. Residual volatile compounds can persist in the soil for months after body removal.[1-6]

Discussion: Forensic botany emerges as a promising tool in PMI estimation, especially when entomological evidence is absent (e.g., cold environments, enclosed spaces, or prolonged decomposition). Root growth alterations and soil chemical changes offer measurable parameters, though subject to environmental variability (e.g., soil type, rainfall, vegetation species). The application of remote sensing to detect vegetation stress due to decomposition opens new operational avenues, particularly in wooded or inaccessible areas. However, standardizing protocols and creating regional reference databases are urgent needs to ensure methodological reproducibility and forensic reliability.

I21 Determining the Utility of Radio Frequency Identification (RFID) Technology for Disaster Victim Identification (DVI)

Makena P. McLean, Simon Fraser University, Pitt Meadows, British Columbia, Canada; Vienna Lam, MA, Simon Fraser University, Vancouver, British Columbia, Canada; Megan Bassendale, MSc, Forensic Guardians International, West Vancouver, British Columbia, Canada; Gail S. Anderson, PhD, Simon Fraser University, Burnaby, British Columbia, Canada*

Learning Objectives: After attending this presentation, attendees will understand the importance of using electronic tracking technology for human remains during a disaster as rapidly and as safely as possible, with reliable RFID technology that will survive the rigors of decomposition.

Impact Statement: This presentation will impact the forensic science community by demonstrating the use of a rapid, accurate, and reliable technology that can help practitioners during the dangerous work they do during a disaster.

Abstract Text: Identifying and returning the body of an individual who has died in a disaster is of the utmost importance, but disaster environments are dynamic, so those working within them must be prepared for potentially dangerous situations and must be able to tag a body for future identification as fast and safely as possible. Current non-RFID tags can become damaged and useless, preventing bodies from returning home, thus prompting the need to test the utility of more robust electronic options.

Electronic tracking RFID technology was assessed for tracking bodies and identifying information during mass disasters. Nine types of uniquely numbered RFID tags were deployed in decompositional and burial environments, through four seasons in the Canadian Coastal Westen Hemlock Ecozone, to assess: (1) the survivability of RFID tags buried, inserted, and attached to four juvenile pig carcasses and six pig shoulders; (2) the best method of insertion or attachment to keep tags *in situ*; and (3) whether physical writing in pencil or permanent marker remained on the tags' surfaces.

In a series of three studies of whole carcasses, pieces of meat as human proxies, and burials in soil, all but two tags were determined to work during decomposition. All tags displayed movement issues, so bone attachment sites are recommended. Many tags' physical writing disappeared, though could be used if prepared in a dry environment and left out of contact with decompositional fluid.

We believe that RFID offers an inexpensive, easily portable, reliable means of maintaining continuity and long-term information storage in humanitarian and forensic contexts.

I22 *Lucilia Coeruleiviridis* (Diptera: Calliphoridae) as a Primary Blow Fly on Carrion in East Alabama

Kianna Harris, BSc, Alabama State University, Montgomery, AL; Gulnaz T. Javan, PhD, Alabama State University, Montgomery, AL; Jonathan J. Parrott, PhD, Arizona State University, Glendale, AZ*

Learning Objectives: By the end of this presentation/study, participants will be able to: (1) describe the succession and developmental patterns of necrophagous blow flies, specifically *Lucilia coeruleiviridis*, during carrion decomposition in a Southeastern United States environment; (2) explain how ambient temperature influences blowfly development and its implications for estimating the minimum Postmortem Interval (mPMI); (3) evaluate the benefits and limitations of using fetal pig models for forensic entomology research in field settings; and (4) interpret region-specific entomological data to enhance the accuracy of forensic casework in underrepresented geographic areas such as East Alabama

Impact Statement: This study provides region-specific forensic entomology data for East Alabama, a previously underrepresented area in entomological casework. By integrating both molecular and morphological methods to identify *Lucilia coeruleiviridis* as the primary colonizer of carrion, this research enhances the accuracy of PMI estimations in the Southeastern United States. The findings contribute to standardizing species identification practices and underscore the importance of local environmental data in forensic investigations, ultimately strengthening the evidentiary reliability of entomological analysis in medicolegal contexts.

Abstract Text: Forensic entomology leverages the predictable patterns of insect succession and development in decomposing remains to assist with medicolegal investigations. Necrophagous insects, particularly blow flies (Diptera: Calliphoridae), are among the first to colonize cadavers, and their life stages can be used to estimate mPMIs. This study examined the decomposition of *Sus scrofa* Linnaeus to identify local blow fly assemblage active in East Alabama. A fetal pig carcass was placed in a partially wooded area in Auburn, AL, in mid-April 2024, and monitored for six consecutive days. Environmental temperatures, stages of decomposition, and arthropod activity were documented bi-daily. Blow fly larvae and adult specimens were collected using entomological nets and forceps, preserved in ethanol, and used for both morphological examination and molecular analysis.

Total DNA was extracted from larval samples using the QIAGEN DNeasy Blood and Tissue Kit. The extracted DNA underwent Polymerase Chain Reaction (PCR) amplification targeting the mitochondrial Cytochrome Oxidase I (COI) gene, followed by Sanger sequencing. Sequences were compared to reference databases using NCBI BLAST. All samples matched *Lucilia coeruleiviridis* (Macquart) (Diptera: Calliphoridae) with 100% identity and query coverage, confirming it as the primary species colonizing the carrion during the experiment. Morphological identification supported this finding, noting distinctive features such as metallic coloration and specific bristle patterns on adult blowflies. Although *Lucilia Mexicana* presented a close genetic match, ecological and geographic factors affirmed the identification of *L. coeruleiviridis*, which is commonly reported in the Southeastern United States. The pig carcass progressed through all five decomposition stages within six days, a timeline accelerated by its small size and high ambient temperatures. Larval development was rapid, with third-instar maggots observed by day 3. Larval activity correlated strongly with temperatures ranging from 21°C to 32°C, confirming that thermal conditions significantly influence the blowfly lifecycle and, consequently, the rate of decomposition. A decline in blow fly activity was noted on day 4 when ambient temperature dropped below 16°C.

This research contributes to forensic entomology by providing new region-specific data on blowfly activity and development in Alabama, a state with limited forensic entomological profiling. The findings underscore the importance of integrating both morphological and molecular methods for accurate species identification, especially when species exhibit high genetic similarity. Additionally, understanding temperature-dependent insect behavior enhances the reliability of mPMI estimations. Limitations included reliance on a fetal pig model and challenges associated with field conditions, such as vertebrate scavenger exclusion and non-ideal sample preservation methods. Despite these limitations, this study confirms *L. coeruleiviridis* as the predominant blowfly species in East Alabama during spring and reinforces its forensic importance.

I23 Resource Quality and Its Effects on the Developmental Stages in *Dermestes Maculatus*: Implications for Postmortem Interval Estimations

*Maria J. Zamora *, John Jay College of Criminal Justice, Jamaica, NY; Jennifer Rosati, PhD, John Jay College of Criminal Justice, New York City, NY*

Learning Objectives: Audience members will learn how nutritional resource quality influences survival and development in *Dermestes maculatus*, a beetle species commonly found on remains in advanced stages of decomposition. They will gain an understanding of how these developmental patterns can affect the accuracy of Postmortem Interval (PMI) estimations and improve beetle-based forensic timelines.

Impact Statement: This presentation will enhance forensic scientists' abilities to interpret insect evidence from late-stage decomposition more accurately by determining whether resource quality is a critical developmental factor. Improved understanding of dermestid development will support more reliable PMI estimations and better preservation of osteological evidence in both forensic and biological research contexts.

Abstract Text: Forensic entomology involves the use of insects in legal investigations. When the time since death exceeds 72 hours, the analysis of entomological evidence can help provide valuable information that can aid in the estimation of the PMI.[1] The estimation of the PMI is an important aspect in forensic investigations; however, this becomes increasingly difficult as remains progress through the decomposition process.

The dermestid beetle, *Dermestes maculatus* (DeGeer), is frequently considered to be a later successional species that colonizes remains during advanced stages of decay, often providing important clues for successional-based PMI estimations.[2] However, very little is currently known with regard to the factors that influence their development and how these factors affect their reliability as PMI indicators. Previous studies have shown that *D. maculatus* can exhibit developmental plasticity with anywhere from 6 to 9 larval molts.[3] As with many necrophagous insects, the effects of certain environmental conditions, like temperature, have been well studied in *D. maculatus*; however, the cause of this molt variation is currently unknown.[4,5] The aim of this study was to examine the effects of resource quality on the larval development of *D. maculatus*. Larvae were fed resources of varying quality (dried chicken thigh meat, dried chicken livers, and dried chicken skin) and larval development was measured, including survival, number of molts during the larval stage, the time required to reach the pupal stage, and the total time to adulthood. Additionally, adult size factors such as abdominal length and thorax length were measured. It was found that resource quality did have significant effects on survival and larval development.

These findings refine developmental benchmarks associated with *D. maculatus* and emphasize the importance of understanding resource effects on the developmental patterns of necrophagous insects. It is imperative to understand the factors that influence the developmental patterns of forensically important insect species when utilizing them as PMI indicators.

I24 Shifting Sands: A Longitudinal Study of Changes in Soil Microbial DNA in Relocated Remains in a Desert Environment

Katelyn L. Bolhofner, PhD, Arizona State University, Phoenix, AZ; Pamela A. Marshall, PhD, Arizona State University, Glendale, AZ*

Learning Objectives: After attending this presentation, attendees will be aware that relocated remains in a desert environment leave a traceable and long-lasting soil microbial signature and will learn when and in what ways that signature changes over time.

Impact Statement: This presentation will impact the forensic science community by demonstrating the potential of microbial analyses to inform investigative strategies in the search and recovery of relocated remains, even in harsh environments.

Abstract Text: Microbiomes—complex communities of microorganisms including bacteria, fungi, and archaea—have gained significant attention in forensic science in recent years largely due to their critical role in decomposition. As remains decompose, the microbial communities associated with the body and its surroundings undergo distinct changes that can be influenced by environmental factors such as soil composition, temperature, and moisture levels. Previously, we confirmed that even in a harsh desert environment microbial communities associated with decomposing remains exhibit distinct signatures and that these are detectable at a primary site for an extended period following relocation of remains.[1] Here, we further explore these signatures and the ways in which they change through time.

In June 2020, two 90.7kg, freshly deceased, clothed male porcine models were placed in an area of undisturbed Sonoran Desert ~64km north of Phoenix, AZ. One porcine model was placed in the shade under a palo verde tree and the other in full sun. After 25 days of exposure, the remains were relocated to secondary burial locations. Soil samples from the primary, secondary, and control sites for each model were obtained in March 2021 and October 2023 and microbiome analysis performed.

As we have published previously, microbiome analysis of the 2021 samples demonstrated that the porcine models left a unique microbial signature at the site of primary deposition—different from nearby undisturbed soil and distinct from the microbiome of the secondary sites—evident after only 25 days of decomposition, followed by nine months of exposure. This distinction includes both microbial diversity and organism type. When the 2023 soil samples are examined, they demonstrate that the signatures associated with decomposition are no longer evident in the primary burial location under the tree, but the fully exposed primary site had a unique microbiome signature, albeit different from the original signatures and more similar to the 2023 control soil. For example, analysis at the class level indicates that the primary exposed site was 0.8% Thermoleophilia (control was 5.2%), and the primary shade site was 2.9% (control of 3.6%) in 2023. Thermoleophilia was less than 1% in both primary 2021 sites, while the controls were 8.2% (exposed) and 5.0% (shade). The 2023 primary exposed location was 32.1% Alphaproteobacteria (control 25.9%), and the primary shade location was 25.5% (27.0% control), while the 2021 exposed was 5.9% site and 13.9% control and hade was 1.9% site and 21.8% control.

Results from this ongoing study represent an extensive effort to better understand the complexities of decomposition in a desert environment. We have demonstrated that the harsh environment of the Sonoran Desert retains indicators of decomposition for an extended period (9 months), even when remains are quickly relocated to secondary sites. But here our results also indicate that this period is limited, and those signatures may be lost in the span of several years. This finding has significance for the structuring of investigative inquiries, but also for our understanding of soil health and biotaphonomy following disruption of microbial communities in undisturbed areas.

I25 Dissecting Disparity: Jurisdictional Challenges to Sudden Cardiac Death Surveillance in the Balkans

Djordje M. Alempijevic, PhD, Faculty of Medicine University of Belgrade, Belgrade, Vojvodina, Serbia; Davide Radaelli, PhD, University of Trieste, Trieste, Friuli-Venezia Giulia, Italy; Stefano D'Errico, PhD, University of Trieste, Trieste, Friuli-Venezia Giulia, Italy; Tijana Petrovic, PhD, Faculty of Medicine University of Belgrade, Belgrade, Vojvodina, Serbia*

Learning Objectives: After attending this presentation, attendees will: (1) understand how, in the absence of a medical examiner system, autopsy decisions in the Balkans default to prosecutors or police using minimal clinical data; (2) recognize how decentralized forensic pathology services create regional variability in Sudden Cardiac Death (SCD) case capture and autopsy scope; and (3) appreciate the role of postmortem genetic counseling for SCD families as an exemplar of personalized medicine.

Impact Statement: By exposing how legal discretion and fragmented infrastructures impede systematic SCD surveillance, this presentation will equip forensic stakeholders to advocate for harmonized, medically guided death investigation protocols linked to preventive public health measures.

Abstract Text: In the Balkan region, many countries lack a dedicated medical-examiner system. Instead, public prosecutors or police—relying on scant medical information—ordinarily authorize autopsies only when foul play is suspected. This practice omits a substantial proportion of SCDs, obscuring true incidence and undermining both judicial and epidemiological objectives. Furthermore, in states where forensic pathology services are decentralized, access to comprehensive cardiac dissection, full-block histology, immunohistochemistry, and advanced toxicology varies widely by region.

We conducted a web-based survey (July–August 2025) of forensic-pathology coordinators across 13 Balkan nations—Türkiye, Greece, Bulgaria, North Macedonia, Kosovo, Albania, Serbia, Romania, Hungary, Montenegro, Bosnia-Herzegovina, Croatia, and Slovenia—supplemented by a review of legislative texts and standard operating procedures.[1,2] Preliminary findings reveal that autopsy mandates frequently exclude non-traumatic sudden deaths, decision delays exceed 24 hours in some jurisdictions, and no country integrates postmortem genetic counselling or cascade testing for next-of-kin into routine practice. These systemic gaps generate blind spots in SCD surveillance and prevent the forensic system from contributing fully to public health prevention. These findings underscore the urgent need for harmonized, medically guided protocols that mandate cardiac-focused autopsies in all sudden deaths and integrate genetic counselling into standard forensic practice. Establishing a centralized Balkan SCD registry would bridge current gaps and align forensic pathology with modern preventive family medicine.

I26 Pancarditis With Concurrent Metastatic Adenocarcinoma of the Colon: A Case Report and Review of the Literature

Mira Basuino, DO, University of Utah, Salt Lake City, UT; Neil G. Haycocks, MD, PhD, Utah Office of the Medical Examiner, Salt Lake City, UT*

Learning Objectives: Attendees will have a better understanding of the autopsy and pathological findings associated with pancarditis and its lethal complications. The presentation will also discuss how to generate a differential diagnosis for the causes of pancarditis based on clinical and histologic findings.

Impact Statement: This presentation highlights the importance of obtaining a thorough history of the decedent and performing histological examination and confirmatory testing in cases with multiple unique findings. Forensic professionals will be able to develop a broad differential related to causes of pancarditis and their concurrent histology.

Abstract Text: Pancarditis is a rare inflammatory manifestation of cardiac damage that may emerge secondarily from a variety of pathogens, toxic insults, and inflammatory conditions.[1-3] This is a complicated entity in the context of sudden death and medical malpractice with limited histomorphological data collected at autopsy, especially in the forensic setting.[4] This report details the case of a 48-year-old Hispanic male who presented to the emergency department with acute shortness of breath and left flank pain. Imaging studies showed a pulmonary embolism, a non-obstructive colonic mass near the splenic flexure, and metastatic nodules in the omentum. He was treated with heparin, and a biopsy of the colonic mass showed adenocarcinoma. No further treatment was sought. Three months later he became unresponsive while driving. No traumatic injuries occurred, but lifesaving efforts proved unsuccessful.

An autopsy was performed, which demonstrated an obese adult male with mucinous adenocarcinoma involving the colon, and with metastatic spread to the omentum and liver. There was marked cardiomegaly and severe coronary artery disease. The heart also showed an unexpected finding of diffuse lymphohistiocytic inflammation involving the epicardium, myocardium, and endocardium of both ventricles (lymphohistiocytic pancarditis). No giant cells or granulomata were seen. Inflammation of the heart has a broad differential, including various infectious agents, hypersensitivity reactions, toxic insults, autoimmune disorders, and the use of immune checkpoint inhibitors. The extent of inflammation in this case also raised the possibility of a so-called hot phase of arrhythmogenic cardiomyopathy. The observed pattern is most suggestive of an infectious etiology, possibly a tickborne illness such as *Borrelia burgdorferi* (Lyme disease).[5] The current literature has two notable reports of fatal pancarditis associated with Lyme disease.[6,7]

The patient was born and lived in the northwest region of the United States, liked spending time outside, and did not have any known infectious diseases at the time of death. Although rare, the patient's proclivity for outdoor activity, male sex assigned at birth, and age below 50 years raise the suspicion for his pancarditis originating from an infectious etiology. The significance of concurrent adenocarcinoma in this case, if any, is unclear. Tumor cells are well known to be immunogenic, and many inflammatory paraneoplastic syndromes have been described.[8] Cancer may also suppress the immune system, rendering one more susceptible to infectious diseases.

To our knowledge, this is the first reported case of lymphohistiocytic pancarditis occurring in an individual with concomitant mucinous adenocarcinoma of the colon. It underscores the importance of thorough histologic examination as part of the forensic autopsy, especially in complex cases with multiple findings.

I27 Sudden Death Due to Arrhythmogenic Mitral Valve Prolapse: A Case-Based Study From a Large Urban Medical Examiner's Office

Abdel Rahman Qabaja, MBBS, Almaarefa University, Riyadh, Ar Riyad, Saudi Arabia; Lorenzo Gitto*, Cook County Medical Examiner's Office, Chicago, IL*

Learning Objectives: After attending this presentation, attendees will gain an enhanced understanding of the forensic and pathological features of Arrhythmogenic Mitral Valve Prolapse (AMVP) as a cause of Sudden Cardiac Death (SCD). The session will highlight key diagnostic findings observed at autopsy, relevant cardiac pathology markers, and population characteristics associated with AMVP-related fatalities.

Impact Statement: This presentation will impact the forensic science community by discussing sudden cardiac deaths related to AMVP, emphasizing the typical demographic profile of affected individuals, the mechanisms underlying arrhythmogenesis, and the characteristic autopsy and histopathologic findings. The study underscores the importance of recognizing AMVP during postmortem examinations to improve classification of natural deaths and enhance understanding of this under-recognized entity.

Abstract Text: Sudden, unexpected deaths, particularly those occurring in young individuals without a known medical history or outside a health care setting, fall under the jurisdiction of the medical examiner, as they require a comprehensive investigation to determine the cause and manner of death. A range of natural conditions can result in sudden death, including rare and underrecognized cardiac disorders.

AMVP is an uncommon but increasingly acknowledged cause of SCD.[1] In affected individuals, death is attributed to the pathological interaction between the mitral valve apparatus and the left ventricle, resulting in life-threatening ventricular arrhythmias that may lead to SCD.[2] AMVP affects approximately 2% to 3% of the population and has been associated with up to a threefold increased risk of sudden death.[3]

Mitral valve prolapse (MVP) is a condition in which the mitral valve leaflets bulge (or "prolapse") backward into the left atrium during systole, sometimes leading to mitral regurgitation and arrhythmic complications, potentially leading to AMVP. MVP may be detected in living individuals through specific echocardiographic and electrocardiographic findings, which, when combined with clinical evaluation, can support the diagnosis.[4] In fatal cases, autopsy and detailed cardiac examination, along with postmortem data, are essential for identifying AMVP as a potential cause of sudden death.

This study reviews over six cases from the Cook County Medical Examiner's Office in which MVP or AMVP was determined to be the cause of death, with the manner of death classified as natural. Collected variables include demographic information (age, sex, race), physical characteristics (height, weight), smoking status, toxicology results, and cardiovascular pathology consultation findings.

The subjects' ages ranged from 24 to 44 years (average: 24 years), and there were three male and three female individuals. In all cases, gross and microscopic findings consistent with MVP were identified, including thickened and redundant mitral valve leaflets due to myxomatous degeneration, myocardial fibrosis involving the papillary muscles, and varying amounts of replacement fibrosis in the left ventricle.

According to the literature, AMVP-related sudden deaths disproportionately affect young females, often in the absence of significant coronary artery disease and with negative toxicology results.

AMVP should be considered in the differential diagnosis of sudden death when morphologic findings consistent with MVP are present in young individuals without significant coronary artery disease or toxicologic contributors. In selected cases, consultation with a cardiovascular pathology consultant can provide critical information to confirm AMVP, improving diagnostic accuracy and contributing to more precise mortality classification and potential clinical implications for risk assessment and prevention.

I28 A Case of Multiple Silent Steam Pops During Radiofrequency Ablation Leading to Cardiac Rupture

Marco Parenti, MD, Department of Public Health, Experimental and Forensic Sciences, University of Pavia, Pavia, Italy, Pavia, Lombardia, Italy; Greta Seveso, MD*, Department of Public Health, Experimental and Forensic Sciences, University of Pavia, Pavia, Italy, Pavia, Lombardia, Italy; Gulnaz T. Javan, PhD, Alabama State University, Montgomery, AL; Silvia D. Visonà, MD, PhD, Department of Legal Medicine and Forensic Sciences, University of Pavia, Italy, Pavia, Lombardia, Italy; Luca Tajana, MD, Department of Public Health, Experimental & Forensic Medicine. Division of Legal Medicine & Forensic Sciences 'A.Fornari'. University of Pavia., Pavia, Lombardia, Italy; Giovanni Cecchetto, MD, PhD, Department of Legal Medicine and Forensic Sciences, University of Pavia, Italy, Pavia, Lombardia, Italy*

Learning Objectives: After attending this presentation, participants will be aware of the cardio-pathological and histological features observed in a heart affected by a rare complication of cardiac ablation procedures: the formation of Steam Pops (SPs). In addition, they will be provided with tools to critically assess the medicolegal implications and potential professional liability in similar scenarios.

Impact Statement: This presentation enhances the forensic science community's competence in identifying and understanding the mechanisms underlying iatrogenic cardiac rupture resulting from thermal injury during radiofrequency ablation procedures.

Abstract Text: A 76-year-old male with a history of valvular heart disease and unstable angina underwent Radiofrequency Ablation (RFA) for frequent polymorphic Premature Ventricular Complexes (PVCs) and fixed bigeminal rhythm. During the procedure, the patient developed cardiac tamponade and required emergency pericardiocentesis. He was subsequently transferred to another hospital for surgical intervention. Intraoperatively, multiple bleeding sites were identified on the left ventricular wall, and hemostasis could not be achieved. The patient ultimately died in the operating room.

A forensic autopsy was performed. In addition to signs of recent surgical intervention, gross examination of the heart revealed multiple transmural lesions, including a full-thickness defect in the anterolateral myocardial wall and a cavitated intramural lesion in the mid-lateral left ventricle, filled with coagulated blood.

Histological examination of myocardial samples revealed widespread recent hemorrhagic infiltration and multiple areas of acute myocardial necrosis. Focal myocardial sclerosis was also noted in some regions. Notably, the sample taken from the lateral wall of the left ventricle showed a cavity with well-defined margins, composed of compact, denucleated cardiomyocytes, and lined by a small amount of well-preserved, layered erythrocytes. The cause of death was identified as cardiogenic shock due to iatrogenic rupture of the left ventricular wall during the RFA procedure.

A thermal mechanism was hypothesized as the underlying cause of the cardiac rupture, potentially related to device malfunction or suboptimal catheter handling. To explore this possibility, a bioengineering analysis was conducted. After thorough technical evaluation, no device malfunction was identified. Instead, the lesion was deemed compatible with the occurrence of multiple, inaudible SPs, a complication of ablation procedures resulting from excessive heating of myocardial tissue.[1] Target temperatures during RFA typically range between 50–60°C (122–140°F) to induce coagulative necrosis of arrhythmogenic foci.[2] However, under certain poorly understood conditions, likely involving structural heterogeneity of the myocardium and increased tissue impedance, energy delivery may become erratic, leading tissue temperatures to exceed 100°C (212°F).[3] At such temperatures, intramyocardial water vaporizes, forming expanding bubbles that may explode within necrotic tissue, potentially causing cardiac rupture.[4] Usually, the operator can hear these SPs and respond accordingly, but silent SPs, undetectable by the operator, have been reported in the literature.[5]

In the present case, the integration of clinical and histopathological data, consistent with findings reported in the literature, demonstrated that the iatrogenic cardiac rupture was caused by the formation of multiple silent SPs, which went unheard by the surgical team. Our examinations ultimately allowed for the exclusion of professional liability of the health care professionals involved. This case highlights how a thorough understanding of this rare RFA-related complication is crucial for the proper medicolegal assessment of similar events.

I29 A Hemorrhage in the Atrioventricular Septum Caused by Infective Endocarditis

Mio Okada, MD, University of Tokyo, Bunkyo-ku, Tokyo, Japan; Shigeki Tsuneya, MD, PhD, The University of Tokyo, Bunkyo-ku, Tokyo, Japan; Yohsuke Makino, MD, PhD, The University of Tokyo, Bunkyo-ku, Tokyo, Japan; Taka-Aki Matsuyama, MD, PhD, Showa medical university, Shinagawa-ku, Tokyo, Japan*

Learning Objectives: This presentation aims to gain a new perspective on an intramyocardial hemorrhage caused by infective Endocarditis (IE)and its risks, contributing to the cause of death.

Impact Statement: This presentation will impact the forensic science community by providing a unique case report of IE and raising awareness of the potential for an intramyocardial hemorrhage caused by IE.

Abstract Text: IE is a severe infection of the endocardial surface and cardiac valves, leading to a variety of complications such as heart failure, abscess formation, and thrombosis. Although relatively uncommon, with an incident rate of 11-15 cases per 100,000 population from 2000 to 2011 in the United States, IE could be critical if proper treatment is not provided.[1]

A Japanese homeless man in his 60s was found lying in front of the bathroom outside. Even though he was administered cardiopulmonary resuscitation, the patient remained unresponsive. The autopsy revealed vegetation on the non-coronary cusp of the aortic valve and a periannular abscess. There was also a hemorrhage in the Atrioventricular (AV) septum around AV node and the epicardial fat around the coronary sinus. We retrospectively identified the hemorrhage by postmortem Computed Tomography (CT). Neither occlusion or severe stenosis inside the coronary artery nor any recent ischemic signs were found. Additionally, there were no findings to explain the cause of death.

Periannular abscess associated with aortic valve endocarditis usually occurs near the membranous septum and AV node due to its structural weakness and, therefore, complete heart block and left bundle branch block are likely to ensue.[2] However, there are few reports of a hemorrhage in the AV septum by IE. There is a case report that an acute hemorrhage into the AV conduction produced arrhythmia that contributed to death.[3] Accordingly, there is a possibility that the hemorrhage caused by IE triggered an arrhythmia leading to death in our case.

Furthermore, postmortem CT detected the hemorrhage. Recently, cardiac CT has been shown to have high accuracy in diagnosing perivalvular complications such as abscesses, pseudoaneurysms, and fistulae [4] Possibly, postmortem CT may also be useful to find IE, and the hemorrhage around the heart may facilitate the recognition of IE.

In conclusion, this case shows that IE could give rise to a hemorrhage, which might be a cause of death. If a hemorrhage is discovered in the AV septum, we should consider not only myocardial infarction or heart trauma, but also IE. In this process, CT can be beneficial to learn some clues related to IE.

I30 Lethal Parvovirus B19 Myocarditis in a 9-Month-Old Infant: Crucial Insights From the Autopsy in a Challenging Diagnosis

Michela Gabelloni, APM, University of Pisa, Pisa, Piemonte, Italy; Margherita Sgroi, MD, University of Pisa, Pisa, Toscana, Italy; Ilaria Marcacci, APM, University of Pisa, Pisa, Toscana, Italy; Matteo Leoni, MD, Università di Pisa, Pisa, Toscana, Italy; Rebecca Maggi, MD, University of Pisa, Pisa, Toscana, Italy*

Learning Objectives: This presentation is directed not only to forensic pathologists but also to pediatricians to understand both the challenges posed *en vivo* by rare viral infections with an aspecific symptomatology in non-verbal-pediatric patients, and the autoptic steps to comply in order to get to an accurate postmortem diagnosis.

Impact Statement: This presentation will impact the forensic science community by enhancing the competence of forensic practitioners in diagnosing rare causes of infant death and improving the ability to suspect and identify viral myocarditis in order to arrive at a more accurate autoptic performance.

Introduction: Acute myocarditis is an inflammatory heart disease that poses a significant diagnostic challenge in pediatrics, carrying high rates of morbidity and mortality, particularly in infants under one year of age. The clinical presentation is often heterogeneous and non-specific, frequently mimicking common, benign childhood illnesses such as gastroenteritis or colic.[1,2] This ambiguity can lead to delayed diagnosis and treatment, increasing the risk of sudden, life threatening cardiovascular collapse. Viral infections are the most common trigger, with Parvovirus B19 emerging as a notable, albeit difficult to diagnose, cardiotropic pathogen.[3-5] We present a fatal case of Parvovirus B19-induced fulminant myocarditis in an infant whose initial symptoms were misleadingly benign.

Case Summary: A 9-month-old, previously healthy female infant presented with symptoms initially interpreted as infantile colic and later as gastroenteritis. She was initially managed for two days via remote telephone consultations with her pediatrician, who advised symptomatic treatment for abdominal pain and vomiting. The infant's condition acutely worsened on the third day, with the parents witnessing severe pain, crying, circumoral cyanosis, and loss of consciousness en route to the emergency department. Upon arrival, a supraventricular tachycardia with a wide QRS complex was detected, along with a severe metabolic acidosis (pH 7.09, lactate 10.4 mmol/L), and marked leukocytosis, though C-reactive protein was negative. Despite aggressive resuscitation efforts, including vagal maneuvers, adenosine administration, intubation, and cardioversion for subsequent ventricular tachycardia, the infant's condition progressed to pulseless electrical activity. She was transferred to a tertiary pediatric intensive care unit, where cardiopulmonary resuscitation was unsuccessful, and she was declared deceased.

Investigations: A comprehensive postmortem examination was performed. The heart, while macroscopically normal, revealed a massive, diffuse inflammatory infiltrate on histological analysis. This infiltrate, composed predominantly of lymphocytes and macrophages, affected the pericardium, myocardium, and endocardium (pancarditis), and was accompanied by multiple foci of myocyte necrosis. Immunohistochemical staining was strongly positive for leukocyte common antigen (CD45) and macrophage antigen (CD68), suggesting an active inflammatory process. Subsequent real-time Polymerase Chain Reaction (PCR) analysis performed on cardiac tissue sections definitively identified the presence of Parvovirus B19 genomic material.

Conclusion: This case underscores the critical diagnostic challenge posed by fulminant myocarditis in infancy. The initial presentation with non-specific gastrointestinal symptoms masked a rapidly progressing, lethal cardiac disease, leading to a fatal outcome before effective intervention was possible. The definitive diagnosis of Parvovirus B19 pancarditis was only achieved through postmortem histopathological and virological analysis. This report highlights the necessity for primary care clinicians to maintain a high index of suspicion for myocarditis in infants presenting with persistent, evolving, or atypical symptoms, even in the absence of classic cardiac or respiratory signs. The case illustrates the tragic speed at which this condition can advance from a seemingly mild illness to cardiovascular collapse, emphasizing the limitations of current diagnostic approaches in facilitating early detection, thus, the importance of a deep and wide-angle postmortem investigation.

I31 Not Everything Is What it Seems: A Case Report of Developmental Cardiac Defects Masquerading as Neglect

Christian Perez-Torres, MD, Office of the Chief Medical Examiner, Commonwealth of Virginia, Richmond, VA; Amy M. Tharp, MD, Office of the Chief Medical Examiner, Commonwealth of Virginia, Roanoke, VA*

Learning Objectives: After attending this presentation, attendees will have a better understanding about different causes of failure to thrive in the forensic context. The importance of thorough investigations will be emphasized.

Impact Statement: The forensic science community will be impacted by highlighting the importance of the autopsy in cases of alleged neglect. Gaining knowledge of possible scenarios of alleged neglect will also be impactful for those involved directly or indirectly in death investigations.

Abstract Text: A 4-month-old infant male was found unresponsive at home after sleeping with his parents. Parents reported giving the decedent an indeterminate amount of over-the-counter cough medication. They had not taken the infant to a doctor since birth except for a visit to the Emergency Room (ER) for cough-type symptoms. He was hypoxic on exam and imaging showed a prominent "cardiothymic silhouette." Studies for viral diseases were negative. No further tests were performed, and he was discharged home from the ER. He had never been vaccinated and was born at term, of average weight, and "passed" his congenital heart defect screen.

Postmortem examination revealed severe heart defects, including atrial and ventricular septal defects, insertion of at least one pulmonary vein into the coronary sinus, right ventricular hypertrophy, and aortic stenosis. Another significant finding was intussusception of the small bowel with associated ischemic changes. He had mild dehydration and was severely underweight. Toxicology was non-contributory. Cause of death was complications of severe congenital heart disease and intussusception of the small bowel. Manner of death was natural.

Neglect is defined as the failure to meet a child's basic physical and emotional needs. These include housing, food, clothing, education, access to medical care, and having feelings validated and appropriately responded for. Approximately 14% of children experience neglect or abuse in the United States. One of the risk factors is living in poverty.[1]

Failure to thrive is commonly used for children below the fifth percentile in weight according to age and gender. The most common cause is malnutrition, and it can impair proper development in all facets.[2] In our case, there was concern due to the decedent's failure to thrive and his less than "ideal" living circumstances. However, it is important to note that there are many causes of failure to thrive, including natural ones, such as in our case. Causes include inadequate caloric intake (esophageal abnormalities and pyloric stenosis), malabsorption (celiac disease, inflammatory bowel disease, and cystic fibrosis), and increased systemic caloric demand (congenital heart disease, malignancy, and chronic infectious diseases).[3]

In cases of alleged neglect, it is essential to perform a thorough investigation, including a full autopsy and ancillary studies to rule out natural causes. This case illustrates the importance of the autopsy because the medical records may lack important information and critical features such as cardiac malformations may be missed on the clinical exam. In our case, the failure to thrive was caused by the significant congenital heart defects that the child had and not due to neglect by the parents. Continued communication and collaboration are essential.

I32 Not Just Drowning: Malignant Arrhythmia and Involuntary Submersion in a Young Male

Alessandro N. Nicolosi, MD, Unime, Messina, Sicilia, Italy; Simona Calabrese, MD*, Unime, Messina, Sicilia, Italy; Alessio Asmundo, PhD, Unime, Messina, Sicilia, Italy; Daniela Sapienza, PhD, Unime, Messina, Sicilia, Italy; Vincenzo Cianci, MD, Unimr, Messina, Sicilia, Italy; Cristina Mondello, PhD, University of Messina, Messina, Sicilia, Italy*

Learning Objectives: Participants will gain both theoretical and practical tools to evaluate cases of drowning related to cardiac disease. The presented case will explore indirect signs of malignant arrhythmias that can potentially determine drowning and, particularly, the limitations of traditional morphological criteria, the importance of integrating clinical, circumstantial, histopathological, and genetic data, with a focus on inherited channelopathies.

Impact Statement: This presentation will enhance the forensic pathologist's ability to recognize underlying cardiac disease masked by drowning, promoting an integrated approach that includes the evaluation of inherited channelopathies and primary electrical heart disorders. This will lead to more accurate diagnoses, identification of at-risk family members, and prevention of further deaths through targeted screening programs.

Abstract Text: In forensic medicine, postmortem diagnosis of drowning remains challenging, particularly when there is suspicion that other pathological processes may have contributed to death. Autopsy findings often rely on indirect morphological signs, such as massive pulmonary edema, abundant whitish foam in the airways, and overinflated, fluid-laden lungs.[1] In such cases, additional diagnostic challenges arise in understanding the possible underlying pathological mechanisms that may lead to drowning, especially when it occurs in controlled environments like a swimming pool.

We present the case of a 21-year-old male who died suddenly shortly after vigorous swimming, during a friendly competition in a private swimming pool, just at the end of an intense physical effort. Having reached the opposite side of the pool together with his father and a friend, the subject was seen lying motionless at the bottom after a few seconds. He was pulled out of the water and resuscitation attempts were initiated, but unsuccessfully. The anamnestic data revealed an emergency room visit five months prior, during which a cardiologist reported a rhythmic cardiac rate of 65 with an early repolarization pattern without any additional specification regarding the inferior and lateral derivations. The autopsy revealed the presence of a thin foamy fungus on the buccal rim. Internal examination showed signs of diffuse pulmonary edema, observed also at histological examination together with areas of emphysematous distention.

The routine histology of the heart revealed bundles of distended myocardial cells alternating with hypercontracted cells, widened or fragmented at the level of intercalated discs; myocardial nuclei in the hypercontracted cells appeared "square-shaped." Additionally, non-eosinophilic bands of hypercontracted sarcomeres alternated with stretched sarcomeres. Toxicological analysis for drugs and psychoactive substances was negative.

Case analysis suggests the subject experienced a syncopal episode of arrhythmic origin, which likely led to involuntary submersion, reflex inspiration, and subsequent water inhalation. Death would have occurred rapidly (within 2–5 minutes).

The reported signs of early repolarization could be associated with an increased risk of idiopathic ventricular fibrillation in individuals with inherited channelopathies, such as Early Repolarization Syndrome (ERS). These conditions predispose young, predominantly male individuals, to Sudden Cardiac Death (SCD) due to fatal arrhythmias, often triggered by physical exertion, stress, or water immersion.[2] In this case, myocardial microscopic findings were consistent with the occurrence of a malignant tachyarrhythmia. The cause of death was identified as acute asphyxia due to drowning related to a syncopal episode from a malignant tachyarrhythmia.[3]

This case represents an example of how an apparent drowning can actually conceal a cardiac disease possibly responsible for SCD.

It also illustrates how channelopathies and primary electrical disorders of the heart may leave no morphological trace at autopsy. Therefore, the integration of clinical history, circumstantial evidence, and functional or genetic evaluations becomes essential. Finally, recognizing such syndromes is not only crucial for correctly determining the cause and mechanism of death, but also plays a pivotal role in promoting targeted screening programs for the deceased individual's relatives as well as discussing (in confirming or excluding) juridical responsibilities of the rescuers.

I33 A Postmortem Diagnosis of PAU Rupture in the Ascending Aorta

Vincenzo Cianci, MD, University of Messina, Sicilia, Italy; Beatrice Spadaro, MD, University of Messina, Sicilia, Italy; Alessio Asmundo, PhD, University of Messina, Sicilia, Italy; Daniela Sapienza, PhD, University of Messina, Sicilia, Italy; Lorenzo Tornese, MD, University of Messina, Sicilia, Italy; Cristina Mondello, PhD*, University of Messina, Sicilia, Italy*

Learning Objectives: The importance of a multidisciplinary integrated approach for reaching a correct postmortem diagnosis of uncommon pathologies is highlighted: autopsy, histopathology, and postmortem forensic radiology led to diagnosis of a Penetrating Atherosclerotic Ulcer (PAU) rupture in the ascending aorta.

Impact Statement: This case highlights the critical importance of histopathological examination in identifying rare causes of sudden cardiac death such as PAU of the ascending aorta. In forensic investigations, especially where malpractice is suspected, recognizing PAU can prevent misattribution of surgical failure and supports accurate medicolegal conclusions.

Abstract Text: PAU is a rare and potentially fatal condition, being part of Acute Aortic Syndromes (AAS). It consists of an atherosclerotic plaque that ulcerates through the intima and can extend into the tunica media, sometimes leading to hematoma formation, aneurysm, up to a full-thickness aortic rupture.

We report the case of a 74-year-old man with multiple cardiovascular comorbidities who underwent surgical replacement of both the mitral valve and ascending aorta due to a critical aneurysm. Twelve days after surgery, he died suddenly during cardiopulmonary rehabilitation. Autopsy revealed a hemopericardium due to rupture of a 4-mm lesion near the distal anastomosis of the aortic prosthesis. Histological analysis showed typical features of a subacute PAU, including intimal ulceration, thinning of the tunica media, and inflammatory infiltrates extending into the adventitia and media. No signs of surgical failure were found. The cause of death was identified as cardiac tamponade secondary to ascending aortic rupture due to PAU. This case highlight the importance of integrating gross, histological, and radiological data for reaching an accurate and correct diagnosis. In light of these aspects, especially in forensic contexts where malpractice is suspected, being able to correctly identify PAU is fundamental to ensure a proper medicolegal evaluation.

I34 Sudden Cardiac Death in Undiagnosed Late Stage Pompe Disease

Kenna Saiidi, BS, Loyola University Chicago Hospital, Chicago, IL; Tracy Wadsworth, MD, Cook County Medical Examiner's Office, Chicago, IL; Lorenzo Gitto, Cook County Medical Examiner's Office, Chicago, IL*

Learning Objectives: After attending this presentation, attendees will learn how Late-Onset Pompe Disease (LOPD) can present with subtle or unrecognized signs in young adults and how it may lead to sudden cardiac death. This presentation will emphasize the importance of integrating molecular testing and autopsy findings in the diagnostic workflow to uncover rare metabolic disorders postmortem.

Impact Statement: This presentation will impact the forensic science community by enhancing the competence in recognizing and investigating metabolic myopathies during forensic casework. It will demonstrate how forensic autopsy and genetic testing can impact public health outcomes, particularly regarding support for newborn screening programs and identifying hereditary conditions.

Abstract Text: Pompe disease, or glycogen storage disease type II, is a rare autosomal recessive disorder caused by biallelic mutations in the GAA gene, leading to deficiency of lysosomal acid maltase (acid alpha-glucosidase). This results in pathological glycogen accumulation, disrupting cellular metabolism and affecting muscle, connective tissue, and organ systems. While Infantile-Onset Pompe disease (IOPD) typically presents with severe cardiac and skeletal muscle involvement, LOPD may remain undiagnosed until adolescence or adulthood, with progressive skeletal muscle weakness, diaphragmatic insufficiency, and less frequent—but possible—cardiac involvement.

This case presents a 21-year-old White male with a childhood history of heart murmur, transient speech delay, and hearing loss, who experienced sudden cardiac death during meditation. Witnesses reported abnormal breathing, snoring, and shaking. Despite prompt resuscitation, he was pronounced deceased. Postmortem examination revealed cerebral edema, pulmonary congestion and edema, and cardiomegaly with a bulbous heart. Histologic evaluation showed an early circumferential acute myocardial infarction in an arrhythmogenic distribution, left ventricular hypertrophy, myxomatous aortic valve, coronary fibromuscular dysplasia, and cardiomyocyte hypertrophy with mild disarray. Toxicology was non-contributory. Molecular testing identified a homozygous pathogenic variant in the GAA gene, confirming the diagnosis of LOPD.

LOPD is the most prevalent form of Pompe disease, typically presenting in childhood or adulthood, affecting an estimated 1 in 8,000 to 1 in 30,000 individuals in the United States. Diagnosis involves genetic testing, enzyme activity assays, and Cross-reactive Immunologic Material (CRIM) status to predict prognosis and response to Enzyme Replacement Therapy (ERT), the primary treatment. Morbidity stems from progressive muscle weakness leading to diaphragmatic insufficiency, gait abnormalities, respiratory failure, and death. Cardiac involvement is less frequent than in IOPD, but hypertrophic cardiomyopathy and life-threatening arrhythmias can still occur. Although respiratory failure remains the leading cause of death for Pompe disease, sudden cardiac death may occur particularly if undiagnosed and untreated. Untreated LOPD reduces life expectancy by 10 to 30 years. Enzyme replacement therapy improves quality of life and allows many patients to survive into late adulthood. Nationwide newborn screening, initiated in 2015, enhances early diagnosis and survival. In this case, screening was unavailable at birth, delaying diagnosis. Therefore, it highlights the importance of newborn screening in preventing similar avoidable deaths and underscores the need for genetic testing in suspicious cases.

I35 Sudden Death in a Two-Year-Old Child With Suspected Abuse: The Key Role of Forensic Pathology in the Differential Diagnosis

Irene Pradelle, MD, Università degli Studi di Modena e Reggio Emilia, Ferrara, Emilia-Romagna, Italy; Matilde Ruju, MD*, Università degli studi di Modena e Reggio Emilia, Sassari, Sardegna, Italy; Luca Diani, MD, Università di Modena e Reggio Emilia, Ferrara, Emilia-Romagna, Italy; Biagio Solarino, MD, PhD, Università degli Studi di Bari Aldo Moro, Bari, Puglia, Italy; Giada Rovito, MD, Università degli Studi di Modena e Reggio Emilia, Ferrara, Emilia-Romagna, Italy; Letizia Alfieri, MD, PhD, AUSL Ferrara, Ferrara, Emilia-Romagna, Italy; Margherita Neri, PhD, University of Ferrara, Ferrara, Emilia-Romagna, Italy*

Learning Objectives: After attending this presentation, attendees will understand how important the role of the forensic pathologist is in differential diagnosis between fatal child abuse and sudden unexpected death in pediatric age.

Impact Statement: This presentation will impact the forensic science community by reporting an emblematic case of a two-year-old baby's death. By applying rigorous forensic methodology, practitioners will improve their ability to distinguish inflicted injuries from medical conditions, ultimately supporting more accurate determinations of cause and manner of death.

Abstract Text: Child abuse is a critical issue in forensic medicine, as are sudden deaths occurring in infancy and early childhood. Forensic pathologists play a crucial role in the differential diagnosis between inflicted injuries, whether physical or sexual, and those resulting from natural causes. On the one hand, a thorough investigation is needed to support prosecution when abuse is present; on the other, rigorous forensic methodology must exclude, beyond a reasonable doubt, natural causes unrelated to third-party involvement.[1,2]

We present the case of a 2-year-old girl who died suddenly in a dysfunctional family environment, initially raising suspicions of abuse. On November 7, 2015, the child was found dead at home by her mother. The Judicial Authority ordered a forensic inspection of the house and a complete autopsy. The child's past medical history includes pre-term birth, psychomotor and developmental delays, and ongoing antipsychotic treatment for a psychiatric disorder involving recurrent self-injury (hair pulling, finger biting, head banging). The mother also reported that the child's father was her half-brother.

Fifteen days before death, the child was brought to the emergency department following a reported fall down the stairs. She presented with facial trauma and a left humerus fracture, which was treated conservatively during hospitalization. Despite a history of repeated self-injurious behavior, the presence of multiple bruises raised suspicions of abuse, prompting a report to Child Protective Services.

A cardiological assessment during hospitalization revealed rhythmic and effective heart sounds, an innocent systolic murmur, and a sinus rhythm with incomplete right bundle branch block on the ECG. The child was discharged on November 3, 2015, at her mother's request, against medical advice. Shortly before death, during the night between November 6 and 7, the parents reported that the child showed signs of dyspnea.

External examination revealed diffuse scalp alopecia, multiple bruises in various stages of healing, and areas of skin de-epithelialization on the fingers and auricles. Autopsy revealed cerebral and, more significantly, pulmonary edema and congestion. The heart was of normal size but presented a markedly narrow left ventricle (maximum diameter 0.4 cm), consistent with restrictive cardiomyopathy. This diagnosis was confirmed histologically.

Histopathological examination of the eyes excluded retinal hemorrhages, and brain analysis revealed no additional findings suggestive of abusive head trauma.

The cause of death was identified as sudden cardiac death due to previously undiagnosed congenital restrictive cardiomyopathy. A syndromic or genetic condition underlying both the psychiatric and cardiac features could not be excluded but remained unclarified. The lesions observed during the external examination, including bruises, alopecia, and areas of skin de-epithelialization, were consistent with recent and repeated self-inflicted injuries, likely secondary to the underlying psychiatric condition.

In many cases of sudden childhood death, the cause is revealed only through autopsy. In this case, circumstantial and external findings alone may have led to a misdiagnosis of fatal abuse. The autopsy was crucial in identifying a natural cardiac pathology as the underlying cause of death, highlighting the importance of forensic pathology in safeguarding both justice and diagnostic accuracy.

I36 The Correlation of Biomarkers and Cardiac Dimensions in Sudden Cardiac Death (SCD)

Matteo Antonio Sacco, MD, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Valerio Riccardo R. Aquila, PsyD, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Saverio Gualtieri, MD*, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Aurora Princi, MD*, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Maria Eugenia Caligiuri, MEng, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Alessandro Schettini, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Federica Riillo, MD, Hospital of Crotone, Crotone, Calabria, Italy; Santo Gratteri, MD, PhD, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Isabella Aquila, MD, PhD*, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy*

Learning Objectives: After reading this presentation, attendees will understand the existence of a correlation between morphological alterations, biomarkers, and causes of death, enabling the development of specific preventive strategies for at-risk individuals.

Impact Statement: This work will significantly impact the forensic science community by highlighting how the integration of laboratory testing with autopsy findings and histopathological analyses is essential to establish a comprehensive and scientifically robust reconstruction of the cause and mechanism of death, particularly in complex or ambiguous forensic cases.

Introduction: SCD is defined as an unexpected fatal event occurring within one hour of symptom onset, often in individuals with or without known cardiac disease. It represents a major cause of mortality with significant forensic implications, especially for determining underlying mechanisms. Although etiologies vary, most SCDs are of cardiovascular origin—arrhythmogenic, ischemic, valvular, or myocardial. Accurate diagnosis requires a comprehensive autopsy protocol, supported by histological evaluation and postmortem biochemical analyses, which allow identification of structural and molecular cardiac changes and measurement of specific biomarkers of myocardial injury.

Materials and Methods: We conducted a retrospective observational study on 40 autopsies performed at the Institute of Legal Medicine, University Magna Graecia of Catanzaro. Cases were divided into two groups: SCD cases and non-cardiac death controls. For each case, demographic data, cause of death, and cardiac morphometrics (transverse/longitudinal diameters, heart weight, valvular features) were recorded, with attention to fibrofatty myocardial replacement. Biological fluids collected during autopsy (blood serum, pericardial fluid, vitreous humor) were analyzed for CK-MB, troponin I, myoglobin, BNP, and D-dimer. Results were compared between groups. Cardiac biomarkers were measured using immunofluorescence-based point-of-care testing, with rapid quantification.[1] The Postmortem Interval (PMI) ranged from 12 to 96 hours, and all samples were immediately analyzed during autopsy.

Results: SCD cases exhibited significant morphological cardiac changes compared to controls, including increased heart weight and diameters, valvular fibrosis or calcification, and fibrofatty replacement—particularly in the right ventricle and interventricular septum—suggesting arrhythmogenic substrates. Biochemical analyses revealed markedly elevated CK-MB, troponin I, and D-dimer in SCD cases, indicating acute myocardial injury. Myoglobin showed inconsistent results, while BNP levels were elevated in some SCD cases but not all, depending on the underlying pathology (e.g., heart failure versus acute ischemia). Troponin values were not correlated with PMI (12–96 h), while remaining influenced by the analytical method (immunofluorescence POCT). Integration of morphological and biochemical findings confirmed the presence of structural and/or functional abnormalities in most SCD cases, validating the need for a multidimensional postmortem diagnostic approach.

Discussion: A significant proportion of SCD cases revealed pre-existing structural abnormalities—such as cardiomyopathies, myocardial fibrosis, or valvular pathologies—often undiagnosed in life. In other instances, congenital electrical disorders, myocarditis, or coronary anomalies were implicated. Recognizing these conditions postmortem can guide preventive screening for at-risk populations. Cardiac biomarkers, especially troponin I, proved to be sensitive indicators of myocardial injury and helpful in confirming a cardiac cause of death when interpreted alongside autopsy and histological findings. Nevertheless, due to postmortem degradation and the risk of false interpretations, biomarker data alone are insufficient and must be corroborated with morphological evidence. Troponin levels may vary with analytical methodology, particularly immunofluorescence POCT, but in our series no correlation with PMI (12–96 h) was observed, underscoring the need for standardized procedures.

Conclusion: This study supports a comprehensive autopsy protocol that includes detailed morphological examination and biochemical testing to improve diagnostic accuracy in SCD. Such integration enhances forensic evaluations and contributes to broader public health insights regarding sudden death in seemingly healthy individuals.

I37 Understanding Cause and Manner of Death in the Transgender, Non-Binary, and Gender-Incongruent Community

Sonia M. Kominek, MA, King County Medical Examiner's Office, Seattle, WA; Rhonda M. Mittenzwei, MD, King County Medical Examiner's Office, Seattle, WA*

Learning Objectives: Attendees will identify health care disparities in transgender and Gender-Incongruent (GI) populations and how those disparities manifest in causes and manners of death in King County, WA. Potential challenges in tracking gender and gender identity will be specified, and changes deployed in King County are explored, enabling learners to identify opportunities for improved reporting.

Impact Statement: This presentation will impact the forensic science community by highlighting the importance of transgender, non-binary, and gender diverse inclusivity throughout the recording and reporting within the medicolegal system. Attendees will gain awareness of the public health concerns reflected through discrepancies in causes and manners of death throughout the general population and the gender diverse, transgender, and non-binary populations.

Abstract Text: There are an estimated 1.6 million people over the age of 13 who identify as transgender in the United States.[1] Washington state has an estimated population of 7.96 million people, of whom an estimated 1.09% identify as transgender.[2] Furthermore, Washington is one of 17 states in which an individual may specify gender "X" on a birth certificate or other state-issued identification.[3] GI populations experience higher rates of suicide, substance use disorders, and mental health disorders.[4] As of 2025, significant changes have further impacted the gender diverse population in the United States, complicating legal identification and access to care.[5]

To characterize the transgender and GI population in King County, WA, and to understand trends in this subpopulation compared to the general population in our jurisdiction, we conducted a retrospective review. Deaths categorized as suicide and homicide are notably higher in the transgender and gender diverse population as compared to the general population. The largest discrepancy in manner of death is suicide, with the general population being 8% and the GI and transgender population being 21%. Homicide in the general population is noted to be 4% of cases, while in the transgender and GI population, it is 9%. Accidental manner of death in the total population and in the transgender and gender diverse populations are similar: general population rate: 48%; transgender/gender-diverse rate: 54%; however, 58% of transgender and gender-diverse accidental deaths were noted to be caused by the combined effects of mixed drug intoxication, polysubstance use, or combined intoxication of substances. The gender diverse, non-binary, and transgender community included in this study is ethnically diverse and ranges from 14 to 80 years of age**.**

Inaccuracies and inconsistencies in reporting and recording of sex, gender, and gender identity predictably impact the number of individuals and gender identities recognized in this population. Adaptations in recording methods have enabled more inclusive terminology and the deployment of internal tracking systems. These tools and internal systems allow us to better understand the relationship between cause and manner of death in the gender diverse and transgender populations. Alternative gender identities are recognized and reported during death investigations to reflect gender identities legally recognized in WA. In light of recent federal policy, it is more important than ever to utilize local systems to track this critical data that may be omitted on federal forms of identification such as passports. Furthermore, our office employs continued efforts to adapt and innovate to capture more nuanced information to describe and characterize this population. Because language used in death investigations can contribute to the perpetuation of stigmas within the transgender and gender diverse populations, thereby exacerbating marginalization, it is of vital importance that we recognize the factors that may impact our investigations, data tracking, and disparities in the broader context of the health care system.[7-9]

I38 DNA on a Deadline: Interagency Cooperation for Genetic Testing of Unidentified Human Remains

Kiana C. Miller, BS, King County Medical Examiner's Office, Seattle, WA; Andrew C. Seidel, PhD, King County Medical Examiner's Office, Seattle, WA*

Learning Objectives: After attending this presentation, attendees will gain an appreciation for how inter-agency cooperation can facilitate wide-ranging genetic testing of Unidentified Human Remains (UHRs) despite budgetary, procedural, and time constraints.

Impact Statement: This presentation will impact the forensic science community by demonstrating how forensic anthropologists are well-positioned to coordinate the efforts of multiple independent agencies toward the resolution of cases involving unidentified decedents. Further, through a discussion of the obstacles encountered in this process and the successes achieved, this presentation will help other practitioners optimize the handling of the unidentified cases over which their agencies have jurisdiction.

Abstract Text: In July of 2023, the Washington State Missing and Murdered Indigenous Women and People (MMIWP) Task Force requested a meeting with the King County Medical Examiner's Office (KCMEO) Anthropology section to better understand the role of DNA testing in the identification process. In March of 2024, and in direct response to the advocacy efforts of the MMIWP Task Force, the Washington State Legislature approved a $500,000 appropriation from the state's general fund to be used for the resolution of long-term unidentified cases across the state of Washington. These funds were distributed to the Washington State Patrol (WSP) in June, and KCMEO Anthropology, providing forensic anthropology services for the state, agreed to facilitate sample selection, collection, and submission. Although funds were made available for the entire fiscal year, the necessities of (1) establishing a formal vendor contract and (2) having deliverables in-hand prior to the close of the fiscal year effectively reduced the project duration to the six-and-a-half-month period from October 2024 until mid-April 2025.

An Advisory Council, consisting of representatives from KCMEO Anthropology, the Washington State Patrol's Missing and Unidentified Persons Unit, the Washington State MMIWP Task Force, and the Washington State Attorney General's Office, prioritized UHR cases for genetic testing using two primary criteria: (1) reasonable belief that the decedent may be Indigenous, and (2) reasonable belief that the decedent was a victim of violence. Cases on the priority list that had never had any genetic testing were submitted for Short Tandem Repeat (STR)the testing with the intention of developing profiles suitable for submission to the Combined DNA Index System (CODIS); cases with profiles that had been running in CODIS without any matches were submitted for forensic genetic genealogy testing. Ultimately, all cases on the priority list received some form of genetic testing, significantly advancing efforts to identify longstanding UHR's across the state of Washington.

The completion of this project depended upon the collaboration and coordination of multiple agencies both across the state of Washington and beyond. Here, we share both the successes and the limitations of how this project was implemented in the hope that other practitioners may learn from our experiences.

I39 A Study on Time-Dependent Changes in the Degradation Index (DI) of DNA From Postmortem Blood

Chong Min Choung, PhD, National Forensic Service, Wonju, Kangwon-do, Republic of Korea; Ho Jun Lee, MS, National Forensic Service, Wonju, Kangwon-do, Republic of Korea; Heywon Hong, MS, National Forensic Service, Wonju, Kangwon-do, Republic of Korea; Joo-Young Kim, PhD, National Forensic Service, Wonju, Kangwon-do, Republic of Korea*

Learning Objectives: This study aims to serve as a preliminary investigation for estimating the Postmortem Interval (PMI) based on the observed pattern of DI changes in autopsy blood.

Impact Statement: This study provides empirical data on the time-dependent changes in the DI, offering a practical reference for evaluating the quality and suitability of postmortem blood samples for DNA analysis.

Abstract Text: The degradation of DNA in postmortem blood samples poses a significant challenge in forensic analysis.[1] This study aimed to observe the changes in the DI of DNA extracted from stored autopsy blood over time. DNA was extracted at specific time intervals from a single source of postmortem blood stored under controlled conditions. The DI values were measured using quantitative Polymerase Chain Reaction (qPCR) -based assay that compares the relative abundance of short and long DNA targets. A total of 80 postmortem blood samples were collected between 37 and 85 days after autopsy and were analyzed to quantify their DI. To evaluate temporal changes in DNA integrity, the same samples were reprocessed 4 weeks later, and the newly obtained DI values were compared to the initial measurements. The results showed a gradual increase in DI value over time, indicating progressive DNA degradation as at storage time increased. This trend was consistent across replicates, suggesting that the integrity of DNA in postmortem blood diminishes in a time-dependent manner even under refrigerated conditions. These findings provide insight into the temporal stability of DNA in stored autopsy blood and highlight the importance of timely DNA extraction for optimal forensic analysis. The observed pattern of DI changes may serve as a reference for estimating sample quality in delayed or retrospective forensic investigations.

I40 A Comparison of Sample Pretreatment and DNA Extraction Methods From Human Ribs

Daniel Arend, BS, Sam Houston State University, Department of Forensic Science, Coeur d'Alene, ID; Ethan S T Smith, MS, Washington State Patrol Crime Laboratory, Cheney, WA*

Learning Objectives: After attending this presentation, attendees will have learned some similarities and differences of three bone pulverization methods and three bone DNA extraction methods utilized in forensic laboratories.

Impact Statement: This study found no significant differences in the analyzed metrics between the three bone pulverization methods and three bone DNA extraction methods utilized. As all methods performed similarly, the choice of methods for implementation at a laboratory may depend on budget, ease of implementation, or other factors.

Abstract Text: As the structural composition of bones help preserve DNA after tissue decay [1], bones may be the only remaining source of DNA for human identification.[1-3] Pretreatment and extraction methods for isolating DNA from bones must be robust.[4] Pretreatment helps to remove exogenous DNA and Polymerase Chain Reaction (PCR) inhibitors, while extraction methods aid in freeing the DNA from the mineral matrix in bones and removing endogenous PCR inhibitors.[1,4] Although no standard method for DNA extraction from bones is widely used, many methods incorporate decontamination, pulverization, and demineralization steps prior to extraction.[5,6] Several bone pulverization methods and bone DNA extraction kits are commercially available.[5]

This study compared three different commercially available bone pulverization methods using human rib bones. No significant differences in the DNA yield (ng DNA per mg of bone powder) or degradation index were found. No significant difference in the amount of bone powder lost during pulverization was found. Full or near-full profiles were developed for all profiled bone powder samples, and no contamination was detected. As all tested methods performed similarly, the choice of the pulverization method and extraction method for bones may depend on other factors (cost, ease of use/implementation, automation, or bone type/condition).

I41 Pre-Analytical Barriers to Postmortem Invitae Testing: A Retrospective Review of Genetic Test Failures and Successes

Manisha Bastola, MD, Western Michigan University Homer Stryker M.D. School of Medicine, Kalamazoo, MI; Patrick Hansma, DO, Western Michigan University Homer Stryker M.D. School of Medicine, Kalamazoo, MI; Victoria Roby, MS, Western Michigan University Homer Stryker M.D. School of Medicine, Kalamazoo, MI*

Learning Objectives: The goals of this presentation are to: (1) identify key pre-analytical factors that contribute to failed or inconclusive postmortem genetic test results in forensic autopsy cases; (2) evaluate the diagnostic yield of repeat genetic testing in cases with initial partial or complete test failure; and (3) recommend postmortem best practices to optimize genetic test success, including timely sample collection and adjunct testing such as vitreous chemistry and toxicology.

Impact Statement: This study identifies modifiable pre-analytical barriers to postmortem genetic testing and demonstrates that repeat sampling can yield clinically relevant results after initial test failure. These findings support improved protocols for forensic casework and enhance the diagnostic utility of postmortem molecular testing.

Background: Postmortem genetic testing has become an essential tool in investigating sudden and unexplained deaths, particularly in younger individuals. However, test failures and inconclusive results remain prevalent, often due to pre-analytical variables. This study retrospectively evaluates postmortem Invitae testing outcomes with a focus on factors affecting sample quality and the utility of second sampling.

Methods: We reviewed 26 autopsy cases submitted for Invitae panel testing between 2024 and 2025. Data included demographics, specimen type, toxicology, vitreous chemistry, culture results, collection and accession timing, and test outcomes. Genetic test results were categorized as "pathogenic," "Variant of Uncertain Significance (VUS)," "negative," or "partial failure." Cases with initial test failures were re-evaluated with repeat sampling to assess diagnostic recovery.

Results:

Out of 26 cases:
- 7 (26.9%) yielded pathogenic variants
- 9 (34.6%) resulted in VUS
- 9 (34.6%) were negative
- 1 (3.8%) showed persistent partial failure

Initial partial failure occurred in 6 cases. Upon second sampling:
- 3 (50%) produced pathogenic results
- 1 (16.6%) yielded a VUS
- 1 (16.6%) remained negative
- 1 (16.6%) continued to show partial failure

All pathogenic cases had at least partial toxicology and vitreous data, though many still showed delays in processing or non-standard specimen selection.

Common patterns among negative or uncertain cases included:
- Delayed autopsy or shipment (>48–72 hours postmortem)
- Absence of vitreous glucose and/or elevated potassium, consistent with degradation
- Minimal contributory toxicology or culture findings

Conclusion: Pre-analytical factors—including delayed sampling, prolonged postmortem intervals, and biochemical markers of degradation—appear to be significant contributors to failed or inconclusive Invitae testing outcomes. However, our findings suggest that second sample testing can recover actionable results in a subset of these cases. To optimize the success of postmortem genetic analysis, early collection and preservation of multiple blood sources accompanied by comprehensive toxicology and vitreous chemistry studies, are recommended. In instances of initial test failure, a second attempt at genetic testing should be considered, as repeat sampling may yield clinically relevant findings that were not detected initially.

I42 A Comparison of DNA Quality in Gray and White Matter of the Brain

Dong Yeon Lee, BS, Sungkyunkwan Univ., Suwon-si, Kyonggi-do, Republic of Korea; Ga Eun Kim, MS, Sungkyunkwan Univ., Suwon-si, Kyonggi-do, Republic of Korea; Moon-Young Kim, MD, PhD, Sungkyunkwan Univ., Suwon-si, Kyonggi-do, Republic of Korea; Eun-Byoul Jung, BS, Sungkyunkwan Univ., Suwon-si, Kyonggi-do, Republic of Korea; Eugene Choi, MD, Sungkyunkwan Univ., Suwon-si, Kyonggi-do, Republic of Korea; Chae Min Lee, BS, Sungkyunkwan Univ., Suwon-si, Kyonggi-do, Republic of Korea; Im Soyoun, MS, Sungkyunkwan University*

Learning Objectives: The following areas will be covered in this presentation: (1) describe the differences in DNA quantity and quality between gray and white matter in postmortem brain tissue. Participants will learn how quantification results differ by method: spectrophotometry shows higher values in gray matter, while quantitative Polymerase Chain Reaction (qPCR) shows higher values in white matter. These differences reflect each method's target and tissue-specific degradation; (2) assess the impact of RNA contamination on DNA quantification and the benefits of RNase treatment. Attendees will understand that RNA contamination inflates DNA measurements in gray matter. RNase treatment reduces this interference, especially in spectrophotometry and fluorometry, and improves consistency across quantification methods; and (3) interpret how tissue-specific degradation affects Short Tandem Repeat (STR) profiling in decomposed brain samples. Attendees will recognize that white matter yields better STR results in decomposed samples due to superior short-fragment preservation, while RNase treatment enhances STR performance in gray matter.

Impact Statement: This study provides new insights into tissue-specific differences in DNA quality between gray and white matter of the brain and their implications for forensic DNA analysis. By demonstrating how RNA contamination and tissue composition affect the accuracy of quantification methods and STR profiling, this study offers practical guidance for selecting optimal brain tissue and quantification strategies in postmortem cases. These findings can improve the reliability, efficiency, and interpretability of forensic DNA testing, especially in degraded or limited samples.

Abstract Text: Although the brain undergoes rapid morphological degradation after death, its DNA is relatively well preserved compared to other tissues.[1-4]. Previous studies suggest that brain-derived DNA may serve as a valuable source of evidence in forensic investigations.[2-6] The brain is a unique organ composed of gray and white matter, which differ structurally and cellularly.[7-9] These distinctions may influence the quality of extracted DNA and affect the results of DNA quantification, a crucial step for downstream genetic analyses.[10] However, few studies have investigated differences in nucleic acid quality between gray and white matter, particularly under conditions of decomposition.

Among the autopsies performed between May 2023 and July 2024, 50 cases, including decomposed cases, were selected for this study. The mean age of the individuals was 59.6 years (range: 24–85 years), and decomposition was defined based on Total Body Score (TBS): cases with a TBS of 0–1 were classified as fresh, and cases with a TBS greater than 1 were classified as decomposed. DNA was separately extracted from gray and white matter in all cases, and to more accurately assess differences in DNA quality, RNA-free DNA was additionally extracted from 26 of these cases by applying RNase treatment. DNA quality was evaluated using spectrophotometry, agarose gel electrophoresis, fluorometry, and qPCR-based methods. The effects of RNase treatment on DNA quality and quantification outcomes were also examined. Furthermore, STR analysis was conducted to assess the potential impact on DNA profiling. In the quantification results of the samples without RNase treatment, as decomposition progressed, gray matter showed more pronounced degradation in spectrophotometry and gel electrophoresis assessments, whereas white matter exhibited greater degradation in qPCR results. These discrepancies are attributable to the differing nucleic acid targets of each quantification method. Following RNase treatment, all quantification methods showed markedly lower measured values in gray matter, indicating RNA contamination in prior results. RNase treatment minimized inconsistencies among quantification methods by reducing RNA interference, particularly in spectrophotometry, gel electrophoresis, and fluorometry results. STR profiling showed comparable results between gray and white matter in non-decomposed samples. In decomposed samples, white matter demonstrated better preservation of short DNA fragments. RNase treatment improved STR results in gray matter and enhanced the amplification efficiency of short DNA fragments.

By characterizing differences in DNA quality between gray and white matter, this study provides practical insights into selecting appropriate quantification methods specific to brain tissues. It is advisable to use quantification methods specific to double-stranded DNA, and RNA removal, particularly in gray matter, enables more accurate quantification and improves STR results. For a decomposed brain, white matter is recommended as it better preserves DNA. Improving DNA quality at the initial stages enables more accurate and reliable forensic analyses. Furthermore, selective sampling based on tissue characteristics in degraded brain samples can reduce sample waste and enhance the efficiency and precision of forensic DNA testing. These findings offer practical guidance for DNA analysis in forensic casework involving brain tissues.

I43 Elder Abuse and Long-Term Health Outcomes: A Comprehensive Meta-Analytic Review

Antonietta Porzio, MD, , Università Degli Studi Della Campania "Luigi Vanvitelli, Italy, Naples, Campania, Italy; Maria Grazia Violante, Università Degli Studi di Bari Aldo Moro, Bari, Puglia, Italy; Carlo Pietro Campobasso, MD, PhD, University of Campania "Luigi Vanvitelli", Naples, Naples, Campania, Italy; Paola Ciamarra, MD, Università Degli Studi Della Campania "Luigi Vanvitelli, Italy, Naples, Campania, Italy; Ignazio Grattagliano, PhD, Università Degli Studi di Bari Aldo Moro, Bari, Puglia, Italy; Graziamaria Corbi, PhD, University of Naples Federico II, Naples, Campania, Italy*

Learning Objectives: After attending this presentation, attendees will gain an enhanced understanding of the long-term health impacts of elder abuse and major outcomes such as hospitalization, mortality, falls, and depression.

Impact Statement: This study highlights the potential long-term consequences of elder abuse on major health outcomes, emphasizing the need for early identification, prevention strategies, and targeted interventions to reduce its impact on the aging population.

Abstract Text: With the global population aging, elder abuse has emerged as an increasingly significant public health concern, increased during the COVID-19 pandemic due to extended periods of isolation.[1] The World Health Organization (WHO) defines elder abuse as a harmful act or omission within a relationship of trust, encompassing physical, emotional, sexual, and financial abuse, as well as neglect and abandonment.[2] Victims may experience severe consequences, including injuries, depression, cognitive decline, premature mortality, and institutionalization.[3,4] However, evidence regarding the long-term effects such as hospitalization, falls, mortality, and mental health remains limited.

The aim of this study is to review the available literature to determine whether, in the long term, elder abuse could be considered a risk factor for major outcomes. A meta-analysis was performed by searching Medline, Scopus, Web of Science, PubMed, and CENTRAL Cochrane. Studies were eligible whether reporting the development in the long-term of any outcome (hospitalization, death, falls, disability, depressive symptoms) and an available control group. The risk of bias was assessed using GRADE. A $p < 0.05$ was considered statistically significant. The systematic review consisted of 74,253 screened articles. However, only 25 studies satisfied the inclusion criteria, that included 29,366,038 older subjects. The total population consisted of 42,637 older abused and 29,323,401 not abused subjects. At least one outcome was present in 11,005 victims and in 10,115,628 non-abused subjects. In a random-effects method, the abuse favored ($p < 0.0001$) the development of any outcome, whereas the data suffered from high heterogenicity ($I^2 = 94.09\%$). So, sub-analyses were performed to assess the possible factors affecting this relationship.

Abuse appears to be linked to a higher risk of developing outcomes, and despite high heterogeneity and data variability, the findings are statistically significant. Addressing elder abuse requires interventions to improve detection, raise awareness, reduce victims' mental health symptoms, and prevent abuse. Risk factors like health conditions, caregiver burden, and social isolation increase vulnerability. The awareness of these factors could guide future research and preventive strategy in protecting older adults.

I44 Beyond the Bullet: A Histopathological Evaluation of Gunshot Injuries Enhanced by Experimental Animal Models

Federica Cascone, MD, University of Campania "Luigi Vanvitelli", Naples, Campania, Italy; Alessandro Feola, MD, PhD, University of Campania "Luigi Vanvitelli", Naples, Campania, Italy; Paolo Palermo, MD, University of Campania "Luigi Vanvitelli", Naples, Naples, Campania, Italy; Pasquale Mascolo, MD, Local Sanitary Unit, ASL Napoli 3 Sud, Naples, Campania, Italy; Orlando Paciello, PhD, Department of Veterinary Medicine and Animal Production, University of Naples "Federico II", Naples, Campania, Italy; Giuseppe Piegari, PhD, Department of Veterinary Medicine and Animal Production, University of Naples "Federico II", Naples, Campania, Italy*

Learning Objectives: After attending this presentation, attendees will better understand the gross and histological characteristics of gunshot wounds at different range fire in humans and in animal cadavers.

Impact Statement: This presentation will impact the forensic science community by addressing the most common macroscopical and histological features associated to gunshot wounds at different range of fire in humans and animal cadavers.

Abstract Text: Investigating ballistic injuries can be challenging for forensic pathologists. In gunshot wound examination, histological analysis generally plays a secondary role. However, it can provide significant information to differentiate between entry and exit wounds, as well as to estimate the range of fire.[1] In humans, research has been conducted primarily through case-based studies. In this context, animal models may provide valuable additional information under experimentally controlled conditions.

Tissue samples from 18 gunshot wounds were collected from nine human victims (eight males and one female) who died due to firearm injuries by single-barreled weapons. The manner of death was: four homicides, four suicides, and one accident. The head was the most injured anatomical site (9 out of 18), followed by the trunk (6 out of 18), the neck, the chest, and upper limb (each with 1). In some cases, the circumstantial data (eyewitnesses, video-recorded images) provided confirmatory details about the dynamic of the fatal event, whereas in other cases, the shooting reconstruction was based on the autopsy results. According to macroscopic and histological findings, 11 entry and 7 exit wounds were identified and the range of fire was assessed as contact or near contact in 4 out of 11 cases and distant range of fire in 7 of 11 cases. The features were then compared with those of gunshot wounds experimental determined in animal cadavers.

Tissue samples from 40 gunshot wounds were collected from 20 animal cadavers (dogs and pigs), dead due to natural causes and not sacrificed for the purpose of the study. Three different shooting distances were applied: close contact, 60 cm and 6 meters away. Although the gunshot wounds on animals showed no signs of tissue vitality like hemorrhages or inflammatory infiltrate, some common macroscopic and histological features due to the bullet's effect and secondary effect of the discharge were appreciated according to the fire distance, the type of ammunition, and the animal species. The results of this comparative study on human and animal cadavers will be presented and discussed with the attendees.

Macroscopic and microscopic examination of gunshot wounds can support the assessment of exit/entrance wounds and the range of fire. The integration of histological analysis of gunshot wounds into standard autopsy protocols can play a decisive role, especially in challenging cases. These findings promote greater standardization in forensic methodologies and emphasize the importance of the microscopic examination of firearm injuries and of animal models in forensic practice.

I45 A Preliminary Discussion on the Effects of Clothing on Soot Deposition at Varied Ranges of Fire and on Cylinder Gap Marks

Barbara M. Herfel, MD, Marion County Coroner's Office, Indianapolis, IN; Gregory M. Schmunk, MD, Marion County Coroner's Office, Indianapolis, IN; Christopher M. Poulos, MD, Marion County Coroner's Office, Indianapolis, IN; Matthew Cain, MD, Marion County Coroner's Office, Indianapolis, IN*

Learning Objectives: After this presentation, attendees will understand limitations of using adult pig skin to evaluate range of fire findings, the basic effects of clothing on soot deposition surrounding gunshot wounds (and range of fire), and the basic effects of clothing on cylinder gap marks on the body.

Impact Statement: This presentation will impact the forensic community by allowing them to better construct test firing studies for range of fire and will better allow them to evaluate the range of fire of gunshot wounds through clothing.

Abstract Text: A 24-year-old male was shot in the head with a .38 caliber revolver with a four-inch barrel. More than one ammunition type was noted to have been fired from the revolver. During the autopsy examination, the decedent was determined to have an intermediate range gunshot wound of the head with surrounding gunpowder stippling (tattooing). Additional stippling was documented underneath a medium-weight sweatshirt on the decedent's torso. Although it is documented that clothing does affect range of fire determination, the precise effects of clothing on range of fire determination are not extensively reported. Additionally, the source of the stippling on the torso was in question because the authors were unsure if material from the cylinder gap could penetrate clothing and cause areas of stippling that are distinct from that surrounding the gunshot wound.

To assess the effects of clothing on range of fire, we utilized a .38 caliber revolver with a 4-inch barrel and ammunition from the same ammunition manufacturer as some of the ammunition associated with the case. This was test fired against the skin of a large hog that had died of natural causes and had been donated for the study. Despite cleaning and shaving of the skin, the dark and thickened skin of the elderly hog did not adequately demonstrate soot or stippling. As a replacement, white cloth was used to test range of fire. The revolver was fired into the cloth at predetermined ranges, with and without a medium-weight sweatshirt covering the cloth. Stippling was not readily visible on this cloth type; however, the size and presence of the area of soot deposition for each range of fire was recorded. Further, the size and presence of soot deposition was assessed with and without the sweatshirt covering the cloth target. Additionally, the revolver was fired parallel to the cloth (with and without the sweatshirt) to examine the effects of the clothing on the cylinder gap effect. The presence of clothing overlying the target limited both the size of the area of soot deposition and the range at which soot deposition occurred. Also, the presence of clothing did not eliminate markings from the cylinder gap.

This preliminary study demonstrates three key points. First, the skin of older hogs is not an acceptable material for range of fire testing. Second, clothing can decrease both the extent of soot deposition at a given range and the range at which soot deposition occurs. Finally, the study demonstrates that effects of the cylinder gap can readily penetrate medium-weight clothing. This suggests that the gunpowder tattooing on the decedent's torso may be related to the cylinder gap of the revolver that was fired into the decedent's head. Further study with a more suitable simulant of human skin is planned.

I46 Beware: BB Guns Can Kill

Whitney Carriveau, BA, University of North Dakota School of Medicine and Health Sciences, Grand Forks, ND; Selly Strauch, MD, University of North Dakota School of Medicine, Grand Forks, ND; Susan Roe, MD, University of North Dakota School of Medicine and Health Sciences, Grand Forks, ND*

Learning Objectives: This presentation will cover: (1) an analysis of an atypical ballistic trajectory leading to a fatal outcome in an unintentional pediatric BB gun injury, and (2) an examination of a specific injury mechanism demonstrating disproportionate impact within Native American and Alaska Native populations.

Impact Statement: This presentation will illuminate a singular case demonstrating the potential for ordinarily non-fatal projectiles to inflict lethal injury. Although BB gun-related injuries are generally considered non-life-threatening, the precise ballistic trajectory in this particular instance proved to be the causative factor in the fatality. Moreover, the discussion will underscore the significant disparities in the incidence of gunshot wound injuries experienced by Native American and Alaska Native populations relative to the broader demographic.

Abstract Text: Accidental or unintentional injury is the leading cause of death in children ages 1-17 years old, with firearm injury being a leading method. Around one-half of these firearm injuries occur at home, often during playtime.1 In addition, American Indian (AI) and Alaskan Natives (AN) are disproportionately affected by firearm injury; with an increase of 43% in gun-related death rates from 2019-2023.2-4

A 3-year-old Native American male was playing with his sibling at home when he sustained a gunshot wound to the chest from a BB gun. He was brought to emergency medical services with agonal breathing and a palpable pulse. Enroute to the hospital, he became unresponsive, and resuscitation attempts upon arrival were unsuccessful.

Autopsy revealed perforations of the 3rd-4th left intercostal space, upper lobe of the left lung, the pulmonary artery, and descending aorta as well as a hemopericardium and hemothorax. The cause of death was determined to be a gunshot wound of the chest. The manner of death was classified as an accident.

This unique case will review the forensic pathology of a fatal BB gun injuries. It will highlight a leading cause of death in children, firearm injury, which disproportionately affects our AI/NA population as compared to the general population.

Disclosures: The authors received no outside funding for this work and have no known competing financial interests or personal relationships related to this work.

I47 Considerations and Implications of Homemade Firearm Sound Suppressors: A Case Series

Megan Schwietert, MD, Hillsborough County Medical Examiner Department/University of South Florida, Tampa, FL; Carolina McEnnan, MD, Hillsborough County Medical Examiner Office, Tampa, FL; Henry Alberto Giraldo Jimenez, Sr., Instituto Nacional de Medicina Legal y Ciencias Forenses, Medellín, Antioquia, Colombia*

Learning Objectives: After attending this presentation, attendees will be able to: (1) analyze wounds and gunshot residue at autopsy to determine potential use of firearm sound suppressors; (2) identify the differences between close-range gunshot wounds involving sound suppressor use versus distant-range gunshot wounds; (3) recognize key forensic evidence within a wound track that may be created from a homemade sound suppressor; and (4) apply expanded knowledge of ballistic patterns to future autopsy investigations.

Impact Statement: As the use of firearm sound suppressors may be increasing in certain parts of the world, it is crucial for forensic pathologists and ballistic experts to identify discrepancies in gunshot residue patterns and ranges of fire evaluations. Moreover, debris from homemade firearm sound suppressors should be recognized and collected as evidence at the time of autopsy. This will enable proper communication with law enforcement and lead to the correct identification of the firearm used in the crime.

Abstract Text: Firearm sound suppressors, otherwise known as silencers, are a possible complicating factor in death investigations. They are often created for pistols or rifles or can be made as an attached accessory.[1] While legal models are highly regulated in the United States, homemade models created with items such as plastic bottles, pipes, steel wool, or rubber plugs can be found at crime scenes or as part of the investigative process.[2] The use of firearm silencers lessens the sound created when firing a gun, but potentially more importantly, will affect the ballistic patterns seen at autopsy.[1] First, the use of sound suppressors may reduce gunshot residue distribution to an item shot or at the periphery of the decedent's wound.[3] Gunshot residue within the wound and wound track may be greatly reduced or entirely absent.[4] Additionally, homemade sound suppressors can leave trace debris within the wound path, which requires further investigation of the scene and potential weapon used in the crime.[5]

This case series will take a deeper look at scenarios in which homemade silencers played a crucial role in the investigation and findings at autopsy. The cases occurred in Medellín, Colombia, where homemade silencers are prohibited by law, but have increased in their frequency of use in crimes. In Medellín, approximately 50% of the analyzed firearms submitted to the Forensic Ballistics Laboratory of the National Institute of Legal Medicine and Forensic Sciences are submitted with homemade sound suppressors. Examining these cases of homemade silencer use can help forensic pathologists and ballistic experts have a more accurate understanding of the differences in ballistic and injury patterns. Ultimately, this can lead to improved communication with law enforcement, identification of the correct firearm and range of fire, and have potential medicolegal implications.

I48 A Fatal Gunshot Wound From a Test Shot: A Forensic Case Report

Annachiara Vinci, MD, University of Bari "Aldo Moro", Medical-Legal Section of Policlinico di Bari, Bari, Puglia, Italy; Paolo Visci, University of Bari "Aldo Moro", Medical-Legal Section of Policlinico di Bari, Bari, Puglia, Italy; Davide Ferorelli, MD, University of Bari "Aldo Moro", Medical-Legal Section of Policlinico di Bari, Bari, Puglia, Italy; Natalia Sebastiani, MD, University of Bari "Aldo Moro", Medical-Legal Section of Policlinico di Bari, Bari, Puglia, Italy; Gianmarco Sirago, MD, Università degli Studi di Bari "A.Moro", Bari, Puglia, Italy; Francesco Calò, MD, Università degli Studi di Bari "A. Moro", Bari, Puglia, Italy*

Learning Objectives: After attending this presentation, attendees will be better able to: (1) identify key forensic autopsy findings that differentiate fatal gunshot wounds from other penetrating chest injuries and determine the mechanism of death in cases involving hypovolemic shock; (2) apply ballistic trajectory analysis to reconstruct the shooting dynamics and assess firing distance based on entrance wound morphology and ancillary tests such as sodium rhodizonate; (3) integrate toxicological and histological findings to establish victim condition at the time of death and evaluate their relevance in reconstructing the circumstances of homicide; (4) recognize forensic patterns indicative of weapon testing scenarios and understand how medicolegal expertise can uncover atypical motives behind firearm-related fatalities; and (5) collaborate effectively with law enforcement and judicial authorities using comprehensive medicolegal documentation to influence investigative outcomes and legal proceedings.

Impact Statement: This case highlights a rare and underdocumented category of firearm fatalities: deaths resulting from test firing weapons on human targets. By presenting a detailed medicolegal workflow that combined autopsy, histology, toxicology, and ballistic reconstruction, the study underscores the indispensable role of forensic pathology in uncovering concealed criminal dynamics. The findings contribute to forensic literature by expanding the understanding of atypical homicide motives and demonstrating the integration of scientific evidence with investigative leads to establish intent. This presentation provides a framework for forensic practitioners to approach similar complex cases, ultimately strengthening the collaboration between forensic experts, law enforcement, and the judicial system. It emphasizes the need for heightened awareness regarding modified blank firearms and their forensic signatures, thereby enhancing both investigative accuracy and preventive strategies within the field of forensic science.

Abstract Text: Firearm-related fatalities typically occur due to intentional assaults, accidental discharges, or suicides. Deaths resulting from test firing a weapon are exceptionally rare in forensic casework.[1] We report an unusual homicide involving a firearm test discharge, elucidated through meticulous medicolegal investigation and interdisciplinary collaboration.

On May 31, 2024, in Bari, Italy, the body of a 38-year-old man, N.S., was discovered in an abandoned building frequently inhabited by transient individuals. Initial examination at the crime scene revealed the deceased in a supine position with a single gunshot wound to the chest. Preliminary investigation indicated N.S. was socializing peacefully with acquaintances prior to being shot. Witness testimonies confirmed the absence of any altercation or conflict preceding the incident.

Subsequent autopsy findings detailed a single entrance wound approximately 2 cm to the left of the midline thoracic region. The projectile trajectory penetrated the sternum, heart, vena cava, and left lung, resulting in extensive internal hemorrhage and rapid death. A bullet was recovered lodged adjacent to the 8th intercostal space. The autopsy also identified significant blood loss, quantified at approximately 1,479 ml, establishing hypovolemic shock as the direct mechanism of death.

Toxicological analyses revealed an extremely high blood alcohol level of 3.62 g/L, consistent with severe intoxication, corroborating historical testimonies of the victim consuming whiskey shortly before death. Histological evaluations supported autopsy findings, identifying acute hemorrhagic damage and extensive fragmentation of myocardial tissues, alongside significant pulmonary congestion and hemorrhaging. No pre-existing medical conditions or pathological anomalies were found that might have contributed to the victim's demise.

A critical component of the investigation was forensic ballistics and crime scene reconstruction. Notably, meticulous examination by the author, incorporating detailed forensic assessments and ballistic analyses, indicated that N.S. was fatally shot when perpetrators tested a firearm, specifically a modified blank-firing weapon, initially purchased illegally for other criminal activities. The firearm testing hypothesis was confirmed by combining medicolegal evidence with investigative testimonies and ballistic data, significantly influencing the legal interpretation of the incident and subsequent criminal proceedings.

This forensic case highlights the rare but lethal consequence of using human targets to test firearms and emphasizes the importance of thorough medicolegal examinations in complex homicide cases. The coordinated forensic and investigative approach proved vital in unraveling the criminal motive, underscoring the need for heightened awareness regarding modified firearms' dangers and robust preventive strategies within forensic and criminal justice frameworks.

I49 How the Misinterpretation of Formalin Pigment Artifacts in Postmortem Histology Can Influence the Forensic Diagnosis

Stefano Tambuzzi, MD, University of Milan, Milan, Lombardia, Italy; Guendalina Gentile, BSc, University of Milan, Milan, Lombardia, Italy; Riccardo Zoia, MD, PhD, University of Milan, Milan, Lombardia, Italy; Lorena Ferraroli, MSc, University of Milan, Milan, Lombardia, Italy*

Learning Objectives: Participants will learn a basic concept of postmortem histological examination, in particular the possible presence of formalin pigment artifacts in tissue fixed in formalin. They also will learn that these artifacts can be very similar to other physiological or exogenous pigments that are relevant from a forensic point of view, which can lead to misinterpretation. The laboratory techniques used for differential diagnosis and the forensic implications of the findings will be discussed.

Impact Statement: Formalin pigment, which is morphologically very similar to physiological or exogenous pigments of significant forensic interest, may mimic or obscure them, making their identification challenging. Forensic pathologists should be aware that possible formalin pigment artifacts can actually mask a wide range of pigments, the misinterpretation of which can have a negative impact on the diagnosis of cause of death and other forensic aspects.

Abstract Text: Formalin pigment is the most important artifact found in postmortem histological analysis. Although it has no forensic relevance, if it is abundant or the pathologist is not very experienced, it can mimic or hide physiological or exogenous pigments of considerable forensic interest due to its morphological similarity, making their identification challenging and causing diagnostic difficulties.[1]

To investigate these aspects, a retrospective study was performed on 35 autopsy cases in different states of preservation in which postmortem histological analysis had revealed the presence of brown/blackish precipitates requiring differential diagnosis with formalin pigment artifacts. In 29 cases (83 %) it could be proven that the precipitates were not formalin artifacts. However, in some cases they were of low forensic relevance (anthracose and lipofuscin), while in others they were characterized as pigments of high forensic significance. Among the most important are: hemosiderin, lead from Gunshot Residues (GSR), granular deposits as a result of acute poisoning with various toxic substances, and malaria pigment. It has been shown that pigments that at first glance appear to be formalin artifacts may in fact conceal a wide range of pigments of different types and etiologies, the forensic significance of which may vary according to the circumstances and investigative context of each case. This finding emphasizes the importance of forensic pathologists always questioning whether it is appropriate to further investigate the diagnosis of suspected formalin-related pigment deposits in autopsy specimens to pursue the final correct assessment.

I50 γ-H2AX—A Useful Tool to Detect DNA Damage in Sudden Cardiac Death Heart Tissues: An Experimental Study

Angelo Montana, PhD, Marche Polytechnic University, 60121 Ancona, Italy, Ancona, Marche, Italy; Francesca Licitra, PhD, Marche Polytechnic University, 60121 Ancona, Italy, Ancona, Marche, Italy; Francesco Paolo Busardò, MD, PhD, Univpm, Ancona, Marche, Italy; Sonia Fantone, PhD, Marche Polytechnic University, 60121 Ancona, Italy, Ancona, Marche, Italy; Rosanna Zamparese, PhD, Legal Medicine Unit, Ascoli Piceno Hospital C-G. Mazzoni, Viale Degli Iris 13, 63100 Ascoli Piceno, Italy., Ascoli, Marche, Italy; Giovanni Tossetta, PhD, Marche Polytechnic University, 60121 Ancona, Italy, Ancona, Marche, Italy*

Learning Objectives: After attending this presentation, attendees will learn how a multimodal forensic approach—combining autopsy, histologica, immunohistochemical, and immunofluorescence analysis—can lead to the identification of specific markers of DNA damage in case suffering Sudden Cardiac Death (SCD).

Impact Statement: Postmortem diagnosis of SCD due to myocardial ischemia is a major concern and a challenge in forensic autopsy. Our data suggest that γ-H2AX expression may be a useful marker to help the postmortem diagnosis of Computer-Aided Design (CAD) -related SCD.

Abstract Text: SCD is defined as death due to cardiovascular or unidentifiable causes that occurs within an hour of the onset of symptoms. Several lines of evidence suggest that oxidative stress, which is due to an increased production/accumulation of Reactive Oxygen Species (ROS) in cells, may be associated with SCD. ROS can induce DNA damage leading to DNA Double-Strand Break (DSB) that, if not repaired, can lead to cell death. In presence of a DNA DSB, H2AX (a histone H2A variant) is phosphorylated to form γ-H2AX, which binds the DNA DSBs and recruits DNA repair proteins. If DNA damage is excessive and cannot be repaired, cells undergo apoptosis.

This was a single-center, observational, cross-sectional study using human postmortem heart samples obtained from autopsies ordered by the prosecutor. A total of 20 human heart tissue samples from autopsy cases were analyzed: 10 from sudden cardiac death and 10 from decedents for non-cardiac causes. Hematoxylin and eosin, Phosphotungstic Acid Haematoxylin (PTAH), and Sudan-Black-B stainings shows myofiber waviness, interstitial oedema, hypereosinophilia, and coagulative necrosis of cardiomyocytes with contraction bands and neutrophilic granulocytes infiltrate (B) while PTAH staining shows the typical contraction band necrosis in SCD. Immunohistochemical analysis showed that γ-H2AX was expressed in the nuclei of cardiomyocytes in both normal and SCD tissues. Statistical analysis of γ-H2AX expression in normal and SCD heart tissues showed a statistically significant increase of γ-H2AX expression (increased number of positive nuclei) in SCD compared to normal heart tissues.

The expression of γ-H2AX in normal and SCD heart tissues was also demonstrated by immunofluorescence analysis; γ-H2AX foci in the nuclei (green dots in the nuclei) are clearly visible in both normal and SCD heart tissues. Statistical analysis showed a significant increase of mean fluorescence intensity in SCD samples compared to control samples, demonstrating an increase of γ-H2AX foci in SCD heart samples.

In this study, we attempted to explore the role of γ-H2AX expression as DNA damage marker in myocardial tissues from SCD decedents. We found γ-H2AX expression in the nuclei of cardiomyocytes of both normal and SCD tissues but its expression was statistically significant increased in SCD compared to normal heart tissues. We also demonstrated, by immunofluorescence analysis, the presence of γ-H2AX foci in the nuclei of both normal and SCD heart tissues with a significant increase of γ-H2AX foci in SCD samples.

Our data showed an increased DNA damage in SCD tissues and demonstrated that the evaluation of γ-H2AX expression in these tissues is a good tool to evaluate this type of damage in SCD heart tissues. Thus, evaluation of γ-H2AX expression in postmortem heat tissues, in conjunction with other cardiac histological and circumstantial data, can reinforce and facilitate SCD diagnosis.

Our data suggest that γ-H2AX expression may be a useful marker to help the postmortem diagnosis of CAD-related SCD. Further studies are needed to implement this immunohistochemical technique in forensic practice, making the use of this marker applicable as a routine in forensic cases.[1-4]

I51 Beyond the Cold: Re-Establishing Wound Vitality in Frozen-Thawed Bodies With Glycophorin A Immunohistochemistry

Giulia Berneschi, MD, University of Pisa, Arezzo, Toscana, Italy; Pietro Ciulli, MD, University of Pisa, Pisa, Toscana, Italy; Marco Di Paolo, MD, PhD, University of Pisa, Pisa, Toscana, Italy; Naomi Iacoponi, MD*, University of Pisa, Pisa, Toscana, Italy; Andrea Scatena, MD, university of Pisa, Pisa, Toscana, Italy; Michela Gabelloni, MD, University of Pisa, Pisa, Toscana, Italy*

Learning Objectives: This work aims to describe the specific histological artifacts, such as erythrocyte shrinkage, induced by postmortem freeze-thaw cycles. It also seeks to highlight the significant limitations and potential for false negatives of conventional Hematoxylin & Eosin (H&E) staining in determining wound vitality in these specific cases. Furthermore, it intends to show the methodology and diagnostic value of using anti-Glycophorin A (GPA) immunohistochemistry, which can therefore be a reliable and essential alternative for validating vital ecchymotic lesions.

Impact Statement: This presentation aims to provide a validated protocol to overcome a significant diagnostic challenge: by introducing a reliable method to confirm wound vitality in compromised samples, this research can enhance the accuracy of forensic investigations, prevent the misinterpretation of crucial evidence, and uphold the integrity of the judicial process.

Abstract Text: The distinction between perimortem and postmortem injuries is a cornerstone of forensic pathology, with the vitality of a lesion often serving as pivotal evidence in judicial proceedings.[1] The standard method for confirming the vitality of ecchymosis is the histological detection of extravasated Red Blood Cells (RBCs) using H&E staining. However, procedural requirements and judicial delays frequently necessitate the prolonged storage of bodies in refrigerated cells, subjecting them to one or more freeze-thaw cycles. This practice introduces significant histological artifacts, most notably cellular shrinkage and erythrocyte microstructure damage, which can render H&E staining unreliable and lead to false-negative findings, potentially jeopardizing the outcome of an investigation.[2-4]

This study, based on two challenging forensic cases—a road traffic accident and a suspected homicide—investigates a solution to this critical issue. We conducted an experimental analysis on ecchymotic tissue samples collected from seven deceased individuals. Samples were histologically analyzed at three stages: pre-freezing (t0), after one freeze-thaw cycle (t1), and after a second cycle (t2). While H&E staining successfully identified dermal hemorrhagic infiltration at t0, its reliability was markedly reduced at t1 and failed completely at t2, showing no definitive evidence of RBCs.

To overcome this limitation, we employed immunohistochemical staining with a monoclonal antibody against GPA, a stable protein on the erythrocyte membrane.[5,6] The anti-GPA antibody successfully and consistently detected extravasated RBCs in all samples at both t1 and t2, reaffirming the vitality of the lesions where H&E had failed.

Our findings demonstrate that conventional H&E staining is inadequate for assessing wound vitality in frozen-thawed bodies. We propose that the use of anti-GPA immunohistochemistry is not merely an alternative but an essential validation tool in such cases. This approach is based on the application of advanced technology, which ensures the identification of vital reactions, thereby preserving the integrity of forensic evidence and reinforcing the foundations of justice.

I52 A Comparative Evaluation of Four Histological Stains for Skeletal Fracture Time Since Injury Estimation

Alexis L. VanBaarle, APM, Michigan State University, East Lansing, MI; Carolyn V. Isaac, PhD, Michigan State University, East Lansing, MI; Joseph A. Prahlow, MD, Medical Examiners Office, City of St. Louis, St. Louis, MO; Amanda O. Fisher-Hubbard, MD, WMed, Kalamazoo, MI; Jered B. Cornelison, PhD, Western Michigan University Homer Stryker M.D. School of Medicine, Kalamazoo, MI; Joyce L. deJong, DO, Michigan State University College of Osteopathic Medicine, East Lansing, MI; Brandy Shattuck, MD, BLS Forensic Pathology PLLC, De Pere, WI; Theodore T. Brown, MD, Arkansas State Crime Laboratory, Little Rock, AR; Wendy Lackey-Cornelison, PhD, Department of Medical Education, University Toledo School of Medicine and Life Sciences, Toldeo, OH*

Learning Objectives: After attending this presentation, attendees will have a better understanding of the appropriate stains to use for histological Time Since Injury (TSI) estimation of skeletal fractures.

Impact Statement: This presentation will impact the forensic science community by providing guidance for practitioners on skeletal histologic slide preparation to contribute to best practices in forensic anthropological and pathological assessment of skeletal fracture TSI.

Abstract Text: Estimating a skeletal fracture's TSI may be an important aspect to the forensic investigation, providing contextual evidence for the cause and timing of trauma. A barrier to accurate TSI assessment is the lack of standardization in histological slide preparation and staining methods. This research assesses the performance of four stains for the purpose of histological TSI estimations: (1) Hematoxylin and eosin (H&E), (2) Masson's trichrome, (3) Alcian Blue Hematoxylin/Orange
G (ABOG), and (4) Russel-Movat pentachrome.

Sixty-five cranial vault fracture samples with known TSI were excised from 58 decedents at autopsy at the Western Michigan University Homer Stryker M.D. School of Medicine Department of Pathology. Samples were fixed in formalin, decalcified with either EDTA, nitric acid, or hydrochloric acid, embedded in paraffin, and cut into thin sections. Each sample was sectioned four times and stained with one of the four stains, resulting in a total of 318 slides. Three experienced observers randomly selected from a group of seven pathology and histology specialists, were asked to assess a random subsample of the slides for the presence of 17 healing features that are recorded throughout the healing micro-cascade for the inner table, outer table, and diploe regions. These features included: hematoma, hematoma organization, pigment-laden macrophages, fibrin, inflammation, connective tissue, mesenchyme, fibroblasts, collagen, new capillaries, cartilage matrix, bone formation, bone resorption, bone matrix, woven bone, lamellar bone, and cement/reversal lines. For each of the regions on a single slide, democratic voting between the observers for each of the features' presence was recorded to condense the repeated observations. Then, to condense the regions, presence was recorded for each of the features that were recorded as present in at least one of the regions. To assess stain performance for each of the features, a chi-square analysis and a Cochran's Q were performed.

The chi-square analysis yielded insignificant results for all healing features. Cochran's Q resulted in significant proportional differences for cartilage matrix ($p=0.046$) presence under the Nitric decalcification agent. Cartilage matrix was identified as present more often in Russel-Movat pentachrome. The results indicate that practitioners may use any of these four stains to histologically assess skeletal tissue at any point during the healing process for the purposes of estimating TSI. In addition, nitric acid decalcification coupled with Russel-Movat pentachrome is especially useful when attempting to identify cartilage in histological sections of skeletal fractures.

I53 A Case of Homicidal Necrophilia

Joseph A. Prahlow, MD, Medical Examiners Office, City of St. Louis, St. Louis, MO; Susan K. Zuiderveen, JD, Van Buren County Prosecutor's Office, Paw Paw, MI; Jay T. Blair, JD, Van Buren County Prosecutor's Office, Paw Paw, MI; David Walker, Van Buren County Sheriff's Department, Paw Paw, MI*

Learning Objectives: The goal of this presentation is to provide the details of a very unusual and disturbing necrophilia case. Attendees will gain valuable knowledge regarding how the case was solved and successfully prosecuted due in large part to the high-quality, rapid, cooperative efforts of multiple investigating agencies.

Impact Statement: The presentation will impact the forensic community by highlighting numerous important factors involved in the investigation and successful prosecution of a necrophilic homicide involving a perpetrator who sought out and intentionally struck and killed a woman who was taking her usual early morning walk. After killing her, the perpetrator transported her body to a remote location to engage in necrophilic activities. A multidisciplinary approach to the case involved numerous agencies and forensic specialty areas, including law enforcement investigators, canine units, crash reconstruction, air surveillance, digital forensics, DNA technology, and death investigation/forensic pathology.

Abstract Text: "Necrophilia" means "obsession with and usually erotic interest in or stimulation by corpses."[1] Acts of sexual gratification from a corpse range from fantasies to actual sexual intercourse.[2] Necrophilia is one of several types of abnormal sexual behaviors known as paraphilias. Its true incidence is unknown. Although having sexual relations with a human corpse is a repugnant act and is considered illegal in most countries, it is not generally considered a "severe" crime.[3] In contrast, the act of committing a homicide in order to obtain a dead body for necrophilic purposes represents an unconscionable criminal act. Such cases are exceedingly rare. We present a case of necrophilic homicide.

A healthy, active woman in her mid-60s was reported missing by family when she failed to return after leaving her home for her daily morning walk in a rural area. During a search of the area, police discovered items of the woman's clothing along the side of a road, with a set of tire tracks nearby, as well as fragments of a Ford pickup grill. Police were able to track the ping of her cell phone into an adjacent county. Investigators were also able to determine that the SIM card for the woman's phone had been transferred into a different phone. Police were then able to identify the other person and confirm that he had a Ford pickup. He was tracked by his cell phone and confronted by police the following day, at which time he admitted that he had accidentally struck the woman while she was walking on the road. He stated that he stopped, discovered that she was deceased, and then panicked, placed her body in the pickup bed, and transported her to a remote rural area in a different county. He agreed to lead police to the body.

Medicolegal autopsy showed that she had died of multiple blunt force injuries, including an atlanto-occipital dislocation and multiple extremity fractures, consistent with a vehicle-versus-pedestrian incident. Patterned lividity on the victim indicated that her body had been on the floor of the cab compartment of the pickup truck for an extended time. Additional forensic analysis of the man's phone led investigators to a car wash, where multiple items of the decedent's clothing and a used condom were discovered in the trash. Subsequent analysis disclosed that, during the hours after the woman had been killed, the suspect had viewed multiple necrophilia videos. The suspect had also searched and viewed other necrophilia-related sites on his devices in the days/weeks prior to this event. Analysis of the condom showed DNA from both the man and the victim. The man was charged and convicted of 1st-degree premeditated murder and was sentenced to life in prison without the possibility of parole.

Necrophilic homicide is a rare event, the discovery of which requires a high index of suspicion, along with high-quality and efficient cooperation between multiple agencies. The presented case exemplifies how a horrible crime can be solved and successfully prosecuted in order for justice to be served.

I54 The Forensic Face of Vampirism: A Singular Case of Manual Cardiac Removal in a Homicide

Angela Colucci, MD, University of Bari, Bari, Puglia, Italy; Enrica Macorano, MD, University of Bari, Bari, Puglia, Italy; Francesco Introna, MD, PhD, University of Bari, Bari, Puglia, Italy; Giovanni de Gabriele, MD, University of Bari, Bari, Puglia, Italy; Andrea Marzullo, MD, PhD, University of Bari, Bari, Puglia, Italy*

Learning Objectives: Attendees will gain in-depth knowledge of a rare forensic case involving manual cardiac avulsion and postmortem cannibalism, with a focus on interdisciplinary investigative methods. The session will demonstrate the application of Postmortem Computed Tomography (PMCT) and histology in reconstructing complex homicidal events and identifying symbolic or psychiatric elements in unusual cases.

Impact Statement: This presentation will enhance attendees' competence in recognizing atypical injury patterns and integrating cultural or symbolic frameworks into forensic interpretation. It contributes to performance improvement in death investigation, particularly where delusional or ritualistic elements obscure standard motives. The case also highlights the forensic utility of PMCT and histology in reconstructing severe thoracic trauma.

Abstract Text: Do vampires (still) exist? Though long relegated to folklore and horror fiction, echoes of vampiric belief still emerge in extreme criminal cases. This report describes a rare and brutal matricide involving the manual extraction of the heart and subsequent cannibalism, driven by delusional conviction rooted in vampiric myth.

A woman was found dead with multiple stab wounds to the neck, thorax, and abdomen. A large precordial laceration had been created, and PMCT showed complete absence of the heart. Autopsy confirmed the finding, revealing only atrial stumps with no evidence of incised or sawed margins. Histological and immunohistochemical examination demonstrated vital traction injury consistent with manual extraction during cardiac systole. No tool marks were observed on the pericardium or great vessels. These findings supported a diagnosis of cardiac tearing.[1,2]

The study of the thoracic wound trajectory was performed, confirming compatibility with knife injuries and the thoracic breech but excluding its use in cardiac removal. The combined findings pointed toward an act of manual cardiac avulsion.

Several days after the killing, during a police questioning, the perpetrator confessed to having eaten the heart. He further stated that the victim had fed him human flesh (reported to be from his deceased father) and accused her of being a vampire. These claims align with documented cases of clinical vampirism, or Renfield's syndrome, a rare psychotic phenomenon involving the compulsion to consume blood or organs for perceived supernatural benefit.[9,14] Though exceedingly rare, parental cannibalism has been documented in forensic literature, particularly in the context of severe psychosis and mythologically framed violence.[3,14]

The multiple cultural practices reflect the enduring psychological symbolism of the heart as source of vitality, soul, and moral essence and its role in magical or purifying acts. Psychoanalytic literature has long interpreted cannibalism as a complex expression of grief, identity collapse, or symbolic retribution.[10,12,13]

Forensically, this case demonstrates the essential value of integrating pathological, imaging, cultural, and psychological analysis in investigating complex homicides. The integrated forensic investigation combining autopsy, histology, and PMCT allowed for a robust reconstruction of events in the absence of a complete heart and clarified the homicidal mechanism. Ultimately, this case challenges the boundaries between pathology and belief, reaffirming the need to consider symbolic behavior even in modern forensic medicine.

Laboratory of Human Genetics, Scientific Institute for Research, Hospitalization and Healthcare (IRCCS), Giannina Gaslini Institute, 16147 Genoa, Italy, Genova, Liguria, Italy*

Learning Objectives: Attendees will learn how to apply a multidisciplinary forensic approach—combining pathology, toxicology, and genetic analysis—to interpret complex death scenarios involving both suspected homicide and postmortem dismemberment. They will also gain tools for improving diagnostic accuracy in cases where natural and violent causes may overlap.

Impact Statement: This presentation will improve the forensic community's ability to handle ambiguous deaths by promoting systematic integration of scientific findings across disciplines. It will enhance the quality and defensibility of medicolegal conclusions, ultimately contributing to more accurate determinations of cause and manner of death in both investigative and judicial contexts.

Abstract Text: In November 2019, a 3-year-old child was found dead by their mother upon waking. Autopsy and histopathological examinations revealed findings generally consistent with asphyxia. Additionally, genetic testing was initiated to investigate potential mutations associated with cardiomyopathies, identifying five Variants of Uncertain Significance (VUS).

Several months later, while these assessments were ongoing, the child's mother appeared at a police station declaring that she had dismembered the body of her own mother after finding her hanging.

The inspection of the apartment revealed multiple bags and buckets containing human remains. External examination showed complete dismemberment and defleshing of the body down to the skeletal level (excluding the head), as well as near-total evisceration. The margins of the amputated areas didn't show hemorrhagic infiltration. The face showed marked bilateral scleral and conjunctival hyperemia and protrusion of the tongue between the gingival arches. Examination of the residual cervical area revealed the presence of a short segment of hard skin ligature mark with associated hemorrhagic streaks. Microscopic analysis revealed minimal lymphocytic inflammatory infiltrate, consistent with vital injury.

The postmortem mutilating dismemberment of the corpse and the absence of several organs did not, however, allow for the exclusion of other modes of death with certainty. Additionally, toxicological investigations, conducted on biological fluid mixed with blood found in the buckets containing human remains, tested positive for alcohol and benzodiazepines.

The investigation also led to the discovery of additional elements related to the child's death. To better define the cause, further genetic analyses were performed, confirming that the child did not carry an increased genetic risk for cardiomyopathy. In particular, genetic testing was extended to both parents, revealing that all previously identified VUS were inherited and not *de novo* mutations.[1,2] These findings, along with the autopsy results, supported the conclusion that the child's death was due to violent mechanical asphyxia by suffocation, with homicidal dynamics considered more likely than accidental causes, especially given the child's age.

At the conclusion of the first trial, the woman was convicted of murdering both her son and mother and sentenced to life imprisonment. On appeal, partial insanity was recognized, and her sentence was reduced to 27 years, which was later upheld by the Supreme Court of Cassation.

I56 Hack and Slash: Machete Homicides in Harris County, Texas

Marianne E. Beynon, MD, Harris County Institute of Forensic Sciences, Houston, TX*

Learning Objectives: By the end of this presentation, conference attendees will be able to recognize the characteristics of chop wounds inflicted by machetes and will become aware of common autopsy and investigative features of machete-related homicides.

Impact Statement: This presentation will impact the forensic science community by reviewing the autopsy and investigative features of a large number of homicides involving machetes in a busy metropolitan area. Machete-related homicides are relatively uncommon in the United States and very sparsely discussed in the literature.

Abstract Text: The machete is a large, heavy knife with a long, wide blade that is easily accessible due to lack of governmental regulations and low cost to purchase.[1] These implements are most commonly used as a tool to clear vegetation in tropical regions, but may also be wielded as a weapon.[2,3] Due to their unique shape and size, blows from machetes create distinct chop wounds that have features of both sharp and blunt force injuries. Limited literature exists on the subject of machete-related homicides.

Between 2004 and 2024, the Harris County Institute of Forensic Sciences performed autopsies on 12 cases of machete-related homicides. Of note, during this time frame, there were no machete-related accidents or suicides. The study cohort included ten males and two females, with ages ranging from 15 to 67 years old (median age, 30 years). Five decedents were Hispanic, four were Black, two were Asian, and one was White. Two decedents were transported to the hospital and underwent surgical intervention. Of the cases with known circumstances, two involved altercations between neighbors, three were associated with family violence, and four interconnected cases were related to the international gang Mara Salvatrucha (MS-13). Two decedents were recovered from deep graves in a wooded area by law enforcement.

In agreement with the literature, machete-related chop wounds involved the head in nearly all cases (n=11), with less common involvement of the neck (n=7), upper extremities (n=5), torso (n=3), and lower extremities (n=3). In several cases, overlapping wounds precluded accurate determination of the number of injuries. Chop wounds resulted in bone fractures in all cases, most commonly involving the skull. Every case had at least one additional type of trauma, including sharp force injuries (n=11), blunt force injuries (n=10), gunshot wounds (n=1), and neck compression (n=1). Most decedents had chop and/or sharp force injuries involving the hands (n=10). Three decedents were decomposed, which limited evaluation of wound numbers and characteristics. In two cases, some or all of the machete injuries may have been sustained postmortem during dismemberment and/or decapitation of the bodies.

Although deaths associated with machetes are uncommon in the United States, it is critical for death investigators and medical examiners to know common investigative information and recognize wound characteristics associated with this weapon. This study contributes to the limited literature describing the features of machete-related homicides.

I57 Homicide by Heart Attack: A Case Series

Michelle Kao, BS, Saint Louis University School of Medicine, St Louis, MO; Joseph A. Prahlow, MD, Medical Examiners Office, City of St. Louis, St. Louis, MO; Kanayo Tatsumi, MD, St Louis City Medical Examiners Office; Saint Louis University School of Medicine, St. Louis, MO; Tatiana Bihun, MD, Saint Louis City Medical Examiner's Office, St. Louis, MO; Katie Hanson, MD, St Louis City Medical Examiner's Office, St Louis, MO*

Learning Objectives: After attending the presentation, attendees will recognize how physical assault can exacerbate underlying cardiovascular disease and trigger fatal cardiac events that may be classified as homicide.

Impact Statement: This presentation will impact the forensic science community by reviewing multiple cases that highlight the intersection between physical assault and cardiovascular disease, emphasizing the importance of accurate classification of stress-mediated cardiac death due to assault.

Abstract Text: Physical assault may serve as a trigger for cardiac events in individuals with pre-existing cardiovascular disease. When trauma provokes a fatal cardiac event rather than causing death through direct physical injuries, it can blur the lines between a natural manner of death and homicide. We will review four cases in which physical assault exacerbated underlying cardiovascular disease and contributed to the death of the individuals.

Three of these cases involve a 45-year-old male, 44-year-old male, and 68-year-old female who were assaulted and subsequently experienced fatal cardiac events. In each instance, autopsy revealed varying degrees of coronary artery disease and hypertensive disease. Their physical injuries from the assault were not severe enough to cause their death; instead, the assault served as an acute physiologic stressor that triggered a fatal cardiac event. Drug use as noted by toxicological analyses (fentanyl in the first case and methamphetamine in the second case) may have contributed to the fatality as an additional physiologic stressor. Ultimately, the Cause Of Death (COD) in all three cases was atherosclerotic and hypertensive cardiovascular disease exacerbated by physical assault. The Manner Of Death (MOD) in all three cases was homicide.

The fourth case can be used as a representative example to illustrate the pattern observed in the first three cases. A 65-year-old male with multiple chronic illnesses, including Coronary Artery Disease (CAD), diabetes, and COPD, was found unconscious and bleeding after a physical altercation. He quickly went into sinus tachycardia, then cardiac arrest, with cardiopulmonary resuscitation being unsuccessful. Similar to the previous cases, no fatal physical injuries were identified. However, autopsy revealed moderate coronary atherosclerosis and left ventricular hypertrophy. Toxicological analyses also revealed cocaine use. The COD was cardiac dysrhythmia associated with hypertensive and atherosclerotic cardiovascular disease induced by an acute stressful event. The MOD was ruled as a homicide.

The term “homicide by heart attack” can be used to refer to the sudden death of an individual with underlying cardiovascular disease that is triggered by a criminal act involving physical or emotional stressors.[1,2] The four cases reviewed underscore the role of physiologic stress in exacerbating the decedent’s pre-existing cardiac problems, leading to myocardial infarction or cardiac dysrhythmia regardless of physical injuries. Ruling these cases as homicides reflects the significant role of physical assault in precipitating the death. Accurate death certification in these cases requires thorough examination, review of medical records, and collaboration with law enforcement or other health care colleagues. Greater awareness of stress-mediated cardiac deaths can ensure more accurate death investigations by forensic pathologists and medicolegal investigators.

Learning Objectives: From this presentation, attendees will learn about overkilling and afterkilling. The presentation describes a case in which these killing methods are often associated with psychotic syndromes in a family context.

Impact Statement: This presentation will impact the forensic science community in terms of competence/ability in managing a multidisciplinary forensic approach. In this case, forensic activities are described in the diagnosis of cause of death and liability in cases of overkilling and afterkilling accompanied by a diagnosis of psychotic syndrome.

Abstract Text: In the field of forensic science, homicides within the family account for 43% of the total in Italy, according to statistical surveys and in line with the European and global average. Fratricides represent an even smaller percentage of homicides that occur in the domestic sphere, at approximately 4.5%. The authors illustrate this type of crime by presenting the case of a middle-aged woman diagnosed with chronic schizophrenia who experienced mystical-religious delusions. She killed her older brother, who was also her legal guardian, in their shared home.

The primary weapon was a pair of scissors, which were used to inflict multiple wounds of varying depth across different body regions. Death was caused by a wound to the vascolonervous bundle in the neck, resulting in hemorrhagic shock. Blunt force trauma to the head was additionally inflicted using glass bottles and drinking glasses. Then, a knife was inserted into the victim's anus, which is consistent with postmortem disorganized and excessive violence.

Forensic pathology and scene reconstruction confirmed a sequence of vital injuries followed by postmortem wounds, which align with a psychotic episode. This violent intrafamilial homicide, which was exceptionally committed by a woman, highlights the role of active psychotic symptoms in extreme violence associated with schizophrenia spectrum disorders. Evidence shows that homicides involving overkill are often accompanied by delusional misidentification or mystical beliefs.

Systematic reviews in the scientific literature confirm that schizophrenia significantly increases the risk of homicide, particularly in the presence of untreated symptoms or comorbidities, and even more in a family context.[1,2] Forensic psychiatric evaluations are essential for determining criminal responsibility in such cases.

This case highlights the importance of a multidisciplinary approach, combining forensic pathology, psychiatric assessment, and legal analysis, to understand the dynamics and determine responsibility in extreme psychotic homicide.

I59 Asthma-Related Deaths in Los Angeles County, CA: Forensic Insights Into an Alarming Trend

Sarah Y. Edminster, DO, Los Angeles County Department of Medical Examiner, Los Angeles, CA; Andrew Nguyen, PhD MPH, Los Angeles County Department of Medical Examiner, Los Angeles, CA; Robyn Parks, MD, Los Angeles County Department of Medical Examiner, Los Angeles, CA*

Learning Objectives: Attendees will learn how forensic case data can uncover emerging public health concerns by analyzing patterns in asthma-related deaths investigated by a large urban medical examiner's office. The presentation will introduce attendees to geospatial and environmental health tools such as CalEnviroScreen, demonstrating how these can be applied in medicolegal death investigations to evaluate environmental and sociodemographic risk factors. The session will empower forensic practitioners to recognize their role in advancing public health surveillance and contributing to environmental justice.

Impact Statement: This presentation will enhance attendees' competence in identifying environmental and social determinants of health using forensic data. It will improve performance by introducing practical tools for spatial and temporal analysis of mortality trends in forensic casework. These skills may ultimately contribute to more informed public health policies and equitable healthcare interventions in environmentally and medically underserved communities.

Abstract Text: Asthma is a chronic respiratory disease and one of the leading causes of potentially preventable deaths in the United States.[1] Although national asthma mortality rates have declined over the past two decades, the Los Angeles County Department of Medical Examiner observed a notable rise in asthma-related deaths from 2023 to 2025.[2] This study aimed to determine whether these deaths reflected broader structural and environmental disparities across the region. Medical examiner data offer a unique perspective on asthma deaths that occur outside the clinical setting and can serve as a vital complement to traditional public health surveillance tools.

This retrospective case series describes the frequency and patterns of asthma-related deaths investigated by the Los Angeles County Department of Medical Examiner from January 2023 through mid-2025. Cases were identified through the department's death investigation database, and all types of examination were included (full autopsy, external examination, and record review). Collected variables included decedent demographics, cause and manner of death, investigative and autopsy findings (including gross and microscopic features), contributing conditions, evidence of airway irritants, geographic location of the terminal event, declared death location, residence, and housing status. Microscopic slides were reviewed when available. Relevant data were analyzed for patterns and compared to the existing literature and public environmental data. Decedent locations were geocoded to assess proximity to major roadways and environmental hazard sources. Buffer zones were applied based on prior evidence suggesting increased asthma risk in close proximity to high-traffic areas, where pollutant concentrations are known to decline with distance.[3]

A total of 55 asthma-related deaths were identified. Cases rose from 10 in 2023 to 28 in 2024, with 17 additional cases occurring in the first half of 2025. Most decedents were between the ages of 19 and 64 years, with African American individuals representing the largest racial group. Most had a known history of asthma and died in areas with high CalEnviro Screen scores, which measure environmental and socioeconomic stressors.[4] These findings align with established research showing asthma disproportionately affects minority communities and is associated with exposure to pollution and social disadvantage.[2,5,6] A bimodal distribution in time of death was also observed, with peaks between 2–10 a.m. and 3–9 p.m., consistent with published reports of asthma symptom exacerbation due to circadian patterns.[7]

This case series highlights the valuable role of forensic pathologists in identifying potential public health trends. In a diverse urban setting such as Los Angeles County—with wildfire exposure, proximity to industrial corridors, and persistent health care disparities—these findings raise urgent questions about environmental justice and barriers to care. By applying foundational forensic methods and maintaining scientific rigor in death investigations, forensic professionals are uniquely positioned to detect patterns of mortality that inform public health, guide policy, and promote equitable outcomes.

I60 Comparing Standard Clinical Laboratory Beta-Hydroxybutyrate Testing of Vitreous Fluid Against Standard Toxicological Blood Analyses in Ketoacidosis Deaths

Quinn Basso, MD, University of Ottawa, Ottawa, Ontario, Canada; Betty Chow, MSc, Centre of Forensic Sciences, Toronto, Ontario, Canada; Christopher Milroy, MD, University of Ottawa, Ottawa, Ontario, Canada; Jacqueline Parai, MD, University of Ottawa, Ottawa, Ontario, Canada*

Learning Objectives: Ketoacidosis is an important cause of death encountered in forensic practice. It is typically based upon Beta-Hydroxybutyrate (BHB) testing in a forensic toxicology laboratory.[1] Some authors have advocated that routine BHB analysis is not needed, while a recent study has found that point-of care testing had comparable performance to Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) standard testing.[1,2] Standard (hospital-based) clinical laboratory testing of vitreous fluid has been used in medicolegal death investigations as such results are rapid and hospital laboratories require robust quality control measures.[3] This study compares routine toxicological analysis (Gas Chromatograph/Mass Spectrometry [GC/MS] and LC/MS/MS) for postmortem blood BHB levels against assay-based testing of vitreous fluid and establishes thresholds for vitreous BHB for the diagnosis of Alcoholic Ketoacidosis (AKA) and Diabetic Ketoacidosis (DKA).

Impact Statement: This study will impact the forensic community by demonstrating that clinical laboratory testing can be reliably used to diagnose ketoacidosis in the postmortem setting. This study will also provide thresholds for vitreous BHB to assist in the diagnosis of DKA and AKA in forensic investigations.

Abstract Text: A retrospective case-control study of adult autopsy records was undertaken. Deaths between January 2016 and December 2024 where toxicological testing for postmortem blood BHB had been ordered were included. Information from autopsy records, including age, sex, Body Mass Index (BMI), cause of death, prior history of diabetes mellitus or alcohol use disorder, hemoglobin A1C (HbA1c), and both vitreous and blood concentrations of ethanol and BHB, were recorded where available. Using BHB levels determined by GC/MS or LC/MS/MS, HbA1c levels and autopsy findings, deaths were divided into one of five categories: no ketoacidosis, AKA, DKA, hypothermia deaths, and ketoacidosis deaths Not Otherwise Specified (NOS). The latter included ketoacidosis of unknown etiology and deaths with more than one potential source of ketoacidosis. Mann-Whitney U test was used to compare groups. Receiver Operating Characteristic (ROC) curves were constructed for both vitreous AKA and DKA deaths. The optimum diagnostic thresholds were calculated using Youden's J statistic. Deaths without ketoacidosis were used as the control group.

During the study period, 453 blood BHB analyses (GC/MS or LC/MS/MS) were conducted, of which 406 (90%) were included for statistical analysis. Pediatric cases, cases where decedents had prolonged hospitalization prior to death, and cases with an undetermined cause of death were excluded. The study group's ages ranged from 19-92 years (mean 54.4; median 56); 244 (60%) were male and 162 (40%) were female. BMI values ranged from 11.2-109.6 kg/m^2 (mean 25.4; median 24.2). Blood BHB concentrations (mg/L) were obtained using GC/MS in 159 (39%) cases and LC/MS/MS in 247 (61%) cases.

Vitreous BHB concentrations (mg/L) were elevated in AKA deaths (n=33; median 380.0; $p < 0.0001$), DKA deaths (n=39; median 1121; $p < 0.0001$), and ketoacidosis NOS (n=24; median 518.5; $p < 0.0001$). There was a strong positive correlation between the clinical laboratory vitreous and the standard toxicology methodology with a Pearson correlation coefficient for vitreous to blood toxicological testing of 0.944 for GC/MS and 0.947 for LC/MS/MS. ROC curves for vitreous BHB for the diagnosis of AKA (area under the curve = 0.978) established a threshold of > 283 mg/L; the curve for the diagnosis of DKA (area under the curve = 0.969) established a threshold of > 478 mg/L.

In summary, there was a strong positive correlation between clinical laboratory testing and GC/MS, and with LC/MS/MS. With that AKA and DKA can be reliably diagnosed at autopsy using hospital based clinical laboratory testing of vitreous BHB. Finally, a diagnosis of AKA can be made with a vitreous BHB > 283 mg/L and DKA can be made when vitreous BHB is greater than 478 mg/L.

I61 An Unusual Suspect: Group B Strep Strikes in Spontaneous Peritonitis

Paloma Johnson, BS, University of North Dakota School of Medicine and Health Sciences, Fargo, ND; Emma Weisner, BS, University of North Dakota School of Medicine and Health Sciences, Fargo, ND; Susan Roe, MD, University of North Dakota School of Medicine and Health Sciences, Fargo, ND; Selly Strauch, MD, University of North Dakota School of Medicine and Health Sciences, Fargo, ND*

Learning Objectives: Attendees will learn about a rare case of Group B Streptococcus causing Spontaneous Bacterial Peritonitis (SBP) in a young adult without a prior liver disease diagnosis, highlighting the importance of recognizing atypical pathogens in SBP. The presentation will review key autopsy findings, microbiologic results, and the clinical implications for early recognition and treatment of rapidly progressive infections in similar patient populations.

Impact Statement: This case expands the differential for spontaneous bacterial peritonitis to include Group B Streptococcus, even in young adults without a known history of liver disease, emphasizing the need for early recognition and treatment of uncommon but rapidly fatal pathogens in SBP.

Abstract Text: SBP caused by group B Streptococcus (GBS, *Streptococcus agalactiae*) is exceedingly rare, with few cases reported in the medical literature. We present the case of a 27-year-old man who initially presented to the emergency department with abdominal pain and was discharged despite ongoing symptoms. His medical history included methamphetamine use, cannabis use disorder, and schizophrenia. He was found deceased the following day in his shower.

Autopsy examination revealed three liters of cloudy peritoneal fluid and early hepatic cirrhosis. Cultures from peritoneal fluid, spleen, and blood all grew GBS. The cause of death was *S. agalactiae* sepsis secondary to SBP; the manner of death was ruled natural.

SBP is most commonly caused by gram-negative aerobic bacteria, such as *Klebsiella pneumoniae*, with gram-positive organisms accounting for less than half of cases. When GBS causes invasive disease in adults, it typically occurs in those with significant comorbidities, including diabetes, liver disease, or malignancy.

This case illustrates a rare presentation of GBS-SBP in a young adult with no prior diagnosis of liver disease, underscoring the importance of early recognition, diagnosis, and treatment of SBP, particularly when caused by rapidly progressive pathogens. It also highlights the value of forensic autopsy in identifying unexpected infectious disease processes contributing to sudden death

I62 Cerebral Vasculitis Associated With SARS-CoV-2 Infection: The Role of the Autopsy in the Postmortem Diagnosis and Preventive Insight

Matteo Antonio Sacco, MD, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Maria Daniela Monterossi, MD*, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Saverio Gualtieri, MD*, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Eugenio Garofalo, MD, PhD, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Andrea Bruni, MD, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Pino Pasqua, MD, Cosenza Hospital, Cosenza, Calabria, Italy; Federica Riillo, MD, Hospital of Crotone, Crotone, Calabria, Italy; Alessandro Di Cello, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Isabella Aquila, MD, PhD*, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy*

Learning Objectives: After attending this presentation, attendees will understand the role of SARS-CoV-2 infection in the pathogenesis of systemic vascular injury and the critical importance of the autopsy in identifying undiagnosed vascular complications.

Impact Statement: This presentation will impact the forensic science community by demonstrating how autopsy, within a multidisciplinary framework, allows for the recognition of systemic vascular lesions associated with COVID-19, enables accurate reconstruction of the death mechanism in apparently healthy individuals, and provides clinically actionable data for therapeutic decision-making in related cases.

Introduction: SARS-CoV-2 infection has been associated with a range of vascular complications, including microangiopathies and systemic vasculitis. Several reports in the literature describe cases of acute endothelial damage and sudden death in young individuals, often clinically unrecognized.[1-3] This presentation examines the case of a young unvaccinated woman who died within days of SARS-CoV-2 infection. Postmortem examination revealed a systemic pattern of acute vascular compromise.

Materials and Methods: The investigation involved a multidisciplinary team, including forensic pathologists, general pathologists, infectious disease specialists, intensivists, and anesthesiologists. A complete autopsy was performed with organ sampling for histopathological, virological, and genetic analyses. A literature review was conducted through PubMed, Scopus, and Web of Science using the keywords "COVID-19," "vasculitis," "autopsy," "endothelial damage," and "sudden death," selecting peer-reviewed articles published in English between 2020 and 2025.

Case Report: A 35-year-old woman presented to the emergency department accompanying her daughter and tested positive for SARS-CoV-2. Initially asymptomatic, she rapidly developed acute clinical deterioration with neurological and respiratory failure, and died after three days. No underlying chronic conditions were known. Her daughter also developed a severe clinical picture, requiring intensive care, but subsequently recovered fully.

Results: The autopsy revealed acute cerebral vascular stasis, massive cerebral edema, and terminal pulmonary thromboembolism. The heart showed left ventricular hypertrophy and fatty degeneration of the papillary muscles. The absence of extensive pneumonia supported a vascular pathogenesis rather than direct pulmonary involvement. Further investigations identified a systemic pattern of acute vascular damage consistent with inflammatory vasculopathy, with a predominant impact on the brain.

Discussion: This case describes a lethal vascular manifestation of COVID-19 in a young, previously healthy, and initially asymptomatic individual. Identification of cerebral vasculitis as the cause of death enabled the initiation of high-dose corticosteroid treatment in the daughter, which contributed to her survival and recovery. The unexplained death was elucidated through an autopsy-based, multidisciplinary approach involving forensic medicine, pathology, infectious diseases, and critical care. The findings suggest a SARS-CoV-2-triggered autoimmune systemic vasculitis. This integrated approach provides an operative model for managing COVID-19-related deaths and reaffirms the dual diagnostic and preventive value of autopsy.

I63 Diagnostic Challenges in Post-Transplant Acute Liver Failure: A Case of Suspected Large-For-Size Syndrome

Jayalakshmi N. Alagar, MPhil, Lewis Katz School of Medicine, Philadelphia, PA; Julius Nani, MD, Temple University Health System, Philadelphia, PA; Duy Doan, MD, Temple University Health System, Philadelphia, PA; Jared Hassler, MD, Temple University Health System, Philadelphia, PA*

Learning Objectives: Attendees will learn how Acute Liver Failure (ALF) can be challenging to diagnose in the post-transplant setting, especially when multiple potential causes—such as acetaminophen overdose or reduced liver perfusion from structural issues—are involved. Through a real case example, they will see how pathology, including biopsy and autopsy, can clarify patterns of liver injury and support clinical decision-making. This presentation will also emphasize the importance of recognizing rare complications like Large-For-Size Syndrome (LFSS) to improve patient outcomes and transplant planning.

Impact Statement: This presentation will enhance forensic and clinical pathologists' abilities to interpret ambiguous or overlapping patterns of liver injury in ALF, especially after transplantation. By highlighting the importance of autopsy and thorough histologic evaluation in rare syndromes like LFSS, the case promotes more accurate postmortem diagnostics, supports improved graft-recipient matching practices, and strengthens communication between pathology and transplant teams to guide patient care and stakeholder understanding.

Abstract Text: ALF is a rare, rapidly progressive, and life-threatening condition characterized by the sudden loss of hepatocyte function in individuals without pre-existing liver disease. Approximately 2,000 new cases are diagnosed annually in the United States, with preference for women aged 20-40.[1] Given the diverse etiologies of ALF, accurate and timely diagnosis is critical for guiding appropriate treatment strategies and intensity. Acetaminophen toxicity remains one of the most favorable causes, with about 65% of affected individuals recovering spontaneously without the need for transplantation.[2] In contrast, we hypothesize that ALF occurring in the post-transplant setting is even rarer and thus frequently under-recognized. The resulting gap may impede clinical decision-making and accelerate patient deterioration. We present a fatal case from our institution to illustrate the vital role of pathology in real-time ALF management moving forward.

A 40-year-old woman was transferred to our institution out of concern for ALF from presumed unintentional acetaminophen toxicity. To manage pain after a mechanical fall resulting in a left humerus fracture, she was reportedly taking three Percocet tablets (5 mg oxycodone/325 mg acetaminophen) plus three additional 500 mg acetaminophen tablets daily for five days. There was no significant alcohol use. On admission, her vital signs were unstable. Laboratory evaluation revealed profound hypoglycemia (glucose < 10 mg/dL), leukocytosis (32.7 $\times 10^9$/L), anemia (hemoglobin 8.1 g/dL), severe lactic acidosis (lactate 17.5 mmol/L, venous pH 6.99), hyperbilirubinemia (2.8 mg/dL), markedly elevated transaminases (AST 7400 U/L, ALT 6000 U/L), and coagulopathy (INR 20.0). Both acetaminophen and ethanol levels were mildly elevated at 31 mcg/mL. A transjugular liver biopsy demonstrated extensive centrilobular necrosis (zone 3). With her worsening picture, she was emergently listed for liver transplantation.

Post-transplant, the patient developed early allograft dysfunction attributed to a size mismatch between the relatively large donor liver and her small abdominal cavity. Surgical interventions—including right hepatectomy, splenic artery ligation, and biliary reconstruction—temporarily improved liver function. However, she subsequently developed distributive shock, metabolic acidosis, and multiorgan failure.

Autopsy revealed greater than 50% centrilobular necrosis without histologic evidence of acute rejection or graft-versus-host disease. The injury pattern was consistent with ischemic hepatopathy secondary to LFSS. Although acetaminophen toxicity and other systemic insults could not be completely excluded, pathology indicated that graft-recipient size mismatch was a central contributor to her decline.

This case highlights the diagnostic complexity of ALF, especially in emergent transplant recipients where multiple insults may coexist and converge to a common pathological endpoint. While ALF remains a clinical diagnosis per the American Association for the Study of Liver Diseases guidelines, our case underscores the importance of comprehensive histopathological evaluation as an essential adjunct to clarify the extent and etiology of liver injury.[3] Postmortem analysis may be particularly valuable for confirming rare complications such as LFSS, which currently lack standardized diagnostic and management protocols. Greater awareness of size-mismatch syndromes and improved preoperative graft-recipient matching may help prevent similar adverse outcomes and clarify when forensic assessments are warranted in complex transplant cases.

I64 Endocrine Enigmas

Morgan R. Mastrud, BS and BA, University of North Dakota School of Medicine and Health Sciences, Grand Forks, ND; Alexus Meduna, BS, University of North Dakota School of Medicine and Health Sciences, Grand Forks, ND; Susan Roe, MD, University of North Dakota School of Medicine and Health Sciences, Grand Forks, ND; Selly Strauch, MD, University of North Dakota School of Medicine and Health Sciences, Grand Forks, ND; Wai Szeto, MD, University of North Dakota School of Medicine and Health Sciences, Grand Forks, ND*

Learning Objectives: The goals of this presentation are to: (1) discuss the role of treatment non-compliance and delayed diagnosis in the rapid and possibly fatal outcomes of endocrine conditions, with emphasis on vulnerable populations such as individuals with intellectual disabilities and children; (2) evaluate the influence that caregiver education and support from medical systems has on the prevention of endocrine-related deaths while considering strategies for promoting early recognition and symptoms management prior to forensic investigation; and (3) identify key case report findings associated with fatal outcomes of poorly managed or unidentified endocrine disorders, including hypothyroidism and thyroid storm, in both pediatric and adult populations.

Impact Statement: This presentation highlights case reports that display the vital role of forensic investigation in identifying fatal complications of endocrine disorders, particularly in individuals reliant on caregiver support. By assessing pathological findings and systemic gaps in diagnosis and treatment, this presentation encourages forensic professionals to recognize subtle indicators of endocrine dysfunction within their work. Additionally, it reinforces the importance of integrating a patient's medical history, social context, and caregiver dynamics into cause of death reported at autopsy. The goal of this work is to inform and promote more accurate death certifications, improve interprofessional communication, and potentially influence public health interventions aimed at preventing similar fatalities.

Abstract Text: The endocrine system is necessary for the regulation of vital body functions. Without prompt recognition of endocrine disruption, there can be rapid deterioration. We present two distinct cases of endocrine disorders. One case is that of an adult with Down syndrome and the other is that of a child. Both populations may rely heavily on caregiver support.

The first case is a 49-year-old male with history of chronic kidney disease, Down syndrome, and hypothyroidism. He had not filled his levothyroxine prescription in 3.5 years. Laboratory studies demonstrated an elevated TSH, with severe decreases in both Free T3 and Free T4, indicating significant hypothyroidism. In the days prior to death, he reported respiratory symptoms without seeking care. Autopsy revealed a large pericardial effusion. Cardiac tamponade was determined to be the cause of death.

The second case is a 5-year-old female who presented with abdominal pain, tachycardia, tachypnea, and altered mental status. In the prior months, her mother noticed increased thirst, urination, and weight loss. Laboratory studies revealed elevated HbgA1C (11.6%), Free T3, and Free T4, as well as decreased TSH; consistent with hyperthyroidism and diabetes mellitus. During treatment, the patient became bradycardic and died following resuscitation efforts.

These cases demonstrate life-threatening sequelae of thyroid dysfunction on both ends of the age spectrum. Early diagnosis, treatment compliance, and proper education is vital for all patients, but exceedingly so for vulnerable patients who rely on their support systems for care. Therefore, it is essential to incorporate support systems into patient education to ensure treatment adherence and improved outcomes.

I65 A Fatal Airway Obstruction Due to Laryngeal Papillomatosis: A Clinically Occult Complication

Mariana Voudouri, MD, District Nine Medical Examiner's Office, Orlando, FL; Amber R. Wang, MD, Maricopa County Medical Examiner's Office, Phoenix, AZ; Katherine Kenerson, MD, Miami Dade Medical Examiner Department, Miami, FL*

Learning Objectives: This presentation will enable attendees to understand the pathophysiology, clinical progression, and potential fatal complications of laryngeal papillomatosis. Attendees will learn to recognize the postmortem findings associated with upper airway obstruction due to benign squamous neoplasms and appreciate the histopathological features that distinguish papillomatosis from invasive malignancy. The presentation will also highlight the importance of thorough autopsy examination in cases with limited clinical history and demonstrate how to correlate scene investigation, gross pathology, and histologic evaluation to accurately determine the cause and manner of death in cases of sudden and unexpected fatal airway compromise.

Impact Statement: This presentation contributes to the forensic science community by emphasizing the importance of considering benign laryngeal neoplasms as potential causes of sudden death due to airway obstruction. It reinforces the need for careful laryngeal examination during autopsy, particularly in cases with unexplained respiratory symptoms or minimal antemortem documentation. By drawing attention to a rare but preventable mechanism of death, this case supports enhanced awareness among forensic pathologists, clinicians, and public health professionals regarding the lethal potential of untreated or under-monitored laryngeal papillomatosis.

Abstract Text: Laryngeal papillomatosis is a benign epithelial neoplasm typically characterized by slow growth and low malignant potential. However, in rare instances, it may exert a critical mass effect when located in anatomically confined spaces such as the airway. The condition is associated with Human Papillomavirus (HPV) infection, often presenting with dysphonia or airway compromise depending on lesion size and location. Histologically, these lesions are defined by squamous epithelium overlying fibrovascular cores, without invasion into the underlying stroma. While not considered inherently life-threatening, airway obstruction may occur if growth is unchecked, particularly when lesions develop along the glottic or subglottic regions. The case of a 59 year old man presented herein exemplifies this complication.

The decedent had a known history of squamous papillomas with viral cytopathic changes diagnosed on the left and anterior vocal cords in 2006 and 2007, respectively, and a remote history of illicit substance use. He had been residing alone at a vacant property and recently complained of having trouble breathing. He was found deceased in a supine position on the floor in a state of early decomposition. Paraphernalia consistent with marijuana use was found at the scene. Initially, there were minor concerns of trauma or foul play; however, these were excluded based on autopsy findings and the investigation. At autopsy, a 2.4 cm friable, papillary lesion was identified on the anterior wall of the larynx, extending from the supraglottic to the subglottic area, centered on the right true and false vocal cords, and was found to be completely occluding the airway. Microscopic examination confirmed a squamous papillary neoplasm, consistent with squamous papillomatosis, without histologic evidence of stromal invasion. Toxicology was positive only for cannabinoids.

This case illustrates the rare but fatal consequence of benign squamous papillomas leading to airway obstruction and eventual asphyxia. It underscores the importance of maintaining clinical vigilance in patients with known laryngeal papillomatosis, as even benign lesions may evolve into life-threatening airway obstructions. Furthermore, it highlights the critical role of postmortem examination in identifying the precise mechanism of death in cases with limited antemortem documentation.

I66 Sweet But Deadly: Pyogenic Hepatic Abscesses in Diabetes

Claire Westby, BA, University of North Dakota School of Medicine & Health Sciences, Bismarck, ND; McKenzie Burian, BS, University of North Dakota School of Medicine & Health Sciences, Bismarck, ND; Susan Roe, MD, University of North Dakota School of Medicine & Health Sciences, Bismarck, ND; Selly Strauch, MD, University of North Dakota School of Medicine & Health Sciences, Bismarck, ND; Wai Szeto, MD, University of North Dakota School of Medicine & Health Sciences, Bismarck, ND*

Learning Objectives: Through the analysis of two detailed autopsy cases, participants will gain insight into recognizing clinical signs and symptoms associated with pyogenic hepatic abscesses in individuals with diabetes and prediabetes. Learners will also explore the polymicrobial nature of these infections, highlighting common pathogens such as *Escherichia coli*, *Klebsiella*, *Staphylococcus*, *Streptococcus*, and anaerobes. Finally, participants will understand the critical importance of early recognition and prompt intervention of hepatic abscesses to prevent life-threatening outcomes.

Impact Statement: This presentation will have a significant impact on the forensic science community by highlighting the often-overlooked association between diabetes and fatal infections such as pyogenic hepatic abscesses. Through the analysis of two autopsy cases, this presentation will enhance the medical community's ability to recognize patients' histories and postmortem findings associated with this rare but serious complication. This will ultimately contribute to more accurate diagnoses, improved health data, and greater awareness of diabetes-related mortality risks.

Abstract Text: Recent estimates suggest that 11.6% of the United States population has diabetes mellitus, with an additional 38% having prediabetes.[1] Diabetes can cause serious consequences, including immunosuppression, making individuals susceptible to infections. As described in these two cases, one rare but serious infection that diabetic patients are at increased risk for is hepatic abscesses. The infection is often polymicrobial, including pathogens such as *Escherichia coli*, *Klebsiella*, *Staphylococcus*, *Streptococcus*, and anaerobes. Symptoms may include fever, right upper quadrant abdominal pain, nausea, dark urine, and weight loss.[2] The first patient was a 65-year-old female with a history of obesity, hypertension, and prediabetes who presented with vomiting, diarrhea, and gastrointestinal bleeding. A computed tomography scan revealed a liver mass with a benign appearance on subsequent magnetic resonance imaging. Days later, the patient collapsed and became unresponsive. At autopsy, a ruptured pyogenic hepatic abscess was found with peritonitis and sepsis. The second patient was a 65-year-old male with a history of diabetes. At autopsy, he was found to have a pyogenic hepatic abscess and acute splenitis. Postmortem vitreous studies indicated hyponatremia, azotemia, and hyperglycemia. These cases emphasize the need for increased awareness and prompt treatment of hepatic abscesses in diabetic patients to reduce life-threatening risks.

I67 Medicolegal Patterns in Homicide-Suicide Cases Related to Crimes of Passion, Altruistic Motives, or Psychiatric Disorders: A Retrospective Autopsy-Based Study

Eugenia Marta Leonzio, MD, Department of Public Health, Experimental & Forensic Medicine. division of Legal Medicine & Forensic Sciences "A. Fornari". University of Pavia, Pavia, Lombardia, Italy; Gianmarco Argentiero, MD, Department of Legal Medicine and Forensic Sciences, University of Pavia, Italy, Pavia, Lombardia, Italy; Gennaro Baldino, MD, PhD, Messina University, Messina, Sicilia, Italy; Biagio Solarino, MD, PhD, Università degli Studi di Bari Aldo Moro, Bari, Puglia, Italy; Laura Secco, MD, University of Padova, Department of Cardiac, Thoracic, Vascular Sciences and Public Health, Padova, Veneto, Italy; Filippo Pirani, PhD, University of Bologna, Bologna, Emilia-Romagna, Italy*

Learning Objectives: The attendees will gain insight into how forensic findings, such as the injury patterns and interpersonal dynamics, can assist the medicolegal interpretation of complex Homicide-Suicide (H-S) cases by analyzing common characteristics and features and dividing the cases by motives in three macro-categories (crimes of passion, mercy killings, and psychiatric disorder driven).

Impact Statement: This study presents a structured forensic framework for the assessment H-S events based on motivational patterns. The findings aim to offer guidance to the forensic science community in real-world case scenarios.

Abstract Text: Homicide-suicide (H-S) is a rare but complex forensic event in which the perpetrator kills one or more victims before attempting, often successfully, suicide. In the majority of cases, the dynamic cannot be easily reconstructed and the reason behind the act remain unknow or not readily understandable.[1] Several studies have attempted to investigate H-S cases based on criminological profiles.[2] However, the existing literature is limited by small sample sizes and the lack of a standardized forensic classification system.[3]

To address these limitations, we conducted a retrospective multicenter study analyzing autopsy data from 70 H-S cases collected at various Italian forensic institutes between 2010 and 2025. Complete autopsy files—including medico-legal reports, toxicological, histopathological, and radiological findings, as well as investigative records—were reviewed. Cases were classified by motive into one of three categories: crimes of passion (CP), mercy killings (MK), and psychiatric disorder-driven (PD).[4-6] Variables analyzed included victim and perpetrator demographics, relationship type, type of homicide (single vs. multiple), weapon used, wound characteristics, cause of death, and method of suicide. We also assessed spatial and temporal aspects (e.g., whether suicide occurred at the scene or elsewhere, and immediately or with delay).

A total of 70 H-S cases were analyzed: 24 classified as CP (21 single and 3 multiple homicides); 20 as MK (19 single and 1 multiple homicides), 26 as PD (22 single and 4 multiple homicides). In all categories, most victims were female and perpetrators predominantly male. Survivors among perpetrators were rare. In CP cases, intimate partner relationships were most common, while MK and PD cases more often involved intrafamilial victims (partners and first- degree relatives equally). In CP cases, suicide often occurred at a different location and after a time delay, though immediate suicide was still the most frequent. Causes of death revealed distinct patterns. In CP cases, victims most often died due to the laceration of major blood vessels (resulting in massive blood loss - MBL) caused by firearms or sharp-weapons, while perpetrators died equally from MBL, severe brain injury (SBI), or asphyxial death (AD): In MK cases, MBL and AD (mainly suffocation) were the most frequent causes of death, while perpetrators died from MBL, SBI, AD, or acute intoxication (AI), involving several methods. Lastly, in the PD cases, homicide included MBL and SBI, and suicide most often resulting from firearm-related SBI. This resulted in the following observations: in almost half of the cases studied, the perpetrator used a different method for suicide than for homicide. Overkilling was significantly more frequent in CP cases.[7]

The findings of our study highlight the multifactorial nature of H-S events temporal and spatial analysis revealed behavioral differences between categories. Notably, CP and PD perpetrators appeared more intent on inflicting suffering, while MK offenders acted with perceived compassion to end the victim's pain. Divergences between homicide and suicide methods may reflect psychological dissociation or evolving emotional states.[8] Additionally, overkilling (excessive or repetitive violence) observed in CP cases suggests heightened emotional intensity or personal conflict in these dynamics.

I68 Law Enforcement Ballistic Fatalities: What Can We Gain From Autopsy Reviews?

Andrew Davis, MPH, Wayne State University, Detroit, MI; Cynthia Bir, PhD, Wayne State University, Detroit, MI*

Learning Objectives: In this presentation, attendees will learn about the circumstances surrounding fatalities of Law Enforcement Officers (LEO) due to ballistic threats. Attendees will learn how to utilize the Officer Down Memorial Page (ODMP) to conduct research-related LEO fatalities.

Impact Statement: This presentation will impact the forensic community by providing information related to an existing dataset (ODMP) and related limitations. Increased understanding of the importance of autopsy reporting and data collection will lead to a better understanding of fatal ballistic injuries in the LEO community.

Abstract Text: The Officer Down Memorial Page (ODMP) is a nonprofit organization dedicated to honoring law enforcement officers (LEOs) who have died in the line of duty. The website maintains a comprehensive record of officer fatalities, including basic demographic details and a summary of the incident that resulted in each officer's death. The ODMP's searchable database allows users to filter entries by officer name, agency, state, year, and cause of death (e.g., gunfire, automobile crash, duty-related illness). Although the narrative summaries are not standardized, they frequently include valuable contextual information that may highlight risk factors beyond demographics. The objective of the current project is to use this resource to establish a structured database that can be further analyzed to better understand the circumstances surrounding ballistic-related fatalities among law enforcement personnel. The procurement of autopsy reports, when possible, aided in this analysis.

A query of the ODMP between the years of 2005 and 2024 resulted in 1,058 total ballistic-related fatalities. A total of 159 autopsy reports were then obtained from across the United States. These reports were reviewed for the number and location of ballistic impact(s). An analysis of head, torso, extremity, and combined impacts was conducted. The presence of protective gear and the threat level of the ammunition used were also noted when possible. Of the 159 cases reviewed, 65 (40.9%) sustained gunshot impacts to the head/neck, 31 (19.5%) to the torso, and 2 (1.3%) to the extremities alone. Additionally, 18 cases (11.3%) involved both the head/neck and torso, 7 (4.4%) involved the head/neck and extremities, 18 (11.3%) involved the torso and extremities, and 18 (11.3%) sustained impacts to all three regions: head/neck, torso, and extremities. 65.5 percent of the single-shot impacts occurred to the head. The average number of impacts was 2.4, with the maximum being 21. Specific cases will be discussed to enhance the overall presentation.

I69 Autoerotic Deaths: A Review and Examination of Investigative and Autopsy Findings

Nichole Miller, BS, Harris County Institute of Forensic, Humble, TX; Hannah C. Jarvis, MRCS, Harris County Institute of Forensic Sciences, Rosharon, TX*

Learning Objectives: The goal of this presentation is to highlight the principles of death investigation and postmortem examination in deaths associated with autoerotic behavior in order to determine an accurate cause and manner of death and considerations for preventative interventions.

Impact Statement: This presentation will impact the forensic science community by providing increased awareness regarding investigative strategies and consideration for postmortem examination in cases of autoerotic behavior and the importance of a thorough scene investigation as a fundamental strategy to assist in determining an accurate cause and manner of death.

Abstract Text: Autoerotic deaths are accidental deaths occurring during individual sexual activity in which a device, apparatus, or prop used to enhance the sexual stimulation of the deceased caused unintended death.[1] There are an estimated 1,000 autoerotic deaths every year in the United States, and during the COVID-19 pandemic, there was a reported increase in autoerotic behavior by 40%.[2,3] The investigation into these deaths illicit additional responsibilities and inquires to determine the cause and manner of death, and a more in-depth investigation is usually required.

Autoerotic deaths are most frequently asphyxial involving ligatures. The scene findings can appear concerning for homicide or suicide. It is important to document evidence indicative of autoerotic behavior such as adult novelties items, bondage, pornographic material; indicators of prior autoerotic behaviors such as ligature markings; and the absence of suicide notes, signs of struggle or forced entry. Safety mechanisms of asphyxial devices should be noted. These scene findings, in conjunction with social and medical histories obtained from prior medical records, friends and family, toxicological and autopsy findings, allow the accurate determination of cause and manner of death.

The electronic database of the Harris County Institute of Forensic Sciences was searched for all fatalities associated with autoerotic behavior. This study presents 23 cases.

The manner of death in all cases was accident (n=23). The cause of death was asphyxial (n=19) – hanging by ligature alone (n=14) - or in combination with a plastic bag over the head (n=1) or airway obstruction with a ball (n=1), bondage with covering of the face with a mask (n=1), plastic bag over the head and inflation by propane (n=1), and inside an inflatable mattress with a gas mask (n=1); substance abuse during autoerotic activity (n=3); and electrocution (n=1).

Most of the decedents were male (n=21) and were found dead in a bedroom or closet (n=12). The ages ranged between 13 and 65 years. Most deaths occurred in the winter (n=10). Six cases had indicators of prior autoerotic behavior on scene, such as scratches on an exercise bar, or was reported by family and/or friends. Pornographic material and/or adult novelty items were located on scene in 12 cases. Autopsy findings included a ligature furrow (n=16), petechial hemorrhages (n=12), decompositional changes (n=8), and cardiovascular disease (n=7). Five were nude, and three males were wearing female clothing. Postmortem toxicological analysis (n=20) was negative (n=8), or revealed ethanol (n=3), cocaine (n=2), methamphetamine (n=2), amphetamine (n=1), propane (n=1) and prescription drugs (n=3).

Although most deaths were associated with a ligature, several atypical methods were used. Scene investigation may reveal the presence of multiple modalities of autoerotic behavior, although not all methods will relate to the cause of death. A death scene might also have been altered by a family, to minimize perceived social shame, and can lead to inaccurate conclusions. Reviewing these cases enhances our understanding of the complex analysis involved in determination of autoerotic associated deaths, highlighting the need for an extensive scene investigation, as well as providing awareness to initiate preventative interventions.

I70 Racehorse Fatality Investigation: The Roles of the Pathologist and Regulatory Veterinarian

Alina Vale, DVM, Equine Welfare & Forensics, San Diego, CA*

Learning Objectives: After attending this presentation, attendees will understand the importance of racehorse fatality investigation in maintaining the sport's social license to operate. Attendees will become familiar with the investigation steps performed by the regulatory veterinarian and the racehorse postmortem examination protocol performed by the pathologist. Attendees will develop a basic understanding of fatal musculoskeletal injuries in racehorses and learn the most common finding in affected horses. Attendees will uncover the findings from recent high-profile racehorse fatality investigations.

Impact Statement: This presentation will impact the forensic science community by educating and empowering veterinarians and veterinary pathologists to participate in racehorse fatality investigations. Additionally, others in the forensic science community will be empowered to discuss racehorse fatalities with concerned family, friends, and other stakeholders.

Abstract Text: Equine fatalities at the racetrack have garnered widespread public concern and sparked change in the racing industry across the United States. Racehorse fatality investigations are performed to uncover potential violations of laws or regulations, and serve as an educational tool for trainers, event organizers and regulators by providing relevant information for developing new policies and strategies to prevent injuries in the future.

Recent high-profile racehorse fatality investigations include the cluster of fatalities at Santa Anita Park in 2019 which sparked the California Horse Racing Board investigation[1]and the Los Angeles District Attorney's Office criminal investigation, the sudden death of Medina Spirit, and the Horseracing Integrity & Safety Authority's 2023 investigations into fatalities at Churchill Downs and Saratoga Springs.[1-5]

The veterinary pathologist and racetrack regulatory veterinarian play key roles in a racehorse fatality investigation. A formal process for racehorse postmortem examination was initiated in California in 1990 to improve the safety and welfare of racehorses.[6] While this has been an effective program and replicated in other racing jurisdictions globally, the recent addition of a fellowship program in the musculoskeletal pathology of racehorses has modernized the process. The main goals of this fellowship are to train pathologists in the detailed examination of the musculoskeletal system of racehorses, and to improve consistency of case description, case documentation and turnaround time of reports. Specimens from selected cases can be shipped from the pathology laboratory to the J.D. Wheat Veterinary Orthopedic Research Laboratory at the University of California, Davis for in-depth analysis. This helps to more precisely determine the causes and risk factors that led up to catastrophic injuries in racehorses resulting in their death or euthanasia.

In addition to reviewing the findings from the necropsy, the regulatory veterinarian reviews an incident report, video footage of the race, workout, or barn surveillance, and training, racing and medical records.[7] The regulatory veterinarian interviews the attending veterinarian and horse trainer, and collaborates with others in the racing industry such as investigators, safety stewards and stewards then writes a report.

Most fatal musculoskeletal injuries in racehorses are repetitive, overuse injuries and are associated with pre-existing lesions (stress fractures or stress remodeling in the bone that ultimately fractured). While a skilled pathologist may find these lesions on the postmortem examination, they may not have been clinically apparent or obvious. It is important that individuals associated with the investigation remain unbiased as the presence of lesions on the postmortem examination does not indicate the trainer or others associated with the horse were aware of such an issue. However, a review of the necropsy findings and possible risk factors in the horse's history with the trainer is a useful educational program to reduce racehorse fatalities.

I71 Neglect in the Pediatric and Elderly Population: A Nine-Year Retrospective Review From the Cook County Medical Examiner's Office

Antonietta Porzio, MD, , Università Degli Studi Della Campania "Luigi Vanvitelli, Italy, Naples, Campania, Italy; Maria Rosaria Forte, APM, Università Degli Studi Della Campania "Luigi Vanvitelli, Italy, Naples, Campania, Italy; Lorenzo Gitto, Cook County Medical Examiner's Office, Chicago, IL; Carlo Pietro Campobasso, MD, PhD, University of Campania "Luigi Vanvitelli", Naples, Naples, Campania, Italy*

Learning Objectives: After attending this presentation, attendees will gain an enhanced understanding of the serious consequences of child and elderly neglect as documented in a major metropolitan area.

Impact Statement: This presentation will impact the forensic science community by addressing neglect-related pediatric and geriatric deaths, highlighting the most common causes of death, circumstances of neglect, characteristic autopsy findings, and the profile of the responsible caregiver.

Abstract Text: Child and elderly abuse can take many forms, ranging from physical to psychological, and often includes neglect. Active neglect is generally referred to as the failure or refusal of a caregiver or another person responsible for providing care and protection to vulnerable individuals. Examples include both intentional and unintentional acts, such as not providing adequate nutrition, hygiene, or access to necessary health care, as well as failing to prevent exposure to unsafe activities or environments. Neglect can result in serious injury or death, particularly in fragile individuals due to age, physical or mental disability, or dependence on the perpetrator, such as the elderly and infants/toddlers.

A retrospective review of cases from the digital database '*LabLynx*' of the Cook County Medical Examiner's Office in Chicago, IL, was conducted for the period from June 2016 to September 2025 to identify deaths due to neglect in pediatric and elderly populations. Subjects were classified into two main age groups: pediatric (under 18 years) and elderly (over 65 years). The pediatric group was further subdivided according to age classifications proposed by the Centers for Disease Control and Prevention (CDC) into infants, toddlers, and children. Only cases with a complete autopsy performed were included in the study; cases of self-neglect were excluded. Cases were reviewed for age, sex, race, cause and manner of death, circumstances of death, location of the event, and autopsy and toxicology findings. Information regarding comorbidities, previous episodes of abuse, and the responsible caregiver was obtained from investigative and police reports.

Fourteen cases (8 minors and 6 elderly) were identified. In all cases, the manner of death was certified as homicide. The pediatric victims (6 males and 2 females) were classified into three main CDC age groups: 5 infants (0 and 9 months old), 1 toddler (19 months old), and 2 children (4 and 10 years old). Most subjects were White (5 cases), followed by African American (3 case). The primary causes of death were malnutrition, starvation, and/or dehydration (4 cases). Two cases involved the drowning of infants, both classified as homicide due to the mother's failure to supervise the victims while in the bathtub. Only a white child had a reported previous episode of abuse.

In the elderly group (1 male and 5 females), all victims were White, with ages ranging from 78 to 94 years. The primary cause of death was sepsis (5 cases), followed by complications from scalds caused by hot bath water (1 case). In most cases, deep pressure sores exposing bone were observed. All subjects had comorbid natural diseases. Hypertension and atherosclerosis were the most frequent comorbidities, followed by dementia. No signs of prior physical abuse were found except in a female with abrasions on the face, ecchymosis and contusions at the upper arms.

This study will examine distinct features of deaths by neglect in the pediatric and elderly populations, addressing an important public health issue through the experience of a large medical examiner's office. A thorough discussion of the results will be presented to the attendees.[1,2]

I72 Work-Related Suicide: 25 Years of Forensic Cases in a European Province

Bianca Beltrame, MD, University of Brescia, Venice, Veneto, Italy; Lorenzo Franceschetti, MD, PhD, University of Milan, Milan, Lombardia, Italy; Sofia Bodini, MD, Spedali Civili di Brescia, Brescia, Lombardia, Italy; Andrea Verzeletti, MD, PhD, University of Brescia, Brescia, Lombardia, Italy*

Learning Objectives: This presentation concerns a series of autopsy cases of work-related suicides over 25 years from a single forensic institute, highlighting their specific features and comparing to suicides in general and to other deaths in the workplace.

Impact Statement: By analyzing real case studies, practical tools will be acquired to distinguish between work-related suicide and alternative manners of death in occupational settings (work-related death) and to understand the influence of working factors on suicide. A structured approach from practical cases will improve accuracy and consistency of forensic investigations in these complex cases in determining cause and manner of death.

Abstract Text: "Work-related suicide" represents a rare but complex occurrence in forensic practice, often subject to interpretative controversy and underestimated in epidemiological data.[1] This category includes suicides occurring in the workplace, those involving the use of work tools, or those motivated by work-related factors.[2] Certain professions or specific occupational activities carry an increased risk of work-related suicide, sometimes providing access to means that can facilitate death, such as service firearms.[3,4] The specific features of such cases, compared to general suicides and fatal occupational accidents, are numerous and warrant careful investigation.

This study aims to retrospectively analyze all autopsies of work-related suicide conducted between January 1, 2000, and December 31, 2024, in Brescia province, one of the most industrialized area not only in Italy but in all Europe, in order to identify recurring patterns, interpretative challenges and medico-legal implications. All cases underwent complete autopsy and histological examination, with toxicological and radiological investigations performed when indicated.

Most of the individuals were male (17 cases, 89,5%), aged between 21 and 66 (mean= 41 years). The work place was chosen to commit suicide in 16 cases out of 19. A service firearm was used in six cases. The motive for suicide was attributed to work- related stress in one case and to a recent job loss in another. Half of the cases involved hangings at the workplace, followed by suicide by firearm (six cases), voluntary falls from height (two cases), and, finally wrist-cutting injuries. Only one victim had a diagnosed depressive disorder, while in all other cases, no psychiatric disorders were known. Toxicological exams were performed only in seven cases and they were positive in three.

These findings underscore the importance of considering work-related suicide as a sub-category of work related death. A multidisciplinary approach can enhance diagnostic accuracy and support appropriate forensic interpretation. Such evidence highlights the need for increased awareness and more systematic investigation of potential work-related suicide in forensic casework, with significant implications for both scientific rigor and occupational health policies.

I73 Patterns of Heat-Related Mortality in Southern Nevada: Forensic and Public Health Implications

Liam J. Johnson, MA, Department of Anthropology University of Nevada, Las Vegas, Las Vegas, NV; Katherine Gaddis, MA, University of Nevada, Las Vegas, Arcata, CA; Lisa Gavin, MD, Clark County Office of the Coroner/Medical Examiner, Las Vegas, NV; Stephanie Yagi, DO, Clark County Coroner's Office, Las Vegas, NV*

Learning Objectives: After attending this presentation, attendees will have a better understanding of the physiological process of thermoregulation during extreme heat events and the role of existing comorbidities in mortality trends. Local trends in heat-related deaths from the Clark County Office of the Coroner/Medical Examiner, NV, will be discussed.

Impact Statement: This presentation will impact the forensic science community by contributing new data on heat-related mortality trends and how the thermoregulatory process is affected by comorbidities, namely the use of Central Nervous System (CNS) stimulants.

Abstract Text: Exceeding any other climate-related hazard (e.g., tornadoes, floods, and hurricanes), extreme heat events cause more serious health incidents in the United States, with a yearly average of 67,512 emergency room visits, 9,235 hospitalizations, and 702 deaths.[1] The National Association of Medical Examiners Ad Hoc Committee on the Definition of Heat-Related Fatalities recommends that a "heat related death" be defined as one that is either significantly contributed to or caused by exposure to high ambient temperatures.[2] However, the diagnosis of heat-related deaths in individuals found deceased is challenging, particularly when body temperature cannot be measured (such as when individuals are found in more advanced stages of decomposition), which may result in underestimation of heat-related mortality in relation to other potentially contributing factors.[3]

This study sought to contribute to this understanding by exploring patterns of heat-related mortality in Southern Nevada, which has one of the hottest and fastest-warming climates in the United States. Death records at the Clark County Office of the Coroner/Medical Examiner (CCOCME) from 2004-2022 were reviewed using keywords commonly associated with environmental heat stress. After excluding false positives (e.g., fire related deaths), the remaining 1,527 decedent case files were included. In 2021 alone, there were 256 heat-related deaths in Clark County, Nevada. As one might expect, the summer months of June, July, and August accounted for the majority of heat related deaths; representing over 87% (n=1336) of the total sample with the total monthly trend peaking in July (n=693). Cases were also analyzed according to demographic variables from death certificates (e.g., age, sex, and race) and location where the deaths occurred (i.e. zip codes). Preliminary results suggest that heat related deaths are more likely to occur on the first "hot day" (defined as having a daily heat index of one standard deviation higher than the monthly heat index mean), rather than during prolonged extreme heat events. This finding highlights the importance of allowing the body to acclimatize gradually to hot environmental conditions.

Approximately 33.99% of the total sample were identified as having both high ambient temperatures and recent drug use listed as contributing factors. The use of Central Nervous System (CNS) stimulants (e.g., methamphetamine, cocaine, MDMA) have been found to have an effect on the preoptic area of the hypothalamus and can cause hyperthermia and hypertension. This has direct public health implications as hyperthermia related to CNS stimulant use often puts focus on drug use alone. Identifying the role of environmental heat exposure in the deaths of individuals (with or without CNS stimulant use), allows for direct intervention particularly in areas where those deaths occur. The role of behavioral thermoregulation and how some existing conditions are exacerbated by physiological heat stress is an area of research that needs to be further understood in order to accurately identify, classify, and ultimately prevent heat-related fatalities, particularly as extreme heat events become increasingly frequent.

I74 Homeless Deaths Investigated by a State-Wide Medical Examiner System

Maura E. DeJoseph, DO, CT OCME, Farmington, CT; Katherine L. Kenyon, MD, CT OCME, Farmington, CT; James R. Gill, MD, Connecticut Office of the Chief Medical Examiner, Farmington, CT*

Learning Objectives: Attendees will learn the causes and manners of death of undomiciled individuals who are investigated by a state-wide medical examiner office. This presentation will equip attendees with current definitions of undomiciled individuals.

Impact Statement: This presentation will enhance the community's understanding of causes and manners of death among undomiciled individuals and ability to recognize which deaths should be classified as undomiciled. It will inform on trends that could drive public policy discussions and highlight the need for interventions for undomiciled people.

Abstract Text: Homelessness affects over 700,000 persons in the United States, and impacts all parts of the country. Homelessness is complex with numerous causes and contributors. It carries excess mortality with a reduced life expectancy due to the intersection of medical and mental health disorders and substance use disorders. It is defined by the United States Federal Code (42U.S.C§11302) and includes individuals who lack a fixed, regular, and adequate nighttime residence or live in a shelter. Medical Examiners and Coroners (MEC) commonly investigate the deaths of homeless persons due to the high incidence of mental health and substance use disorders, and the possibility of an unnatural death.[1,2] During the investigation, it is important to record housing status because undomiciled deaths may need special attention and it allows for easy case identification for later review.

A retrospective study using statewide data from the Connecticut Office of the Chief Medical Examiner (CT-OCME) for all certified deaths in 2023 and 2024 identified 338 in which the death narrative contained the keywords "homeless" or "shelter." Forty-seven deaths were excluded as false positives. The remaining 291 deaths underwent further review and the application of the US Code 11302 homeless definition; 203 met criteria for being classified as homeless. Eighty-eight (88) deaths contained information suggesting "at risk for homelessness," but did not conform to the federal definition.

Of the 203 fatalities meeting inclusion criteria (70% of those originally described with "homeless" or "shelter"), the manners were: accident 70%, natural 16%, undetermined 7.4% suicide 3.3%, and homicide 3.3%. The most frequent causes of death included drug intoxication (58%), alcohol use disorder (7%), cardiovascular disease (7%), blunt injuries in pedestrians (6%), undetermined cause and manner (5%) and environmental hypothermia (4%). The ages ranged from 19 to 83 years (mean = 48) and 77% were men. The known ethnic breakdown was 71% White and 18% Black. The living arrangements included "homeless" shelters, tents, abandoned buildings, and vehicles.

This study demonstrates challenges in classifying undomiciled decedents.[3] Death investigations are limited by third-party information and lack of next of kin information. Not all undomiciled deaths fall under MEC jurisdiction (a natural death in the hospital likely would not be reported) so the cohort is likely skewed toward unnatural and out-of-hospital deaths. To improve identification and tracking, the CT-OCME added a triage question and checkbox for "homeless at the time of reporting." There were 88 deaths that did not meet the Federal definition, but had a narrative that conforms to the "at risk for homelessness" definition. The use of the Federal definition resulted in an underestimation of decedents who do not have a permanent residence. Individuals self-paying for hotel stays or "coach surfing" do not meet the Federal definition of "undomiciled."

Accurate data is critical for public health initiatives particularly for interventions and strategies for mortality and harm reduction in persons experiencing homelessness.[4] With enhanced education and attention, and noting the death investigation record regarding homelessness, the MEC can provide valuable information to help understand the mortality impact.

I75 Invisible Deaths: A Forensic Window Into Homeless Mortality in Milan (2014–2024)

Chiara Carsana, MD, University of Milan, Milan, Lombardia, Italy; Stefano Tambuzzi, MD*, University of Milan, Milan, Lombardia, Italy; Cristina Cattaneo, MD, PhD, University of Milan, Milan, Lombardia, Italy; Devis Valleriani, MD, University of Milan, Milan, Lombardia, Italy*

Learning Objectives: After attending this presentation, participants will explore the predominant causes and dynamics of mortality in Milan over a ten-year period and how a refined forensic classification can enhance death investigation accuracy. Attendees will learn how specific pathological findings interact with social vulnerability and how postmortem evaluation can improve medico-legal insight and public health surveillance.

Impact Statement: This presentation will impact the forensic science community by demonstrating how full autopsy and toxicological analyses can uncover invisible patterns of preventable deaths among homeless individuals. It also emphasizes how forensic pathology contributes to social epidemiology by clarifying mortality causes in marginalized groups often excluded from conventional health data.

Abstract Text: This is the first retrospective systematic forensic analysis of homeless mortality ever conducted in Italy. The study analyzed all homeless deaths in the city of Milan between 2014 and 2024. Each case was extrapolated based on all available information. A total of 104 homeless people (91 males, mean age of 49 years and 13 females, mean age of 47 years) were included in the study. Of these, 6 remained unidentified. Annual deaths ranged from 2 (2015) to 15 (2024), with peaks in 2019-2021 and 2023-2024. More than 70% of individuals died in public places, while fewer were found in hospitals, abandoned buildings or shelters, underlining the extreme marginalization and limited access to healthcare.[1] Death due to acute circulatory failure accounted for 59.6% of cases (n=62 and in only 17 cases there were relevant cardiac macroscopic pathological signs), reflecting a pattern consistent with advanced but untreated cardiovascular conditions often seen in homeless populations.[2,3] Other natural causes of death accounted for 24.0% of cases (n=25), including respiratory, infectious, gastrointestinal and hematological diseases. Traumatic deaths accounted for 16.4% of cases (n=17), including fatal blunt injuries, gunshot wounds and thermal injuries, which were often associated with self-harm or violence and unsafe urban environments. In general, the high proportion of middle-aged men dying from a "natural" disease indicates an accelerated deterioration in health associated with homelessness, reflecting international data that the average age of death in this population group is about 25 years younger than in the general population.[1,3] At the same time, the retrospective analysis has also highlighted a lack in histological and toxicological postmortem examinations. In fact, in more than 50% of cases, no macroscopic certain cause of death was found, as it could be an acute, undiagnosed poisoning. In Italy, authorization from the judicial authorities is required for further laboratory tests to be carried out during forensic autopsies. At the same time, forensic pathologists must adequately inform prosecutors of the importance and usefulness of such tests. This has clearly not been done adequately in these cases, giving rise to the disturbing suspicion that deaths on the margins of society are chronically underestimated. This is not just an Italian problem, as literature reports that almost 60% of cases of homelessness could not be definitively confirmed without a comprehensive autopsy and lab analyses due to unclear circumstances or lack of anamnesis.[2,5] Therefore, the study illustrates the limitations of nonspecific death certification and the value of refined forensic protocols through lab analyses. Sudden deaths in this context often reflect complex interactions between chronic disease, inadequate healthcare access, exposure, and substance use-factors commonly invisible in routine epidemiologic datasets.[2,6] The forensic approach advocated here would offer a more granular understanding of cause of death trends and can guide targeted health and safety interventions since there is a high load of preventable deaths, both natural and violent, within a population living in extreme marginality.[6] The high rate of undetermined or ambiguous causes underscores the need for expanded diagnostic resources, especially in vulnerable populations.

I76 Evaluating Quality in Hospitalized Patients: Using a Retrospective Review of Hospital Autopsies at a Single Institution

Omid Golestanian, MD, West Virginia University, Morgantown, WV; Bushra Sayeed, MD, West Virginia University, Morgantown, WV; Shahrier Amin, MD, PhD, Mayo Clinic, Morgantown, WV; Erona Reza, MD, West Virginia University, Morgantown, WV*

Learning Objectives: This presentation will enable attendees to: (1) recognize the role of autopsy as the gold standard for establishing accurate diagnoses postmortem;
(2) identify discrepancies between clinical diagnoses and autopsy findings; (3) appreciate the value of autopsies in improving clinical practice, medical education, and quality assurance; and (4) demonstrate how retrospective autopsy reviews can guide clinicians in reducing missed or incorrect diagnoses in future cases.

Impact Statement: By highlighting discrepancies between clinical and postmortem findings, it reinforces the value of autopsies in identifying missed diagnoses and improving patient care. For the forensic science community, this work emphasizes the importance of maintaining high autopsy standards, supports advocacy for autopsy utilization, and contributes to a broader understanding of how postmortem examinations can inform both clinical and medicolegal investigations.

Abstract Text: Despite advancements in diagnostic imaging and laboratory medicine, discrepancies between clinical diagnoses and post-mortem findings remain a significant challenge in modern healthcare. Autopsies continue to be the definitive method for identifying diagnostic errors and revealing missed or underestimated conditions. Our study aimed to evaluate the frequency, types, and clinical implications of diagnostic discrepancies identified through autopsy in Ruby Memorial Hospital, West Virginia.

A retrospective review was conducted on 115 consecutive autopsy cases. Discrepancies between the clinical diagnoses made before death and the findings observed during autopsy were classified using a modified Goldman classification system, which categorizes errors based on their severity and relevance to patient outcomes, familial risk, and diagnostic accuracy.

A significant number of diagnostic discrepancies were identified in 30 cases, representing 26.1% of the total. The most common errors were Type I errors, which involve major missed diagnoses that could potentially impact patient outcomes; these errors were observed in 22 cases 19.1%.

Frequently missed/unsuspected conditions included pulmonary thromboembolism, diffuse alveolar damage, and mesenteric ischemia. In addition, the extent of mismatches, where the severity of the disease was underestimated, was noted in 6 cases 5.2%. There were also Type III errors, which have potential implications for family members, such as undiagnosed metabolic or genetic disorders, occurring in 2 cases (1.7%). Despite the medical complexities involved complete clinical-pathological concordance was found in 16 cases, representing 13.9%, indicating that despite advances in antemortem diagnostic modalities, autopsy unveiled significant findings in >80% cases. This study emphasizes the ongoing importance of autopsies for clinical feedback and education.[1-5]

The results underscore the necessity for increased clinical vigilance when evaluating nonspecific or rapidly changing symptoms. We advocate for continued surveillance autopsies for maintaining quality assurance, education and improving patient safety.

I77 Standards Development Activities in Medicolegal Death Investigation and Forensic Pathology

J. Keith Pinckard, MD, PhD, Travis County Medical Examiner, Austin, TX*

Learning Objectives: After attending this presentation, attendees will have a better understanding of the documentary standards development process and the current state of affairs of documentary standards within the fields of forensic pathology and death investigation.

Impact Statement: This presentation will impact the forensic science community by creating greater awareness of how standards are developed and the players involved in standards development in the medicolegal death investigation realm as well as their implementation.

Abstract Text: The Organization of Scientific Area Committees for Forensic Science (OSAC) was created to strengthen the nation's use of forensic science by facilitating the development of technically sound standards and guidelines and encouraging their use throughout the forensic science community.[1] OSAC has many discipline-specific subcommittees that conceive of and draft proposed standards that would be useful to the forensic science community. OSAC, however, is not a standards development organization (SDO) and therefore cannot publish documentary standards on its own. Thus, draft standards are then submitted to appropriate SDOs that put them through defined, consensus-based processes to vet, write, and publish them.

One such SDO is the Academy Standards Board (ASB), a wholly owned subsidiary of the American Academy of Forensic Sciences, established and accredited by the American National Standards Institute (ANSI). The ASB develops consensus-based forensic science standards and provides training to support those standards.[2] Similar to the subcommittees of OSAC, ASB has several consensus bodies that focus on the various specialties within forensic science.

OSAC and ASB work closely together, and in fact, many members participate in both organizations to promote cross-talk and facilitate standards development. Once a standard has been published by an SDO such as ASB, it can be submitted to OSAC for evaluation to be placed on the OSAC Registry, which is a centralized repository for high-quality, technically sound standards.

This process has been used extensively in the field of medicolegal death investigation. However, standards development in the field of forensic pathology is unique in that it is the practice of medicine and thus, consensus-based, documentary standards are not appropriate. Professional practice standards developed by a professional practice organization (such as the National Association of Medical Examiners) are the appropriate venue for standards development for the medical practice of forensic pathology. The history of how OSAC and ASB have navigated this issue will be discussed in terms of how standards are conceived, drafted, and developed by the OSAC MDI Subcommittee and the ASB MDI Consensus Body.

During this presentation, the state of standards development within medicolegal death investigation and forensic pathology will be discussed, to include the current status of each of the individual standards within the standards development process. These include draft standards being developed by the OSAC MDI Subcommittee, draft standards that have been sent to an SDO (such as ASB) for further development, standards that are being drafted independently by ASB, and SDO-published standards being considered for placement on the OSAC Registry. In addition, priorities for future standards development will be discussed.

I78 Conrad-30 Waiver Program for Forensic Pathologists: An Overview

Mario A. Rascon, MD, El Paso County Office of the Medical Examiner, El Paso, TX*

Learning Objectives: After this presentation, attendees will be provided with an efficient framework to successfully tackle the United States immigration system to secure permanent resident status and join the American workforce.

Impact Statement: Shedding light into the steps involving the most common path to full-time employment as an international medical graduate in the United States will help combat the forensic pathologist shortage.

Abstract Text: Most non-US-citizen international medical graduates (IMG) undergo their postgraduate medical training in the United States (US) on a J-1 visa. The United States Citizenship and Immigration Services (USCIS) makes graduating IMGs on J-1 visas subject to a mandatory 2-year home residency requirement. However, these doctors on J-1 visa can seek continued, uninterrupted employment in the US after training by applying to a home residency requirement waiver, which can be obtained after securing a job offer within a medically underserved area (MUA) as designated by the Department of Health and Human Services (HHS). Each state participates in the Conrad-30 program, which grants thirty of these positions annually for exchange visitor physicians willing to service these communities under these terms by issuing a favorable recommendation to the US Health and Human Services (HHS) waiver review division following the applicant's submission.

Once the applicant has secured a J-1 waiver job, their visa status will change to H1b visa – a high priority, dual-intent type of visa, under which the applicant may successfully apply for permanent resident status under one of five employment-based (EB) programs, each with decreasing chances of success, including: (1) EB1-priority workers; (2) EB2-professionals with exceptional ability; (3) EB3-skilled worker; (4) EB4-special immigrants; and (5) EB5-investors. Most forensic pathologists will optimize their chances of success by applying in the EB2-3 categories. One key difference between J-1 waiver jobs and most EB categories is that most EB categories (i.e., EB1, EB2, and EB5) can be self-sponsored, meaning the application does not have the contingency of requiring a job offer for the applicant, since they can self-petition based on their own professional merits.

Tenuous understanding of the immigration process by prospective employers may be followed by hesitancy to explore the hiring of these professionals. A better understanding of the intricacies involved in navigating immigration procedures will optimize results for both sides. Furthermore, interventions geared towards making this process seamless for forensic pathologists could represent helpful implementation towards combatting forensic pathologist shortage.

I79 Pseudo-Gunpowder Stippling: An Image-Based Case Series

Kori L. Mecklenburg, MD, Cedars Sinai Medical Center, Van Nuys, CA; Lauren M. Moshea, DO*, Los Angeles County Department of Medical Examiner, Los Angeles, CA; Joseph A. Prahlow, MD, Medical Examiners Office, City of St. Louis, St. Louis, MO; Kanayo Tatsumi, MD, St Louis City Medical Examiners Office; Saint Louis University School of Medicine, St. Louis, MO; Robyn Parks, MD, Los Angeles County Department of Medical Examiner, Los Angeles, CA; Katie Hanson, MD, Medical Examiners Office, City of St. Louis, St. Louis, MO*

Learning Objectives: After attending this presentation, attendees will be able to recognize the causes and manifestations of "pseudo-gunpowder stippling," a phenomenon that may obscure determination of range-of-fire at autopsy.

Impact Statement: This presentation will impact the forensic science community by educating attendees about the diagnostic challenges and autopsy findings associated with pseudo-gunpowder stippling. A variety of scenarios will be presented where skin markings or injuries may be mistaken for gunpowder stippling.

Abstract Text: Firearm deaths accounted for approximately 48,000 deaths in 2022, over half of which were classified as suicides and greater than 40% as homicides.[1] To elucidate the circumstances surrounding these deaths, the forensic science community must accurately interpret wound characteristics using scene investigation and autopsy examination.

In gunshot deaths, examination of the entrance wound is crucial to determine range of fire, or the distance between the firearm muzzle and the victim's body when the shot is fired.[2] In forensic science, the term "gunpowder stippling" is used to describe multiple tiny, scattered punctate abrasions associated with a gunshot entrance wound. These abrasions are caused when small unburned or partially burned gunpowder particles and debris strike the skin.[3-5] Also known as "gunpowder tattooing," gunpowder stippling represents true injury and cannot be washed away from the wound. The presence of gunpowder stippling around an entrance wound suggests a range of fire within approximately two to three feet.

It is important to note that there are semantic issues which arise when using the less specific term "stippling." Even though many forensic pathologists use the term to refer to gunpowder stippling, strictly speaking, the term "stippling" can refer to *any* aggregate or clustering of pinpoint or similarly-sized skin injuries produced by traumatic skin injuries, *no matter the cause*. As such, skin stippling can occur from broken glass, splintered wood, dust debris from an explosion, insect activity, etc. These latter examples are best classified as "pseudo-gunpowder stippling," since, by definition, they do, in fact represent true stippling (skin stippling due to traumatic injury). The most etiologically specific term when "typical" stippling is associated with gunfire is the term "gunpowder stippling." It should also be noted that the term "pseudo-stippling" should be limited to situations where non-traumatic skin markings mimic true traumatic stippling. Pseudo-stippling and pseudo-gunpowder stippling may obscure interpretation of the range-of-fire, a critical piece of evidence in firearm-related death investigations. In cases of pseudo-gunpowder stippling, careful macroscopic and possibly even histologic correlation is warranted to differentiate this finding from true gunpowder stippling.[6,7]

This presentation introduces a diverse series of gunshot-related deaths where pseudo-gunpowder stippling was identified at autopsy. Cases selected from multiple medicolegal death investigation offices will be utilized to illustrate the mechanisms and autopsy findings associated with gunpowder stippling mimics. Selected cases include pseudo-gunpowder stippling due to broken glass, shotgun filler, gravel impact, insect activity, as well as cases of non-traumatic pseudo-stippling, as may occur with various skin conditions, such as freckles or acne.

I80 Beneath the Surface: Exploring Aquatic Decomposition in Sweden

Clara Alfsdotter, PhD, National Board of Forensic Medicine, Division of Forensic Medicine Lund, Lund, Skane Lan, Sweden; Anja Petaros, PhD, National Board of Forensic Medicine, Division of Forensic Medicine Linköping, Linköping, Ostergotlands Lan, Sweden*

Learning Objectives: After attending this presentation, attendees will have a better understanding of the variation and specific aspects of decompositional changes in bodies recovered from water in cooler climates, such as Sweden. Attendees will also become aware of the complexity involved in scoring decompositional morphological variation using existing scoring systems and understand the challenges associated with Postmortem Interval (PMI)/Postmortem Submersion Interval (PMSI) estimation in aquatic environments.

Impact Statement: This presentation will impact the forensic community by improving the understanding of decompositional variation in aquatic environments, which may also prove useful in the search and recovery of human remains from water. The presentation will emphasize the need for context-specific approaches, not only in estimating the PMI, but also in interpreting decompositional changes.

Abstract Text: In medicolegal practice, decedents disappeared in aquatic environments pose a number of challenges for subsequent forensic examinations. Bodies recovered from water frequently exhibit varying stages of decomposition, as they are sometimes not easily found due to factors such as transportation by currents, sinking, or entrapment in underwater structures. The rate and pattern of decomposition are influenced not only by time, but also by environmental factors, including temperature, water properties, water depth, and scavenging activity. To ease the interpretation and to break down the complexity of decompositional changes and support PMI estimation, several scoring systems have been developed.[1,2] However, significant gaps in the understanding of aquatic decomposition and its relationship to PMI persist. Research on the topic remains limited, as existing studies often involve small case numbers or show an overrepresentation of cases with short PMIs.

In this presentation, we share the results of a national retrospective study conducted in Sweden, which examined decomposition features in decedents recovered from various aquatic environments. Data from 2010 onwards were derived from police reports, medicolegal documentation, and autopsy photograps from the National Board of Forensic Medicine. A total of 296 cases were analyzed and scored using the Heaton decomposition scoring system.[1] The cases analyzed were recovered from freshwater (73%), brackish water (19%), and saltwater (8%). PMIs ranged from 6 days to 77 years, with 66% of cases recovered between 1 and 6 months after disappearance. Total aquatic decomposition scores (TADS) ranged from 3 to 25 (with a median of 13). Saponification was observed in 13% of cases, sometimes as early as two weeks postmortem, often in bodies missing during colder months. Skeletonization occurred in 14% and disarticulation in 7% of cases. In 1% of cases, desiccated areas were observed. Evidence of scavenging was noted in 25% of cases. Scoring using the Heaton system presented challenges, which included discrepancies between the descriptive criteria and observed changes, or the inability to score whole-body saponification or capture its nuances, since this feature is only included for one body region in the scoring system. In many Swedish cases, assigning a score was difficult due to discolorations caused by hypothermia, or the presence of a biofilm/sediment covering the face, a feature rarely discussed in the literature but potentially relevant to PMI/PMSI estimation, and present in 23% of our cases.[3] To assess the utility of the scoring system for PMI estimation, a preliminary regression model was built using 46 cases, where TADSs was regressed against $\log_{10}$ADD (Accumulated Degree Days, based on recorded water temperatures). The model showed limited fit ($R^2 = 0.43$) and unsatisfactory ADD estimation, with outliers reflecting hard-to-code cases.

The results of the study highlight the need to: (1) increase our understanding on factors affecting decomposition progression in aquatic environments, and (2) adapt decomposition scoring systems to reflect region-specific variations.

I81 An Examination of the Potential for Fly Transfer of Blood to a Suspect's Clothing

David Rivers, PhD, Loyola University Maryland, Baltimore, MD*

Learning Objectives: Attendees of this presentation will develop an understanding of the foraging behavior of necrophagous flies attracted to human blood, the morphological characteristics of insect stains deposited on porous surfaces like clothing fabrics and be able to assess whether blood transfer by insects to a suspect's clothing is a viable defense.

Impact Statement: This presentation will impact the forensic science community by serving as a source of foundational information that can augment traditional means of investigation of trace evidence and insect pattern evidence associated with violent crimes characterized by bloodshed.

Abstract Text: Fly feeding on human blood yields unique stains through modifications of existing bloodstains and via the deposition of fluids from the digestive tract onto a variety of surfaces.[1] The latter are referenced as digestive stains and occur as regurgitate and defecatory stains.[2] When flies modify or produce stains due to interacting with human blood, the resulting trace is termed an insect stain.[3] Insect stains have long been recognized by investigators as occasional to frequent phenomena at crime scenes.[4] However, in practice, insect stains are not processed if discovered. This lack of interest has contributed to a dearth of information in the case and research literature regarding any aspect of insect stains.

In 2023, defense attorneys representing Alex Murdough in South Carolina noted that bloodstains on a white tee shirt worn by the accused showed similarity to contact stains produced by insects.[5] Further investigation was not performed in that case, but it did raise the question of whether insects transfer blood to the clothing of other individuals who attend the scene for any reason. The case and research literature do not provide an answer. Consequently, this investigation was conducted to examine if adult necrophagous flies transfer blood to the clothing of an individual at or near a crime scene.

Mock indoor and outdoor crime scenes were set up using stillborn fetal pigs, human blood, and mannikins with new white cotton tee shirts. Fly activity was monitored with continuous high-definition video recordings. In outdoor scenes, adult blow flies arrived in >5 min of carcass placement, landing frequently on the piglet and mannikin. Flies did not demonstrate a location preference on the mannikin, as adults were observed landing and walking on the shirt, pants, head, arms and legs randomly. Digestive stains were deposited on the shirt within 2 h of fly arrival. In contrast, piglet carrion with large maggot masses and exposed muscle and organs attracted more flies, more total insect stains were deposited, and stain deposition occurred in the shortest time after placement (>5 min) by comparison to piglets in the fresh and bloat stages. Human blood was detected in 54.6% of the fly stains using BlueStar Identi-Hem lateral flow assays. Indoor scenes were set up in nylon mesh cages (96 x 70 x 48 in) in a controlled environment with adults of *Calliphora vicina* released into the cages. In all scenarios tested, flies landed on the piglet and mannikin in >5 min. Insect stains were deposited randomly on the mannikin, and the first stains were evident within 30 min after fly introductions into the cages. Far more stains were deposited on mannikin tee shirts indoors than outdoors, and the dominant stain type were tarsal tracks.

The results of this investigation indicate that flies do frequently land on individuals at indoor and outdoor crime scenes and blood is transferred by the flies to clothing of a bystander. However, the timing of stain deposition is highly variable, and blood transfer is more likely to occur indoors than at outdoor scenes.

I82 Environmental Forensic Entomology: What Can the Basic Biology of Flies Reveal About Environmental and Wildlife Crimes?

Charity G. Owings, PhD, University of Tennessee, Knoxville, TN*

Learning Objectives: After attending this presentation, attendees will understand the relevance of the new subdiscipline of forensic entomology, known as environmental forensic entomology, to forensic casework. Attendees will learn about the ways in which carrion insects have been used previously to provide a snapshot of the local environment and how such data can be leveraged for use in death investigations, missing persons cases, and even investigating environmental crimes.

Impact Statement: This presentation will broaden the forensic science community's perspective of what is possible with carrion insects by demonstrating their value as non-invasive tools for detecting and interpreting evidence in environmental and wildlife crime investigations. By bridging entomology with other disciplines (e.g., forensic toxicology, DNA analysis, genetic genealogy), these methods have the potential to expand the reach of the forensic sciences and inform the development and integration of interdisciplinary approaches to forensic investigations.

Abstract Text: The application of arthropod biology to forensic cases has become well-established over the last several decades and now forms an almost integral part of forensic death investigations.[1] Primarily, entomology is utilized in forensic casework to estimate at least a portion of the postmortem interval through the analysis of arthropod life cycles and community composition.[2] However, the unique biological strategies of these insects, such as their ability to detect, locate, and exploit ephemeral resources, in addition to their high dispersal capacities, suggest that they can provide much more than just time interval estimations. Recent research has demonstrated that carrion arthropods, especially blow flies, can serve as biological indicators, revealing vital chemical and biological information about their environment and the substrates they colonize, including human biological fluids, animal carcasses, feces, microbes, parasites, and hazardous chemicals.[3-10] These insects effectively act as biological drones, passively collecting and transporting environmental data, which can be harnessed by investigators when the appropriate analytical methods are applied.[11] By analyzing the biological and chemical signatures carried by flies and other carrion insects, this methodology enables practitioners to gather critical evidence related to environmental contamination, illegal dumping, habitat degradation, or wildlife trafficking, making it of particular significance for wildlife forensic casework. This approach offers a non-invasive, rapid, and cost-effective means to assess environmental health and detect environmental crimes, making it highly relevant and valuable to environmental scientists, wildlife crime investigators, and forensic practitioners alike.

Environmental forensic entomology, a burgeoning sub-discipline encompassing these key applications, employs carrion arthropods as non-invasive collectors of environmental data that can be used as evidence relevant to environmental and wildlife crimes. While promising, the application of these techniques also raises ethical considerations, particularly concerning the potential collection of sensitive information (e.g., human genetic material), highlighting the need for clear ethical guidelines. Furthermore, establishing the scientific validity of these methods is crucial; they must meet the *Daubert* criteria (i.e., testability, reproducibility, known error rates, peer review, and general acceptance) before they can be reliably used in legal proceedings. Standardized protocols for evidence collection, analysis, and interpretation, developed through organizations like OSAC, are essential to ensure methodological consistency and minimize errors.

This presentation will explore how the basic biology of flies can be leveraged specifically in wildlife and environmental forensics, providing insights into environmental health and aiding in the investigation of wildlife crimes. We will discuss current methodologies, outline future research directions, and propose guidelines for integrating environmental forensic entomology findings into the legal system.

I83 How to Combine the Exigencies of Histopathological and Forensic-Genetic Investigation: Critical Issues in the Use of Medicolegal FFPE Samples for DNA Analysis

Giulia Soldati, PhD, Unit of Forensic Medicine, Department of Diagnostic and Public Health, University of Verona, Verona, Veneto, Italy; Rebecca Rigosa, MS, Unit of Forensic Medicine, Department of Diagnostic and Public Health, University of Verona, Verona, Veneto, Italy; Nicola Pigaiani, MD, PhD, Section of Forensic Medicine, Department of Diagnostics and Public Health, University of Verona, Italy, Verona, Veneto, Italy; Pamela Rodegher, MS , Unit of Forensic Medicine, University of Verona, Verona, Veneto, Italy; Federica Bortolotti, MD, PhD, Unit of Forensic Medicine, Department of Diagnostics and Public Health, University of Verona, Italy, Verona, Veneto, Italy; Francesco Ausania, MD, PhD, Unit of Forensic Medicine, Department of Diagnostic and Public Health, University of Verona, Verona, Veneto, Italy*

Learning Objectives: Attendees of this presentation will gain information on: (1) the conventional histological preservation methods for cadaveric tissues that are unsuitable for forensic genetic analysis; (2) the variability in the minimum duration required for formalin fixation of cadaveric specimens; and (3) the gradual decline in DNA quality associated with prolonged formalin fixation.

Impact Statement: This presentation will have an impact on the forensic science community by emphasizing the importance of re-envisioning the conservation methodology for Formalin-Fixed Paraffin-Embedded (FFPE) samples, particularly within judicial settings, in order to safeguard the potential for subsequent genetic analysis.

Background: In forensic autopsies, it is standard to collect tissue portions for fixation in formalin and inclusion in paraffin (FFPE samples) to ensure long-term histological preservation.[1] In some circumstances, this type of specimen provides the only residual source of biological material available for postmortem genetic analysis. However, using FFPE samples in forensic genetics presents many critical issues, as formalin compromises DNA integrity, thus reducing the chances of obtaining complete genetic profiles.[2] Although the literature does not provide unambiguous guidance as to a minimum time for formalin fixation of a cadaveric specimen, recent studies have indicated that fixation intervals of up to 14 days allow DNA recovery.[1,3] However, both studies mentioned how this range far exceeds ISO indications.[3,4]

Methods: Lung FFPE samples from 20 subjects undergoing forensic autopsy were selected. FFPE blocks were selected according to the residence time of the tissue in formalin, ranging from 1 to 30 days. Three slices from each FFPE sample were used for the DNA extraction. Briefly, the deparaffinization was performed by soaking the slides in 1 ml of xylene, vortexing at full speed for 10 min, and centrifuging at 12.000 rpm for 2 min; the supernatant containing the solubilized paraffin was removed. The procedure was repeated a second time. The same process was then performed using 100% ethanol to extract residual xylene from the sample. The samples were incubated at 37°C for 10 min. The pellet was resuspended in 300 µl of Buffer ATL, and after the addition of 20 µl of Proteinase K, an incubation at 56°C until the samples were lysed entirely was performed. An incubation at 90°C for 1 h was carried out, and after a brief centrifugation, 200 µl of Buffer AL and 200 µl of 100% ethanol were added. The entire lysates were transferred to the QIAamp MinElute column, and the washing was performed with 500 µl of Buffer AW1 and AW2. Finally, 50 µl of Buffer ATE was applied to elute the DNA.

The femoral blood of each subject was taken during autopsies, as reference samples; the DNA was extracted using the QIAamp DNA Mini Kit.

Results: The trend line obtained from the results produced in this study evidences a decreasing exponential trend, indicating a progressive loss of efficiency in allele typing as formalin fixation time increases. At minimal fixation times, the percentage of correctly typed alleles is 100%; this value progressively decreases to 50% when the fixation time is 13-14 days and then proceeds with a further decline with longer fixation time.

Conclusions: This study assesses, through an experimental framework, the correlation between DNA degradation and the duration of sample fixation in formalin. Significant questions have emerged regarding the reliability of investigations performed on postmortem inclusions. In forensic practice, FFPE tissues obtained from cadavers are seldom fixed in formalin for periods shorter than ten days. Although originally intended for pathological purposes, the reutilization of FFPE tissues in forensic genetics would necessitate modifications to protocols to accommodate both histopathological and forensic requirements.

I84 The Effect of Soil Particle Size and Depth on Dogs' Detection of a Buried Odor

Glenna N. Cupp, MSc, Canine Olfaction Research and Education Laboratory, Texas Tech University, Lubbock, TX; Madalyn Bower, BS, Scientific Animal Welfare, Olfaction, and Behavior Solutions Laboratory, Lubbock, TX; Paola Tiedemann, PhD, Texas Tech University, Lubbock, TX; Daniel Hirmas, PhD, Department of Plant and Soil Science, Texas Tech University, Lubbock, TX; Nathaniel J. Hall, PhD, Canine Olfaction Research and Education Laboratory, Texas Tech University, Lubbock, TX; Edgar O. Aviles-Rosa, PhD, Scientific Animal Welfare, Olfaction, and Behavior Solutions Laboratory, Lubbock, TX*

Learning Objectives: Attendees will learn how soil particle size and depth affect the ability of detection dogs to find buried odors. They will gain insight into how dog detection performance changes under different burial contexts within controlled laboratory conditions.

Impact Statement: This presentation will enhance the forensic science community's understanding of how soil particle size and burial depth may influence dog odor detection. These findings can help support more effective coordination of clandestine grave searches based on local soil characteristics.

Abstract Text: Dogs are commonly used to detect buried targets, but the effects of soil characteristics and burial depth on their performance are poorly understood. This study established a controlled laboratory approach using an olfactometer to investigate how soil particle size and burial depth affect canine odor detection, utilizing 1-bromooctane as the target compound.

In Experiment 1, six dogs were tested across three particle-size conditions – 2-4 mm, < 2 mm, and a 50:50 mixture of the two – at burial depths of 2.9 cm, 5.7 cm, and 11.4 cm. Detection accuracy remained high in the 2-4 mm with only a modest decline as depth increased (M = 0.87 at 2.86 cm to M = 0.80 at 11.43 cm). In contrast, both the 50:50 mixture and < 2 mm showed steeper declines. Accuracy in the 50:50 mixture dropped from M = 0.85 at 2.86 cm to M = 0.63 at both 5.72 cm and 11.43 cm, while the < 2 mm fell from M = 0.88 at 2.86 cm to M = 0.54 at 11.43 cm.

In Experiment 2, a new group of six dogs was tested with two new particle-size conditions – 0.05-0.25 mm and 0.76-2 mm at the same depths used in Experiment 1. Dogs had overall better performance in 0.76-2 mm, although accuracy decreased with depth (M = 0.72 at 2.86 cm to M = 0.50 at 11.43 cm). Performance in 0.05-0.25 mm was lower across all depths, with accuracy falling from M = 0.54 at 2.86 cm to M = 0.35 at 11.43 cm.

Across both experiments, dogs' odor detection accuracy declined with increasing depth and was generally higher in substrates with larger particle sizes. These findings suggest that soil particle size affects dog detection performance. The developed method provides a framework for further evaluation of the effect of different soil characteristics on detection performance.

I85 Winter Taphonomy and Vertebrate Scavengers in the Northern Plains

Lavinia Iancu, PhD, University of North Dakota, Grand Forks, ND; Piper O'dell, BS*, Missouri Stare Highway Patrol, Sheridan, WY; Thomas Sikorski*, University of North Dakota Forensic Science Program, West Fargo, ND; Ranna Dawlaty, BAS, Grand Forks, ND, United States, Fargo, ND*

Learning Objectives: After attending this presentation, attendees will gain a deeper understanding of winter taphonomic processes under North Dakota's extreme cold conditions, as well as the activity patterns and successional behavior of vertebrate scavengers interacting with exposed pig carcasses in an uncaged outdoor environment.

Impact Statement: This presentation contributes to the forensic science community by offering new insights into cold-weather decomposition and providing novel data on vertebrate scavenger foraging behavior during North Dakota winters, enhancing the interpretation of outdoor death scenes in similar climates.

Abstract Text: The progression of the decomposition process is primarily influenced by the environmental temperature, followed closely by the microbiome, necrophagous insect species, and vertebrate scavengers' activities. During winter, when temperatures fall below the threshold for insect activity, vertebrate scavengers, primary or secondary, are the only ones that can forage and consume a carcass. Most of the studies focused on investigating scavenging in North America are reported from Texas, Colorado, Tennessee, and North Carolina, with no records for taphonomy scavenging data for North Dakota extreme winter months.[1]

Given the forensic importance and need of data on vertebrate scavengers' activity, this study aimed to document decomposition and vertebrate scavenging patterns under extreme winter conditions in North Dakota. In November 2024, three 55 kg pig carcasses were placed at the Mekinock Field Station (47.951751, -97.428484) in Grand Forks County, ND, and monitored until complete consumption in March 2025. The carcasses were left uncaged to allow unrestricted scavenger access. Six trail cameras (two per carcass), mounted at 1.5 meters and angled at 30°, recorded decomposition and scavenger activity. Environmental temperature was recorded hourly via temperature data loggers, while humidity and precipitation data were obtained from a nearby weather station 10 km from the site.

Over 5,300 images and videos were analyzed, with 2,300 capturing vertebrate species either feeding or visiting the carcasses. Among vertebrate scavengers, the coyote (*Canis latrans* Say, 1823) and red foxes (*Vulpes vulpes* (Linnaeus, 1758)) were predominant, while the bald eagle (*Haliaeetus leucocephalus* (Linnaeus, 1766)) had a sporadic occurrence and was recorded for the first time in a taphonomic study in this region. During the investigated period, temperatures ranged from -30.5°C to 14.7°C, with lower-than-average snowfall, while February was the driest month.

This study provides novel data on vertebrate scavenging patterns during winter in the Northern Plains, offering valuable insights for forensic investigations in cold climates. Understanding scavenger activity can improve postmortem interval (PMI) estimations, aid in locating dispersed remains, and enhance the effectiveness of cadaver dog search strategies. Moreover, the research outcomes can be used for the development of a local database to assist in outdoor death scene investigations in North Dakota and areas with similar environments.

I86 The Impact of Opioids and Benzodiazepines and Their Metabolites on Black Blow Fly (*Phormia Regina*) Larval Length

Linnea N. Briley, Northern Michigan University, Marquette, MI; Cambria Jansen, BS, Northern Michigan University, Marquette, MI; Hayden S. McKee-Zech, PhD, Northern Michigan University, Marquette, MI*

Learning Objectives: This presentation will explore the influence of morphine and lorazepam and their metabolites that can affect forensic Postmortem Interval (PMI) estimations based on larval length and provide a dataset for validation.

Impact Statement: This research enhances the reliability of PMI estimations by demonstrating how common prescription drugs, such as morphine and lorazepam, can alter blowfly larval development—an essential consideration in forensic casework involving decomposed or drug-exposed remains.

Abstract Text: Entomotoxicology studies have demonstrated that drugs present in a rearing substrate can influence the physiology and development of insect larvae, particularly flies.[1] This research is crucial for forensic science in refining minimum postmortem interval (PMIMIN) estimations, as prescription drugs can alter the biological parameters of black blowfly (*Phormia regina*) larvae.[2]This study analyzed preserved *P. regina* larvae stored in 70% ethanol from a 2021 development study. All experiments were performed with a laboratory colony of the black blow fly, *Phormia regina* (Meigen). Each experiment followed fly development from first instar larva through adult emergence. Each replicate within a treatment was comprised of primary drugs of interest (morphine, M; lorazepam, L), metabolites (morphine-3-glucoronide, M3G; lorazepam-glucuronide, LG), or drug/metabolite combinations (L:M, M:M3G, L:LG, M3G:LG) blended into ~100 g of organic, antibiotic-free lean pork. Additional treatments using field-collected human decomposition fluid were made in the same manner. Decomposition fluid samples were originally collected from four human donors decomposing at the Anthropology Research Facility (ARF) at the University of Tennessee. Confirmation of morphine and lorazepam in the fluids was confirmed by HPLC MS/MS. Control replicates consisting only of pork were also implemented in the study design. Each replicate was inoculated with N = 100 first instar larvae and maintained at 25°C and 70% relative humidity with a 12:12 light:dark cycle. Four replicates were run per treatment.[3,4] Length and width were taken for each larva via CaptaVision microscope program, development stage was assessed of the posterior spiracles.

This study compared the age and length of preserved *P. regina* larvae from drug-exposed and control groups, to determine whether significant developmental differences exist between treatment conditions. Data was analyzed using a one way analysis of variance (ANOVA) with a post-hoc Tukey honest significant difference (HSD) test. Results indicated that drug and decomposition fluid treatment significantly impacted larval length ($P < 0.001$). Treatment lengths were analyzed via Welch's t-test, assuming unequal variances between groups. Each treatment was compared to the positive control (CON +) and the negative control (CON -). Each of the control groups were consistent in size and showed no statistical differences in size. All treatments with donor decomposition fluid (Tox 012, 004, 021, 007) show increasing mean lengths ($P < 0.001$), highest in Tox007 (1.53). These could indicate dose-dependent or compound-specific effects but further exploration is needed. M:M3G and L:LG have very high means (1.66mm and 1.61mm respectively), and very low standard deviations, suggesting strong, consistent effects ($P < 0.001$).While treatments containing LOR and L:M has a smaller difference (~1.32) but is still significant ($P = 0.013$; $P = 0.022$). The results of this study indicate that both decomposition fluid taken from human donors with known concentrations of drugs and lab treatments of drug and their metabolites influence the development of insect larvae. Future directions are to compare these larval lengths with published *Phormia regina* datasets for PMI estimation to determine the effect on the forensic community.

I87 Tiny Traces, Big Impact: Fingertip Microbiomes in Forensic and Pathology Research

Michele Di Nunzio, MCS, University of Barcelona, Barcelona, Catalonia, Spain; Sarah Gino, MD, Department of Health Sciences, University of Eastern Piedmont, Novara, Piemonte, Italy; Noemi Procopio, PhD, University of Lancashire, Preston, England, United Kingdom; Nengi Ogbanga, PhD, University of Lancashire, Newcastle, England, United Kingdom; Anna Franzoni, MSc, Copan Italia Spa, Brescia, Lombardia, Italy; Miquel Serra-Forteza, BSc, Universitat de Barcelona, Portocolom, Islas Baleares, Spain*

Learning Objectives: After attending this presentation, participants will gain a deeper understanding of the variability in microbial communities found on human fingertips and how these microbial signatures can be analyzed to support forensic discrimination, individual identification, and the potential detection of pathological conditions.

Impact Statement: This presentation will impact the forensic science community by presenting an approach to characterizing fingertip microbiomes as trace evidence. It will demonstrate how microbial signatures can enhance individual discrimination, support forensic investigations, and potentially reveal medically relevant information from biological traces left at crime scenes

Abstract Text: Microorganisms are ubiquitously present on both interior and exterior human body surfaces, outnumbering human cells 3:1.[1] Like human DNA shed from skin cells, microbes are also transferred to the environment.[2,3] The circular structure of bacterial DNA and peptidoglycan walls makes it highly preserved, resisting degradation better than human DNA. Microbiome analyses are becoming increasingly relevant in forensics for individual identification, and fingerprints contain enough microbial DNA to create trustworthy profiles.[2] This presentation explores semi-standardized recovery of microbiomes from fingertips.

This pilot study examines the potential of fingertip microbiomes to reveal biologically and forensically relevant inter-individual differences. Specifically, it investigates whether distinct microbial signatures correlate with sex (male vs. female), handedness (dominant vs. non-dominant), and medical conditions like celiac disease or gluten intolerance. The goal is to evaluate microbial profiles' discriminatory power for identifying individuals and inferring physiological or pathological traits. Findings may offer new insights into forensic microbiology, where microbial traces could complement medico-legal evidence.

Twenty donors (10 male and 10 female) were enrolled in the study. Volunteers were allowed to choose their usual mode of transportation to the laboratory (e.g., walking, subway, bus, or private vehicle). Upon arrival, a trained operator collected a sample from each single donor's fingertip of both the dominant hand (DH) and non-dominant hand (NDH) using dried Self Skin FLOQSwabs.[4] Participants then completed a lifestyle questionnaire. Total DNA was extracted using the Qiagen QIAamp DNA Blood and Tissue Kit, allowing for the co-isolation and quantification of both human and microbial DNA.[5] Following the protocols recommended by the Human Microbiome Project, the V4 region of the 16S rRNA gene was PCR-amplified and sequenced using the Illumina MiSeq System. The resulting FASTQ files were imported into QIIME2 (version 2024.5.0) for processing. Quality filtering and denoising were performed using the DADA2 plugin (QIIME2 DADA2 denoise-paired), and sequences were trimmed accordingly. Taxonomic classification was conducted using the SILVA 138-99 reference database. Downstream analyses were performed in R (version 4.2.3) using the 'phyloseq' package.

Microbiome profiles were successfully typed for all out of 200 samples. Interestingly, it was possible to consistently identify unique taxa on all ten fingertips from an individual that were not detected in any other donors within the group. These unique taxa may have relevance for personal identification studies and may be useful to provide forensic intelligence information also when "touch DNA" fails. Additionally, the fingertip microbiome across the ten fingers of an individual is relatively consistent, but differs significantly between individuals, including distinctions based on sex.[3] Furthermore, the study revealed significant differences between 'non-pathological' donors and those with food-related conditions such as celiac disease or gluten intolerance, as well as between alcohol consumers and non-consumers, and between individuals who commuted to work on foot versus those using public transportation.

During the presentation, a detailed comparison of the donors' results will be provided, focusing on the microbial signatures identified among participants and their potential application in forensic investigations.

I88 Front End Separation of Biological Mixtures Based on Time-Since-Deposition of Contributor Cell Populations

Christopher Ehrhardt, PhD, Virginia Commonwealth University, Richmond, VA;Arianna DeCorte, MS, Virginia Commonwealth University, Richmond, VA; Gabrielle J. Wolfe, BS, Virginia Commonwealth University, Richmond, VA*

Learning Objectives: After this presentation, attendees will understand how cellular autofluorescence signatures can improve forensic casework procedures for processing mixtures. Specifically, they will learn how autofluorescence signatures can be used to not only determine the Time-Since-Deposition (TSD) for biological material recovered as evidence, but also how specific cell populations can be separated from complex mixtures based on their TSD.

Impact Statement: This research introduces a brand-new approach for determining age of evidence and a way to physically separate contributor cell populations from complex biological mixtures in a fast and high-throughput manner prior to DNA profiling. This can increase the probative value of evidence and simplify mixtures that would otherwise be uninterpretable.

Abstract Text: Due to increased sensitivity of DNA profiling systems, the central focus in many forensic cases has shifted from focusing on the DNA profiles obtained (i.e., who deposited the DNA) to activity-level data (i.e., how/when the DNA was deposited). In these occasions, determining the timeframe of when biological material was deposited can provide key context to a crime scene and add probative value to DNA profiles. A novel approach for determining TSD is to use native autofluorescence signatures of cell populations. Previous research has shown that autofluorescence profiles of certain cell types change in a systematic fashion over time in forensically-relevant samples and may be used to determine intervals of time in which biological material was deposited.[1,2]

The goal of this study was to develop autofluorescence-based TSD signatures for a new cell type: epithelial cells derived from saliva. Further, we tested whether the autofluorescence signatures could be used to separate contributor cell populations from mixtures of saliva on the front end of the DNA profiling workflow. Signatures were first developed by analyzing saliva samples from 35 different individuals that were aged between one day and approximately one year. Cell populations were collected using standard swabbing techniques, eluted into buffer, and analyzed directly via flow cytometry with no other preparative steps. Autofluorescence profiles were characterized with five lasers and across 64 detector channels ranging between 535nm-800nm. Results showed that two fluorescence channels had strong TSD signatures for saliva: UV-4 (excitation: 355nm; emission: 436-451nm) fluorescence increased over time and R-1 (excitation: 640nm; emission: 653-670nm) fluorescence decreased over time. A biplot of these fluorescence channels displayed major differences in cell populations that were less than a week old and more than three months old.

Next, 10 different two-person saliva mixtures were created wherein each donor's saliva had different TSDs between ~ one week to ~ 10 months to determine whether autofluorescence signatures could be used to physically separate donor cell populations from the sample. In all mixtures tested, results showed that biological material from each contributor could be effectively separated from the mixture, and produce clearly interpretable DNA profiles corresponding to each donor. Specifically, mixture profiles with a contributor ratio ~ 1:1 yielded profiles in the sort fractions that were at least 2:1 for the correct donor, or in some cases became a single-source profile. In mixture samples with a clear major contributor, sorting produced a DNA profile that was clearly enriched for the minor contributor.

These results suggest that autofluorescence profiling can be used on the front-end of the DNA profiling workflow to separate a variety of biological mixtures based on TSD of the contributor cell populations. This can not only provide a novel way of processing complex mixtures, but add crucial probative value to DNA evidence by contextualizing sub-source-, source- and activity-level propositions.

I89 Integrating NGS-Based DNA Workflows Into the Postmortem Toolkit for Kinship and Identification

Mayra Eduardoff, PhD, Sam Houston State University, Conroe, TX; Sheree Hughes, PhD*, Sam Houston State University, Huntsville, TX*

Learning Objectives: Attendees will learn how Single Nucleotide Polymorphisms (SNP) -based Next Generation Sequencing (NGS) workflows can be applied to degraded human remains in realistic postmortem scenarios to enhance kinship identification. The presentation will highlight the use of validated, field-deployable tools suitable for challenging forensic cases, such as unidentified decomposed or skeletal remains. Attendees will gain practical insight into how these methods could be integrated into medical examiner, pathology, and death investigation workflows as additional tools used to enhance identification outcomes and resolve more complex cases.

Impact Statement: This presentation offers a practical framework for how SNP-based kinship analysis using NGS workflows and secure offline bioinformatics platforms can serve as an additional and complementary tool to traditional methods in medical examiner, pathology, and death investigation settings. It will enhance the ability of forensic pathologists and death investigators to resolve complex identification cases involving degraded or skeletonized remains. Adoption of these tools supports improved performance in forensic casework and mass fatality contexts, ultimately strengthening identification outcomes for families and stakeholders.

Abstract Text: Next Generation Sequencing (NGS) and Single Nucleotide Polymorphism (SNP) testing are advancing the capabilities of forensic DNA analysis in the identification of degraded evidence or skeletal human remains and allowing for inference of distant genetic relationships which is often critical in missing persons cases, mass disasters, and complex forensic identifications.1-3 While the potential is significant, transitioning from traditional Short Tandem Repeat (STR)-based workflows to SNP-based NGS methods introduces operational and interpretive challenges. These obstacles include the need for specialized training, new analytical platforms, rigorous data quality metrics and most importantly effectively interpreting and reporting results back to the medico-legal community.

This presentation details the validation and implementation of an end-to-end SNP-based kinship workflow at the Southeast Texas Applied Forensic Science (STAFS) facility at Sam Houston State University which is a unique academic-medico-legal hybrid setting that includes a human decomposition research facility and forensic body donation program. This environment allows for controlled generation of realistic, complex postmortem samples that mimic challenging casework scenarios encountered by forensic pathologists, law enforcement and death investigators.

Using SNPSuite, a secure offline-compatible software platform, in combination with KinSNP for reference-based kinship analysis, we evaluated an end-to-end workflow for analyzing severely degraded human remains.4 Testing included both simulated kinship scenarios and authentic highly degraded biological samples obtained from actual donor remains representing real-world decomposition conditions. Results using simulated data support the ability of KinSNP® to generate reliable shared centimorgan results across a broad range of near and distant relationships (up to 9th degree relationships in some cases), and accuracy maintained even with a high degree (up to 75%) of missing data.

Key insights include the successful use of the systems without the need for internet connectivity, enabling secure, local databasing and kinship inference in morgue or field-based environments. These capabilities enable deployment in field settings, making the technology suitable for resource-limited environments, mass casualty responses or high-pressure conditions such as those encountered by medical examiners, law enforcement, mass casualty and disaster victim identification teams.

In addition to presenting case-relevant and technical results, this presentation will address workflow integration within forensic casework and medicolegal settings, offering practical guidance for pathologists and investigators tasked with resolving complex identifications. Attendees will gain insights into how SNP-based NGS workflows can be incorporated into postmortem operations, providing a powerful complement to existing STR-based methods for resolving unidentified remains and kinship inquiries.

By illustrating both educational and operational applications, this presentation supports a growing movement toward equipping forensic professionals with the tools and knowledge needed to meet the evolving demands of complex forensic casework and unidentified human remains investigations.

I90 That's Some Pig: Protocol Optimization for the Analysis of DNA in Unpulverized Cremated Remains

Kendall Kroha, MS, Charles R Step Funeral Home, Rochester Hills, MI; Stephanie Gladyck, PhD, Madonna University, Livonia, MI; Austin Wickham, MS, SeqOnce Biosciences Inc., Freeport, MI*

Learning Objectives: Attendees will learn a validated method for extracting mitochondrial DNA from unpulverized cremated remains using a protocol refined through porcine proxies and successfully applied to human samples.

Impact Statement: This presentation will impact the forensic science community by providing a reliable DNA extraction method for identifying cremated remains adaptable to real-world cases. It can improve performance in criminal investigations, mass disaster victim identification, and military causalities.

Abstract Text: The identification of cremated remains has long been a challenge for law enforcement and the broader field of forensic science. Having a method for extracting a genetic profile from cremains would provide valuable information for criminal investigations and disaster response, including the positive identification of cremated decedents or in situations where cremains have been comingled or switched. This research can be extrapolated to assist in homicide investigation of burnt remains, military personnel deaths in action, and mass disasters.

This study was split into two phases. Phase one assessed the efficacy of using unpulverized cremated *Sus scrofa domesticus* remains as a proxy for human cremains to optimize a protocol for the extraction of mitochondrial DNA (mtDNA). Porcine bone is frequently used as a proxy due to its similarities in size, structure, and genetic makeup to that of humans.[1-9] The cranium of a pig was selected for cremation due to the volume of bone and privately cremated at a temperature of 1,600°C for 105 minutes. Samples were chosen for extraction based on the amount of compact bone retained in the fragment. Phase two applied the optimized protocol to human unpulverized cremated remains. A modified lysis protocol was used in conjunction with an established extraction protocol. Extracted DNA was amplified by traditional polymerase chain reaction (PCR) and analyzed through capillary electrophoresis.

Results demonstrated that a mtDNA genetic profile can be isolated and successfully analyzed from unpulverized cremated remains for identification. When applied to the human cremains in the study, preliminary results showed the mitochondrial haplotype was consistent with the maternal cousin's sample. Additionally, another haplotype was present in the unpulverized cremains, which occurred often during the period the cremation took place. Future research will use the established protocol to determine how many individuals are present in the cremains.

I91 Jay Dix Lecture Series

Andrew M. Baker, MD, Hennepin County Medical Examiner, Minnetonka, MN; James R. Gill, MD, Connecticut Office of the Chief Medical Examiner, Farmington, CT; Joseph A. Prahlow, MD, Medical Examiners Office, City of St. Louis, St. Louis, MO; Susan F. Ely, MD, Yale University School of Medicine, Pelham Manor, NY; Melissa A. Pasquale-Styles, MD, Connecticut Office of the Chief Medical Examiner, Farmington, CT; Katherine Maloney, MD, Erie County Medical Examiner, Buffalo, NY

Learning Objectives: A proper medicolegal death investigation is a multidisciplinary process that often involves non-medical personnel as well as medical professionals. This annual lecture series provides non-forensic pathologist forensic scientists with a basic review of selected topics in forensic pathology in order to increase familiarity and understanding and enhance inter-discipline communication. This year's lecturers will discuss the medicolegal investigation of postmortem changes and deaths due to firearms, blunt force trauma, asphyxia, hyperactive delirium, and chronic alcohol use.

Impact Statement: This presentation will impact the forensic science community by presenting a comprehensive review of what causes and contributes to deaths related to the previously specified topics. Attendees will be able to systematically evaluate deaths in which the previously specified topics may have played a role that they encounter in their daily practices.

Program Description: Firearm fatalities are a major cause of non-accidental morbidity and mortality in the United States. Multiple factors and mechanisms are involved in producing firearm injuries. Understanding and evaluating firearm injuries requires basic understanding of how these injuries are produced and how to distinguish them from other types of trauma. This lecture will provide a comprehensive review of these issues. (Presenter—Andrew Baker, MD)

Postmortem changes include intrinsic (autolysis and putrefaction) and extrinsic (environmental conditions, animal/insect activity, funeral/burial procedures) factors which affect the time course of this process and the body appearance. Proper evaluation of postmortem changes may help to estimate the time since death. This lecture will review postmortem changes, their causes and appearances, their proper recognition, their significance, and the usefulness and limitations of utilizing this information in a medicolegal death investigation. (Presenter—Joseph Prahlow, MD)

Chronic alcohol use disorder is commonly encountered by the forensic pathologist. This lecture will examine the chronic effects of alcohol on the body as well as the role acute alcohol intoxication plays in traumatic causes of death. The role of liver disease in causing or contributing to natural and traumatic findings will be reviewed, including scene investigation and death certification. (Melissa Pasquale-Styles, MD)

Mechanical asphyxia includes strangulation, smothering, choking, hanging, and traumatic and positional mechanisms. Humans require the uptake and utilization of oxygen along with the release of carbon dioxide. An unnatural interruption in these processes leads to asphyxia. Proper evaluation of asphyxial deaths requires knowledge of the entities that cause asphyxia, pathophysiologic mechanisms, asphyxia death scenarios, and factors that contribute to death. This lecture provides comprehensive discussion of the investigation of deaths that may involve asphyxia. (Presenter—Susan Ely, MD)

Blunt force injuries are one of the major categories of mechanical injury. These injuries include abrasions, contusions, and lacerations. Knowing the physics at play and how different organ systems react is key to understanding blunt force injuries. Understanding and evaluating injuries and deaths in which these forces may have played a role requires basic knowledge of these injuries and how to distinguish them from other types of trauma; recognition of patterned injuries; and recognition of patterns of injury. This lecture will provide a comprehensive review of these issues. (Presenter—Katherine Maloney, MD)

Hyperactive delirium (previously called "excited delirium") is a potentially fatal delirium that may be caused by a variety of diseases and intoxications. It may be encountered by first responders who need to recognize it as a medical, not a criminal condition. If death occurs while in police custody, the differential diagnosis becomes expanded. This lecture reviews the investigation and certification of these deaths as well as the role of restraint. (Presenter—James Gill, MD)

I92 A Forensic Investigation of Kratom-Related Fatalities: The Mitragynine Paradox

Giulia Bambagiotti, MD, Department of Biomedical Sciences and Public Health, "Politecnica delle Marche" University, Ancona, Italy, Ancona, Marche, Italy; Diletta Berardinelli, PhD, Department of Biomedical Sciences and Public Health, "Politecnica delle Marche" University, Ancona, Italy, Ancona, Marche, Italy; Eva Montanari, PhD, Azienda Ospedaliero Universitaria delle Marche, Ancona, Marche, Italy; Prentiss Jones, Jr., PhD, Western Michigan University Homer Stryker MD School of Medicine, Kalamazoo, MI; Gary W. Kunsman, PhD, Broward County OME Forensic Toxicology Laboratory, Lauderdale, FL; Francesco Paolo Busardò, MD, PhD, Department of Biomedical Sciences and Public Health, "Politecnica delle Marche" University, Ancona, Italy, Ancona, Marche, Italy; Marilyn A. A. Huestis, PhD, Institute of Emerging Health Professions, Thomas Jefferson University, Philadelphia, PA*

Learning Objectives: Attendees will learn the latest information on kratom-related fatalities to better assess cause of death in these cases. Through almost all unpublished autopsy reports, the presentation highlights limitations in postmortem pathology and toxicology, with an emphasis on the misinterpretation of mitragynine as cause of death without complete autopsies and analytical evaluations. Participants will acquire the knowledge to evaluate case completeness, interpret mitragynine findings, and recommend more rigorous forensic standards.

Impact Statement: This presentation aims to improve the forensic community's knowledge of kratom-related deaths by encouraging analytical rigor and standardized methodology when certifying cause of death. As a result, improved postmortem data interpretation, identification of toxicological inconsistencies, and the role of all other exogenous substances will lead to more valid medicolegal conclusions.

Abstract Text: Kratom (*Mitragyna speciosa*) is an increasingly popular psychoactive botanical taken for its stimulant and analgesic effects and, by those with opioid use disorder. Although frequently promoted as a safe alternative for pain relief or opioid withdrawal, the toxicological consequences of kratom remain under investigation. Kratom and its main alkaloid, mitragynine, are not approved by the FDA or EMA for any indication. Mitragynine is identified in a low but increasing percentage of intoxications and fatalities. This research provides a comprehensive and integrated forensic toxicological review of 216 autopsy cases collected from multiple forensic US institutions between 2013 and 2024.[1,2]

All cases were systematically analyzed, focusing on toxicological findings, rigor of the medicolegal approach and consistency of cause-of-death determinations. Data were systematically extracted and listed, including mitragynine concentrations across matrices, instrument methodologies, co-detected substances, subjects' psychiatric and medical histories, circumstantial evidence, autopsy findings and completeness of toxicology testing.

Mitragynine was detected in all reviewed cases; however, it was frequently listed as the cause of death, even when toxicological data were incomplete, absent, or did not support such attribution, highlighting the complexity of attributing causality in polydrug cases. The "mitragynine paradox" is that, in over 216 analyzed cases, mitragynine was the only detected substance in only 19 (blood concentration range 0.02-1.4 mg/L), with wide interindividual variability in concentrations, often overlapping with those reported in living kratom users. Among the 197 polydrug cases, synthetic opioids were the most frequently co-detected substances, followed by cannabinoids and stimulants. In these, mitragynine blood levels ranged between 0.006 and 7.2 mg/L.

Although in medicolegal practice autopsy findings frequently determine the cause of the death, toxicological testing is essential. A limitation observed during the study was that confirmatory toxicological analyses were, in some cases, conducted only partially, revealing substantial variability in forensic practice.

As kratom use continues to rise, the forensic toxicology community faces growing challenges in interpreting and accurately assessing its role in fatal outcomes. This study underscores the importance of comprehensive and standardized methodologies to support accurate cause-of-death determination. In conclusion, a harmonized approach to postmortem kratom evaluation is essential to ensure the accuracy, transparency and integrity of the forensic assessment of emerging substances for public health purposes.

I93 Trends in Cannabinoid Positivity in Fatal Motor Vehicle Collisions: A Retrospective Toxicological Analysis in Connecticut (2018–2024)

Stacy K. Thomas, MD, PhD, Yale New Haven Hospital, Wallingford, CT; James R. Gill, MD, Connecticut Office of the Chief Medical Examiner, Farmington, CT; Amanda L. A Mohr, MS, The Center for Forensic Science Research and Education, Horsham, PA; Michelle S. Clark, MS, CT OCME, Farmington, CT; Susan F. Ely, MD, Department of Pathology, Yale University School of Medicine, New Haven, CT*

Learning Objectives: Attendees will learn how the rate of cannabinoid positivity in fatal Motor Vehicle Collisions (MVC) in Connecticut has changed following legalization of recreational cannabis in 2021, by retrospectively examining cases between 2018 and 2024. This presentation will equip attendees to identify trends in the demographics of cannabinoid users and multidrug use among deceased drivers and pedestrians.

Impact Statement: This presentation will enhance the community's understanding of the impact of cannabis legalization on cannabinoid positivity in MVC fatalities. It will inform on trends that could affect public policy discussions and highlight the need for novel cannabinoid toxicology testing to better predict the extent of impairment.

Abstract Text: Cannabinoid positivity in MVC fatalities has become a topic of public interest, particularly as cannabis legalization expands. In Connecticut, the legalization of recreational cannabis in 2021 has raised questions about potential impacts on impairment and the prevalence of cannabinoids detected in fatal crash victims.[1,2]

A retrospective study was conducted using data from the Connecticut Office of the Chief Medical Examiner for all MVC fatalities between January 1, 2018, and December 31, 2024, providing 3.5 years of data both before and after legalization of cannabis in the state. We hypothesized that cannabinoid-positive MVC fatalities would significantly increase in the years following legalization. Two groups for analysis were created: drivers and pedestrians. Inclusion criteria included that death occurred within seven days of the MVC and that the manner of death was accident. The State's Division of Scientific Services and a commercial forensic toxicology laboratory performed the toxicologic testing that included delta-9 THC, carboxy THC, and 11-hydroxy THC. Data were stratified by year, pre- and post-legalization of cannabis in the state, age group, sex, race, ethnicity, and co-intoxicants. Statistical analysis included chi-square tests with significance defined at $\alpha = 0.05$.

Of the 1,168 driver fatalities meeting inclusion criteria, cannabinoid positivity increased from 32.8% in the 3.5 years pre-legalization of cannabis to 37.9% in the 3.5 years post-legalization ($p=0.789$). Among positive driver cases, the most common demographic was White men, aged 20-29 years. Multidrug detection was common in cannabinoid-positive cases, occurring in 66% of instances, most frequently with ethanol (54%), and cocaine (9%).

Of the 380 pedestrian fatalities meeting inclusion criteria, cannabinoid positivity increased from 11% in the 3.5 years pre-legalization of cannabis to 20.6% in the 3.5 years post-legalization ($p=0.016$). Among positive pedestrian cases, the most common demographic was white men, aged 20-49 years. Multidrug detection was common in cannabinoid-positive cases, occurring in 68.3% of instances, most frequently with ethanol (46.7%) and cocaine (20%).

This study demonstrates a rise in cannabinoid positivity in driver and pedestrian MVC fatalities in Connecticut after cannabis legalization. The findings suggest that cannabis may play a growing role in fatalities involving motor vehicles, and/or a demonstration of greater cannabinoid use following legalization. The challenges with interpreting cannabinoid concentrations and the multidrug findings in many of these deaths complicates the ability to attribute cannabinoid use to operator/pedestrian impairment. These data are useful for understanding and responding to evolving drug trends in traffic fatalities.

I94 A Fatal Mimicker of Gastroenteritis: Pediatric Midgut Volvulus

Isaiah Germolus, BS, University of North Dakota School of Medicine and Health Sciences, Bismarck, ND; Hannah M. Rathgeber, BS, University of North Dakota School of Medicine and Health Sciences, Fargo, ND; Selly Strauch, MD, University of ND school of medicine, Grand Forks, ND; Susan Roe, MD, University of North Dakota School of Medicine and Health Sciences, Grand Forks, ND*

Learning Objectives: After attending this presentation, attendees will: (1) be able to identify life-threatening causes of abdominal pain in pediatric patients; (2) be able to describe the essential parts of a history and physical tailored to determine emergent from non-emergent causes of abdominal pain; and (3) understand the treatment for acute malrotation with volvulus (a.k.a. Lass procedure, detorsion of volvulus, bowel resection if needed).

Impact Statement: This presentation will highlight the importance of ruling out life-threatening causes of abdominal pain such as volvulus, intussusception, and bacterial peritonitis in pediatric patients, while educating the audience on the workup and treatment of these conditions. Secondarily, the presentation will show the crucial role that complete and accurate pathology reporting play in the informed practice of medicine.

Abstract Text: Abdominal pain and digestive symptoms are among the most common presenting symptoms for pediatric emergency department (ED) visits, comprising an estimated 4-5% of all pediatric ED cases.[1] The often-vague presentation of abdominal pain poses a diagnostic challenge, as providers must rely heavily on history and physical examination to distinguish emergent from non-emergent causes.

We present the case of a 4-year-old female who was brought to the ED with 'stomach' problems and was initially discharged with a diagnosis of gastroenteritis based largely on a family member's history of recent gastroenteritis. The patient was returned several hours later due to abdominal distention and deterioration in her condition. She was transferred to a tertiary care center for surgical intervention. Upon laparotomy, extensive bowel infarction was identified; the patient died intraoperatively prior to resection.

Autopsy revealed midgut volvulus with infarction of the small and large bowel with bacterial peritonitis. Additionally, anatomical variations, including a longer mesentery and Meckel's diverticulum, were identified and may have contributed to the condition. The cause of death was determined to be intestinal infarction due to volvulus, classified as a natural death.

This case underscores the importance of maintaining a high index of suspicion for life-threatening causes of abdominal pain in pediatric patients with seemingly benign clinical histories.

I95 A Rare Pediatric Case of Concomitant Gorham-Stout Disease, Symptomatic Tarlov Cysts, and Undiagnosed Chiari I Malformation: Clinical and Medicolegal Implications

Sharon Duzioni, MD, Department of Neurosciences, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health (DINOGMI), University of Genova, Genova, Italy, Genova, Liguria, Italy; Francesca Buffelli, MD, PhD, IRCCS-Istituto Giannina Gaslini, Genova, Italy, Genova, Liguria, Italy; Alessandro Bonsignore, MD, PhD, IRCCS-Istituto Giannina Gaslini, Genova, Section of Legal and Forensic Medicine, Department of Health Sciences (DISSAL), University of Genova, Genova, Italy, Genova, Liguria, Italy; Francesco Lupariello, MD, Legal Medicine Unit, Department of Public Health and Paediatrics, University of Torino, Torino, Italy, Torino, Piemonte, Italy*

Learning Objectives: This presentation aims to provide attendees with a comprehensive understanding of the clinical, surgical, and medicolegal complexities involved in managing rare neurosurgical conditions in pediatric patients. Through the detailed analysis of an unprecedented case involving the coexistence of Gorham-Stout disease, symptomatic Tarlov cysts, and an undiagnosed Chiari I malformation, participants will learn how to recognize the subtle diagnostic signs of each condition, assess the compounded risks they pose when occurring simultaneously, and appreciate the critical importance of a thorough, multidisciplinary preoperative evaluation. Emphasis will be placed on the role of cerebrospinal fluid dynamics in surgical planning, the consequences of underestimating rare anatomical vulnerabilities, and the professional responsibilities associated with managing high-risk cases. The session will also highlight how systematic documentation and forensic analysis can offer valuable insights to enhance clinical decision-making and prevent similar adverse outcomes in future practice.

Impact Statement: This presentation offers a rare and thought-provoking contribution to the forensic science community by analyzing the intersection of clinical complexity and professional liability in a unique pediatric case involving three exceptionally rare neurosurgical conditions. By exploring the diagnostic oversights, surgical risks, and pathophysiological dynamics that led to a fatal outcome, this case highlights critical gaps in risk assessment and multidisciplinary coordination. The medicolegal analysis provides valuable guidance for evaluating standard of care in rare disease management, emphasizing the importance of vigilance, accurate imaging interpretation, and preoperative planning. Ultimately, the case serves as a powerful reference for forensic professionals tasked with assessing medical accountability in scenarios marked by high clinical uncertainty and low prevalence, reinforcing the need for specialized expertise in the evaluation of complex pediatric neurosurgical litigation.

Abstract Text: This paper describes the clinical and medicolegal evolution of an extraordinarily complex pediatric case, culminating in a fatal outcome, characterized by the simultaneous coexistence of three exceptionally rare neurosurgical conditions: Gorham-Stout disease, symptomatic spinal radicular cysts (Tarlov cysts), and a previously unrecognized Chiari I malformation. The combination of these three conditions in a single patient is not currently documented in the international scientific Literature, giving the case a high forensic and cognitive value.[2,6]

Gorham-Stout disease (GDS) is a lymphangioproliferative disorder with progressive osteolysis and vascular invasion of bone tissue, documented in fewer than 350 cases worldwide; spine involvement is even rarer, with about 70 cases described so far.[1,3,4,7] Tarlov cysts, relatively common incidental findings, become symptomatic in pediatric age in less than 1 percent. Chiari I malformation, defined by caudal descent of the cerebellar tonsils, is also rare in childhood but it carries significant risks if not properly diagnosed.[6,8]

Our reported case involves a nine-year-old boy who presented with progressive sciatic pain, later attributed to multiple radicular cysts and widespread osteolytic changes in the spine and pelvis. Total-body MRI revealed findings compatible with Gorham-Stout disease and documented bilateral descent of the cerebellar tonsils, suggestive of Chiari I malformation.[6] Nevertheless, this finding was not recognized preoperatively or considered in surgical planning. During the neurosurgical procedure, aimed at marsupialization of the cysts with dural opening, there was significant cerebrospinal fluid leakage, which was followed by cerebellar herniation with brainstem compression and the patient's death.[4,8]

From a careful medico-legal investigation of the documentation and analysis of radiological images, the fatal event appears pathogenetically attributable to an acute liquor hypotension dynamic in a patient with potential multilevel craniospinal compromise.[6,8] Indeed, the concomitant presence of Chiari I and possible skull base fragility from GSD may have promoted rapid tonsillar displacement with a fatal outcome.[5,7]

In the forensic setting, the professional liability in this case was based on the failure to diagnose and recognize Chiari I Malformation and the underestimation of the anatomical risk associated with the rare systemic condition, Gorham-Stout disease, from which the patient was suffering.

Failure to perform a thorough preoperative multidisciplinary evaluation, together with failure to take appropriate risk-containment measures, such as the use of CSF-preserving techniques or timely review of craniocervical imaging, represents a significant deviation from the standards of prudence, expertise, and diligence required in the clinical-surgical management of low-prevalence, high-complexity conditions.[6,7]

Beyond the obvious need for a multidisciplinary approach in the management of pediatric patients with rare and complex conditions, the reported case represents a significant contribution to the scientific community. Its uniqueness, brought about by the coexistence of three exceptionally rare neurosurgical conditions, makes it a useful reference for understanding the pathophysiological mechanisms involved, assessing surgical risk, and guiding therapeutic planning in similar clinical settings. Documenting and analyzing cases such as this one expands available medical knowledge, offering concrete insights for the development of safer and more personalized operative strategies.[6,9]

I96 *Bacillus Cereus* Pneumonia Causing Death in Infants

Daniel Nguyen, MD, University of New Mexico, Office of the Medical Investigator, Albuquerque, NM*

Learning Objectives: Attendees will: (1) understand the possibility of *B. cereus* in causing pneumonia in infants, (2) understand diagnostic requirement to rule *B. cereus* pneumonia in infants; and (3) understand the standard treatment for *B. cereus* pneumonia in infants.

Impact Statement: The immune system of infants is generally weaker than that of adults, and they are vulnerable to numerous infectious diseases. *B. cereus* is associated with gastrointestinal disturbance in adults with a lesser known effect on infants. Here, our case report highlights that *B. cereus* could cause severe pneumonia and sepsis in infants and could be fatal.

Abstract Text: Early onset pneumonia happens quite common in stillborn and neonates. Multiple bacteria, viruses, fungi have been associated with neonate pneumoniae.[1] *Bacillus cereus* is a gram positive, spore-forming bacterium that is most associated with food poisoning but also reported in localized wounds and systemic infections. There are little reports of *B. cereus* causing fatal pneumonia in neonates.[2] Here we report a case of *B. cereus* fatal in a 24-week-old gestational age female.

The patient was a 24-week-old gestational age female who was born from a 38-year-old mother with little prenatal care and underwent C-section. The neonate developed respiratory failure after two days of being born. The Complete Blood Count was significant for leukopenia with neutropenia. Her respiratory was worsening, so she was then transferred to our hospital for higher level of care. The neonate was first treated with ampicillin and cefepime, and later switched to ampicillin, ceftazidime, and fluconazole. However, the patients showed no improvement, and her clinical status rapidly declined. The patient developed severe metabolic acidosis, bradycardia and subsequently cardiac arrest. The neonate was pronounced dead 3 days after admission and 5 days after born. Autopsy was done with culture of blood, lungs and pleural fluid taken. The autopsy findings were consistent with severe acute pneumonia with necrosis and hemorrhage. Severe bilateral pulmonary and hepatosplenic congestion were also found. Multiple focus of *bacillus* bacteria was also found with in the lungs parenchyma. Blood and lung cultures were both positive for *Bacillus cereus*. The final cause of death was sepsis from acute pneumonia.

Bacillus cereus is a rare cause of acute pneumonia in neonate. It is associated with aggressive process. The mechanism of acquisition is unclear, although there are reported association with surfactant was the source in premature neonates.[2] Due to the rarity of disease, no specific antibiotic treatments are found, although there are reports of meropenem and vancomycin could be effective.[3] This case highlights the importance of considering *B. Cereus* as a cause of pneumonia in neonate to provide the best treatments to the patient.

I97 The Hazards of Hydranencephaly

Jake O'Hearn, BS, University of North Dakota School of Medicine and Health Sciences, Grand Forks, ND; Lily Johnson, BA, University of North Dakota School of Medicine and Health Sciences, Grand Forks, ND; Jared T. Ahrendsen, MD, PhD, Northwestern University Feinberg School of Medicine, Chicago, IL; Susan Roe, MD, University of North Dakota School of Medicine and Health Sciences, Grand Forks, ND; Selly Strauch, MD, University of North Dakota School of Medicine and Health Sciences, Grand Forks, ND*

Learning Objectives: The goals of this presentation are: (1) explain the clinical aspects and pathophysiology of hydranencephaly; (2) identify the risks associated with enteral feeding in pediatric patients with medical complexities; (3) recognize pathogens associated with polymicrobial sepsis; (4) examine the challenges in caring for children with congenital neurological conditions; (5) understand public health implications of infections with *Cronobacter sakazakii*; and (6) acknowledge the role of forensic pathology and autopsy in determining the cause of death in pediatric patients with complex medical histories

Impact Statement: Our case emphasizes the important role of forensic pathology in investigating complex causes of death in medically fragile pediatric patients, particularly those with congenital neurological conditions. More specifically, it showcases the role of thorough postmortem evaluation (autopsy, microbiological testing, and detailed clinical correlation) in evaluating the disease progression from congenital deformity, iatrogenic complication, and infectious etiology to life threatening medical conditions. The identification of *Cronobacter sakazakii*, a reportable pathogen due to public health implications, reinforces forensic pathology's crucial role in disease surveillance as well as outbreak detection and prevention. Additionally, this case broadens the understanding of hydranencephaly by showing an atypically prolonged survival in addition to a rare example of polymicrobial sepsis following enteral intervention. This case aims to contribute valuable insight on cause of death in patients with significant congenital neurologic impairment. Ultimately, this clinical presentation of hydranencephaly with polymicrobial sepsis highlights what is at the core of forensic pathology: to serve both individual families and public health through meticulous investigation, accurate death certification, and timely reporting.

Abstract Text: Hydranencephaly is a rare congenital disorder characterized by absent cerebral hemispheres with preserved basal ganglia, brainstem, and meninges. This condition affects approximately 1.4-2.8 per 100,000 live births per year, but those affected often die in-utero.[1] Neonates born with this condition have a life expectancy rarely exceeding one year.

We report the case of an 18-month-old female with hydranencephaly who suffered from recurrent seizures, development delays, and feeding difficulties. Her survival was aided by a ventriculoperitoneal shunt placed at birth as well as a feeding tube placed just prior to her death to assist with nutrition. Approximately two weeks after feeding tube insertion, she became febrile. Later that night, she had three seizures and struggled to fall asleep. She was found lifeless in bed between her parents the following morning.

Autopsy confirmed findings consistent with hydranencephaly. Postmortem cardiac blood cultures yielded four pathogens: *Enterobacter cloacae*, *Bacillus cereus*, *Acintobacter baumanni*, and *Cronobacter sakazakii*. Human rhinovirus and enterovirus were also detected. This case was reported to the state health department because of the presence of *Cronobacter sakazakii.* The cause of death was determined to be polymicrobial sepsis.

This case highlights the vulnerability of those with hydranencephaly to systemic infections and the risks associated with interventions, such as enteral feeding, in these individuals.

I98 Mitochondrial Disorders Mimicking Child Abuse: A Case of Misdiagnosed Munchausen by Proxy

Lina De Paola, MD, Sapienza University of Rome, Rome, Lazio, Italy; Miriam Ottaviani, MD, Sapienza University of Rome, Rome, Lazio, Italy; Gabriele Napoletano, PhD, Sapienza, University of Rome, Rome, Lazio, Italy; Alessandro Ghamlouch, MD, Sapienza, University of Rome, Rome, Lazio, Italy; Gaia De Angelis, MD, Sapienza, University of Rome, Rome, Lazio, Italy*

Learning Objectives: Participants will learn how mitochondrial genetic disorders can closely mimic clinical presentations of abuse such as Munchausen Syndrome by Proxy (MBP), posing significant challenges in forensic investigations. This presentation will emphasize the critical importance of thoroughly considering metabolic and genetic causes to prevent misdiagnosis, avoid wrongful accusations, and ensure that judicial interventions are based on accurate, evidence-driven conclusions. Understanding these complexities is essential for forensic professionals to uphold justice while safeguarding vulnerable patients and families.

Impact Statement: This presentation will help forensic professionals better recognize rare genetic conditions that can look like signs of child abuse. It will improve diagnostic accuracy and reduce the risk of harm to patients and innocent family members caused by incorrect medicolegal decisions. This knowledge is important to ensure fair and evidence-based forensic investigations.

Abstract Text: Genetic disorders associated with mitochondrial fatty acid β-oxidation deficiency are rare autosomal recessive conditions that typically manifest in early childhood. Affected patients may present with a wide spectrum of symptoms, including hypoglycemia, intermittent hemoglobinuria, muscle weakness, liver dysfunction, as well as neurological and cardiac abnormalities.[1] These clinical presentations may mimic Munchausen Syndrome by Proxy (MBP), a form of factitious disorder imposed on another, often involving the child's mother.[2] In suspected MBP cases, ruling out underlying genetic or metabolic causes is critical to prevent misdiagnosis and potentially severe consequences for both the child and the caregiver.[3] In forensic settings, investigating metabolic and genetic abnormalities can be instrumental in differentiating between abuse, poisoning, and organic disease.

A Caucasian 3-year-old female was hospitalized for upper airway inflammation accompanied by drowsiness and episodes of oxygen desaturation, which rapidly progressed to cardiac arrest. Upon regaining consciousness, the patient experienced abdominal pain and a rapid loss of consciousness following airway suctioning and oxygen administration, requiring intensive care admission and intubation. Toxicological screening was negative for all tested substances except for benzodiazepines. Following a judicial order, the child was placed under supervision while her mother was removed and detained on suspicion of MBP. However, the mother's psychological profile did not align with the typical characteristics of MBP, despite a forensic psychiatrist supporting the diagnosis based solely on toxicological findings. A more comprehensive evaluation, including genetic testing, subsequently revealed a familial mitochondrial disorder, thereby excluding caregiver involvement and refuting the abuse hypothesis.

Timely exclusion or confirmation of alternative diagnoses to MBP is essential before initiating a specific diagnostic or therapeutic pathway or isolating the child from the caregiver. Separation should aim primarily to resolve any ongoing intoxication and prevent the administration of unauthorized medications. Nonetheless, this process is not always straightforward. The resolution of MBP cases can take years and may involve retrospective analyses of medical records and the coordinated input of multiple health care professionals.[4] The largest study on MBP to date, involving 796 cases, confirms the diagnostic complexity and emphasizes the need for clinicians to carefully assess caregivers' behavioral nuances to reach accurate conclusions.[5]

Cases of this nature require investigation by a multidisciplinary team, including forensic physicians, toxicologists, and geneticists, to assess the child's individual pharmacokinetics and evaluate the caregiver's psychological status. Such a comprehensive, integrated approach is essential to avoid overlooking rare genetic conditions. Given the profound familial, social, financial, and legal repercussions of abuse allegations involving minors, a steadfast commitment to objective and rigorous forensic methodology is imperative.[6]

This case warrants attention from the broader scientific community as it highlights the complex overlap between factitious disorder and underlying genetic disease in pediatric patients. It also underscores how delays or misinterpretations in toxicological analysis, when not guided by a stringent forensic approach, can lead to serious diagnostic and ethical failures.

I99 Problems With Popcorn: The Dangers of Pediatric Foreign Body Aspirations

Hunter Olstad, BS, University of North Dakota School of Medicine and Health Sciences, Fargo, ND; Mya Winjum, BS, University of North Dakota School of Medicine and Health Sciences, Fargo, ND; Susan Roe, MD, University of North Dakota School of Medicine and Health Sciences, Fargo, ND; Selly Strauch, MD, University of North Dakota School of Medicine and Health Sciences, Fargo, ND*

Learning Objectives: The objectives of this presentation are to: (1) recognize the age-related risks associated with foreign body aspiration in pediatric populations, particularly in children aged one to two years; (2) understand the critical need for early intervention, including emergent bronchoscopy, in cases of suspected foreign body aspiration to prevent hypoxic injury and fatal outcomes; and (3) discuss prevention strategies, including parental education and anticipatory guidance, to reduce the incidence of foreign body aspiration in pediatric populations.

Impact Statement: This case contributes to the scientific community's understanding of preventable pediatric mortality by highlighting the risks of foreign body aspiration in young children despite widespread awareness of choking hazards. It shows the need for continued education targeting both caregivers and healthcare providers. Additionally, it reinforces the importance of prompt recognition and intervention through emergent bronchoscopy in suspected aspiration cases to improve outcomes. By documenting and analyzing this fatal event, this report calls for strengthened public health initiatives and clinical protocols to reduce morbidity and mortality from foreign body aspiration to improve pediatric patient safety.

Abstract Text: Foreign body aspiration in pediatric patients most commonly occurs between the ages of one and two years and remains a significant contributor to accidental household mortality in this age group.[1] At this stage of development, children lack the necessary dentition and neuromuscular coordination to safely ingest foods such as popcorn and nuts, placing them at elevated risk for airway obstruction.[2] Despite longstanding awareness of these choking hazards, cases of fatal aspiration continue to occur, underscoring the need for ongoing vigilance and prevention efforts, especially in rural locations.[3]

We present the case of a one-and-a-half-year-old child who aspirated a popcorn kernel, leading to bronchial obstruction. The child's mother promptly administered the Heimlich maneuver, reportedly expelling some popcorn; however, the child became unresponsive shortly thereafter. Initial resuscitation efforts were successful, and the return of spontaneous circulation was achieved, but the patient subsequently suffered cardiac arrest and could not be revived. Postmortem examination revealed a corn kernel obstructing the left lower lobe bronchus, with multiple additional kernels found within the gastric contents, confirming aspiration as the cause of death.

This case highlights the critical need for early recognition and emergent bronchoscopy in known or suspected cases of pediatric foreign body aspiration to prevent irreversible hypoxic injury and death.[4] Additionally, targeted public health interventions are necessary to reduce the incidence of these preventable tragedies. Providing parents and caregivers with accessible, clear educational materials emphasizing the risks of specific high-choking-risk foods and outlining safe feeding practices by developmental stage could serve as a valuable preventive measure. Strengthening anticipatory guidance during pediatric visits and incorporating structured mealtime safety education for caregivers of children between one and four years of age may help reduce the frequency of foreign body aspiration and its associated morbidity and mortality in the pediatric population.

I100 The Postmortem Microbiology (PMM) and Its Role in Decoding Sudden Childhood Deaths

Federica Cascone, MD, University of Campania "Luigi Vanvitelli", Naples, Campania, Italy; Mariavictoria De Simone, MD, University of Campania "Luigi Vanvitelli", Naples, Campania, Italy; Carlo Pietro Campobasso, MD, PhD, University of Campania "Luigi Vanvitelli", Naples, Naples, Campania, Italy; Alessandro Feola, MD, PhD, University of Campania "Luigi Vanvitelli", Naples, Campania, Italy; Vittorio Panetta, BSc, UOC Microbiology and Virology, A.O.R.N. "Sant'Anna and San Sebastiano", Caserta, Campania, Italy; Andrea Ronchi, MD, PhD, University of Campania "Luigi Vanvitelli", Naples, Campania, Italy*

Learning Objectives: After attending this presentation, attendees will better understand the diagnostic potential of the Postmortem Microbiology (PMM) in the assessment of the cause of death in sudden childhood deaths, focusing on the sampling protocol and the reliability of the results.

Impact Statement: This presentation will impact the forensic science community by addressing the sampling protocol for biological fluids in forensic autopsy of pediatric deaths and the results of microbiological analysis.

Abstract Text: Postmortem microbiology (PMM) represents a diagnostic tool that, unfortunately, remains underused in routine forensic practice due to the risk of contamination. The recommended sampling protocol showed the reliability of PMM, especially in sudden pediatric deaths, occurred without or with brief medical assistance.[1,2] In these cases, the microbiological analysis of swabs and samples of biological fluids can be crucial for determining the cause of death. Recommended and complementary specimens include samples of blood, serum, nasopharyngeal swab, lung, myocardium, spleen, the cerebrospinal fluid (CSF), but also throat and bronchial swabs, pleural and pericardial fluids, liver, kidney. In this context, two cases of sudden childhood deaths are reported. In both cases, the microbiological analysis showed significant results for the assessment of the cause of death, otherwise unidentified, thanks to an accurate and complete sampling protocol.

Case 1: An 8-year-old female was found dead in her bed, after a history of mucous secretions and respiratory disorders 3 months old. A diagnosis of adenoidal hypertrophy was assessed after medical checks. At autopsy a dark discoloration of the mid-brain was suspicious. Swabs and samples for the PMM were collected. Histological findings showed acute and chronic multifocal inflammatory cell population at the brain, lungs, heart, thymus and adenoidal tissue. The sample from the CSF was positive to *Human Herpesvirus* 6 (HHV-6). Therefore, meningoencephalitis was assessed as cause of death. Pediatricians involved in the medical checks were indicted for medical malpractice.

Case 2: A 6-year-old female, with Down syndrome and ventricular septal defect, showed a rapid deterioration in health with fever, nausea and vomiting. She died a few hours after being admitted to the hospital. An acute gastroenteritis was suspected. During the autopsy several swabs and biological samples were collected for the PMM. Fecal and Intestinal samples were negative. Samples from the pericardial fluid (PF) were positive for *Streptococcus pneumoniae*, *Candida glabrata* and *Enterococcus faecium*. This result was consistent with the histological findings of the heart showing non-ischemic myocardial injuries represented by multifocal inflammatory cells and myocyte necrosis along with fibrosis. The cause of death was attributed to myocarditis. No medical malpractice was assessed for diagnostic delay or misdiagnose.

The two cases show the potential of the PMM in sudden death investigation. This approach requires to follow the recommended protocols for the collection of samples from different biological fluids. In our cases, the microbiological analysis of sterile biological fluids, such as PF and CSF, proved to be highly valuable in determining the cause of death, allowing for the identification of both the site and nature of the infectious.

I101 Thirty Years of Forensic Analysis on Child and Adolescent Deaths in Taiwan: Trends, Risk Factors, and Homicide Characteristics

Szu-Yu Lin, MMed, Institute of Forensic Medicine/Ministry of Justice, Taipei City, Taipei, Taiwan; Hsiao-Ting Chen, BASc, Institute of Forensic Medicine/Ministry of Justice, New Taipei City, New Taipei, Taiwan; Kai-Ping Shaw, PharmD, retirement, New Taipei City, New Taipei, Taiwan*

Learning Objectives: Attendees will understand the analysis of the mortality patterns of children and adolescents in Taiwan over the past 30 years and understand the potential risk factors for each age group.

Impact Statement: The results can serve as a basis for medical frontliner, social work, and child protection systems to identify high-risk cases and support the planning of child abuse prevention, accident protection promotion, and related public policies.

Abstract Text: As Taiwan transitions into an aging society, declining birthrates and child protection have become pressing public concerns. Notably, despite a decreasing youth population, the number of child protection cases continues to rise, underscoring persistent issues of child maltreatment. In response, this study analyzed 46,187 forensic autopsy cases conducted by the Institute of Forensic Medicine, Ministry of Justice, Taiwan, between 1993 and 2022. Of these, 4,180 cases (9.1%) involved decedents under 18 years of age. These cases underwent detailed epidemiological analysis to identify trends in manner of death, associated risk factors, and the characteristics of child homicide.

Natural death represented the most common manner of death (47.3%), followed by accidental death (27.2%). Age-stratified analysis revealed that infant deaths (under 1 year) predominantly resulted from natural causes, particularly pulmonary disease (37.0%) and neonatal conditions (29.7%). Conversely, adolescents (12-18 years) showed increased accidental deaths, primarily from airway obstruction/asphyxia (28.5%) and traffic accidents (18.6%). External causes of death demonstrated positive correlation with increasing age, including falls, drowning, and vehicular incidents.

Suicide cases were characterized by falls from height (37.3%) and drug intoxication (22.0%), indicating significant adolescent self-harm concerns. Homicide cases predominantly involved blunt force trauma (40.7%) and mechanical asphyxia (16.5%). Children under 12 were primarily victimized by parents or close relatives, demonstrating strong associations with domestic violence. Adolescent fatalities more frequently resulted from interpersonal violence involving blunt and sharp force injuries.

This study establishes a comprehensive, nationwide 30-year forensic database of pediatric and adolescent deaths. By delineating age-specific patterns in cause and manner of death, it provides critical insights into risks associated with abuse and neglect. These findings offer an evidence base for medical professionals, social workers, and child protection agencies to identify high-risk individuals and to inform the development of targeted policies and public education aimed at preventing child maltreatment and safeguarding minors.

I102 What to Expect When You Don't Know You're Expecting: A Cryptic Pregnancy With Fatal Consequences

Anna Claudia Caruso, MD, Sapienza University of Rome, Roma, Lazio, Italy; Monica La Greca, APM*, Sapienza, Università di Roma, Roma, Lazio, Italy; Benedetta Baldari, PhD, Sapienza University, Roma, Lazio, Italy; Anna Maria Manta, MD*, Sapienza University of Rome, Rome, Lazio, Italy; Marida Imbriani, MD, Sapienza University of Rome, Rome, Lazio, Italy*

Learning Objectives: Following the presentation, attendees will be able to identify the potential maternal and neonatal risks associated with undiagnosed pregnancies, particularly in patients with significant comorbidities, and discuss the forensic and medicolegal implications of intrapartum neonatal death following unassisted out-of-hospital delivery.

Impact Statement: This case portrays the clinical presentation of cryptic pregnancy and its potential for catastrophic perinatal outcomes, particularly in women with multiple comorbidities. By illustrating the fatal consequences of a missed prenatal diagnosis, the study emphasizes the need for heightened clinical vigilance in women of reproductive age presenting with prolonged amenorrhea. In this sense, comprehensive postmortem investigations can clarify the timing and causes of neonatal death and contribute to improved diagnostic protocols, risk stratification, and, ultimately, patient safety in obstetric care.

Abstract Text: Pregnancy is a paraphysiological state that requires strict monitoring of both the woman and the fetus. In some cases, the woman may be unaware of her gravid state until late gestation or labor (cryptic pregnancy). Unlike concealed pregnancies, cryptic pregnancies may occur in non-psychotic forms, occasionally lacking hallmark signs such as amenorrhea, weight gain, or fetal movements. These conditions carry important clinical and forensic implications, including absence of prenatal care, increased risk of adverse perinatal outcomes, and, in extreme cases, neonaticide.[1-3] A case of a preterm neonate who died following an unassisted out-of-hospital delivery is hereby presented and analyzed.

A 39-year-old woman with multiple comorbidities—type II diabetes mellitus with microvascular complications, dyslipidemia, obesity, hypertension, homozygous MTHFR gene mutation, chronic tobacco use, and a history of recurrent spontaneous miscarriages—reported to her physician prolonged amenorrhea lasting approximately eight months, which had initially been attributed to pharmacological therapy and her underlying chronic conditions. The pregnancy was incidentally diagnosed at around the 32nd week of gestation during a hospital visit for nonspecific abdominal pain.

Three days later, the woman experienced spontaneous labor at home. The emergency response system was activated, and an unresponsive newborn in breech presentation was delivered shortly after. Despite immediate resuscitative efforts, the newborn was declared dead. The mother presented with severe hypertension (180/110 mmHg), consistent with a preeclamptic state. Due to her uncooperative behavior and desire for self-discharge, she underwent psychiatric evaluation, which ruled out the need for compulsory treatment, as she eventually accepted the hospitalization.

The autopsy performed on the newborn revealed signs of acute perinatal asphyxia and hemorrhagic infiltrates on the internal surface of the scalp and on the galea capitis, consistent with obstetric maneuvers performed to assist the delivery. Histological examination showed cerebral edema, subserosal petechial hemorrhages, and the presence of keratin lamellae in the bronchial lumen, indicative of amniotic fluid aspiration. Moreover, the pulmonary architecture appeared predominantly subatelectatic. Taken together, these findings supported a diagnosis of intrapartum death. Toxicological screening ruled out the use of labor-inducing substances, detecting only trace amounts of lidocaine, likely administered during emergency care.

The overall findings were consistent with intrapartum death due to acute cardiorespiratory failure following a sudden, unattended delivery, complicated by breech presentation and significant maternal clinical vulnerability. The failure to diagnose the pregnancy earlier, likely due to the patient's obesity and absence of classic symptoms, resulted in a critical delay in obstetric assessment and management.

This case underlines the importance of maintaining high clinical suspicion in women of reproductive age with prolonged amenorrhea and systemic comorbidities, even in the absence of classic pregnancy signs. It also reaffirms the crucial role of medico-legal autopsy, including histological and toxicological analysis, in distinguishing intrauterine from intrapartum death, identifying exogenous contributing factor, and objectively assessing the adequacy of perinatal care.

I103 A Case of Complex Suicide by Captive-Bolt Gunshot and Hanging

Irene Pradelle, MD, Università degli Studi di Modena e Reggio Emilia, Ferrara, Emilia-Romagna, Italy; Matilde Ruju, MD*, Università Degli Studi di Modena e Reggio Emilia, Sassari, Sardegna, Italy; Luca Diani, MD, Università di Modena e Reggio Emilia, Ferrara, Emilia-Romagna, Italy; Margherita Neri, PhD, University of Ferrara, Ferrara, Emilia-Romagna, Italy; Giada Rovito, MD, University of Modena and Reggio Emilia, Ferrara, Emilia-Romagna, Italy; Alessandra Bergonzini, MD, AUSL Ferrara, Ferrara, Emilia-Romagna, Italy*

Learning Objectives: After attending this presentation, attendees will by familiar with a particular case of complex suicide and about autopsy findings and their relevance in reconstructing the dynamics of death, with emphasis on pathological, histological, and toxicological evaluation.

Impact Statement: This presentation will impact the forensic science community by reporting a case of complex suicide by captive-bolt (slaughterer's gun) gunshot combined with hanging. It will provide a structured approach to determine the sequence of events and lesion vitality, ultimately supporting more accurate cause and manner-of-death determinations in challenging forensic scenarios.

Abstract Text: A "complex suicide" refers to the use of more than one method—either simultaneously or sequentially— to maximize the likelihood of a fatal outcome, typically due to the fear that a single method may fail. We report a case of complex suicide in a 64-year-old man from the province of Ferrara, Italy, involving a self-inflicted captive-bolt gunshot associated with hanging. The man was affected by stage IV colorectal cancer with multiple liver, lung, and bone metastases, for which no further active treatment was available.

The victim was found dead in his home, hanging from a ceiling beam, with a circular penetrating wound on the forehead. Several tools were found nearby, including a ladder, a rope, wires, pliers, and a captive-bolt gun. These findings suggested that the victim climbed the ladder, placed the rope around his neck, and then shot himself in the forehead with the captive-bolt gun, causing him to fall and thereby complete the hanging.

A complete forensic autopsy was performed, including toxicological testing and the sampling of skin specimens from the neck ligature mark and forehead wound for histopathological and histochemical analysis. External examination revealed, in the cervical region, a hard, oblique, and discontinuous ligature mark, with serous vesicles and hemorrhagic ridges. The forehead showed a circular wound, 1 cm (0.4 in) in diameter, with regular margins and an abrasion-contusion ring, without evidence of burning, soot deposition, or gunpowder stippling. Internal findings included subarachnoid and cerebral hemorrhage—especially in the frontal lobes, where bone fragments were embedded—hemoventricle, fractures of both superior horns of the thyroid cartilage, mild pulmonary congestion and edema, metastatic masses in the lungs and liver, peritoneal carcinomatosis, Amussat's sign (transverse intimal lacerations of the internal carotid arteries), and Simon's sign (hemorrhages of the anterior longitudinal ligament at the thoracolumbar junction). Histopathological analysis confirmed vital reactions in the cervical ligature mark. The sodium rhodizonate test on the forehead wound was negative, as were toxicological analyses. The collected findings confirmed suicide as the manner of death, with the cause of death being acute traumatic encephalopathy due to blunt-force injury, combined with acute asphyxia.

Captive-bolt guns are typically used in the meat industry to stun animals before slaughter. These devices consist of a cylindrical metal barrel with a central bolt propelled by compressed air or a blank cartridge and retracted by a spring. The injury produced is usually insufficient to cause death and only serves to render the animal unconscious. In many European countries, captive-bolt guns are classified as tools and do not require a firearms license. Although most fatalities involving captive-bolt guns are suicides, a multidisciplinary forensic approach remains essential to reconstruct the mechanism and the dynamics of death, to rule out any criminal offense.[1,2]

I104 Back to Basics: Defining the Histology of Suicidal Ligature Furrows

Caroline Durham, MD, University of Toledo Medical Center, Toledo, OH; Dwayne A. Wolf, MD, PhD, Lucas County Coroner's Office, Toledo, OH; Nicole Dominiak, MD, Department of Pathology/University of Toledo Medical Center, Toledo, OH*

Learning Objectives: Attendees will gain a clear understanding of the histologic features of typical suicidal ligature furrows and how the histologic features correlate with the gross findings. Attendees will realize why "abrasion" as a common descriptor of these injuries is a misnomer. Finally, attendees will appreciate the larger context (and future goal) of this work, that the very back-to-basic concepts presented here may serve as one differentiator between suicidal hanging vs. homicidal strangulation.

Impact Statement: The impact of this presentation will be to impart a clear understanding of the gross and microscopic features of this common injury and to dispel the loose jargon that has crept into regular usage (even in textbooks); the forensic community will understand how this basic data may serve as one important distinction between cases of suicidal hanging and homicidal strangulation.

Abstract Text: Common forensic textbooks describe suicidal ligature furrows as abrasions, or in many instances, descriptors are simply "groove," or "furrow."[1-3] To our knowledge, none of the current commonly-used textbooks include histology images or even descriptions of the histologic findings. We examined a series of suicidal hanging cases and will present the common and less common features of ligature furrows, correlating the gross features with the histologic appearance. In almost all of these, the epidermis is intact, thus the injuries are not abrasions. Rather, they consist of flattened, hyperchromatic, thinned epidermis, with nuclear streaming (a feature often associated with burns), and denaturation/ compression and desiccation of the underlying dermis with dermal capillary congestion. Intraepithelial collections of serous/proteinaceous material in the stratum corneum is a less common feature, appearing in approximately half of the cases.

Dermal hemorrhage is rare. The time of suspension was documented for each case in this series, with the goal of identifying a "least amount of time" required to create the "typical" appearance of a ligature mark. In our current series, a period of 2 hours is sufficient to create such a lesion (although we cannot exclude the possibility that shorter times may suffice). Demographics, suspension (full/partial), and ligature apparatus were recorded. Our findings on gross and microscopic features in suicidal hanging furrows provide a starting point for the collection of data on histologic features of common injuries, with the future goal of using this data to potentially differentiate cases of suicidal hanging and homicidal strangulation.

I105 Diagnostic Challenge in Forensic Autopsy: Possible Hydrogen Peroxide Ingestion in Caffeine Overdose Suicide

Casem Ballouk, MD, Chief Medical Examiner, Tidewater District, Commonwealth of Virginia, Norfolk, VA; Amber S. Silva, MS, Office of the Chief Medical Examiner, Tidewater District, Commonwealth of Virginia, Norfolk, VA;Wendy M. Gunther, MD, Office of the Chief Medical Examiner, Tidewater District, Commonwealth of Virginia, Norfolk, VA; Nicole M. Masian, APM, Office of the Chief Medical Examiner, Tidewater District, Commonwealth of Virginia, Norfolk, VA*

Learning Objectives: After attending this presentation, attendees will review the clinical and autopsy findings in caffeine and hydrogen peroxide toxicity; evaluate the differences in presentation of caffeine and hydrogen peroxide toxicity; and compare postmortem findings to determine contribution of peroxide versus caffeine to the cause of death.

Impact Statement: This presentation will impact the forensic community by reviewing and comparing the toxicologic and autopsy findings in cases of hydrogen peroxide ingestion and caffeine ingestion suicide.

Abstract Text: Hydrogen peroxide (H_2O_2) is a common household and industrial chemical, with high-concentration formulations (10%–35%) posing serious health risks. Ingestion of H_2O_2 is uncommon in both clinical and forensic settings. Most reported exposures, involving 3% household products, result in mild symptoms; however, ingestion of high-concentration peroxide is far less frequent and significantly more dangerous. 13% of high-concentration ingestions led to serious complications, including gas embolism and, rarely, death.[1] The rapid decomposition of hydrogen peroxide within the mucosa into water and oxygen gas can cause mucosal oxidative injury; high-concentration peroxide ingestion is associated with oropharyngeal burns, hemorrhagic gastritis, and esophagitis.[2]

Caffeine overdose is also rare as a mechanism of suicide. Typical caffeine levels in normal users lie below 25 mcg/mL; toxicity occurs at a mean concentration of 35 mcg/mL; death may occur over 100 mcg/mL.[3] Caffeine toxicity may include tachycardia, gastrointestinal distress, seizures, and death; rarely, erosive esophagitis has been reported from ingestion of caffeine tablets.[4,5]

Symptoms of hydrogen peroxide ingestion vary with concentration. In the emergency setting, diagnosis is clinical, as no specific toxicologic test exists; treatment is supportive, with hyperbaric oxygen used in suspected gas embolism. Mild exposures cause nausea, vomiting, and oral irritation. High-concentration ingestions may result in foamy or bloody emesis, respiratory distress, neurologic symptoms, seizures, or sudden collapse. Unlike aspirin or caffeine, hydrogen peroxide uniquely causes vascular gas embolism and caustic mucosal injury. Esophageal and gastric erosions may progress to perforation. CT imaging, if available, may show portal venous gas, cerebral embolism, or gastric pneumatosis.[6]

A 27-year-old man with a history of mental illness and recent emotional stressors was found vomiting at home after a suspected suicide attempt; family alerted medical staff to a possible hydrogen peroxide ingestion, along with aspirin and caffeine pills. He was last seen alert around 1:00 p.m., was vomiting by 1:30 p.m., and was found unresponsive later that afternoon. He was pronounced dead on arrival at the hospital.

Toxicology revealed a blood caffeine level of 190 mcg/mL. Law enforcement inquired whether autopsy findings could rule out concomitant hydrogen peroxide ingestion. Autopsy revealed pulmonary edema, cerebral edema, focal hepatic steatosis, and mucosal erosions of the distal esophagus extending into the stomach and duodenum. No vascular gas embolism was detected, and the oropharynx and stomach were spared caustic mucosal injury.

Death was ascribed to caffeine toxicity, and hydrogen peroxide, if ingested, likely played no role in the death. This case highlights the forensic difficulty of confirming hydrogen peroxide ingestion at autopsy, and underscores the importance of scene investigation, witness accounts, and unusual autopsy findings in establishing the cause of death.

I106 Engineered Exit: A Multidisciplinary Reconstruction in a Loader Blade Self-Inflicted Death

Damiano Marchesini, MD, Sapienza Università di Roma, Rome, Lazio, Italy; Anna Claudia Caruso, MD, Sapienza University of Rome, Roma, Lazio, Italy; Benedetta Baldari, PhD, Sapienza University, Roma, Lazio, Italy; Flavia Sciuttini, MD*, Sapienza University of Rome, Roma, Lazio, Italy*

Learning Objectives: Attendees will learn how multidisciplinary forensic analysis—including autopsy, mechanical inspection, video surveillance review, and digital evidence—can converge to establish the manner of death in technically complex suicides. This presentation demonstrates the critical value of integrating non-traditional forensic domains to achieve an unequivocal medicolegal determination in the absence of witnesses.

Impact Statement: The case contributes to the forensic understanding of complex suicides involving mechanical systems by demonstrating the value of an integrative methodological approach. It highlights how the convergence of physical, digital, and pathological evidence allows for accurate scene reconstruction and the formulation of a scientifically sound, legally defensible conclusion. Furthermore, the case contributes novel insights to forensic literature, where such self-inflicted deaths by remote-activated machinery remain virtually undocumented and underscores the pivotal role of interdisciplinary evaluation in resolving deaths with ambiguous or atypical dynamics.

Abstract Text: Unusual suicide methods involving heavy machinery pose significant challenges in the forensic determination of the manner of death. This case highlights the importance of scene-based evidence in reconstructing a complex deliberate fatal act and illustrates how structured scientific analysis contributes to the formation of a reliable cause-of-death determination in ambiguous contexts.

A 43-year-old man was found dead inside a private warehouse, with his head trapped beneath the front blade of a loader vehicle. The body was in prone position, lying perpendicularly to the axis of the front blade. The blade rested firmly on the posterior cervical and cranial regions. The deceased was employed at the company operating the facility and had unrestricted access to both the premises and the machinery. A 4.3-meter-long purple load strap with terminal loops was tied to the hydraulic control lever, enabling remote blade activation. The strap's opposite end was located near the body, suggesting intentional manipulation by the victim. The vehicle was turned off at the time of discovery. On-scene documentation included photographic evidence of the body and machinery configuration and the seizure of the strap as physical evidence. No signs of third-party involvement were noted. The mechanical controls of the vehicle were intact and consistent with deliberate use. Surveillance footage confirmed that the victim entered the facility alone, tested the machinery multiple times and ultimately activated the hydraulic blade remotely while positioned beneath it. Digital forensic analysis of his smartphone revealed recent WhatsApp messages expressing psychological distress and suicidal ideation.

Scene documentation and autopsy findings were consistent with the video analysis. The autopsy revealed fatal cervico-cranial trauma, including internal decapitation and extensive hemorrhagic infiltration of the cervical musculature. The injury pattern was anatomically compatible with the reconstructed mechanical event and no defensive injuries were observed. Histological examination confirmed extensive hemorrhagic infiltration and tissue disruption consistent with the compressive trauma. This case underscores not only the value of multidisciplinary forensic investigation, but also the critical role of a detailed medicolegal scene inspection in guiding the reconstruction of complex deaths involving machinery. Although internal decapitation has been documented in forensic literature, it is typically linked to different suicide methods—such as railway impacts, hanging, or sharp-force decapitation. Similarities with known cases concern the anatomical outcome rather than the mechanism of injury, making the present case, marked by a remote, self-inflicted mechanical action, particularly distinctive in its characteristics. When direct eyewitness accounts or conventional evidence are lacking, the integration of dynamic scene analysis, digital video review, technical inspection, autopsy and histological findings allows for the construction of a coherent scientific narrative. It exemplifies how scientifically grounded, convergent findings may support a non-contestable conclusion in the forensic and judicial setting, particularly in rare and technically complex suicides.

I107 Suicide by Evisceration: A Presentation of Three Cases and a Review of the Relevant Literature

Raffaella Campagna, MD, University of Foggia, Bitonto, Puglia, Italy; Maria Antonella Bosco, MD, Università Degli Studi di Foggia, Foggia, Puglia, Italy; Christian Pallante, University of Foggia, Foggia, Puglia, Italy; Wanda Nocerino, PhD, University of Foggia, Foggia, Puglia, Italy; Angela Procaccino, PhD, University of Foggia, Foggia, Puglia, Italy; federica genchi, MD, Università degli studi di Foggia, Foggia, Puglia, Italy*

Learning Objectives: This presentation provides a detailed account of rare suicide cases involving evisceration. Attendees will learn about the value of integrated forensic methods—including scene investigation, histology, and toxicology—in achieving diagnostic certainty in atypical suicides. The presentation also outlines injury patterns and behavioral elements that can mislead early investigative interpretations.

Impact Statement: These findings offer critical insights for forensic pathologists and crime scene investigators dealing with ambiguous death scenarios. By reinforcing the importance of methodical, interdisciplinary analysis, the study promotes higher standards in the evaluation of violent and atypical suicides, ultimately supporting more accurate forensic conclusions and judicial outcomes.

Introduction: Victims of suicide may inflict severe self-injuries and, in cases where death does not occur immediately, may engage in a series of actions that impart complexity to the suicidal act. Such individuals can alter the scene in various ways, potentially raising suspicion of third-party involvement and thus requiring a differential diagnosis between suicide and homicide.[1] This specific typology of suicide accounts for only 1–3% of all suicidal events . The present study reports three cases of suicide by evisceration encountered in our forensic practice, along with a review of the relevant scientific literature.

Methods: Case 1: A male subject was found in an apartment partially destroyed by fire, with signs of evisceration and blood traces distributed across multiple rooms. Case 2: A subject was discovered in his apartment with multiple abdominal wounds; a segment of severed intestinal loops was found at a distance from the body. Case 3: A male individual was found in his residence with multiple abdominal stab wounds and a knife embedded in the epigastric region.[2]

Results: Autopsy findings in all three cases revealed abdominal wounds with protrusion of the intestinal loops, evidence of hemorrhagic infiltration, and, in one case, partial transection of the bowel. Blood traces were widely distributed at the scenes, with signs of footprints and smearing, suggesting post-injury movement within the environment.[3]

Conclusions: Suicides involving evisceration present highly complex scenarios that require a thorough investigation of the victim's personal history, meticulous crime scene examination, and comprehensive autopsy supported by histological and toxicological analyses. The injuries tend to be localized predominantly on the left side of the body, which contains several vital organs, and hesitation wounds are commonly observed. In the presented cases, the scenes were characterized by extensive bloodstains, fire damage, and dissection of intestinal loops—circumstances that necessitated not only contextual analysis but also histological and toxicological testing to confirm the vitality and contemporaneity of the lesions. Only an integrated forensic approach enabled a definitive diagnosis of the cause of death. The rigorous application of appropriate scientific methodologies proved essential in establishing a solid evidentiary basis for the subsequent judicial determinations in each case.

I108 The Ear as a Clue to Asphyxiation: A Rare Case of Otorrhagia in Hanging

Anna Messina, MD, Messina University, Messina, Sicilia, Italy; Vincenzo Cianci, MD*, UNIME, Messina, Sicilia, Italy; Daniela Sapienza, PhD, Unime, Messina, Sicilia, Italy; Cristina Mondello, PhD, University of Messina, Messina, Sicilia, Italy; Beatrice Spadaro, MD, Unime, Messina, Sicilia, Italy; Maria Manno, MD, ASL Novara, Novara, Piemonte, Italy*

Learning Objectives: Attendees of this presentation will understand the awareness regarding otorrhagia as a rare pathological finding detectable in asphyxia caused by compression on the neck exerted by a ligature. Therefore, the importance of defining the pathogenic mechanisms of otorrhagia for a better understanding of the mechanism of death has been stressed.

Impact Statement: The forensic science community will gain a specific focus on otorrhagia in hanging, acquiring expertise on the pathophysiology of the cadaveric sign and its interpretation in terms of vitality or not. The case presentation will also allow the acquisition of knowledge regarding autopsy investigations aimed at determining the cause of otorrhagia.

Abstract Text: Otorrhagia in subjects deceased from asphyxiation caused by neck mechanical compression is a condition rarely described in literature; the few cases documented include both strangulation and hanging cases. However, the pathophysiological mechanisms that lead to otorrhagia in cases of death characterized by signs of neck compression have not yet been fully clarified. Here, we present a case of hanging with bilateral otorrhagia and a review of the literature aimed at summarizing the main evidence related to this rare post-mortem finding.[1-3]

An 84-year-old man was found hanging from a tree by an electric cable; on the body there were, also, signs attributable to a previous suicide attempt. The collection of anamnestic data revealed previous herpetic encephalitis with mild cognitive impairment and psychic disorders under treatment. On cadaveric inspection, the following findings were highlighted: slightly dehydrated skin furrow in the neck with hemorrhagic stains, conjunctival petechiae, bilateral otorrhagia. At the cadaveric section, no fractures of the vault and the base of the skull were observed; an area of bone erosion at the level of petrous rock (on the right) was detected. Otoscopic examination revealed tympanic laceration.

The examination of the organs/tissues of the neck showed: small hemorrhagic areas in both peri-thyroid muscles bilaterally and prevertebral soft tissue; transverse intimal lesions of both carotid arteries (Amussat's sign). The main histological findings at routine hematoxylin-eosin staining were organs congestion, large respiratory areas due to rupture of interalveolar septa, cerebral edema and myocardial myofibers break up. The cause of death was traced back to acute mechanical asphyxiation by hanging.

From the literature review, only four cases of otorrhagia were found in subjects who died from strangulation, while five were the cases related to hanging, supporting the exceptional nature of the case presented. The literature reports cases of tympanic injuries with and without otorrhagia (i.e., hemotympanum). Regarding the mechanisms, two dynamics are suggested. The first is triggered by the obstruction of venous return from the jugular vein, which affects the veins that drain the middle ear, thereby causing vascular congestion and otorrhagia. The second mechanism is based on the hypothesis that an extreme respiratory effort with closed glottis (the ligature pushes back and up the base of the tongue, causing the closure of the upper respiratory tract) can lead to an increase in pressure that, through the Eustachian tube, also affects the middle ear, promoting barotrauma.

The presented case and the review of the literature suggest that otorrhagia is a rare sign of vitality in asphyxia due to neck compression by ligature. Furthermore, the case suggests the use of otoscopy as a useful diagnostic tool in such deaths.

I109 Troubles With Dying? Plan Your Suicide

Niccolo' Melloni, MD, ASL Città di Torino, Rivoli, Piemonte, Italy; Enrico Gerace, BS, Centro Regionale Antidoping "Alessandro Bertinara", Torino, Piemonte, Italy; Roberto Testi, MD, ASL Città di Torino, Torino, Piemonte, Italy; Silvia Boca, MD, ASL Città di Torino, Torino, Piemonte, Italy*

Learning Objectives: After attending this presentation, attendees will learn how toxicological analysis, combined with autopsy findings and histological analysis, are crucial in a case of planned suicide via voluntary ingestion of multiple pharmacological substances.

Impact Statement: This presentation will impact the forensic science community by providing information on effects of Sodium Nitrite Poisoning associated with other drug substances ingestion, in a case of planned suicide.

Abstract Text: This forensic pathology case involves the death of a 56-year-old European male found deceased in his home in Northern Italy, in the summer 2023. A detailed suicide plan was reconstructed from multiple handwritten and computer-typed notes found at the scene, which provided explicit instructions regarding the substances used and the intended physiological effects. The decedent had extensively researched suicide methods online, particularly through contact with an anonymous individual on an illegal website specializing in euthanasia techniques.

The deceased documented a multi-step suicide protocol involving:

- A preparatory fasting period (at least 12–24 hours) and limited fluid intake.
- Prophylactic administration of metoclopramide (Plasil) to prevent vomiting (10 mg tablets every 8 hours the day prior, and 30 mg on the night of death).
- Oral ingestion of approximately 600 mg of oxazepam (20 tablets of 30 mg), a benzodiazepine with sedative properties.
- Immediate ingestion of 25 grams of sodium nitrite, dissolved in water—a dose significantly above the estimated human lethal threshold (~4 g).
- Positioning of the body on a prepared resting area to minimize trauma during the terminal phase.
- The deceased also left digital documentation (note files in his cellphone) and physical instructions intended to facilitate identification, evidence preservation, and the management of his remains.
- The autopsy revealed:

External Examination: Cyanosis of the face and nail beds, conjunctival hyperemia, reddish foam and blood-tinged fluid in the oral cavity, dorsal petechiae.

Internal Examination: Mild cerebral edema and vascular congestion. Lungs were markedly edematous and congested, with foamy blood exudate on sectioning. The heart showed no gross structural pathology but had signs of early myocardial stress. Other organs showed signs of vascular congestion but no acute pathology. The histological analysis confirmed multi-organ vascular congestion, severe hepatic steatosis with porto-portal and porto-central fibrotic bridges, and pulmonary edema.

Toxicological analysis, performed on blood, urine, vitreous humor, gastric contents, and hair samples, identified the following substances:

Blood:
Oxazepam: 0.23 mg/L
7-Aminoclonazepam (active metabolite of clonazepam): 0.55 mg/L (toxic range)
Lormetazepam: 0.01 mg/L
Metoclopramide: 0.60 mg/L
Loperamide: 0.008 mg/L
Ethanol: 0.18 g/L
Methemoglobin: 32.7% (indicative of severe nitrite poisoning; normal < 2%)

Urine:
Oxazepam: 43.6 mg/L
7-Aminoclonazepam: 1.04 mg/L
Lormetazepam: 3.05 mg/L
Lorazepam: 0.10 mg/L

These findings support acute intoxication by multiple central nervous system depressants—benzodiazepines and alcohol—in combination with sodium nitrite, a potent oxidizing agent that induces methemoglobinemia, impeding oxygen transport and causing hypoxia.

Death was attributed to acute heart failure and pulmonary edema secondary to voluntary intoxication with sodium nitrite and CNS depressants (benzodiazepines and ethanol). The combination led to profound hypoxia, sedation, and cardiovascular collapse. The scene investigation, autopsy, toxicology, and circumstantial evidence collectively support a conclusion of planned suicide without external signs of traumatic events.[1-3]

I110 The Application of Postmortem Micro-Computed Tomography (PM-microCT) in the Analysis of Fatal Neck Compression in Advanced Decomposed Bodies

Matteo Scopetti, MD, PhD, Sapienza University of Rome, Rome, Lazio, Italy; Martina Padovano, MD*, Sapienza University of Rome, Rome, Lazio, Italy; Maria Chiara David, PhD, Ministry of the Interior, Department of Public Security, Health Central Directorate, Research Center and Forensic Toxicology Laboratory, Rome, Italy, Rome, Lazio, Italy; Chantal Milani, PhD, University of Salerno, Salerno, Campania, Italy; Francesca Consalvo, MD, University of Salerno, Salerno, Campania, Italy; Stefano Vanin, PhD, University of Genoa, Geona, Liguria, Italy; Alessandro Santurro, MD, PhD*, University of Salerno, Salerno, Campania, Italy; Vittorio Fineschi, MD, PhD, Sapienza University of Rome, Rome, Lazio, Italy*

Learning Objectives: This paper aims to explore operative advantages and limits of PM-microCT in the analysis of fatal neck compression, illustrating the possible applications in case of advanced decomposed bodies.

Impact Statement: This presentation will impact the forensic scientific community by potential advantages and limits of cervical lesions detection through postmortem imagining techniques conducted by PM-microCT. Operative analysis and comparison with other imaging techniques (conventional radiography by Postmortem plan X-ray and Postmortem Computed Tomography [PMCT]) and immunohistochemistry will also be explored.

Abstract Text: Micro-computed tomography (micro-CT) is a non-destructive and highly sensitive technique allowing the acquisition of high-resolution cross-sectional images with pixel size in the micrometer range, providing high qualitative and quantitative information. In the last decade, forensic applications have progressively increased, with current main applications of this tool in forensic pathology, anthropology, odontology, and neonatology. In particular, regarding bone and cartilage, micro-CT has been used for evaluating morphometric features and obtaining detailed information about tissue micro-architecture and composition, allowing detection and characterization of skeletal injuries with a sub-millimeter accuracy by high-definition 3D reconstructions.

We present a case of a 29-year-old woman, found dead in a state of advanced decomposition, almost skeletonized and poorly preserved. Autopsy and anthropological-odontological investigations were performed on the cadaveric remains, documenting the presence, in the cervical region, of a portion of hyoid bone corresponding to the body and the right greater horn, with the left greater horn being completely absent. Residual peri-hyoid soft tissues were also present, while all other cervical structures were absent.

Therefore, conventional radiography investigations were performed using Postmortem plan X-ray and Postmortem Computed Tomography (PMCT), which did not allow the detection of useful elements. A Postmortem micro-Computed Tomography (PM-microCT) was then performed using the Bruker Skyscan 1272 micro-CT system (X-ray source 20-100 kV, 10W, < 5 µm spot size at 4 W, X-ray detector 16Mp, Maximum object size 75 mm diameter 80 mm height, Detail detectability 0.35 µm at highest magnification), obtaining multi-planar and volumetric images. PM-microCT allowed to detect the presence of a traumatic lesion of the hyoid bone, in the region located between the body and the absent left greater horn, characterized by an irregular surface with exposure of the spongiosa and the bone trabeculation.

The traumatic aspect was confirmed by subsequent histological exams, with evidence of irregularities and interruptions in the continuity of the osteo-cartilaginous structure in the area of interest, with a fragmented and disintegrated appearance, as well as by immunohistochemical exams, with evident positivity to the reaction with anti-glycophorin A (anti-GYPA) antibodies at the level of the peri-hyoid muscle tissues and near to the fragmented end of the hyoid body, indicative of a peri-hyoid blood infiltration characterized by vitality. Ultimately, therefore, these elements were found to be overall coherent and certainly indicative of a fatal neck compression.

This case demonstrates the potential of PM-microCT - in case of advanced decomposed bodies - in the study and investigation of lesions of the cervical structures, even of minimal entity, which could be undetected even with an accurate examination. In this sense, PM-microCT has proven to be a particularly useful tool in cases of suspected neck compression, especially in cases where conventional radiology and PMCT are not able to provide decisive data. In such cases, PM-microCT has allowed the detection of even minimal alterations with greater detail. Finally, it should be emphasized that, however, for the evaluation of the soft tissues, even if residual, histological and immunohistochemical examinations are fundamental, also for determining the vitality of the lesion.

Postmortem Micro-Computed Tomography; Fatal Neck Compression; Decomposed Bodies

I111 From Suicide to Homicide: About One Charred Body and the Contribution of Postmortem Computed Tomography Coupled With Scanning Electron Microscopy Coupled With Energy Dispersive X-Ray Spectroscopy

Fabrice Dedouit, MD, PhD, Toulouse Hospital, Toulouse, Midi-Pyrenees, France; Lise Pestourie, MD, Toulouse Hospital, Toulouse, Midi-Pyrenees, France; Frederic Savall, MD, PhD, Toulouse Hospital, Toulouse, Midi-Pyrenees, France; Norbert Telmon, MD, PhD, Toulouse Hospital, Toulouse, Midi-Pyrenees, France; Marion Vergnault, MD, Toulouse Hospital, Toulouse, Midi-Pyrenees, France; Celine Guilbeau Frugier, MD, PhD, Toulouse Hospital, Toulouse, Midi-Pyrenees, France*

Learning Objectives: This case highlights the crucial contribution of postmortem imaging scanning electron microscopy coupled with energy dispersive X-ray spectroscopy in complex forensic investigations, particularly when bodies are severely degraded. This case can be considered a game changer in the investigation of charred bodies and the need of a multi-disciplinary work. Autopsy alone is not enough in those kinds of cases to reveal crime.

Impact Statement: This presentation will impact the forensic community by providing an example of multi-disciplinary investigation of charred bodies. This presentation will impact the forensic community by providing an example of use of postmortem imaging and scanning electron microscopy coupled with energy dispersive X-ray spectroscopy in complex forensic investigations.

Abstract Text: We present the case of a charred body found inside a car in a forest. The victim was believed to be a single man with a history of depression who had been missing for a week.

Investigators initially suspected suicide, given the deceased's unusual behavior prior to his death and his decision to stop taking his psychiatric medication. Initial investigations of the car revealed no evidence, except for the charred vehicle itself. The Public Prosecutor ordered a medicolegal autopsy, primarily to take toxicological samples and formally identify the deceased. As the body was not examined on site by a forensic pathologist, it was transferred to the medico-legal institute. Investigators collected numerous biological samples (including burnt teeth and bones) near the body. These additional samples were collected in paper bags and left with the charred body in the mortuary bag.

Prior to the autopsy, postmortem computed tomography (PMCT) scans were performed. The PMCT images showed that the body was severely charred, with large parts of the upper and lower limbs and the anterior part of the body missing. However, the PMCT revealed elements that could be used for identification, such as evidence of past double knee surgery and dental care. Furthermore, two centers of tiny metallic foreign bodies were revealed by the PMCT. One center was located at the absent skull base. The other center was located between the remains of the lower limbs and was found in one of the three paper bags left by the investigators with the body. Analysis of the bone fragments revealed that they were from a multi-fragmented skull and calvaria. The foreign objects were suspected to be pellets or bullet fragments. Based on these observations and the suspicion of ballistic trauma, the case became highly suspect. The investigators confirmed that no firearm had been found in the car or near the body.

An autopsy was performed, but the advanced state of charring and fragmentation of the body meant that the cause of death could not be conclusively determined during the procedure. However, tissue samples were taken, guided by the PMCT and the location of the foreign bodies.

As the metal objects were not visible during the autopsy, imaging results were used to inform the decision to examine the skull fragments using scanning electron microscopy coupled with energy dispersive X-ray spectroscopy. This technique determines the chemical composition of metal particles and is primarily employed in routine forensic practice to detect gunshot residue. Scanning electron microscopy coupled with energy dispersive X-ray spectroscopy revealed the presence of metallic particles consistent with gunshot residue, including lead, barium and antimony. This discovery led to the reopening of the investigation and a new examination of the vehicle, revealing bullet holes and impacts.

Several months later, a suspect was arrested and confessed to the firearm-related murder.

I112 The Legal and Investigative Impact of Postmortem CT Imaging in Forensic Deaths

Ilayda Sam, MD, The Council of Forensic Medicine, Amasya Branch Office, Merkez, Amasya, Turkey; Bedirhan sezer Oner, MD, Amasya University Faculty of Medicine, Merkez, Amasya, Turkey; Savas Gorgulu, MD, The Council of Forensic Medicine, Amasya Branch Office, Merkez, Amasya, Turkey; Burcu Akman, MD, Amasya University Faculty of Medicine, Merkez, Amasya, Turkey; Selcuk Cetin, MD, Tokat Gaziosmanpasa University Faculty of Medicine, Tokat, Tokat, Turkey*

Learning Objectives: The goals of this presentation are to evaluate the comparative diagnostic utility of Postmortem Computed Tomography (PMCT) and conventional autopsy or external postmortem examination in forensic investigations and to identify specific case types—such as traffic accidents and firearm-related deaths—in which PMCT can function as a reliable adjunct or, in selected scenarios, a viable non-invasive alternative to traditional autopsy methods.

Impact Statement: This study highlights the diagnostic value of PMCT as a non-invasive and effective complement—or, in specific contexts, an alternative—to traditional autopsy. Particularly in regions where autopsy rates are declining due to cultural, emotional, or religious factors, PMCT offers a promising solution. By systematically comparing imaging findings with autopsy results across a variety of forensic cases, this research provides essential insight into the role of advanced imaging technologies in enhancing modern forensic practice.

Introduction: Forensic science is a specialized discipline within the legal system that applies scientific principles and methodologies to the systematic collection of data through observation and experimentation. Traditionally, postmortem examinations in humans have relied on invasive autopsy techniques, which have long been considered the gold standard.[1] However, autopsy rates have declined globally in recent decades, influenced by various factors including cultural sensitivities, emotional concerns, and religious objections to anatomical dissection.[2] In this context, postmortem computed tomography (PMCT) has emerged as a promising and relatively novel technique. PMCT can be utilized either as an adjunct to conventional autopsy or as an independent, non-invasive alternative for detecting abnormalities, trauma, fractures, and foreign bodies.[3] The aim of this study is to evaluate the comparative advantages of conventional autopsy and postmortem computed tomography to identify the types of cases in which PMCT can be effectively utilized, and to assess the situations in which it may offer superiority over traditional autopsy.

Methods: This retrospective study evaluated forensic cases that underwent postmortem computed tomography followed by autopsy or external postmortem examination in Amasya, Turkey, between 2020 and 2025. The findings obtained from the autopsy or external postmortem examinations were systematically compared with the imaging data acquired through PMCT. All imaging studies were independently reviewed and interpreted by a radiologist at a training and research hospital. Determination of the cause of death was performed according to standard medico-legal protocols

Results: Out of 452 total forensic cases, postmortem imaging was performed in 61 cases (15 females, 46 males), with ages ranging from 1 month to 87 years. Full autopsies were conducted in 32 cases, while 29 underwent external postmortem examination only. Causes of death included traffic accidents (n=24), firearm injuries (n=15), natural causes (n=6), undetermined (n=4), and miscellaneous causes (n=12).

Discussion: According to Article 87 of the Code of Criminal Procedure (CMK), a complete autopsy requires the examination of all three major body cavities. In cases involving severe bodily trauma, Postmortem Computed Tomography has demonstrated superior capability in detecting skeletal injuries that may remain unidentified through conventional autopsy procedures. In one particular case, while an entry wound was evident, no corresponding exit wound could be observed during the autopsy. PMCT imaging facilitated the localization of the bullet, thereby providing critical information regarding the projectile's trajectory. While it may be overly idealistic to consider replacing conventional autopsy with postmortem CT in Turkey at this stage, it is an undeniable fact that PMCT serves as a valuable adjunct to traditional autopsy procedures.

I113 EyePhone: Ocular Pathology Imaging at Your Fingertips

Ashley L. Smith, MD, Wake Forest University School of Medicine Pathology Department, Winston Salem, NC; Patrick E. Lantz, MD, Atrium Health Wake Forest Baptist Medical Center, Winston Salem, NC; Mark Giffen, DO, Wake Forest University School of Medicine, Winston Salem, NC; Joseph Fortin, BS, Atrium Health Wake Forest Baptist Medical Center, Winston Salem, NC*

Learning Objectives: This presentation will: (1) explain a simplified approach to postmortem retinal imaging using a smart phone with a macro lens; (2) recognize practical techniques for capturing clear, detailed retinal images in a forensic setting; and (3) discuss the advantages and limitations of using smart phone-based imaging as an alternative to traditional retinal documentation methods.

Impact Statement: This presentation introduces a simple, cost-effective method for postmortem retinal imaging using smart phone technology, thereby improving the forensic community's capacity to document ocular findings without the need for specialized equipment. This technique supports more accurate forensic retinal evaluations, especially in resource-limited environments.

Abstract Text: Accurate documentation of postmortem retinal pathology is crucial in forensic autopsies, particularly in cases of suspected abusive head trauma and retinal hemorrhages associated with natural disease processes and accidents. While conventional imaging techniques, such as indirect ophthalmoscopy, fundus photography, and optical coherence tomography, yield high-quality images, they often require specialized equipment and expertise that may not be available in many medical examiner offices.

This study evaluates the efficacy of utilizing a smart phone camera equipped with a macro lens as a widely accessible tool for capturing detailed postmortem retinal images of formalin-fixed, enucleated eyes. A 13 mm equivalent ultra-wide lens with an aperture of approximately f/2.2 and a minimum focusing distance of 2 cm was employed.

Upon enucleation, the globes were fixed in 10% neutral-buffered formalin and sectioned coronally through the pars plana or along the pupil-optic nerve plane to expose the retina. The smartphone was stabilized on a tripod to photograph the internal surface of the globe. Despite common challenges associated with retinal photography, including glare and the globe's curvature, high-resolution images were obtained, revealing detailed retinal findings. Proper stabilization and optimal imaging angles were essential for capturing quality images.

This method offers a low-cost alternative to traditional imaging modalities, providing sufficient detail for identifying and documenting forensic findings in postmortem retinas. By leveraging the widespread availability of smart phones with macro lenses, we enhance access to ocular documentation for medical examiners and forensic pathologists, particularly in resource-limited settings. With further refinement and standardization, smartphone-based imaging could become an integral part of routine forensic protocols for postmortem eye examinations.

Postmortem Retinal Photography; Retinal Hemorrhage; Smart Phone

I114 The Postmortem Application of Bioelectrical Impedance Analysis (BIA): Correlations Between Electrical Parameters, BMI, and PMI in a Series of 29 Cases

Maria Cristina Verrina, MD, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Ennio Avolio, PhD, University of Cosenza, Catanzaro, Calabria, Italy; Matteo Antonio Sacco, MD*, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Alessandro Pasquale Tarallo, MD*, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Sabrina Raffaele, MSc, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Ludovico Abenavoli, MD, PhD, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Wandamaria Mazzuca, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Isabella Aquila, MD, PhD*, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy*

Learning Objectives: After attending this presentation, attendees will understand the potential application of BIA in forensic casework and its correlation with Postmortem Interval (PMI).

Impact Statement: This presentation will impact the forensic sciences community by introducing BIA as a promising tool for the estimation of the PMI through a non-destructive, reproducible, and standardized approach.

Introduction: Estimating the postmortem interval (PMI) is a key challenge in forensic medicine. An ideal method should combine simplicity, rapidity, reproducibility, and scientific reliability. Bioelectrical Impedance Analysis (BIA), widely used in clinical settings to assess body composition, measures tissue resistance and reactance to a low-intensity alternating current.[1,2] This experimental study applied BIA to human cadavers to investigate the behavior of bioelectrical parameters—resistance, reactance, impedance, phase angle—and Body Mass Index (BMI) in relation to PMI. The working hypothesis was that specific electrical patterns emerging after death might correlate with PMI, suggesting a new objective and standardized method for postmortem timing.

Materials and Methods: The study was conducted from September to November 2024 at the Institute of Legal Medicine, University Magna Graecia of Catanzaro. Twenty-nine deceased individuals were included, and BIA was performed using a Quantum V Segmental Analyzer (RJL Systems, USA) with standard electrode placement (right hand–right foot). Autopsy was conducted in 13 cases, while 16 were non-autopsied. A subset of the autopsied subjects underwent a second post-autopsy BIA to assess changes induced by autopsy procedures. Recorded data included age, sex, height, weight (used to calculate BMI), cause of death, comorbidities, time of death, and time of BIA. Electrical parameters recorded were resistance (R, Ω), reactance (Xc, Ω), impedance (Z, Ω), and phase angle (°). PMI was expressed in decimal hours. All data were recorded in Excel and analyzed statistically.

Results: PMI ranged from 1.6 to 192.87 hours (mean 38.67 h). Mean resistance was 464.77 Ω (range: 105.5–1053), mean reactance 83.79 Ω (range: 26.9–256.9), mean impedance 472.54 Ω (range: 110.6–1073), and mean phase angle 11.24° (range: 3.3–22.4). Mean BMI was 26.02 kg/m² (range: 9.87–57.03). A moderate positive correlation was found between phase angle and PMI ($r = +0.46$). Reactance had a weak positive correlation with PMI ($r = +0.25$), while resistance and impedance showed no significant correlation ($r = –0.07$ and $–0.05$, respectively). BMI and PMI had no significant association, though a weak negative trend was noted ($r = –0.20$). In ten subjects with double BIA, phase angle increased in post-autopsy readings.

Discussion: This study supports the technical feasibility of postmortem BIA as an auxiliary method for PMI estimation. Among all electrical parameters, phase angle showed the strongest correlation with PMI, with a moderately increasing trend over time. Interestingly, this contrasts with in vivo findings, where cell membrane breakdown leads to a decreasing phase angle. This divergence may reflect unique postmortem electrolyte and structural changes that deserve further investigation. Post-autopsy measurements revealed higher phase angles, likely due to anatomical and volumetric modifications from internal manipulation. Although preliminary, these findings suggest that BIA could become a reproducible, low-impact, and objective tool in forensic thanatochronology.

I115 Rare Fatal Complications of Hemorrhoidal Banding: A Case Series

David B. Behrman, MD, Travis County Medical Examiner's Office, Austin, TX; Bernadette DeRussy, MD, PhD, Travis County Medical Examiner's Office, Austin, TX*

Learning Objectives: After attending this presentation, attendees will be familiar with the rare, potentially fatal complications that can result from hemorrhoidal banding procedures and the importance of a thorough forensic autopsy.

Impact Statement: This presentation will impact the forensic science community by raising awareness of the uncommon, potentially fatal complications associated with hemorrhoidal banding and the importance of a thorough forensic autopsy.

Abstract Text: Hemorrhoidal banding, or rubber band ligation, is commonly used in the outpatient setting for the non-surgical treatment of first- to third-degree internal hemorrhoids. Complications from banding are rare, with the most common being pain and bleeding. Severe infections, including pelvic sepsis, are an extremely rare complication.[1] Since 2022, the Travis County Medical Examiner's Office has reported two cases in which the decedents suffered complications from recent hemorrhoidal banding procedures that caused or contributed to death, occurring up to two weeks after the procedure.

Case 1: A 50-year-old male presented to the hospital and was diagnosed with sepsis and acute proctitis one week after undergoing banding for internal hemorrhoids. He began treatment with antibiotics. He went into cardiac arrest on the second day of admission, and death was pronounced at the hospital despite resuscitative efforts. Autopsy demonstrated edema and thickening of the rectum with rubber bands in place and hemorrhagic soft tissue surrounding the rectum. Microscopic sections of the rectum showed full thickness inflammation and hemorrhage of the rectum and perirectal fat, and sections of the lungs demonstrated acute pneumonia.

Case 2: A 57-year-old female with a history of alcohol abuse and prolapsing hemorrhoids had complained of intermittent bleeding following a banding procedure. She was found deceased in her residence 13 days after undergoing a banding procedure; scene investigation demonstrated blood in and surrounding the toilet in her residence. Autopsy demonstrated erythematous and hemorrhagic rectal mucosa, as well as findings consistent with chronic alcoholism (jaundice, hepatic cirrhosis, and ascites). Of note, hemorrhoids are a common finding in people with hepatic cirrhosis.[2] The postmortem hemoglobin concentration was 2.4 g/dL.

These cases highlight rare complications of hemorrhoidal banding that can cause or contribute to death. Examination of the rectum in decedents with a history of hemorrhoidal banding is crucial for this diagnosis. Quantitation of postmortem hemoglobin can also be helpful when significant bleeding is suspected.[3]

I116 The Fragility of Fistulas: Two Cases of Exsanguination Via AV Fistula

Mikale Kuntz, BS, UND SMHS, Grand Forks, ND; Ally Feland, BS, UND SMHS, Grand Forks, ND; Selly Strauch, MD, UND SMHS, Grand Forks, ND; Susan Roe, MD, UND SMHS, Grand Forks, ND*

Learning Objectives: This presentation will explore two fatal cases of Arteriovenous (AV) fistula disruption, one intentional and one accidental, to highlight the rare but life-threatening complication of exsanguination. Attendees will gain insight into the clinical, forensic, and preventative aspects of AV fistula hemorrhage, emphasizing the importance of patient education and vigilant monitoring. By the end of this presentation, attendees will be able to: (1) describe the pathophysiology and risk factors that contribute to hemorrhage from AV fistulas; (2) differentiate between intentional and unintentional AV fistula disruptions using clinical and forensic findings; and (3) identify key strategies for prevention, including patient education and monitoring practices, to reduce the risk of fatal AV fistula complications.

Impact Statement: This presentation will enhance the forensic science community's understanding of the unique and often overlooked risks associated with AV fistulas. By analyzing two contrasting cases of fatal exsanguination, one intentional, one accidental, it will provide valuable insight into the forensic differentiation of manner of death in AV fistula-related hemorrhage. The discussion will aid forensic pathologists, death investigators, and medical examiners in recognizing key postmortem findings and contextual clues, ultimately improving accuracy in cause and manner of death determinations. Additionally, the presentation emphasizes the need for interdisciplinary collaboration to promote preventive strategies, reinforcing the role of forensic science in informing public health and patient safety initiatives.

Abstract Text: A known and potentially catastrophic complication of arteriovenous (AV) fistulas is life-threatening hemorrhage. Although this complication is rare, the high-flow, arterialized pressure of an AV fistula can result in rapid hemorrhage if disrupted, leading to possible rapid exsanguination. We present two distinct cases of exsanguination via disruption of arteriovenous fistula, contrasted by their intentional and accidental natures. The first case is that of a 54-year-old male found deceased in a bathtub filled with blood, with a needle and attached catheter in his AV fistula. Needle punctures were identified in the exterior and interior aspects of the fistula. The cause of death was ruled exsanguination due to intentional disruption of the AV fistula. The second case is that of a 56-year-old female patient who was found unresponsive, bleeding from her right arm. Despite immediate medical intervention, the patient succumbed to the effects of acute blood loss. The cause of death was determined to be exsanguination due to an unintended disruption of the AV fistula. These cases serve to illustrate the inherent risks associated with AV fistulas and underscore the critical importance of proactive patient education and vigilant monitoring and management to prevent intentional or unintentional harm.

I117 Benzimidazole Opioid-Associated Fatalities Observed at the Harris County Institute of Forensic Sciences: A Case Series

Karan Goel, MD, University of South Alabama , Mobile, AL; Si Gao, MS, Harris County Institute of Forensic Sciences, Houston, TX; Hannah C. Jarvis, MRCS, Harris County Institute of Forensic Sciences, Rosharon, TX*

Learning Objectives: Attendees will learn about the growing prevalence of Benzimidazole Opioids (BOs)/nitazene analogs within the illicit drug supply and trends in the use of the drugs. Pathological findings associated with benzimidazole opioid use will also be conveyed.

Impact Statement: This presentation will provide information on both increased usage of BOs as well as common pathological findings observed in benzimidazole-related fatalities. This study will add to the growing body of research on Novel Synthetic Opioids (NSOs) that the forensic science community at large will refer to and will thereby better recognize trends and effects of these drugs. Disseminated knowledge of NSOs and BOs will allow for better recognition of BO-related deaths and could possibly allow for the development of treatment strategies to prevent overdose deaths from NSOs.

Abstract Text: **Background:** Synthetic benzimidazole opioids (BOs), colloquially known as "nitazenes," are a group of new synthetics opioids (NSOs) increasingly found within the illicit drug supply.[1] Burgeoning pharmacological analysis has shown that multiple analogs are similar in potency to fentanyl if not more so, with high potential for overdose. With the increased presence of nitazenes and ever-growing number of nitazene analogs, a concomitant increase in benzimidazole-related overdoses and fatalities has also occurred.[2] This study aimed to elucidate the prevalence of and trends regarding BO use in the catchment area represented by the Harris County Institute of Forensic Sciences (HCIFS) as well as identify pathological findings in BO-associated fatalities.

Methods: The HCIFS Laboratory Information System database was queried to identify cases in which BOs were detected via postmortem toxicology. case descriptions, dates, demographic data, symptoms, autopsy findings, and toxicology results were tabulated.

Results: 16 cases in which BOs were detected via postmortem toxicology were identified within the database. Among these cases, etonitazepyne (n-pyrrolidino etonitazene) (6.25%, *n=1*), metonitazene (6.25%, *n=1*), protonitazene (12.5%, *n=2*), and protonitazepyne (n-pyrrolidino protonitazene) (75%, *n=12*) were identified. A date range of October 2021 to January 2025 encompassed all the cases included in this study, with 1 case in 2021 (6.25%), 3 cases in 2023 (18.75%), 11 cases in 2024 (68.75%), and 1 case in 2025 (6.25%). Autopsy findings included pulmonary edema (56.25%, *n=9*), urinary retention (37.5%, *n*=6), cerebral edema (31.25%, *n=5*), hypertensive cardiovascular disease (31.25%, *n=5*), cardiomegaly (25%, *n=4*), ventricular hypertrophy (12.5%, *n=2*), hepatosplenomegaly (12.5%, *n*=2), splenomegaly (12.5%, *n*=2), foam cone/plume of froth (12.5%, *n*=2), and atherosclerotic cardiovascular disease (12.5%, *n*=2). Other toxicological findings also included alprazolam (37.5%, *n*=6), bromazolam (18.75%, *n=3*), ethanol (18.75%, *n=3*), promethazine (18.75%, *n=3*), and cocaine metabolites (12.5%, *n*=2).

Conclusions: N-pyrrolidino protonitazene represented the predominant analog found amongst the case cohort and is the only analog represented in cases from 2024 onward. A concomitant increase in BO-related fatalities also occurred within the same period of time, with 68.75% of the cases occurring in 2024. Pathological findings associated with opioid overdoses were also seen amongst the cohort, with pulmonary edema, cerebral edema, and urinary retention representing the most common findings. Postmortem toxicology resulted with concurrent detection of benzodiazepines in the majority of cases.

I118 A Forensic Diagnosis of Acute and Fatal Phosphine Exposure: Environmental, Toxicological, and Histopathological Findings

Elena de Laurentiis, MD, University of Salerno/University of Foggia, Sassano, Campania, Italy; Cristina Elia, MD*, University of Salerno/University of Foggia, Salerno, Campania, Italy; Raffaele Cirillo, MD*, University of Salerno, Agropoli, Campania, Italy; Francesca Consalvo, MD, University of Salerno, Salerno, Campania, Italy; Carmen Sementa, MD, AORN San Giuseppe Moscati, Avellino, Campania, Italy; Vittorio Fineschi, MD, PhD, Sapienza University of Rome, Rome, Lazio, Italy; Alessandro Santurro, MD, PhD, University of Salerno, Salerno, Campania, Italy*

Learning Objectives: This presentation provides a detailed forensic workflow to approach suspected phosphine-related fatalities, especially when direct toxicological markers are undetectable. Attendees will learn how the integration of clinical history, autopsy findings, histopathology, toxicological testing, and environmental data can establish cause of death in complex toxicological cases. The case highlights the value of indirect biomarkers—such as postmortem aluminum levels—as diagnostic aids in cases of suspected phosphine exposure.

Impact Statement: This case expands forensic diagnostic competence in identifying phosphine poisoning even in the absence of direct toxicological confirmation. It promotes the adoption of a multidisciplinary and evidence-integrated approach, increasing diagnostic reliability in environmental toxicology cases. This methodology strengthens the forensic community's capacity to detect and interpret misrecognized or delayed-onset environmental intoxication.

Abstract Text: Phosphine (PH_3) is a highly toxic gas released from aluminum phosphide (AlP), a fumigant pesticide widely used in grain storage. Its cytotoxic effects stem from inhibition of mitochondrial oxidative phosphorylation and the generation of reactive oxygen species (ROS), resulting in severe metabolic dysfunction, acidosis, and cardiopulmonary failure. Human exposure generally occurs via ingestion or inhalation, and early symptoms primarily gastrointestinal are often nonspecific, contributing to delays in diagnosis.

This case underscores the forensic complexity of identifying fatal toxic exposure when direct toxicological confirmation is absent.

A 46-year-old woman presented to the emergency department with abdominal pain and vomiting and was discharged with a diagnosis of gastroenteritis. The following day, she returned in hypovolemic shock, mixed acidosis and pulmonary edema. Despite intensive care for suspected botulinum toxin exposure, she died within hours. Autopsy revealed acute cardiorespiratory failure due to respiratory distress syndrome, cardiac decompensation, and mixed acidosis.

Autopsy findings were nonspecific macroscopically but revealed generalized enteritic changes and submucosal hemorrhages. Histopathological examination demonstrated multiorgan involvement, including diffuse leukocyte infiltration (thyroid, peribronchial, subepicardial, and intramyocardial), alveolar, myocardial, splenic, renal, and intestinal hemorrhages, centrilobular hepatic necrosis, vacuolar hydropic degeneration of hepatocytes, and grade II colliquative myocytolysis. Postmortem microbiological investigations were negative for common enteric and respiratory pathogens.

Toxicological analyses using gas chromatography with flame ionization detection in headspace (GC-FID/HS) performed on both ante- and post-mortem biological samples were negative for phosphine, likely due to its rapid metabolism and exhalation within 12–24 hours. However, inductively coupled plasma mass spectrometry (ICP-MS) detected aluminum concentrations ranging from 30 to 218 µg/L, significantly exceeding the reference value (< 10 µg/L), indicating recent exposure to aluminum phosphide. Upon contact with gastric hydrochloric acid or respiratory mucosa, AlP releases phosphine gas according to the following reaction: $AlP + 3H_2O \rightarrow Al(OH)_3 + PH_3$.

The environmental investigation revealed the recent use of aluminum phosphide for fumigation in the proximity of the victim's home five days before her death. The integration of clinical, autopsy and histological findings, toxicological results, and circumstantial-environmental data supported the diagnosis of acute and fatal phosphine poisoning.

This case highlights the diagnostic challenges associated with environmental toxic exposures, particularly when direct biomarkers are no longer detectable. It underscores the importance of a systematic, multidisciplinary forensic approach. Notably, post-mortem quantification of aluminum may serve as a reliable indirect marker of exposure to metallic phosphides in suspected cases of phosphine intoxication.In conclusion, the identification and forensic interpretation of lethal environmental toxic exposures require comprehensive integration of clinical data, autopsy and histopathological findings, microbiological testing, toxicological analyses, and environmental context. This approach is essential for making well-founded etiologic diagnoses even in cases with high interpretative complexity.

I119 It's Lit: A Case of Accidental Fire and Inhalant Abuse

Luca Tomassini, MD, University of Camerino, Camerino, Marche, Italy; Piergiorgio Fedeli, University of Camerino, Camerino, Marche, Italy; Anna Maria Manta, MD*, Sapienza University of Rome, Rome, Lazio, Italy; Massimo Lancia, MD, PhD, Institute of Legal Medicine, University of Perugia, Perugia, Umbria, Italy; Flavia Sciuttini, MD*, Sapienza University of Rome, Roma, Lazio, Italy; Daniele Paolini, MD, Sapienza University of Rome, Civita Castellana, Lazio, Italy*

Learning Objectives: This case portrays the underestimated dangers of popper use, particularly when combined with other substances like cocaine. It illustrates how their psychoactive and flammable properties can contribute to accidental death in hazardous environments. Forensic professionals should recognize the role of altered psychophysical states in triggering fatal outcomes.

Impact Statement: This presentation will enhance the forensic science community's competence by showing the risks associated with volatile inhalants, substances known for both their psychoactive effects and inflammable properties. Nevertheless, these substances can cause significant dangers in domestic settings and may play a potential role in fatal fire-related accidents, especially in subjects experiencing psyco-physical alterations. Furthermore, this case offers an original contribution to forensic pathology literature, considering the limited number of studies on death following poppers use, since the majority of them focus on the side effects or on the increase in risky sexual behaviors.

Abstract Text: Nitrites are rapid-onset and short-acting potent vasodilators, which gained popularity for recreational use during the 1970s as "poppers". The most common types of inhaled poppers are amyl nitrites and butyl nitrites, which are widely available in the US, often sold as air deodorizers and cleaners, at adult stores, bars, clubs and online.[1] Poppers produce a rush characterized by warm sensations and dizziness, and they are reported to enhance sexual experience and induce euphoria.[2,3] While these are commonly perceived as substances with minimal long-term risk, their psychoactive and flammable properties can contribute to fatal outcomes when combined with other impairing substances and environmental dangers, such as open flames. The following case concerns the accidental death of a 57-year-old man under the influence of poppers and cocaine with the aim of highlighting the potentially fatal consequences of inhalant abuse, particularly in hazardous domestic environments.

A 57-year-old man was found dead by firefighters as his neighbors reported smoke coming from his house. During crime scene investigation, a burnt armchair in the vicinity of a fireplace was noted, with small bottles containing a liquid substance and traces of white powder on the surroundings. The body was on the floor, in a prone position, with the left lower limb flexed at the knee and hip, as in a dynamic crawling position. Upon external examination, the body showed clear signs of carbonization, although limited. Autopsy findings included pulmonary anthracosis, which was confirmed histologically with intense granular accumulation of black material, as a result of aspiration of combustion products. Toxicological analyses of biological fluids and tissues detected the presence of cocaine and its primary metabolite, as well as alkyl nitrites, correlating with the circumstantial evidence of numerous bottles of poppers found on the crime scene. It was concluded that death was caused by accidental exposure to flames, an event facilitated by the subject's psyco-physical impairment due to acute substance intoxication and the use of poppers, known for their flammable as well as psychoactive properties.

This case highlights the potentially fatal consequences of popper use, particularly when combined with other psychoactive substances and hazardous environmental factors such as open flames. Despite their reputation as low-risk recreational drugs, alkyl nitrites possess both psychoactive and highly flammable properties that can significantly impair judgment and motor function. In this case, acute intoxication with poppers and cocaine likely contributed to the victim's inability to respond effectively to a fire, ultimately resulting in accidental death. The findings emphasize the need for greater awareness among forensic experts, and public health authorities regarding the underestimated dangers of inhalant abuse, and the critical role that environmental context plays in substance-related fatalities.

I120 Neuromuscular Death: A Histological and Toxicological Approach to a Rare Strychnine Fatality

Raffaella Vetrini, MD, UNITS, University of Study of Trieste, Trieste, Friuli-Venezia Giulia, Italy; Calogero Cuttaia, MD, UNITS, University of Study of Trieste, Trieste, Friuli-Venezia Giulia, Italy; Riccardo Addobbati, PhD, IRCCS "Burlo Garofolo" Children Hospital and Scientific Institute, Trieste, Italy, Trieste, Friuli-Venezia Giulia, Italy; Emiliana Giacomello, PhD, UNITS, University of Study of Trieste, Trieste, Friuli-Venezia Giulia, Italy;Filippo Bolzan, MD, UNITS, University of Study of Trieste, Trieste, Friuli-Venezia Giulia, Italy; Tommaso Bruscagin, MD, UNITS, University of Study of Trieste, Trieste, Friuli-Venezia Giulia, Italy*

Learning Objectives: At the conclusion of this presentation, attendees will be able to identify the pathological features of strychnine poisoning, recognize the rarity of this suicidal modality in modern forensic practice, and evaluate the added diagnostic value of immunohistochemical and immunofluorescence techniques in neuromuscular toxicology.

Impact Statement: This case demonstrates the forensic and histopathological relevance of integrating advanced molecular tools in the investigation of rare and historically obsolete suicide methods, such as strychnine ingestion, which may otherwise be misdiagnosed without targeted toxicological and histological analysis.

Abstract Text: Strychnine poisoning, a historically known but now virtually obsolete form of suicide in developed countries, presents a unique diagnostic challenge due to its rarity and dramatic clinical presentation. This report describes a case of fatal suicidal strychnine ingestion investigated using advanced forensic histological techniques.

A 50-year-old male with a history of chronic alcoholism was found deceased in a vineyard near his home . A flashlight and an empty canteen containing a vial labeled "Strychnine nitrate" were discovered next to the body. No signs of external trauma or third-party involvement were observed. Autopsy revealed pulmonary edema with abundant foam in the airways and generalized vascular congestion. Histological analysis confirmed these findings and revealed characteristic muscle fiber waviness in the diaphragm, pectoral, and cardiac muscles. Immunohistochemistry for myosin and myoglobin was performed to assess muscle integrity and damage. Also, immunofluorescence techniques using alpha-bungarotoxin were performed.

Toxicological analyses detected high concentrations of strychnine in blood, vitreous humor, and gastric contents, along with a blood alcohol concentration of 1.64 g/L. These findings supported a diagnosis of acute strychnine intoxication, resulting in fatal respiratory muscle hyperexcitability and respiratory failure, exacerbated by alcohol-induced central depression.

This case highlights the forensic importance of combining toxicological data with histological and molecular tools in cases involving rare poisons. Although strychnine is no longer a common suicidal agent, awareness of its pathophysiology and integration of advanced techniques—such as immunofluorescence targeting neuromuscular receptors—can significantly enhance diagnostic accuracy and reinforce cause-of-death determinations in complex cases.[1-3]

I121 A 14-Year Retrospective Analysis of Crash Characteristics in Accidental Motor Vehicle Deaths

Donald Turbiville, MD, Bexar County Medical Examiner's Office, San Antonio, TX; D. Kimberley Molina, MD, Bexar County Medical Examiner's Office, San Antonio, TX*

Learning Objectives: This presentation will: (1) review the epidemiology of traffic fatalities; (2) evaluate for novel crash characteristics in traffic fatalities; and (3) Highlight the potential public health ramifications of trends and patterns seen in motor vehicle deaths.

Impact Statement: The presentation will highlight the demographic features and different crash characteristics, including ejection rates and seat belt use, between vehicle types in traffic fatalities. There are relatively few studies in the forensic pathology literature on crash characteristics in motor vehicle deaths. This presentation will correlate local retrospective data in traffic fatalities with national data and prior studies.

Abstract Text: Motor vehicle collisions are a common cause of fatalities in the United States. Despite advances in motor vehicle, roadway, and crosswalk safety features, motor vehicle deaths remain a significant public health concern. This study aims to analyze the crash characteristics, including demographic features and vehicle type, in accidental motor vehicle fatalities.

All transportation related deaths reported to the Bexar County Medical Examiner's Office from 1/1/2011-12/31/2024 were reviewed. Cases were included if an autopsy was performed and the manner of death was accident. Deaths due to train impacts and aircraft mishaps were excluded as were transportation related deaths where the cause was not related to the collision (i.e., acute intoxications). Demographic information and crash details were extracted and statistical analysis was performed utilizing the Student T-test (continuous variables) and Pearson's Chi-square (categorical variables).

There were 2,088 fatalities identified that met the inclusion criteria. Of those, 1,125 involved motor vehicles, 311 motorcycles, 46 bicycles, and 606 pedestrians. The decedent ages ranged from 0 to 92 years, averaging 40 years, and included 1536 males and 552 females. Among motor vehicle deaths, 847 were drivers, and 270 were passengers. Decedent vehicles included: 493 sedans, 225 pickup trucks, 275 sport utility vehicles (SUVs) and vans, 55 sports cars, and 34 commercial trucks. There were 849 incidents on highways, 1,048 on streets, and 34 in fields and grassy/wooded areas. For motor vehicle deaths, 249 were ejected, 812 were not ejected, 635 had airbag deployment and 204 had no airbag deployment. Crashes involving sedans showed significantly more seatbelt use and airbag deployment and had less ejections; SUVs showed significantly less seatbelt use and airbag deployment and more ejections. Motor vehicle fatalities occurred more often on the highway than pedestrian and bicycle fatalities, which occurred mostly in non-highway settings. The potential reasons for these findings will be discussed along with future directions.

I122 Deaths by Drowning: A Ten-Year Overview in Western Michigan

Jordan Roberson, BS, Western Michigan Homer Stryker M.D. School of Medicine, Kalamazoo, MI; Christopher Nwoke, BA, Western Michigan University Homer Stryker M.D. School of Medicine, Kalamazoo, MI; Abigail J. Grande, MPH, Western Michigan University Homer Stryker M.D. School of Medicine, Kalamazoo, MI; Amanda O. Fisher-Hubbard, MD, Western Michigan Homer Stryker M.D. School of Medicine; Nicolas Kostelecky, MD, Western Michigan University Homer Stryker M.D. School of Medicine, Kalamazoo, MI*

Learning Objectives: The goal of this presentation is to review data from drowning deaths investigated by a Medical Examiner's Office in western Michigan from 2015 to 2024, including demographics of the decedents, location of death, and manner of death. Attendees will become familiar with the importance of accurate and complete death investigation and certification for the purposes of public health and vital statistics as well as potentially for the appropriate implementation of death prevention strategies.

Impact Statement: This presentation will impact the forensic science community by providing a better understanding of the variability of drowning deaths based on location. It will also shed light on the necessity for varied death prevention tactics, an essential public health endeavor as drownings are preventable.

Abstract Text: According to the Centers for Disease Control and Prevention, nationally, unintentional drowning deaths constitute upwards of 4,000 deaths per year and affect all strata of society.[1] Established risk factors include the extremes of age, male sex, limited/no swimming ability, several disabilities, and the use of exogenous substances (e.g., drugs and alcohol) while in or near water.[2] Those unfamiliar with Michigan may not realize that the state is two peninsulas. Additionally, the Great Lakes behave very differently than smaller inland lakes. As the Medical Examiner for multiple counties along the coastline of Lake Michigan and other inland counties with numerous and varied bodies of water, statistics specific to this area would be important for understanding drowning trends as well as for drowning prevention.

The case management system used by the Office of the Medical Examiner at Western Michigan University Homer Stryker M.D. School of Medicine was queried for death certificates where "drowning" was included in Part I (a, b, c, and d) or in Part II. Cases in which a "Drowning" form was completed were also included. This form is used to gather details surrounding circumstances of the drowning event and allows for categorization of the death within the case management system.

The search resulted in 631 cases. Incomplete and duplicate cases were excluded, yielding 303 cases meeting study criteria. Decedents ranged from six months to 96 years in age. Seventy-nine (26%) were female and 224 (74%) were male. The decedents were majority white (238: 79%), followed by African American/Black (44; 15%), Asian (4; 1%), and American Indian/Alaskan Native (3; 1%). Thirteen decedents had a race/ethnicity listed as Other or Unspecified (4%). Eighty-eight percent of deaths were classified as accidents, followed by 9% as suicide. Eleven deaths were classified as indeterminate and two were deemed homicides. Lakes were the most common body of water type for injury occurrence. The zip code with the highest injury rate was 49441, which is located within Muskegon County. The location of injury was most often outside the zip code of residence (54%); however, 60% of drownings occurred within the county of residence.

This review demonstrates that most drowning deaths are accidental and that drowning affects a remarkably wide age range. Notably, lakes were the most common body of water implicated in these water-related fatalities, and most of these incidents occurred outside of the zip code of residence; this raises the possibility that visitors to the state/region may be unfamiliar with the nature of the Great Lakes.

More recently, there have been national, collaborative efforts to develop a Drowning Case Registry focused mainly on childhood drowning fatalities.[3] One of the goals of this registry is to develop a nationally standardized drowning investigation tool. Ultimately, the performance of high-quality death investigations, as well as complete and accurate death certification, will allow for the appropriate allocation of death prevention strategies, including signage, life rings/lifejackets, and even lifeguards.[4]

I123 Fascinating and Mesmerizing: The Deadlier Side of Fireworks

Ami L. Jackson, DO, Pierce County Medical Examiner Office, Milton, WA*

Learning Objectives: Attendees will learn how to safely approach a sudden death involving fireworks, from the scene to the autopsy, and become familiar with additional agencies involved in the investigation of a firework-related death.

Impact Statement: Firework-related deaths are rare, and those involved in the investigation need to be familiar with the unique aspects of these cases, including safety of staff and facilities and the involvement of additional agencies in comparison to an average trauma case.

Abstract Text: Firework related fatalities are relatively rare in the United States, and medicolegal death investigators and forensic pathologists experience with these investigations and autopsies are therefore limited.[1] Deaths due to fireworks have been increasing and those involved in the investigation need to be familiar with the unique elements of these cases, such as fireworks composition and operation, safety considerations, and the resources of additional agencies.[1]

A firework is a device that contains material that is flammable, that upon detonation, will produce a display of vivid colors and loud noises.[2,3] The subsequent explosion is capable of fascinating and mesmerizing children and adults alike, but also capable of causing injuries of many people and fatalities of a few.

An adolescent was holding a firework close to their chest when it detonated, leading to fatal blunt force injuries and retention of firework components in their chest. A scene investigation was performed by the Pierce County Medical Examiner's Office (PCMEO) medicolegal death investigators, and they were told the bomb squad had already been consulted and declined to respond to the scene. An autopsy, with variations to the office's established protocols, was done by a forensic pathologist, with members of the bomb squad in attendance.

This case will be presented to demonstrate the components of investigating a firework related death and the lessons learned. These include scene and autopsy safety, injuries seen in close contact small explosions, safe collection of firework device components retained in a decedent, and working with outside agencies such as bomb squad for optimal safety.

I124 Pediatric Perpetrators and Unusual Weapons: Investigation, Injury Biomechanics, and Manner Determination

Danielle L. Mack, MD, University of Iowa Hospitals and Clinics, Iowa City, IA; Melissa M. Blessing, DO, Johnson County Medical Examiner and University of Iowa Health Care, Iowa City, IA; Maura Thurber, MHS, University of Iowa Health Care, Iowa City, IA; Zeel Naik, MS, Johnson County Medical Examiner Department, Coralville, IA*

Learning Objectives: Attendees will: (1) better understand manner of death determination when the perpetrator is a child, (2) request and compile investigative information to assess volition and biomechanical feasibility of imparting the injury(ies) alongside autopsy findings, and (3) describe central nervous system injuries incurred by penetrating metal hot dog skewer trauma.

Impact Statement: This presentation will strengthen the forensic science community's ability to assess fatal injuries perpetrated by a young (<10 years old) child including biomechanics and manner determination, highlighting the importance of investigation. It will report the first documented metal hot dog skewer death involving the actions of a child as a framework for approaching cases involving a child perpetrator.

Abstract Text: Manner of death classification is a primary responsibility of medical examiners/coroners/justices of the peace (ME/C/JP). Paucity of investigative information is a common limitation. Assessing whether a young child performed a volitional act leading to another person's death, particularly when unwitnessed, adds complexity. Published guidelines address specific scenarios involving a young child, but novel circumstances and injuries provide challenges.[1]

Homicide perpetration by children is uncommon, usually involving firearms and young teenage boys, but occasionally children or girls.[2,3] Accidental deaths caused by a child are more common and frequently involve unintentional firearm discharge.[4] However, classification of these cases as accident is unlikely uniform.[1] Injuries and deaths involving skewers are rare. Those reported are often self-inflicted and occasionally involve children.[5-7] We herein present the case of a 10-year-old boy who died following penetrating head injury caused by a metal hot dog skewer wielded by a 6-year-old girl, including medicolegal investigation, autopsy findings, and manner determination.

The decedent was a normally developed 10-year-old boy engaged in unsupervised "play fighting" with neighborhood girls aged 6 and 7 using metal hot dog skewers with tapered prongs. During this activity, the 6-year-old girl reportedly directed her skewer toward the ground while the decedent simultaneously moved into the skewer path, resulting in right scalp, skull, and brain penetration. The boy was initially conscious, removed the skewer, and alerted his grandfather indoors. He quickly became unresponsive, and emergency responders noted fixed, dilated pupils.

Hospital imaging revealed a right parietal lobe defect with subdural and subarachnoid hemorrhage. He underwent emergent decompressive craniectomy with blood evacuation, removal of injured parenchyma, and dural graft. He was declared brain dead several days later and compassionately extubated. Forensic autopsy showed an indistinct entrance wound within the surgical defect and bone flap with an irregular 0.6 cm right parietal defect near the squamoid suture where the bone was 0.1 cm thick, in addition to several similarly sized smooth, periodic surgical defects. A large hemorrhagic defect involved the right temporal, parietal, and occipital lobes. Global hypoxic ischemic injury and herniation with secondary brainstem ("Duret") hemorrhage were present. Parietal bone histology was within normal limits. Additional investigative information including weight and height of the 6-year-old perpetrator, photograph with scale of a similar skewer, body camera footage, and reenactment description or photographs were requested. The neurosurgical team confirmed scalp and skull entrance wounds. Videotaped interview by a Department of Children and Family Services investigator demonstrated rapport building with the perpetrating child resulting in the sharing of her event account. Following review of all available information including biomechanics literature, the death was classified as accident.[8,9]

This case highlights the unique and difficult determination of manner of death when a child is the responsible party for the injury, and is magnified by a rare weapon type. Deaths caused by children require careful consideration, especially when unwitnessed by adults. Correlation of autopsy examination, injury mechanics, and interviews with the involved children by specialists informed the final manner determination in this case.

I125 "Seventy Years of Forensic Experience (1943-2016): Evolution of Forensic Management in Mass Disasters"

Enrica Macorano, MD, University of Bari, Bari, Puglia, Italy; Francesco Introna, MD, University of Bari, Bari, Puglia, Italy*

Learning Objectives: Participants will gain an in-depth understanding of the methodological foundations of forensic Disaster Victim Identification (DVI) through a comprehensive review of historical mass disaster cases in Apulia, Italy. They will learn how to integrate anthropology, odontology, and genetics in a standardized approach and how these fundamentals can be translated into a regional protocol for unidentified remains.

Impact Statement: By bridging historical evidence with modern forensic techniques, this research highlights the essential role of methodological standardization in mass disaster scenarios. The proposed protocol represents a model for other jurisdictions, reinforcing the scientific fundamentals of DVI and improving both local and national disaster preparedness.

Abstract Text: Background: Mass disasters require coordinated forensic responses to ensure accurate victim identification and dignified handling of remains. In Southern Italy, multiple incidents-from wartime maritime tragedies to recent railway collisions-have emphasized the critical need for structured, multidisciplinary methodologies. This study revisits more than seventy years of experience in Apulia to identify enduring forensic fundamentals and propose a unified protocol.

Methods: A retrospective review of mass disaster cases (1943-2016) in Apulia was conducted, analyzing autopsy reports, anthropological and odontological assessments, and genetic testing outcomes. Data were evaluated against the INTERPOL DVI framework and recent literature on disaster victim management to identify strengths and procedural gaps.[1-3]

Results: The analysis revealed recurring critical issues: heterogeneous documentation, variable integration of anthropological and odontological data, and inconsistent coordination among agencies. Despite these challenges, key forensic fundamentals emerged, including the early application of multidisciplinary approaches and the central role of comparative data collection. Building upon these findings, a new Protocollo d'Intesa was developed to integrate medical-legal authorities, law enforcement, and forensic laboratories under a single standardized framework. The protocol mandates: (1) immediate activation of a DVI task force, (2) mandatory anthropological and odontological examination for unidentified remains, (3) the creation of a shared digital registry, and (4) strict chain of custody guidelines for all post-mortem samples.[4-6]

Conclusion: Revisiting historical cases confirmed that, despite advances in technology, the accuracy and efficiency of DVI rely on the consistent application of fundamental forensic principles. The proposed protocol translates these essentials into an operational model, ensuring methodological rigor and inter-agency cohesion. Returning to the basics of forensic science not only honors past lessons but also provides a resilient framework for future mass disaster responses.

I126 A Rare Death Caused by a Falling Taxidermy Elk Head and an Injury Pattern Analysis

John X. Hu, MD, PhD, Pinal County Medical Examiner's Office, Florence, AZ*

Learning Objectives: After attending this presentation, attendees will be able to recognize the potential dangers associated with a taxidermy elk head mount and be familiar with the injury patterns caused by the antlers.

Impact Statement: This presentation will have a significant impact on the forensic science community by raising awareness of specific patterns of injury caused by harmless taxidermy elk heads, which may be of medicolegal significance for documenting any pathologic features of the wounds and facilitating future assessments of any unwitnessed incidents. Presented here is a study highlighting such an incident that is rarely mentioned in the available literature.

Background: A death directly caused by a falling taxidermy elk head mount has not been reported. We present an incident in which a falling elk head caused fatal injury and analyze the wound patterns.

Scene and autopsy findings: The taxidermy elk head, mounted on the wall at 11 feet high, was being relocated for wall painting. It inadvertently fell and struck a 61-year-old woman, who was standing on the floor. The tines of the antlers made contact and pierced her left shoulder region. She collapsed to the floor, and the elk head dislodged. A copious amount of blood was noted from the wounds and the mouth. She was pronounced deceased at the scene. The elk head taxidermy weighed 35 pounds. Each antler measures 27 inches from the frontal bone and 26 inches across. Five tines were on each antler, ranging from 2 inches to 15 inches in length; the middle three tines ranged from 4 to 6 inches in length. Each tine had a relatively sharp end (0.3 cm) that gradually thickened to a diameter of approximately 3 cm near its base. The puncture wound on the left shoulder displayed features of blunt force and sharp force injuries. There are focal abrasions on the edge of the wound with jagged edges. There is a curved indentation in the rib with a greenstick fracture. Internally, there are puncture wounds to the left main bronchus, left pulmonary artery, and the descending thoracic aorta. There is extensive internal bleeding, including aspiration pulmonary hemorrhages bilaterally.

Conclusion and Discussion: We are not aware of any reports of such an incident. We believe the combination of the weight (35 pounds), falling from a great height (11 feet), and antlers with long, pointy tines leads to fatal injuries. The puncture wounds possess features of both sharp force and blunt force injuries. We aim to raise awareness of the potential dangers associated with a mounted elk head and to understand the patterns of injury caused by antlers.

I127 The Advantages and Limits of Postmortem Computed Tomography (PMCT) and 3D Reconstruction in Characterization of Fatal Injuries by Hammers

Elena de Laurentiis, MD, University of Salerno/University of Foggia, Sassano, Campania, Italy; Raffaele Cirillo, MD*, University of Salerno, Agropoli, Campania, Italy; Cristina Elia, MD*, University of Salerno/University of Foggia, Salerno, Campania, Italy; Carmen Sementa, MD, AORN San Giuseppe Moscati, Avellino, Campania, Italy; Federico Battipaglia, Post Graduate School of Forensic and Legal Medicine, University of Foggi, Foggia, Puglia, Italy; Vittorio Fineschi, MD, PhD, Sapienza University of Rome, Rome, Lazio, Italy; Stefania De Simone, PhD, University of Foggia, Foggia, Puglia, Italy; Alessandro Santurro, MD, PhD, University of Salerno, Salerno, Campania, Italy*

Learning Objectives: This presentation aims to explore operative advantages and limits of Postmortem Computed Tomography (PMCT) in the analysis of fatal injuries by hammers, illustrating the characteristic patterns of contusive-fracture injuries caused by a typical blunt instrument.

Impact Statement: This presentation will impact the forensic scientific community by potential advantages and limits of application of postmortem imagining techniques, conducted by PMCT and subsequent 3D reconstruction. An operative analysis will also be conducted on the injury patterns, with a particular focus on blunt instruments such as hammers.

Abstract Text: Postmortem Computed Tomography (PMCT) and 3D reconstruction provide a powerful tool in the evaluation of the causes of death, extremely useful in case of violent deaths as a support to the traditional autopsy. In fact, PMCT and 3D reconstruction can provide crucial information about the localization, number, shape, extension and severity of bony injuries, while external examination and autopsy investigation can better detect soft tissue injuries and vascular injuries. In general, both PMCT and autopsy are considered essential in detecting a considerable number of injuries missed by the other modalities.

We present a homicide case of a 56-year-old man, killed following an assault by an altered subject, who hit the victim and another present and survived person with a blunt instrument. Preliminary to the autopsy, a PMCT with 3D reconstruction was performed, which allowed to highlight different injuries localized at the head, with the presence of multiple fractures of the cranium and in particular 3 areas of depression with multiple bone fragments, oval in shape, with maximum dimensions of approximately 2 x 1.5 cm, located respectively in correspondence with the left parieto-occipital region, the right parieto-occipital region and the occipital region along the posterior median line. The PMCT also showed the presence of acute subdural hemorrhage underlying the large traumatic lesion and signs of pneumocephaly, multiple lacerated-contusive foci of the cerebral parenchyma and diffuse cerebral edema. Finally, in the other body districts, a fracture of the posterior arch of the VI-VII-VIII and IX rib on the right was detected, in the absence of effusions and traumatic lesions to the parenchymatous organs.

The subsequent autopsy examination, in addition to the lesions detected by PMCT, allowed to highlight the presence of numerous cutaneous lesions in the different body districts, some of which had an ecchymotic-excoriated appearance and were semilunar in shape, others were rectangular in shape and parallel to each other, for a total of 22 lesions. The subsequent investigations allowed to identify and recover 2 hammers as possible blunt instrument causative of the lesions, of which hammer "A" was of the carpenter-type and hammer "B" was of the ball-type.

The macroscopic evaluation and comparison analysis allowed to identify hammer "A" as the one used by the murderer to determine the lesions and kill the victim. The reconstruction of the dynamics in the exposed case therefore, starting from the PMCT and the 3D reconstruction, was necessarily based on the macroscopic and detailed analysis of the cutaneous lesions detectable by external examination and autopsy, finally allowing an identification of the blunt instrument used by the murderer by a combined PMCT and autopsy-based evaluation.

I128 Airbag: Lifesaving Device or Lethal Mechanism? A Forensic Analysis of an Emblematic Case

Lucia Tarda, MD, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Matteo Antonio Sacco, MD, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Saverio Gualtieri, MD*, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Roberto Arcadia, MSc, Catanzaro Motor Vehicle Office, Catanzaro, Calabria, Italy; Gerardo Perozziello, PhD, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Roberto Raffaele, MSc*, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Claudia Catia De Pasquale, MSc, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Isabella Aquila, MD, PhD*, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy*

Learning Objectives: After attending this presentation, attendees will understand how a car safety device, if defective or malfunctioning, can become a potentially lethal injury mechanism, emphasizing the crucial role of the autopsy in the dynamic reconstruction of the event.

Impact Statement: This presentation will impact the forensic sciences community by demonstrating how autopsy can contribute not only to determining the cause of death in individual cases but also to revealing public health issues with global implications, as in the case of airbag system malfunctions.

Introduction: The implementation of airbags in vehicles has represented one of the most significant innovations in road safety. However, the use of defective or poorly maintained devices has highlighted cases of serious injuries or deaths, raising growing international concern.[1,2] The forensic analysis of such events allows not only to determine the cause of death but also to identify possible systemic technical defects, with implications for recall policies and industrial revisions.

Materials and Methods: A judicial autopsy was performed, with systematic sampling of organs according to the Ghon technique, by en bloc removal of the heart and lungs. Tissues were subjected to macroscopic examination and then sampled for histopathological analysis. At the same time, biological fluids were collected for toxicological investigations.

Case Report: The victim was a young woman, driver of a vehicle, involved in a frontal collision with another car coming from the opposite direction. The impact occurred at moderate urban speed, in an urban setting.

Results: The autopsy revealed that the cause of death was mechanical asphyxia and hemorrhagic shock secondary to laceration of the right lung and trachea, with simultaneous obstruction of the tracheal airways (asphyxia) and hemorrhagic effusion, caused by a single perforating laceration. Already at external examination, in the right thoracic region, an oval-shaped lacerated wound measuring 3 x 2.2 cm was found, with a skin flap showing jagged and inverted edges; the track extended into the deep muscular layers. The lesion involved the right pectoral muscle, with signs of infiltration, and after removal of the sternal plate and inspection of the thoracic cavity, the lungs appeared anemic and a massive right hemothorax of about 600 cc was observed. The right lung, at the level of the middle lobe, showed a large area of hemorrhagic infiltration with a clear pulmonary laceration. Upon examining the airways, the tracheal carina appeared lacerated and infiltrated, with a metallic object completely obstructing it. At the terminal tracheal niche, a cylindrical, rounded metallic object weighing approximately 20 grams was identified, featuring a flat upper surface and an elongated lower surface resembling a bottle neck, with semi-sharp margins. Additionally, esophageal laceration and pericardial infiltration were observed. During the autopsy, the wound edges were compared with the object, and complete compatibility was found. The investigation of the vehicle's safety system components revealed that the metallic object was part of the airbag device. This defective component had exploded and, like a projectile, fatally injured the woman.

Discussion: In the literature, only a few cases have been reported in which death was caused by the explosion of a defective airbag containing a similar cylindrical object found during autopsy. In those cases, injuries to the carotids, jugular veins, penetrating neck injuries, and cervical vertebral trauma were described. These findings reflect the need to increase oversight of vehicle safety systems, which—while designed to be lifesaving—can become potentially lethal mechanisms if defective.

I129 The Analysis of a Sudden Death Case Related to a Wild Boar Trap Injury

Saverio Gualtieri, MD, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Matteo Antonio Sacco, MD*, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Massimo Musardo, LLB, Italian Finance Police, Catanzaro, Calabria, Italy; Aurora Princi, MD, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Pietro Tarzia, MD*, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Stefano Lombardo, MD, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy; Isabella Aquila, MD, PhD*, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Calabria, Italy*

Learning Objectives: After attending this presentation, attendees will understand the critical importance of performing a thorough autopsy in trauma-related cases that may be associated with injuries caused by wildlife trapping devices, enabling accurate forensic reconstructions and legal accountability.

Impact Statement: This presentation will impact the forensic science community by demonstrating how autopsy plays a fundamental role in the multidisciplinary evaluation of complex forensic cases like sudden deaths.

Introduction: Sudden cardiac death is one of the leading causes of mortality in industrialized countries, with an estimated 4 million deaths globally each year. The pathogenesis is often multifactorial, involving acute myocardial ischemia, arrhythmias, and psychophysical stress. This presentation analyzes a peculiar case in which a traumatic event—likely resulting from accidental contact with a rudimentary wild boar trapping device—acted as a potential trigger in a subject with preexisting severe heart disease.

Materials and Methods: A full judicial autopsy was performed, including external inspection with thanatochronological assessment and internal examination of organs, with a particular focus on the heart. Biological fluids were sampled for toxicological and clinical pathology analyses, targeting the detection of psychotropic substances, alcohol, medications, and illicit drugs. Histological analysis of the myocardium and coronary arteries was also carried out. The investigation was supplemented by environmental surveys at the site where the body was found and by a literature review using PubMed and Scopus databases with the keywords: "Forensic sciences," "sudden cardiac death," "traumatic stress," "animal trap injury," and "myocardial ischemia."

Case Report: A 64-year-old man was found in a state of agony near his rural home, with a bleeding wound on his left calf. He was autonomously transported to the emergency department, where he arrived in cardiac arrest. Despite resuscitation attempts, death was pronounced. External inspection revealed a 17 cm curvilinear lacerated-contused wound on the left calf, with an irregular upper edge and a clean lower margin, sutured with eight silk stitches, and a smaller adjacent lesion. The autopsy revealed an enlarged heart with diffuse fatty degeneration of the myocardium, myocardial fibrosis, and severely calcified and occluded coronary arteries. Toxicological analyses were negative except for urinary ethyl alcohol, which was not temporally correlated with the acute event. A forensic site inspection conducted by law enforcement revealed a damaged rope with animal hair, consistent with a rudimentary wild boar trap.

Results: The autopsy confirmed the presence of advanced chronic heart disease, characterized by cardiac hypertrophy, extensive myocardial fibrosis, fatty myocardial degeneration, and marked coronary atherosclerosis with critical occlusions. The traumatic injury—a 17 cm curvilinear wound on the left calf—was not considered lethal. Environmental findings documented a damaged rope with animal hair, consistent with a rudimentary trapping device for wild boars. The medicolegal analysis concluded that death resulted primarily from a natural (cardiac) cause, with a possible contributory stress-related role from the traumatic event, capable of triggering acute ischemia in a vulnerable subject.

Discussion: The collected data revealed a scenario of high cardiac vulnerability, where an acute external stimulus of modest severity—absent other evident causes—may have acted as a trigger, inducing acute ischemia in a subject with severely impaired coronary reserve. The case required an integrated approach, combining autopsy, histology, toxicology, and environmental investigation to determine the pathophysiological cause of death.[1,2]

I130 Beneath the Surface: What a Burned Body Still Reveals

Biancamaria Treves, MD, Sapienza, University of Rome, Rome, Lazio, Italy; Alessandro Ghamlouch, MD, Sapienza, University of Rome, Rome, Lazio, Italy; Gabriele Napoletano, PhD, Sapienza, University of Rome, Rome, Lazio, Italy; Gaia De Angelis, MD, Sapienza, University of Rome, Rome, Lazio, Italy; Maura Racciatti, MD, Sapienza, University of Rome, Rome, Lazio, Italy; Fabio Del Duca, MD, Tor Vergata University, Rome, Lazio, Italy*

Learning Objectives: The aim of this work is to highlight the diagnostic importance of integrating autopsy findings, histological analysis, and Postmortem Computed Tomography (PMCT) in complex forensic cases, with a focus on distinguishing antemortem carbonization from postmortem burning, and clarifying the cause of death in cases involving multiple trauma mechanism (multiple contusions [ecchymoses], head blunt force trauma, mechanical asphyxia due to neck compression, thermal injury).

Impact Statement: This case highlights the critical importance of a multidisciplinary forensic approach—including radiology, autopsy, histology, and entomology—in accurately reconstructing the sequence of events in complex homicides. The integration of postmortem imaging and microscopic analysis was essential to distinguish antemortem trauma from postmortem alterations such as burning. The case underscores how thorough medicolegal investigation can overcome the diagnostic challenges posed by advanced decomposition and thermal damage.

Introduction Complex forensic cases involving multiple trauma mechanisms and post-mortem alterations pose significant diagnostic challenges. Accurate reconstruction of the events leading to death requires a multidisciplinary approach combining autopsy, radiological imaging, histology, toxicology, and entomological analysis. This case illustrates how such integration clarifies both the cause and manner of death, particularly in cases involving burned bodies.

Case Report The body of a 53-year-old woman was discovered in a woodland area in Southern Italy, severely burned and in an advanced state of decomposition with areas of scheletrization and extensive larval colonization. External examination and postmortemCT revealed a depressed skull fracture and a near-complete transection of the right forearm. Autopsy and histological analysis confirmed vital reactions in several injury sites, including subcutaneous hemorrhage in ecchymotic areas. A key finding was a unilateral fracture of the hyoid bone with associated macroscopic and microscopic hemorrhagic infiltration of the sternocleidomastoid muscle, strongly supporting a mechanism of mechanical asphyxia due to neck compression. Macroscopic and microscopic absence of soot or combustion-particles in the airways, with no detectable levels of COHb in toxicological analysis, excluded antemortem inhalation, confirming post-mortem burning.

Discussion The integration of radiological, autoptic, and histopathological findings enabled the reconstruction of a complex lethal sequence involving blunt force head trauma, sharp force wounds, mechanical asphyxia, and postmortem burning. Interpretation was complicated by advanced decomposition, larval colonization, and thermal tissue destruction, which obscured many postmortem signs, making injury timing and vitality assessment particularly challenging. This case underscores the value of multidisciplinary forensic approaches in detecting concealed homicides amid severe cadaveric alterations.[1-6]

I131 Complete Lumbar Spine Transection in an Unrestrained Motor Vehicle Fatality: A Case Study in Biomechanical Failure

Afifa Bhutta, MD, Pinal Country Medical Examiner's Office, Florence, AZ*

Learning Objectives: Attendees will learn to recognize complete lumbar spine transection as a rare but critical injury pattern associated with unrestrained motor vehicle collisions. Through this case, they will understand the forensic significance of spinal trauma as a marker of high-energy flexion-distraction forces and gain insight into how seat belt usage—or lack thereof—shapes injury outcomes during autopsy evaluations.

Impact Statement: This presentation brings attention to a rare but telling autopsy finding—complete lumbar spine transection—in the context of an unrestrained motor vehicle fatality. By highlighting the biomechanical forces involved and the absence of seat belt use, it reinforces the importance of spinal examination in trauma cases and supports injury pattern recognition as a tool for scene reconstruction and public health advocacy. This case has the potential to inform forensic protocols, injury prevention efforts, and medicolegal interpretations of crash fatalities.

Background: While cervical spine injuries are commonly associated with motor vehicle collisions (MVCs), complete transection of the lumbar spine remains a rare and dramatic autopsy finding. When present, it suggests high-energy trauma with specific mechanical forces acting on the torso. This case highlights a complete lumbar spine transection in an unrestrained driver, demonstrating how the absence of seatbelt restraint can lead to catastrophic biomechanical failure.

Case Presentation: A19 year old male was pronounced dead at the scene of a high-speed single-vehicle collision. Scene investigation confirmed no seatbelt use. At autopsy, the most striking finding was a complete transection of the lumbar spine at L2-L3, with full separation of the vertebral column and surrounding soft tissue disruption. The spinal cord was sharply severed, and the torso exhibited additional signs of massive blunt force trauma, including crush injury to the liver, multiple rib fractures, and approximately 1.5 liters of intra-abdominal hemorrhage. No signs of decomposition were present.

Discussion: This injury pattern is consistent with jackknife-type flexion-distraction forces typically modulated by lap belts. In the absence of any restraint, the torso underwent unmitigated forward flexion during rapid deceleration, converting the lumbar spine into a mechanical hinge point—ultimately exceeding its structural integrity. While incomplete lumbar injuries (e.g., Chance fractures) have been well-documented, complete transections remain rare and often indicate violent, unopposed biomechanical loading.

This case underscores the forensic value of spinal examination in crash fatalities. It also emphasizes the narrative power of autopsy findings—particularly in situations where scene reconstruction is limited. Importantly, this case reflects a completely preventable death that reinforces long-standing public health messaging on seatbelt use.

Conclusion: Complete lumbar spine transection is a rare but telling autopsy finding in high-energy MVCs. In the absence of seatbelt restraint, the body is subjected to destructive forces that may lead to otherwise survivable trauma becoming lethal. For forensic pathologists, this case serves as a reminder that injury patterns tell the story—and sometimes, that story is simply: no seatbelt.

I132 Electricity and Home Safety: The Role of Collaboration Between Forensic Pathologists and Engineers in Investigating a Fatal Incident

Raffaele Cirillo, MD, University of Salerno, Agropoli, Campania, Italy; Elena de Laurentiis, MD*, University of Salerno/ University of Foggia, Sassano, Campania, Italy; Davide Radaelli, PhD, university of Trieste, Trieste, Friuli-Venezia Giulia, Italy; Raffaella Vetrini, MD, University of Trieste, trieste, Friuli-Venezia Giulia, Italy; Cristina Elia, MD*, University of Salerno / University of Foggia, Salerno, Campania, Italy; Maria Buffon, MD, University of Trieste, Trieste, Friuli-Venezia Giulia, Italy; Alessandro Santurro, MD, PhD, University of Salerno, Salerno, Campania, Italy; Carmen Sementa, MD, AORN San Giuseppe Moscati, Avellino, Campania, Italy*

Learning Objectives: After this presentation, participants will have gained an in-depth understanding of the distinguishing features of electrocution. They will be able to identify specific manifestations on the body, such as the cutaneous electrical mark, and appreciate its diagnostic value. The importance of a multidisciplinary approach integrating medicolegal and engineering expertise in investigations of suspected electrocution deaths to accurately determine the cause of death will also be underscored.

Impact Statement: This case illustrates how the combination of medical-forensic and engineering expertise can clarify the causes of unusual deaths, prevent diagnostic errors, and contribute to improved product safety. It describes the dramatic consequences of using a non-compliant charger, reinforcing awareness of counterfeit or defective electrical devices and fostering initiatives to prevent their distribution and use. We present the case of an accidental electrocution in a domestic setting due to a non-compliant phone charger, highlighting the importance of a multidisciplinary approach in the medicolegal investigation of such events.

Abstract Text: A 15-year-old girl was found lifeless in the bathroom of her home, inside the bathtub, immersed in water with only her head and neck above the surface, alongside a mobile phone connected to the power outlet via its charger. Upon external examination, the most significant finding was a peculiar skin lesion on the palm of her right hand-firm to the touch and yellowish-brown in color-compatible with an electrical mark at the point of contact with a conductor. No other traumatic external injuries or evident preexisting pathological alterations were noted. In this case, the identification of the mark on the right hand immediately pointed toward the hypothesis of electrocution, later confirmed by technical investigations. The autopsy revealed signs indicative of a rapid death caused by terminal cardiac dysfunction: edema and congestion of the lungs, brain, liver, and kidneys, along with dilation of the right heart chambers and congested vessels, typical evidence of ventricular fibrillation, the usual mechanism of death in electrocution cases.

To clarify the dynamics, a forensic engineering consultation was requested regarding the electrical devices involved. The forensic engineers found a severe manufacturing defect in the phone charger: the device had inadequate insulation and did not comply with current electrical safety standards (non-compliant device). In particular, a failure in the internal insulating component had connected the high-voltage primary circuit (220 V mains) to the low-voltage output circuit of the charger, allowing the direct passage of lethal current.

In this case, only the combined medicolegal (autopsy and inspection) and engineering analysis made it possible to fully reconstruct the incident, distinguishing it from other possible causes of sudden death. This case report highlights the necessity of multidisciplinary forensic investigations in electricity-related deaths and reinforces the importance of using exclusively safe and certified electrical devices.

I133 A Fatal Fall From Flight: A Forensic Case Study

Jerielle Cartales, MSc, Michigan State University, East Lansing, MI; Carolyn V. Isaac, PhD, Michigan State University, East Lansing, MI; Joseph T. Hefner, PhD, MSU, East Lansing, MI*

Learning Objectives: Attendees will gain insight into the issues surrounding the distribution and patterning of skeletal trauma in a fall from extreme height, as well as the reconstruction of a decedent's fall path and estimation of possible fall height range using forensic anthropology, fractography, and aviation data.

Impact Statement: This case report addresses a current lack in the forensic anthropological literature regarding the interpretation of skeletal injury in falls from extreme heights and will supplement the experience of the forensic expert in complex, uncommon death investigations.

Abstract Text: Fall-related aircraft fatalities are relatively rare and present unique challenges to forensic investigators due to the extreme forces involved and numerous individual and environmental variables.[1] This case report presents an adult individual who exited a single-occupant Cessna 172 Skyhawk mid-flight and sustained extensive trauma upon ground impact. The aircraft continued on autopilot until it exhausted its fuel and crashed in a woodland over 500 miles from the decedent's location.

This poster documents the injury pattern of the decedent through a full-body skeletal analysis and fractography study and correlates these findings with known data from high-altitude and free-fall trauma cases. Injuries include extensive comminuted fractures of the axial skeleton and significant cranial vault deformation. At the same time, this individual is unique in the lack of lower limb fractures.[2] In addition to the trauma analysis, we reconstructed the aircraft's possible flight path using publicly available aviation data to assess how aircraft speed, altitude, drag, and possible human behaviors in the moments before exit may have influenced the fall behavior. By integrating osteological data with aviation and geospatial information, this case highlights the forensic potential of injury pattern interpretation in reconstructing dynamic and unusual death events. It underscores the importance of multidisciplinary approaches in interpreting complex skeletal trauma in the field of forensic anthropology.

I134 Homicide by Vehicle Escape: Death From a Leap From a Car in Motion to Escape Sharp Force Injury Inflicted by the Driver

Christian Perez-Torres, MD, Office of the Chief Medical Examiner, Commonwealth of Virginia, Richmond, VA, Richmond, VA; Wendy M. Gunther, MD, Office of the Chief Medical Examiner, Tidewater District, Commonwealth of Virginia, Norfolk, VA*

Learning Objectives: After attending this presentation, attendees will review characteristics of pedestrians struck by vehicles versus persons who sustained injury exiting the vehicle in motion, re-examine sharp force defensive injuries, and evaluate the relative contribution of victim and perpetrator actions in complex homicides.

Impact Statement: This presentation will impact the forensic science community by evaluating the role of sharp force injury assault in death by blunt head trauma in complex homicides and acknowledging the importance of being open to amend prior medicolegal decisions on manner based on new information.

Abstract Text: Blunt force trauma, a common finding in forensic practice, is rarely accompanied by defensive sharp force injuries. Studies have attempted to distinguish injuries caused accidentally from those inflicted by assailants. One such study indicated that the number of facial injuries after blows tends to be higher than those sustained after falls.[1]

Defensive wounds occur when a victim is attempting to shield the body from an attacker.[2] They are usually found on the upper extremities but can also involve other areas. They are essential in reconstructing the events leading to death.[3] Although most are seen in cases of sharp force injury, they can co-occur with other types of injury, such as blunt force.

A 51-year-old female was found unresponsive lying in the street; medics described her as a hit and run pedestrian. Hospital evaluation found multiple blunt force injuries to the head and face, including facial and skull fractures, and subdural hematoma extending into the parenchyma; a hemi-craniectomy did not alleviate the brain swelling. She succumbed to her injuries the following day.

Autopsy confirmed the skull and facial fractures and the brain injury but also documented multiple sharp force injuries to her hands and torso, consistent with defensive wounds. Extensive areas of "road rash" suggested a pedestrian struck by a vehicle, but there were no lower leg injuries to confirm bumper impact. Fingerprint identification provided a history of prior drug offenses. Toxicology demonstrated a low level of fentanyl, methadone, and benzoylecgonine.

Ejection from a vehicle was considered versus hit and run, but no proof was forthcoming. The death was certified as due to blunt force head trauma, with sharp force injuries to the hands and torso contributing, without contribution from the drugs. The manner was undetermined.

Two years after the death certification, police developed perpetrator information from living victims who were able to escape a moving vehicle when attacked by the driver. He confessed to picking up the decedent, sharing cocaine with her, and attacking her with a knife while he drove the vehicle; he said that she had thrown herself from the car through the window. Because she had done so in order to escape sharp force injury, the manner of death was amended to homicide.

The perpetrator confession allowed elucidation of the injuries identified at autopsy. The victim sustained hand tendon injuries while attempting to fend off the knife. It was likely that she could not use her hands to open the vehicle door latch. The automated window could be opened by pressure from her elbow; this left it as the only escape hatch. Falling from the window while the vehicle was in motion resulted in the road rash and the blunt force head injuries that led to her death. She was not a pedestrian struck by a vehicle, but a victim whose death occurred in the process of attempting to escape assault by a knife. Following the trial, the perpetrator was convicted of second-degree murder, forcible sodomy, and abduction; he will serve life in prison.

I135 Justice Across Jurisdictions: An Integrated Analysis of Domestic Violence in the United States and Italy

Cheli Calderon, BS, Florida Gulf Coast University Human Identity and Trauma Analysis Laboratory, Fort Myers, FL; Micki Besse, MS, Florida Gulf Coast University Human Identity and Trauma Analysis Laboratory, Fort Myers, FL; Heather A. Walsh-Haney, PhD, Florida Gulf Coast University, Fort Myers, FL; Melodie Eichbauer, PhD, Florida Gulf Coast University, Fort Myers, FL; Joanna Salapska-Gelleri, PhD, Florida Gulf Coast University, Department of Psychology, Fort Myers, FL; Roshni Ladny, PhD, Florida Gulf Coast University, Department of Justice Studies, Fort Myers, FL*

Learning Objectives: By attending this presentation, attendees will learn more about differences in canon law in Italy and the common law system in the United States with implications on domestic violence identification, reporting, and intervention using a global framework.

Impact Statement: This research impacts the forensic science community because it provides attendees with new information that compares two judicial systems with diverging definitions of domestic violence. This study also provides novel research related to the forensic anthropologist's responsibility to participate in multidisciplinary efforts in addressing this public health crisis.

Abstract Text: Over the past decade, Florida consistently reported high per capita rates of domestic violence (DV).[1] Current literature indicated that increasing mandatory DV training requirements for medicolegal professionals correlated to increased detection and prevention of DV.[2] However, the statutory definition of DV can constrain these practitioners as several preceding well-known risk factors (e.g., psychological abuse, financial abuse, suicide, coercion) for DV homicide do not appear in this legislation.[3] This DV pandemic extends beyond the United States, with one in four females experiencing DV in life globally, and this statistic is gradually approaching one in three females.[4] While these global statistics are widely understood, intercontinental comparisons occur less commonly. This study aims to address this gap in knowledge by comparing the Italian canon law to the United States common law systems.

This study comprised a sample (n=223) of closed, adjudicated forensic anthropology case reports of positively identified adult males (n=151) and females (n=72) who evinced antemortem trauma, perimortem blunt force trauma (BFT), perimortem gunshot trauma (GST), or perimortem sharp force trauma (SFT). The study also included cases of known DV irrespective of trauma presence. These data were statistically evaluated using IBM SPSS statistical analysis software. Blunt force trauma was the most common trauma type in DV and non-DV cases. However, in DV cases, SFT was the second most common trauma type. In contrast, GST was the second most common in non-DV cases ($p > 0.05$). Congruent with the literature, trauma presence alone was not a reliable predictor of DV. However, DV was identified in three male case reports (and represented 2% of all males included in this study) and sixteen females (that represented 22% of all females in this study; $p < 0.001$). These findings coincide with the statewide, national, and global DV averages. Italy's canon law system codifies laws more comprehensively, allowing for a broader legal recognition to include psychological and economic abuse. Other open-access resources with survey data from Italy revealed a low societal tolerance for DV and decreasing rates of physical, psychological, and economic forms of DV though sexual violence and threats of violence slightly increased since 2013.[5] Nevertheless, Italy's social stringency for DV, coupled with the broader definition of DV to include economic and psychological violence manifestations of DV, warrant further investigation in the prevention of DV homicides and DV-motivated suicides.

These findings supported the need for broadening the scope of the state statutory definitions, enhancing forensic training and injury documentation protocols, and implementing integrated interdisciplinary teams of clinical personnel who work with living individuals and those who are employed in medicolegal death investigations contexts, to include the forensic anthropologist. Drawing upon interdisciplinary methods from forensic science, anthropology, criminology, and history, this study investigated how integrated medicolegal frameworks influence the way DV is defined, reported, and adjudicated. While these locations broad recognize DV as a systemic issue, the U.S. and Italy diverge in terms of legal definitions, prosecutorial discretion, mandatory reporting requirements, and survivor support services.

I136 Silent Danger: A Companion Case of Carbon Dioxide Asphyxiation in a Wine Cellar Due to Dry Ice Exposure

Josue L. Fonseca, BS, University of Texas Rio Grande Valley, Houston, TX; Emma Henrie, MD, Harris County Institute of Forensic Sciences, Houston, TX*

Learning Objectives: Attendees will gain an understanding of the fundamental mechanisms of asphyxia due to oxygen displacement by Carbon Dioxide (CO_2), recognize scene and autopsy findings consistent with CO_2-related deaths, and appreciate the forensic significance of environmental context in death investigation.

Impact Statement: This presentation reinforces the importance of scene awareness and foundational knowledge of gas dynamics in the evaluation of suspected asphyxial deaths. The findings will enhance practitioner competence in recognizing environmental contributors to death and foster accurate certification of similar cases in the future.

Abstract Text: This case report presents a companion death investigation of a 67-year-old woman and a 68-year-old man found deceased at the bottom of a staircase within a residential wine cellar during a social gathering. The scene revealed four open buckets of dry ice and a leaking water system, producing conditions conducive to rapid carbon dioxide sublimation. On-scene gas measurements showed carbon dioxide concentrations exceeding 50,000 parts per million (ppm), a level far surpassing the asphyxiation threshold due to oxygen displacement. Autopsies revealed superficial blunt force trauma and skeletal fractures in both individuals, including a left-sided rib and L2 vertebral fracture in the woman, and a C3 vertebral fracture with evidence of gastric aspiration in the man. Chronic age-related comorbidities were identified but determined to be non-contributory. Both decedents were certified as having died from asphyxia due to oxygen displacement by carbon dioxide.

While isolated CO_2-related deaths have been described in the literature, this case is notable for the rare presentation of dual fatalities in a residential wine cellar associated with recreational dry ice use.[1,2] It provides a unique contribution to forensic medicine by emphasizing the lethal potential of carbon dioxide in confined, poorly ventilated environments outside of occupational or industrial settings.

The investigation underscores the importance of integrating scene gas measurements, environmental context, and core pathophysiologic principles in the evaluation of suspected asphyxial deaths. It also highlights the often-subtle autopsy findings in gaseous asphyxia, reinforcing the reliance on multidisciplinary collaboration and rigorous scene analysis. This case serves as a timely reminder that foundational scientific knowledge—specifically, the behavior of gases and the mechanics of respiration—remains essential in modern forensic practice, particularly when death results from invisible environmental hazards.[3,4]

I137 A Work-Related Death in an Olive Oil Processing Plant: A Case Report of a Complex Forensic Analysis

Bianca Beltrame, MD, University of Brescia, Venice, Veneto, Italy; Angela Colucci, MD*, University of Bari, Bari, Puglia, Italy; Antonio Marzaioli, MD, University of Bari, Bari, Puglia, Italy; Alessandro Cristalli, MD, University of Bari, Bari, Puglia, Italy; Riccardo Amirante, MD, PhD, University of Bari, Bari, Puglia, Italy; Francesco Introna, MD, PhD, University of Bari, Bari, Puglia, Italy*

Learning Objectives: This presentation concerns a work-related death that occurred in an oil mill during the repair of industrial machinery. Attendees will learn a comprehensive, multidisciplinary approach to investigating and reconstructing work-related fatalities, especially those involving complex machinery.

Impact Statement: This presentation will enhance the forensic community's competence in conducting thorough and accurate investigations of industrial workplace deaths. By demonstrating the value of interdisciplinary collaboration, it will improve the quality and reliability of cause-of-death determinations, ultimately supporting both judicial processes and the safety of workplace stakeholders.

Abstract Text: Work-related deaths are a growing global concern, as evidenced by data from the International Labor Office, which reports a 12% increase in work-related deaths between 2000 and 2023.[1]

In Italy, the number of work-related deaths reported in 2024 was 1,077—an increase of 48 compared to the 1,029 cases reported in 2023.[2] The work-related context does not merely imply that the fatality occurred during working hours; rather, it requires that the injury resulted directly from work activities.[3] For this reason, determining the cause of death and reconstructing the event's dynamics is essential, often necessitating a forensic autopsy in collaboration with an industrial engineer with expertise in the machine's operation and malfunction.[4]

This case report concerns a 38-years-old worker who died in an olive oil processing plant—a particular industrial place where no cases are reported. Autopsy findings included a lacerated wound involving the middle and lower thirds of the face, exposing soft tissues and fractured bone, and severe craniofacial destruction with multiple fractures of the splanchnocranium and extensive comminuted fractures of the frontal bone with necrosis of the frontal lobes. Also, fractures of the right first five ribs were discovered along the mid-clavicular line. Toxicological analyses were negative. The cause of death was identified as extensive cranioencephalic injuries in a subject with multiple skeletal traumas.

Regarding the dynamic of the death, the laceration in the frontal region and the fracture of the frontal bone were consistent in both size and morphology with a direct impact by a metallic tube in a top-down trajectory. An on-site inspection with a forensic engineer was conducted to verifying the dimensions of the pipe and the movement of the machinery in relation to the injuries observed on the body. Green stains were noted on the ceiling, consistent with the high-velocity expulsion of the pipe's contents and a rotation in a clockwise direction. Despite the death being captured by surveillance cameras, to fully understand the exact dynamics of the fatal incident, it was necessary to integrate the autopsy findings with an on-site inspection and the technical assessments of a forensic engineer.

I138 Corpse Recovery in Extreme Environments: A Forensic Case Study From a Manure Pit

Raffaele Cirillo, MD, University of Salerno, Agropoli, Campania, Italy; Elena de Laurentiis, MD*, University of Salerno/University of Foggia, Sassano, Campania, Italy; Cristina Elia, MD*, University of Salerno/University of Foggia, Salerno, Campania, Italy; Roberto Raimo, MD, University of Foggia, Sassano, Campania, Italy; Donato Morena, MD, PhD, Sapienza University of Rome, Rome, Lazio, Italy; Gabriele Casaburi, MD*, ASL Salerno, Salerno, Campania, Italy; Alessandro Santurro, MD, PhD*, University of Salerno, Salerno, Campania, Italy*

Learning Objectives: After this presentation, participants will be able to describe the postmortem changes that occur in bodies submerged in extreme environments and how these affect forensic investigations, recognize the challenges in distinguishing antemortem from postmortem injuries in highly degradative conditions, and explain the role of histological and immunohistochemical analyses in determining cause and manner of death when macroscopic findings are compromised.

Impact Statement: This case underscores the complex forensic challenges posed by bodies recovered from particular places, such as manure pits, where accelerated decomposition and environmental factors can complicate trauma interpretation and cause-of-death determination. It emphasizes the critical need for integrating histological and immunohistochemical analyses into standard forensic protocols when dealing with advanced decomposition, promoting more accurate postmortem evaluations in extreme environments.

Abstract Text: Workers in the livestock sector are routinely exposed to a wide range of occupational hazards inherent to the nature of their tasks, including animal care, facility maintenance, and, in particular, manure management. Manure pits can become the setting for complex forensic scenarios, which may include deaths in which manure is the direct cause—primarily due to hydrogen sulfide intoxication or accidental asphyxiation from submersion—or cases in which the body is found in the manure, but death is attributable to other causes. In the latter, the marked acceleration of putrefactive changes can pose significant challenges in determining the time, cause, and manner of death.[1-3]

We present the case of a 38-year-old man found in the prone position inside an open-air manure pit during emptying operations. The body was in an advanced stage of decomposition (chromatic-emphysematous phase), exhibiting a batrachian aspect, green-dark discoloration, and significant swelling. External examination revealed a large linear laceration involving the left orbital region and an area of tissue loss in the left temporal area. Internal examination showed that this lesion extended to the bony structures of the ethmoid, establishing a continuity between the anterior cranial fossa and the left orbit. Severe putrefactive changes, exacerbated by high temperatures, acidic environment, and the heavy microbial load typical of manure, compromised the macroscopic interpretation of the lesions and hindered the assessment of their vitality. Histological investigations were also severely limited by putrefactive phenomena. Overall, the elements available suggested that the lesions detected did not appear certainly vital, meaning that they had probably been caused at the time the body was discovered and removed from the manure pit. On the other hand, the evidence collected and the absence of elements capable of supporting alternative dynamics, therefore converged towards a primary hypothesis of a manure pit-related fatality.

This case highlights the medicolegal difficulties associated with prolonged postmortem exposure to highly degradative environments such as manure pits. These conditions can significantly alter both external and internal findings, complicating lesion interpretation, cause-of-death determination—even in cases of natural death—and estimation of the postmortem interval. In such contexts, different investigations must be integrated to ensure accurate and reliable forensic conclusions.

I139 When Words Cut Deep: A Rare Accidental Sharp Force Death During a Domestic Altercation

Marida Imbriani, MD, Sapienza University of Rome, Rome, Lazio, Italy; Gianluca N. Piras, MD, Local Health Authority, Belluno, Italy, Belluno, Veneto, Italy; Benedetta Baldari, PhD, Sapienza University, Roma, Lazio, Italy*

Learning Objectives: This presentation explores the forensic challenges posed by sharp force injuries caused by atypical mechanisms, such as architectural glass. Attendees will gain insight into how the systematic integration of autopsy findings, scene findings, and circumstantial context enables not only the accurate determination of the manner of death, but also the assessment of potential liability among individuals involved in or present at the scene. The session will also highlight the importance of recognizing vascular injuries of the upper limbs and their potential lethality even in constancy of prompt medical care.

Impact Statement: Accidental sharp force deaths are exceedingly rare, accounting for only 2–4% of cases in autopsy series, yet their medicolegal evaluation requires a high degree of forensic precision. This case contributes to the forensic literature by demonstrating how structured crime scene analysis, contextual data, and anatomical findings can clarify the dynamics of unusual injury mechanisms. It offers a valuable model for handling sharp force fatalities where typical diagnostic cues are absent.

Abstract Text: Sharp force injuries constitute a complex area in forensic pathology, commonly associated with homicidal or suicidal violence; however, accidental deaths by this mechanism are rare, described in only 2–4% of autopsy reports.[1,2] While knives are most frequently implicated in such fatalities, other mechanisms—such as falls against architectural glass—present rare but diagnostically challenging scenarios.[3-5] The forensic interpretation of these injuries requires a multifactorial approach, considering wound morphology, severity, anatomical location, and scene dynamics. Vascular injuries of the upper limbs, although potentially survivable in clinical settings, may lead to fatal exsanguination when emergency care is delayed or trauma is particularly severe.[6]

We report the case of a 42-year-old man who died following an altercation with his 15-year-old nephew, whom he suspected of mistreating his elderly mother. The man arrived at the family residence—a two-story home with outdoor stairs leading to a balcony and a glass patio door—where his mother and nephew lived. After overhearing a conversation between the two of them that seemed to confirm his suspicions, he confronted the nephew verbally from the garden, then ascended the stairs to gain entry.

The nephew, who was inside the house with his grandmother, locked the glass door. In an emotionally agitated state, the man struck the door forcefully with his fists. The glass shattered, and he fell forward through the broken pane, sustaining severe bilateral injuries to the upper limbs. Emergency services were activated, but he experienced cardiovascular collapse during transport and was pronounced dead shortly afterward.

Crime scene investigation was pivotal: sharp-edged glass fragments remained embedded in the door frame, and a curtain behind the door showed lower hematic staining. Blood was pooled extensively both inside and outside the threshold area. External examination of the body revealed a large, bruised-edged-sharp wound in the proximal region of the left arm with full exposure of soft tissues and complete transection of the neurovascular bundle. A symmetrical deep, bruised-edged-sharp wound was observed on the right arm, with sectioning of vascular structures. A third bruised-edged-sharp wound on the right cubital fossa extended to the deep tissues without vessel disruption. The body and surrounding environment were heavily bloodstained. Autopsy confirmed that death was due to massive hemorrhage following bilateral transection of major upper limb vessels, including both brachial arteries. No defensive wounds or injuries suggestive of assault were found. Toxicological screening on urine was negative for common drugs of abuse; however, blood ethanol concentration measured 1.85 g/L, indicating mild intoxication, which likely impaired judgment and motor control.

This case highlights the need to integrate autopsy findings with scene reconstruction to distinguish rare accidental trauma from violent death. It emphasizes that the manner of death hinges not only on lesion characteristics but also on their contextual interpretation—how, where, and why the injuries occurred. It thus underscores the enduring value of fundamental forensic principles: systematic observation, anatomical-pathological correlation, and thorough scene analysis to assess both the cause of death and potential legal liability.

I140 A Fatal Invasive Candidiasis Diagnosed at Autopsy in a Long-Term Hospitalized Patient: A Case Report

Geon Kim, Jeju National University College of Medicine, Yongin-si, Kyonggi-do, Republic of Korea; Eugene Choi, MD, Sungkyunkwan Univ., Suwon-si, Kyonggi-do, Republic of Korea; Ga Eun Kim, MS, Sungkyunkwan Univ., Suwon-si, Kyonggi-do, Republic of Korea; Dong Yeon Lee, BS, Sungkyunkwan Univ., Suwon-si, Kyonggi-do, Republic of Korea; Moon-Young Kim, MD, PhD, Sungkyunkwan Univ., Suwon-si, Kyonggi-do, Republic of Korea; Eun-Byoul Jung, BS, Sungkyunkwan Univ., Suwon-si, Kyonggi-do, Republic of Korea; Im Soyoun, MS, Sungkyunkwan University*

Learning Objectives: This presentation describes a case of fatal invasive candidiasis diagnosed at autopsy in a long-term hospitalized patient without prior immunocompromising conditions. Attendees will be able to identify key clinical risk factors for invasive candidiasis in patients without overt immunosuppressive condition and apply clinical and forensic criteria to consider invasive fungal infections as a differential diagnosis in cases of unexplained sepsis or death.

Impact Statement: This presentation will enhance awareness within the community of the critical, yet often underrecognized, role of invasive fungal infections in sepsis-related deaths. By highlighting a case in which the diagnosis was only made postmortem via thorough autopsy, it underscores the importance of comprehensive histopathological evaluation in those without classic immunocompromised conditions. This case reinforces the need for forensic pathologists to broaden differential diagnosis in unexplained deaths and encourages integration of fungal pathology considerations into routine autopsy protocols.

Abstract Text: Invasive candidiasis is a severe fungal infection caused by *Candida* species, typically affecting immunocompromised individuals.[1,2] However, emerging evidence shows that even previously immunocompetent patients can develop invasive candidiasis under conditions such as prolonged hospitalization, broad-spectrum antibiotic use, and post-sepsis immune suppression.[3]

We report a case of a 62-year-old male who experienced severe but nonfatal head trauma and required long-term hospitalization due to persistent delirium. During his stay, he developed recurrent febrile episodes that responded poorly to empirical antibacterial treatment. He ultimately deteriorated and died from sepsis. Autopsy revealed disseminated invasive candidiasis with *Candida* myocarditis, bilateral pulmonary involvement, and renal pyelonephritis, leading to acute renal failure and *Candida* sepsis. Notably, no antifungal therapy had been administered during hospitalization, and fungal organisms were not suspected clinically.

This case implies the diagnostic challenges of invasive candidiasis, particularly in patients without classic immunocompromised conditions and in the absence of positive blood cultures for fungal organisms. From a forensic perspective, this case highlights the importance of comprehensive histopathological evaluation in suspected sepsis-related deaths. We emphasize that both clinicians and forensic pathologists must be aware of the risk of fungal infections in long-term hospitalized patients, as prompt diagnosis and appropriate treatment are critical to preventing fatal outcomes.

I141 3D Technologies in Forensic Medicine: From Complexity Perception to Practical Integration

Federica Amirante, MD, Università degli Studi di Bari Aldo Moro, Bari, Lombardia, Italy; Gianmarco Argentiero, MD, Department of Legal Medicine and Forensic Sciences, University of Pavia, Italy, Pavia, Lombardia, Italy; Marcello Benevento, MD, Università degli Studi di Bari Aldo Moro, Bari, Puglia, Italy; Laura Ambrosi, MD, Università degli Studi di Bari Aldo Moro, Bari, Puglia, Italy; Biagio Solarino, MD, PhD, Università degli Studi di Bari Aldo Moro, Bari, Puglia, Italy*

Learning Objectives: Participants will learn how 3D scanning technologies can support technical and research activities in forensics, improving the accuracy, reproducibility, and digital documentation of evidence. The main scanning systems, their applications in forensics (such as virtual autopsies, injury analysis, and crime scene reconstruction), and the operational flow from detection to virtual reality visualization will be illustrated. At the end of the presentation, participants will be able to recognize the advantages, critical issues, and future prospects of the different types of 3D scanners in medicolegal practice.

Impact Statement: Despite the technological maturity of 3D scanning techniques, their diffusion in medicolegal practice is still limited, often due to the perception of an operational complexity greater than the real one. This presentation will show how the use of 3 D scanners is actually accessible and beneficial, significantly improving the accuracy, documentation, and communication of forensic evidence and facilitating the communication of results to juries, magistrates, and stakeholders.

Abstract Text: The present work analyzes the potential of 3 D scanning technologies applied to forensics, with the hypothesis that such tools, although technologically mature, are still underused in forensics due to a misperception of their complexity of use and accessibility. The aim is to show how these techniques can significantly improve the precision, documentation and communicative effectiveness of forensic analyses, while offering high reproducibility and new ways of storing and presenting evidence.[1]

Traditionally, forensic medicine has relied on invasive methods and two-dimensional images to analyze injuries, reconstruct criminal events and identify the causes of death. 3D technologies introduce a paradigm shift: they allow the three-dimensional digitization of crime scenes, biological finds and human bodies, allowing the creation of virtual autopsies and detailed spatial reconstructions.[2] The work examines in particular non-contact scanning technologies – structured light, laser triangulation, photogrammetry, time-of-flight and laser interferometry – describing their operating principles, advantages and limitations in the forensic field.

Structured light scanners, for example, offer rapid acquisition and are ideal for documenting wounds while maintaining the color of the tissues; those with laser triangulation are more suitable for complex surfaces, thanks to their high resolution. Photogrammetry, although more expensive in the processing phase, represents an economically accessible solution, particularly useful in mobile operational contexts. The comparison between these technologies allows us to outline criteria for an informed choice of the most suitable tool based on the type of investigation and operating conditions.[3]

The work then illustrates the standard operational flow for the integration of 3 D scanning in the medicolegal context: from point cloud generation to mesh construction, from texture mapping to visualization in immersive environments such as virtual reality. Particular attention is paid to the issue of instrument calibration, essential to guarantee accuracy and reliability of the acquired data, crucial elements in the judicial field.

Applications covered include: virtual reconstruction of crime scenes, analysis of injuries on living bodies or corpses, identification of skeletal remains, study of ballistic trajectories and comparison of footprints or instruments. Virtual autopsies, in particular, allow for non-invasive investigation that integrates CT scans, MRI scans, and surface 3 D surveys, offering a conservative alternative in sensitive cultural or religious settings.[4]

In conclusion, the study highlights that, despite some obstacles (high initial costs, need for training, data management and legal acceptance), the adoption of 3 D technologies in forensic medicine is not only possible, but desirable. Technological progress, combined with the interdisciplinarity between medicine, engineering and law, makes the possibility of their systematic integration increasingly concrete. By demonstrating that these techniques are more accessible than is often believed, the work aims to overcome the cultural and operational barriers still present and encourage their wider diffusion in the forensic community.

I142 Micro-CT and Histopathology of the Hyoid-Larynx Complex in Cases of Fatal Trauma to the Neck

Sofia Goia, PhD, Warwick Manufacturing Group (WMG), The University of Warwick, Coventry, England, United Kingdom; Charlotte Primeau, PhD, University of Warwick, Coventry, England, United Kingdom; Mark A. Williams, PhD, University of Warwick, Coventry, England, United Kingdom*

Learning Objectives: This presentation will cover the findings of ten homicide investigations in which external neck compression and/or sharp/blunt force trauma to the neck was confirmed to have occurred at or around the time of death. The data acquired from the micro-Computed Tomography (micro-CT) scanning of the neck structures submitted to the Warwick Manufacturing Group (WMG), the University of Warwick, United Kingdom, will be correlated with the subsequent findings of the bone histopathology examination. Moreover, the presentation will focus on the processes involved in such homicide investigations and the types of injuries observed on the anterior neck structures submitted for scanning.

Impact Statement: Over 400 police investigations have taken advantage of the micro-CT, laser scanning, and 3D printing facilities at the university since 2014 through the partnership between WMG and West Midlands Police. Given the prevalence of homicides and domestic homicides in the United Kingdom in which trauma to the neck is encountered, an overview of how micro-CT complements the bone histopathology examination of neck structures is given.

Abstract Text: Through the work performed within the forensic center at the University of Warwick, micro-CT is used as a complementary technique to aid Home Office Pathologists or other experts (e.g., histopathologists) and the police in their (medicolegal) investigations.[1,2] In the year ending March 2024 there were 570 victims of homicide recorded in England and Wales, with 414 male victims and 156 female victims.[3] Of the total, 108 (~19%) were domestic homicides, and of these 83 (~77%) were female victims. Adult female domestic homicide victims accounted for 60% of all adult female victims. From the total number of female victims, 12% were killed by strangulation asphyxiation, with 3% of the male victims killed in this manner.[3] The most common method of killing was sharp force trauma for both males and females, with hitting without a weapon and blunt force trauma also being common. Within our forensic center and in terms of the preliminary suspected method of killing, the most common cases received by the center are suspected strangulations, which account for ~43.5% of total cases received since 2014. Sharp force trauma (SFT) and blunt force trauma (BFT) are also common, with 14% and 11% of all cases, respectively. In suspected strangulations, the most common type of samples submitted for micro-CT scanning are the anterior neck structures comprising the hyoid bone, thyroid cartilage, cricoid cartilage, and trachea. However, injuries to the anterior neck structures can be a result of applied pressure to the neck or sharp/blunt forces, and sometimes these injuries can be very subtle.

As a non-destructive imaging technique, micro-CT is usually employed prior to any further destructive analysis, such as bone histopathology, which is the gold standard in fracture identification and ageing. Through the high-resolution images acquired from micro-CT, subtle fractures and features of interest can be highlighted, which could be missed macroscopically or from postmortem imaging. Moreover, by complementing the bone histopathology examination with the micro-CT images, this can be used to help target the histopathology sectioning and analysis. Through this presentation, an overview of 10 forensic cases (4 females, 6 males, aged 31-72 years) in which the anterior neck structures were submitted for micro-CT scanning prior to bone histopathology will be discussed. The 10 cases comprise criminal investigations in which external neck compression and/or sharp/blunt force trauma to the neck was confirmed to have occurred at or around the time of death. Of these, 2 cases in which the victim was a female involved domestic abuse, and 2 cases in which the victim was a male involved a domestic homicide. The injuries observed from the micro-CT images of the neck structures are correlated with the findings from the bone histopathology examination. Moreover, common areas of trauma observed in external neck compression and examples of anatomical variants within the anterior neck structures are considered. Thus, it is aimed that through this presentation the processes involved in such homicide investigations will be explored, alongside examples of the findings from the micro-CT and bone histopathology examinations of 10 anterior neck structures.

I143 The Past, Present, and Future of Bone Fracture Age Estimation: A Technological Perspective

Charlotte G. Lawrence, MSc, Warwick Manufacturing Group, University of Warwick, Coventry, England, United Kingdom; Mark A. Williams, PhD, University of Warwick, Coventry, England, United Kingdom; Charlotte Primeau, PhD, University of Warwick, Coventry, England, United Kingdom*

Learning Objectives: This presentation will demonstrate the potential of micro-Computed Tomography (micro-CT) as a tool to enhance the visualization and interpretation of bone healing for forensic fracture age estimation. The presentation will synthesize a systematic literature review with a worked forensic case example to illustrate how modern technologies can be used as a research tool to advance the fundamental science behind fracture aging and to support the needs of forensic practitioners.

Impact Statement: This presentation will provide the forensic science community with a succinct insight into the imaging modalities and methods used to estimate the age of bone fractures. Informed by advancements made to the science over the past three decades, the presentation will draw on the strengths and limitations of existing imaging modalities to present micro-CT as a complementary technology with potential to shape the future of fracture aging.

Abstract Text: In forensic investigations, interdisciplinary collaboration between specialists such as forensic pathologists, radiologists, histopathologists, neuropathologists and toxicologists is required to holistically understand the circumstances around suspicious findings like bone fractures and potentially death. If an injury is identified, determining its temporality is critical to understand whether the individual experienced a single traumatic event or incurred repeated injuries over an extended period, and how far these injuries contributed to death.[1] In cases of abuse, establishing a timeline over which injuries were sustained can additionally help clarify accountability, such as when children and vulnerable adults spend time with different caregivers.[2]

This presentation will introduce the findings of a two-stage project, seeking to understand the methods currently used to estimate fracture age, with a view to identify future directions in fracture research and align this with the needs of forensic practitioners.

To firstly understand the methods currently used to age fractures, a systematic literature review of six databases was conducted. For inclusion, publications needed to focus on a method for ageing fractures, with clearly defined age stages accompanied by a timeframe of appearance. No bone or fracture type was excluded. The results, culminated from a final 21 publications, demonstrate that most methods for fracture ageing (n = 15) utilize conventional 2D x-rays. Conversely, bone histology, the undisputed gold standard for fracture aging, was only implemented in 4 publications.[3]
